Framework for Return to Work in Malaysia

YUEN Yee Yen, QUEK Meng Quan, Wendy TEOH Ming Yen and SUGANTHI Ramasamy

Faculty of Business, Multimedia University, Malaysia
yyyuen@mmu.edu.my

Abstract

This research is one of the pioneer study in Malaysia, which is conducted to propose a framework to overcome obstacles that limit persons with disabilities (PWDs) to return to work. This study is important to ensure that effective strategies can be drafted to help PWDs to return to work in both public and private sectors. This research is important as assisting PWDs to return to work will not only increasing PWD's income and quality of life, but also assist the employers and nations enhance the productivity and talent retention. This research applies systematic sampling approach to collect 300 questionnaire responses from PWDs who participated the return to work program to have a better understanding on the challenges faced by the PWDs to return to work.

Keywords: Return to Work, Framework, Persons with disabilities (PWDs).

Introduction

According to Department of Statistics Malaysia, 513,519 Malaysians had registered as persons with disabilities (PWDs) in 2019 (Department of Statistics Malaysia, 2019). PWDs make up of approximately 13% of the total population in Malaysia (Department of Statistics Malaysia, 2019). There are many challenges faced by PWDs in Malaysia, particularly, the return to work rate is relatively low and the unemployment rate is critically high (Islam, 2015).

In order to increase the return to work rate of PWDs, Malaysia Government has implemented the Persons with Disabilities Act 2008 (PWDA 2008) to protect the wellbeing of PWDs and assure PWDs being employed with equal basis as other citizens (Wahab & Jaafar, 2018). Malaysia Government has created rehabilitation center for PWDs to perform vocational and academic trainings for increase their return to work abilities (Lee, Abdullah, & See Ching Mey, 2011). Malaysia Government also encourages PWDs to return to work by implementing "One Percent Employment Policy" which target for at least 1% of the total workforce in public sector should be reserved for PWDs (The Sun Daily, 2015).

As of present, Malaysia is far from achieving the government's proposed target of one percent PWD in public workforce, with only 0.7% of PWDs returned to work in both public and private sectors (Loh, 2018). Social exclusion, discriminations such as lack of respect and being marginalized in all aspects of life hinder PWDs to return to work and leads to high unemployment, low income, and poor quality of life (Islam, 2015).

Many PWDs in Malaysia are still facing great challenges in returning to work due to the employers' lack of understanding on their actual needs and requirements and negative attitudes toward rehiring and retaining PWDs after occupational injuries (Narayanan, 2018). PWDs are generally perceived as weak, dependent, and incompetent, which make them far less likely to be hired and retained at workplace (Hwa & Ang, 2017). Currently, there is limited study in Malaysia that specifically focuses in examining key factors that hinder PWDs to return to work. Low return to work rate among PWDs in Malaysia is not well addressed with no holistic research framework on factors affecting return to work intention among PWDs in Malaysia.

This research is important as it aims to propose a holistic framework to overcome obstacles that hinder

Cite this Article as: YUEN Yee Yen, QUEK Meng Quan, Wendy TEOH Ming Yen and SUGANTHI Ramasamy "Framework for Return to Work in Malaysia" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

PWDs from return to work. A holistic return to work framework is crucial to enable effective strategies to be drafted to help PWDs to return to work in both public and private sectors. This research is important, as the return to work will not only increasing PWDs income and quality of life, but also assist employers and the nation to retain talented workforce.

Literature Review

Return to Work

PWDs who suffer from minor or severe degree of disability, which may lead to temporary absence from work due to their disability. Low return to work among PWDs is not only considered as the major burden for personal, but also it is also a big hurdle for family, financial, employers, government and economy. Cancelliere et al. (2016) discovered that nearly 600 million PWDs worldwide experienced low return to work. An estimated $28 billion of annual productivity losses was incurred from low return to work among PWDs. Total number of PWDs are increasing from year to year worldwide, lead to escalating challenges to return to work (Cancelliere, et al., 2016).

Since work is considered as an important and indispensable activity in human's life, which fulfils human's basic needs by generating income, provide opportunities for social interaction, and promote mental and physical well-being positively (Patterson, 2018), improving return to work will definitely enhance the life satisfaction and quality of life of PWDs (Patterson, 2018).

In Malaysia, there is a substantial gap between the goal of integrating PWDs into the labor force and their actual levels of return to work.

Emotion Barrier

Emotion barrier can be defined by innate and classically conditioned situations that present challenges to the return to work of PWDs (Izard, 2010). The impact of emotion on action, decision making, thinking, wellbeing, physical and mental health of PWDs has been affirmed by many psychological scientists (Izard, 2010). Functionally discrete emotion as sad, joy, interest, anger, low self-esteem, stress, shame, fear, guilt and anxiety may affect their chances of return to work (Murad, O'Brien, Farnworth, & Chien, 2013).

According to the previous research conducted by Eggert (2010), PWDs used to experience negative emotion such as stress, depression, fear of re-injury, and low self-esteem due to discrimination in the workplace, which may lower their intentions and chances to return to work (Eggert, 2010). Eggert (2010) suggested that PWDs experience emotional problems such as depression, and these emotional problems are significant barriers of return to work. The stronger the emotional barrier, the less likely for the PWDs to return to work. PWDs experience negative emotion such as anger due to the inability to perform daily activities and duties, and fear of being rejected from returning to work (Murad et al., 2013).

Behavior Barrier

Return to work can be determined by individual complex behavior barrier towards return to work. The behavior of the PWDs can be an important determinant of return to work since the ability to control their own actions and reactions are crucial in making decision of whether to return to work or continue absence from work (Yean, Johari, & Sukery, 2015).

Both employees and company stakeholders agree that the PWDs' reactions towards their current situations are important factors affecting return to work. For instance, some PWDs do not want to return to work due to refusing to communicating and interacting with the co-worker and refuse to make a move out of their comfort zone to adapt to the working environment (Ahlstrom, Hagberg, & Dellve, 2013).

Occupational Barrier

Occupational barrier refers to the lack of social support from workplace, which includes strong support from employer, manager, and colleagues and close relationship with employer, manager, and colleagues (Heimlich & Ardoin, 2008). Occupational barrier is one of the focal points in investigating the barriers and facilitators of return to work (Eggert, 2010).

Low or inadequate support from supervisors and colleagues will negatively affect return to work intentions of PWDs. A lack of colleagues' support on assigning modified or adjusted for PWDs is perceived as a main barrier for return to work (Yean, Johari, & Sukery, 2015). On top of that, the employer or manager also plays an important role in providing occupational support for PWDs to return to work. Ahlstrom, Hagberg, and Dellve (2013) proposed a positive association between supportive workplace and return to work intentions. PWDs with adequate occupational rehabilitation and supportive workplace environment are having better work ability and positive intention to return to work compared to those without proper occupational rehabilitation and support. Social support, feeling welcomed by colleagues and leadership support are important factors in influencing the outcomes of return to work (Ahlstrom, Hagberg, & Dellve, 2013; He et al., 2010).

Health Condition Barrier

Health condition barrier of PWDs will affect his or her ability to perform daily job-related tasks and activities (Patterson, 2018). Mental problem, work-disabling pain, and physical impairment will potentially influence the abilities of performing work and daily activity and reduce return to work intentions (Yean, Johari, & Sukery, 2015).

As discovered by Pflaum, McCollister, Strauss, Shavelle and DeVivo (2006), PWDs with spinal cord injury and less severe disability are more likely return to work after occupational injury than those with more severe disability. Physical impairment such as inability to walk would be disabling for construction job, but it is not disabling for office accounting job.

Furthermore, another research conducted by He, Hu, Yu, Gu and Liang (2010) also indicated that PWDs with less serious health conditions are more likely to perceive themselves as having better health status, leading to better return to work outcomes and shorter duration of absence from work.

Family Barrier

Lack of sympathy and caring from closed family members (such as parents, children, siblings and more) negatively affects the return to work decision of PWDs. Family plays an important role in encouraging and persuading employees to return to work (Ahlstrom, Hagberg, & Dellve, 2013).

Close family members have the potential to influence injured employee's decision on return to work through providing personal advice related to the financial status of the family. Family is one of the social interpersonal resources, which could influence the PWD's decision to return to work (Pflaum et al., 2006).

PWDs who are suffered from musculoskeletal injuries and disorder, are highly demotivated. Therefore, encouragement from family is an important motivator for them to return to work (Yean, Johari, & Sukery, 2015).

Methodology

As the objective of this study is to identify the barriers of return to work and develop a framework to enhance the return to work opportunities of PWDs in Malaysia, the sampling frame of this study should be focused on those PWDs who has prior working experience and would like to return to work after

losing their job.

The sample size for this study is 300. In the general calculation of sample size, with the population size of registered PWDs is 513,519, at a confidence level of 95%, the sample size of 300 is appropriate in proprosing a reliable and holistic return to work framework

For this research, 300 PWDs in central region of Malaysia were selected through systematic random sampling method. Structured survey questionnaires were conducted where survey questions were distributed to each and every of the selected PWDs to determine key factors affecting return to work before a framework can be built to guide relevant stakeholders in designing policies to recruit and attract PWDs from returning to work. The questionnaires were sent to 5 disability management expert panel reviews to confirm its face validity before the questionnaires were distributed

Results

Majority of the respondents (42.3%) earn an average monthly income of RM1001-RM2000 before they lose their previous job due to disability. 28.7% of the respondents earn an average monthly income of RM2001-RM3000 and 13.0% of them earn monthly income of RM3001-RM4000 before they lose their previous job due to disability.

Approximately 47.7% of the respondents have been hunting for the opportunity to return to work for more than 1 year. 24.3% of them are currently in the treatment and recovery process and they are keen to return to work as soon as possible.

Majority of the respondents have plans to return to work in future ($\bar{x}$ = 4.06 out of 5.00) and have strong determination to return to work despite various internet external constraints ($\bar{x}$ = 4.04 and 4.03 respectively).

Based on the responses of 300 respondents who suffer from occupational injuries, the following sustainable framework for return to work was developed. Emotion barrier, behavior barrier, occupational barrier, health barrier and family barrier are found have significant impact on return to work of PWDs.

Figure 1: Return to Work Framework

Table 1 indicates the reliability test result for dependent (return to work) and independent variables (emotion barrier, behavior barrier, occupational barrier, health barrier and family barrier) in the proposed framework. The Cronbach's Alpha value for all the variables as shown in Table 1 acceptable

as it is more than the threshold value of 0.7. The result suggest that all the variables in the proposed framework are reliable in predicting return to work of PWDs in Malaysia.

Table 1: Reliability Score

Variables	Reliability
Emotion Barrier	0.866
Behavior Barrier	0.733
Occupational Barrier	0.858
Health Condition Barrier	0.639
Family Barrier	0.847
Return to Work	0.809

The return to work framework developed by this study is the pioneer holistic return to work framework in Malaysia based on the response of sizable 300 PWDs. This research framework is useful for government and private organization in enhancing successful employment of PWDs in public and private sectors. This newly developed framework can be used to enhance the understanding of the needs of PWDs to improve their return to work rate at public and private sectors and improve the quality of life and income of PWDs, which are mostly the low income B40 in Malaysia.

This is an important pioneer study in Malaysia that examine factors affecting return to work among PWDs. The finding has an important implication to Malaysia government as it assists Malaysia government to develop a more suitable job initiative and opportunity to promote higher rate of return to work among PWDs.

Acknowledgement

The researchers would like to thank Ministry of Education Malaysia for providing Fundamental Research Grant Scheme (FRGS/1/2017/SS03/MMU/03/1) to support this research project.

Africa's Cybersecurity Posture:

The need for a Regional Cyber Security Capacity Assessment

Olatunji OSUNJI

Abstract

One of the strategies to lead the cause for a secured cyberspace within the private, public or at the national level is to have good visibility into the cybersecurity capacity of entities with the environment. The African Union Convention on Cyber Security and Personal Data Protection is an indication that African leaders has some initiatives to drive cybersecurity within the region, however without fully understanding the national level commitment and distribution of cybersecurity capacity within the region; it will be difficult to transition into a secure continent. Data triangulation of current cybersecurity posture of Africa from previous cybersecurity readiness and maturity assessment, journal articles, reports and websites relevant to cyber security situation in Africa was used to argue that Africa Union Commission does not have holistic visibility into the cyber security capacity posture of its member nations; and that this should be the first step in charting a way forward. The aim of this paper is to raise awareness within the leadership of Africa Union of the need to step up their cybersecurity effort of monitoring and oversight by empowering the newly constituted African Union Cybersecurity Expert Group to perform at full capacity and draw up a plan to perform a region wide cybersecurity capacity assessment. By working jointly with member nations and international community at the forefront of cybersecurity capacity building, the region will be able to build a more secure and resilient structure that will ensure the social-economic transformation that it desires.

Keywords: African Union Cybersecurity Expert Group, Cybersecurity, Cybersecurity Capacity Building, Cybersecurity posture.

Introduction

In the past two decades, the deployment of Information and Communication Technology (ICT) infrastructure in Africa has led to an explosion in the number of people with internet access – most of whom are first time users without a cybersecurity mindset. This experience has been referred to in some quarters as leapfrogging (Schia, 2016) and this internet exposure has created a form of vulnerability in cyberspace. In its 2013 research paper, TrendMicro, a global security firm reported that could become a safe harbor for cybercriminals within 3 years. Schia (2018) reported that developing countries have become safe haven for cyber criminals.

African Union (AU) is the Africa's continental body that's brings together the countries in the region, just like the European Union (EU) or Organization of America States (OAS). One of its aims is to promote peace, security, and stability on the continent [1]– a goal that is now been made complex by the increasing level of cybercrime and cyber-attacks. Effort to maintain peace, stability and security

Cite this Article as: Olatunji OSUNJI "Africa's Cybersecurity Posture: The need for a Regional Cyber Security Capacity Assessment" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

can be undermined by lack of visibility into the cybersecurity posture of the region. For that reason, it is essential for AU, to have a holistic understanding of the level of cyber security readiness and capacity of each member state. Not only does AU as a regional body need to lead the cause for a secure environment with cooperation from private, public and international organizations, the responsibility to have a good visibility into the cybersecurity capacity of entities with their domain also rest on it. In a recent publication by United Nations Institute for Disarmament Research (UNIDIR), it was stated that regional organisations are specially positioned to help member nations in developing cybersecurity capabilities (UNIDIR, 2019).

A top down approach to cybersecurity has always proven to be an ideal strategy to adopt. Intergovernmental organizations at the sub-regional level have developed some cyber security frameworks that could help combat cybercrime. Orji (2015) highlights some of such efforts: in 2011, a model Cybercrime Law was adopted by Common Market for Eastern and Southern Africa (COMESA), while the Economic Community of West African States (ECOWAS) adopted a directive on Fighting Cybercrime. The Southern African Development Community (SADC) also adopted a Model Law on Computer Crime and Cybercrime in 2012. Building on these sub-regional efforts, in June 2014, the AU Convention on Cyber Security and Personal Data Protection was adopted by Africa Union Commission (AUC).

Another aim of AU is to establish the necessary conditions which would enable the continent to play its rightful role in the global economy and in international negotiations, it is expected that this should include ensuring that the cyber security posture of the region no longer constitute a weakness within global cyberspace. Worldwide, research has shown that emerging economies are facing threats emanating from attacks on their critical infrastructure (White, 2014).

In addition to the efforts within the region, the international community has developed frameworks that can assist countries worldwide to assess their cybersecuirty standing in terms of readiness, capability or capacities. The International Telecommunication Union's (ITU) cyber readiness program, Global Cyber Security Capacity Centre's Capacity Maturity Model for Nations (CMM) and The Global Forum on Cyber Expertise (GFCE) are a few of these international initiatives. Several AU member states have participated or have been assessed on one or more of these, with the expectation that the result of such assessment would trigger a push to improving the security posture of such a nation. It appears this is coming at a very slow rate- as an example, only few member nations have ratified the AU Convention on Cyber Security and Personal Data Protection. While there are indications that the AU has some initiates to drive cybersecurity within the region, without fully understanding the level and distribution of cybersecurity capacity or incapacity within the region, it will be difficult to transition into a secure continent.

This paper argues that AUC does not have a holistic visibility into the cyber security posture of its member nations and that this should start with a thorough assessment of cyber capacity of member states. It aim to point out that AU needs not only have visibility into the regions cybersecurity capacity posture, but also lead the effort to ensure that member states take ownership of building necessary cybersecurity capacities. Triangulation of secondary data from current state of affairs of the region through the lens of ITU's cyber security readiness, available CMM assessment reports, journal articles, reports and websites relevant to cyber security situation in Africa was used in preparing this paper.

It recommends the taking of ownership of cyber security oversight of member nations of AU by empowering the newly formed African Union Cyber Security Expert Group to perform a cyber security capacity assessment of the region using CMM and also makes a case for AU to have a monitoring role on the regions cybersecurity capacity building effort.

This paper is divided into four sections. The first section which includes this introduction continues with a general background on Africa and AU. The second section will critically examine the cyber security efforts across the region with emphasis on AU's involvement or oversight. The third section examines how AU member states fairs with ITU cyber readiness program and CMM with some

comparison with Organization of American States' (OAS) efforts. This is then followed by recommendations and the conclusion.

An Overview of Africa

Africa is a continent comprising of 55 sovereign countries with a combined population of over 1.2 billion people. The United Nation estimate that Africa will account for more than 50% of the world population growth between now and 2050[2] and it is one of the fastest growing continents in terms of population, economy, global connectivity and digital transformation. The continent is comprised of five sub-regions, namely Central Africa, East Africa, North Africa, Southern Africa and West Africa. Each of these sub-regions has one or more intergovernmental organizations; Arab Maghreb Union (AMU) in North Africa, (excluding Egypt but including Morocco, which is not an AU member); Economic Community of West African States (ECOWAS) in West Africa; The Intergovernmental Authority on Development (IGAD) in Northeast Africa; Economic Community of Central African States (ECCAS) in Central Africa; and SADC in Southern Africa (Moller, 2009). All these sub-regional organizations play an active role in directing the cybersecurity situation of their member states.

At the regional level, the AU is the intergovernmental organization that unites each of these nations. It was officially launched in July 2002 in Durban, South Africa. Out of the 55 states in the regions, only Morocco is not part of AU. Within the last two decades, the continent has been a focus of both the developed nations and international development organizations like the International Monterey Fund (IMF), United Nations (UN) and World Bank (WB). The sustainable development goals of UN and WB's vision 2030 were both directed towards eradicating poverty in developing nations. As of year 2015, Africa had 27 out of the world's 28 poorest countries.[3]

The sustainable development goals of the UN have been underpinned by ICT and this has led to increase internet access and digital transformation across the region. A country's ICT infrastructure is also the foundation underpinning its digital economy. The dividend of digital transformation within the region is evidenced through improve economy, job creation and increase standard of living of the citizenry. In an effort to spread the benefit of digital dividend across the region, AUC led a multi-stakeholder process to develop a Digital Transformation Strategy (DTS) for Africa in 2019 - a vision to harness digital technologies and innovation to transform Africa's economies, societies, and governments to generate new economic growth, job creation, and poverty reduction (AU, 2019). It is expected that member states will adopt, promote and implement the DTS as the common digitalization strategy. This however is coming at a huge price to the global community as the lag between digital transformation and cyber security transformation within the region has continued to turn the region into a vulnerable zone.

Cyber Situation in Africa

The cyber situation in African is complex. On one side is the misuse of knowledge resulting in continual increase of cybercrime rate, with the region facing a cyber-crime cost of about US$3.5 billion a year (Serianu, 2017); on the other is the increasing misuse of power by government to control access to internet within their jurisdiction. Most African economies have become a fertile ground for cybercrime activities and cybercriminal (kshetri, 2019). The advantages that digitization has brought to the people of Africa through ecommerce, social media online education are obvious and this is been embraced eagerly without consideration for good cyber hygiene. Careless cybersecurity practices leads to vulnerable systems - for instance, it was reported that in 2010, 80% of PCs used in Africa were infected with viruses and malware (Gady, 2010). Cybercriminals often use these unprotected computers to launch cyber-attacks against targets all over the world. Some of the other issues identified as been responsible for increasing cyber-attacks in the continent as identified by Kritzinger and Solms (2012) are:

i. Low cybersecurity budgets which can be less than 1% in many organizations.
ii. Viewing cybersecurity as a luxury and not a necessity.

iii. Shortage of skill and awareness among internet users to protect themselves from rapidly evolving cyber-threats.
iv. Weak national legislation and law enforcement.

One of the debates in cyberspace running in parallel with issues around cybercrime is maintaining norms and governance of the internet. While countries like Russia and China are advocating for internet controlled by the state, United States and several western European countries advocate for an internet that is open and free. African nation has remained in a swing condition between these two factions. Several incidents of internet shutdown –either partially or fully, by Africa countries in recent times has continued to raise concern worldwide. Chad, Sudan, Mauritania, Ethiopia, Zimbabwe and Democratic Republic of Congo are a few of the African states that have all or part of their internet shutdown for at least a day within the last few years.

This situation has already prompted several African countries and the AU to begin carrying out initiatives at the national, sub-region and region levels to improve their cyber security posture. These efforts may have been silo across the continent as recent ITU report indicated low incident report rates and information sharing culture within the continent (ITU 2018). Kshetri (2019) stated that a lot of these efforts have been channelled toward improving cyber related regulations. The AU also acknowledge this by issuing a press release supporting that there is still an evident gap among AU member states in mitigate cyber threats.4

The reminder of this section will highlight a few initiatives at the regional level.

The AU Convention on Cyber Security and personal Data protection

AUC, with cooperation from United Nations Economic Commission for Africa drafted the AU Convention on Cyber Security and Personal Data Protection, which was adopted on 27th June 2014 (AU, 2014). This was after a call for review by civil society and academia over concerns relating to privacy rights, freedom of expression, small consultations scope, and the absence of some critical governance mechanisms (Orji, 2012). It is believed that the adoption of this convention will promote cyber stability in within the region.

With several national laws guiding Cybercrime, Privacy and Data Protection, Consumer Protection and Electronic Transaction across African nations, the AU Convention on Cyber Security and Personal Data Protection comes handy in harmonizing these laws. According to AUC, the convention imposes on member state the obligation to establish national legal, policy and institutional governance mechanisms on cyber security. However, Orji (2015), argued that the convention's framework is not sufficient enough for the much needed cooperation among member nations.

In a November 2016 joint report of the AUC and the security firm Symantec, only 11 African countries had specific laws and provisions in place to deal with cybercrime and electronic evidence (Symantec, 2016). Table 1 shows the status of African nations in respect to some cyber related legislations as of January 2020. [5]

Table 1: Status of cyber related legislations in Africa as of January 2020

Legislation	Status- Number of Countries			
	Available	Draft	None	No data
Cybercrime	28	11	15	0
Privacy and Data Protection	23	7	12	12
Consumer Protection	20	6	10	18
Electronic Transactions	32	10	4	8

Even though several of the nations have legislation on cybercrime and data protection as evident in table 1, without the ratification of AU convention by member nations, the synergy of these individual legislation and legal binding of the convention will be impossible. As of February, 2020 only 4 out of the required 15 member nations have ratified the convention (AU, 2020). It appears that AUC need to do more in the area of working with member nation to ratify the convention. It would be beneficial to the continent if AU leadership would take on the responsibility of engaging nations who have no legislation in place with a view of working with them to identify and resolve any challenges they have.

African Union Cyber security Expert Group

The creation of an Africa Cyber Security Collaboration and Coordination Committee was endorsed in January 2018, during the 32nd Ordinary Session of the Executive Council. This gave birth to African Union Cybersecurity Expert Group (AUCSEG) who has been specifically tasked with the following: [6]

i. Advising the African Union Commission (AUC) on cyber security issues and policies;
ii. Proposing solutions to facilitate the ratification and domestication of the Malabo Convention into national laws;
iii. Sharing best practice on how to mitigate current and new threats and on the protection of critical infrastructure and election systems as well ;
iv. Identification of research areas rewuired for policies, guidelines formulation.
v. Identifying ways to support the establishment and development of Computer Security Incident Response Teams (CSIRTs);
vi. Developing ways for close collaboration among AU Member States and stakeholders, on Cybersecurity;
vii. Proposing ways to build capacities and to increase skills in ICTs security and their proper use;
viii. Supporting AU on building African Position within the international process related to Cybersecurity including ways of cooperation with international stakeholders.

It is hoped that this group will channel the way forward for Africa in terms of cybersecurity challenges. If given the necessary resources, it can possibly transition to and be respected like the European Network and Information Security Agency (ENISA) – EU's Agency for Cybersecurity, whose responsibility include guiding and working with EU Members States and relevant stakeholders on ways to improve their cybersecurity capabilities. However, the terms of reference of the group raises some concerns. As an example, members will serves in voluntary capacity and on termed appointment.[7] This may impair the commitment of members, which can slow down progress.

Agenda 2063

With the realization that African needs to repositioning itself to becoming a dominant player in the global arena, leaders of AU started to priorities inclusive social and economic development, continental and regional integration, democratic governance and peace and security. In 2013, a fifty year agenda, tagged AGENDA 2063 was conceived (AU, 2015). According to AU, AGENDA 2063 is "*the continent's strategic framework that aims to deliver on its goal for inclusive and sustainable development and is a concrete manifestation of the pan-African drive for unity, self-determination, freedom, progress and collective prosperity pursued under Pan-Africanism and African Renaissance*" .[8] Among other things, the agenda identifies key Flagship Projects which can boost Africa's economic growth and development and lead to the rapid transformation of the continent. One of the flagship projects is cyber security. It's worth noting that cyber security was not initially included as one of the flagship projects as indicated by initial documents on AGENDA 2063.[9]

This reflects the lack of importance attached to cyber security at that level of AU regional governance. However, the decision to adopt Cyber Security as one of the flagship projects gives a clear indication that Africa leaders have acknowledge that in addition to incorporating development plans brought about by the rapid changes in emerging technologies, there is also need to ensure that

these technologies are used for the benefit of African individuals, institutions or nation states by ensuring data protection and safety online. The Cyber Security project will use the AU Convention on Cyber Security and Personal Data Protection as its bedrock. The first report on the Agenda's effort identified that in the area of cybersecurity, lack of budgetary resources is delaying the implementation of the cybersecurity initiates and that region plans to look more into the area of capacity building (AU, 2020)

International Cooperation

AU is a member of the Global Forum on Cyber Expertise (GFCE), which is a global platform for countries, international organizations and private companies to exchange best practices and expertise on cyber capacity building.[10] Members are encouraged to develop joint initiatives in cyber capacity building within the GFCE. In 2019, the GFCE Annual Meeting was hosted by the AU Commission with a focus to further strengthen the structure for international cooperation on cyber capacity building. This serves as an advantage for Africa and an opportunity for AUC to take up the leadership position by using their involvement in GFCE to ensure that all AU member states' national cyber security capacity status is known and improved on.

A capacity building workshop on cyber strategies, cyber legislation and setting up national Computer Emergency Response Team (CERT) was organized by AUC in collaboration with U.S. Department of State and Internet Society in 2018. The workshop was aimed at providing African experts with the appropriate cyber security knowledge to prepare and adopt national cyber security strategies and cyber legislations as well as the requirements for setting up and managing CERT.[11]

Africa Cyber Security Capacity Status

There have been several indices and frameworks within the international community to assist nations in knowing their cybersecurity posture and where they stand compare to other nations. This section takes a look at Africa's standing through the lens of three of them and the role of AUC in these efforts.

ITU Global Cybersecurity Index (GCI)

ITU's Global Cybersecurity Agenda (GCA) framework was launched in 2007, with the aim of enhancing international cooperation that will foster confidence and security in the information society. It attempts to measure the commitment of nations to building a secure cyber space through five strategic pillars: As stated by ITU, these pillars are represented in table 2.[12]

Table 2 : ITU Global Cybersecurity Agenda strategic pillars

Pillars	Measures
Legal	The existence of legal institutions and frameworks dealing with cyber security and cybercrime.
Technical	The existence of technical institutions and framework dealing with cyber security.
Organizational	The existence of policy coordination institutions and strategies.
Capacity building	The existence of research and development, education and Training programs, certified professionals and public sector agencies fostering capacity building
Cooperation	The existence of partnerships, cooperative frameworks and Information sharing networks.

Data are collected through online survey and used to produce a composite index refer to as The Global Cybersecurity Index (GCI). These five designated areas form the basis of the indicators for GCI because they shape the inherent building blocks of a national cybersecurity culture

According to ITU (2018), the main objectives of GCI include; the type, level and evolution over time of cybersecurity commitment in countries and relative to other countries; progress in cybersecurity commitment of all countries from a global perspective; progress in cybersecurity commitment from a regional perspective; the cybersecurity commitment divide (i.e. the difference between countries in terms of their level of engagement in cybersecurity initiatives). The entire framework solidifies ITU's role in building confidence and security in the use of information and communication technologies.

The GCI report is one of the indexes that provide a ground to compare the cyber culture and readiness of nations. In the 2018 GCI report, of the 44 ITU member states in Africa region, only 31 carried out the survey. Mauritius, Kenya and Egypt were among the top 50 countries globally with high commitment towards securing cyberspace. The report revealed that Africa lags behind other continents as it has more countries with low cybersecurity commitment.

This result is an eye opener for AUC to step in and engage each country in reaffirming their commitment to cybersecurity and developing a good cybersecurity culture, without which the dividend of digitization will be far fetch.

Cybersecurity Capacity Maturity Model for Nations (CMM)

The CMM was developed in 2014 by the Global Cyber Security Capacity Centre (GCSCC) of the University of Oxford. According to GCSCC, it "*facilitates a comprehensive understanding of effective and efficient national cybersecurity capacity and to enable policy makers to define priorities for capacity building and investments*". It is aimed to assist countries asses themself and based on post assessment recommendations; necessary actions are expected to be taken. As of January 2020, it has been deployed in over 80 nations - 22 are African nations.[13] The model benchmarks a country's across five dimensions of cybersecurity capacity: National Cybersecurity Policy and Strategy; Cyber Culture and Society, Cybersecurity Education, Training and Skills; Legal and Regulatory Frameworks; and Standards, Organization and Technologies. Within each dimension, there are factors, aspects, stages of maturity, and indicators of cybersecurity capacity (GCSCC, 2016). Each of these terms is defined as follows:

Factor: These gives a description of what it means to possess cybersecurity capacity. They are elements that contribute to the enhancement of cybersecurity capacity maturity. Most factors are made up of one or more aspects that structure

Aspect: This represents a smaller division of each factor. Each aspect is composed of a series of indicators within 5 stages of maturity.

Indicator: These are the building blocks which gives the specific stage of maturity within a distinct aspect, factor and dimension. In order to elevate a country's cybersecurity capacity maturity, all of the indicators within a particular stage will need to have been fulfilled. The country will either provide evidence of fulfilling the criteria or not.

Stage: Stages define to which degree a country has progressed in relation to a factor/aspect of cybersecurity capacity. There are 5 distinct stages of maturity that serve as a snapshot of existing cybersecurity capacity, from which a country can improve or decline depending on the actions taken (or inaction). These stages are:

a. Start-up: There is no evidence of cybersecurity maturity or it's at its infancy.
b. Formative: Evidence of activity of some of the aspect can be clearly provided, although this may be ad-hoc or poorly defined.

c. Established: Constituent of this aspect is in place, and working, however the allocation of resources toward cybersecurity is not mature.
d. Strategic: Distinction and choices have been in prioritizing aspect of CMM for the countries depending on the national situation
e. Dynamic: This stage indicates that there is clear framework to adjust to prevailing cybersecurity situations with dynamic reallocation of resources when needed.

Out of 54 nations within the region, only 22 had participated in the CMM review process as of January, 2020, 5 of which have their results published and available online. The publishing of report is at the discretion of the nation assessed. However, if AU had been involve in the assessment or initiate its conduct, just like OAS did in partner with Inter-America Development Bank (IDB, 2016), AU would have access to the results and have visibility into the security landscape of the region. OAS, with cooperation IDB, took ownership of the task to conduct CMM assessment of America regions which gave them insight into each countries cyber security posture. In addition, If AUC has visibility into each member state's result; it will give them a clear view of how they can assist member nations and areas to concentrate cyber security building.

The conduct of the Latin America and the Caribbean (LAC) CMM assessment, championed by OAS and IDB allows for same process and methodology throughout the review process. Meanwhile, the 22 African nations completed were reviewed by one or more international development organizations or national body from 6 different organizations - Commonwealth Telecommunications Organization (CTO), GCSCC, German development agency (GIZ), ITU, Norwegian Institute of International Affairs (NUPI) and World Bank (WB). AU was not involved in any of these in any significant capacity and the methodology may have been slightly different from nations to nation because of the number of reviewing bodies.

In addition, it took four years (between 2015 and 2019) to assess less than half of African nations – same assessment was done within a year for all LAC countries (2015-2016). A reassessment of LAC region has been completed and the report of progress made and areas needing attention were made publicly available in a report (IDB, 2020). OAS, with support from IDB took the initiative and ownership of the process and ensured that the cybersecurity status of their member states was known. AU leadership should follow suite and take ownership of this process. Table 3 shows the list of African nations that have been assessed or working towards assessment as of January 2020.

Table 3: African Nations that has been assessed or preparing for CMM assessment

COUNTRY	ASSESSING ORGANISATION	YEAR	REPORT
Malawi	CTO		
Mozambique	CTO		
Rwanda	CTO		
Tanzania	CTO		
Eswatini	CTO/ITU		
Nigeria	GCSCC	2019	
Uganda	GCSCC	2015	Available
Tunisia	GCSCC/GIZ	2019	
Madagascar	GCSCC/ITU	2016	Available
Sierra Leone	GCSCC/ITU	2016	Available
Senegal	GCSCC/NL	2016	Available
Ghana	GCSCC/NUPI/WB	2018	
The Gambia	GCSCC/WB	2018	Available
Botswana	WB	2019	
Burkina Faso	WB	2019	

Cape Verde	WB	2019	
Ivory Coast	WB	2019	
Namibia	WB	2019	
Niger	WB	2019	
Zambia	WB	2017	
Lesotho	WB/GCSCC	2019	
Mauritius	WB/GCSCC	2019	

Recommendation

Africa is diverse in culture, faith, technology development and social economic and political factors; hence it is obvious that there is no same solution fits all in this region. The establishment of AUCSEG is timely and AU should leverage on such committee to gain insight into the region posture by:

1. The committee should transition into an agency like ENISA and participation should not be voluntary nor based on termed appointment. This will ensure more commitment on the part of members or employees of such agency.
2. The agency should be backed up by necessary policies to drive their initiatives. In order for the group to meet its set goals, it is of necessity to start with a baseline of the current cybersecurity landscape of the continent. ITU's cyber readiness index and the Cybersecurity Capability Maturity Model developed by GCSSC are good frameworks to start assessing countries security preparedness. If given the necessary resources, it can become reputable like ENISA.
3. AUCSEG should develop the necessary capability in house to perform these assessments and be able to take ownership by conducting it in all Africa nations. It should take the leading step and collaborate with other developmental organization and institutions like GCSSC, WBG and ITU to drive the implementation of CMM. A current profile should be developed for each country and a target profile determine based on each countries social economic and political situations. The target profile is the higher level of cyber security capacity that individual country would set as goals to attain within a set period of time, bearing in mind that capacity building takes time and involve capital.
4. There should be leadership effort from AU for a coordinated, multi-stakeholder effort to countering cyber threats in the continent and this should complement the silo works that each member nation is doing across the continent.

Conclusion

Amidst several other initiatives, the commitment of AU to fighting cybercrime and maintaining security and peace within the continent have been reaffirmed through adoption of the AU convention on cyber security and personal data protection, prioritizing cybersecurity as one of the pillars of agenda 2063, becoming a member of GFCE and establishing of AUCSEG. However, the issue at hand is beyond coming up with an agenda or convention, without a way to enforce and monitor. You can only monitor what you have visibility into.

AU, through AUCSEG should be centrally engaged with issues of cybersecurity and cybercrime by having a holistic view of the cyber landscape and channelling directions for nations to take. The approach should be to take ownership and build a profile for each country through assessment using the CMM. This effort should be done alongside the countries.

Future work will be to examine the challenges facing capacity building in Africa nations and explore how CMM can be adapted as a tool to achieving Africa's vision - Agenda 2063 and DTS. This work will be based on data and interviews to be conducted within and outside of the continent.

Abstract

This paper investigates the issue of mechanisms which support the increase in efficiency of collaboration in virtual organizations. Conceptual development and positioning of the research aim at providing a generalizable contribution to management practice, at the same time being accessible to practitioners. The authors focused on working out a pattern for creating mechanisms that allow members of virtual structures to adjust to the organizational-culture-conditioned ways other partners operate. The analysis contributed to the consistency concept which stems from the theory of systems. The practical aspect of the study was presented within multiple case studies, on the example of Turkish organizations. Case studies present a template which serves as a tool for practitioners who exploit network relations and virtual structures.

Keywords: Organizational Culture, Virtual Structures, Collaboration Mechanisms, Consistency Concept

Introduction

In the last two decades the organizational environment has undergone substantial transformation and the key role is played by multi-directional co-dependence of business partners (Mayne et al., 2003; Sakai and Kang, 2000). It results in taking a network collaboration approach (Kickert et al., 1997). The theory of network abandoned an atomic approach to explain reality in favour of a holistic perspective. Thus, a network may be perceived as a collection of long-term, formal and informal, direct or indirect relations between two or more units (Håkansson and Snehota, 1989; Newman et al., 2004; Camagni, 1995; Kilduff and Tsai, 2003; Edelenbos and Klijn, 2007).

The network itself becomes a fundament for development of virtual organizations. Nowadays, cross-border virtual teams are perceived as a valuable source for knowledge creation (Toivanen, 2017). However, the integrator of a virtual organization faces the problem of harmonizing collaboration between partners (Flieger, 2017). Undisputedly, one of the crucial factors influencing effective relations between firms which often operate in different parts of the world is an organizational culture (Wu and Ma, 2018; Peretz et al., 2017). The integrator needs to be aware of cultural differences and similarities, and must know how to adjust to them in order to ensure long-term, effective network collaboration (Stocker et al., 2017). Essential becomes the ability to create such a process of cooperation and communication that will be understood by all concerned (Vetrakova and Smerek, 2016). Such knowledge is needed also for workers at lower levels of an organizational hierarchy, since they are the ones who have a direct contact with other knot groups (e.g. suppliers or internal clients).

Cite this Article as: Marcin FLIEGER, Michał FLIEGER And Ilhan TARIMER " Organizational Culture in Virtual Structures: Mechanisms of Consistent Collaboration" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

According to the consistency concept, an organization needs to harmonize three basic levels of management – strategic, tactic and operational. They create a natural hierarchy in which lower levels are conditioned by higher ones. Understanding of these relations and conditions become especially important in case of inter-organizational networks. Such virtual structures consist of organizations operating in different parts of the globe, which results in different approaches to implementation of mechanisms that are aimed to ensure optimal efficiency. In this context, one of the basic issues are cultural differences.

The analysis presented in the paper provides both theoretical and practical contribution. The authors concentrated on depicting a concise theoretical construct which allowed integration of a consistency concept and organizational culture in network collaboration. It is a new perspective which led to the conceptualization of a pattern of working out consistency mechanisms. This theoretical background serves as a template for practical use by managers. It shows what mechanisms and in what way should be implemented in order to allow members of virtual structures to adjust to the organizational-culture-conditioned ways other partners operate.

Thus, the authors made an attempt to answer the research question: what is the pattern of adjusting to organizational culture in virtual structures in order to ensure consistent collaboration? Identifying this pattern and consistency mechanisms constitutes the main objective of the paper. Understanding of this phenomenon serves as an extremely important contribution to the knowledge concerning proper development of relations between partners in virtual structures and, consequently, an increase in efficiency of the process of creating common value.

Consistency Concept

The theoretical contribution of the study refers to conceptualizing a construct which allows integration of a consistency concept and organizational culture in network collaboration. Consistency concept has its roots in the theory of systems (Churchman, 1971; Bertalanffy, 1969). It has a crucial importance when it comes to organizational harmonization and optimization, which is the essence of consistency. Optimizing an organization by implementing changes requires treating it as one system and looking in different directions, which means detecting possible effects of the changes in various area and dimensions of an organization. Possible effects may appear also in the areas which are very distant from one another (Haken, 1983; Miller and Page, 2007).

In order to make the concept useful for managers, we need to identify key areas that may undergo changes and explain interactions between them. In this way it will be possible to identify how some changes implemented in one area influence other areas. Further, that leads to identification of the process of harmonizing, adjusting and consistency building among different organizational areas. As a consequence, it becomes possible to implement the consistency concept in practice and increase organizational effectiveness.

Consistency Platforms

Theory of systems allows looking at an organization from the perspective of systems, subsystems and metasystems. Thus, systems consist of subsystems, but at the same time systems are the parts of metasystems (Parsons, 1951; Luhmann, 2013). This idea lays at the heart of the consistency concept. It refers to three consistency platforms. Each of them ought to create a consistent system and when this requirement is met, all the elements of each platform are harmonized and consistent (Table 1).

Table 1: General approach for organizations' consistency analysis

Consistency perspective 1	Consistency platform 1	Subsystem 1
		Subsystem n
	Consistency platform n	Subsystem 1
		Subsystem n
Consistency perspective 2	Consistency platform 1	Subsystem 1
		Subsystem n
	Consistency platform n	Subsystem 1
		Subsystem n

Source: own study

The first platform refers to the concepts and methods of management. In both theory and practice of management these two elements logically complement each other. Implementation of one concept triggers off the need to introduce other concepts, so that the first one is complementarily supported. Furthermore, implementation of management concepts creates the need to implement management methods which stem from the concepts in question. Accordingly, platform two consists of two key elements – organizational structure and appropriate style and mechanisms of management – and the third platform refers to human resource management.

Research Approach and Methods

Taking into consideration the objective of the paper and the character of analysed phenomena, the authors adopted methodology of an inter-subjective paradigm, within which they used an idiographic approach which allowed analysing a concrete phenomenon in its context. The research was carried out using the method of a multiple case study (Yin, 2014), following its methodological rigor (Eisenhardt, 1991). The choice of the method is a result of set research objectives and the stage of knowledge development in the investigated research area. Operating of virtual structures still is a relatively new phenomenon. It develops in a very dynamic way and is conditioned by numerous variables. There is a need for a thorough examination which would allow formulating propositions of patterns and development of the phenomenon in question. Therefore, the presented research is interpretative (Eisenhardt and Graebner, 2007) and it leads to in-depth understanding of the phenomenon in some particular context.

During the research the authors worked out a pattern for creating consistency mechanisms. Firstly, they identified organizational culture of Turkish organizations: the levels of language, behavior and infrastructure artefacts, norms, values and cultural traits were examined and their characteristics identified. Such an approach to the research allowed providing results which can become a significant help for organizations which plan to cooperate with foreign partners to adjust to the organizational culture. To make this adjustment effective, the authors worked out the examples of consistency mechanisms, which are presented further in the paper. The mechanisms are based on the organizational culture characteristics collected during the research.

Scrutiny within multiple case study was carried out in two stages: within-case analysis and cross-case analysis. Following the replication logic, case studies constituted a series of independent research which provided data corresponding with the research questions. Outcome of each individual case study was a base for cross-case comparisons with results of other cases. It allowed theoretical generalizations concerning the pattern of identifying collaboration mechanisms.

The paper presents results of 22 case studies. The key criterion of choice was the variety of cases (Flyvbjerg, 2012) – the organizations were chosen in the way which made the research group differential. It included different public organizations, but also private firms from a production and service sector. The companies belonged to different trades and they were of a different size. Such a variety of the research group allowed giving a very realistic perspective on the characteristics of Turkish organizational culture. The access to crucial data constituted additional criterion. It referred

to the possibility of carrying out in-depth interviews with managers and regular workers. Moreover, it ought to be emphasized that it was a very deliberate decision to use a territorial limitation (in this case to the city and province of Muğla). It allowed very precise identification of organizational culture which developed in a particular region. Such an approach corresponds with the needs of organizations which develop collaboration with foreign partners – very often they expect to identify cultural conditions not so much of some country, but rather of a specific region (or regions) in which they operate. It constitutes another strong reason for using a case study method rather than quantitative ones.

Eight of research cases were public organizations and fourteen represented a private sector. Public institutions consisted of university units and health institutions in the city of Muğla. As for the private sector, they were small and medium size entrepreneurships operating in the city of Muğla. Eight of the companies were from a service sector and the rest of them were production companies. The in depth interview was conducted among the total of 78 workers from different levels of organizations' structure, but most of them were lower-level (production) workers. 26 respondents were managers of different levels.

At this point it is crucial to emphasize that the authors did not aim at statistical generalization, but rather understanding, depicting and synthesizing. They made an attempt to understand the reasons and ways of creating strategy and organizational (virtual) structure (Remenyi et al., 2005). They focused not only on repetitive, but also contextual relations between elements of environment. Such an approach allowed capturing experiences of the research group and their interpretation, and complex understanding of the analysed phenomena.

The in-depth interviews were conducted in November and December 2019, supported by a questionnaire which included mostly open questions. The data was coded according to adopted conceptual frames (*a priori* codes) (Miles and Huberman, 2000). Collected answers were grouped, so that it was possible to establish how often a given characteristic was mentioned by the respondents. Then, the crucial artefacts in each group were identified using statistical calculation. For each group the authors calculated the third quartile (Q3). The artefacts which were included in the third quartile constituted the base for working out the consistency mechanisms.

Results and Discussion

Elements of Organizational Culture

The first stage of the research aimed at identifying all elements of organizational culture of Turkish organizations. Each kind of artefacts (language, behavioral, material, norms, values, standards and cultural traits) was analyzed separately and presented in tables 2-6. Each table shows assessment made by members of both public and private organizations.

As presented in table 2, views regarding crucial language artefacts appeared to be very similar. Both groups of respondents stressed importance of verbal communication and face to face contacts. Moreover, there is a clear expectation and openness to exploit new communication technologies. Both kind of organizations prefer using Turkish language, but public organizations also exploit English. In private organizations it is common to use technical language.

Table 2: Language artefacts

Artefacts	Members of public organizations	Members of private organizations
Verbal communication	**32**	**39**
E-mail, Whatsapp and other communicators used	25	18
Traditional phones communication	25	22
Written communication (letters)	17	8
Face to face contacts	**26**	**24**
Body language	9	12
Support and assistance while communicating	9	6
Openness to use/learn new technologies in communication process	**39**	**26**
Confidentiality of communication	13	20
Official way of communicating	20	3
Semi-official and friendly communication	15	18
Meeting presentations	5	2
Bureaucracy in communication process	18	2
Preferring using Turkish language	**31**	**24**
English use	**33**	5
Turkish dialects/slang use	13	14
Office-based, specific language	2	16
Technical language	17	**34**

Source: own study

As for another artefacts, the answers differ substantially. In case of behavioural artefacts, in public organizations dominate official behaviour, bureaucracy and objectives oriented attitude, whereas private organizations stressed rather less official behaviour, team work and task responsibility (table 3). Regarding material artefacts (table 4), representatives of public institutions emphasized importance of rather official dressing and proper interior design. The latter feature was also highlighted by private firms, but it was accompanied by efficient use of technological devices and exploitation of internal communication systems.

Table 3: Behavioural artefacts

Artefacts	Members of public organizations	Members of private organizations
Official behaviour	**28**	17
Semi-official behaviour	10	**39**
Respectful, professional behaviour	17	13
Official manager-employee relations	18	9
Non-official attitude to colleagues	15	**25**
Tolerance to different behaviours	9	8
Strict rules in behaviours	15	18
Helpful behaviours	18	14
Behaviours regulated in organizations	21	13
Bureaucratic	**26**	8
Disciplined	13	18
Positive attitude	**22**	8
Humble and honest attitude	12	6
Behaviours based on task responsibility	16	**25**
Objectives orientation	**27**	19
Team work importance	16	**25**

Table 4: Material artefacts

Artefacts	Members of public organizations	Members of private organizations
Internal communication systems	12	**26**
Grouped and easily reached technical equipment	12	20
Efficient use of technological devices	14	**32**
Semi-official dressing	**22**	24
Official dressing	**38**	2
Dress code implemented	16	22
Work comfort dominates dressing style	17	19
Importance/originality of institutional interior design	**18**	**28**
Care of infrastructure	14	22

Source: own study

Concerning dominating norms, standards and values, in both kinds of scrutinized organizations serious attitude to work and expectation of continuity of relations were picked (table 5). However, in public units also honour and sense of stability is important, whereas private firms underlined some aspects of time management. Finally, in case of cultural traits, public organizations emphasized hard

work, respect, tolerance, information sharing and loyalty to work-place. The latter one was also highlighted by private companies, but it was accompanied by IT orientation, expectation of job satisfaction and financial benefits (table 6).

Table 5: Norms, standards and values

Artefacts	**Members of public organizations**	**Members of private organizations**
Pragmatism	9	12
Time/deadlines respected	13	**26**
In daily routines 'just in time' attitude	12	**25**
Serious attitude to work	**19**	**23**
Importance of ethics	18	20
Team-spirit	16	21
Respect to mission and vision of institution	14	11
Work highly valued by employees	15	18
Love and sincerity	17	10
Hospitality	17	14
Honour	**25**	16
Stability	**19**	14
Continuity of contacts and relations	**26**	**23**

Collaboration Mechanisms for Consistency

Having established the characteristics of organizational culture for Turkish public and private entities, it was possible to work out the mechanisms for consistent cooperation. Below, we present the main characteristics divided according to the organizational culture levels. The analysis was done separately for public and private organizations. Each characteristic corresponds with dedicated mechanisms. What is crucial, the mechanisms created by the authors are just examples - they are supposed to help and encourage managers create their own collaboration mechanisms according to the situation they are in.

Language Consistency

As we can notice in table 7, Turkish public and private organizations are quite similar as for language artefacts and so they require implementing similar consistency mechanisms. It is important to put an emphasis on personal contacts and direct, verbal communication. İt is crucial when starting collaboration with Turkish organizations, but also when the relations develop. Face to face communication is important, so it is necessary to pay regular visits to Turkish partners. İf it is not possible (for instance because of a geographical distance), the Internet tools should be used, so that Turkish partners could see the face of the person they speak to. This way personal, friendly relations develop and the trust between partners is built. Moreover, when employees speak English, they perceive it as an opportunity to practice and develop language skills. Therefore, this aspect of cooperation also should be taken into consideration.

Table 7: Language artefacts characteristic for Turkish public and private organizations and dedicated cooperation mechanisms

	Language artefact for public organizations	**Cooperation mechanisms**
1	Verbal communication	Using phones and other IT communicators allowing direct contacts with Turkish partners; direct negotiating of crucial cooperation terms; verbal confirmation of cooperation terms before formal documents are prepared
2	Face to face contacts	Personal visits in Turkish companies when starting cooperation and then in ongoing contacts; using modern Internet tools allowing face to face conversations; using face to face contacts to strengthen verbal communication; working out friendly relationships based on personal contacts
3	Openness to use/learn new technologies in communication process	Introducing new Internet tools for mutual communication; personal training for Turkish employees concerning the use of new communication tools
4	Preferring using Turkish language	Verbal communication with native translators; written communication in Turkish language;
5	English use	If possible, using English in verbal and written communication (when Turkish employees speak English)
	Language artefacts for private organizations	**Cooperation mechanisms**
1	All the above – see public sector section	As in public sector section
2	Technical language	When the trade requires using Turkish and English technical vocabulary

Source: Own study

Behaviour Consistency

As shown in table 8, regarding behavioural artefacts the mechanisms of cooperation with Turkish public and private organizations are different. Public organizations are more formal, there is a need to follow strict rules and codes, and there is a very little space for informal relations. In a private sector the situation is less formal, it is possible to organize informal meetings outside the company and it is important to pay attention to integration of cooperating partners. İn this case friendly atmosphere helps reaching business objectives.

Table 8: Behaviour artefacts characteristic for Turkish public and private organizations and dedicated cooperation mechanisms

	Behaviour artefact for public organizations	**Cooperation mechanisms**
1	Official behaviour	Organizational code necessary to be followed; formal meetings with managers and workers; formal body language
2	Bureaucratic	Recognizing formal requirements and rules; following formal procedures; making sure all formal requirements are met; preparing to take time when cooperating
3	Positive attitude	Following rules and meeting formal requirements with enthusiasm and patience; being nice and helpful to Turkish workers when following procedures
4	Objectives orientation	Concentrating on meeting requirements and following rules and regulations when cooperating
	Behaviour artefacts for private organizations	**Cooperation mechanisms**
1	Semi-official behaviour	Private meetings outside company; company integration meetings; codes less important to follow
2	Non-official attitude to colleagues	Making friends with Turkish partners allowing informal contacts; creating informal atmosphere in mutual relations; close relations with cooperating workers from different countries
3	Behaviours based on task responsibility	Focusing on objectives to be met; discussing business matters first; paying attention to organizational profits; possible to rely on Turkish partners when reaching objectives
4	Team work importance	Creating teams when cooperating; integrating cooperating workers and companies; various forms of formal and informal integration

Source: Own study

Infrastructure consistency

The research results from table 9 show that there are some substantial differences when we take into consideration material artefacts' importance for public and private organizations. In a public sector it is important to be dressed rather formally, according to a dress code. However, in a private sector material artefacts are mostly connected with the IT systems and devices the companies implement and use on daily basis. Thus, foreign partners need to adjust to the systems, so that the communication process is effective. İn both cases (public and private) the design of office space is important and often it reflects Turkish culture. Thus, other members of an inter-organizational network ought to acknowledge and respect this aspect of relations.

Table 9: Material artefacts characteristic for Turkish public and private organizations and dedicated cooperation mechanisms

	Material artefacts for public organizations	**Cooperation mechanisms**
1	Semi-official dressing	Dressing less officially in routine contacts; less formal way of dressing when meeting the same level co-workers
2	Official dressing	Dressing in an official way when relations are initiated and when official meetings are held; dressing officially when meeting higher level managers
3	Importance/originality of institutional interior design	Respecting originality of interior corresponding with Turkish culture
	Material artefacts for private organizations	**Cooperation mechanisms**
1	Internal communication systems	Effective use of internal communication with the use of IT tools; using electronic documents and signatures; necessity to get familiar with IT applications in communication systems
2	Efficient use of technological devices	Necessary to get familiar with technological devices and adjust to the technological requirements; using new technological solutions during cooperation
3	Importance/originality of institutional interior design	As in public organizations section

Source: Own study

Norms and values consistency

With regard to norms and values, first of all it is necessary to respect workers and the rules they follow in everyday routine. Partners ought to respect Turkish customs and culture, and avoid open criticism. İt is also very important to focus on long-term relations by setting common strategic goals. Generally, it is useful to show that we want to get engaged in the cooperation process seriously and for a long period of time. All the actions which express such intentions may be implemented, which gives foreign managers a possibility to be creative in this process.

Table 10: Norms and values characteristic for Turkish public and private organizations and dedicated cooperation mechanisms

	Dominating norms and values in public sector	**Cooperation mechanisms**
1	Serious attitude to work	Following formal procedures; showing respect and understanding towards procedures and local customs; helping in fulfilling legal requirements; showing respect to the cooperating organizations; avoiding open criticism
2	Honour	Creating win-win solutions; open communication and cooperation process; showing respect to organization, workers and culture; respecting family bonds and relations
3	Stability	Creating clear rules of cooperation; putting emphasis on long term relations; creating friendly atmosphere; giving support to problem solving
4	Continuity of contacts and relations	Long-term orientation of cooperation; creating long-term plans and objectives; mutual exchange of workers; planning and working process in mixed teams
	Dominating norms and values in private sector	**Cooperation mechanisms**
1	Time/deadlines respected	Treating deadlines seriously; trying to do things on time or even

		before deadline; setting realistic deadlines and avoiding crossing them
2	In daily routines 'just in time' attitude	Patience with waiting for output; helping in production process and just-in-time practices; avoiding stressful situations when deadlines have not been crossed yet
3	Serious attitude to work	As in the above section
4	Continuity of contacts and relations	As in the above section

Source: Own study

Cultural Consistency

While cooperating with Turkish partners, it is necessary to pay attention to effective communication systems which will support information transfer between partners. Another findings show that Turkish workers are very loyal to their work places, so it is necessary to show respect to the organizations they work for and to avoid open criticism. Also, Turkish workers are very tolerant, so there is no need for foreign partners to adjust strictly to cultural norms and habits.

İt is also interesting that Turkish organizations are open to the latest technology. Thus, delivering new IT solutions may strengthen cooperation and help build long-term relations. Finally, it is very important to make sure that Turkish partners are financially satisfied. Therefore, business partners should consider implementing different financial bonuses.

Table 11: Cultural traits characteristic for Turkish public and private organizations and dedicated cooperation mechanisms

	Dominating cultural traits in public organizations	**Cooperation mechanisms**
1	Hardworking	Respecting workers duties; offering help with common ventures; being ready for long working hours; spending much time in office with Turkish partners
2	Information sharing	Efficient listening process in contacts with Turkish partners; communicating clear terms, objectives and expectations; sharing information from outside business world; taking an interest and being involved in the process of mutual communication
3	Loyalty to work-place	Respecting the name, nature, tradition and principles of Turkish company; avoiding criticism in an open form; avoiding complaining about own company, rules, managers, procedures; being loyal to Turkish partners, which helps to build up long-term and trustful relations
4	Respectful and tolerant attitude	Being yourself, not trying to copy local behaviour and believes; keeping own originality in look, behaviour and believes; being open in explaining failures and mistakes
	Dominating cultural traits in private organizations	**Cooperation mechanisms**
1	IT orientation	Using various IT tools in cooperation and communication process; offering new tools to be implemented; helping with development of new IT solutions within company
2	Job satisfaction	Taking actions which lead to making Turkish people more satisfied with their job; making friends and creating wide net of relations giving the feeling of family atmosphere; improving local working conditions; financial aspect of satisfaction important (bonuses); rewards system
3	The will to get rich	Putting an emphasis on financial aspect of cooperation; rewards,

		bonuses; life-standard-improving bonuses such as corporate cars, telephones, computers
4	Loyalty to work-place	As in the above section

Source: Own study

Conclusion

Presented analysis allowed more thorough understanding of relational characteristics of virtual structures, which constitute crucial value for the development of network science (Watts, 2004; Hudson, 2004; Moller and Wilson, 1995). The authors made a theoretical contribution of conceptualizing a pattern of adjusting to organizational culture in virtual structures. Furthermore, in order to strengthen the practical contribution of the study, the authors presented a possible use of the template on the example of Turkish organizations. The results show that in Turkey the characteristics of organizational culture differ substantially between private and public units and organizations which collaborate in virtual structures ought to acknowledge this by implementing different mechanisms for each kind of an organization.

Finally, the authors would like to stress that the conceptualized pattern and the process of working out mechanisms ought to serve for integrators in virtual organizations as a general template which shows in what way to increase efficiency of relations in a cultural dimension. Although the analysis was done using the method of a multiple case study, the process is universal and it may be implemented by every unit which develops collaboration within virtual structures.

Abstract

The urgency of this research is predetermined by a significant role of the food industry in securing food independence of the Russian Federation, stiffer competition on the local and foreign markets, lower effectiveness of resource use at oil extraction companies. The objective of the research is to adapt the raw material diversification mechanisms to industry specifics of managing raw materials supplies at oil extraction companies to widen the production range without infringing the interests of plant growing companies, which specialize in oil seeds, and vegetable processing companies. Our article dwells on the scientific and methodological basis of raw material diversification of oil extraction companies and trends of raw materials provision of the Russian Federation's oil extraction enterprises, which became the basis of our recommendations to improve company management when implementing a raw material diversification strategy. Insufficient knowledge of organizational and economic issues of raw materials diversification and scientific and practical importance of raw materials diversification in managing food company supplies predetermined the novelty of our research.

Keywords: Raw Material Diversification, Processing Industry, The Agro-Industrial Complex, Efficient Use Of Raw Materials, Raw Materials Supplies.

Introduction

Stiff competition and economic sanctions made the issue of effective raw materials supplies of the Russian food companies urgent, and raw materials diversification can become a good solution.

Cite this Article as: Irina Petrovna BOGOMOLOVA, Nataliya Mitrofanovna SHATOHINA, Lyudmila Timofeevna TRINEEVA, Sergey Anatolevich LOSKUTOV And Irina Evgenievna USTYUGOVA" Strategies of Raw Material Diversification in Management of Resource Supplies of Oil Extraction Companies" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The fat and oil industry is the backbone of the processing industry in agriculture, which produces highly valuable foods (vegetable oils, margarines, mayonnaises), high demand goods for the households. Besides, products of the industry are used as raw material in bakery, confectionery, vegetable canning industries as well as in production of detergents, cosmetics and medical goods, paintwork and other types of technical products. Oil raw material wastes (oilseed cakes, extracted meal) are an important raw material component for mixed fodder used in cattle breeding and poultry raising.

A research of the Russian market of oilseed cakes and extracted meal established its significant differences from the trends of the international market. First, Russia mainly grows sunflower as opposed to soy worldwide. Second, the Russian Federation virtually uses no oilseed cakes and extracted meal in production of mixed fodder as a source of protein, like the European Union countries do. However, the Russian oilseed cakes and extracted meal market grows steadily adding more than 50% in the last five years. The key qualitative changes of the market can be attributed to the growing production of soy meal in the Kaliningrad region. Rising internal consumption of oilseed cakes and extracted meal is an undisputable fact conditioned by the development of cattle-breeding and fish farming and a fall of their share in exports from 40% to 25%, although exports of oilseeds remains flat. However, imports structure does not change dominated mainly by the soy meal and sunflower cakes.

Our theoretical and analytical research revealed that raising the efficiency of raw materials use is pivotal for the local economy on the whole and the economy of the fat and oil industry companies in particular. The quality and quantity indicators of the raw materials are essentially the basis for organization of production predetermining the level of production capacities use, duration of the working season, the volume and range of products [1].

Literature Review

Critical assessment of theories of the Russian and foreign scientists on diversification management (table 1) as well as multi-dimensional scientific research of practical expertise and special features of industry operations were the basis for adjustment of scientific and methodological foundation of raw materials diversification at food companies. In particular, we singled out the preconditions of diversification, revealed its advantages and disadvantages, defined the factors and criteria, on which the choice of diversification strategies depend.

Table 1: Classification of the key notions and definitions of diversification by different authors

Author	Definition
1 Diversification as a form of capital concentration	
R.Z. Akberdin A. Ya. Kibanov	One of capital concentration forms to enter the market.
T. Eggertsson	Variety of investment for creation of a stake, which would be stable and sustainable to market fluctuations.
P.P.Sorokin	All associations of interconnected and non-interconnected productions within a company.
2 Diversification as a way to expand the product range	
I.Ansoff	Widening the product range to be carried out by isolated enterprises or their associations.
S.M. Sinelnikov, T.G. Solomonnik	Augmentation of a product range with the goods unrelated to the technology in use, or produced goods or services.
A.A.Anfinogentova	Significant widening of the company's scope and creation of production of a large number of interrelated goods and services of the same type.

3 Diversification as a way to widen company structure	
D.S. Sink	Widening of the product range through simultaneous development of many unrelated productions.
V.S. Balandin, N.S. Yashin, E.A. Bagirov	A risk reduction strategy through diversification of investment between several high-risk assets.

Stable functioning and sustainable development of socially important branches of the food industry, on which state food security depends, largely hangs on their raw materials supplies, of which the key control lever is diversification.

Problem

Given the fact that the industry is socially important and raw material intensive, but can use different types oil seed plants (sunflower, soy, rapeseed, flax, mustard greens, castor bean, etc) special attention should be paid to the raw material supplies to the oil and fat industry. The first three account for about 95% in Russia's sown area. The Volga, South, Central and Siberian federal districts account for the bulk of the area sown with sunflower (44.0%; 23.4%; 17.5% and 9.1% respectively). Soybean crops are mainly concentrated in Russia's Far East (50.5 %), Central (31.0 %) and South (8.2 %) federal districts. Rapeseed resistant to the cold climate is grown in the Siberian (40.4 %), Central (22.6 %), Volga (17.3 %) federal districts. At that, the trends confirm sustainable growth of the area under oil seed plants. Thus, in 2015-2018, the Russian Federation's sunflower crops growth amounted to 117.5 %, while the area occupied by soy and rapeseed grew by 38.2% and 55.1 % respectively. The Siberian federal district led the soy area growth (by 350%). The worst growth of rapeseed area was demonstrated by the Urals federal district (+ 1.5%).

A clear positive area growth trend couples with sustainable growth of the gross oil seed crops in the Russian Federation – the rapeseed crop doubled in 2018 compared with 2016 and sunflower seeds by 16% in the same time bracket. The Urals and Siberian districts are the growth leaders. A breakdown of the gross crop by the key oil seed plants demonstrates sustainable leadership of sunflower (from 67.5% in 2016 to 65.6% in 2018). Soy was second largest in the gross harvest of Russia's oil seed plants (from 34.3% in 2016 to 31.3 % in 2018).

Synthesis of statistical information helped us identify the patterns of oilseed crop yield indicators and a close correlation of their values with the weather and climate conditions, as well as compliance with the requirements of cultivation technologies. In particular, the sunflower yield in the period under consideration averaged 13.3-16.0 hundreds kilograms per hectare with the Central, South and North-Caucasian federal districts being the leaders. The soy yields vary by 250% in 2015-2018, while the average country indicators stood at 12.7 (2015) – 14.1 hundreds kilograms per hectare (2016). Russia's average rapeseed yields demonstrated lesser variety (from 9.9 to 14.7 hundreds kilograms per hectare in 2015 and 2019 respectively, or a little over 50%). The stable yield leaders in the period are the North-West, South and Central federal districts. The Volga district is an outsider.

Table 1: Rapeseed yields in Russia's top-10 regions in 2019 hundreds kilograms per hectare.

Region	Yields, hundreds kilograms per hectare	In % to average 2015-2019 yield
Krasnodar region	17.0	115.6
Altai region	10.4	70.7
Tula region	23.6	160.5
Tatarstan republic	14.9	101.4
Kaliningrad region	31.9	217.0
Omsk region	9.6	65.3
Lipetsk region	22.5	153.1
Novosibirsk region	11.5	78.2
Kemerovo region	14.7	100.0
Ryazan region	20.3	138.1

Despite a low soy and rapeseed yield compared to other states, academicians and practitioners say that growth of the sown area is promising because it helps solve one of the key raw material diversification problems in the production of vegetable oil and oil meal (a highly protein feed with a high content of feed plant proteins) and to cement the Russian Federation's export potential. International demand for oil seed plants and products of their processing is confirmed by the following. In the 2017-2018 season, soy exports amounted to 915,387 tonnes (66.9% of total oil seed exports), rapeseeds to 362,717 tonnes (26.5%), sunflower to 89,638 tonnes (6.6%). The key importing states are China (89.4%), Belarus (6.7%), while Iran, the Republic of Korea, Turkey, Azerbaijan, Kazakhstan and others totally account for 3.9%. Practically the same situation can be seen in rapeseed exports where the key customers are China (35.5%), Belarus (35.1%), Mongolia (22%), Nepal (2,3%), Turkey (1.4%) and Germany (1.4%). Russian sunflower is bought by Belarus (26.2%), Turkey (23,2%), Iran (14.5%), Kazakhstan (8.9%), Ukraine (5.6%), Azerbaijan (5.2%) and some other states.

The product of rapeseed processing is rapeseed oil and rapeseed meal (one of the protein animal feed types, which is close to soy and much richer than traditionally used sunflower, pea and bean meal by its energy value, protein activity and amino acid composition). The key Russian regions using rapeseed meal in production and consumption of mixed fodder include the Voronezh, Moscow, Leningrad, Kursk and Lipetsk regions.

Rapeseed oil is not only the basis for production of many foods, including mayonnaise and margarine. It is used for frying, as a dressing for cold dishes, in cosmetics to produce facial masks and in pharmaceuticals in making unguents and injections. Rapeseed oil is also used to produce fatty esters used in biodiesel fuel and lubricants, in the textile and rubber industries.

Our statistic research demonstrated a stable growing tendency of natural and price indicators of the internal and external markets of vegetable oils. This can be partially explained by growing consumption if oils by the Russians in the wake of their transfer to healthy eating and positive dynamics of the Siberian and Far Eastern markets. Although sunflower oil accounts for the key segment of the market (over 83%), corn oil demonstrates the highest growth.

There are goods from foreign partners on the Russian oil seed market. In the 2017-2018 season, Russia imported 104,400 tonnes of unpacked vegetable oil, mainly rapeseed, sunflower and soy. The key exporters are Belarus (75.3%), Ukraine (20.7%) and Israel (2.7%). Rapeseed oil suppliers are also the Republic of Korea, Finland and Germany. At the same time, there is a declining trend of fat

and oil products imports thanks to acquisitions by large Russian holding companies and the launch of production by leading foreign companies on the territory of the Russian Federation.

Our country tries to maintain the balance of export and import operations on the fat and oil market. In the season under research the country exported 2,784,457 tonnes of oil, including 66.5% of sunflower, 19.8% of soy and 13.7% of rapeseed oil. The key consumers of the three types of Russian vegetable oils are China (16.8%), Egypt (15.4%), Turkey (13.1%), Iran (8.3%), Algeria (6.7%), Norway (5.3%).

Given the quality characteristics of Russian imports, which are often genetically modified raw food materials and food (many experts confirm that some imported margarines, vegetable oil and sauces contain transgenic soy, corn and rapeseed, which is detrimental for the health of Russians), we should point to a high competitive potential of local fat and oil companies on the international markets. Practice confirms that compared to foreign producers they use virtually no genetically modified components and Russian products are no worse than their foreign analogues by many indicators, including ecological safety. At the same time the issue of rising competition is exacerbated not only by the absence of effective policies and mechanisms of state regulation of the Russian market of genetically modified oil and fats products, but also the need of boosting provision with resources underpinned by raw materials diversification of companies taking into account international and consumer requirements.

Discussion and Results

Our research outlined the key preconditions of raw material diversification, which could stimulate the growth of companies, widen their product ranges and help them branch out into non-traditional raw material markets. They are:

First, the macroeconomic trend of shrinking margins in the traditional industries, the effect of the law of uneven economic development of some industries when the market changes, the requirements of scientific progress and economic digitalization.

Second, the key economic advantages and disadvantages outlined by the authors. Positive fallout of the organizational and economic mechanism under research includes the possibility of use of the current materials basis and personnel, rhythmic income generation from operations due to elimination of the negative consequences of seasonality typical of food companies, cementing competitive positions and widening markets thanks to the use of non-traditional raw materials and production of new goods. However, we should point to the limitations of diversification – heavy investment in innovations, long implementation and a high risk of the projects, insufficient knowledge of managers and other personnel.

Third, a research of results of the companies, which diversified successfully made the basis of decomposition of the factors they took into account (condition of the world and Russian economies, competitive positions on the local and foreign markets; economic trends, special features of raw materials supplies and production). Assessment of the diversification results should factor in not only the final financial indicators of the company, but also strategic prospects of its production and sales. Defining strategic alternatives will help the management pick the best type of diversification, which will take into account the possibilities of material, labour and financial resources of the company. However, since food production is material intensive, when choosing a diversification strategy one should pay most attention to provision with raw materials based on stronger cooperation with farmers.

Analysis of expert assessment of Russian problems of raw material diversification led us to the following recommendations for development of the system in Russia with the aim of solving the current problems:

1. A diversification decision should be taken basing on the analysis of various forecasts. Traditionally, according to our research, foreign and local enterprises use three key criteria when working on their diversification strategy – industry attractiveness, costs to enter the industry, additional advantages. At the same time, given industry specifics of food production (uneven development; violation of price parity for raw materials, materials, fuel and energy and other resources; quantity and quality fluctuations of raw material supplies thanks to the seasonal type of operations; a low value of the production capacity utilization factor; low margins, etc.), we believe it reasonable to introduce a new criterion, which will incorporate all the qualitative and quantitative elements of raw materials resources supplies and the efficiency of raw material diversification, which would ensure sustainable development of a company and help stick to the chosen strategy.
2. Raw materials diversification should include analytical and controlling instruments to ensure management aimed at an economic effect of a chosen strategy of rapid business development, reducing the risk of unfavourable environment. After analysis of the current market conditions we recommend:
measures to diversify raw materials and products by switching to seasonal processing of rapeseed, whose crop in Russia rises steadily;
the use of economic and mathematical methods to forecast the key parameters of the local oil seed market (gross crop from the sown area, the highest possible yields with a correction factor of compliance of the sum of active temperatures and the amount of precipitation with normative indicators, as well as raw materials' price trends).
3. Raw materials diversification as an organizational instrument to boost production of food without additional financial costs. Plants often have to suspend their operations due to the absence of the necessary amounts of raw materials until a new harvest appears, which results in a market share loss and deterioration of financial standing of a company on the back of rising semi-fixed costs in total production costs because there is shortage on the sunflower market each year with a simultaneous price rise. At the same time, the companies can boast equipment capable of creating multilines to process different types of oilseeds, creating higher efficiency thanks to processing oil extraction wastes.
4. Managerial solutions to implement a raw material diversification strategy with the use of our algorithm of an economic and mathematical model of raw material diversification in managing oil extracting plants resources, which will result in adjustment of the highest crop and getting the highest possible indicators.

Modelling of a forecast includes the following stages. Initially the periods of information collection should be adjusted. Calculation in each area is done with the start of sowing (individual date for each region). Further, information of the Russian Federation Agriculture Ministry on sowing and the sown area as well as the sum of active temperatures and the volume of precipitation compared with their optimal values for the period -- the weather factors have the heaviest impact on the crop -- should be processed daily. The highest possible gross crop is calculated by multiplying the sown area by the highest yield registered in the region. A potential gross crop iscalculated by introducing coefficients to adjust the maximum calculated by dividing the real and normative factors. The work is finished by comparing the Agriculture Ministry's data on the threshed rapeseed and its gross crop forecast. Our recommendations say the deviation should not exceed 5%.

Thus, our research can be used when developing recommendations to improve the mechanisms of raw material procurement management of oil extraction companies while diversifying its raw materials basis.

Abstract

The topic of the article is extremely relevant at the present time, because there is a need to create an economically attractive image of the Ural region. In the article, the authors touch upon an unusual aspect that influences on the development of new industrialization in such an old industrial region as the Urals - the industrial legacy. They put forward a hypothesis, which they argue that brands created on the basis of the industrial heritage of the region can have a significant impact on the development of the Ural region. Through the creation of a special brand on the basis of industrial heritage, it is possible to promote products of the region, develop industrial tourism as one of the competitive products of the region, and gain a competitive advantage in modern economic connections. Arguments and proposals are made for such work by regional authorities and public organizations.

Keywords: Urals, Industrial Heritage, New Industrialization, Image, Brand.

Introduction

The relevance of the research topic is due to the fact that currently the image is becoming an important tool for the economic development of a modern region. Opinion about the territory formed by its residents and tourists among investors has a significant impact on revenue entering to the municipal budget, exports, investment flows and the dynamics of the gross regional product.

Socio-political, cultural, historical, investment attractiveness of the regions does not arise from scratch, but is the result of a formed and updated brand. Each region is represented in the mass consciousness in a manner endowed with unique characteristics. Such representations are a kind of public opinion concentrate.

Ural was originally formed as a region with a number of features that favorably distinguish it from other regions of the country, including industrial ones. This uniqueness of it cannot be used to create an economically attractive image that allows at least partially overcome the growing processes of deindustrialization.

The goal is to consider the industrial heritage of the Ural region and determine the possibilities of using it in order to create and manage the region's brand in the context of new industrialization, which will create opportunities for the development of business, territory (including museums, historical sites or landscapes of historical industrial parks) and industrial tourism.

Within the framework of the institutional and systems approach, the authors used such methods as analysis of materials obtained in the archives; analysis of the works of other researchers, whose articles are devoted to work on imageology, on brand theory, on the theory of new industrialization,

GONCHAROVA "Industrial Heritage as A Brand of The Ural Region in The Context of New Industrialization" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

literature on the industrial heritage of the Urals. The systematic approach made it possible to identify areas of work for the preservation and use of the region's industrial heritage in the context of new industrialization. It is aimed at creating a new industrial basis for the region and does not imply the preservation and use of industrial heritage objects for production and other purposes. Therefore, the conditions for the preservation of the regional industrial heritage are not positive. The authors did not aim to develop a new brand of the territory or its products; historical objects of the region's industrial heritage of the 18th-20th centuries were used for the analysis. This article deals with the development and preservation of regional brands in the form of an industrial heritage as elements of the region's competitiveness and its socio-economic development.

Literature Review

The literature review can be divided into four sections: work on imageology, on brand theory, on the theory of new industrialization, literature on the industrial heritage of the Urals.

Let's consider first of all research on creating the image of the region. For a modern, economically attractive image of the region (Zapariy and Zaitseva, 2017), it is possible to form several territory brands.

In the Urals it is possible to develop and use such a brand as the industrial heritage which was formed as a result of the specific development of the region. Since there are many industrial heritage sites preserved on its territory.

The image of a territory is understood as an aggregate or system of basic (simple) ideas about a certain territory, created, represented and transmitted mainly through the media for specific political, socio-cultural, economic purposes. From the standpoint of image perception by image-making objects, the image of a region is “a relatively stable and reproduced in the mass and / or individual consciousness the totality of people's emotional, rational ideas, beliefs and feelings that arise about the characteristics of the region, are based on all the information received about the region from various sources, as well as personal experience and impressions” ” (Arlashkina and Napalkova, 2014). .

So, the following subjects of image-making are involved in creating the image of a region: the region itself, represented by the authorities, at this level combines the functions of the customer and the performer; media and communications; specialists (political technologists, image makers, press secretaries, etc.); foreign economic and diplomatic services; state and public organizations; sports and cultural organizations and events, the education system, science, personnel policy; separate individuals (immigrants from the region, represented in the central authorities, well-known regional politicians, cultural figures, scientists) (Vasilkonova, 2014).

Among foreign studies of the problem of forming the image of the territory, it is necessary to note the work of N. Clifton (Clifton, 2014), who study the influence of the region’s brand on its image.

The author notes that many products associated with the region can have both positive and negative impact on the brand of the region. It is the regions that can create and maintain their own characteristics in a globalized and standardized world. At the same time, the role of intangible factors in the success of regional images or brands increases.

Within the framework of the brand theory, the economic and marketing approach must be distinguished, it is the dominant direction in the study of the brand phenomenon and is implemented in the framework of the branding theory. This approach is practically oriented. In the theory of branding, there are two directions: brand management and brand building.

Brand management theory examines the principles of brand management as a tool to increase the surplus value and intangible assets of the company. The main provisions of the brand management theory were developed by such Western researchers as D. Aaker, E. Rice, J. Ellwood and P. Temporal. Among Russian researchers, must be mentioned I. Ya. Rozhkov, V.N. Domnin, and E. A. Ruday.

As part of the brand-building theory, the way for the development of the ideological concept of the brand and its attributes - name, logo, packaging, corporate character, etc. is searching, and the problems of creating brand formation techniques in the mass consciousness are being studied. The development of the ideological concept of the brand is devoted to the work of M. Mark and K. Pearson, J.-M. Drew, D. Aaker, as well as M. Vasilyeva and A. Nadein. In the theory of brand building, a brand is interpreted most often as a brand image formed in the mass consciousness (Arkhangelskaya, 2006).

The concept of "new industrialization" is new to domestic science. Its formation began with an article by MSU professor S.S. Gubanov (Gubanov, 2008). The study of the theory of industrialization, including in relation to Russia, was continued by leading Russian scientists (S.D. Bodrunov, S.Yu. Glazyev, R.S. Greenberg, V.V. Ivanter, V.L. Inozemtsev, V. M. Kulkov, E. B. Lenchuk, O. A. Romanova, V. T. Ryazanov, A. S. Sukharev, A. I. Tatarkin (Silin and Animitsa, 2017), (Silin at al., 2017).

The problem of identifying, studying, preserving, rehabilitation and subsequent use of industrial heritage sites is one of the leading themes of foreign scientists (Vargas-Sánchez, 2015). In the Urals, were among the first to raise this problem. V.V.Alekseev, E.V. Logunov, E.A. Kurlaev and others. Nowadays, among historians of the Russian and Ural industrial heritage, historians of Ye.V. Alekseev, V.V. Zapariy, E.S. Lakhtionovu, A.E. Kurlaeva, architects N.S. Solonina, O.A. Shipitsynu et al. (Vargas-Sánchez, 2015).

Thus, the problem of creating and using industrial heritage as a brand of the Ural region in the context of new industrialization has not been well-studied yet. Relying on the results of new studies, regional authorities can develop a completely applicable strategy to overcome the problems of the region.

In recent years, the theory of new industrialization has taken a leading position in economics. It was first formulated by V. Beitman, C. Richter, P. March, S.S. Gubanov, N. Pakhomova and others (Dobos at al., 2012, (Bateman, 2013), (Sharma, 2016), (Marsh, 2012).

In our opinion, this theory most adequately reflects the modern vision of economic development processes taking into account the latest technical and technological trends. Among the processes affecting the new industrialization, there are those that we would like to highlight. In a modern competitive economy in the context of globalization, the most important factor influencing positively on the development of regions there are processes that increase competitiveness (Dvoryadkina at al., 2017).

The distinctive factor that highlighting our region from others is the centuries-old technical and technological history. It is reflected not only in modern scientific and technical achievements of the modern Ural industry, but also in the rich industrial heritage that influences modern scientific and industrial culture. This means that this advantage can and should be used as a competitive one. For this it is necessary to formulate the appropriate brands.

It is through branding of the industrial heritage regional authorities can promote the products of the region, develop industrial tourism as one of the competitive products of the region, and gain a competitive advantage in modern economic ties.

The problem of brands and their impact on improving competitiveness is well studied in the scientific literature and is used in such sciences as management and marketing. Recently, a separate area has been singled out - territorial branding or branding of places, including branding of the city. Among foreign researchers, the names of C. Dinni, T. Moilanen and S. Rainisto et al. (Bivainiene and Tamosiunas, 2017), (Dinnie, 2011), (Green at al., 2018), (Moilanen and Rainisto, 2009) should be mentioned. In Russian science, the study of the theory of branding of places is done by D.V. Vizgalov, M.E. Zykova, V.V. Zyazin, M.M. Smetannikov and others (Vizgalov, 2011), (Zykova, 2010), (Zyazina, 2010).

Practical Relevance, Suggestions and Results of Implementations

Using of branding technologies contributes to the development of investment attractiveness, growth of the region's reputation capital, allows to form loyalty to the region for both internal (permanent residents) and external (immigrants, investors) target audiences.

Attraction of industrial heritage as a brand of the Ural region carries two-sided practical significance. On the one hand, it is an opportunity to raise the level of the industrial region to an even greater degree: the promotion of Russian production and its technical and technological capabilities in order to attract the attention of the state and society to overcome the problem of falling importance of industry in the country's economy, which is becoming uncompetitive in relation to the industry of neighboring countries. On the other hand, the formation of an attractive image of the region through the creation of a voiced brand will accelerate and strengthen the processes of studying, preserving and using monuments of industrial heritage in the Urals (Zapariy and Zaitseva, 2017).

Fig. 1: What do you associate the Ural region first of all with?

In the case of the positive experience of the Urals in creating a working brand that brings economic profit to the region, this example can be used by other regions of Russia.

In terms of achieving the goals of new industrialization in Russia, the formation of a successful image of the leading industrial region of the country will allow to solve the following tasks:

• formation of investment attractiveness of the region for domestic and foreign businesses;

• attracting potential residents (labor force, students, scientists); an obstacle to the outflow of talented youth and skilled labor to other regions and countries (Mihajlov, 2009).

• the formation of the tourist attractiveness of the region and the development of scientific, cultural, entertainment and business tourism; obtaining support from the state budget and ensuring the participation of regional projects in federal programs; attraction of federal orders for enterprises.

Fig. 2: Does the industrial heritage influence the region image?

One of the ways to preserve the monuments of the industrial heritage can and should be tourism (Timothy, 2016). An example of this we can see in Sweden. Closing the unprofitable steel mills and abandoned mines, the Swedes in many cases tried to keep them in the same form in which they were on the day they stopped. After some time, these objects were specially equipped for visiting and showing to tourists. Now they bring significant income, foster patriotism and respect for the past of

the country. In other countries, we can also observe numerous examples of the restoration, reuse or reprofiling of industrial heritage sites (Niu at al., 2018), (Xie, 2015).

In the Urals, in the Sverdlovsk region, there are objects, monuments of industrial heritage associated with such great personalities as N. D. Demidov, V.N. Tatishchev.

In order to preserve, maintain and develop these monuments, it is necessary to develop and implement a new cultural and educational tourist route to places with industrial heritage .

For example, a multi-day tour of the following cities and towns: Yekaterinburg, Verkhniy Tagil, Nevyansk, Byngi, Nizhny Tagil, Kushva, Ust-Utka.

Over 300 years of its existence, entire industries were created in the Urals, among which the mining industry played a major role. Now the region has preserved a number of industries and individual units, which are very interesting in terms of the industrial history of the past and present.

Fig. 3: Do you find necessary a safekeeping of the industrial heritage?

It is naturally surprising that there is no museum complex in the center of the Urals, which would be a museum of the Urals science and technology, covering the main branches of the Urals industry and science. Of course, over the decades of the museum's existence, the Urals have developed their own system of technical museology. So, the issues of preservation, generalization and propaganda of industrial heritage are covered, first of all, by the Sverdlovsk Regional Museum of Local Lore, which has wonderful foundations on the history of technology. Certain exhibitions exist in the Museum of Architecture, the Museum of Radio of A.S. Popov, museum exhibitions of a number of enterprises, universities and organizations.

The main tasks of the museum should be: the manning and preservation of monuments of science and technology of the Ural region, the popularization of scientific and technical knowledge and active educational work. The organization of the technical museum will serve to preserve the monuments of technology, which, due to the introduction of new technologies, modern equipment into production, are subject to dismantling and gradually lost.

The most important part of the national policy of each state and of Russia in particular is the creation of attractive image of the country in the eyes of people from other countries.

Cultural heritage objects now play this important role.

These industrial brands as "the Mining Ural", "Grey-Headed Ural", "Ural mountains – basic edge of power" and others, must become a recognizable brand in the region in the country and in the global stage, and branded the mark of the Ural factories "Siberian sable", if it can be reborn to claim the title of one of the world's oldest trademarks. Due to the fact that there are monuments of industrial heritage, Russia is represented in the eyes of the international community, not only the capital but also the province. Thereby, these centers became the objects of national and international tourism. The total number of visits by tourists (foreigners and Russians) to museums and reserves in the Urals reaches 1.5-1.7 million people annually.

It is important to note that the sector is "small" economy is quite profitable for the regions. In the field of touristic business and Museum service a significant part of the population can and should be

involved. A good example of this is the Museum-reserve Mikhailovskoye in the Pskov region, where in this area involved many hundreds of people.

In this context, it is important to create manifestation of legislative initiatives of local and regional authorities, scientific and public organizations to create a coherent system of record-keeping, research, conservation, rehabilitation and use of monuments of industrial heritage, which are of great interest not only in national but also international scale. And this should not be a distant prospect, because the delay in this case has dangerous ends, because every year we lose a large number of these cultural and material values for future generations, and we should prevent this.

Conclusions

The creation of a sustainable and recognizable brand in the Ural region on the basis of the industrial heritage involves the solution of fundamental tasks: to analyze market situation; development of action plan for brand promotion; the definition of their brand names; create a communication system.

To create an attractive environment for business, both domestic and foreign, on the territory of the region there should be extensively use of Federal laws and adapt these tasks to the regional legislation.

Use quality brand of industrial heritage does not mean that this will be the only brand in the region. On the contrary skilful combination of historical traditions and new tendencies of development looking to the future, augurs a powerful economic development.

According to the foregoing, it is possible to identify a number of areas that will allow for branding of the industrial region on the basis of the industrial heritage. 1. Identification and registration of monuments of industrial heritage. 2. Determination of their further use as museums, historic sites or landscapes of historical industrial parks or their conversion in the other direction. 3. The study of historians and architects of monuments, the creation of the list of architectural and historical descriptions of the objects. 4. A broad advertising campaign in print and on television about the monuments of industrial heritage and the importance of conservation. A series of books and booklets about the industrial heritage of the region. 5. Creating and maintaining a large number of touristic routes in the monuments of the industrial heritage of the region. The use of the monuments themselves and itineraries for educational purposes (schools, vocational and higher educational institutions), as well as in various forms of professional development. 6. Conferences and symposia at national and international level, drawing attention to the objects of industrial heritage. 7. Participation in international organizations working in the field of cultural and industrial heritage (UNESCO and TICCIH). 8. The involvement of the volunteer movement for the development and implementation of tourism products on the monuments of industrial heritage of the region. Besides this also need a broad discussion of problems in scientific and professional circles, the media. Such a discussion will attract public attention to the problem, will contribute to its successful solution in the future.

The Level of Sustainability of Enterprise's Activity as Assessed by Employees - Comparative Analysis in Poland And India

Teresa KUPCZYK

General Tadeusz Kosciuszko Military University of Land Forces, Wroclaw, Poland,
teresa.kupczyk@awl.edu.pl

Abstract

The article aims to diagnose the sustainability of enterprises' activities in the assessment of employees, and its relations with practices used in the enterprise for sustainable development. It was also decided to establish whether employees would like their companies to operate sustainably. Quantitative and qualitative research was carried out based on a questionnaire survey among 449 employees of enterprises in Poland and India. According to 18%, their enterprises operate sustainably, i.e., reduce the harmfulness of their activities to the natural environment and act for the benefit of employees and other social initiatives. In the opinion of 29% of the respondents, their companies' activity is only sustainable to some extent, and 8% believe that it is not sustainable. The respondents from India assess the sustainability of their enterprises to a much higher degree than those from Poland. It was found using the Spearman's rank correlation coefficient that the higher the employees rate the level of sustainability of their enterprise the more often environmental and social issues are taken into account in the enterprise when making critical decisions, employee volunteering is conducted, thus enabling employees to implement charity projects during work, the enterprise communicates and promotes its dedication to sustainable development, supports employees in striving for a balance between work and personal life, and improves their working conditions. The results of these studies may support the managerial staff responsible for implementing corporate strategic plans related to sustainable development. They will allow for a better understanding of how employees assess the level of sustainability of the company's operations and what activities allow them to increase this assessment.

Keywords: assessment of sustainable development, employee expectations, enterprises, Poland, India.

Introduction

Sustainable development is increasingly embedded in the core business strategy, constituting a growing part of corporate strategic goals (Galbreath, 2009; Harmon & Fairfield, 2014; Dutta, Lawson, Marcinko 2013; Gunasekaran & Spalanzani 2012). Nowadays, enterprises are expected to implement corporate social responsibility at the level of responsible company 4.0, where people and technologies cooperate and the increase of revenues and generated profit are perceived as equally important as attention paid to the environment and stakeholders (Deloitte 2020). Still, international statistics and research result reveal unsatisfactory level of implementation of sustainable development at enterprises in Poland (Kubicka, Kupczyk 2018) and in India (ROS 2019; Bertelsmann Stiftung, 2020). It is worth noting that Sustainable Development Goals to be implemented by 2030 concern not only actions aimed at reduction of enterprises' negative impact on the natural environment. They also focus on promoting full and productive employment, decent work for all people, fairness, and gender equality. From this point of view, it has become an interesting and important area of research to study employees' opinions about enterprises' sustainable development. This issue is scarcely researched, but it's very important, because studies show that sustainable development:

- affects the sense of job satisfaction (Magbool, Amran, Nejati, Jayaraman 2016);
- increases trust in the organisation in its relations with new employees or collaborators (Renwick, Redman, Maguire 2012);

Cite this Article as: Teresa KUPCZYK " The Level of Sustainability of Enterprise's Activity as Assessed by Employees - Comparative Analysis in Poland And India" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

- affects good employer image (Cherian, Jacob 2012; Raport Employer Branding w Polsce 2017);
- shapes employees' commitment and their loyalty toward the organisation (Cone Communications 2016).
- companies which have CSR strategies are perceived by employees as more innovative and dynamically developing (Edelman 2018).
- gives a possibility of lasting interaction between society, ecosystems and other living systems without impoverishing the key resources" (Marin, Dorobanțu, Codreanu, and Mihaela, 2012).

A vast majority of employees would like their employer enterprises to operate in a sustainable manner (Kubicka 2017; Kubicka, Kupczyk 2018; Cone Communications 2016; Edelman 2018). In this respect they expect their employers:

- to limit the organisations' negative environmental impact (Cone Communications 2016);
- to support social and charitable projects (GlobeScan Radar 2016);
- that superiors should display personalised interest in the situation and development of individual employees (Cone Communications 2016);
- to cease operations which harm customers or employees (Edelman 2018).

International statistics reflect the level of implementation of all 17 Sustainable Development Goals to be achieved by 2030 (Bertelsmann Stiftung, 2020). However, there are no data concerning assessment of the situation by employees, especially in Poland and India - two states that stand out in the world and European Union by high levels of environmental pollution. This is an important, but hardly studied indicator of effectiveness of changes introduced at enterprises in order to support sustainable development.

The objective of this study is to compensate this gap. Therefore, the purpose of the paper is to diagnose the degree of sustainability of corporate operations as seen by employees in Poland and India, as well as its correlation with pro-sustainable development practices applied by their employers. The presented research results supplement knowledge about the degree of sustainability of corporate operations perceived by employees, and also indicate measures that can significantly improve this assessment. Thus, they can expand the research concerning strategic corporate management focused on corporate sustainable development.

Theoretical Background and Research Hypotheses

The degree of sustainability of corporate operations has been studied and analysed from many perspectives, e.g.:

- pro-sustainable development decision-making (Despeisse, Vladimirova, 2014; Miller, Hickson, Wilson 1996; Arvai, Campbell-Arvai, Steel 2012);
- analytical technique to model and assess sustainable development index at enterprises, the importance of innovation for sustainable development, and the link between economic, social and environmental development indicators (Dvořáková and Zborková, 2014, pp. 686-695; Garbie, 2014, pp. 4876-4915; Shao, 2009, pp. 143-146).
- recognition of the interaction between implementation of SDG and decision-making processes (Nilsson et al. 2016b);
- integration of social, economic, and environmental considerations in significant decision making (Gibson 2006);
- human resources management (Bossink 2012; Bombiak, Marciniuk-Kluska 2019; Haugen 2014; Muller-Christ 2011).

Most researchers emphasize that sustainable development is a way of managing that will enable future generations to carry out tasks and live at the same level as today (Klarin, 2018, pp. 68-69; Sterling, 2010; Vare and Scott, 2007; Weidinger, 2014). It is a process which involves human intelligence, decision making efficiency, planning and management skills, power of imagination, entrepreneurship, development and production with environmental safety etc. (Sagar 2018, p. 161). Therefore,

sustainable development depends to a large extent on the human factor, this is why more attention should be paid to this aspect. In particular, it is qualified employees who understand and apply the principles of sustainable development in their work who play an important role in the process of transforming enterprises into sustainable organisations (Cohen, Taylor & Muller-Camen 2012; Muller-Christ 2011; Bossink 2012; Haugen 2014; Epstein & Buhovac 2014; Bombiak & Marciniuk-Kluska 2019).

Based on the literature the following research theses were formulated:

T1. In the employees' opinion, their enterprises' activity is not fully sustainable, which means that they do not sufficiently reduce their harmfulness to the natural environment and do not act in a sufficient degree for the benefit of employees and other social initiatives.

T2. Age, sex, education, nationality, place of residence, position held, the size of the enterprise, the type of its activity, and the length of its functioning on the market do not significantly differentiate employees' opinions on the sustainable operation of enterprises, or whether they would like their enterprises to be more sustainable.

T3. Employees' assessment of the degree of sustainability of their businesses demonstrates significant positive relationships with corporate sustainable development practices such a: taking environmental and social considerations into account when making key decisions, conducting corporate volunteering, enabling employees to carry out charitable projects during their work, communicating and promoting their commitment to sustainable development, supporting employees in striving for a balance between work and personal life, and taking care to improve their working conditions.

Methods

The hypotheses were verified based on data collected in quantitative and qualitative research conducted at the turn of 2018 and 2019 in Poland and India.

The questionnaire, which was developed for this study and its preparation was preceded by preliminary tests, was used as a research technique. The respondents filled in the questionnaire independently and anonymously, previously giving their consent to participate in the research. The conducted research aimed to find answers to the research problems posed, which took the form of the following questions:
1. How do employees assess the level of sustainability of their employing enterprises' the activity?

2. Are there significant differences in this respect as for the criterion of nationality (Poland, India), sex, age, education (higher, lower), place of residence (urban, rural), position, size of the enterprise, and type of its activity (service, production)?

3. Are there significant relationships between employees' assessment of the sustainability of the company's operations and the use of certain sustainable development practices?

The basic terminology was set as part of the conducted research. Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs (World Commission on Environment and Development, 1987). It was assumed that the company's activity is sustainable if the company reduces its activity harmfulness to the natural environment and acts for the benefit of employees and other social initiatives.

The research subject of the study were:

• assessment of the level of sustainability of enterprises' activities in the employees' opinions,
• the relationship between "employee assessment of corporate sustainability" and the company's application of sustainability practices.

The respondents assessed the degree of sustainability of the enterprises' activity using the five-point Likert scale (Gamst, Meyers, Guarino, 2008), where 1 - definitely unsustainable, 2 - rather not sustainable, 3 – hard to say, 4 - sustainable to some extent, 5 - definitely sustainable.

Research procedures were applied in nomothetic terms. They are directed at repetitive phenomena that allow discovering and formulating general laws, and discovering similarities, universal rules and regularities governing the phenomena under study. This allowed the use of statistical methods of inference about the properties of the examined objects. Non-parametric tests were used as a statistically significant discrepancy between the observed distribution of variables and the normal distribution was revealed after the Shapiro-Wilk test ($p < 0.05$). The results of answers given on rank scales depending on grouping variables were analyzed with the Mann-Whitney U test (for two groups, e.g., taking into account gender, education, nationality, place of residence, position held, type of activity) and the Kruskal-Wallis ANOVA test with Bonferroni adjustment (for more than two groups, e.g., taking into account the criterion of the respondents' age, the size of the enterprise, and the length of its operation on the market) (Dunn 1961, 2017). The existence of a trend for subsequent populations was measured with the Jonckheere-Terpstra test for ordered alternatives. The relationships between the variables "assessment of the sustainability of business activities" and the applied practices in the enterprise for sustainable development were analyzed by estimating the Spearman's rank correlation coefficient (Lieberson 1964). The test probability at $p<0.05$ was considered significant, and $p<0.01$ as highly significant. Statistical analyses were performed using the PQStat statistical package, version 1.6.4.122. The research applied the quota sampling, which required resignation from the statistical condition of representativeness of the research [Lohr 1999; Rao 2000]. It was decided to do so not only because of the research objectives, but above all because of the research possibilities. The criteria that significantly differentiate the population regarding the research subject were defined in the quota selection. As a result, the studied population was divided into groups according to the following criteria and their selection was deliberate: nationality (Poland, India), gender, education (secondary, higher), age (under 35, 35-50, over 50), place of residence (urban, rural), position held (a person not holding managerial positions, managerial staff), the size of the enterprise (micro, small and medium-sized, large), type of enterprise activity (production, service).

This approach was chosen because the adopted sample largely corresponded to the structure of the population due to the distinguished features, and moreover, individuals within the group were characterized by greater homogeneity. To determine the percentage share of the selected groups, their actual distribution in the population was used (according to GUS data from 2019). The minimum sample size was established using the G * Power software (Faul, Erdfelder, Lang, Buchner 2007). The minimum sample size was 134 people with the following parameters: Type of Power analysis - A priori: Compute required sample size, given α and power, and effect size (two groups), power 0.90 (0.9007737), α rr prob = 0.05, effect size | p | = 0.6782266, critical t = 1.9862068. The study was conducted on a sample of 499 employees of enterprises, of which 64% were people from Poland and 36% from India. 75% of the respondents are employees who do not perform managerial functions, 25% are managerial staff. 61% were men and 39% women. The structure of the respondents from the educational point of view was as follows. 53% were people with higher education, and 47% with secondary education. The respondents were mostly young people, under 35 (82%). Middle-aged people (35-50 years old) accounted for 13%, and there were 5% over 50 years of age. 77% of the respondents lived in urban and 23% in rural areas. 43% were employed in large, 35% in medium-sized, 17% in small, and 5% in micro-enterprises. Most enterprises (54%) dealt services, and 47% with production. The management staff accounted for 25%.

Results

The respondents were asked to evaluate the sustainability of their companies' activities.

18% of them stated that their enterprises operate in a sustainable manner, i.e., that they reduce the harmfulness of their activities to the natural environment and act for the benefit of employees and other social initiatives. 29% considered that their companies' activities are only to some extent sustainable. According to 18% of the respondents, the activity of their companies is rather unsustainable, and 8%

believe that it is not sustainable. Others concluded that the activities of their companies are neither unsustainable nor sustainable. The arithmetic mean of sustainability of the company's activity in the respondents' assessment on the 1-5 scale was 3.31 (with S. D. = 1.18 and significance level 0.05). Therefore, it is quite low, which may indicate that companies employing the respondents focus too little on reducing the harmfulness of their activities to the natural environment and on activities for employees and other social initiatives. The assessment of corporate sustainability differed in some groups, as shown in Table 1.

Table 1: Employees' assessment of the sustainability of enterprises' activity (according to the arithmetic mean) made on a scale where 1 - definitely unsustainable, 2 - rather not sustainable, 3 – hard to say, 4 - sustainable to some extent, 5 - definitely sustainable (N = 499).

Respondents	Poland		India	
	means	S.D.	means	S.D.
women	2,96	1,07	3,88	1,02
Men	3,01	1,14	3,88	1,14
age below 35 years	2,96	1,12	3,93	1,04
age of 35-50 years	3,09	1,04	3,79	1,05
over 50 years old	3,00	1,35	3,38	1,56
higher education	3,11	1,06	3,90	1,07
secondary education	2,94	1,13	3,57	1,51
persons not holding managerial functions	2,96	1,07	3,91	1,04
management staff	3,15	1,23	3,86	1,13
living in urban areas	3,00	1,14	3,93	1,06
living in rural areas	2,97	1,05	3,53	1,31
employed in large enterprises	3,14	1,01	3,92	1,17
employed in medium-sized enterprises	2,84	1,11	3,82	1,05
employed in small enterprises	3,05	1,21	3,90	0,91
employed in micro-enterprises	2,78	1,24	4,33	1,15

Source: own research results

The following null hypotheses H_{01}- H_{09} were formulated to verify the thesis consisting in the statement that age, sex, education, nationality, place of residence, position held, as well as the size of the enterprise, and the type of its activity do not significantly differentiate employees' opinions on the sustainability of their enterprises:

• H_{01} There are no statistically significant differences in the distribution of assessments concerning the sustainability of their enterprises' activities in the groups of Polish and Indian employees.
• H_{02} There are no statistically significant differences in the distribution of assessments concerning the sustainability of their enterprises' activities between women and men.
• H_{03} There are no statistically significant differences in the distribution of assessments related to the sustainability of their enterprises' activities in the groups of employees with different education (higher, secondary).
• H_{04} There are no statistically significant differences in the distribution of assessments regarding the sustainability of their enterprises' activities in the groups of employees of various ages (under 35, 35-50, over 50).
• H_{05} There are no statistically significant differences in the distribution of assessments for the sustainability of their enterprises' activities in the groups of employees living in urban and rural areas.

• H_{06} There are no statistically significant differences in the distribution of assessments concerning the sustainability of their enterprises' activities in the groups of employees holding various positions (managerial staff, people not holding managerial positions).
• H_{07} There are no statistically significant differences in the distribution of assessments concerning the sustainability of their enterprises' activities in the groups of employees employed in service and production enterprises.
• H_{08} There are no statistically significant differences in the distribution of assessments concerning the sustainability of their enterprises' activities in the groups of employees employed in enterprises of various sizes (micro, small, medium, large).
• H_{09} There are no statistically significant differences in the distribution of assessments concerning the sustainability of their enterprises' activities in the groups of employees employed in service and production enterprises.

It began with the verification of the null hypothesis H1 that there were no statistically significant differences in the distribution of assessments of the sustainability of their enterprises' activities in the groups of Polish and Indian employees using the Mann-Whitney U test. With such a value of statistics Z (8.393979), the null hypothesis that both groups of employees from Poland and India assessed the degree of sustainability of their enterprises' activities similarly had to be rejected (Table 2).

Table 2: Differences in the distribution of Polish and Indian employees' subjective assessments regarding the sustainability of their companies' activities

Grouping variable	**Country:**
Group name	India
The sum of the group ranks	57610,5
Average group rank	320,058333
Group name	Poland
The sum of the group ranks	67139,5
Average group rank	210,468652
Statistics U	16099,5
Statistics U	41320,5
Value p (exact)	0,0001
Statistics Z (with correction for associated ranks)	8,393979
Value p (asymptotic)	<0,000001

Source: own research results

Therefore, we can conclude with 95% probability that Indian employees assess the sustainability of their enterprises' activity to a significantly higher degree than Polish employees (p=0.0001). The above result is puzzling, because according to the global SDG 2020 index characterizing the state of implementation of 17 Sustainable Development Goals 2030, Poland achieved the indicator 78.19 in 2020 (23rd place out of 166 countries), and India 61.92 (117th place) (Bertelsmann Stiftung, 2020). Therefore, since India has achieved much worse results in terms of sustainable development, its optimistic assessment probably resulted from other factors. It could have been influenced by cultural factors since the business culture in India reflects the social order governed by patriarchalism and hierarchy prevailing there. The prevailing situation on the labor market could have been of some importance. In India, in October 2019 (at the time of the research), the unemployment rate was 8.1% (India Center for Monitoring Indian Economy), while in Poland it was 5% and it was the lowest in 30 years (GUS). Thus, the labor market in Poland at that time was the employee's market. Perhaps some of the factors contributing to the Indian employees' assessment of the situation were that they have insufficient knowledge about the negative impact of enterprises' activities on the natural environment.

Perhaps the respondents from India have slightly different expectations / standards regarding the sustainable development of enterprises than those from Poland. Despite the identified differences in the assessment made between employees from India and Poland, it should be emphasized that both groups think that the current activities for sustainable development in their companies are insufficient or simulated. This allows for the conclusion that a significant part of enterprises in Poland and India still do not operate in a sustainable manner.

In the next step, there was verified the null hypothesis H_{02}, which stated that there are no statistically significant differences in the distribution of assessments concerning the sustainability of business activity among women and men. Although the arithmetic mean of women's assessments (2.96) was lower than that men's (3.01), the differences were not statistically significant (Table 3).

Table 3: Differences in the distribution of subjective women's and men's assessments concerning the sustainability of their enterprises' activities

Group name	**Woman**
The sum of the group ranks	48112,5
Average group rank	246,73077
Group name	Man
The sum of the group ranks	76637,5
Average group rank	252,09704
Statistics U	29002,5
Statistics U	30277,5
Value p (exact)	0,676997
Statistics Z (with correction for associated ranks)	0,417321
Value p (asymptotic)	0,676444

Source: own research results

With the statistic Z (0.417321) and p = 0.676997, the null hypothesis H_{02} that women and men assess the same degree of sustainability of their enterprises' activity similarly should be accepted. This result is puzzling as long as it can be assumed that women similarly assess the sustainability of their enterprises, regarding the reduction of harmfulness of their activities to the natural environment, or activities for social initiatives. However, it is difficult to accept, based on current statistical data, that women and men are treated equally in enterprises in Poland and India. It is worth recalling that "Gender equality" is the fifth of the 17 Sustainable Development Goals to be implemented by 2030 (The United Nations 2019). Indeed, it has been recognized that "gender equality" is not only a fundamental human right but an indispensable foundation for a peaceful, prosperous, and enduring world. An analysis of the current data on gender equality according to the Global Gender Gap Report 2020 shows that women are still discriminated and in a more difficult situation on the labor market. In 2020, Poland has achieved the indicator of 0.736 (where 1 means equality between women and men) and was placed 40th out of 152 countries. India, on the other hand, achieved the index of 0.668 and was placed 112th. In the area of Economic Participation and Opportunity, the Global Gender Gap Report 2020 indicator for Poland is even lower and amounted to 0.711 (57th position) and for India 0.354 (149th position) (World Economic Forum 2020). Given the data, the research results indicate that probably some of the surveyed women are not aware of the gender inequalities existing in their companies or do not associate them with sustainable development.

Like above, the H_{03} hypothesis was verified to determine whether education influences the surveyed employees' assessment regarding the sustainability of their enterprises (Table 4).

Table 4: Differences in the distribution of employees' subjective assessments regarding the sustainability of their enterprises' activities with higher and secondary education

Grouping variable	**Education**
Group name	secondary
The sum of the group ranks	48691
Average group rank	208,081197
Group name	higher
The sum of the group ranks	76059
Average group rank	287,015094
Statistics U	21196
Statistics U	40814
Value p (exact)	0,0001
Statistics Z (with correction for associated ranks)	6,282842
Value p (asymptotic)	<0,000001

Source: own research results

With the statistic Z (6.282842) and p = 0.0001, the H_{03} hypothesis had to be rejected.
It turned out that people with higher education assess their enterprises' sustainability significantly higher than those with secondary education.

This may indicate that people with higher education are better treated in their enterprises and that more activities are carried out for them to ensure their decent work, good working conditions, fairness, and equality. Perhaps their higher assessment of the sustainability of their companies' activities results from the fact that they have greater knowledge and expectations in this regard, and as a result, they perceive activities undertaken by companies for sustainable development, including for employees and other social initiatives.

To verify the hypothesis H_{04}, consisting in the statement that there are no statistically significant differences in the distribution of assessments regarding the sustainability of their enterprises' activities in groups of employees of different ages (under 35, 35-50, over 50), the Mann-Whitney U test was performed (Table 5).

Table 5: Differences in the distribution of subjective assessments concerning the sustainability of their companies' activities between employees of different.

Kruskal-Wallis ANOVA		**POST-HOC (Dunn Bonferroni)**	**below 35**	**35-50**	**50 +**

Value p one-sided	0,2298	35-50	1		1
Value p two-sided	0,4595	50 +	1	1	

Source: own research results

They turned out to be statistically insignificant (p = 0.2298). It was decided to analyze the existence of a trend for subsequent populations using the Jonckheere-Terpstra test for ordered alternatives (Jonckheere 1954; Terpstra 1952). The p value determined from the test statistics was compared with the significance level. It was suspected that people of different ages differently assess their enterprises' sustainability. Therefore, it was decided to conduct a trend analysis. In the surveyed population, the assessment of the sustainability of their enterprises' activity decreases with the increase of age. Successive age categories were assigned successive natural numbers. The obtained one-sided p value = 0.229756 is greater than the set significance level $\alpha = 0.05$, which indicates no trend. Therefore, the null hypothesis H4 had to be accepted.

To verify the null hypothesis H5, it was checked whether the place of residence was an important factor influencing the employees 'assessment of the sustainability of their enterprises' activities (Table 6).

Table 6: Differences in the distributions of subjective assessments regarding the sustainable operation of their enterprises between employees living in urban and rural areas

Grouping variable	**Place of residence**
Group name	Urban
The sum of the group ranks	99773,5
Average group rank	259,151948
Group name	Rural
The sum of the group ranks	24976,5
Average group rank	219,092105
Statistics U	18421,5
Statistics U	25468,5
Value p (exact)	0,007219
Statistics Z (with correction for associated ranks)	2,682343
Value p (asymptotic)	0,007311

Source: own research results

With the statistic Z (2.682343) and p = 0.007219, the H5 hypothesis had to be rejected.
Thus, it can be concluded with 95% probability, that employees living in urban areas assess the state of sustainability of their enterprises' activity to a significantly higher degree than employees living in rural areas (p = 0.007219).

This may indicate that enterprises in cities care more about sustainable development, i.e., they reduce the harmfulness of their activities to the natural environment and more often act for employees and other social initiatives.

To verify the null hypothesis H_{06}, the Kruskal-Wallis ANOVA test was carried out, which allows to determine the differences between the assessment of the sustainability of enterprises' activities in groups of employees occupying different positions divided into management staff and persons not performing managerial functions (Table 7).

Table 7: Differences in the distribution of assessments regarding the sustainable operation of their enterprises between employees living in urban and rural areas

Grouping variable	**Position**
Degrees of freedom	5
Statistics H (with correction for associated ranks)	7,526421
Value p	0,184339

Source: own research results

Although the management staff assesses the sustainability of their enterprises' activity to a slightly higher degree (arithmetic mean 3.15) than people who do not perform managerial functions (2.96), these differences turned out to be statistically insignificant (p = 0.184339). Therefore, the H6 hypothesis had to be accepted. On the other hand, statistically significant differences were found in the assessment of enterprises' sustainability depending on the size of the enterprise in which the respondent was employed (Table 8).

Table 8: Differences in the assessment of the degree of sustainability of enterprises' activities between people employed in enterprises of various sizes (micro, small, medium and large ones)

Grouping variable	**Size of the enterprise**
Statistics H (with correction for associated ranks)	4,963313
Value p	0,174503
Jonckheere-Terpstra trend test	
Sequence number for [micro, small, medium, large]	1, 2, 3, 4
Statistics L	43948,5
Statistics Z	1,967575
Value p one-sided	0,024558
Value p two-sided	0,049117

Source: own research results

The research results show that large enterprises care for the sustainable development to the greatest extent. People employed in micro-enterprises rated the sustainability of their enterprises significantly lower. The obtained value of p = 0.024558 is lower than the set significance level, which speaks in favor of the occurring trend. Therefore, the size of the enterprise significantly affects the sustainability of its operations. Therefore, the null hypothesis H_{08} had to be rejected.

In the last step, the null hypothesis H_{09} was verified, which stated that there were no statistically significant differences in the distribution of assessments concerning the sustainability of their enterprises' activities in the groups of workers employed in service and production enterprises (Table 9). The differences turned out to be statistically insignificant (p = 0.973445). Therefore, the hypothesis

H_{09} had to be adopted (p = 0.973445), which means that respondents from production and service enterprises assessed the sustainability of their enterprises in a similar way.

Table 9: Differences in the distribution of subjective assessments regarding the sustainability of the enterprises' activities between employees from service and production enterprises

Group name	**Production**

Value p (exact)	0,973445
Statistics Z (with correction for associated ranks)	0,033647
Value p (asymptotic)	0,973159

Source: own research results

Based on the Spearman's rank correlation coefficient, statistically significant relationships were established between the employees' assessment of the company's sustainability level and their sustainable development practices. Therefore, the employees of the enterprise assess the level of sustainability of the enterprise higher the more often (N = 499):

• environmental and social issues are taken into account when making critical decisions in the enterprise (r = 0.169282, p = 0.000145);
• the enterprise conducts Employee Volunteering enabling employees to carry out charity projects during their work (r = 0.128601, p = 0.004009);
• the company communicates and disseminates its commitment to sustainable development, both among the non-managerial employees and in the environment (r = 0.120204, p = 0.007185);
• the enterprise supports employees in their pursuit of work-life balance (r = 0.103744, p = 0.020454);
• the employer cares about the improvement of working conditions (r = 0.088706, p = 0.04765).

Conclusion and Discussion

According to employees, only some enterprises in Poland and India follow sustainability practices. This is a confirmation of results of other research indicating that implementation of sustainable development principles is difficult for enterprises (Revell, Blackburn, 2005, Drake et al., 2004), and that in key decision-making enterprises consider other criteria than environmental and social issues (Bonn, Fisher, 2011; Gibson 2006; Ehrenfeld, 2000; Nilsson & Persson 2012; Robért, Broman, Basile, 2013; Baldock & Charveriat, 2018). The discussed assessment by employees may suggest that issues of operations sustainability, especially with respect to human resources management are treated in some of the studied enterprises in a selective or partial way or even are ignored. Age, gender, job position and type of business do not significantly differentiate employees' assessment of corporate sustainability. However, the study has confirmed that employees in India, those with university degree, residents of urban areas and employees of big companies assess the condition of sustainability at their employer enterprises significantly higher. This may suggest that at big cities and big enterprises more attention is paid to sustainable development, including sustainable measures for people with university background. The significant correlations between the employees' assessment and pro-sustainable development practices suggest that the assessment was better at enterprises where more attention was

paid to considering environmental and social issues at key corporate decision-making, where corporate volunteering was applied more broadly to allow employees take part in charity project during their working hours, enterprises with improved communication and promotion of pro-sustainable development measures among employees and in the environment, where employees were supported in searching for work-life balance and where more attention was paid to improvement of working conditions. The obtained results may indicate that at some studied enterprises strong leadership was missing, and this is one of the essential factors that determine introduction of sustainable development. This conclusion is consistent with findings of De Gobbi (2011) and Stewart, Gapp (2011). Another cause of this situation may involve management staff's insufficient understanding of values arising from sustainable development and their impact on satisfaction of employees and customers (Hemingway, Maclagan, 2004 and De Gobbi, 2011). Therefore, it seems reasonable to postulate that enterprises should operate in a more sustainable manner, because previous measures taken seem insufficient or purely declarative, especially in employees' opinion.

Acknowledgments

The authors thank all those involved in the research, as well as Madhumita Chatterji and MH Sharieff for conducting the survey in India.

Abstract

This article describes ongoing research with 152 adolescents from six reform schools and detention homes aged 12-16 years with a risky behavioural disorder (drugs, crime, aggression). The aim is to find out whether young people's understanding of moral values will increase, and social adaptation improves through regular workshops in the forest. On the examples of forest fauna and flora (wolves, wild boars, deers, fungi, bees, ants) the principles of mutual coexistence, cooperation, care for others, adaptation and collaborative animal and plant models were demonstrated to the teenagers using forest pedagogy methods. The theoretical framework is based on the nature ideas exchange. Analogy method and Focus interview with off-topic replicas methodologically approach this research.

Keywords: *Serious behavioural disorders. Morality and values. The analogy method. Collaborative models of forest.*

Introduction

Every living organism manifests itself in a relationship with other organisms in the environment, but sometimes the relationships are disrupted by aggression and social maladaptation, which is more serious when it concerns children and adolescents.

Experts at Stanford University led by dr. Nicole Ardoin systematically analyzed 119 peer-reviewed studies published between 1994 and 2013. These studies measured the impact of environmental education and stay in nature on K-12 children and pupils from 33 countries. The studies have clearly shown that environmental education has led to many positive outcomes, from improving academic performance, enhancing critical thinking skills, developing personal growth, and life-building competencies, including self-esteem, increased civic engagement, and positive environmental behaviour (Ardoin, Bowers, Wyman & Holthuis, 2018; Stern, Powell & Ardoin 2008). It follows from the above that staying in nature improves skills and personal competencies.

Processes and interactions in nature are very similar to proceedings and interactions in human society (Kopčaj, 2007). Ecosystems are not only for nature conservationists and researchers; they have much in common with the community (Salvati &Zitti, 2008). Every day, caring for others, coexistence, cooperation, adaptation, and innovation take place in nature. The constant pressure on assimilation has led to high-level specializations, sophisticated survival strategies and especially collaborative models (Rösler, 1995b). Based on this fact, we hypothesize that ethical behaviour can be well demonstrated in parallels with the living ecosystems of nature. Rösler (1995a) introduces the term "Nature Ideas Exchange": nature offers many analogies applicable to practice, on which the principles of ethics, morality and cooperation can be presented uniquely.

Aim of the Study

As part of the upbringing and reeducational activities of adolescents suffering mental problems with severe risky behaviour (abuse, criminality, truancy, aggression, early sex life), a pedagogical-psychological experiment is performed. The objective of this research is to bring up adolescents from reform schools and detention homes to behave according to the principles of morality, ethics, caring for others and cooperation. The analogy with forest ecosystems has been used for this purpose. This study aims to identify whether the training of ethical behaviour in the form of analogy with the forest ecosystem using forest pedagogy methods (Cornell 1991, 1998, 2012) will improve teenagers' teamwork and social adaptation. The following question guided the study: has adolescents' social competenceincreased? Analogy method and Focus interview methodologically approached this topic.

Method number 1: Pedagogical experiment: “Searching for parallels of natural ecosystem using analogy based on examples of coexistence, adaptation and cooperation of the forest ecosystem.”

Method number 2: Focus discussions with off-topics replicas.

Materials and Methods

Verification must come from confrontation, comparison, real examples, and experiments. Is it an effective training for ethical values if we place adolescents with the severe behavioural disorder into a lecture hall and give them a continuous tutorial on morality? Yes and no: teenagers gain an overview from an interdisciplinary perspective, but due to the chosen (frontal) method of teaching, knowledge acquired in this way may be shallow. Juveniles do not gain enough experience to understand the essence of interrelationships, interdisciplinary links do not develop to a sufficient depth, and attention is declining (Průcha, Walterová, Mareš 2001). Frontal teaching does not develop learning competence (Walberg & Paik, 2000).

Sociological pedagogy and the development of personality through social work and solidarity we can trace in the ideas of E. Durkheim. Emphasis on creative work and the environment is placed by H. Parkhurst, R. Steiner, and C. Freinet, who emphasize the practical application of knowledge, creative work, and the teacher's cooperation with children. By analogy method with a living ecosystem, youthful could gain new perspectives and participate directly in this world to make informed decisions and become change agents.The analogy is crucial for human creativity and the active learning process. It is a relationship between two different things, comparing the unknown to the known (Dvořák, 2007). Analogies help us to find significant parallels between distinct situations (Wilson & Keil, 1999). Hofstadter & Sander (2013) consider analogies as the basis of our thinking. Gentner (2003) claims that people are intelligent because of (1) their extraordinary ability to learn by analogy, (2) mastery of sign systems, and (3) the relationship between the previous two. Analogous reasoning is abstract thinking in everyday life (Smirnova, Zorina, Obosova & Wasserman, 2014). The analogy is also a stylistic means used to support argumentation (Przywara, 2007).

The principles of adaptation, partnerships and cooperation can be explained on forest fauna and flora. A total of 152 adolescents from six reform schools and detention homes aged 12-16 years participated in the pedagogical experiment (n = 152). The maximum group size was eight people.

First, the teacher explained how the individual plants and animals in the forest behave and their specifics. The teacher used in doing so demonstration and experience methods and in nature showed strategic partnerships, cooperation, adaptation, innovation and animal care on the examples of living trees, bees, ants, mushrooms, plants and animals. Teenagers worked in teams, searching for parallels between commonality of the forest ecosystem, and human society through observation, discussion, brainstorming, mind maps, educational games, and experiences using forest pedagogy methods.

Results

Parallels between forest ecosystem and morality, ethics and tolerance in society

The parallels are numbered (1-9); the following text represents the teacher's explanation of the topic, and the arrow → means analogy with society detected by teenagers (Parallel: teacher'sexplanation→ analogy detected).

1. Bee and plant (*Apis mellifera*): the bee is saturated with pollen and guarantees the flower its reproduction → mutually beneficial and altruistic cooperation.
2. Nitrogen fixation: the plant obtains nitrogen and microorganisms are protected in tubers → successful coexistence.
3. Beehive and anthill: division of labour between different castes, some care for protection and safety, others care for larvae, others forage →interconnected and functional system of cooperation and care for others, in which each individual has a role and place, willingness accept their role in the community.
4. Wolf pack, a group of wild boars; deer and roe community: the members of the tribe know each other well, the loss of one member of the group leads the others to look for him. Members share feed and help each other with hunting, caring for cubs and protecting the group → integration into the society of other individuals, caring for others, teamwork, solidarity. The pack or tribe must be cooperative and pull together.
5. Swarm: A flock of animals behaves and moves like one living organism with a certain logic without anyone commanding them → conformity and tolerance of others in the swarm.
6. Ants (*Lasius niger*), termites (*Isoptera*) and aphids (*Aphidoidea*):ants supply the fungi with plant tissue and then these fungi become the primary source of their food. Aphids contribute their organic matter and ants protect them→ if we want to get something, we have to give something ourselves, the principle of exchange.
7. Jay's shout: a warning signal to which other animals also respond → to worry about others.
8. Meadow grasshopper in green grass (*Conocephalus discolour*), and *Syrphus ribesii*: insects blend in colour with their surroundings or mimic the appearance of wasps, bees and bumblebees → if we want to survive, we must confirm the surroundings.
9. The evolutionary theory of Ch. Darwin: change →the advantage is one who cooperates and conforms; not one who is aggressive.

Conclusion (tentative)

We have already obtained challenging empirical data, and our research will continue with ananalysis of communication in the form of focus interview with off-topic replicas. On the examples of forest fauna and flora, adolescents see that values such as cooperation, adaptability, care for others allow them to survive and are completely self-evident in nature.

Abstract

The article investigates the internal structure features of the agricultural insurance market, which resulted in III sectors gradation; each of them forms separate structural elements or their totality. It is determined that the authorized body for supervision of insurance activity (State Financial Services Commission) belongs to the sector I of the internal structure of agricultural insurance market; to sector II - structural elements; to sector III - elements of infrastructure. The external environment of the agricultural insurance market is a system of interrelated factors that surround and affect its internal system. This classification makes it possible to describe the structure of the agricultural insurance market as a complex polystructural system having a three-sector internal structure and surrounded by the external environment and to substantiate the feasibility of complex supervision, regulation and development of all its constituent elements. The essence of the concept of "agricultural insurance market" is investigated and the author's definition is presented.

Keywords: Agricultural Insurance Market, Internal Structure, Regulator Of The Agricultural Insurance Market, Structural Elements, Infrastructure Elements.

Introduction

For Ukraine, the agricultural sector has always been one of the priority areas from the standpoint of both foreign economic and domestic economic development, as the immediacy of the manufacturing process management and support of food facility is acute for each country in all periods of development. This statement is crucial not only to ensure the viability and self-sufficiency of the country as a whole and society in particular, but also many different areas of human activity. Given that the agricultural sector in Ukraine is developing dynamically, agricultural insurance, as a tool to ensure the stability of agricultural producers income, should at least partially meet such dynamics.

The development problems of the agricultural insurance market in Ukraine give rise to the situation that all its participants and, above all, farmers, suffer from. As a result, they are deprived of the opportunity to make informed decisions about the choice of insurance companies with which they plan to enter in cooperation (Nesterchuk et al., 2018). As a result, those wishing to obtain agricultural insurance services in Ukraine, despite the steadily improving performance of the agraricultural sector in the national economy, remain extremely short.

Methodology

For the scientific solution of the goal set out in the article, general scientific methods of scientific cognition and study of economic phenomena were used, in particular the dialectical method of cognition - for the analysis of scientific works of scientists on the domestic and foreign functioning problems of the agricultural insurance market in general, and the study of its structure peculiarities, in particular; the method of empirical research - as part of the assessment of the current state and development of the study object; graphical method - for systematization and visual representation of research results; abstract-logical approach - to summarize the study results and formulate conclusions on this basis.

Analysis of the latest studies and publications

Different aspects of the functioning of such an important tool as agrarian insurance were studied by the number of national scientists and practitioners, among them are Martseniuk-Rozaronova, (2010); Navrotskyi, (2012); Nesterchuk. (2018); Polchanov, (2013) et al. In their research the scientists studied the main development trends of the Ukrainian agricultural insurance market in general and some problematic aspects of its development, generalized historical aspects of its formation and establishing, studied the specific features of insurance legislation, and found out the specific character of the insurance market. Ukrainian scientists researched insurance products and insurance schemes that provide insurance protection of agricultural producers: Nesterchuk, Tsymbalyuk & Rolinskyi (2018); Sinitsina (2011).

Some theoretical and practical aspects of agricultural insurance were profoundly investigated by foreign scientists, among them the following should be mentioned: Adhikari, Belasco & Knight (2010); Assa (2015); Komadel, Pinda & Sakalova (2018).

It is necessary to mention that foreign scientists provide a profound and elaborate analysis of insurance programs, used in the agrarian insurance. This aspect was covered by foreign researchers in the context of classical, parametric and specific insurance schemes.

A great body of scientific literature deals with parametric schemes in the agricultural insurance, that is the index insurance products for agriculture. This aspect is sufficiently and elaborately researched by the following foreign scientists Mußhoff, Hirschauer, Grüner & Pielsticker (2018); Xiao & Yao (2018).

At the same time, the realities of today are such that the structure of the agricultural insurance market is disparate in nature, as it is limited by the classification of structural and partly infrastructural elements, as well as by the supervisory and control bodies and lacks a holistic perception.

In view of this, at this stage, the question of the internal structure peculiarities of the agricultural insurance market requires more and more attention.

Aims

The purpose of the article is to study the features of the internal structure of the agricultural insurance market of Ukraine, in terms of sectoral gradation of the latter in particular.

Results and Discussion

The study of the agricultural insurance market is impossible without an in-depth analysis of its structure, that is, the elements of which it consists and which interact. The agricultural insurance market is a rather complex phenomenon that has its internal structure and external environment.

The interpretation generalization of "agricultural insurance market" concept, with the author's proposal of this definition is reflected in Fig. 1.

AGRICULTURAL INSURANCE MARKET

- the environment in which insurance companies operate and provide services in the agricultural sector of economy
- mechanism for financial resources redistribution of agricultural producers and insurance companies operating in the agricultural sector
- set of structural and infrastructural elements of the agricultural insurance market, which appropriately participate in the implementation of the relevant services
- the sphere of economic relations, where the object of sale is agricultural insurance
- * a complex integrated system covering various structural units and a platform for cross-sectoral interaction of structural elements of the specified market, which are appropriately involved in the production and consumption of relevant services, elements of infrastructure, facilitating the prompt interaction of structural entities (insurance companies and agricultural producers) in their production, purchase and sale and consumption, and the supervisory bodies that oversee the insurance business.

It should be noted that, in contrast to the existing definitions, the proposed one takes into account the interaction not only of structural entities (mainly insurance companies and agricultural producers), but also of other constituent elements of the specified market structure, in particular this concept is considered in the context of balanced and organized cross-sector cooperation and interaction of all key elements of the agricultural insurance market, which are appropriately involved in the production and implementation of the relevant services (Assa, 2015, Komadel, 2018).

Mandatory conditions of the agricultural insurance market functioning are:

- insurance items having a use value;
- insurance protection need;
- possibility to make a decision on participation in the insurance agreement;
- structural and infrastructure entities of the agricultural insurance market that are able to meet mentioned needs or consume them.

Considering the general structure features of the agricultural insurance market, it should be noted that the latter has a complex three-sector internal structure and is surrounded by the external environment. The key sectors that shape its internal structure include: sector I - an authorized insurance supervisor; II - structural elements; III - infrastructure elements. The external environment of the insurance market is a system of interaction between the factors that surround and influence the internal system. It is represented by elements that the insurer can manage (market demand, competition, insurance know-how, insurance market infrastructure) and those that it cannot influence (population, age and sex structure, seasonal migration, consumer purchasing power), but should take into account in their activities.

Let us dwell on each sector of the internal structure of the agricultural insurance market in more detail.

The first sector of the internal structure of the agricultural insurance market

The first sector of the internal structure of the agricultural insurance market is formed by agricultural insurance market regulator which functions are vested in the National Commission, which carries out state regulation in the sphere of financial services markets (National Financial Services Commission).

The mission of the National Financial Services Commission is to create conditions for efficient and transparent functioning of non-banking financial services markets, strengthen systemic stability and improve financial inclusion in these markets, ensure consumer rights protection for non-banking financial services, as well as integrate into the global financial space with no threat to Ukraine's national interests and economic strength.

The second sector of the internal structure of the agricultural insurance market

The structural elements of the agricultural insurance market that form sector II of its internal structure include: insurance companies that perform the functions of developers and insurance/reinsurance providers in this market; agricultural producers - consumers of these insurance services and association of insurers - providers of secondary, ancillary services (Fig. 2).

Fig. 2: Structural elements of the agricultural insurance market
[Author's development].

Insurance companies operating in the Ukrainian agricultural insurance market

According to the National Commission for State Regulation of Financial Services Markets, in 2018 63 insurance companies were licensed to conduct insurance activities in the form of voluntary insurance of agricultural products, while only 14 of them actually insured agricultural risks (Fig. 3).

Fig. 3: Number (units) and share (%) of insurance companies in the agricultural insurance market of Ukraine

[Source: calculated and proposed by the authors].

The Ukrainian insurance industry is characterized by a decrease in the number of such structural entities operating in the insurance market as insurance companies. Thus, if in 2008 their number reached a maximum for the study period and amounted to 469 units, in 2018 - reached a minimum - 291 units.

As for insurance companies engaged in insurance activities in agricultural sector, since 2010 their number has been more or less stable, being volatile between11-14 units.

Analyzing the data of Fig., it should be noted that the number of insurance companies operating in the agricultural insurance market is quite small. Thus, their share in 2018 was almost 5% (or 14 units). The average value of the analyzed indicator for the study period was 6% (or about 25 units).

In addition, it should be noted that a certain center of insurance companies has been formed, which are already constantly and fairly stable in the Ukrainian agricultural insurance market (Fig. 4).

[Source: calculated and proposed by the authors].

Agricultural producers who are consumers of insurance services in the Ukrainian agricultural insurance market

Distributive peculiarities of enterprises engaged in agricultural activities by the size of farm land in 2018 are shown in Fig. 5.

Fig. 5: Distributive peculiarities of enterprises engaged in agricultural activities by size of agricultural land in 2018

[Source: calculated and proposed by the authors].

Analyzing the data of Figs. It should be noted that there are about 166 companies that grow crops on more than 10 thousand hectares of land. And those who cultivate an area of 1000-10 000 hectares, there are almost 5 000. Thus, a little over 10% (13%) of companies control about 80% (77%) of agricultural land in Ukraine.

Instead, 8% of enterprises with up to 5 hectares of land cultivate only 0.05% of all Ukrainian agricultural lands.

The largest number of enterprises – 17 794 units (or 44%) is concentrated in the group of enterprises under the cultivation of which there are from 5 to 50 hectares of land. However, it is only almost 3% (2.5%) of agricultural land in Ukraine. The group of enterprises cultivating from 50-500 ha is quite significant - 12 275 (30%), 11% (2151.4 thousand ha) of all Ukrainian agricultural lands are cultivated.

An association of insurers operating in the agricultural insurance market

The only association of insurers that provide insurance in accordance with the Law of Ukraine "On features of insurance of agricultural products with state support" is the Agrarian Insurance Pool. The participation of insurers in this association is a condition for the implementation of insurance of agricultural products with state support (Fig. 6).

AGRICULTURAL INSURANCE POOL	
General characteristics	non-profit organization that unites insurers of Ukraine on a voluntary basis
Date of foundation	November 07, 2012 (created by four insurance companies)
Main activity	related to the organization and implementation of production risk insurance, storage and circulation of agricultural products (with state support) from agricultural production risks)

was to promote:

improving the quality of agricultural insurance
introduction of general rules of conduct in the market (so that there are no conflicts between insurers and farmers)
introduction of standard insurance products (developed and proposed by the International Finance Corporation (IFC, World Bank Group) Project "Development of Agricultural Insurance in Ukraine", prepared taking into account the world experience and Ukrainian features of agricultural insurance and related to strategically important for Ukraine grain and technical crops)
mediation between the agricultural insurance market and the government (in particular, his task was to revive subsidized insurance)

turned:

to the regulator of financial flows in the field of subsidized agricultural insurance (as soon as the need for this function has disappeared, the need for the pool itself has disappeared - as a result, a situation has arisen in which the pool nominally exists, but in fact does not work).

Fig. 6: General characteristics and functions of the agricultural insurance pool
[Author's development].

Under modern conditions, when the state support of agricultural insurance is purely declarative in nature and does not work in reality, the agricultural insurance pool may be entrusted with the functions of agreeing the rules of the game in the agricultural insurance market, as well as the interests of all its key participants.

The third sector of the internal structure of the agricultural insurance market

The agricultural insurance market of Ukraine in terms of infrastructure elements that form sector III of its internal structure is presented in Fig. 7.

The implementation of insurance services is essential for the formation of proper relationships between insurance companies and customers, which affects the image not only of individual insurers, but of the entire insurance market. At present, insurers pay special attention to the organization and improvement of the insurance products sales system through insurance intermediaries (Adhikari, 2010; Xiao, 2018).

The same situation is typical for the functioning of the agricultural insurance market, in which the intermediaries in the segment of insurance and non insurance types are actively involved in the process of insurance (reinsurance) services sale and their support in the agricultural sector of the economy.

The activity of insurance companies in attracting customers (agricultural producers) to conclude new insurance contracts is called acquisition (acquisition activity of the insurer). Acquisition providers are sales channels for insurance products. It is considered that the acquisition activity of the insurer is normal if the number of new insurance contracts exceeds the number of contracts for which the validity term has expired.

Fig.7. Infrastructure elements of the agricultural insurance market
Source: author's development

The main channels of insurance products sale in the agricultural sector of the economy are shown in Fig. 8.

The channels for insurance products sale are in the agricultural sector of the economy

an office channel for insurance products sale
(agricultural producers independently contact the office of the insurance company - such realization is carried out directly by its staff)

channel sales through insurance intermediaries

(agents and brokers on a commission basis are involved in the sale of insurance products. Their activity increases the efficiency of concluding agricultural insurance contracts)

channels for insurance products sale over the Internet, telephone

Fig .8. The main channels of insurance products sale are in the agricultural sector of the economy
[summarized according to Polchanov (2013); Sinitsina (2011); Vilenchuk (2014)].

At the same time, in Ukraine, the sector of the internal structure of the agricultural insurance market as intermediary or of infrastructure elements is not effectively developed.

Among the insurance intermediaries, operating in the Ukrainian agricultural insurance market, the intermediary services regarding the insurance services support (in particular, insurance risk assessment - underwriters; insurance loss assessment - average commissioners) have been acquired a certain level of development. Instead, insurance services in the domestic agricultural insurance market are mainly provided directly by insurance companies to their consumers - agricultural producers with no direct intermediaries - insurance agents and brokers in this process.

In addition, non-insurance intermediaries operate in the infrastructure of the agricultural insurance market, providing advisory, information, advertising, credit-banking, financial, auditing, notarial, exchange and other services.

Thus, improving the conditions for the development of intermediation in the Ukrainian agricultural market will make it an effective channel for the insurance products sale, which, in its turn, will strengthen the position of insurance companies in both its insurance and its agricultural insurance segment and enhance the culture of agricultural insurance among agricultural producers.

Conclusions

Thus, the study makes it possible to describe the structure of the agricultural insurance market as a complex polystructural system that has a three-sector internal structure (structured in III sectors) and is surrounded by the external environment.

Having investigated the internal structure of the agricultural insurance market, it should be noted that it is divided into III sectors, each of which form separate structural elements or their totality.

Thus, sector I belongs to an authorized body for insurance activity supervision (State Financial Services Commission); to II - structural elements (developers and providers of insurance services - insurance/reinsurance companies providing services in the agricultural sector; users of insurance

services - agricultural producers; providers of ancillary services - association of insurers); to III - infrastructure elements grouped by major infrastructure entities (insurance intermediaries, performing direct intermediary functions - agents and brokers and indirect - assess insurance risks - underwriters and insurance losses - average commissioners) and involved infrastructure entities (no insurance intermediaries) performing other business - auditors, rating agencies, and others). The external environment of the agricultural insurance market is a system of interrelated factors that surround and affect its internal system.

Dorota RYNIO

Professor of Wroclaw University of Economics and Business, Wroclaw, Poland
Dorota.Rynio@ue.wroc.pl

Abstract

The main objective of this paper is to provide an evaluation of the impact of the crisis produced by the COVID-19 pandemic upon the dynamics of unemployment increase in regions at different levels of socio-economic development. The examination involved regions of Germany and Poland. The following research methods were used: literature studies, descriptive statistics, the Hellwig's development measure method, and ANOVA one-way analysis of variance. The most significant finding of the study was as follows: at the present stage of the pandemic, the negative economic effects of the crisis are most profound for regions characterized by a higher level of development, compared to those in less advanced regions. The study presents an important contribution to the economic knowledge of crises, supplemented by detailed analyses of global economic trends produced in response to the pandemic threat. The most important limitation of the study is the preliminary character of the empirical observations made – a direct result of the limited availability of formal statistics and the relatively short time window of the present crisis. Future analyses may be supplemented by a wider selection of regions and factors under examination over longer periods, to ensure effective verification of the preliminary findings. The research results may serve to support governmental activities at different levels of administration in the effective planning of regional socio-economic development, including those made in anticipation of various crisis phenomena.

Keywords: Economic crisis, unemployment, regional development, demographics, regional vulnerability, regional resilience

Introduction

In line with the present approach, planning of socio-economic development is determined by many variables; some of these variables may not necessarily be desired, expected, or foreseeable. Changes in global economy proceed in a rapid fashion, and are unparalleled in their effective extent in this highly turbulent environment [Cortwright 2001].

The present economic crisis associated with the global outspread of the SARS-CoV-2 virus has already brought some negative consequences of unparalleled scale to national and regional economies. However, regions respond differently to its pressure, and the tangible effects of the crisis are varied. The extent of negative outcomes is defined by a region's vulnerability to crisis phenomena. Two elements of the concept of regional vulnerability are of particular note here, namely: exposure and resilience. The former determines a region's strength of response to negative external stimuli. Thus, regional economies which are more actively involved in global exchange and more susceptible to

Cite this Article as: Joanna KUDEŁKO And Dorota RYNIO " Level of Regional Development and The Dynamics of Unemployment During The COVID-19 Crisis, Based on Observations of German And Polish Regions" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

external influence will naturally be more exposed to this type of risk. [Briguglio et al. 2009]. It seems that consequences of strong exposure are most acutely observed in the earliest stages of a crisis. In the long term, a region's capacity of containing the effects of crises will be described in terms of regional resilience. A broad examination of regional vulnerability to various types of crisis situations (brought about by various determinants) can be found in the ESPON study [Territorial Dynamics 2014], covering the period of 2004-2012. However, crises analysed in the above study had not been in any way related to pandemic conditions, and therefore cannot be directly related to the present scenario. In our context, resilience describes a region's adaptive capacity of absorbing or adjusting to changes, adapting to external stimuli, exploiting challenges and opportunities, and coping with unavoidable consequences (Walker, Salt 2006).

Empirical evidence suggests that high vulnerability, in terms of exposure to crisis phenomena, is observed among the most advanced regions; however, these regions are, at the same time, characterized by high resilience (adaptive capacity to absorb the negative shocks) [Zaucha *et al.*, 2015]. Therefore, it may be assumed that the most advanced regions have borne the greatest load of negative effects in the initial phase of the present COVID-19 crisis [Bailey et al. 2020, pp. 1163-1174].

In the light of the above premises, the main objective of this paper was to evaluate the impact of the present crisis associated with the COVID-19 pandemic upon the dynamics of unemployment increase in regions at different levels of socio-economic development. As we are still at the early stage of the pandemic development where exposure to external effects plays the major role, the study's research hypothesis was formulated as follows: at the present stage of the COVID-19 crisis, its negative effects, evidenced mainly through the increase of unemployment, are more acutely experienced by advanced regions, compared to regions at lower levels of economic development. The research gap identified in this context was the more important taken the relatively narrow timeframe of the global economic duress brought about by the pandemic and its effects.

With regard to formulation of the research expectations, it was assumed that regions at different levels of their socio-economic development would present equally varied dynamics of their unemployment rate increase. Specifically, the authors assumed that the largest dynamics of unemployment rate increase would be observed in more developed regions, and that it would be at its lowest in the least developed regions.

Research was focused on regions of Germany and Poland, with the intention of providing a wider perspective for the analytical evaluation of crisis effects. Statistical analyses were performed using standard functions of MS Excel and the IBM SPSS Statistics suite.

Literature Review

Socio-economic development, in this sense, represents the sum of transformations that affect the operation of societies and economies; a complex and long-lasting process [Parysek 2018, p. 39; Lucas 1998, p. 3-42; Amin 1999, p. 365-378].

Demographic determinants represent one of the most important fundaments of socio-economic development. The main concepts of demographics have evolved over the ages, as emphasized by E. Vilquin [Vilquin 2006, pp. 5-26] in his depiction of the development of demographic ideas and theories from antiquity to the present times, analysed in a variety of aspects: cultural, economic, social, psychological, environmental, and natural. While the authorship of the modern demographic school of thought is commonly attributed to Thomas R. Malthus, his theory is outdated and does not withstand criticism. The 20th century has brought three important theories describing the socio-economic determinants of natural migrations of general population with some support from empirical evidence: the concept of the first and the second demographic transition, the economic theory of populations by Alfred Sauvy (1963), and the reformulated theory of fertility by Gary S. Becker (1981).

Current demographic trends, particularly those in the EU area, may constitute a partial barrier to development. Some of the most characteristic trends in this context include: reduction of fertility, rise

of life expectancy, ageing of societies with members of the demographic boom entering their retirement age, and the problem of double ageing [Szukalski 2006, pp. 6-10].
In this context, it may also be useful to present the notion of crisis, as a natural element of the global economic operation and development. As natural occurrences, crises may affect individual sectors and whole economies, including the global economy. Economic crises have been a natural complement to human activities from the earliest history of economic exchange [Wague 2009, p. 81]. According to G. Gorzelak, crisis is a natural phenomenon of any market economy, manifesting itself in a reasonably regular fashion, by 'oscillating between reasonably recognized parameters of an economic decline' [Gorzelak 2009, p. 7]. An economic crisis represents a 'sudden decrease of economic activity (production, employment, investment)' [www1]. According to K. Zimniewicz, a crisis is a process involving a progression of long-lasting events, which are seen as a hazard or even a barrier to existence [Zimniewicz 1990, pp. 223-224]. In effect, an economic crisis typically fathoms a wealth of other negative effects, such as prolonged recession, slump, turbulence, or economic chaos [Blanchard 2009]. The notion of economic crisis is most often and most directly defined in terms of an economic slump, i.e. an observable decline in economic growth [Dzikowska 2015, p. 735]. The notion is typically used with reference to whole economies, but it may also be adopted on regional and local perspective, or even that of individual enterprises [Marek, Wieczorek-Szymańska 2011, p. 227].

As emphasized by A. Nosek and A. Pietrzak, impetuousness and mounting pressure are the most important properties of economic crises; these may manifest themselves in various segments of the economy and lead to periodic decline of economic activities [Nosek, Pietrzak 2009, p. 83]. Similarly, M. Wague argues that an economic crisis represents a slump in global economy evidenced by decline in investment, credit limitations, bankruptcies, rise of unemployment, disintegration of large parts of the banking sector, decline in international trade [Wague 2009, p. 82]. An economic crisis can also be defined as a cyclical decline in economic growth, as postulated by the classical theory of the economic cycle, where crises mark periods of sudden production decline, leading to general income reduction, and followed by increase in unemployment [Szopa, Zamora 2015, p. 16]. Although it is believed that markets are generally reliable due to their stability, durability and resilience (through self-regulation) [Roubini 2011, p. 22], it may not necessarily mean that modern economies are altogether free from the constraints of the traditional economic (or business) cycle. The theory of cyclic fluctuations has been revisited on numerous occasions [Estey 1959, Kalecki 1980, Keynes 2003], and remains in focus, despite changes in general approach to the typical course and duration of such cyclic phases (L. von Mises) [Estey 1959; Kalecki 1980; Keynes 2020; Ebeling 1996, pp. 25-37].

The present crisis is a combination of demand shock (retail outlets closed for quarantine purposes, consumption decline resulting from work loss and general reduction of income) and supply shock (with many production facilities on quarantine, and various disruptions of supply chain and distribution). There are no econometric models available to help us predict the future consequences of the present crisis. This is evidenced in the wide spectrum of Poland's 2020 GDP forecasts issued in the context of the present COVID19 crisis by various financial institutions: from 3.0% by Moody's, through 1.9% by BOŚ, 1.6% by mBank, 0.9% by Citi Handlowy, IGN's 0%, down to -3.6% according to Morgan Stanley [www2]. This is good evidence of the precipitous uncertainty we're dealing with at the moment.

Crises produce various outcomes depending on their spatial context, and the intensity of such consequences is also widely diversified. Some regions may display evidence of an economic slowdown, others may experience periods of stagnation or recession. Variance in regions' responses to the economic crisis is described by each region's individual vulnerability to the new phenomena. Concepts of evolutionary resilience were analysed in numerous studies [Davoudi 2012; Holling and Gunderson 2002; Walker et al. 2004; Folke et al. 2010], with focus on dynamic correlations between duration, adaptation and structural changes observed in the context of various spatial and temporal dimensions in their strife to reach and maintain the unique state of equilibrium. Scientific disputes on measures of economic susceptibility (vulnerability) to external stimuli in a regional and national dimension were initiated in 1970s [O'Keefe et al. 1976] within the context of natural sciences, and were later expanded to cover the macroeconomic dimension [Tobin, 1980, pp. 31–34; Hamilton 1983; Jones and Leiby 1996]. In Turner et al. [2003] and Birkmann [2006], the concept of vulnerability is adopted in three major spheres: social, economic, and environmental. Vulnerability (susceptibility) is

territorially oriented, and context-related (Cutter et al. 2003); it applies to the future, and it may be analysed in both unidimensional and multidimensional fashion [Turner 2003, p. 207]. The economic resilience is defined by the following dimensions: resistance, recovery, or the region's ability to recuperate, reorientation, rebirth [Martin 2010, pp. 1-32].

With reference to the operationalization of the concept of vulnerability to macroeconomic stimuli postulated by the Austrian Institute for Spatial Planning (Österreichisches Institut für Raumplanung) – OIR (2011), the term is identified as a function of the following: shock exposure, shock sensitivity, and adaptive capacity; with exposure and sensitivity conditioning the region's response to external stimuli [Komornicki 2015, p. 39].

Regional vulnerability to crises is a fundament of the long-term economic operation of regions and a measure of regions' attractiveness for investors. In this context, vulnerability may be analysed in various cross-sections, from microeconomic to global [Markowska, Strahl 2015, p. 2]. Resilience mechanisms in regions determine their ability to continue along the chosen path of development in spite of unfavourable and changing conditions.

In the theoretic approach of new economic geography, reactiveness and sensitivity are perceived as two main elements that determine the economic development of a region [Gawlikowska-Hueckel, Szlachta 2016, p. 26]. Management of reactiveness to external macroeconomic stimuli requires careful determination of the pre-existing heuristics, as emphasized by proponents of the behavioural economics approach [Simon 1957; Kahneman and Tversky 1979].

Materials and Methods

The first stage of this research project involved evaluation of demographic determinants of development in regions under study. This was followed by determination of the pre-crisis level of development for each such territorial unit under examination, based on selected statistical measures of regional socio-economic growth. These formed the fundament for the design of a synthetic measure of regional development, and served to segment the research sample into three groups, namely: developed, average, and underdeveloped regions. A diagnosis of the present effects of the COVID-19 crisis was also performed at this stage of research, using information on regional unemployment rate increase as a reliable index of negative changes in the studied NUTS 2 statistical regions. The final stage of the study involved determination of statistically significant differences (if any) between the previously identified groups of regions, in relation to their reported unemployment rate fluctuations.

For the purpose of providing a broader perspective of research and in anticipation of gaining more insightful results, the analytical evaluations were performed for regions of both Poland and Germany. In effect, the study included all the NUTS 2 recognized regions of Poland and Germany, to a total of 55 territorial units (17 regions of Poland, and 38 regions of Germany).

The study involved the use of the following research methods: literature studies, descriptive statistical analysis, Hellwig's development measure method, and ANOVA one-way analysis of variance.

Based on selected diagnostic properties illustrating various aspects of the socio-economic development, a synthetic measure of regional development was formulated using Hellwig's taxonomic spatial measure of development [Hellwig 1968]. Hellwig's method is a model method, meaning that it adopts an ideal model of an object, i.e. one characterized by the highest (for the stimulating factors) or the lowest values (for the hampering factors). The synthetic measure is construed from measurements of distance between the studied object and the model representation of an ideal object, expressed in standard Euclidean metrics [Młodak 2009, Panek 2009]. The resulting measure takes values in the range of (0;1), with higher values signifying closer proximity to the model. Distance of regions to the ideal model representation was each time calculated from the following formula:

$$d_{i0} = \left(\sum_{j=1}^{m} \left(z_{ij} - z_{oj} \right)^2 \right)^{\frac{1}{2}}$$

where:
zoj – coordinates of the model object, determined from the standardized input variables
zij – coordinates of the standardized input variables
m – number of variables
The value of synthetic measure for each region was calculated from the following formula:

$$d_i = 1 - \frac{d_{i0}}{d_0}$$

where:
$d_0 = \overline{\mathrm{d}_0} + 2s_{(d_0)}$,

$$\overline{\mathrm{d}_0} = \frac{1}{n} \sum_{i=1}^{n} d_{i0}$$

$$s_{(d_0)} = \left(\frac{1}{n} \sum_{i=1}^{n} \left(d_{i0} - \overline{d_0} \right)^2 \right)^{\frac{1}{2}}$$

Based on resulting values of the synthetic measure of development, regions were ranked and segmented into groups describing different levels of socio-economic development (developed, average, underdeveloped).

The next phase involved examination of correlations between the resulting measures of socio-economic development and the available unemployment rate statistics (dynamics of unemployment rate increase in June 2020 compared to June 2019). To confirm the existence of statistically significant differences between groups of regions representing different levels of development and their respective dynamics of unemployment rate increase, a dedicated statistical procedure was used, namely: ANOVA one-way analysis of variance. The objective of this method is to provide information on statistical significance of differences between several averages taken from samples representing many population sets [Bedyńska, Brzezicka 2007]. Thus, the method may be applied to study any potential correlations between unemployment rate increases observed in response to the present crisis and the pre-established levels of socio-economic development in the analysed regions.

A one-way analysis of variance is a generalized test of differences between averages in sets, where comparisons are made between values of intragroup and intergroup variance, resulting in F (Fisher) statistic value, calculated from the following formula:

$$\mathrm{F} = \frac{\mathrm{MS}_{MG}}{MS_{WG}}$$

where:

MS_{MG} – intergroup variance, also referred to as within-group variance
MS_{WG} – intragroup variance, also referred to as between-groups variance.

Analysis of variance allows for effective verification of the research hypothesis on the equality of averages. The zero hypothesis for testing was formulated as follows:
$H_o = M_1 + M_2 + \ldots + M_k$
where k is the number of levels (categories) of x factor (the number of tested groups).

For the identification of statistically significant differences between pairs of averages, a post hoc analysis was conducted, involving comparisons of each average within group against every other average. The study assumed the statistical significance level at a value of $p = 0.05$, representing the probability of an error.

Statistical data used in the study was obtained from official statistical institutions, namely: the Statistical Office of the European Union – Eurostat, the German Bundesagentur für Arbeit, and the Polish Główny Urząd Statystyczny. Statistical analyses were performed using standard formulas of the MS Excel and the IBM SPSS Statistics suite.

Descriptive analyses of the development levels of regions under study was performed for the year 2018 (where no data was available, 2017 values were adopted). On the one hand, this approach was dictated by the availability of statistical data and by the lack of more recent indices. On the other hand, the authors' intention was to study the levels of regional development from before the outburst of the present crisis associated with the COVID-19 pandemic. With regard to the observed increase of unemployment in regions following the outburst of the crisis, the authors employed statistical data for June 2020, i.e. the initial period of the crisis development. These figures were examined against the same period of the previous year, to capture differences associated with the pandemic outburst and its effects.

Results and Discussion

Demographic determinants of regional development in Germany and Poland

The study emphasized the basic demographic determinants of regional development in Germany and Poland, as human resources and the associated economic potential are the most important factors defining the development potential of regional economies.

Table 1: Basic demographic data for regions of Germany and Poland (2018)

NUTS 2 regions	Population	Population density	Crude rate of net migration plus statistical adjustment	Total fertility rate	Life expectancy at birth
German regions					
Average	2178746	467	4,8	1,6	80,9
Coefficient of variance	53,1	170,1	39,3	4,0	1,0
Polish regions					
Average	2233923	147	0,2	1,43	77,7
Coefficient of variance	43,9	80,6	1316,0	6,7	1,1

Source: Eurostat, https://ec.europa.eu/, (accessed 25 July 2020).

The studied regions showed a wide variance in population and in other demographic statistics (Tab.1). The largest population density was observed in large metropolitan areas recognized as separate NUTS 2 units, namely: Berlin, Hamburg and Bremen in Germany, and Warsaw metropolitan area in Poland. In terms of average population density values, German regions scored significantly higher (at 467 persons/1 km^2) compared to those in Poland (an average of 147 persons/1 km^2). At the same time, German regions displayed a much more pronounced intergroup variation of this index, with coefficient at 170%, compared to a decidedly lower level of 80.6% for Poland.

German regions were also found to display higher values for the remaining properties under examination. Their migration balance was in positive figures for each German region, signifying their appeal for those seeking employment or economic refuge. The average migration balance was at 4.8. Total fertility rate was at an average of 1.60 and was marginally higher than that for Poland (1.43). German regions ranked higher in life expectancy, at an average of 80.9 years of age, i.e. by more than three years compared to that for Poland. German regions showed moderate variance of migration balance, and were fairly uniform in terms of fertility and life expectancy figures.

Similarly, Polish regions displayed high cohesion with respect to fertility and life expectancy averages from region to region. And conversely to the German scores, the migration balance for Polish regions showed massive variance (with coefficient at 1316%). The most attractive region was that of Warsaw (with migration balance ratio at 8.0). At the same time, many regions displayed negative migration ratio, with national average at a mere 0.2.

Regional levels of socio-economic development in Germany and Poland

The following economic indices were employed for the evaluation of the pace of socio-economic development processes in regions over the period directly preceding the onslaught of the present crisis:

x_1 - Regional gross domestic product (PPS per inhabitant),
x_2 - Disposable income of private households (PPS per inhabitant),
x_3 - Population density,
x_4 - Tertiary educational attainment, age group 25-64 (%),
x_5 - Unemployment rate (%),
x_6 - Employment in high-tech sectors (% of total employment).

For the purpose of defining the set of variables for examination, the following criteria were adopted: availability of accurate and current data for all regions, the analytical value of each variable, as well as the accessibility of each variable's notion and its universal recognition. Other commonly used criteria of selection were also adopted, including data universality, measurability, accessibility, quality, and interpretability.

The adopted set of diagnostic properties provides information on various aspects of regional socio-economic development, such as: global production volume (x_1), affluence (x_2), region's appeal as a migration destination (x_3), quality of human resource capital (general level of education) (x_4), labour market potential and degree of labour utilization (x_5), development of high-tech sectors (x_6).

Compared to their Polish counterparts, German regions received higher scores in the majority of the analysed properties (Tab.2). Their advantage was the most profound with respect to regional gross domestic product per inhabitant and disposable income of private households per inhabitant, with average values in excess of those for Poland by nearly 80%. Strong advantage was also observed in relation to high-tech sector employment (34 %). At the same time, German regions scored lower with respect to unemployment rate, by an average of 18%. As already mentioned, German regions were characterized by a decidedly higher population density, ranking nearly twice as high as the Polish regions. It must be noted, however, that they also displayed high intergroup variance in this context, as evidenced by the elevated value of the coefficient of variance (at 170%).

Table 2: Level of socio-economic development of German and Polish regions, in relation to selected properties (2018; income data for 2017)

NUTS 2 regions	Regional gross domestic product (PPS per inhabitant)	Tertiary educational attainment, age group 25-64 (%)	Employment in high-tech sectors (% of total employment)	Population density	Unemployment rate (%)	Disposable income of private households (PPS per inhabitant)
German regions						
Average	36379	28,1	3,9	467	3,3	21197
Coefficient of variance	21,6	17,2	38,3	170,1	30,9	7,8
Polish regions						
Average	20294	30,0	2,9	147	4,1	11894
Coefficient of variance	37,9	25,6	69,5	80,6	34,6	15,2

Source: Eurostat, https://ec.europa.eu/, (accessed 25 July 2020).

Polish regions are at an advantage over Germany only in terms of the relative share of high education in general working population (age 25-64). However, this advantage is not too pronounced, with difference slightly in excess of 6%.

Apart from the already noted population density advantage, Germany shows much stronger intraregional cohesion in the other studied aspects. Polish regions, in turn, are far more diversified.

Changes of the unemployment ratio associated with the effects of the COVID-19 crisis in regions of Germany and Poland

All the regions under study displayed evidence of a significant increase of unemployment in response to the present COVID-19 crisis. Such evidence includes high values of unemployment ratio fluctuations observed for June 2020 vs. same month last year (Tab.3). These negative effects were decidedly more pronounced in German regions, with unemployment rate increase by an average of 30.06%. Regional variance in this respect was fairly moderate for Germany, as attested by the coefficient value of 37.9%. The most adverse effects were observed in the regions of: Schwaben (unemployment increase by 52.45%), Tübingen (47.33%), Stuttgart (45.96%), and Freiburg (45.26%). The least adverse effects, in turn, were reported in the regions of: Lüneburg (9.82%), Brandenburg (14.00%), Dresden (14.66%), and Sachsen-Anhalt (15.88%).

It may be worth noting that, prior to the present crisis, the general trend of unemployment was in expressed in negative values. Between June 2017 and June 2018, the number of unemployed decreased by an average of 8.13%. Over the next year (June 2018 – June 2019) the decreasing trend continued, amounting to an average of 1.58% on top of the previous figure. However, at the time the economic fluctuations varied considerably between regions (as attested by the coefficient value of 285.1%). Some regions registered fairly significant increases of unemployment (in relation to the previous year), and were most pronounced in Niederbayern (an increase of 8.26%) and Unterfranken (4.32%).

Polish regions were decidedly less affected by the economic slump, as evidenced by the less pronounced increase of unemployment between June 2019 and June 2020, by an average of 18.16%, i.e. by 11.9 percentage points less than that for German regions. The unemployment effects were most adverse in the regions of: Wielkopolskie (29.77%), Pomorskie (25.08%), Małopolskie (24.35%), and Opolskie (23.97%). The least adverse effects were observed in the regions of: Łódzkie (9.66%), Lubelskie (11.28%), Mazowieckie (11.40%), and Kujawsko-Pomorskie (11.56%).

In the years prior to the outbreak of the COVID-19 crisis, all regions of Poland had shown a steady trend of unemployment decrease. Between June 2017 and June 2018, the number of unemployed was reduced by an average of 16.5%, and by further 9.68% between June 2018 and June 2019. Interregional variance in this respect was fairly low and remained at a moderate level throughout the whole period of analysis.

Table 3: Changes in the number of unemployed in regions of Germany and Poland

NUTS 2 regions	June				Change of unemployment rate for June 2018 compared to June 2017 (in %)	Change of unemployment rate for June 2019 compared to June 2018 (in %)	Change of unemployment rate for June 2020 compared to June 2019 (in %)
	Total No. of unemployed						
	2017	2018	2019	2020			
German regions							
Average	64953	59851	58515	74693	-8,13	-1,58	30,06
Coefficient of variance	72,3	72,9	73,5	70,8	24,5	285,1	37,9
Polish regions							
Average	67744	56935	51594	60381	-16,50	-9,68	18,16
Coefficient of variance	43,6	44,7	45,3	43,1	23,5	32,7	33,1

Level of regional development and vulnerability to the COVID-19 crisis

- Changes in unemployment rate constitute of the best available measures of the effects of the present global crisis associated with the COVID-19 pandemic. Benefits of this measure include the availability and timeliness of unemployment data, and its suitability for the purpose of effective interregional comparisons. Thus, the effects of the present crisis were examined on the basis of a percentage value index representing an increase in the number of formally registered unemployed per the end of June 2020 compared to the same month of the previous year, i.e. 2019.
- Statistical analyses were performed in order to examine any potential correlations between levels of regional development and the regions' responses to the present crisis, as reflected by their respective dynamics of unemployment rate increase over the last year.
- Firstly, a synthetic measure of regional development was formulated for each region, to serve as basis for a ranking and a classification of regions into three groups, based on their effective level of socio-economic development.
- The synthetic measure was each time calculated using Hellwig's method, based on the six diagnostic indices described above. Analytical evaluations were made jointly for all the formally recognized regions of Germany and Poland, and their results are presented in Tab. 4. Based on the results of the above, regions were then grouped into the following categories, using their respective values of the synthetic measure of development. Three groups were defined as follows:
- the most advanced regions, with synthetic measure of development > 0.30;
- regions at an average level of development, with synthetic measure of development in the range of (0.15; 0.30];
- the least developed regions, with synthetic measure of development ≤ 0.15

Table 4: Group classification of German and Polish regions, formulated on the basis of the regions' ranks in synthetic measure of regional development

• NUTS 2 regions	• Country	• Dynamics of unemployment June 2020/June 2019 (in %)	• Synthetic measure of development	• Groups of regions, by level of socio-economic development
• Hamburg	• Germany	• 35,68	• 0,57	• Group 1 – the most advanced regions, with synthetic measure of development > 0.30
• Berlin	• Germany	• 37,18	• 0,56	
• Warszawski stołeczny	• Poland	• 21,97	• 0,50	
• Oberbayern	• Germany	• 49,53	• 0,44	
• Darmstadt	• Germany	• 37,30	• 0,39	
• Bremen	• Germany	• 18,18	• 0,37	
• Stuttgart	• Germany	• 45,96	• 0,35	
• Karlsruhe	• Germany	• 42,95	• 0,34	
• Köln	• Germany	• 22,59	• 0,34	
• Mittelfranken	• Germany	• 35,88	• 0,32	
• Tübingen	• Germany	• 47,33	• 0,32	
• Freiburg	• Germany	• 45,26	• 0,31	
• Düsseldorf	• Germany	• 16,82	• 0,29	• Group 2 – regions at an average level of development, with synthetic measure of development in the range of (0.15; 0.30]
• Rheinhessen-Pfalz	• Germany	• 28,08	• 0,28	
• Dresden	• Germany	• 14,66	• 0,28	
• Leipzig	• Germany	• 25,81	• 0,27	
• Oberpfalz	• Germany	• 42,50	• 0,26	
• Unterfranken	• Germany	• 40,05	• 0,25

Swietokrzyskie	Poland	12,88	0,07	
Lubelskie	Poland	20,62	0,07	
Podkarpackie	Poland	15,36	0,07	
Mazowiecki regionalny	Poland	12,95	0,05	
Warminsko-Mazurskie	Poland	17,32	0,04	

Source: own research, based on reports by: Eurostat, Bundesagentur für Arbeit, and Główny Urząd Statystyczny.

Group 1 included the most advanced regions, for which the synthetic measure of development was found to be in excess of 0.3. Twelve regions were classified here, with leading positions held by large metropolitan areas of: Hamburg, Berlin, Warsaw and Bremen; followed by regions of Oberbayern and Mittelfranken (the German state of Bayern); all regions of the Baden-Württemberg state, i.e.: Stuttgart, Karlsruhe, Tübingen and Freiburg; Darmstadt (the state of Hessen), and Köln (the state of Nordrhein-Westfalen).

Only one Polish region was classified in this group, namely: the metropolitan area of Warsaw, formally identified as a separate NUTS 2 region.

Group 2 was the most populated of the three, with thirty regions at an average level of socio-economic development, for which the synthetic measure of development was found to be in the range of (0.15; 0.30].

Group 3 included the least developed regions, a set of thirteen regions for which the synthetic measure of development was equal or less than 0.15. Polish regions represent a majority of those classified at the lower end of the ranking. Of all the seventeen NUTS 2 regions of Poland, as many as 10 were classified in this group. The least developed regions were those of the eastern part of Poland: Warminsko-Mazurskie, Mazowieckie (region), Podkarpackie, Lubelskie, and Świętokrzyskie. Also, the group of the least developed regions included only three German regions, namely: Sachsen-Anhalt and Mecklenburg-Vorpommern (each with state competences, both are situated in the eastern part of Germany), and Weser-Ems (a region of the Niedersachsen state).

The above classification seems to support the earlier conclusions suggesting a significantly higher level of development in German regions, compared to their Polish counterparts.

In order to test for any statistically significant differences between the three groups or regions representative of different levels of development in terms of their reported dynamics of changes in unemployment ratio, the authors decided to employ the ANOVA one-way analysis of variance (Tab.5). For the dependent variable, an index was adopted representing a percentage increase in the number of officially registered unemployed in June 2020 compared to June 2019 data. In this approach, the dynamics of unemployment rate increase serves to illustrate the magnitude of effects caused by the present COVID-19 crisis.

Table 5: Statistical parameters of the AVOVA analysis for the index – dynamics of unemployment between June 2019-June 2020 (in %) – in groups of regions representative of three levels of development

Specification	Group 1	Group 2	Group 3
Arithmetic mean	36,65	26,26	17,18
Maximum value	49,6	52,5	29,1
Minimum value	18,2	9,7	11,3
Coefficient of variance (in %)	28,9	39,2	32,7
Parameters of property distribution	$Z_{1(12)}$ = 0,214; ni	$Z_{2(30)}$ = 0,154; ni	$Z_{3(13)}$ = 0,162; ni
Levene test results	$F_{LEVENE'A\ (2,52)}$ = 1,647; ni		
Fisher statistics	$F_{(2,52)}$ = 13,127; p < 0,05		

Source: own research, based on reports by: Eurostat, Bundesagentur für Arbeit, and Główny Urząd Statystyczny.

The normality of dependent variable distribution was tested using the Kolmogorov–Smirnov test, yielding the following results for each group: $Z_{1(12)}$ = 0.214; ni; $Z_{2(30)}$ = 0.154; ni; $Z_{3(13)}$ = 0.162; ni. Based on test results, normality of the variable distribution in each group was confirmed. This was followed by verification of the equality of variances for the variable using the Levene's test, yielding the following result: $F_{LEVENE'S\ (2.\ 52)}$ = 1.647; ni (statistically insignificant). The test results attested to statistical insignificance of the test, giving way to an assumption that there are no fundaments for rejecting the hypothesis on the equality of variances in the groups under study. Thus, such equality of variances was assumed to hold true.

Further examinations yielded the following Fisher statistics: $F_{(2.52)}$ = 13.127; $p < 0.05$, suggesting that the result is statistically significant, giving no reason to reject the zero hypothesis (H_0) on the equality of result averages between groups. Hence, it may be assumed that there are statistically significant

differences between the three groups under study in terms of their reported dynamics of unemployment ratio increase.

The last step involved a post hoc analysis using the Bonferroni correction for multiple comparisons in pairs, to ensure that differences between results obtained for each pair of comparable groups are statistically significant.

Conclusions

This study places focus on examination of short-term response to the crisis brought about by the present COVID-19 pandemic. At this initial phase, the most pronounced effects are those of regional exposure. Thus, it was assumed that the most advanced regions, for the fact of being more exposed to crisis phenomena through their stronger global interconnections, will be more adversely affected by negative effects of the first phase of the present crisis. These assumptions were verified on the basis of formal reports of increases in unemployment rates resulting from the present crisis.

Analyses involved regions of Germany and Poland, with evidence to suggest that the former had been more advanced in terms of their socio-economic development compared to the latter. German regions were also characterized by more favourable demographic conditions.

The research hypothesis formulated at the initial stage has been verified. The results of the study seem to confirm that, at the present stage of the COVID-19 crisis, its negative effects epitomized by the increase of unemployment rates, are more acutely experienced by advanced regions, compared to regions characterized by lower levels of socio-economic development.

The effects of the crisis, as manifested in the increased unemployment rates, were most pronounced in Group 1 regions (the most advanced ones). Their reported increase of unemployment between June 2019 and June 2020 was at an average of 36.65%. Regions classified under Group 2 (medium level of development) came decidedly second in this respect, with a significantly lower index value of 26.26%. Unemployment increases were the least pronounced in Group 3 (the least developed regions), and averaged at 17.18% over the same period.

Based on results of statistical one-way analysis of variance between groups of regions representing three different levels of development in terms of their reported unemployment rate increase, it may be concluded that the negative effects of the first phase of the present crisis were decidedly more adverse in the group of the most advanced regions, compared to that of less developed regions, in confirmation of the initial assumptions.

It may be assumed that more advanced regions will also be more resilient to external shocks, defined here as the ability to return to the pre-established path of development after an external shock. This assumption, however, may only be verified at a later stage, and in a long-term perspective.

Abstract

The main purpose of the article is to present the results of the survey on pricing strategies for hotel services in a selected region of Poland, namely the Kujawsko-Pomorskie and Pomorskie provinces. The survey was carried out twice, with a five-year interval, i.e. in 2014 and 2019. This enabled the comparison of the obtained data. The survey was aimed at verifying the thesis that determining the prices of hotel rooms is made on the basis of certain factors, mainly such as: the wealth of the society and its tourist awareness, the attractiveness of the region, the state of development of both domestic and international tourism, as well as the needs of business in terms of the need for hotel services.

Keywords: The Pricing Policy For Hotel Services, Tourism, Hotel Industry

Introduction

The beginnings of the hotel industry in Poland go back to the beginnings of Polish statehood. The first lodging facility was established by Mieszko Stary in 1187. It was a hospice located in Poznań next to the customs house (Mitura, Koniuszewska, 2006).

Moving to modern times, the 1990s were a breakthrough period for hotel services in Poland. It was then, that the rapid development of the Polish hotel industry of various standards and forms began. Many individual hotels have been built, and hotel chains such as Marriott, Holiday Inn, Louvre and Accor have also expanded. There have been changes in the management of accommodation facilities and in the ownership structure of hotel buildings. The commenced privatization process covered state-owned property. At the same time, all unprofitable or not promising facilities were liquidated. As a result of economic and social changes, an increasing number of medium income citizens took part in shorter or longer trips organized for various purposes. Another important moment for the development of the hotel industry was Poland's accession to the European Union. The hotel services market began to mature and the offer of hotel services was being adapted to the requirements of both Polish and foreign guests. The years 2008 - 2013 brought Poland a 50% increase in the number of hotels. The use of hotel services has also increased. This period in Poland was unanimously called the hotel boom (Milewska, Włodarczyk, 2015).

The main purpose of the article is to present the results of the survey on pricing strategies for hotel services in a selected region of Poland, namely the Kujawsko-Pomorskie and Pomorskie provinces. The survey was carried out twice, with a five-year interval, i.e. in 2014 and 2019. This enabled the comparison of the obtained data. The survey was aimed at verifying the thesis that determining the

prices of hotel rooms is made on the basis of certain factors, mainly such as: the wealth of the society and its tourist awareness, the attractiveness of the region, the state of development of both domestic and international tourism, as well as the needs of business in terms of the need for hotel services.

Strategies for setting prices for hotel services in the literature on the subject

Determining the price for hotel services is an extremely difficult task for the managers of this type of enterprise. This is primarily related to the specific features of the tourism sector, such as for example high price elasticity of demand for tourist services, a long lead time between pricing decisions and the sale of products, immateriality of services and the inability to store them, relation of fixed costs to variable costs (Bosiacki et al., 2008).

Ultimately, the price for the product must be set against the value delivered to the customer. Both too high and too low a price will lead to lower profits. The selection of a pricing strategy should therefore consist of the following stages (Kotler, 2005): selecting the target of the pricing strategy, determining the size of demand, determining the size of costs, analyzing costs, prices and competitor offers, selecting the pricing method and selecting the final price.

When setting the price of a hotel service, it is also worth paying attention to its characteristic elements. It is a combination of various values provided to the client, both of a tangible and intangible nature. The material elements include such factors as (Jaremen, Panasiuk, 2008): goods purchased by hotel guests (e.g. a meal in a hotel restaurant,), goods without which the service could not be provided (e.g. hotel facility), and goods constituting the material basis for the services provided (e.g. catering equipment). Among the intangible elements of a hotel product, we can distinguish, for example hospitality, an appropriate atmosphere or making reservations.

According to the literature on the subject, pricing for tourist services can be set in various ways. The best known forms of pricing are: the cost method, the demand method and the competitive method (Kotaś, Sojak, 2010).

In the cost method, the price should cover the profitability of the capital employed and the cost of the hotel enterprise. It is less beneficial for customers, but most credible for the company and tax authorities. From the point of view of costs, price calculations should include: the amount and structure of total costs, the amount of fixed and variable costs per service unit, the possibility of using the economies of scale and possible changes in the cost structure (Turkowski, 2003).

The demand method is based on the observation and analysis of the relationships between the demand for a service and its price. In the case of hotel services, the demand is most often flexible in relation to the price. Price elasticity of demand is the intensity of consumer reaction, which is manifested in the scale of changes in the volume of purchases to the change in price. It is necessary to know the size of the demand, the purchasing power and the nature of the segment targeted by the offer (Altkorn, 2002).

The competitive method consists in comparing a certain own pricelist with the competitors' prices for a similar service. Using this method, the hotel should first define which segment is the most important for it, and then it should define which companies are its competitors. (Turkowski, 2003).

It should be noted that basic prices are not final prices in the hotel industry. Their planning, apart from the basic price, also takes into account differentiated prices. In the hotel industry, the following differentiation criteria are most often used (Rapacz, 2007):

- time of making a purchase,
- features of the recipients of the hotel product and the nature of the trip,
- sales volume,
- form of payment,

– distribution channel.

The topic of pricing strategies for hotel services has been discussed many times in the world literature. Particular attention was devoted, among others, to such issues as: the methods of determining the price and factors affecting its level (Saló, Teixidor, Fluvià, Garriga, 2020), the use of selected models to adjust the pricing policy to changing market conditions (Mariello, Dalcastagné, Brunato, 2020; Fadly, Ridwan, Deni Akbar, 2019; Zhuang, Chen, Fu, 2017; Wei, Hoffer, 2009), analysis of selected price determinants (Mandić, Petrić, 2020; Lin, 2017; Raya, 2011), analysis of pricing policy on the example of hotels operating in a given region (Pulina, Santoni, 2019; Vives, Jacob, 2019; Kim, Cho, Kim, Shin, 2014), analysis of pricing policy in the context of high competition (Enz, Canina, Liu , 2008; García, 2013; Dong, Ling, 2015), psychological aspects of pricing (Liu, Denizci Guillet, Xiao, Law, 2014; Ahmad, 2015; Pelegrín-Borondo, Arias-Oliva, 2015).

Methodology of Survey

The conducted survey is part of the stream of regional research focusing on selected issues related to the functioning of the tourism industry in individual provinces in Poland. Regional research on the broadly understood tourism sphere in the Kujawsko-Pomorskie Voivodship entitled "*Directions of development in the field of tourism and their impact on the economy of the Kujawsko-Pomorskie Voivodship*" were conducted, among others, in 2009-2011 by a team of employees of the Nicolaus Copernicus University in Toruń and Kujawsko-Pomeranian Tourist Organization (Anszperger, Radkiewicz, 2011). In the case of the Pomeranian Voivodship, for example, a study was carried out under the name "*National tourism in the Pomeranian Voivodship*", carried out by the team of employees of the Institute of Tourism in Warsaw (Alejziak, 2010). It should be emphasized that the pricing strategy was not the main subject of the above-mentioned studies.

The survey carried out in 2014 and then repeated in 2019 was aimed at collecting data on the basis of which it would be possible to answer the following questions:
- what is the methodology for pricing in the surveyed hotels,
- what external factors, in the opinion of the respondents, influence the price formation,
- what is the impact of competition on shaping prices in the hotel industry,
- how the price is perceived by the customer.

The questionnaire form containing the above questions was sent out electronically for the first time in the fourth quarter of 2014. In response, 60 completed questionnaires were obtained from hotels located in northern Poland, mainly in cities (90%), mostly with 4 (40%) or 3 (35%) stars, and to a lesser extent 5-star (20%) and those with 2 stars (5%). The number of beds in the surveyed establishments ranged from 120 to 378, and in most cases, hotels had single and double rooms. Survey questionnaires were completed by hotel owners, directors or chief accountants.

The responses obtained in 2014 showed that when setting the price, respondents largely rely on the cost strategy, taking into account such factors as: demand for hotel services, customer wealth, hotel location, length of stay, specific season, time and form of payment. In order to verify the obtained results and check whether this is a constant trend, the survey form was sent again in the fourth quarter of 2019. This time, 40 correctly completed questionnaires were obtained. The collected data show that a typical respondent, as before, were hotels operating in northern Poland, 95% located in the city, with a majority of 4 (45%) or 3 (35%) stars, and a minority of 5-star hotels (10%) and those with 2 stars (10%). Most hotels had from 100 to 185 hotel places, mainly single and double rooms. Due to the size of both samples, the obtained survey results are not representative but only informative, aimed at the presentation and analysis of the collected material.

The survey questionnaire included 27 questions assigned to the following areas: general information, pricing methodology, external factors shaping the price, price and competition, price from the customer's perspective. The article presents the respondents' answers to selected questions from the individual, above-mentioned parts of the survey.

Survey Results

The first question asked of the respondents related to the pricing strategy chosen by the hotel. The survey shows that in 2019 the strategy most often chosen by hoteliers when determining room prices was the cost strategy. This answer was indicated by as many as 80% of the respondents. A much smaller proportion (15%) of the respondents chose the demand-driven strategy, and only 5% of them chose the competitive strategy. In relation to the results from 2014, one can notice an increase in interest in the cost strategy by 5% and a similar increase in interest in the demand strategy. On the other hand, the interest in the competitive strategy clearly decreased - from 15% to 5%. The distribution of results is presented in Chart 1.

Chart 1. What pricing strategy has your hotel chosen?

Source: Based on the survey results.

Another question was about the purpose of the pricing strategy. In 2019, the vast majority of respondents replied that the goal of their strategy was to increase the number of hotel services sold (85%). The creation or stabilization of the hotel's image was indicated by 10% of the respondents. Only 5% has chosen to increase market share as its target. On the other hand, during the 2014 survey, the answer "increase in hotel services sold" reached the result of 90%, while the remaining two statements were at the level of 5%. The answers indicated by the respondents are presented in Chart 2.

Chart 2. What is the purpose of the pricing strategy?

Source: Based on the survey results.

When asked "How often is the price in your hotel changed", the vast majority of respondents replied "once a year" (75%), but five years earlier this tactic was used by almost all hotels, hence the result of 95%. The obtained results are graphically presented in Chart 3.

Chart 3. How often the price is changed at your hotel?

Source: Based on the survey results.

The survey shows that in 2019, the offer addressed to companies (75%) was very important for the operation of hotels. However, only 25% of the respondents opted for basic prices. In 2014, the price addressed to business guests was even more important and was indicated by 85% of respondents. In addition, all surveyed entities in the course of both studies confirmed that they applied a price differentiation system depending on the length and date of stay.

Another question addressed to hoteliers concerned the costs that influence pricing. The respondents agreed that the costs of marketing (90%) and personnel costs, e.g. employee remuneration (90%) had the greatest impact on the pricing of their services. Insurance costs (75%), Internet, TV and telephone costs (65%), building maintenance costs (65%) as well as product and material costs (60%), administration and management costs (60%) and depreciation (55%) and hotel interior design costs (55%) have a slightly smaller, although still significant impact on the price. The obtained results were at a similar level during the first and the second survey.

Convergent results in both studies were also obtained by asking a question about internal factors influencing the setting of prices for hotel services. The vast majority of hotels indicated that the factors such as length of stay 80%, seasonality 80%, time and form of payment 75%, an offer tailored to groups 60%, the location of a room in a hotel building 60% as well as also the number of beds in the hotel 60%. Only then are taken into account: place of purchase of services 50%, additional room equipment 35% as well as access to additional services in the hotel 30%, room equipment and design 20%. The image of the hotel - 10%, hotel staff - 10%, and entertainment venues - 10% are much less important. Only 5% of the respondents believe that the factor that influences the price is the availability of parking for guests and the technical condition of the equipment.

The next part of the survey was to find out which of the external factors, according to the respondents, affect the price. The respondents had the following options: location of the hotel, potential of the region, hotel categorization, degree of customer wealth, level of infrastructure, and they could also add another factor which, in their opinion, was the most important. According to a 2019 survey, the most important factor in price planning was the degree of customer availability (40%). The location of the hotel is a slightly less important factor (35%). The categorization of the hotel is also important (20%) and, to a small extent, the potential of the region (5%). In the earlier survey, according to the respondents, the greatest impact when planning the price was the degree of customer wealth, ie 80%. Factors such as the location of the hotel 70% were also important. Next, the categorization of the

hotel was indicated as 35% and the potential of a given region was 5%. The distribution of results is presented in Chart 4.

Chart 4. Which factor turned out to be the most important when planning the price?
Source: Based on the survey results.

The next questions in the questionnaire related to the competition. When asked if competition influences the price setting, as many as 85% of the respondents in 2019 answered yes, in 2014, almost all respondents answered yes, i.e. 95%. Taking into account the frequency of competitor analysis, in 2019 60% of respondents conducted a competition analysis every six months, 30% performed it once a quarter, and 5% did it once a year. The same number of hotels conducted a competition analysis once a month. Similar results were obtained in the previous survey. Similar results were also obtained when asked about the assessment of the price level compared to the competition. The vast majority of respondents (90%) admitted that the prices they set are at the same level as those of competing hotels. On the other hand, 10% indicated that their prices are at a higher level than those of their competitors.

When analyzing the prices of hotel services through the prism of customers, a question was asked about the discounts offered. Discounts for regular customers are the most popular among hotels (85% in 2019 and 80% in 2014). Discounts offered to groups (50% in both studies) and season-specific discounts (65% in 2019 and 50% in 2014) are in second place. The answers given by the respondents are presented in Chart 5. The respondents in both surveys agreed in 100% that the location of their hotels has a huge impact on consumers' decisions.

Chart 5. Does your hotel offer discounts?

Source: Based on the survey results.

Discussion

The conducted surveys show that hotel managers in most cases choose a cost strategy when determining room prices. On the other hand, they apply a competitive strategy to a small extent, which seems quite dangerous to them. Hoteliers using this strategy do not pay attention to the quality and difference in the services provided. The cost strategy is the most favorable, it distinguishes both the quality and the differences in the services offered. It pays attention to the fact that the total income covers at least the total costs. Targeting the strategy of increasing the number of hotel services sold proves that hotels care most about selling as many services as possible. This is understandable in light of the growing competition in the hotel industry every year. The problem in the hotel industry is the frequency of price changes, which is very high. Frequent fluctuations in price changes may adversely affect the image of hotels as they lose their credibility. For this reason, most managers adopt the tactic of changing prices in the largest possible time intervals. The frequency of price changes can be influenced by various factors, ranging from changes in costs incurred by the hotel, to local charges, which also increase or decrease. For hotels, the most important type of activity is the offer addressed to companies. The prices offered to enterprises are significantly lower than the basic prices. Discounts range from 10 - 30% and can sometimes be as high as 50%. Such a client usually books almost a complete set of hotel rooms. Each hotel facility will strive for such a consumer, because the corporate market is a very profitable enterprise for them. In the survey conducted, the respondents agreed that their prices are subject to differentiation. This is a very important activity as it allows them to shift some of the demand into dead periods. Price differentiation allows not only to determine the amount of demand for the services provided at a given time, but also has an impact on the maximization of revenues related to the appropriate choice of the price level in relation to the degree of demand. Improperly differentiated prices may cause the hotel to fail to achieve the planned margin and even incur a loss. Most of the respondents replied that the factor which is taken into account in price differentiation is the length of stay of hotel guests. The first night is always the most expensive, because to rent a room, no matter how long the stay is, the costs of cleaning the room, washing bed linen and towels must be included. The longer the stay, the lower the price the hotels can offer. Seasonality is the second important factor. Different prices will be offered during the week and weekends, similar to the season. When determining prices, both fixed costs and variable costs are taken into account. On the basis of the obtained results, it was found that marketing costs, which are related to the specific features of hotel services, have a decisive influence on the setting of prices. They are both an opportunity and a challenge for people who deal with hotel marketing. Their rational reduction may help to set the appropriate price to a level that will satisfy both the hotelier and the client. According to the survey, the most important external factor taken into account in the hospitality industry when planning prices is the degree of customer wealth. Hotels are aware of the role of compe-

tition in their environment. It is also connected with its constant analysis. Most often, hotels analyze the situation in the competitive environment every six months. Hoteliers are aware that their competition is growing year by year. In order to stand out from these competitors, hotels use different prices, additional services, and increase their standard and quality. The prices of hotel services are very similar to the competition. Especially hotels located in cities have a very large number of competitors. In a situation where the offer of the hotel is similar to that of its most serious competitors, it will be forced to keep its prices close to those of its competitors, which will help to keep customers. Only 10% of hotels have prices higher than competition. This may indicate that they have a strong position in the market or offer services that others do not have. When hotel prices are at a similar level, the most important role is played by the location, appearance of the hotel and the additional services it provides. Hotels apply many kinds of discounts. They encourage their regular customers to visit again, the size and type of discounts are adjusted to the seasonality, and they also attract groups through specially adapted discounts. Discounts offered to regular customers allow hotels to build a loyalty program for their frequent visitors. Location is one of the key factors influencing consumers. This is where customers start choosing a hotel. After determining the place, they look for a hotel that meets their requirements. Customers often want the hotel to be in the center, as close to the sea as possible or in another attractive place. In order to make their offer more attractive, hoteliers additionally include breakfast in the room price, provide their guests with swimming pools and saunas, and provide rooms with additional equipment such as a dryer, iron and air conditioning. This type of service can be a decisive factor in consumer choice of a hotel.

Conclusions

The task of hotels is to meet the increasingly complex and unusual needs of their potential guests. The greatest role in this process is played by market observation and responding to new customer requirements. Hotel facilities must be modernized and have a varied offer of additional services. The goal of every hotel is to generate profit. Many factors influence the achievement of the goal. The most important ones include the idea for the formula of the facility, meeting the unsatisfied needs of potential customers and ensuring competitive prices, adequate to the quality of services offered. The literature on the subject indicates the following ways of influencing the quality of hotel services (Witkowski, 2002):

1. market competition between hotels and growing requirements of guests - they force hotel managers to have an appropriate attitude to quality - the market of hotel services is the buyer's market and this fact forces the development, provision and development of guest service standards the most;
2. supervision and control activities carried out by state and local government bodies and specialized institutions - control activities contribute to the maintenance of standards, quality, sanitary condition and safety;
3. activities of the hoteliers' professional self-government - the Polish Hotel Association may influence the quality level of hotel services, e.g. through the recommendation system and organization of industry competitions;
4. legal regulations - they can be treated very broadly and refer to the provisions of construction law, sanitary regulations or environmental protection, while the main way of influencing the level of hotel services by the legislator should be categorization.

The current epidemiological situation poses many challenges for the tourism industry, not only in terms of the quality of its services. Despite the fact that most sectors are trying hard to return to normal operations, there are still industries that, despite the lifting of most of the restrictions, are strongly affected by COVID-19. Reports of an increase in the number of infections or the introduction of global restrictions also cause serious concern to people working in the tourism industry (horecatrends.pl).

A study commissioned by the Polish Tourist Organization shows that in 2020, due to the current situation related to COVID-19, as many as 82% of tourists pay attention to increased hygiene standards during their trip. Therefore, facilities that stand out in this field may gain a competitive ad-

vantage both on the domestic and foreign markets. Therefore, the Polish Tourist Organization, meeting these expectations, created the Industry Team for Self-Certification of Hotels and Accommodation Establishments, the aim of which was to prepare a self-certification program and develop a program of further activities in this area (Polish Tourist Organization).

Attempts to stimulate the tourist activity of consumers in the form of a travel voucher are one of the ideas for solving the current problems of the industry. The effects of the actions currently taken by both the Polish government and the managers of hotel enterprises will be visible in the near future. They will certainly be the subject of further studies by the authors on the scope and nature of changes in the hotel strategy made in connection with COVID-19.

Abstract

The purpose of this research article is to develop a methodological approach to determining the integral rating of business development in the regions of Kazakhstan on the basis of the proposed indicators, the forecast of business development. **Methodology** – statistical methods were used in the preparation of the article, such as the use of the geometric mean to determine the rating of regions, trend analysis, and the rating method was used as a mathematical model. **The result** *(value)* of this work is to conduct a statistical analysis and substantiate the possibility of using the proposed integral index as a tool for assessing the development of the level of entrepreneurship in the regions.
Conclusions – methods of statistical analysis, namely on the basis of calculating the integral index, are applicable to assess the development of entrepreneurship in the regions of the country, to form a rating based on the geometric mean.

Keywords: Small and Medium-Sized Businesses, Rating, Index, Integral Index, Assessment of Business Development.

Introduction

Small and medium-sized businesses in Kazakhstan accounted for 10.5% of GRP in 2005 and 28.4 % of GRP in 2018 [1]. The development of this sector of the country's economy, built on the formation of a class of entrepreneurs and their support, is one of the key tasks of Kazakhstan. The experience of developed countries demonstrates the need for comprehensive support for the development of small and medium-sized businesses, which makes it possible to ensure a significant level of their contribution to the economy of their countries. Thus, the share of small and medium-sized businesses in the GDP of developed countries is 50-60 % [2]. However, it is impossible to make effective management decisions without feedback and without accurate and effective mechanisms for evaluating the performance of this sector of the economy. In this regard, in our opinion, it is relevant to conduct research to assess the development of entrepreneurship for our state.

Cite this Article as: V. ZARUBINA, M. ZARUBIN, D. KENZHEBEKOVA, A. KURMANGALIEVA and YE. VASSILCHUK“ Statistical Assessment of The Development of Small and Medium-Sized Businesses in The Republic of Kazakhstan” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The level of development of entrepreneurship in the regions is different. This can be explained both by a number of objective reasons and by the effectiveness of business support in this region. It is known that the problem of the development of small and medium-sized businesses has been widely studied, however, modern understanding requires additional study of the influence of the actualized factors affecting its development.

Various methods of assessing the development of entrepreneurship are known as tools. For example, statistical analysis of small and medium-sized businesses allows you to determine the factors, trends, and dependencies that affect the state economy, use the forecast of the dynamics of indicators, and choose the best models. However, the use of these methods presents disparate views on different parameters. At the same time, statistical analysis uses methods of integral estimates, which, in our opinion, can be applied to the assessment of business development.

Literature Review

Studies aimed at studying the essence of entrepreneurship, its role in the formation of the state are presented in the works of A. Smith, K. Keynes [3, 4].

Assessment of the effectiveness of modern entrepreneurship is presented in the works of Russian scientists L. A. Kolesnikov, A. Yu. Chepurenko, support of entrepreneurship in the field of strategic planning by E. M. Bukhvald, A. V. Vilensky [5, 6, 7]. The assessment of infrastructural support of small business is considered in the works of L. G. Rudenko, V. M. Karaulov and many others [8, 9].

The development of entrepreneurship in Kazakhstan is considered by domestic scientists - A. Toksanova, G. Ukubasova, A. Asenova and others [10,11]. Various directions of assessing the development of entrepreneurship in Kazakhstan are presented in the works of N. N. Kulbatyrov, A. A. Tulepbekova [12].

A retrospective analysis of the scientific works of classics and contemporaries makes it possible to draw conclusions about the possibility and necessity of conducting research in the field of supporting and managing the development of small and medium-sized businesses, bringing together development assessment factors into a single system. The development of the digital economy and its globalization, the acceleration of decision-making processes and an increase in the number of influencing factors significantly, in our opinion, exacerbate the problem of effective management of business development.

The lack of a comprehensive system for assessing the development of entrepreneurship in the context of the development of the digital economy that takes into account the listed factors has led to scientific research devoted to the statistical assessment of the development of small and medium-sized businesses in the Kazakhstani situation.

Main Part of The Study

An important component in the effective development of Kazakhstan, integration into the world space is the dynamic development of entrepreneurship.

In modern conditions, the assessment of the effectiveness of the development of entrepreneurship in the regions can be performed on the basis of the geometric mean, the use of which becomes possible when assessing entrepreneurship by relative indicators [9]. The authors propose to determine the rating of the development of entrepreneurship in the regions on the basis of statistical indicators - the number of small and medium-sized businesses, including active ones, the output of products by small and medium-sized businesses per 1000 people of the region's population, the output of products per one small and medium-sized business. Such an assessment integrates a number of factors into a single index and can be called an integral index of entrepreneurship development.
The authors of the article, based on [8,13], to calculate the integral index of the development of small and medium-sized businesses, it is proposed to use the following formula:

$$I = \sqrt[4]{I_1 * I_2 * I_3 * I_4}\ , \qquad (1)$$

where I – integral index of the development of small and medium-sized businesses;

I_1 – growth index of small and medium-sized businesses;

I_2 – growth index of active small and medium-sized businesses;

I_3 – index of production output by small and medium-sized businesses per 1000 people of the region's population;

I_4 – growth index in output per one small and medium-sized business entity.

One of the most important indicators of entrepreneurship development is the number of registered, including active small and medium-sized businesses (SMBs). Table 1 shows the growth index of registered SMBs in Kazakhstan for 2017-2018 as a whole in the republic and regions. The analysis used statistical data of the Committee on Statistics of the Ministry of National Economy of the Republic of Kazakhstan [1]. A positive dynamics of an increase in the number of entrepreneurs is observed in the country as a whole, the growth over the period under review was 2.4%, the highest growth rate is in the city of Nur-Sultan. A decrease in the number of registered SMBs took place in Almaty, Kostanay, Turkestan, North Kazakhstan, East Kazakhstan regions.

Table 1: Growth index of registered SMBs

Regions	2017	2018	Growth index
The Republic of Kazakhstan	1 540 592	1 577 747	1,024
Akmola	55 836	55 862	1,000
Aktobe	63 120	65 832	1,043
Almaty	142 607	142 103	0,996
Atyrau	55 210	57 135	1,035
West Kazakhstan	48 047	49 646	1,033
Zhambyl	76 878	80 019	1,041
Karaganda	100 710	102 423	1,017
Kostanay	65 237	64 011	0,981
Kyzylorda	49 991	51 078	1,022
Mangystau	56 256	59 784	1,063
Turkestan	213 028	141 082	0,662
Pavlodar	52 132	53 045	1,018
North Kazakhstan	36 656	36 154	0,986
East Kazakhstan	111 162	111 036	0,999
Nur-Sultan city	148 536	162 128	1,092
Almaty city	265 186	274 689	1,036
Note - calculated by the authors based on the source [1]			

The growth index of active SMBs is calculated and presented in Table 2. The share of active SMBs in 2018 was 78.7%, in 2017 - 74.3%. The highest growth rate of active entities in the capital is 1.282, the lowest is in the Turkestan region - 0.737.

In all regions, except for Turkestan (with an index less than 1), there is a positive growth trend in the number of active SMBs, which positively characterizes the development of entrepreneurship in these regions.

Table 2: Growth index of active SMBs

Regions	2017	2018	Growth index
The Republic of Kazakhstan	1 145 994	1 241 328	1,083
Akmola	41 719	44 106	1,057
Aktobe	50 209	54 430	1,084

Pavlodar	41 311	43 820	1,061
North Kazakhstan	27 587	28 969	1,050
East Kazakhstan	79 966	87 678	1,096
Nur-Sultan city	97 251	124 685	1,282
Almaty city	169 985	174 509	1,027
Note - calculated by the authors based on the source [1]			

The population density in the regions of Kazakhstan is different, as well as the population size. In this regard, it is interesting to determine the production output by small and medium-sized businesses per one inhabitant of the region. Table 3 shows the output of products by SMBs per 1000 people of the population of the regions for 2017-2018, as well as the index of output. The largest volume of production is in Nur-Sultan, Almaty, as well as in the west – Atyrau, West Kazakhstan, Mangistau regions. The smallest volume of output is in Zhambyl, Kyzylorda, Turkestan regions. Only in the Turkestan region, the growth rate is less than one and amounted to 0.458 for the period under review, which indicates a decrease in the growth in the level of output by entrepreneurs in the region. The growth index in Nur-Sultan is also less than one – 0.955, however, the volume of production per capita is the highest in the country – 4531.14 million tenge / person. in 2018, in other areas, the growth index is more than one, which indicates an increase in the volume of output in monetary terms in the period under review. In general, in the Republic, the production index was 1.124.

Inflation in the Republic of Kazakhstan in 2018 was 5.3% [14]. The growth rate of output is 12.4%, which is 7.1% higher than the inflation rate. This positively characterizes the dynamics of production by SMBs.

It should be noted that in Kazakhstan comprehensive support is provided for the development of entrepreneurship for the activation and formation of its own production of products, the development of the manufacturing sector of the economy. For this purpose, a number of programs have been adopted and are being implemented [16, 17, 18].

Note – calculated by the authors based on the source [1]							

The next indicator in assessing the development of entrepreneurship is the index of product output per SMB entity for 2017-2018 (table 4). The maximum volume of production per one SMB entity in 2018 was observed in Nur-Sultan, West Kazakhstan, Atyrau regions. The smallest volume of production is in Turkestan, Zhambyl, Almaty, East Kazakhstan regions. The range of changes in the volume of production by SMBs in 2018 varies from 41.75 million tenge / unit in Atyrau region, up to 3.77 million tenge / unit in the Turkestan region. The highest index of output per SMB entity for 2017-2018 received in the Atyrau region.

Based on the calculated indices, the integral index of entrepreneurship development in Kazakhstan was determined (Table 5).

Table 5: Integral index of development of small and medium-sized businesses for 2017-2018

Region	**Growth index of SMBs entities**	**Growth index of active SMBs entities**	**Index of production output by SMBs entities per 1000 people in the region**	**Index of production output for one SMB entity**	**Integral index**
The Republic of Kazakhstan	1,024	1,083	1,124	1,112	1,085
Akmola	1,000	1,057	1,203	1,202	1,112
Aktobe	1,043	1,084	1,165	1,133	1,105
Almaty	0,996	1,052	1,184	1,201	1,105
Atyrau	1,035	1,090	1,418	1,399	1,223
West Kazakhstan	1,033	1,080	1,034	1,009	1,039
Zhambyl	1,041	1,078	1,104	1,069	1,073
Karaganda	1,017	1,060	1,294	1,271	1,154
Kostanay	0,981	1,059	1,192	1,211	1,107
Kyzylorda	1,022	1,131	1,152	1,143	1,111
Mangystau	1,063	1,087	1,170	1,131	1,112
Turkestan	0,662	0,737	0,458	0,693	0,627
Pavlodar	1,018	1,061	1,002	0,983	1,015
North Kazakhstan	0,986	1,050	1,173	1,180	1,094
East Kazakhstan	0,999	1,096	1,157	1,153	1,099
Nur-Sultan city	1,092	1,282	0,955	0,916	1,052
Almaty city	1,036	1,027	1,100	1,093	1,063
Note - calculated by the authors based on sources [1], [15]					

According to the integrated development index in Kazakhstan as a whole, we can note the positive dynamics of small and medium-sized businesses.

- the integral index was 1.281. However, the range of changes in the index ranges from 0.204 in the Turkestan region to 1.74 in the Atyrau region. Therefore, in 2017-2018, the progressive development of small and medium-sized businesses can be noted in Atyrau (1,740) and Karaganda regions (1,481) as having the largest and significantly higher than the average for Kazakhstan;

- requiring a more in-depth analysis of the situation in the region, significant correction of mechanisms and/or tools for the development of entrepreneurship in the Turkestan region (0.204).

The distribution of regions by output and the share of active actors in the region is interesting. Table 6 and figure 1 show the distribution of regions according to the proposed criteria.

Table 6: Distribution of regions by production output and share of active entities for 2018

Region	Production output per SMB entity, million tenge	Share of active SMB entity
Akmola	14,06	78,955
Aktobe	13,59	82,680
Almaty	9,62	81,371
Atyrau	*41,75*	*81,834*
West Kazakhstan	*30,42*	*80,695*
Zhambyl	5,99	79,059
Karaganda	13,02	82,044
Kostanay	14,19	79,819
Kyzylorda	7,45	82,897
Mangystau	15,78	85,468
Turkestan	3,77	92,715
Pavlodar	14,06	82,609
North Kazakhstan	15,79	80,127
East Kazakhstan	9,34	78,964
Nur-Sultan city	30,14	76,905
Almaty city	25,01	63,530
Note - calculated by the authors based on the source [1]		

Table 6 and figure 1 demonstrate the dynamic development of entrepreneurship, again in the Atyrau and West Kazakhstan regions.

The effectiveness of entrepreneurship development in Nur-Sultan and Almaty requires additional study. These cities demonstrate a high output per one entity, but the share of active entities is low.

Fig. 1: Distribution of regions by the share of active SMBs entities and product output.
Note: compiled by the authors based on the source [1]

Turkestan region is again an outsider in terms of the share of active SMBs entities and production output. The lowest level of production per SMB entity is in this region.

The range of variation is 0.596 (1.223-0.627). According to the obtained level of the rating of development of small and medium-sized businesses, the regions of Kazakhstan can be conditionally divided into three groups: the first group – dynamically developing regions (lagging behind the leader by no more than 20%), the second group – with an average level of development of SMBs (lagging behind the leader in the range of 20 -80%, the third group – low development of SMBs (lagging behind the leader by more than 80%).

Table 7: Distribution of regions of the Republic of Kazakhstan by the level of development of SMBs

Groups of regions by the level of SMB development	Characteristic	Regions
Group 1 - dynamic development	the gap from the leader is no more than 20%	Atyrau is a leader Akmola, Aktobe, Almaty, Karagandy, Kostanay, Kyzylorda, Mangistau
Group 2 - medium development of SMBs	the gap from the leader in the range of 20-80%,	West Kazakhstan, Zhambyl, Pavlodar, North Kazakhstan, East Kazakhstan, Nur-Sultan city, Almaty city
Group 3 - low development of SMBs	the gap from the leader by more than 80%).	Turkestan

We will calculate the dispersion, standard deviation, coefficient of variation of the obtained rating of SMB entrepreneurship development in the Republic of Kazakhstan.

Table 8: data for calculating dispersion, standard deviation, coefficient of variation

Region	X_i	X_i^2
Akmola	1,112026601	1,2366032
Aktobe	1,105358279	1,2218169
Almaty	1,105165175	1,2213901
Atyrau	1,223158809	1,4961175
West Kazakhstan	1,038783758	1,0790717
Zhambyl	1,072745747	1,1507834
Karaganda	1,153938675	1,3315745
Kostanay	1,106732945	1,2248578
Kyzylorda	1,110548434	1,2333178
Mangystau	1,11187515	1,2362664
Turkestan	0,627171614	0,3933442
Pavlodar	1,015334857	1,0309049
North Kazakhstan	1,094166388	1,1972001
East Kazakhstan	1,099434242	1,2087557
Nur-Sultan city	1,051811438	1,1063073
Almaty city	1,063350189	1,1307136
Total	**17,0916023**	**18,499025**

The dispersion is determined by the following formula:

$$D_e = x^2 - (\bar{x}_e)^2 = \frac{\sum_{i=1}^{n} x_i^2}{n} - \left(\frac{\sum_{i=1}^{n} x_i}{n}\right)^2, \qquad (2)$$

where D_e – dispersion,

n – number of values,

x_i – value of the integral index of the development of SMBs in the region in the Republic of Kazakhstan.

$D_e = (18{,}499025/16) - (17{,}0916023/16)^2 = 0{,}015084103$

In addition to the mean, it is also of interest to identify trends in how the observations are scattered relative to the mean. The standard deviation is the measure of the deviation of the observations from the mean.

The standard deviation is determined by the following formula:

$$\delta = \sqrt{De}, \qquad (3)$$

Standard deviation δ= 0,122817356

The coefficient of variation was:

$$Кв = \frac{\delta}{\bar{x}} = 11{,}497$$

In modern conditions of development, it is necessary to activate small and medium-sized businesses in all regions of the country to ensure a significant increase in the volume of production.

Obtained Results (Conclusions)

There is a sufficient amount of research in the field of small and medium-sized businesses. However, we identified the need to form an integrated assessment of business development based on the proposed indices, which forced us to study this issue more deeply. We have proposed an assessment of the development of entrepreneurship based on statistical indicators, using the geometric mean to determine the rating of regions for the development of entrepreneurship. The integral index is calculated on the basis of private data: the growth index of small and medium-sized businesses entities; growth index of active small and medium-sized businesses entities; index of output by small and medium-sized businesses per 1000 people population of the region; index of output growth per small and medium-sized business entity. The results of calculations show:

- regions with successful business development – Atyrau region;
- regions that require a more detailed analysis of the situation – Nur-Sultan and Almaty cities;
- regions that are outsiders in the development of entrepreneurship that require a radical revision of decisions – Turkestan region.

According to the results of the study, it is proved that the use of an integral indicator not only allows you to reduce a set of indicators to a convenient and visual assessment system, but also to identify hidden, yet undiscovered problem points in the development of entrepreneurship.

Further development of small and medium-sized businesses can be ensured by activating its development in the regions, forming development vectors using digital technologies.

Abstract

Nowadays teaching is closely related to new technologies of information and Covid-19 has been a catalyst to accelerate the transition to magisterial course to distant learning, proving the importance of NTI to education. But curriculum are slow to change and skills with technology are not generalized among teachers and students in pedagogy. One of the reasons may be the fact that there are nine different types of intelligence. This paper reports on an investigation to find if there is a relation between digital literacy and intelligence style. It also studies the relationship between the different components of digital literacy/competency and if there is a there is a significant relationship between the different multiple intelligence types. Results show that the digital literacy/competency level of the respondents is moderate, hence the need to enhance this skill, especially that society is more digitally dependent. Furthermore, the respondents are mostly strong in existential intelligence, with intrapersonal intelligence as their secondary strength. Correlation findings between digital literacy/competency level and multiple intelligences show that intrapersonal intelligence is significantly correlated with safety, content creation, and communication. In addition, musical intelligence is significantly correlated with problem-solving. With these findings, the authors suggest an emphasis be made on enhancing digital literacy or competencies or teachers, especially that education in the 21st century rely largely on technology, allowing the teachers to fully and successfully interact with their students.

Keywords: multiple intelligence, teacher, digital literacy, teaching, information technology

Introduction

The 21st century sees plenty of significant changes in lifestyle, required job skills, and even social behavior as compared to past eras. Technological innovation has played a significant role in this transition. Such innovations allow day-to-day tasks at the tip of one's fingertips to be carried out online – emails, news, banking, shopping, gaming, social media, and more – without physically needing to leave the chair. Therefore, it is crucial that each individual have a wide range of skills and competencies in this rapidly evolving and highly interconnected world, and will need to learn them continuously throughout life (Council of the European Union, 2018; Uerz, Volman, & Kral, 2018; Benali, Kaddouri, & Azzimani, 2018; Van Laar, van Deursen, van Dijk, & de Haan, 2017).

PETEROS "Exploring the Digital Literacies and Multiple Intelligences of Teachers in Graduate School" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

It is important to recognize, with all this internationalization and globalization, that the skills required to create a functioning community have also developed or have been modified (Schwab, 2016). Human society has experienced various kinds of technological innovations, or industrial revolutions, namely (1) Industry 1.0 with water and steam as the source of power for production, (2) Industry 2.0 with mass manufacturing and assembly lines, (3) Industry 3.0 with electronics and computer technology to mechanize production; and (4) Industry 4.0 with artificial intelligence and more sophisticated technologies (Benešová & Tupa, 2017; Lu, 2017; Schwab, 2016). The key goals of these developments are to improve productivity and quality of life, with Industry 4.0 making better use of internet technology and advanced artificial intelligence (Lu, 2017).

Such emerging innovations have profound effects on people's education, resulting in a professional and highly educated workforce, as skills taught decades earlier vary from what would be expected over the next few years (Benešová, & Tupa, 2017; McKendrick, 2015). Because of these developments, governments have agreed on reference frameworks, especially in the area of learning outcomes, to guide schools to produce learners who are ready to satisfy the needs of society. The value of digital literacy is demonstrated by numerous national and regional initiatives to establish and enforce digital literacy frameworks and strategic plans to promote digital literacy amongst its citizens (Law, Woo, De la Torre, & Wong, 2018).

The Council of the European Union (2018) recommends key competencies for lifelong learning, with the aim that "everyone has the right to quality and inclusive education, training, and lifelong learning to maintain and acquire skills that enable them to participate fully in society and manage successfully transitions in the labor market." The United Nations (UN) set 17 global goals covering various socio-economic issues for all member nations to achieve by the year 2030, and one of these goals focuses on education – "to ensure inclusive and equitable quality education and promote lifelong learning opportunities for all" (UN, 2017). The Association of Southeast Asian Nations (ASEAN) established the ASEAN Qualifications Reference Framework, which is equal to all and gives a universal standard on education criteria, or qualifications, across participating ASEAN Member States (ASEAN.org, 2016). Objectives of this framework include (1) support recognition of qualifications; (2) encourage the development of qualifications frameworks that can facilitate lifelong learning; (3) promote the development of national approaches to validating learning gained outside formal education; (4) promote and encourage education and learner mobility; (5) support worker mobility; (6) improve understanding of qualifications systems; and (7) promote higher quality qualifications systems.

The Philippine educational system has also made a major paradigm change in consonance with these developments. The new K-12 curriculum is on its 2-year mark for its elementary and secondary education, and shift from content-based education to outcomes-based education for its tertiary education. The goal of these changes is to see graduates fully prepared and qualified for the workforce.

As emerging technologies constitute an inextricable part of the young people's everyday lives, some analysts argue that the present generation of learners thinks and learns differently from their predecessors. With the rapid growth of digital technology in recent years, there is no doubt that many young people have gained enormous technical experience, especially in economically developed countries, before they reach the university (Lai & Hong, 2014). Higher education must, therefore, adapt to respond to these differences in learning to accommodate the "more technology-driven, spontaneous, and multi-sensory" learning styles (Prensky, 2001). The growing use of these modern innovations by the present generation has placed tremendous pressure on their educators to understand the importance of digital communication, to discover new ways of thinking and processing the learners' knowledge, and incorporate it into their academic environments (Buragohain, 2019; Krumsvik, 2014).

It is, therefore, the focus of this study to determine the digital literacy of teachers. By now, educators should have realized that being digitally literate, knowing how to incorporate technology into the

curriculum, and being positive about using it in the classroom would have an effect on student learning (Michalakis, Vaitis, & Klonari, 2019).

Theoretical Background/Related Literature and Studies

Digital Literacy/Competence

In recent years, the notion of literacy has shifted. Literacy usually refers to the ability to read and write to communicate and/or get information (Pate & Grote, 2011). Proponents of 21st-century skills have proposed the integration of digital literacy into the curriculum, along with the other skills such as collaboration, creativity, communication to name a few, as these are essential for work and life (Envision, 2017; Campbell & Kresyman, 2015; Hixson, Ravitz, & Whisman, 2012; Voogt & Roblin, 2012). George-Palilonis & Watt (2018) defined digital literacy as the ability or skill to effectively make and share meaning in different types and media, to effectively create, collaborate, and communicate in digital settings, and to understand when and how digital technology can support these tasks. A summary of definitions of digital literacy and competencies taken from some studies are reflected in Table 1.

Table 1: Summary of Definitions of Digital Literacy and Competencies

Author	Definition
Cornell University as cited in Yazon, Ang-Manaig, Buama, & Tesoro (2019)	Ability to find, evaluate, utilize, share, and create content using information technologies and the internet
List, A. (2019)	Necessary competencies or skills that are interrelated with one another for success in the digital environment
Yazon, Ang-Manaig, Buama, & Tesoro (2019)	Includes a wide range of skills that are required to thrive in a growing digital environment
Council of the European Union (2018)	Involves the confident, critical and responsible use of, and engagement with, digital technologies for education, work, and participation in society
George-Palilonis & Watt (2018)	The ability or skill to effectively make and share meaning in different types and media, to effectively create, collaborate, and communicate in digital settings, and to understand when and how digital technology can support these tasks
Law, Woo, De la Torre, & Wong (2018)	The ability to access, manage, understand, integrate, communicate, evaluate, and create information safely and appropriately through digital technologies for employment, decent jobs, and entrepreneurship. It includes competencies that are variously referred to as computer literacy, information and communication technology (ICT) literacy, information literacy and media literacy
Uerz, Volman, & Kral (2018)	Refers to the ability to use technology in general and is not specifically related to teaching and learning
Sauro (2017)	Refers to having several skills and competencies in the context of ICT
Yu, Lin, & Liao (2017)	Includes the fundamental ICT operational skills and the capability to use or manipulate complex ICT communication applications
Author	**Definition**
Greene, Yu, & Copeland (2014)	Refers to the cognitive processes that people engage by using computer-based knowledge found in different hypermedia
Ilomäki, Paavola, Lakkala, &	Defines that digital competence consists of technical

Kantosalo (2014)	competence, the ability to use digital technologies in a meaningful way for working, learning and in daily life, the ability to assess digital technologies critically, and the desire to engage and contribute in the digital culture
Meyers, Erickson, & Small (2013)	Includes aspects of cognitive authority, safety and privacy, ethical, and responsible use and reuse of digital media
Chase & Laufenberg (2011)	Offers a range of learning experiences, creativity, and opportunities for expression that were not previously accessible
UNESCO (2011)	For teachers, this refers to the ability to help students become collaborative, creative and problem-solving learners through the use of ICT so they will be effective citizens and members of the workforce
Eshet-Alkalai & Chajut (2009)	The ability to use a wide variety of cognitive and emotional abilities in digital technology
Eshet (2004)	Requires more than just the ability to use software or use a digital device; it involves a wide range of diverse sociological, cognitive, emotional, and motor skills that users need to work successfully in digital settings
Ministry of Education, British Columbia, Canada	The interest, attitude and ability of individuals to use digital technology and communication tools appropriately to access, manage, integrate, analyze and evaluate information, construct new knowledge, and create and communicate with others

The incorporation of these new skills does not replace the conventional curricula on essential reading, writing, mathematical skills, as well as history, science, and others, but will also find instructional strategies and/or create instructional materials that represent the development of these skills or competencies and make learning more meaningful (Geisinger, 2016; Abril, 2013). These skills are more than rote learning as they focus more on experimentation, creativity, use of multimedia imagination, which allows one to be participants and contributors of technology, and not just as consumers (Davidson, 2012; Davidson, 2016). Such critical and needed skills, not just knowledge, should be taught and instilled in the learners – skills that are crucial for success in an ever-changing, digitally dependent society (Schoen & Fusarelli, 2008; Siddiq, Gochyyev, & Wilson, 2017).

Digital literacy has many components. In Soo Jung Moon's and Sang Y. Bai's (2020) study, digital components of Radovanović, Hogan, & Lalić (2015) were the basis for predicting youth civic engagement and the role of social media news attention in South Korea. These components are formal operational skills, information retrieval, and analytical skills, digital communication skills, and creation skills. Voogt and Roblin (2012), in their comparative analysis of 21st-century competencies of various international frameworks, determined that digital literacy includes basic scientific, economic, technological visual and information, multicultural literacies, and global awareness. George-Palilonis & Watt (2018), together with the Professor Garfield Foundation, introduced the digital literacy website to K-5 teachers in Midwest, USA, which emphasizes the 21st-century skills of creativity, critical thinking, collaboration, and communication, along with functional meaning-making, cultural and social understanding, finding and selecting information, and e-safety. The Ministry of Education in British Columbia, Canada elaborates that the characteristics of digital literacy are research and information literacy; critical thinking, problem solving, and decision making; creativity and innovation; digital citizenship; communication and collaboration; and technology operations and concepts. In addition, UNESCO, along with the European Commission, emphasizes the following dimensions of digital literacy: (1) research and information literacy, (2) critical thinking, problem-solving, and decision making, (3) creativity and innovation, (4) digital citizenship, (5) communication and collaboration, and (6) technology operations and concepts (Law, Woo, De la Torre, & Wong, 2018).

H1: There is a significant relationship between the different components of digital literacy/competency.

Multiple Intelligence

The concept, measurement, and development of intelligence have long been debated by many – psychologists and educators to name a few (Sternberg, 2003). It has been a question of nature versus nurture, individual versus group influence, or the classification of the different types of intelligence (Walinga & Stangor, 2014). Intelligence, which was initially regarded as a single entity acquired during birth, has been identified as one of the main factors in the teaching-learning environment and academic achievement (Dolati & Tahriri, 2017; Çeliköz, 2017). In the study of Mujis and Reynolds (2011), the Intelligence Quotient (IQ) Theory states that intelligence is the determining factor for people's ability to learn and achieve academically, which then allows them to assume leadership positions in society. Because of this view, standardized tests are given to measure IQ, which allows educators to have a glimpse of the learners' capacity to achieve (Çeliköz, 2017).

A new paradigm that counter-flowed with this one-standard-for-all intelligence viewpoint was the Theory of Multiple Intelligence (MI) which was discovered by Howard Gardner in 1983. This theory changed the way psychologists, educators, and even parents view the learners (Alhamuddin & Bukhori, 2016). It stresses that intelligence is not just developed logically nor linguistically, but is also developed in other ways (Alhamuddin & Bukhori, 2016). MI consists of different types that are not usually reflected in IQ tests, and that each one is equally important as the other types of intelligence (Gardner, 1993). This theory also notes the fact that each person is smart, but in vary in degrees of strength, which may even change from time to time depending on his/her exposure to different factors (Kennedy-Murray, 2016; Yaghoob & Hossein, 2016). The different intelligence types are logical-mathematical, verbal-linguistic, visual-spatial, bodily-kinesthetic, interpersonal, intrapersonal, musical, naturalistic, and existential (Gardner, 1993; Shearer, 2019; Shi, 2019; Çeliköz, 2017; Dolati & Tahriri, 2017; Kennedy-Murray, 2016; Alhamuddin & Bukhori, 2016; Yaghoob & Hossein, 2016; Walinga & Stangor, 2014).

Since individuals have all nine intelligences, though in varying degrees, and that these intelligences are dynamic – develop through time and various learning experiences, it may be safe to assume that individuals have more than one dominant intelligence and that each of these intelligences are interrelated with each other (Yaghoob & Hossein, 2016). According to Shi (2019), MI has the following characteristics: (1) different – there are nine (9) types of intelligence that vary in each individual; (2) practical – intelligence allows individuals to discover new knowledge, create and be innovative, and are able to solve problems; (3) integrity – all nine intelligences are interrelated and interact with each other; and (4) developmental – strength of each intelligence may change depending on the different learning opportunities, training, or environment. The study of Overchuk and Niemczyk (2009) on the applicability of MI theory in pilot assessment and training shows that the respondents are strong in both intrapersonal and spatial intelligence. In addition, Çeliköz's (2017) study showed that prospective teachers of Yildiz Technical University are dominant in mathematical-logic, verbal, interpersonal, and intrapersonal intelligences.

H2: There is a significant relationship between the different multiple intelligence types.
H3: There is a significant relationship between digital literacy/competency and multiple intelligence types.

Statement of the Problem

This study assessed the perceived digital literacy levels of teachers pursuing their masteral or doctoral degrees and aimed to answer the following questions:

1. As perceived by the respondents, what is their digital literacy levels as to information processing, communication, content creation, safety, and problem-solving?

2. What is the multiple intelligence profile of the respondents?

Methodology

This study used the descriptive-correlational survey method to determine the digital literacy competencies and distribution of multiple intelligences of teachers pursuing graduate studies in the province of Cebu, Philippines. These teachers come from different areas of the region, both in the urban and rural areas, as well as working in either private or public schools.

After permission from the deans of the colleges to conduct the research was granted, hard copies of two (2) questionnaires were distributed to 287 respondents, including a letter of consent to take part in the research. Confidentiality of data was emphasized, including proper storage of answered sheets.

The digital competency survey was adapted from the study of Al Khateeb (2017). The survey was used to measure the respondents' perception of their digital competencies and was based on the European Digital Competencies Framework for Citizens (DigiComp), which was formulated by the European Commission. The study of Law, Woo, De la Torre, and Wong (2018) through UNESCO, also referred to this framework to propose a global framework of reference for digital literacy skills for all. Indicators of the said framework are information processing, communication and collaboration, digital content creation, safety, and problem-solving. Scoring procedure is a 7-point Likert scale wherein competency levels are rated as “expert” at seven (7) and “digital illiterate” at one (1).

The second questionnaire on multiple intelligence was adapted from the study of McClellan and Conti (2008), wherein the authors have developed a reliable and valid instrument to measure the learners’ preferences. There are three (3) groups with nine (9) statements in each group. Statements in each group are ranked where one (1) describes the respondent the most and nine (9) describes the respondent the least. Scores of each statement are tallied according to each intelligence type and sum of each type determines which is the dominant intelligence type of the respondent, as well as the least dominant type.

ANOVA, Cronbach’s Alpha, and principal component analysis were done to treat the data before Pearson r was used to check the relationship of the variables.

Results and Discussion

Profile of the Respondents

Table 2 shows that the average of the respondents is 32 years. GradschoolHub.com (2019) mentioned that the average age of graduate school students is 33 years, with older students taking up doctoral degrees. Most of the respondents of Rungduin and Miranda (2018) in their study on factors on completing graduate degree completion are within the 31-40 years age range. Most of the respondents are pursuing their masters degree, with 95 (33.1%) of the respondents are taking up Early Childhood Education. For the doctoral program, 17 (5.9%) of the respondents are taking up Special Education. The domination of female teachers (241 or 64%) can also be seen in the census taken by UNESCO Institute for Statistics (2018) wherein 91.08% are female teachers in pre-primary education in the Philippines.

Majority of the respondents are teachers (247 or 86.1%) working in the public sector (170 or 59.2%). It is interesting to note that despite knowing that public school teachers have more workload aside from teaching tasks, many still prefer to be part of the government service (David, Albert, & Vizmanos, 2019). This study focused on the data of the teachers.

Table 2: Profile of the Respondents

Demographics		Frequency (n = 287)	Percentage (%)
Age (*Average age: 32*)			
	21 – 30	138	49.7
	31 – 40	89	32.1
	41 – 50	46	16.6
	51 and above	5	1.9
	Missing	9	
Sex			
	Female	241	84
	Male	43	15
	Prefer not to say	3	1
Program and Major			
	Masters	***254***	***88.5***
	Early Childhood Education	95	33.1
	Special Education	77	26.9
	Guidance and Counseling	32	11.0
	Administration and Supervision	23	8.0

	Teaching	247	86.1
	Non-teaching	40	13.9
Institution Type			
	Public	170	59.2
	Private	88	30.7
	Non-academic or no affiliation	29	10.1

Digital Literacy/Competency Profile

Digital literacy in the 21st century has now become one of the important and fundamental competencies alongside reading, arithmetic, oral skills, and writing (Almås, A.G. & Krumsvik, R., 2007). Therefore, having digitally literate students, along with improving technology tools for blended learning, flipped classroom, online classes, and other innovative teaching strategies, will require teachers to also be digitally literate. Table 3 gives a description of the digital literacy profile of the respondents.

Information processing, communication, and safety indicators scored high on the respondents' profile. Information processing is the ability to know what information is needed, to know how to properly search and recover data, and to verify the source and content of the information, including data management and organization (Law, Woo, De la Torre, & Wong, 2018). Teachers search the internet for various needs such as looking for affordable or free instructional materials, seminars for professional development, research, connecting the classroom to the world, and many more. Furthermore, the communication indicator is the ability to use digital technologies to collaborate, communicate, interact, and share information, among others. When physical presence or face-to-face meetings are not possible, teachers are able to meet with their students and continue lessons using

various media. Lastly, the Safety indicator is being able to protect one's device and one's data privacy, especially that digital transactions and activities are becoming part of daily routine.

Table 3: Digital Literacy/Competency Profile

Indicators	Mean	Verbal Description
Information Processing	5.48	very literate/competent
Communication	5.55	very literate/competent
Content Creation	4.46	moderately literate/competent
Safety	5.53	very literate/competent
Problem Solving	4.71	moderately literate/competent
Overall Profile	**5.14**	**moderately literate/competent**

Legend: 1.00-1.86 digitally illiterate/incompetent, 1.87-2.72 very illiterate/incompetent, 2.73-3.58 mildly illiterate/incompetent, 3.59-4.44 fairly literate/competent, 4.45-5.30 moderately literate/competent, 5.31-6.16 very literate/competent, 6.17-7.00 digital expert

Results show that there is a need to update the digital literacy or competencies. Quality teaching and school leadership are two of the most important factors in increasing student achievement. In order to have quality and effective teachers, professional development to develop and hone their expertise and skills are one of the best practices of an institution (Mizell, 2010). A professional and upgraded teacher would have the confidence and credibility to teach, giving students a more engaging learning environment and experience. He/She is then updated with new teaching strategies that will meet or address the students' learning needs or challenges.

The new generation of students are more tech-savvy than the previous generation, using the internet and other digital resources in most of their daily activities. With the shift to focus on student learning, teaching with technology gives teachers a wide variety of strategies that enhance student outcomes. Teachers who are able teach with technology are, therefore, at an advantage. With the dependency on smart devices and technology, students are able to adapt quickly to technology-rich learning environments such as flipped classroom, blended learning, and online classes. With the rise of the corona virus-19 pandemic worldwide, teachers are forced to use technology to reach students who are not able to physically go to school (Anft, 2020). Teachers who are comfortable and are capable to use technology will find it easy to use any of these methods, while those who are not may find it challenging. Therefore, it is important and advantageous that digital literacy be integrated into the pre-service teachers' curriculum or that professional development on digital literacy be emphasized for teachers to be able to use various digital tools to meet the needs of their learners.

With all of the respondents taking up their masters or doctoral degrees, it is a given that promotion is part of the goal. They will be involved more in educational administration or management than the teachers who have no postgraduate degrees. Digital literacy skills are important in accomplishing administrative functions which are, but not limited to, collation/submission of administrative reports, teacher evaluation reports, budget proposals, research, personnel files and monitoring, plotting of teacher class loads, facilities management, project management, online enrollment procedures and approvals, choosing the appropriate learning management system (LMS), and others (Aduwa-Ogiegbaen & Iyamu, 2005). As administrative procedures are transitioning from manual to digital, it is important that all teaching and non-teaching staff know how to process basic protocols online such as filing of leaves of absence, attendance logs, monthly accomplishment reports, facilities requests and purchases, computation of grades, making digital instructional materials, research, online banking, usage of the appropriate LMS, and many more.

Multiple Intelligence (MI) Profile

The theory of MI gives opportunities for diverse teaching strategies to maximize learning. Since intelligence is dynamic, it believes that a person's intelligence strength or weakness may change over

time through exposure to different factors. Furthermore, a person can be "smart" in more than one area. Table 4 shows the profile of the MI of the respondents, with "A" as the primary strength and "B" as the secondary strength.

Table 4: Multiple Intelligence Profile

Intelligence Type	A	B	Total
Bodily-Kinesthetic	53 (18.5%)	49 (17.1%)	102 (35.6)
Existential	72 (25.1%)	60 (20.9%)	132 (46%)
Interpersonal	40 (13.9%)	53 (18.5%)	93 (32.4%)
Intrapersonal	55 (19.2%)	63 (22.0%)	118 (41.2%)
Logical-Mathematical	46 (16.0%)	33 (11.5%)	79 (27.5%)
Musical	42 (14.6%)	31 (10.8%)	73 (25.4%)
Naturalistic	16 (5.6%)	21 (7.3%)	37 (12.9%)
Verbal	15 (5.2%)	15 (5.2%)	30 (10.4%)
Visual-Spatial	27 (9.4%)	29 (10.1%)	56 (19.5%)

Results show that most respondents are existentialists as the primary strength and intrapersonal as secondary strength. Existentialists have strong intuitions and have a solid belief system that enable them to understand others and, eventually, the world around them (Kelly, 2019). McCoog (2010) stated that existentialists are very introspective, recognizing that in order to understand the world, they need to understand themselves first. Filipinos are innately religious, with emphasis on the question, "Who am I?" as part of the development or of their whole persona (Ramos, 2017). Culturally, the belief in God, who is the reason for existence, is the very nature of Filipinos.

In addition, understanding how life is through their own experiences, most existentialists are also strong in intrapersonal intelligence (McCoog, 2010), as seen in the results of this study. Intrapersonal intelligence, as compared with interpersonal intelligence, is the awareness of one's strengths and weaknesses, and how to use these effectively in life (Parker, 2016).

Correlations Between Digital Literacy and MI

Digital literacy/competency is an important skill, especially in the 21st century teaching-learning environment. It is interesting to know how each MI strength of the respondents affects the way the respondents develop their digital skills.

Table 5 used Pearson r Correlation Coefficient to find out whether there are relationships between the different components of digital literacy/competency at 0.01 level of significance using two-tailed test. All coefficient values showed that there are positive and significant correlations between the paired literacies, namely: information processing and communication ($r = .763$, $p < 0.01$), information processing and content creation ($r = .565$, $p < 0.01$), information processing and safety ($r = .709$, $p < 0.01$), information processing and problem solving ($r = .763$, $p < 0.01$), communication and content creation ($r = .647$, $p < 0.01$), communication and safety ($r = .733$, $p < 0.01$), communication and problem solving ($r = .668$, $p < 0.01$), content creation and safety ($r = .649$, $p < 0.01$), content creation and problem solving ($r = .745$, $p < 0.01$), safety and problem solving ($r = .742$, $p < 0.01$). Therefore, hypothesis is supported.

Table 5: Pearson correlation between the different components of digital literacy/competency (2-tailed)

	Communication	Content Creation	Safety	Problem Solving
Information Processing	r=.763** sig=.000,n=244	r=.565** sig=.000, n=243	r=.709** sig=.000, n=242	r=.614** sig=.000, n=245
Communication		r=.647** sig=.000, n=245	r=.733** sig=.000, n=243	r=.668** sig=.000, n=246
Content Creation			r=.649** sig=.000, n=242	r=.745** sig=.000, n=245
Safety				r=.742** sig=.000, n=245

The above-mentioned components are equally important for one to be able to participate fully in the digital society (mediasmarts.ca, 2019). They are interrelated and as one navigates through the digital platform, each component is actively seen.

Table 6 presents the correlations between the different multiple intelligence types using Pearson Product Moment Correlation Coefficient.

Table 6: Pearson correlation between the different multiple intelligence types (2-tailed)

MI	Existential	Inter-personal	Intra-personal	Logic	Musical	Naturalistic	Verbal	Visual
Bodily Kinesthetic	r=.060 sig=.351, n=243	r=.247** sig=.000, n=243	r=.111 sig=.085, n=243	r=-.035 sig=.586, n=243	r=.038 sig=.556, n=243	r=.222** sig=.000, n=243	r=-.151* sig=.019, n=243	r=-.009 sig=.885, n=243
Existential		r=.245** sig=.000, n=243	r=.462** sig=.000, n=243	r=.118 sig=.067, n=243	r=-.043 sig=.506, n=243	r=-.068 sig=.289, n=243	r=-.105 sig=.101, n=243	r=-.036 sig=.575, n=243
Inter-personal			r=.248** sig=.000, n=243	r=.107 sig=.097, n=243	r=-.012 sig=.858, n=243	r=-.028 sig=.663, n=243	r=.024 sig=.705, n=243	r=-.026 sig=.685, n=243
Intra-personal				r=.272** sig=.000, n=243	r=-.015 sig=.816, n=243	r=-.103 sig=.110, n=243	r=-.041 sig=.525, n=243	r=-.089 sig=.167, n=243
Logic					r=.046 sig=.480, n=243	r=.142* sig=.027, n=243	r=.029 sig=.654, n=243	r=.121 sig=.059, n=243
Musical						r=.020 sig=.752, n=243	r=.110 sig=.088, n=243	r=.035 sig=.590, n=243
Naturalistic							r=.181** sig=.005, n=243	r=.023 sig=.723, n=243
Verbal								r=.250** sig=.000, n=243

The results revealed that some correlations of the paired intelligences were positive while others were negative. Moreover, 10 correlations out of 36 are statistically significant but having weak correlations. The positive and significant correlations were bodily-kinesthetic and interpersonal ($r = .247$, $p < 0.01$), bodily-kinesthetic and naturalistic ($r = .222$, $p < 0.01$), existential and interpersonal ($r = .245$, $p < 0.01$), existential and intrapersonal ($r = .462$, $p < 0.01$), interpersonal and intrapersonal ($r = .248$, $p < 0.01$), intrapersonal and logic ($r = .272$, $p < 0.01$), logic and naturalistic ($r = .142$, $p < 0.05$), naturalistic and verbal ($r = .181$, $p < 0.01$), and verbal and visual ($r = .250$, $p < 0.01$). These correlations, therefore, support the hypothesis. On the other hand, bodily-kinesthetic and verbal ($r = -.151$, $p < 0.05$) had a negative and significant correlation, and therefore do not support the hypothesis.

There are several possible factors that influence the development of an intelligence type, such as environmental conditions or opportunities that foster its development (Ahvan & Pour, 2016; Raissi Ahvan, Zainalipour, Jamri, & Mahmoodi, 2016). A person may have, not just one, but multiple

intelligences due to motivational, cultural, and experiential factors (Luo & Hwang, 2018; Gardner & Hatch, 1989 as cited in Ahvan & Pour, 2016).

Table 7: Analysis of Differences of Literacy and Intelligence Style

Table 7 presents the ANOVA test conducted between the codification of preferred intelligence style (A, B or other) and the summary measure of each of the five dimensions of digital literacy. As an example, in the computation of MIFBodilyK, "A" means that it is chosen as the first preferred style, "B" that it is the second preferred style and "C" that it is another choice. The coefficients presented in the table reflect the existence of a difference or not in the digital literacy of respondents given his intelligence style preferences.

As the reader sees, only three (3) statistically significant differences are observed. The Content Creation skill is different for those with "intra," or intrapersonal, intelligence style (F=3.054, sig=.049); similarly, the Safety component is different for those with that type of intelligence (F=4.667, sig=.010). Finally, Problem Solving may be different or those with "musical" as preferred intelligence style. Since there are only three (3) significant relationships, one should exercise caution in the interpretation of these results.

This is also seen in the study of Sherman (2014) wherein findings showed that verbal-linguistic intelligence did not have significant correlation with digital literacy. Most common intelligence with correlations to digital literacy is the intrapersonal intelligence, specifically with the communication, content creation, and safety components. It is not surprising because working in the digital setting is often an individual activity, allowing the person to be aware of his/her own personal thoughts, experiences, and behaviour while online. Musically-inclined individuals often use their right brain and are typically more creative when looking for a solution to a problem (Sholihah, Saefudin, & Priyandoko, 2020).

Discussion

Given the importance of information technology in life and in education of new generations, this study focus was to determine the literacy level of teachers and explore its potential relationship with their dominant style of intelligence. From our respondent's self-estimation, it appears that they report having a competency profile varying from moderately literate / competent (content creation and

problem-solving) to very literate/competent (information processing, communication and safety). As teachers, digital literacy/competency is a necessity especially when doing blended or online teaching.

Our paper proposed three hypotheses: the first one was about the existence of a significant relationship between the five dimensions of the concept of literacy /competency. A Pearson correlation study was made among those, which resulted into high coefficient, ranging from .565 to .763, all with a 2-tails significance of .000. Clearly the literacy/competency is sufficiently captured by the 62 questions of the instrument. The second hypothesis was suggested the existence of a significant relationship between the nine intelligence types.

Results show the "existential" style as the primary intelligence type and "intrapersonal" as the secondary intelligence type. All the components of digital literacy/competency are correlated to one another, as each one is equally important to have a successful and effective digital experience. Significant and positive correlations between MI pairs are found, such as (1) bodily-kinesthetic and interpersonal, (2) bodily-kinesthetic and naturalistic, (3) existential and interpersonal, (4) intrapersonal and logic, (5) logic and naturalistic, (6) naturalistic and verbal, and (7) verbal and visual. The most important relationship is found for existential – intrapersonal intelligence style (r=.462). However, bodily-kinesthetic and verbal had a negative and significant correlation. Only 13 of the 36 correlations were found statistically significant; this may indicate the effect of the hazard, since the coefficients are relatively low, even for those with a significance of .000.

The third hypothesis postulated the existence of a correlation between intelligence type and digital literacy skills. Findings showed that intrapersonal intelligence is significantly correlated with communication, content creation, and safety, while musical intelligence is significantly correlated with problem-solving. Although the results of this study indicate some associations between certain intelligences and digital literacy skills, only 5 out of 45 are significant, with a low coefficient "r", the highest being .177, limiting confidence on the reality of the observed relationship.

Conclusion

This study brings has shown that teachers master many aspects of the main dimension of digital literacy. It has also indicated that intelligence style might not be so important to explain or impact the digital literacy level.

This study suffers from several limits and flaws. It was conducted among a limited number of teachers on a single university in Philippines. It is suggested that a more representative sample of teachers be taken from the country to eliminate the bias due to this convenience selection of respondents. Additionally, the self-assessment of competencies should be compared to objective tests, although the instrument was based on literature review. Further researches are suggested in order to overcome these limitations, namely a more objective measure of literacy could be used to correlate skills with intelligence style.

This study has opened a first step to the understanding of the role (or the impact) of intelligence on digital literacy. Our mixed results suggest that a better understanding is needed of both constructs. The information technology is not a monolithic knowledge and the five dimensions used as surrogate of this construct might not be sufficient to assess it. Also, this study shows that digital literacy might have a different meaning depending on the society in which it is used so further studies may be done to understand the cultural and contextual impact of environment.

Authors suggest also that since the education of the 21th century will largely rely on technology, studies should be conducted to take into account the psychological aspects of dematerialization of the teaching, giving more importance to computers for information transmission (prepared by a technology skilled teacher) and more importance to the teacher for supporting projects, class animation and personal motivation, especially given the growing popularity of flipped classroom. As students' interactions and teacher interactions are expected to be more mediated by technology, authors suggest that studies be conducted in the area of sociology to examine the capacity of teachers

to efficiently manage interactions in the classrooms. The authors are actually planning a replication of their study with Canada, in order to see if economic development and or cultural differences can provide a better understanding.

How Behaviour of Firms Change Due to Public Interventions: The Concept of Behavioural Additionality Effect

Paulina KUBERA

Poznan University of Technology, Poznań, Poland, Paulina.Kubera@put.poznan.pl

Abstract

Measuring average impacts of public interventions, which is a dominant approach in the evaluation of public programmes has little to offer to inform policy making. For instance, the ultimate goal of innovation policy is about a qualitative change, not the numbers of patents obtained or applied, product or process innovations introduced or employment growth in the supported firms in terms of R&D personnel. Hence, the key concept advanced in this paper is behavioural additionality effect, which takes account of the difference in behaviour of a target population (firms) owing to a public intervention. The article addresses three research questions: How behavioural additionality is conceptualised in extant literature? What are the major obstacles in assessing behavioural additionality effect of public interventions? And how these problems can be overcome? Based on literature review and evaluation practice it can be argued that the term 'behavioural additionality' suffers from conceptual confusion and terminological ambiguity. Two major hindrances can be identified that impede the behavioural additionality research. The first it is the confusion between the potential and actual behaviour. The second is called 'project fallacy' and entails the problem with causal explanation. To remedy these problems – the conceptualisation of behavioural additionality as changes in organisational routines and capabilities are suggested as well as process tracing and contribution analysis that are grounded in generative causality. The article contribution lies in providing a common reference frame for evaluation of behavioural additionality at the firm's level that incorporates the element of persistency of the changes induced, what is vital from the public policy perspective.

Keywords: evaluation, behavioural additionality, organisational behaviour, organisational routines

Introduction

Public programmes are primarily viewed in terms of effects with little attention paid to how those effects are produced. Measuring average impacts of public interventions, which is a dominant approach in the evaluation of public programmes has little to offer to inform policy making: whether the programme can be successfully scaled-up, implemented elsewhere or for other recipients, what to do when a programme does not yield expected effects. Hence, recently more attention is paid to the variation in program effects and mechanisms through which these effects occur (Astbury & Leeuw, 2010). Addressing these kinds of problems means moving beyond the traditional input/output approach and trying to understand what is inside the 'black box' of a policy instrument, inspecting the inner-workings of a public intervention.

The typical output (result) indicators used in the evaluation of innovation policy instruments are: the number of patents obtained or applied, number of product or process innovations introduced, employment growth in the supported firms in terms of R&D personnel, etc. However, are they really the primary goals of innovation public policy? Rather not. Innovation policy, as the term suggests, is a policy, a set of instruments, that affect innovation. Innovation can be defined in a broader or narrower manner, however, a key point is that it implies 'the introduction of new solutions in response to problems, challenges or opportunities that arise in the social and/or economic environment' (Edler & Fagerberg, 2017, p.4) From this perspective, the term is applicable to high-tech and low-tech, to manufacturing and services, to the private as well as the public sector (see, e.g. Osborne & Brown, 2013), and, importantly, denotes a qualitative change.

Cite this Article as: Paulina KUBERA "How Behaviour of Firms Change Due to Public Interventions:The Concept of Behavioural Additionality Effect" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The key concept advanced in this paper is behavioural additionality, which takes account of the difference in behaviour of a target population (firms) owing to a public intervention. Producing the outputs is not only a matter of having the right resources of various types (material, human, capital) this is also a matter of their right combination, coordination in time and space. We can reformulated the above mentioned examples of output additionality using behavioural lenses: what organisational routines and capabilities have been built/enhanced due to a public intervention, how a public intervention interacts with strategies and capabilities of firms? It can be argued that behavioural additionality is closely related to output additionality, since it creates prerequisites for improvement of firm's economic performance. However, the focus should not be limited to the problem: how public support modifies manner in which a subsidised project is carried out (the analogy to opening a 'black box' of public interventions.). An important question is also about the persistency of the behavioural changes of firms after the intervention (completion of the subsidised project). Moreover, the concept of behavioural additionality captures a shits in firm's orientation (greener or more social focus) as public innovation policy carries horizontal objectives as well.

The paper is organised into five parts. An introduction accentuates the need for complementing (not substituting) the traditional input/output approach to innovation policy evaluation with behavioural additionality effects. The subsequent part deals with the question of how behavioural additionality is conceptualised in extant literature and suggests a common reference frame for evaluation of behavioural additionality at the firm's level taking into consideration the persistency of policy effects. In the third one – two interrelated lines of inquiry are followed, namely: what are the major obstacles in assessing behavioural additionality effect of public interventions, and how these problems can be overcome. The considerations are based on literature review and evaluation practice. The article ends with concluding remarks and the indication of avenues for further research.

A common reference frame for evaluation of behavioural additionality effect at the firm's level

Behavioural additionality in scholar literature and evaluation practice is defined in many different ways (for the review – see: Gök & Edler 2011; Kubera, 2018).

Table 1: Conceptualisation of behavioural additionality effect

Firm-level one off effects	Firm-level persistent effects	System-level effects
Public support influences the decision to launch a project, to expand its scope and scale, or the pace in which project is implemented. In State aid law these constitute the "incentive effect" of aid, together with a situation when public support affects the decision concerning the location of a project (regional State aid).	Public support influences the firm's behaviour beyond the frames of the supported project, either by inducing changes in the firm's strategic management (e.g. adopting a more strategic approach to R&D), or inducing changes at the operational level (e.g. the application and reporting requirements (greater rigour) are institutionalised into the firm's further activities	Public support influences behavioural changes of other entities (actors of innovation system), who are not the target population (e.g. knowledge spill-overs).

Authors: Polt & Streicher (2005), Falk (2006) Wanzenböck, Scherngell & Fisher (2013).	Authors: Davenport, Grimes & Davies (1998), Hall & Maffioli (2008), Neicu, Teirlinck & Kelchtermans (2016).	Authors: Meuleman & De Maeseneire (2012), Larrea, Aranguren & Karlsen, (2012), Wu (2017).

Source: Own elaboration based on the systematic literature review carried out by the Author (Kubera, 2018).

A separate and a very common conceptualisation of behavioural additionality effect which cannot be neatly categorised to one of the three types mentioned above is collaboration additionality (Breschi et al., 2009; Teirlinck & Spithoven, 2012; Cerulli, Gabriele & Poti, 2016). Its prominent role in innovation processes stems from the fact that cooperation with other firms or institutions creates opportunities to gain complementary resources and skills, and as a consequence, can lead to faster development of innovations, improved market access, cost and risk sharing. Cooperation additionality can be viewed as a firm-level one-off effect, when a beneficiary firm enters into collaboration only to carry out the subsidised project, or a firm-level persistent effect (e.g. due to a public intervention a firm changes the pattern in which it cooperates with others); or system-level effect, in the form of e.g. improved coordination. The effects at a firm level certainly do not exclude those at the system level. Moreover, the problem - how changes occurring at the beneficiary firms (target population of a public intervention) modify behaviours of other actors of innovation system is an interesting line of inquiry deserving further investigation (the knowledge spill-over effects, technology diffusion), which are frequently not captured adequately in evaluation of public programmes in the field of RDI (e.g. Autio, Kanninen & Gustafsson 2008).

It follows that present definitions of behavioural additionality effect suffer from conceptual confusion and terminological ambiguity, impending a proper theoretical understanding and hindering empirical research. In order to introduce a common reference frame for evaluation of behavioural additionality at the firm's level and incorporating the element of persistency of the changes induced (what is vital from the public policy perspective), in this paper behavioural additionality is conceptualised as modification of the beneficiary firm's organisational routines, which are the building blocks of the firm's organisational capabilities; these can be, in turn, linked to the firm's dynamic capabilities and firm strategy.

Fig. 1: Focal points in the search for the behavioural additionality effect of public support

Source: Own elaboration.

Research on behavioural additionality effect incorporating the element of persistency can be related to one or more of these focal points. They are organised in a hierarchy, with organisational routines as a basic unit of analysis for organisational behaviour, however, it should be borne in mind that the relations between these constructs are two-directional, thus, a cross-level analysis is advocated (Salvato & Rerup, 2011).

The term 'organisational routines" refer to 'repetitive, recognizable patterns of interdependent actions carried out by multiple actors' (Pentland & Feldman, 2008, p.235). They can be treated as basic components of organisational behaviour and repositories of organisational capabilities. For that reason, they are relevant for capturing and understanding organisational change. Analysing how

organisational routines and capabilities change can help to recognize the pathways and mechanisms by which external factors shape the organisation's behaviour (Becker et al., 2005).

Although all four: organisational routines, organisational capabilities, dynamic capabilities and firm strategy are distinct constructs, they are linked. Organisational capabilities are larger scale units of analysis in comparison to organisational routines. Following Winter (2003, p.991), Felin et al. (2012) define organisational capability as 'a high level routine or collection of routines that together with its implementing input flows, confers upon an organisation's management a set of decision options for producing significant outputs of a particular type (p.1355). Hence, organisational capabilities involve patterned activity which is oriented to relatively specific objectives. They entail deploying resources (inputs), usually in combination, and using organisational processes to produce firm's outputs that matter for organisation's survival and prosperity. While (operational) capabilities enable an organisation to earn a living at present, dynamic capabilities concern change, as they include: a capacity to identify the need or opportunity for change, to respond to such a need or opportunity and implement a course of action. Hence, they extend, modify or create (ordinary) capabilities (Winter, 2003). They are crucial for developing and maintaining a competitive advantage of the firm and thus have a direct link to the firm's strategy.

Problems to overcome in behavioural additionality research – putting puzzles together

There are two major hindrances that impede the behavioural additionality research. The first it is the confusion between the potential and actual behaviour. The second is called 'project fallacy' and denotes 'the failure to distinguish between a single sponsored project and the longer-term business innovation effort to which it is part' (Georghiou & Clarysse 2006, p.10).

Hall and Maffioli (2008) while evaluating the impact of technology development funds in Latin America applied subjective indicators- innovation surveys to detect behavioural additionality defined as a more proactive attitude of beneficiary firms towards innovation activities and a firm's willingness to interact with external sources of knowledge and financing. In a similar vein, Chapman and Hewitt-Dundas (2018) examined effect of public support on senior managers' attitudes to innovation, such as support for innovation, risk tolerance and openness to external knowledge. However, we know that potential means that something might chance to happen or not to happen, or being a little more precise, potential is actualised when conditions are right. (Not to mention the common method variance problem involved in self-reporting techniques). On the other hand, though, it should be admitted that numerous public interventions are about changing (forming) attitudes. First, there is an intervention, which causes the attitude change, which, in turn lead to the behaviour change. It is hard to deny the worth of such studies as they shed some light on the effects of public interventions, but we might have the impression that we have stopped somewhere in the middle , we do not get the full picture of the phenomena under investigation, only a piece of it. Similarly, entering into collaboration, number of collaborating partners used as indicators of behavioural additionality effect (Aschhoff, Fier & Löhlein, 2006) say little and mean only scale and scope aditionality, which can be confused with input/output approach. They create opportunities for spill-over effects, but behavioural change trigger three factors that must be in place simultaneously. Apart from the right conditions (opportunities), there is an emotional factor (motivation) and cognitive factor (knowledge, skills). Public interventions are frequently aimed at only one factor, assuming that the rest are present, what is not always the right approach. It is important for public interventions to yield intended behavioural effects to verify (with a feasible level of confidence) whether these assumptions really hold true.

The recent conceptualisation on organisational routines as generative systems, where the ostensive and performative aspects are distinguished and interlinked, along with artifacts, might be a solution. These three aspects (i.e. ostensive, performative and artifacts) must be in place for a pattern of interdependent actions be identified as a routine. Public policy interventions produce behavioural additionality effect by creating and/or reinforcing one or more of these aspects.

An ostensive part of a routine denotes the abstract aspect of the routine stored in people's mind, an idea, how to act. Performative part is an enactment of the ostensive part in particular time and space. In other words, while the ostensive dimension of a routine is the abstract and generalised understanding of the routine (usually plural, as the understanding of a routine may differ across an organisation), the performative dimension designates a specific action taken by specific people at specific times (Salvato & Rerup, 2011). They are mutually constitutive, with the performances creating and recreating the ostensive aspect and ostensive aspect constraining and enabling the performances (Becker, 2020). A routine does not exist without being enacted, at most we can call it an aspirational or espoused routine.

Artifacts, the third dimension of a routine, can take a variety of different forms, such as written rules, procedures, software and computers or forms of general physical setting (e.g. an outline of an office). They are often used to ensure the reproduction of particular patterns of action. They influence and represent the ostensive and performative dimensions of a routine, however, they cannot be confused with organisational routines as such (Pentland & Feldman, 2008). Standard operating procedures are sometimes used as proxies of routines. While for some questions they may work well, substituting the representations for the routine accentuates the static nature of organisational routines and does not allow to capture their dynamics properly (Feldman, 2016) If we want to get a full picture of behavioural additionality effect of a public intervention we need to break organisational routines (and capabilities) into parts and map their interrelationships.Include figures and tables within the body of your paper.

Source: Own elaboration. (1), (2), (3) – drivers of behaviour change

The next identified hindrance impeding the progress in behavioural additionality research lies in the additionality concept as such. While we are evaluating public interventions we want to know what was in fact caused by a given intervention not by some other factors. Hence, the focus is on those changes/effects which have been brought about over and above what would have taken place anyway without the examined intervention. Thus, the root problem entails causal explanation. In many

situations it is difficult to separate the effects, in particular behavioural effects, of a subsidised project from the larger ongoing activity of the beneficiary firm (the so called project fallacy problem).

The prevailing input/output approach in evaluation of public interventions which relies heavily on successionist model of causation is not suitable for behavioural additionality research. This is because of its inability to capture the contextual features properly. In organisational setting our actions are conditioned by history and intent (backward- and forward-looking), and power structure, in this sense they are consequential, however, they are also constitutive for organisational structures and processes (they shape the context). Moreover, the successionist approach is unable to explain the causal connection, i.e. the process leading from cause to effect, what happens in-between cause and effect. Generative causation, by contrast, attaches great importance to this transformation, as it tries to provide fine-grained explanation of the behaviour of specific actors (thinking, decision-making, action) in a given context with specific resources, opportunities and constraints (Befani 2016).

Two approaches are suggested, both of which are grounded in generative causality, to address the problem of 'project fallacy', namely : contribution analysis (CA) and process tracing (PT). However, we need to come to terms that they do not measure an impact of a public intervention in a strict sense, but rather increase our confidence that a public intervention had an influence on a target population. In other words, behaviour change might not be caused solely by an intervention (as in the case of attribution). An intervention is one of many factors which contribute to a given change. At best, we can talk about the 'causal package , in which a given intervention plays a vital role (Mayne, 2012).

CA belongs to theory-based-evaluations, where the starting point is a theory of change, a comprehensive description of a path how a given intervention is expected to bring about the intended changes. It specifies the activities taken within an intervention and subsequent changes, along with assumptions for each causal link that must hold true for the change to occur and the associated risks as well as other influencing factors. In spite of appearances, this path does not need to be linear, but involve many feedback loops that need to be understood. All of these elements of a theory of change are assessed against available empirical evidence. Mayne (2012) developed six key steps in contribution analysis to follow to make the whole approach more systematic.[1]

Moreover, the application of process tracing, its principles and tests, may additionally increase the strength of causal interference made in contribution analysis. PT is a case-based approach to causal inference with a focus on the use of clues within a case (causal-process observations, CPOs) to adjudicate between alternative possible explanations. Miles and Cunningham (2006) write: 'The issue at stake is not just a matter of more or less activity at one point in time. Activities have been reshaped, there has been a learning process in the individuals and organisations concerned" (p.160). Of interest are long-term and persistent effects. On the whole, in recent years one can observe that process and practice approaches to organisational topics have gained momentum, 'de-emphasizing the entity-like features and emphasizing more the continuity of becoming', 'dynamic unfolding' processes. This entails 'refocusing on enactment rather than representation, on process and potentiality rather than likelihood, and on relationality rather than correlation' (Feldman 2016, p.26).

The recent incorporation of the informal Bayesian logic into process –tracing allows for assessing the type and strength of inferences we can make using different forms of empirical evidence. Hence, it is not the quantity of observations that affect strength of evidence (unless they are independent), but the probability of observing a given piece of data. The aim is to design data collection so as to maximise our confidence in the existence of the theorised causal mechanisms. If the probability of a given piece of data before and after empirical research is similar, it means that this evidence is weak. Accordingly: the bigger the difference between the two probabilities, the stronger is the evidence (Befani & Mayne, 2014). In what follows, we should assess each piece of potential evidence in terms of its certainty and uniqueness; i.e. whether we have to find a given piece of evidence for the theory to be valid, and whether there are any plausible alternative explanations for finding it. For example, a 'hoop test' involves making a prediction with high certainty and low uniqueness, in that there are many plausible alternative explanations for finding the evidence. In this case finding the predicted

evidence means little updating of our beliefs, however, not finding this evidence has a disconfirmatory power (Schmitt & Beach, 2015).[2]

Conclusions and avenues for future research

In order to ensure policy learning the traditional input/output approach to evaluation of innovation policy should be complemented with the third type of additionality effect, namely behavioural additionality, which takes account of the difference in behaviour of a target population owing to a public intervention. However, the literature review and evaluation practice reveal that a diverse array of meanings is attached to the term, hindering empirical research and cumulation of knowledge.

Two major hindrances can be identified that impede the behavioural additionality research. The first is the confusion between the potential and actual behaviour, (changing attitudes, our understanding versus changing behaviour, activities undertaken). The second is called 'project fallacy' and entails the problem with causal explanation, as in many situations it is difficult to separate the effects, of a subsidised project from the larger ongoing activity of a beneficiary firm and this pertains in particular to behavioural effects. Moreover, from the policy perspective, of interest are not only one-off behavioural changes but persistent changes which are not confined to the implementation of a subsidised project.

To remedy the first problem the definition of behavioural additionality as changes in organisational routines and capabilities are suggested . The recent conceptualisation of organisational routines as generative systems, where the ostensive (an idea how to act – abstract) and performative (enactment, real) aspects are distinguished and interlinked, along with artifacts, might help to capture the behavioural changes induced by a public intervention. Common frames and units of analysis can bring greater coherence in behavioural additionality research.

Regarding the second problem, given the complexity surrounding the ways in which firms' behaviour is modified (context sensitivity, path dependence, power structure etc.) the only viable manner in which we can deal with the problem of 'project fallacy' is to strengthen our confidence that a given intervention contributed to an intended behaviour change and that the intervention was a vital part of a 'causal package' . Contribution analysis by Mayne (2012) combined with process-tracing and its recent developments consisting of the incorporation of informal Bayesian logic are suitable for this purpose.

Nevertheless, there are still many questions concerning the assessment of behavioural additionality effect that remain unanswered and deserve further attention. I would suggest the following avenues for future research. First, the concern is about the methods/ research approaches suitable for tracking behavioural effects of public interventions. Case study and ethnographic research is particularly relevant for investigating behavioural additionality, as the main research questions they are aimed at are 'how' and 'why' questions, the researcher has little or no control over behavioural events, and the focus of study is a contemporary (as opposed to entirely historical) phenomenon (Yin, 2018). However, the question remains whether can we get beyond the case-study design in the assessment of behavioural aditionality effect and still provide rich insights how firms behave and how the behaviour of firms can be influenced through public policy instruments. Perhaps, modelling approaches could be employed for that purpose to a greater extent. Secondly, behavioural additionality is usually assumed to be positive, that the public intervention will affect the firm's propensity to innovate so that they can perform better and create competitive advantage, or in the worst case – there is no behavioural additionality, meaning that a public intervention has no persistent impact on the firm's behaviour. However, too little attention is paid to the case of negative behavioural additionality. Georghiou and Clarysse (2006) mention about negative behavioural additionality providing the example of a public intervention that encourages firms to take risks which they cannot afford. Public intervention are also associated with adverse behavioural effects when they lead to the wrong direction in terms of technology or the market, or encourage firms to enter into alliances which are unproductive and costly. However, defining negative behavioural additionality remains particularly

challenging. Even when a subsidised project does not yield desired outputs we can still talk about positive behavioural additionality when the knowledge and capabilities gained during its implementation turn out to be valuable in subsequent projects, the firm can capitalize on them in other innovation endeavours. Shepherd et al. (2009) describe it aptly: ' within some failures lie the seeds of subsequent project success' (p.589). It is argued that not only organisations are more likely to learn from failures than from successes, but also that the knowledge derived from failure depreciates more slowly than when derived from success (Rhaiem & Amara, 2019). Hence, the question is – how can we capture properly these instances of behavioural additionality of public interventions, in particular what time frames should be adopted.

[1] Six steps to be taken to produce a credible contribution story: (1) : Set out the cause-effect issue to be addressed; (2) Develop the postulated theory of change and risks to it, including rival explanations; (3) Gather the existing evidence on the theory of change; (4) Assemble and assess the contribution claim, and challenges to it; (5) Seek out additional evidence; (6) Revise and strengthen the contribution story.

[2] The three other tests are: (1) a doubly- decisive test, which combines high uniqueness and high certainty; not finding the evidence downgrades our confidence, while finding it increases our confidence, since there are few plausible alternative explanations for the evidence; (2) a straw-in-the-wind test combines low certainty and low uniqueness which means little updating our beliefs, and (3) a smoking gun test – involves making a theoretically unique prediction but not certain; finding the evidence enables strong confirming inferences, whereas the opposite is not very informative.

Granting State Aid to Entrepreneurs in The Context of Coronavirus

Paulina KUBERA

Poznan University of Technology, Poznań, Poland
Paulina.Kubera@put.poznan.pl

Abstract

The spread of the coronavirus hit the global economy unexpectedly and with great force. Many so far healthy undertakings had to (and still have to) deal with the looming lack of liquidity. In order to counter the damage inflicted on undertakings and to perverse the continuity of economic activity during and after the coronavirus pandemic, public authorities were forced to launch various types of support measures for entrepreneurs. As the extraordinary times call for greater activity on the part of the state, the question is how freely can EU member states design their interventions and what support measures for entrepreneurs are utilised to deal with the effects of the COVID-19. State activity in the form of providing support for entrepreneurs is discussed as a trade-off between the need to mitigate the disruptive impact of the coronavirus pandemic on the economy and the need to maintain a level playing field for all enterprises in the EU. Considerations are based on literature review, the analysis of relevant legal provisions and guidelines as well as state aid cases related to coronavirus. The article provides a better understanding of the rationale behind the EU state aid control and state aid admissibility in the context of the coronavirus outbreak.

Keywords: State aid, general measures, operating aid, coronavirus

Introduction

The spread of the coronavirus hit the global economy unexpectedly and with great force. In response, countries around the world implemented several containment measures to halt the pandemic, including social distancing measures, travel restrictions and lock downs. These had a stifling effect on economic activities, not only in tourism, entertainment or transport sectors, but in almost all sectors, without even sparing large enterprises. Moreover, uncertainty surrounding the near and distant future led to flight to safety in consumption and had a negative effect on investment plans. Many so far healthy undertakings had to (and still have to) deal with the looming lack of liquidity.

In order to counter the damage inflicted on undertakings and to perverse the continuity of economic activity during and after the coronavirus pandemic, public authorities were forced to launch simultaneously various types of support measures for entrepreneurs.

The article examines how freely can EU member states design their interventions and what support measures for entrepreneurs are utilised to deal with the effects of the COVID-19. The problem is vital for the avoidance of harmful subsidy races among EU member states where those member states that have larger funds at their disposal can outspend neighbours to the detriment of cohesion within the EU. The level playing field in the EU internal market must be preserved. Considerations are based on literature review, the analysis of relevant legal provisions and guidelines as well as state aid cases related to coronavirus.

The remainder of the paper is structured as follows. The first part is devoted to the problem of the differentiation between state aid and general public measures that is crucial in determining the competences of EU member states to implement their own support measures. In the next sections the notion of state aid is further clarified, its admissibility criteria are discussed in the context of

coronavirus pandemic as well as relevant state aid cases are invoked for illustrative purposes. The article ends with final conclusions.

What is state aid and how does it differ from general public measures

Generally, economic policy falls within the remit of each EU member state. Nevertheless, the process of economic policy coordination at the EU level takes place in either 'soft' as well as 'hard' forms. The former denote moral persuasion and peer pressure through benchmarking and exchange practices, the latter – strict rules to be respected with a sanction mechanism attached to them. The example of 'soft' coordination is the broad economic policy guidelines and employment guidelines, the example of the 'hard' cooperation is the stability and growth pact, a set of rules designed to ensure that member states pursue sound public finance. Currently, these coordination processes, reformed, work in parallel under the 'European Semester'. The European Semester brings together within a single policy co-ordination cycle many EU instruments. The EU institutions set priorities for the EU, review national performance, economic reform and budget plans and issue Country-Specific Recommendations (CSRs).[1] As Verdun and Zeitlin (2018) point out: 'Although the Semester involves no legal transfer of sovereignty from the member states to the EU level, it has given the EU institutions a more visible and authoritative role than ever before in monitoring, scrutinizing and guiding national economic, fiscal and social policies, especially within the euro area' (p.138).

Moreover, member states enjoy discretionary power in reference to the implementation of general public measures. Selectivity is a feature that differentiates state aid form general measures which are applicable to all undertakings in all sectors within the state (Sciskalová & Münster, 2014). Shaping the tax system or social security system are examples of general public measures as long as they do not favour certain undertakings or the production of certain goods. Then they are not contradictory to the EU internal market and any possible distortions of the competition being their result are eliminated through the harmonisation of the law of member states and coordination of economic policies (Schütte, 2006; Kubera 2011). State aid, in turn, implies granting an advantage in a selective way 'over other undertakings that are in a legal and factual situation that is comparable in the light of the objective pursued by the measure'.[2] Being a selective intervention in the market, state aid is under the EU control.[3]

A word of caution must be mentioned here. The very fact that undertakings are treated differently in public policy instruments does not automatically imply the existence of state aid. As a matter of fact, general measures frequently differentiate between recipients of public interventions. When general measures incorporate detailed provisions applicable to certain undertakings only, they still can have their rationale in logic and nature of the system of which they are part.[4] An example are special purpose levies such as environmental taxes which are imposed exactly to discourage some activities or production of some products which are detrimental to the environment. Differentiation between undertakings derives directly from the intrinsic objective of the system (in this case this special-purpose levy). The assessment, however, would be opposite when a given regulation differentiating between undertaking was a part of a corporate income tax system. In this case environmental policy objectives are external policy objectives as criteria applied are unrelated to the reference system (i.e. corporate income tax system) and therefore cannot be relied upon by member states to justify a difference in treatment of undertakings. In this case possible justification could be the progressive nature of income tax and its redistributive purpose. Other legitimate grounds for introducing a differentiation between undertaking in public policy measures may result from inherent mechanisms necessary for the functioning and effectiveness of the system, such as the need to avoid double taxation, to fight fraud or tax evasion. In any case member states should ensure that those measures are proportionate and do not exceed what is necessary to achieve the objective being pursued, (see: Commission Notice on the notion of State aid as referred to in Article 107(1) of the TFUE).

It is also pertinent to stress that material selectivity can also be established de facto. When a state measure which appeared to be applied to undertakings in general way, i.e. its formal criteria are formulated in general and objective term, in reality produces an advantage for certain undertakings or

the production of certain goods, to the exclusion of others, hence, is selective to a certain extent. It can be the case of applying a tax credit only to investments exceeding a certain threshold. Such a measure is de facto reserved for undertakings with significant financial resources.[5] The same holds true for export aid even when the measure is potentially applicable to all domestic undertakings , or measures applied on an experimental basis to certain undertakings (Kociubiński, 2012). Moreover, selectivity can also stem from discretionary power of member states, where fulfilling the eligibility criteria of a given measure does not automatically result in an entitlement to the measure.

To sum up, three main conclusions can be drawn from the above discussion. First, adoption of general public measures which are applied to all undertakings in all sectors within a state falls within the competence of member states. What is under the Union control are selective public measures that can have an impact on competition and trade exchange between member states (i.e. state aid measures). Secondly, general measures frequently involve differentiation between economic actors making the assessment of a given public measure more problematic. In such a case, selectivity of the measure can be established de jure and de facto. The former (de jure) results directly from the legal criteria for granting a measure that is formally reserved only for certain undertakings, e.g. those having a certain size, operating in certain sectors, having certain characteristics or exercising certain functions. However, the assessment of a measure should not stop here as selectivity can be hidden, seemingly neutral and objective criteria for granting a measure can de facto privilege certain undertakings or production of certain goods. Thus, a measure should be considered selective also on the basis of its effects. Thirdly, even when selectivity of a public measure is established it does not automatically mean that this measure constitutes state aid. When there is justification for the selectivity in logic and nature of the system of which they are part, or the selectivity is the result of inherent mechanisms necessary for the functioning and effectiveness of the system (e.g. a corporate tax system), a measure falls outside the state aid rules.

Admissibility criteria for state aid granting in the context of coronavirus

In the previous section the selectivity feature of state aid has been discussed to distinguish state aid from general public measures what is crucial in determining the competences of EU member states to implement their own support measures. However, there are four criteria that must be met cumulatively for a measure to be qualified as state aid. Apart from being selective, these are: the measure must be financed through state resources and be imputable to the state[6] ; it must confer an economic advantage on its recipient (which an undertaking could not get under normal market condition) ; as well as the measure must distort or threaten to distort competition and affect trade between member states [7](Article 107(1) TFUE). It suffices that one of the above-specified criteria is not fulfilled to escape the state aid rules. The rationale for the EU state aid control stems from the fact that it is perceived as a mechanism which underpins the functioning of the internal market and supports economic integration (Kubera, 2020). It is also worth mentioning that state aid control has evolved from 'its initial internal market niche to encompass broader efficiency and fiscal discipline considerations' (Bacon 2017, p.11).

State aid is generally incompatible with the EU internal market and is admissible only on the conditions stipulated in EU law. In order to introduce more clarity and speed up state aid decisions related to coronavirus the Commission has issued Temporary framework for state aid measures to support the economy in the current COVID-19 outbreak. The Temporary Framework indicates six support measures that can be relied upon by member states. However, two of them do not qualify as state aid. These are:

1) measures that apply to all undertakings such as general wage subsidies, suspension of payments of corporate and value added taxes or social contributions that apply to all undertakings. These measures do not constitute state aid since they do not confer a selective advantage;

2) financial support provided directly to consumers, such as for cancelled services or tickets not reimbursed by the operators concerned. These measures do not constitute state aid since they do not confer an advantage on undertakings.

The next group of support measures can be implemented by member states also without the involvement of the European Commission, and this group encompasses:

3) measures designed in line with Block Exemption Regulation.[8] They constitute state aid, however, since they are less likely to lead to undue distortions of competition in the EU internal market due to the limited amount and rules on which aid is granted, do not have to be notified to the Commission.

The remaining three qualify as state aid and will be discussed more in detail in the further sections of the article. These are:

(4) rescue and restructuring aid (Article 107(3)(c) TFEU)

(5) aid to make good the damage caused by exceptional occurrences (Article 107 (2) (b) TFUE)

(6) aid to remedy a serious disturbance in the economy of a member state (Article 107(3)(b) TFUE)

Rescue and restructuring aid (Article 107(3)(c) TFEU)

According to Article 107(3)(c) TFUE, state aid may be granted to facilitate the development of certain economic activities or of certain economic areas, provided that such aid does not adversely affect trading conditions to an extent contrary to the common interest. This group encompasses support measures which are developed to meet acute liquidity needs and to support undertakings that face financial difficulties including those caused and aggravated by the coronavirus outbreak. However, these need to be in line with the strict criteria set out in the Rescue and Restructuring Guidelines[9] , in particular the principle 'one time last time', which means that aid can be granted to undertakings in difficulty in respect of only one restructuring operation. Moreover, it must be shown that the aid is truly in the public interest in a given case, in the sense that saving the undertaking would prevent social hardship or address market failures. The exit of firms and their replacement by others is not only a natural market process but also an important driver of productivity. Therefore, public interventions that interfere with that process is under particular EU scrutiny (Maier-Rigaud & Milde, 2015).

Rescue aid is designed to allow undertakings which face imminent collapse to stay in business for long enough to develop a restructuring plan. It takes the form of liquidity support (loans or guarantees) and has a maximum duration of six months. When further support is needed, restructuring aid can be granted which aims at supporting a firm's restructuring and its return to long-term viability. Member states are free to choose the form that restructuring aid takes as well as it can be granted for a longer period of time, nevertheless the aid must be accompanied by a detailed restructuring plan that meets a number of conditions (the Competition Directorate-General of the European Commission, 2014).

This was the case with a public guarantee on a loan in favour of Romanian airline BlueAir. The measure was divided into two parts and assessed under two different legal basis. In part (EUR 28 million), it was designed to compensate the airline for the damages suffered as a result of the coronavirus outbreak (assessment was carried out on the basis of Article 107(2)(b), which will be discussed in a subsequent section), and partially (EUR 34 million), to provide it with the necessary resources to address part of its urgent and immediate liquidity needs (assessment on the basis of the

Rescue and Restructuring Guidelines). What is important, Blue Air qualified as a company in difficulty[10] before the coronavirus outbreak, i.e. on 31 December 2019. The Rescue and Restructuring Guidelines enable member states to support such undertakings, where the pandemic worsened the situation of a given undertaking that was already poor before the outbreak. The airline was loss making due to the extensive investments it undertook since 2016 to improve its network of routes. The airline had returned to profitability in 2019 and early 2020, however, as other undertakings active in the aviation sector, it suffered significant losses as a result of the coronavirus outbreak and the travel restrictions that Romania and other governments had to impose to limit the spread of the virus. As a result the airlines suffered urgent liquidity needs. The Commission approved the rescue aid since it was limited in time and scope and its contribution to an objective of common interest was satisfactory demonstrated. Romania committed to ensure that, after six months, the public guarantee will be terminated, or BlueAir will either submit a liquidation plan or carry out a through restructuring to become viable in the long-term (subject to the Commission's separate approval) and that aid is necessary to ensure regional connectivity for the significant number of citizens working abroad and for small local businesses that depend on affordable tickets offered by BlueAir on a network of routes it operates, (SA.57026 Romania, COVID-19 – Aid to Blue Air).

Aid to make good the damage caused by exceptional occurrences (Article 107 (2) (b) TFUE)

According to Article 107 (2) (b) TFUE, state aid which is granted to redress the damage caused by natural disasters or other exceptional occurrences is exempted from the general prohibition of state aid. However, for the sake of legal certainty member states can notify such aid to the European Commission, which apart from the classification of the event as a natural disaster or another extraordinary event, takes into account the following when assessing a given aid measure with respect to it being compatible with the requirements stipulated in Article 107 (2) (b) TFUE: (1) proof of a direct relation between the damage and natural disaster or other extraordinary event, (2) proper assessment of damage, and (3) whether any mechanism to avoid excessive compensation has been introduced. It must be emphasised that only aid, which is aimed at the restoration of the condition prior to the natural disaster or other extraordinary event is compatible with internal market.

On the basis of Article 107(2)(b) TFUE member states can provide support for undertakings in sectors that have been particularly hit by the coronavirus pandemic, such as tourism, transport, hospitality or culture, as well as organisers of cancelled events for damages suffered due to and directly caused by the outbreak, e.g. part of the aid granted to previously mentioned BlueAir to compensate the damage directly caused by the coronavirus outbreak and the travel restrictions imposed by public authorities.

Another example is Danish compensation scheme for cancellation of events related to COVID-19. On 6 March 2020 Danish authorities made an official recommendation that all public events with more than 1000 participants as well as those events which were targeted at COVID-19 vulnerable and high risk groups (e.g. elderly) , irrespective of the number of participants, be cancelled, postponed, or substantially modified. The subsequent losses and additional costs suffered by the organisers of such events resulted from the implementation of the recommendation are to be compensated from state budget. The Commission has found a EUR 12 million Danish aid scheme to be in line with EU state aid rules. The Commission considers that the COVID-19 outbreak qualifies as an exceptional occurrence, referred to in Article 107(2)(b) TFUE, as it is an extraordinary, unforeseeable event having a significant economic impact. It clearly distinguishes itself from ordinary events by its character and by its effects on the affected undertakings and the economy in general and thus lays outside of the normal functioning of the market, (Commission decision SA. 56685, Denmark – Compensation scheme for cancellation of events related to COVID-19).

Aid to remedy a serious disturbance in the economy of a member state (Article 107(3)(b) TFUE)

As the above stipulated option (based on Article 107(2)(b) TFUE) is restricted to compensation for damage directly caused by the coronavirus outbreak (e.g. damage suffered by the organisers of cancelled events, damage suffered by an airline caused by travel restrictions), aid addressing more generally the economic downturn from the coronavirus pandemic is assessed on the basis of Article 107(3)(b) TFUE, according to which aid to promote the execution of an important project of common European interest or to remedy a serious disturbance in the economy of a member state can be considered to be compatible with the internal market. Member states can invoke this ground for support measures granted for a limited period to remedy the liquidity shortage faced by undertakings that were not in difficulty on 31 December 2019 and to ensure that the disruptions caused by the coronavirus outbreak do not undermine their viability, in particular that of small and medium sized enterprises.

The Temporary Framework provides more detailed guidance on admissibility of the aid granted by a member state to remedy a serious disturbance in its economy. According to it, when aid is granted in the form of direct grants, tax and payment advantages, the Commission considers this type of aid to be compatible with the internal market if it meets the following conditions: (1) the total nominal value of such measure does not exceed EUR 800,000 per undertaking, (2) the aid is granted on the basis of a scheme with an estimated budget, (3) the aid is granted no later than 31 December 2020.[11] Secondly, when aid is granted in the form of new public guarantees on individual loans in response to the COVID-19 outbreak, the Commission considers this type of aid be compatible with the internal market if: (1) the guarantee premiums are set at a minimum level, as defined in the Temporary Framework, (2) the guarantee is granted by 31 December 2020 at the latest, (3) for loans with a maturity beyond 31 December, the amount of loans per undertaking does not exceed double the 2019 annual wage bill of the undertaking, or 25% of its total 2019 turnover; (the amount of the loan may be higher in justified cases and for loans with a maturity date until 31 December 2020), (4) the duration of the guarantee is limited to maximum six years and the public guarantee does not exceed: 90% of the loan principal where losses are sustained proportionally and under the same conditions, by the credit institution and the state, or 35% of the loan principal, where losses are first attributed to the state and only then to credit institutions; in both cases the guaranteed amount must decrease proportionally with the size of the loan as it starts to be reimbursed; (5) the guarantee relates to investment and/or working capital loans. Thirdly, aid can also be granted in the form of subsidised interest rates for loans. In that case the reduced interest rates should be at least equal to the base rate (1 year IBOR) plus a credit risk margin as specified in the Temporary Framework. Additional conditions are set where aid in the form of guarantees and loans is channelled through credit institutions or other financial institutions. Moreover, in the context of coronavirus, the Temporary Framework makes public short-term export credit insurance more widely available until 31 December 2020.

A good example is a Danish aid scheme for self-employed. First, the scheme was developed to compensate self-employed undertakings for losses of revenues caused by temporary prohibitions and implementation of recommendations issued by Danish authorities trying to contain the spread of the coronavirus, and as such the aid scheme was assessed on the basis of Article 107(2)(b) TFUE (aid to make good the damage caused by exceptional occurrences). However, along with the progressive re-opening of the Danish economy and partial lifting of prohibitions and recommendations, the aid scheme has been amended as the main purpose of the measure changed from initial compensation scheme to direct grant scheme to mitigate liquidity problems for the undertakings concerned. Therefore, the compatibility assessment of the modified aid scheme was based on Article 107(3)(b) (aid to remedy a serious disturbance in the economy of a member state) and found compatible with the internal market since all the conditions set in the Temporary Framework (and specified above), were met. What is worth mentioning, the rule is that from this type of support measures cannot benefit undertakings that were already in difficulty on 31 December 2019. However, the exemption applies to micro and small enterprises provided that those enterprises, at the moment of granting the

aid, are not subject to collective insolvency procedure under national law and they have not received rescue aid or restructuring aid. Thus, the Danish grant scheme has been made available for those undertakings, (SA.57919 (2020/N) Denmark. COVID-19: limited amounts of aid scheme for self-employed).

Conclusions

State aid has always been thought as the 'second best' option, meaning that member states may resort to state aid only when other less distortive policy measures, such as general and regulatory measures, cannot be applied instead to achieve a given objective. For instance, deferrals of payments of taxes and social security contributions could be a valuable tool to reduce the liquidity constrains of undertakings. When applied generally (i.e. are not restricted to certain undertakings, regions, sectors etc.), they fall outside state aid rules. Member states can also grant compensation for damage suffered due to and directly caused by the coronavirus outbreak for undertakings particularly impacted by the pandemic, such as transport, tourism or hospitality. Operating aid, which now is flowing in a wide stream as a response to the coronavirus crisis, has been repeatedly considered by the European Commission and EU courts as being distortive for competition 'in principle' since it keeps undertakings artificially afloat by covering costs they should cover themselves. Such aid can only be regarded as compatible with the EU internal market when is granted on a temporary basis and is digressive[12] (Nicolaides, 2008).

The current coronavirus crisis seriously affected the economic situations of many so far healthy undertakings and their employees. Against this backdrop, there are no doubts that state aid is necessary to compensate the economic losses inflicted upon undertakings impacted by the pandemic and ensure that sufficient liquidity remains available in the market. Everything indicates that the total amount of state aid granted in response to the coronavirus outbreak, in particular in Western countries, will be at levels exceeding those of all previous crises (Kraus et al., 2020). However, in order to preserve European unity state aid measures should not go beyond what is needed to preserve the continuity of economic activity during and after the outbreak. It can be argued that the Temporary framework for state aid measures to support the economy in the current COVID-19 outbreak does not undermine the fundamental rules of state aid granting. Member states are not free in designing their support measures which constitute state aid. The temporary framework sets limits on state aid, establishes the temporary nature of those instruments and does not lose sight of the aid effectiveness considerations. For instance, undertakings which were already in difficulty by 31 December 2019, i.e. before the crisis, cannot benefit from most of the measures (only to rescue and restructuring aid, however, exemptions apply to micro and small enterprises, see: above). Moreover, the overall amount of temporary state aid measures cannot exceed EUR 800 000 per undertaking, what is important in situations when aid from different sources are cumulated, (different limits apply to the agriculture, fishery and aquaculture sectors). Finally, the Commission has made it imperative that aid cannot be conditioned on the relocation of the beneficiary's activity from one country within the European Economic Area to the member state granting the aid, since such a condition would be particularly harmful for the internal market.

While state aid addressing a lack of liquidity is certainly justified, not all member states are able to support their undertakings at the same level creating the risk of market distortions. In this context, the establishment of the EU-wide fund offering such liquidity interventions may be worth considering (see: Motta & Peitz, 2020). Moreover, as the focus of this article is placed on short-run liquidity support measures that may not be enough, the next step could be to examine what measures states can take to support entrepreneurs in the longer time perspective in their path towards objectives of common interest.

---

[1] As the current economic downturn caused by the coronavirus outbreak is becoming a huge strain on the budgets of member states and the debt-to –GDP ratios are rising, the European Commission

launched in February 2020 the public discussion on the EU fiscal rules and economic governance (see: for example: Dullien et al., 2020).

Abstract

Marketing strategies adopted in many destinations do not take into consideration the potential of the senses to generate memorable experiences. By ignoring a driving force of intangibility, such strategies do not value a major source of differentiation. In fact, in a time where the intangible assumes an essential role, the senses emerge as a key for the differentiation of a particular destination when compared to other alternatives. This article puts in evidence the importance of the sensory marketing at the destination level. We develop a conceptual model where sensory contact points emerge as the central element in the 3 different phases of the tourist experience: a priori to capture the attention and provide (or recall) sensations of the destination, in loco for the generation of a multisensory image of the destination, and a posteriori inspiring a new visit to the destination or it's recommendation to others. The model proves to be particularly useful for practitioners, offering relevant insights for managers and policy makers.

Keywords: Sensory Marketing, Senses, Destination, Tourism, Experiences

Introduction

Marketing applied to regions has become a central activity in regional management as it achieves to generate competitive advantages that originate a differentiation of the destination, valuing the intangible and making it unique (Correia & Brito, 2011). Due to the intensification of competition in tourism and a world market that seeks unique and memorable tourist experiences, destinations and tourist companies should look for more innovative marketing strategies in order to attract more tourists. Tourism can thus be perceived as a consumer experience (Pine & Gilmore, 1998), where the tourist is seen as a consumer (Agapito, Mendes, Valle, & Almeida, 2014; Quan & Wang, 2004).

Marketing strategies of companies producing traditional consumer goods, such as cars, cosmetics and food products, have recognized the importance of the senses for the purchase process, however tourism marketing has neglected the significant role of olfactory, tactile, taste and auditory sensations during consumer experiences (Gretzel & Fesenmaier, 2004). Although tourism studies in the past gave greater importance to the visual dimension of the tourist experience (Urry, 1992), recent studies support the importance of the five senses for the marketing of tourist experiences (Agapito, et al., 2014; Dann & Jacobsen, 2003; Gretzel & Fesenmaier, 2004; 2010; Kastenholz, Carneiro, & Marques, 2012; Pan & Ryan, 2009). However there is not yet a concrete model that allows inserting the five senses roles in the territorial management in a dynamic and interactive way. In this paper, taking advantage of all the existing knowledge about the relevance of the senses to destination touristic

experience an operational model has been developed that places sensory marketing as a central element in the entire destination management strategy.

The article is structured as follows. Section 2 offers a comprehensive overview of the theoretical background. Firstly, the sensory marketing is contextualized as one of the most relevant elements for consumer experience and offer value. Secondly, it addresses the application of sensory marketing to touristic destinations, highlighting its central role for the touristic experience. Section 3 presents the model developed with the aim of making sensory marketing at the destination level operational. Finally section 4 summarizes the main contributions of the paper and concludes with limitations and suggestions for further research.

Conceptual Background

Sensory Marketing

Human senses have been progressively recognized over time as important factors that influence consumer behaviour, emotions and perceptions (Rupini & Nandagopal, 2015). In the 1950s, major brands began to work on the colours and design (visual marketing) of products and their advertisements, such as the Coca-Cola bottle that reminds consumers the shape of a woman. Then music (audio marketing) started to be introduced in television ads and in sales outlets, and today there is no point of sale without background music. In the 1970s, the first “blind tests” appeared and the brands started to modify the taste of their products in order to adapt them to consumers (taste marketing). In the 90s the scent (olfactory marketing) started to be used to influence the consumer through the creation of artificial scents in the sales points, since 75% of our emotions are generated by the scent. The texture of the products (tactile marketing) also began to be worked on as a way of influencing the consumer, such as the weight of cutlery, the softness of napkins and the comfort of chairs in restaurants. Thus, the role of the senses in the individual perception of the environment attracted the attention of different disciplines, revealing its multidisciplinary nature and importance. Specifically, the evolution in neuroscience, psychology and marketing research has led to interesting results in terms of the role of human senses in consumer behaviour, leading to the emergence of sensory marketing (Krishna, 2011).

According to Krishna (2012, p. 332), sensory marketing is defined as “marketing that engages the consumers' senses and affects their perception, judgment and behavior” and can therefore be used to subconsciously trigger the perception of consumers about abstract notions of the product such as its sophistication, quality, elegance, innovation and modernity.

Sensory marketing begins by understanding consumer perceptions, starting with the stimuli that affect the senses, and reaches consumer responses through the interpretation of those stimuli. Thus, sensory marketing argues that the strategies that aim to create multisensory experiences with products, places, events and communications, influence consumer behaviour (Ditoiu et al., 2014).

The five senses give rise to conscious and unconscious sensory experiences, so sensory marketing can also be defined as the use of stimuli and expressed elements, which consumers perceive through the senses, to create certain environments (Suárez & Gumiel, 2012). The use of sensory stimuli in the creation of environments that appeal to the consumer's senses should not be understood as a form of manipulation, but as a process of improving marketing activities aimed at generating a greater value for the consumer.

According to Trierweiller et al. (2011), sensory marketing aims to tie a brand, product or service in the consumer's mind, generating sensations through the senses in order to create an emotional bond, seducing consumers through messages that stimulate the right hemisphere of emotion, as opposed to the messages that stimulate the left hemisphere of the human brain, responsible for reason (Schmitt, 1999). Sensory marketing aims to capture the attention of the five senses of the customer and thereby

create sensory experiences in order to differentiate brands, motivate and create value in the minds of consumers (Schmitt, 1999).

For Guzel and Dortyol (2016), the visual stimulus is the most focused by researchers and is considered the most powerful of the senses, namely associated with colours and light; the auditory stimulus is considered the easiest and strongest to arouse emotions, feelings and memories in the consumer, namely in the case of music; the olfactory stimulus is considered to be one of the most subconscious, namely in the case of pleasant aromas that make the consumer stay in a place longer, in contrast to unpleasant aromas that keep the consumer away; gustatory stimulation is another sense that strengthens the experience, attracting the consumer's attention, namely in the case of the pleasant taste of food and drinks; the tactile stimulus is considered the least important, but should not be ignored.

Fig. 1: Sensorial perception process. Source: The authors.

As can be seen in Figure 1, sensory stimuli (visual, acoustic, olfactory, taste and tactile) give rise to sensations (colours, sounds, scent, flavours and textures, respectively), which will be assimilated by the human being through the process of perception (Agapito, et al., 2014). The sensation occurs when the stimulus collides with the cells of a receptor sensory organ, originating the reception of information; perception is awareness or understanding of sensory information / stimulus, transforming it into an experience (Krishna, 2012). Sensory marketing is an application of sensation and perception understanding for the marketing area.

In this context, sensory marketing points to the stimulation of the five senses as essential to encourage consumers' experiences with products and services, influencing their perceptions and, consequently, their preferences and behaviours (Hultén et al., 2009; Krishna, 2011). All the senses play an important role in the consumption experience of individuals (Hultén et al., 2009). According to Hultén (2011), a sensory experience is defined as an individual perception of goods and services or other elements in a service process, as an image that challenges the human mind and senses. And, since the experiences are personal, existing in the mind of the individual who has been involved on an emotional, physical, intellectual or even spiritual level, they can be enacted through the stimulation of human senses, in order to involve consumers emotionally and intellectually in their interaction with products and services (Pine & Gilmore, 1998).

Sensory marketing can be used in a wide range of activities and it has three main characteristics: (1) it focuses on the remarkable and positive experiences that it can offer to the consumer in contrast to the functional attributes and benefits that traditional marketing focuses on; (2) considers consumption to be a holistic experience, where the consumer pays attention to the environment and the experience it provides; (3) takes into account not only the reason but the emotion of the consumer, through which he makes a choice based on feelings and emotions (Schmitt, 1999). In this way, sensory marketing is a complex concept, as it analyses consumers' subconscious, their perceptions, feelings and tastes.

The five senses are, therefore, essential for the consumer to know and understand the environment that surrounds him. In this way, sensory marketing aims to stimulate these senses in order to influence, without the consumer being aware, the consumption experiences and, thus, the consumer's behaviour and decisions.

The Sensory in Tourism

Tourism has evolved more and more in search of sensations and experiences. Tourists seek trips and experiences where all the senses can be involved (Gálvez, Granda, López-Guzmán, & Coronel, 2017). The study of the sensorial dimension of tourist experiences has been recently pointed out, by several authors, as crucial to support marketers to make tourist experiences memorable, since these are considered a source of competitive advantage of destinations and can be stimulated through the five senses (Agapito et al., 2013; Agapito, Pinto, & Mendes, 2017; Agapito, Valle, & Mendes, 2014; Campos, Mendes, do Valle, & Scott, 2016; Gretzel & Fesenmaier, 2004; Gretzel & Fesenmaier, 2010; Pan & Ryan, 2009).

According to Kastenholz (2002), it is the experiences at the destination that give rise to a greater involvement and familiarity, stimulating the recommendation, the repetition of the visit and the choice of similar destinations. According to the same author, there is a positive relationship between a good experience at the destination and the repetition of the visit, resulting in tourist loyalty to the destination. This positive experience has a strong impact not only on the tourist who has enjoyed it, but also on the opinion that will be transmitted by him to family and friends. In this way, each destination should seek to arouse the interest of potential tourists by transmitting and providing positive experiences of the same.

Pan and Ryan (2009) highlight that multisensory tourism is an enriching element, stating that the more interactive the tourist or traveller is with the surrounding environment, the more their senses are stimulated, and the greater value will be attributed to the experience of traveling. Involving all the senses is therefore important because the more sensory an experience is, the more memorable it will become.

The endogenous resources of certain destinations offer multiple sensory stimuli, creating sensory experiences unique to that destination capable of attracting tourists. Therefore, local resources must be used in order to create sensory experiences that attract the attention of tourists (Agapito, et al., 2014).

Tourism products must contain a significant number of sensory contact points with the consumer, involving all the senses for a complete tourist experience. For example, to create a complete visual experience, marketers must permanently consider and analyse the colours used, the brightness, transparency, volume, area used; as for hearing, the analysis should focus on intensity, pitch, timbre and sound vibration to identify new opportunities in order to improve the experience; the smell, characterized by quality, intensity, emotional valence and duration must also be studied and explored. The scent characterizes the places, making it easier to identify and remember them in the tourist's mind (Dann & Jacobsen, 2003; Stancioiu, Teodorescu, Pargaru, Botos, & Anamaria-Cătălina, 2013); taste is mainly addressed in the context of gastronomic tourism (Everett, 2008), with the consumption of local food being an important part of the tourist experience, or even the main motivation of the tourist on his trip (Gálvez et al., 2017), providing a most memorable travel atmosphere (Quan & Wang, 2004).

According to Xiong et al. (2015), the vision can be considered the most immediate, essential and reliable sense to know the destination; hearing on the other hand can arouse emotions in the tourist about the destination; smell is considered an important sense in appreciating the destination and in remembering it; the palate represents the culture of the destination and opportunities for tourists to experience the same, with many researchers arguing that each region should promote its local cuisine as an attraction for tourists (Gálvez et al., 2017); touch can provide proximity to the destination, in

addition to serve as a form of communication between the tourist and the locals in case of difficulty of communicating through the language.

The relative place occupied by each sense in the formation of a tourist experience, can provide a structure for the creation of a sensory marketing strategy allowing the creation of touristic products or services based on sensations susceptible to be "absorbed" by consumers (Stancioiu et al., 2013).
Sensory marketing thus offers an important contribution to tourism marketing, since the senses are responsible for processing the sensory stimuli that, in turn, originate the appearance of tourist experiences (Agapito et al., 2013). This recognition of the experiential nature of tourism and new consumer trends requires marketing approaches that use innovative ways to communicate tourism experiences (Schmitt, 1999).

Xiong et al. (2015) and Son & Pearce (2005) use the term "multisensory image", to describe individual perceptions based on sight, hearing, smell, taste and touch, formed through the interpretation of sensory stimuli of the destination by tourists. These stimuli can be obtained either through the experience of visiting the destination, or by searching for information about it through various means. The touristic experience starts before the destination visit, at the stage of planning the trip and choosing the place to visit, and continues after the tourist returns home, in the form of memories. In this way, marketing can explore the different phases of the tourist experience through sensory appeals to the five senses as a way of capturing the attention of tourists, attracting them to their destination (Agapito, et al., 2014). According to the authors, the multisensory image that tourists have of a destination affects their feelings and emotions, influencing their intentions to visit or revisit the destination. In this way, the multisensory image becomes important in the presentation, strengthening or weakening of a destination (Xiong et al., 2015).

Sensory Marketing Model

So far we have focused on the most strategic elements of sensory marketing. These elements include the stimuli, sensations, perceptions and experiences. All the destinations have resources with the potential to generate sensorial stimuli and memorable experiences. Defining the sensory contact points of the territory that can generate those memorable experiences is a key element in the sensory marketing strategy. However the definition of these elements is only part of a long journey that should include the integration of diverse actions.

The complex features associated with the territories and their resources are very different, so there are no generic recipes of actions to implement in order to develop and enhance their offer. Nevertheless, some essential steps are referred to the operationalization of a sensorial marketing strategy (Figure 2).

The tourist experience goes through three phases: a priori, in loco and a posteriori, during which the perception of the experience can change and influence the future behaviour of the tourist (Agapito et al., 2017). In all of these three phases sensory contact points should be provided to the tourist. These sensory contact points should be consistent, coherent, and aligned with the resources of the destination and the experiences that it wishes to generate.

In the a priori stage, websites and tourist pamphlets can capture the attention of the senses through the use of images, videos and sensory maps, as well as interactive contests. Virtual environments, such as Second Life, are also a way for tourists to experience the destination virtually, appealing to their senses in order to attract them (Neuhofer, Buhalis, & Ladkin, 2012). This phase is decisive as tourists explore, seek inspiration and interact with the destination for the first time. Thus, destination marketers must add multisensory information to their promotional communication, through advertisements and pamphlets with multisensory suggestions or the use of multimedia to present their multisensory images, in order to provide or recall sensations of the destination in the tourist's mind. Travel agencies must also develop a multisensory environment around the destination, through images, music, smells, flavours, food, local products in order to promote the destination and influence tourists in choosing it (Xiong et al., 2015).

The in loco phase is crucial for the delivery of sensory contact points. When well implemented these are going to improve the interactions with the destination, that in turn will foster the stimuli potentiating the arousal of memorable experiences. All the integrated experiences will then generate a multisensory image of the destination (Figure 2). Apart of generating new interactions (and consumption) for the tourist while in the destination, if this multisensory image will be positive exceeding the initial expectation of the tourist it will remain on its memory longer increasing the odds to revisit the destination and recommend it to others.

Marketing can use some techniques to deliver sensory contact points like multisensory routes, sharing experiences in real time through, for example, applications for mobile phones and tablets (Agapito, et al., 2014). Through social networks, such as Facebook, tourists can interact with others in real time, sharing photos and comments about the destination (Neuhofer et al., 2012), while experiencing it sensorially.

In the a posteriori phase, tourists continue to receive sensory stimuli from the destination through stories told to friends and family, sharing experiences on travel blogs or virtual communities (such as TripAdvisor), offering souvenirs, sharing photos with family, friends and on social networks (Agapito, et al., 2014). All these activities remind the tourist of his past tourist experience, thus developing the intention to revisit the destination and his recommendation to friends and family, based on the level of satisfaction of the tourist, which is influenced by the sensory stimuli received in all phases of your tourist experience (Diţoiu, et al., 2014). It can therefore be said that the tourist experiences a destination through the five sensory channels (visual, auditory, olfactory, taste and tactile) during their entire experience (a priori, in loco and a posteriori) (Diţoiu et al., 2014).

Fig. 2: A Model for the Development of a Sensory Marketing Strategy. Source: The authors.

When sensory information is communicated, it is usually presented in isolation, that is, or smell, taste, touch or sound, and is often simply translated into visual signals (Gretzel & Fesenmaier, 2004). Destinations shouldn't attract only by sight (Dann & Jacobsen, 2003; Pan & Ryan, 2009), but through an integrated perspective of all the senses. The current literature on tourism studies claims a holistic approach to the five senses as a way of understanding their role in global tourist experiences, since previous studies have privileged only the sense of vision (Agapito et al., 2012; Agapito, Valle, et al., 2014; Dann & Jacobsen, 2003; Gretzel & Fesenmaier, 2004; 2010; Kastenholz, Carneiro, & Marques, 2012; Pan & Ryan, 2009). This approach emphasizes the importance of understanding the sensory relationship between tourists and destinations, suggesting that sensory marketing can be used to create, communicate and boost tourist experiences, increasing tourists' satisfaction and, consequently, increasing long-term recall and recommendation through word of mouth. In fact, when sensory marketing strategies are aimed at providing the most positive tourist experiences possible, the tourist ends up revisiting the destination or recommending it. Taking into account the fact that if more than one sensory stimulus affects the consumer at the same time, he will remember the destination more quickly (Dițoiu & Căruntu, 2014). Thus, the more senses are called in an integrated way, the stronger the message will be transmitted.

According to Guzel and Dortyol (2016), tourism specialists should pay special attention to generate memorable tourism experiences for tourists in order to create and maintain a sustainable competitive advantage in the destination. They must discover ways to appeal to the senses of tourists in an

emotional and rational way, creating a relationship between tourism and the multisensory experience. These memorable experiences are built by tourists through individual and subjective evaluation of experiences, such as the collection of pleasant memories during their vacation at the destination (Agapito et al., 2017).

Conclusion

All the destinations are different, as different are their associated resources and the senses they can trigger on the tourists. The destinations should evaluate themselves trough the tourist eyes of and define the multisensory image (or images) that they want to deliver. For that they should identify and deliver sensory contact points in the 3 phases of the tourist experience in a consistent and integrated manner.

In conclusion, the tourist creates his own image of the destination according his own perception that is, through the experimentation of the destination, combining the five sensory dimensions. Thus, it is necessary to create a unique atmosphere at the destination level to generate / stimulate positive associations with the place and, at the same time, eliminate negative ones, providing sensory experiences that can seduce the senses of tourists and offer some memories that can leave a visible mark of the destination, together with the overall memorable experience (Diţoiu & Căruntu, 2014). In this way, determining and promoting the multisensory experiences that tourists find most rewarding and unique in the destination has become an essential marketing strategy to attract a greater number of tourists (Guzel & Dortyol, 2016). On the other hand, less pleasant or negative multisensory experiences in the destination must also be considered in the marketing strategy as aspects to be targeted for improvement (Xiong et al., 2015).

This research should be viewed as an exploratory exercise, translated into a model of analysis of a reality that involving multiple actors revels itself to be very complex. The model now proposed therefore lacks an empirical validation that at first should occur through a qualitative methodology. Another line of future research will be to measure and relate the relation between experiences and the multisensory image of the destination comparing tourist that have been exposed to more sensory contact points to other less exposed. It will also be interesting to be able to quantify and relate the relative importance of each of the senses for the multisensory image as well as the relation between them.

Abstract

This paper investigates how the international context regarding the integrated reporting influences the economic entities in the European area. In this context, reference is made to the manner of application and the extent to which the economic entities prepare reports in compliance with the international integrated reporting framework. The hypotheses formulated start from knowing the principles drafted by the International Integrated Reporting Council (IIRC). The research was carried out on a sample consisting of 30 economic entities belonging to one state in Europe and the integrated reporting of which has been studied through the content analysis and scoring method. The results obtained as a result of the research carried out made it possible to validate or invalidate the hypotheses. The application of the IIRC principles proved to be relevant in reflecting the performances of economic entities in the European area. One of the IIRC specific principles that has been noted refers to the credibility of the integrated reports drafted, proving by means of the score obtained that the specified principle best governs the reporting of economic entities in the European area.

Keywords: Integrated Reporting, Conceptual Framework, IIRC Principles, Economic Entity, European Area.

Introduction and Motivation

Globally, the international integrated reporting framework of IIRC is the manner of rapid implementation of adopting the integrated reporting. IIRC was constituted by the interest to internationally adopt the integrated reporting ((KPI, 2018). Organisationally, IIRC presents itself a global coalition consisting of representatives who are members of the council and promotes the interactions with the social and economic environment in order to coordinate and carry out the initiatives and related activities (Caraiani et. al., 2015).

The objectives and concepts underlying the IIRC are based on creating value (in the long, medium and short term), presenting the (social, intellectual, natural, human, manufactured and financial) capital, in other words presenting enough information so it would answer to the needs of interested individuals (Dima and Man 2015). Moreover, highlighting the connection between the sustainable development and economic value is taken into account, meaning to detail the interconnection between elements, highlighting the performance indicators and creating the context required in the reporting process. In this whole process, the transparency of the information provided is promoted (Dima, Popa, and Farcane, 2015).

Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The purpose and motivation of this research is to find answers to some questions that arise from the analysis of annual integrated reports published in 2018 by many economic entities in the European area. This research has as reference the framework of the IIRC integrated reporting concept that appeared in December 2013. By the combined use of the two methods, the level of compliance of the reports drafted with the requirements of the integrated reporting principles could be determined. In order to measure the quality level of the reports, it is required to compare them with the requirements imposed by the IIRC international reporting framework IIRC (2013). This model is proposed by authors such as Eccles, Krzus and Ribot (2015).

Literature Review

The conceptual framework of the IIRC is the main support in addressing the financial and non-financial nature, and it defines the integrated reporting as a way of concise communication regarding the strategy, governance, external environment and creation of short, medium and long term value (IIRC, 2013). Through the fact that there is a merging of financial information with the non-financial, the access to information is facilitated for a wide category of users: customers, authorities, community, employees, customers (Deloitte, 2012).

Internationally, the social responsibility practices are encouraged, by which the opportunity to apply the sustainable principles is proven (Caraiani et. al., 2015). Moreover, the economic entities are tempted to expose more management elements and less performance ones, which does not conclude the positive influence or good practices, meaning it does not present utility for that economic entity (Bonila-Priego, Font and Rosario Pacheco-Olivares, 2014). Meeting the requirements of third parties is an aspect that has been achieved through the publication of non-financial information, but these are included into the entity's strategy. Therefore, we can say that it is desired to exceed the responsibility threshold only by simply presenting the social, environmental and economic aspects (García-Sánchez, Rodríguez-Ariza, Frías-Aceituno, 2013).

Regarding the integrated performance reporting, studies have been drafted, which focused on the factors that influence the integrated reporting (Frías-Aceituno, Rodríguez-Ariza and García-Sánchez, 2013) and Hurghiş (2017), as well as studies that represented the compliance degree of integrated reports according to the IIRC, being drafted by Eccles, Krzus and Ribot (2015), Dumitrana et al., (2009), Ruiz-Lozano and Tirado-Valencia (2016). By going through these studies, it was found out that the common point is represented by the IIRC conceptual framework. This conceptual framework provides a good reporting base, establishing the guiding principles and elements required to be addressed in an integrated report (Bratu, 2017).

Studies such as that drafted by Caraiani et. al., (2015) proposes another model and namely the preparation of a list of factors that refer to the content, and these factors are identified in reports. This method aims to increase the degree of objectivity. Followers of the same method are also authors Ruiz-Lozano and Tirado-Valencia (2016) who analysed the extent to which industrial companies meet the principles of integrated reporting, and the results of their research prove that not all entities are at the same level of integrated reporting (Kot, Măcriş, 2015).

The integrated report supports the sustainable development strategy and provides a full set of information in an organised and compact manner (Bonilla-Priego, Font and Pacheco-Olivares, 2014). Moreover, a long-term vision is presented regarding the value creation and the interdependence of the aspects presented in the integrated report is emphasised. Being considered one of the most efficient methods by which existing problems are identified, the integrated reporting entails an efficient allocation of the resources within the economic entity and in this way the reporting quality is significantly improved (Hurghiş, 2017).

According to the IIRC framework, the elaboration of the integrated can have a stand-alone structure, being distinct from other document or may be included in the reports made by the economic entity on a regular basis. The usual practice within the economic entities is to include the integrated report in the financial statements drafted. Seen as a means of

communication, an integrated report is an introduction to the detailed information available generally in electronic form on the entity's web page so that the access to them is easy for as many people as possible.

The definition given to integrated reporting by the international framework of the IIRC is that of a process resulting from an integrated thinking, finalised by a centralised result and transmitted periodically by an economic entity (IIRC, 2013).

Methodology Research

In the research carried out, the *content analysis* and *scoring method* were used. *The content analysis* facilitated the identification and description of objectives in rigorous manner. By this method, the characteristics of the objectives subject to analysis have been identified and counted. The purpose of the content analysis consisted in the initial description of the requirements that should be met, in testing and comparing the content of the reports with the international requirements. An important characteristic of this method refers to formulating the hypotheses regarding the relationships between the concepts analysed. The advantage of using the content analysis refers to the methodical character, more precisely to the objective and quantifiable character. This analysis allows highlighting both the constant elements and those subject to change.

The scoring method is a method based on the discriminating analysis and is often used by those from the economic entity's external environment. The analysis methodology based on scores refers to simultaneously dealing with the multiple characteristics the economic entities have. The method principle is to statistically determine a separation between the economic entities belonging to a group, environment or geographical region. An economic entity's opening towards new horizons of exploitation is the reason why this exploits the opportunities appeared. Affiliation to the European area provides an advantage cultivated in the desire for change. The particularities of each country depend on the national development strategy and on the economic entity's capacity to comply with the highest standards.

In order to achieve an evaluation grid, the *requirements of the IIRC international reporting framework* (2013) have been analysed, and *seven principles of integrated reporting* are highlighted:

- P1 – *Strategic concentration and orientation of the entity towards the future;*
- P2 – *Information connectivity;*
- P3 – *Relationships with third parties;*
- P4 – *Importance and relevance;*
- P5 - *Significance;*
- P6 - *Credibility;*
- P7 – *Comparability and coherence.*

Once the principles are known, in order to carry out this research, two hypotheses have been formulated, which based on the results obtained will be validated or invalidated:

Hypothesis (H_0): *Most of the economic entities in the European area emphasise the credibility and significance of the reports when they draft integrated reports.*
Hypothesis (H_1): *The integrated reports drafted by the economic entities in the European area comply with the requirements of the IIRC International Reporting Framework, depending on the field of activity.*

Following the economic entities' analysis, through the principles pursued, it was possible to identify both the strengths and weaknesses, the opportunities and the risks, and for a fairest assessment, it is useful to give coefficients of importance, in order to determine an average score, as a weighted average, following the calculation formula (1):

$$\bar{I} = (\sum_{x=1}^{n} xi)/\sum x \quad (1)$$

where:
$\bar{I}$= average score;
$x_1, x_2 ... x_n$ = the principles, with the scores obtained;
i= constant coefficient.

The scoring method is a method used mainly by investors or creditors to calculate the risk factor that an economic entity has. The method represents a linear combination of a group of significant indicators (principles), each having a statistical base coefficient. The application of the method involves the achievement of two distinct groups, namely the economic entity that meets the principles of the IIRC reporting framework and the economic entity implementing the principles. Thus, for these groups, a linear combination is determined that allows the differentiation of the two groups, by means of the scoring method Z (2):

$$z = a_1x_1 + a_2x_2 + a_3x_3 + \ldots + a_nx_n \quad (2)$$

where:
z = the score;
x = the elements involved in the analysis;
a = weighting coefficients.

The formula for calculating the average (3) was used in order to establish the average scores, so that the average scores obtained by the economic entities were calculated according to the formula:

$$m = (x_1 + x_2 + ... + x_n)/n \quad (3)$$

where:
m = average;
x_1, x_2 = elements;
n = the maximum number of analysed.

The validation/invalidation of the hypotheses depended on the results obtained based on the methods applied. The data collected were mainly from the category of reports published periodically by the economic entities concerned. The data collection sources have an official character, being processed further. Data collection involved the use of several techniques and establishment of various sources, a process specific also to empirical research. The data presented have been enough for the relevance of the results obtained, materialised through tables, conclusions and discussions.

The Assessment of The Extent to Which the Integrated Reporting Complies with The IIRC Requirements. Case Study for The Economic Entities in The European Area

Adopting the integrated reports internationally in order to reflect the non-financial performance of economic entities had considerable impact on the entities, as it is deemed that these aspects have the greatest interest for third parties (Bogeanu-Popa, Man, 2019).This was the reason why this paper addresses the economic entities at European level.

The research analyses the economic entities in the European area that have drafted and published integrated reports. By consulting the international IR Examples Database and through their own websites of the economic entities, a sample of 30 economic entities was obtained, in the reports of which there are or are not references to the IIRC integrated reporting concept. The sample is represented by a number of 30 economic entities from the European area that have reports published for 2018 (Sustainable Development Knowledge Platform, 2019). The aim was to choose a representative economic entity from the European countries that adhered to the integrated reporting standards. When choosing the sample, the random selection technique was used, provided that the economic entity would provide the public with the online environment informatio. By selecting the sample, it was aimed to cover as many economic sectors as possible, and the entities selected for the research are presented in table 1.

Table 1: List of the selected economic entities in the European area

No.	Country	Name of the economic entity	Economic sector
1	Austria	OMV	Oil and gas
2	Belgium	Louis Delhaize Group	Retail
3	Bulgaria	Bulgargaz	Oil and gas
4	Czech Republic	Skoda	Production
5	Cyprus	Bank of Cyprus	Banking services
6	Croatia	Bonbon	Telecommunications
7	Denmark	Novo Nordisk	Pharmaceutical industry
8	Estonia	Tallinna farmatsiatehas	Pharmaceutical industry
9	Finland	Finnair	Aviation
10	France	Carrefour	Retail
11	Germany	Continental AG	Production
12	Greece	Alpha Bank	Banking services
13	Ireland	Ryanair	Aviation
14	Island	Actavis	Pharmaceutical industry
15	Italy	Enel	Energy and resources
16	Latvia	Latvian airlines	Aviation
17	Lithuania	Air Lithuanian	Aviation
18	Luxembourg	RTL Group	Telecommunications
19	Malta	AirMalta	Aviation
20	Great Britain	BT Group	Telecommunications
21	Norway	Aker Solutions	Oil and gas
22	Holland	KLM Royal Dutch Airlines	Aviation
23	Poland	PKO Bank Polski	Banking services
24	Portugal	Coindu	Production
25	Romania	Banca Transilvania	Banking services
26	Slovakia	Rova	Production
27	Slovenia	Adria Airways	Aviation
28	Spain	Telefonica	Telecommunications
29	Sweden	Electrolux	Production
30	Hungary	OTP Bank Group	Banking services

Source: The projection of authors based on the data taken from the web pages of the economic entities

For the sampled economic entities that have subsidiaries in several countries, the country of origin of that economic entity was taken into account, and in terms of the annual reports drafted, the *consolidated report* drafted by the *parent entity* was taken into account. Based on the constructed sample, Table 2 presents the economic sectors where the researched economic entities operate.

Table 2: The economic sectors where the selected economic entities operate

No.	Economic sector	Number of economic entities	Share
1	Banking services	5	16.66%
2	Oil and gas	3	10%
3	Production	5	16.66%
4	Aviation	7	23.34%
5	Retail	2	6.66%
6	Telecommunications	4	13.34%
7	Pharmaceutical industry	3	10%
8	Energy and resources	1	3.34%
Total		**30**	**100 %**

Source: The projection of authors based on the data taken from the web pages of the economic entities

It is observed that the most representative economic sectors are the *aviation* with a number of 7 economic entities and a percentage of 23.34%, followed by the sectors of *production* and *banking services*, which have a number of 5 economic entities and a percentage of 16.66% each, and the least representative is the sector of *energy* and *resources* with a single economic entity and a percentage of 3.34%.

Taking into account the *principles of integrated reporting* established, the principle ***P7-Comparability and coherence*** is a difficult one to evaluate in an objective manner, given that the research has been done only for 2018, the comparability of reports from one period to another not being possible. As a result, this principle was removed from the analysis. Although this principles can be assessed in terms of comparability of the reports of economic entities from the same sector of activity, the score given would not be complete, and the analysis of this principle would be insignificant for this research.

The *principles* were graded individually starting from 0 to 3. If the report did not provide information on this element, grade 0 was given, and if the report describes the factor very well, the grade obtained was 3. Having said this, *a report may obtain a maximum score of 18*. In order to increase the degree of objectivity, components were created in order to establish which of these are identified in the content of the reports and intermediary scores have also been given. The intermediary scores were summed and rounded up so that there are no decimals, therefore a score was obtained for each principle. *Total scores and average scores were calculated for each economic entity, and average scores for each individual principle.* Table 3 details the scores obtained by the economic entities.

Table 3 : Total score given for the compliance with the principles specific to integrated reporting

Total score/economic entity	17-18	15-16	13-14	11-12	9-10	7-8
Number of economic entities	7	5	6	2	6	4
Percentage	23.33%	16.67%	20 %	6.67 %	20 %	13.33%

Source: Authors' projection

The average score resulting from the analysis of the degree of compliance with the integrated reporting principles is 2.20. Four economic entities are emphasised to have obtained a maximum score, respectively Banca Transilvania (Romania), PKO Bank Polski (Poland), BT Group (Great Britain), OMV (Austria). According to table 3, it is observed how the score was registered in a percentage of 50% from 13-14 points upwards, up to the score of 18 points, therefore it is a high score. For the entities in the second half of the classification, legislative issues may be involved to a greater extent than the entity's internal policy. Although not all economic entities have recorded maximum scores, they made considerable efforts to align with the international standards of integrated reporting. Even if the level of integrating certain economic entities is lower, the desire to

align with the international requirements of that entity must be appreciated and, more than that, the support must be noted that the country of origin of that economic entity provides to be able to implement the European or international regulations on integrated reporting.

The aim of this study aims to give scores objectively, the economic entities presenting the most complete and elaborate set of information in reports are rewarded with maximum scores, while the lower scores are obtained by the economic entities presenting in their reports less information or where the absence of information is noticeable.

Figure 1 shows the average scores for each of the principles; it is observed that there is a difference of 0.63 between the maximum and minimum values, which leads to the conclusion that the integrated reports are compliant with the international reporting framework to a great extent.

Figure 1: Average scores calculated for the integrated reporting principles
Source: Authors' projection

According to the data obtained from Figure 1, six of the seven principles will be detailed according to the average scores obtained. The analysis of the principles, together with the average scores obtained by the economic entities will be detailed below.

In the case of the principle ***P1- Strategic concentration and orientation of the entity towards the future***, an average score of 1.97 was obtained. This score is one of the lowest scores obtained, because some of the economic entities did not focus to a large extent on the promoting strategy or on the opportunities the entity has in the future of the activity. Table 4 details the situation of the scores obtained by the economic entities in compliance with the IIRC requirements for this objective.

Table 4: Scores specific to the principle P1 – Strategic concentration and orientation of the entity towards the future

Score	Name of the economic entity
Score 0	Bulgargaz; Bank of Cyprus
Score 1	Bonbon; Tallinna farmatsiatehas; Finnair; Coindu; Adria Airways; Electrolux.
Score 2	Louis Delhaize Group; Skoda; Novo Nordisk; Carrefour; Ryanair; Actavis; Enel; Latvian airlines; Air Lithuanian; RTL Group; AirMalta; Aker Solutions; Telefonica.
Score 3	OMV; Continental AG; Alpha Bank; BT Group; KLM Royal Dutch Airlines; PKO Bank Polski; Banca Transilvania; Rova; OTP Bank Group.

Source: Authors' projection

Following the scores obtained, we can say that the entities studied do not elaborate reports fully compliant with the international integrated reporting framework. Even though most entities obtained scores of 2 and 3, scores of 0 and 1 were also recorded. The main problem was that in the available reports, no element was found regarding the *long-term economic entity's strategy*, aspects regarding the *allocation of resources in order to achieve the objectives*, elements related to *capital*, respectively

the effects produced on capitals and, last but not least, aspects regarding the *way in which the entity creates value in the long, medium or short term*.

Regarding the principle ***P2-Information connectivity***, score 2 was obtained, a value close to the previous principle, meaning the idea that the entities did not focus very much on this principle, it can be said that its level is an acceptable one. Table 5 details the scores obtained by the economic entities in order to find out the degree of compliance with the international standards for integrated reporting.

Table 5: Scores specific to the principle – *P2 Information connectivity*

Score	Name of the economic entity
Score 0	Bank of Cyprus; Rova.
Score 1	Louis Delhaize Group; Bulgargaz; Tallinna farmatsiatehas; Finnair; Actavis; Adria Airways; Coindu.
Score 2	Skoda; Bonbon, Continental AG; Ryanair; Enel; Latvian airlines; Air Lithuanian; Aker Solutions; Telefonica; Electrolux
Score 3	OMV; Novo Nordisk; RTL Group; AirMalta; BT Group; KLM Royal Dutch Airlines; PKO Bank Polski; Banca Transilvania; OTP Bank Group; Carrefour; Alpha Bank.

Source: Authors' projection

From the table presented, we can see that most of the economic entities have good scores, meaning of 2 and 3, which proves that they either achieved a connection in terms of the *capitals and business model*, or focused on *qualitative information and qualitative indicators*. The entities that received low scores, between 0 and 1, had problems regarding the non-correlation of the presentation of financial information with the non-financial information or deficiencies in the non-correlation of the resources allocated in the entity's strategy. All these lead to reducing the connectivity effect and affect the process of alignment with the standards imposed by the international reporting framework.

In connection with the principle ***P3-The principle of relationships with third parties***, the entities analysed registered a good score of 2.13. It results that a set of information has been presented on third parties, particularly on the parties interested in the economic entity; all except for one economic entity that scored 0 on this principle, according to Table 6.

Table 6: Scores specific to the principle *P3-Relationships with third parties*

Score	Name of the economic entity
Score 0	Coindu.
Score 1	Tallinna farmatsiatehas; Finnair; Actavis; Adria Airways.
Score 2	Louis Delhaize Group; Bulgargaz; Bank of Ciprus; Bonbon; Alpha Bank; Ryanair; Latvian airlines; Air Lithuanian; AirMalta; Aker Solutions; Rova; Telefonica; Electrolux.
Score 3	OMV; Skoda; Novo Nordisk; Carrefour; Continental AG; RTL Group; BT Group; KLM Royal Dutch Airlines; PKO Bank Polski; Banca Transilvania; OTP Bank Group.

Source: Authors' projection

By means of the P3 principle, the relationships that the entities have with the interested parties were mainly aimed at, but also the extent to which the entity takes into account their opinion and wants to meet their expectations. This is highly important because the group of users of this type of information largely consists of capital providers. Also the international integrated reporting framework encourages the provision of as much information as possible to capital providers, as they are an important category of information users (Soyka, 2013).

Regarding the principle ***P4-Importance and relevance***, the scores obtained by entities are high, the average score being 2.20. The analysis of this principle took into account the identification of significant elements regarding the important aspects in the process of operating the entity's activity. Table 7 details the status of the scores obtained by each individual entity, reflecting the degree of compliance with the international integrated reporting requirements.

Table 7 Scores specific to the principle *P4-Importance and relevance*

Score	Name of the economic entity
Score 1	Tallinna farmatsiatehas; Finnair; Actavis; Coindu; Adria Airways; Electrolux
Score 2	Bulgargaz; Bonbon; Bank of Ciprus; Alpha Bank; Ryanair; Enel; Latvian airlines; Air Lithuanian; RTL Group; Aker Solutions; Rova; Telefonica; OTP Bank Group.
Score 3	OMV; Louis Delhaize Group; Skoda; Novo Nordisk; Carrefour; Continental AG; AirMalta; BT Group; KLM Royal Dutch Airlines; PKO Bank Polski; Banca Transilvania; OTP Bank Group.

Source: Authors' projection

Following the analysis, descriptions of the activity were found in all reports, which led to a score of at least 1, for providing minimal information. However, most economic entities provided significant, relevant and important information regarding their activity. Significant, well-detailed and well-argued matrices of significance were noted in the reports, and this indicates that the aspects on the international integrated reporting policies have been complied with. Moreover, the presentation of the significant risks, of the method to combat the risks or mitigate them is an aspect of major importance in an economic entity. On this topic, authors such as Eccles, Krzus and Ribot (2015) believe that an entity can identify the main risks better than to explain them.

Regarding the principle ***P5- Significance***, it obtained almost the highest average score, meaning 2.3. This score is reflected in the effort made by economic entities to repeat the information presented, and what the entities develop consists of logical and concise information that follows a well-defined and coherent structure. According to Table 8, most entities obtained scores between 2 and 3.

Table 8 : Scores specific to the principle *P5-Significance*

Score	Name of the economic entity
Score 1	Bonbon; Alpha Bank; Telefonica; Air Lithuanian; Rova.
Score 2	Bulgargaz; Novo Nordisk; Tallinna farmatsiatehas; Carrefour; Ryanair; Enel; Latvian airlines; AirMalta; Aker Solutions; Bank of Ciprus; Coindu; Electrolux; Finnair; Actavis; Adria Airways.
Score 3	OMV; Louis Delhaize Group; Skoda; Continental AG; RTL Group; BT Group; KLM Royal Dutch Airlines; PKO Bank Polski; Banca Transilvania; Telefonica; OTP Bank Group.

Source: Authors' projection

The failure to give the maximum score to this principle was due to repetitive information, meaning the presentation of the same information in several sections of the report. Although authors such as Eccles et al (2012) consider that the integrated reports have a narrative character, according to the international reporting frameworks, they must be precise and concise.

The principle ***P6- Credibility*** obtained the highest average score, respectively 2.6. As a result, it can be concluded that the economic entities have presented information where a clear, credible and coherent picture of the annual reports drafted results from, which are also in line with the international reporting framework, with no errors in this process. These data are detailed in Table 9.

Table 9: Scores specific to the principle *P6-Credibility*

Score	Name of the economic entity
Score 1	Rova.
Score 2	Bulgargaz; Louis Delhaize Group; Bank of Ciprus; Bonbon; Finnair; Air Lithuanian; Aker Solutions; Coindu; Adria Airways; Electrolux.
Score 3	OMV; Novo Nordisk; Skoda; Continental AG; Enel; Latvian airlines; RTL Group; BT Group; KLM Royal Dutch Airlines; PKO Bank Polski; Tallinna farmatsiatehas; Carrefour; Alpha Bank; Ryanair;Actavis; AirMalta; Banca Transilvania; Telefonica; OTP Bank Group.

Source: Authors' projection

For more credibility in this regard, part of the economic entities confirmed and validated the information through the audit, which also brought assurance on the accuracy of the information provided (IIRC, 2013). Moreover, external opinions have been formulated regarding the elaborated reports, which is a key element of the international integrated reporting policies (Man, Bogeanu-Popa, 2020).

Discussions and conclusions

The most relevant results of the research were obtained with the help of the entities which registered scores greater or equal to 2. Aspects such as information importance, relevance, significance and credibility are the elements most used by the economic entities through the integrated reports, but the aspects such as future planning, information connectivity or the third party relations are not the be neglected. Due to this, the most parts of the economic entity from the European space respect the IIRC specific principles and guide their activity after them.

Useful recommendations for the interested parties regarding the drafting of the analysis within the entity as well as in the reporting activity would be the permanent improvement of the ways of communication at every existent level. Through permanent access to information, the strategy, the vision and the mission of the entity can reach every IIRC specific principle and can have compatibility and coherence with time accomplishing the last principle of IIRC.

In this paper, the research represents the direct reflection of the reality. Two research methods were used, respectively qualitative and quantitative research. Through the *qualitative research*, we could collect and analyse data not represented by numbers, the former being of exploitation and understanding character. The processes are described without interfering with them and important characteristics of a subject are emphasised. In the qualitative research, description was used to detail and describe the characteristics and to highlight the existing links. Through *quantitative research*, we could collect and process the data and the results of processing the data could be emphasised.

We observe that the economic entities in the European area that have complied exactly with the requirements or those that have come as close as possible to them have recorded high scores for each of the principles analysed. They provided well-structured, logical, detailed reports, which presented the value created and promoted the business model. By comparison, the entities that obtained lower scores need to make additional efforts to draft integrated reports. It can be said that the economic entities in this situation are entities in an early stage of integrated reporting. Having said this, we can establish the validation or invalidation of the hypotheses.

In the case of *hypothesis (H_0),* this *is validated* because most of the companies in the European area emphasise *the credibility and significance of reports*, when they draft integrated reports, which is proven by the highest averages scores obtained. In the case of *significance*, the score of 2.3 was obtained and in the case of *credibility*, the score of 2.6 was obtained. This is reflected in Figure 1. *Average scores for the principles of integrated reporting*, in Table 8. *Scores specific to the principle P5-Significance* and Table 9. *Scores specific to the principle P6-Credibility*.

In the case of hypothesis (H_1), this *is not validated*. The invalidation of this hypothesis is justified by the fact that the economic entities in the European area do not draft *integrated reports in compliance with the requirements of the International Reporting Framework of the IIRC depending on the field of activity*. In this case study, there is a relatively homogeneous distribution of business sectors and the scores obtained by the entities are varied and differ depending on the principles they comply with. This is confirmed by Table 1 *The economic sectors in which the economic entities operate* and reflected in Figure 1 *Average scores for the integrated reporting principles*.
The limits of this research refer to the relatively low number of economic entities, but representative for the European states that have adopted the principles of integrated reporting according to international requirements. The limitation of the study is given by the fact that a report was made for Europe, and not for several continents. Another limitation of this research refers to how the scores are given, because it can be a subjective one and influences the results. In order to overcome the limitations of this case study, the research can be extended to several continents and for a longer period of time, which would allow the possibility of a better comparison, spread over several years. The advantage offered would be to observe the evolution of the reports drafted from one year to another or from the first reference year to the last reference year.

In conclusion, this research refers to integrated reports specific to economic entities in the European area on the compliance with the international principles of integrated reporting (IIRC, 2013). The research sample analysed consisted of 30 economic entities from the European area, being analysed for each integrated reporting. For the research, methods were used by which the extent to which the principles were complied with were aimed at. By means of the study carried out, the general conclusion is that the economic entities in the European area are in different stages of compliance with the requirements imposed by the IIRC.

ioan.adascalitei@ie.ase.ro

Abstract

Recent technological developments are increasingly impacting the interaction between people and the way they communicate, distribute information and exchange opinions. Since the advent of social networks, the element of novelty has been represented by communication between people through technology. This paper proposes to analyze the architecture of a social network application that integrates an electronic payment service based on blockchain technology. The working methodology is qualitative and is based both on the study of existing resources and on experience in the field of software development. The purpose of the paper is to analyze the use cases of the solution and to briefly present the architecture of the solution through the modules it integrates.

Keywords : blockchain, electronic payment systems, social networks

Introduction

Recent technological changes pose new challenges for the financial system and generate new opportunities for institutions involved in economic activities. Thus, emerging technologies have the potential to innovate in the financial field and to change the balance in this sector dominated by financial institutions. From the use of artificial intelligence to fraud prevention, machine learning to creating customer profile and learning to behave, investing in new blockchain-based security systems, financial institutions are increasingly incorporating new technological innovations.

At present, blockchain technology is one of the most important topics of discussion both in academia and in the technology industry worldwide. This technology was first introduced in 2008, together with Bitcoin, as a peer-to-peer system for making electronic payments between various actors, individuals or financial institutions. The system based on blockchain technology makes electronic payments without an interaction of a market regulator (central bank, for example) and avoids the problem of duplicate payments (Nakamoto, 2009) (Duplicate payments are a problem specific to digital currencies; thus, doubled expenses can be defined as a transaction in which data from another transaction already sent for network processing are used).

In the e-commerce market, blockchain technology is used to improve efficiency in electronic payments and payment processing; the blockchain can also support the improvement of companies' economic indicators by extending operations across the borders of the home country and facilitating online transactions securely without the intermediation of a third party involved and performing real-time security checks.

Blockchain-based systems are data structures that create a digital register of transactions and transmit them to a distributed network. They use cryptography to allow each participant to manipulate

Cite this Article as : Ion-Costel-Marius BALTOI And Ioan ADASCALITEI "The Proposed Architecture for The Integration of Electronic Payment Systems Based on Blockchain Technology Within Social Networks" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

information in a secure way without the need for central authority regulation. Also, once a block is registered in the blockchain register, it is difficult to modify or delete.

Blockchain technology allows the verification of financial transactions in a real-time network, without the intervention of an intermediary, compared to traditional electronic payment systems in which the execution of transactions is based on the regulations of a central authority or other intermediary for making payments. The blockchain architecture allows a distributed network of computers in which they interact and reach a consensus without the need for an intermediary.

Currently, the financial field is based on a system of intermediaries (banks or other financial institutions) that facilitates clearing of sums of money to payment processing networks. Eliminating or reducing the number of intermediaries can reduce costs by hundreds of billions of dollars each year, making real-time transactions easier (Anon., 2016).

The paper further presents a section dedicated to previous papers that have researched this topic and captures the useful aspects of this research. Next, is presented the research methodology.

The central part of the paper captures the architectural part of the system proposed for research and implementation. Thus, are presented the main cases of use and architecture of the solution based on its main components: the payment module, the RESTful web service and the social application.

Literature Review

World Bank Group (International Finance Corporation, 2019) defines blockchain technology as "a very interesting technology that can prove to be a radical innovation - similar to technologies such as the steam engine and the Internet that triggered the industrial revolutions." Also, the impact of this technology is manifested in other sectors of activity such as the financial sector, energy, supply chains, public sector, etc. There are also uncertainties about the scalability, interoperability or costs of the transition to the blockchain. Next, the paper presents an analysis of the evolution towards the blockchain starting from a centralized environment (the central core controls the information about transactions and records, and the other actors maintain their own copies), the decentralized environment (intermediaries maintain local records of transactions, and other parties maintain their own copies) and up to the distributed environment (all parties involved manage the same records in each transaction).

In the paper (Avital, et al., 2017), the authors propose for research the concept of "smart money" (in short, smart money is a customizable value exchange tool that relies on computerized protocols to facilitate, verify and impose certain payment conditions; for example, who can use the money, where and for what purpose). The payment customization is a feature of DLT-based infrastructure (distributed ledger technology).

The paper (Yoo, 2017) presents examples of applications of blockchain technology in the financial sector. Electronic blockchain payments will be able to be made through the American startup Ripple and it is expected that this global system will be used in the international currency settlement market and in the foreign exchange market. ABRA (Yoo, 2017) is also working on a payment system through which people can send money to people around the world. In the foreign exchange market, TenX, a company that offers virtual money settlement services in Singapore, works with VISA and MasterCard on a service that allows customers to pay in virtual currency on a regular credit card network.

G. Dolinski in paper (Dolinski, 2018) presents a new model for making payments abroad, a system also based on Ripple technology. Compared to the analyzed model, the new model proposes a smaller number of intermediary actors (each additional intermediary obstructs visibility, creates a potential point of delay or error and adds additional costs for customers). Thus, intermediaries are given up in exchange for connecting to the blockchain network to make more efficient use of global payment processing.

The article (Zhong, et al., 2019) summarizes the results of the development of the FIPS (Flexible Instant Payment System) to improve payment flexibility so that users can make offline payments without doubling expenses. The system is based on a digital signature scheme. Thus, starting from the idea that the blockchain system, smart contract and digital signature have a high level of security, and the FIPS system will be a secure one and will have properties such as flexibility, high security, real-time payments, high efficiency and scalability.

Methodology

This paper is based on qualitative research. In the first phase, a research was carried out at the level of scientific resources at the moment in specialized literature (articles in the field, papers presented at conferences or published in journals, online articles), being extracted the current state of knowledge in the field.

The architecture of the proposed solution

Use cases

In establishing the prototype architecture, an important role is played by clearly establishing the use cases and the way in which the application flow takes place. In this sense, figure 1 shows the analysis of use cases within the prototype proposed for research. In order to use the social network and the payment service, the user will need to log in; if it does not have an account, there is the possibility to create a new one.

Once logged in, the user will be able to use the functions available in the solution prototype for 2 main cases: social interaction (messaging services, image sharing, audio files, location, various links to external sites) or use of available wallet services (transfer money, view account details).

The use of the electronic wallet within the solution implies the fulfillment of some essential conditions: the electronic wallet to be active and to be available in the account. In case of problems using the payment module, the user will be able to consult the help page.

Within the prototype, the money transfer between 2 users will be made based on the unique ids of the user accounts, so we can also benefit from additional checks performed by the social network. During processing, the id will be encrypted so as to ensure increased security and avoid unauthorized attempts to perform transactions.

For the use of the payment module by the user, 3 screens are available, each with a specific functionality: the first screen is dedicated to viewing the account information (balance, account currency) and involves the initialization of transactions by the user); the second screen involves filling in the information needed for a transfer between accounts (recipient user id, amount transferred), and during processing will contain a message with the status of the request. The third screen is dedicated to displaying and changing the information in the payment module.

Fig. 1: Prototype use cases

Within the prototype, a special use case refers to the possibility of charging the electronic wallet. This operation can take place through any other electronic means of payment. The use case presented below is customized for charging through a banking application. Thus, after the authentication operation, the operation of uploading the electronic wallet or updating the information can be performed.

Fig. 2: Electronic wallet charging

The solution proposed for analysis in this research involves the integration of electronic payment services in social networks. Within the solution, we identified 3 main components: the social network, the web service and the payment service, the benefits to be further analyzed.

Fig. 3: System components

Figure 3 shows the components of the system and how they interact. Thus, we can highlight:

- social network - within the developed prototype, it is an Android open source solution that allows users to interact and transfer various amounts of money between their accounts, each with a specific unique ID;
- a RESTful web service - allows various operations in order to execute transactions between users, respectively the obtaining of new available balances. Thus, this service has the role of mediating the interaction between the client applications and the payment module;
- the payment module is a solution developed based on blockchain technology and simulates money transfer between users; it can be considered the core of the solution because all user transactions will be executed by it;
- auxiliary databases: have the role of storing various temporary or permanent information (for example, user data).

Payment System

Blockchain innovation depends on the possibility of P2P (distributed) organizes and gives a solid widespread informational index between hubs, regardless of whether they don't have any acquaintance with one another. It likewise gives a common and believed exchange sign in which put away duplicates of changeless and scrambled data are put away on every hub in the system. Truth be told, the idea of blockchain first showed up in October 2008 as a major aspect of the Bitcoin arrangement so as to make P2P systems for cash move, without the intermediation of banks (Voshmgir, 2019).

P2P network is a type of architecture that creates partitions of work within a network. A node within the blockchain network can be called a peer and describes how it works together with the other nodes to perform multiple tasks on the network. The P2P network allows nodes to provide information to another node in the network via the Transmission Control Protocol (TCP), and connections between peers are automatically generated by IP addresses on the same network. (Rahmadika & Rhee, 2018).

P2P networks are the mechanism used in the blockchain system for disseminating information within the system, keeping the whole system decentralized. The main objectives of such a network are to allow network members to synchronize the overview of the system and to update the information of all nodes after any change (Delgado-Segura, et al., 2018). Storing data on a P2P network eliminates

issues that arise from the vulnerability of centralized servers while using different cryptographic methods to secure the network.

Communication between nodes in a P2P network allows them to exchange data without the intermediation of another node in the network; thus, people or institutions that do not know or trust each other, live in different areas or are subject to different legal rules, do not have a legal agreement between them, can interact through technology without intermediaries such as banks, brokerage platforms or other institutions (Voshmgir, 2019).

Blockchain is a mutual, believed, open exchange log that anybody can review, however no client controls. It is a conveyed database that keeps up a developing rundown of exchange information records, cryptographically shielded from alteration and correction (Voshmgir, 2019). The vault is assembled utilizing a Linked List structure (a progression of affixed squares where each square contains a specific number of exchanges that have been approved in the system at a given time and the connection to the past square utilizing a pointer - factors that store data about the area of another variable).

The registry runs on a peer-to-peer (P2P) network. Distributed consensus based on game theory concept, combined with cryptography, allows secure validation of P2P transactions, thus bypassing the need for traditional trusted third parties:

- P2P - each node in the network stores a copy of the entire blockchain (transaction logging is ensured);
- Game theory - each new block is added to the blockchain based on a consensus of validators at a given time;
- Encryption - the network stores all information encrypted in the form of blocks. The first block is called the "genesis block", and the next blocks store the address / hash of the previous block so as to ensure that the blocks are chained.

The hash function is a cryptographic protocol and is created similarly for multiple input values, but it is difficult to find the original value of the input. Whenever an attacker tries to modify a block of data in the blockchain network, each peer detects the attacker's activity. Specifically, the attacker must change the entire data block in the network, which is impossible.

The architecture of blockchain-based systems has a number of key features, among which we can list encryption, immutability, provenance, decentralization, anonymity and transparency (Lastovetska, 2019).

- Encryption - within a blockchain, transactions are validated based on complex calculations and following the application of data encryption algorithms between the parties involved;
- Immutability - blockchain records cannot be modified or deleted;
- Provenance - you can track the origin of each transaction recorded in the blockchain;
- Decentralization - each node in a blockchain has access to the distributed system due to the consensus algorithm that ensures network control;
- Anonymity - each node in a blockchain network has a generated address, not the user's identity. Through this procedure, network anonymity is maintained, especially within a public blockchain;
- Transparency - the blockchain system cannot be corrupted because it requires a huge computing power to completely overwrite the blockchain network.

RESTful web service

REST (Representational State Transfer) is an architectural style for designing network applications and defines a set of constraints that are used to create web services in order to ensure interoperability between computer systems on the Internet. RESTful web services permit mentioning frameworks to get to and control printed portrayals of web assets, utilizing a uniform and predefined set of activities (Wikipedia, 2020).

Web resources were first characterized on the World Wide Web as records or documents distinguished by their URLs. These days, they have a significantly more nonexclusive and theoretical definition that envelops anything, substance or activity that can be recognized, named, tended to, controlled or executed, in any capacity, on the Web. In a RESTful web administration, solicitations to an asset's URI will create a payload reaction designed as XML, JSON, YAML, or another configuration. The reaction may affirm that an adjustment in the status of the asset has been made, and the reaction may give connects to other related assets.

The advent of RESTful web services has brought a number of benefits and novelties for software developers. Thus, the benefits include simplicity in development (RESTful architecture is simpler than SOAP services, and adaptation to new technology is fast), exposure of APIs as HTTP services (services can be accessed by applications running in various environments - web or mobile (Android, iOS, etc.), RESTful offers flexibility in communication (compared to SOAP which only uses XML files for communications, REST also uses other file types). client information is never stored on the server between requests, each request must contain the necessary information, improving scalability and allowing the server to quickly release resources when they are no longer needed (Medium, 2018).

In the literature, good practices in the field have been studied and the results have been presented in multiple researches, for example, the paper (Fielding, 2000) presents the design principles in the REST architecture. It also provides a number of examples of how web services can be used as the core of the solution and how they can communicate with other components.

B. Mulloy in paper (Mulloy, 2012) presents different design principles and good practices for web APIs and brings to the analysis the concept of “pragmatic REST”, a concept that refers to the fact that the usability of the API is more important than following the design and development guidelines. However, non-compliance with good practice guidelines does not mean ignoring fundamental concepts in RESTful services.

The paper (Fielding, et al., 2017) analyzes the architectural style of REST and offers a diverse perspective on it. The authors propose to extend the field of interest to the REST architecture and explore software technologies that can integrate these services. The article also proposes for analysis the applicability of RESTful services within the decentralized software architecture.

Social Network

Within the system proposed for analysis, the social network component is an application that offers instant messaging services, similar to other platforms such as WhatsApp, Facebook Messenger, WeChat, platforms already existing in the market. Features of this application include conversations between users, sharing information, images, audio files, creating user accounts or creating a user profile with personal information.

From a technical point of view, the application is an open source product, developed in the JAVA language and works on the Android platform. The information needed by the application's function is stored in a Firebase database, stored in the cloud. Benefits of cloud-based databases include real-time information processing, low database maintenance costs, disaster data recovery, scalability, or rapid expansion of functionality to meet current needs.

Among the opportunities offered by mobile social networks, the paper (Jabeur, et al., 2013) presents the integration of cloud platforms such as Amazon Web Services, Google App Engine or Salesforce that can be used with mobile applications to create mobile ecosystems where the user experience is enhanced, with cloud technology providing users with a robust, scalable, low-cost infrastructure. maintenance. Also, the mobile cloud is considered a major improvement of the infrastructure by offering advantages such as distributed computing, multi-core processors, service-oriented architectures (SOA) or virtualization services.

In using the services of mobile social networking solutions, the challenge is the high expectations of users who want an experience similar to that offered in the desktop version. In this regard, social networks must have an easy adaptation to various mobile devices on which they operate, with different information processing features or different screen sizes. Social mobile networks must also provide opportunities for integration and standardization so as to ensure good interoperability between various hardware and software solutions (Jabeur, et al., 2013).

Conclusions

Social networks offer multiple possibilities to users; starting from classic functionalities such as social interaction, distribution of information, audio, video materials or location distribution and up to electronic payment services. They can function both as an integral part of the social application, and as external services whose development can be done independently of the social network.

This paper analyzes the 2 main cases of use of the solution, among which is the monetary transfer between 2 electronic wallets, as well as the supply of one wallet at a time. These features could be expanded in the future with other features such as automatic payments, user behavior analysis or estimates of future developments. Also, in this paper were presented the 2 main modules of the application that interact with each other and offer the possibility of money transfer: the social network, the RESTful web service and the payment module. Each component represents an independent module so that any evolutions are treated independently and do not accidentally impact the functionality of the system.

In the future works, we will propose for analysis the development part of a functional prototype that integrates electronic payment services in social networks. Based on this prototype, we will be able to measure the impact that such a solution has on users and how it can work in reality.

Acknowledgment

Abstract

The effectiveness of public management depends on the civil service performance. Civil service is one of the types of public service. Since one of its priorities is personnel policy, civil servants deal with the issues related to the social, legal and professional spheres. A civil servant should be competent and qualified for the position he/she holds. In the article, the authors focused on the theoretical and practical aspects of assessing the competencies of civil servants in high-risk environments. The purpose of the study is to develop tools for assessing the competencies required in high-risk environments. The authors used a methodology which consists of seven stages. The researchers made the necessary preparations at the preliminary stage and created a working group of specialists to develop a civil service competency framework. Apart from that a content analysis was carried out and core competencies were determined. According to the group of specialists working in the regional civil service system, civil servants should have analytical thinking skills, communication skills, personal efficiency, leadership and decision-making skills.

Keywords: Personnel Management, Staff Assessment, Civil Servants, Competency Assessment

Introduction

The competency-based approach is fundamental to all HR management activities: it can be used to select personnel, to assess the quality of their work and to build a career and training system. In this regard, almost all countries in the world use a competency-based approach to the personnel selection in the civil service system. Most often, the competency model is used to establish a culture of state bodies, to assess candidates in the process of personnel selection, to assess the working efficiency of public servants, to prepare training and professional development programs and human resources plans, to develop an effective salary system, etc.

According to A.V. Khutorsky and A.V. Yeryomin "competence" includes a set of interrelated personal qualities (knowledge, abilities, skills, work methods) an employee should have in relation to certain objects and processes to work efficiently. To sum up, we can conclude that competence refers to a required level of knowledge, abilities, skills and qualities an individual needs to work in a certain

area of professional activity, while competency refers to the ability and readiness of a person to independently apply them in professional activity.

In fact, management activity is associated with risk. Researchers define the concept of risk in many ways. In economic theory, risk is associated with unexpected expenses in projected profits due to negative factors affecting the working environment and labor activity.

Most Russian economists define risk as uncertainty about potential losses. Russian dictionaries define the word risk as: "Risk is the possibility of danger, failure". According to a second definition, "Risk is a venture at random". Apart from that risk is defined as unforeseen consequences, or the possibility of expenses. All these definitions imply that risk is associated not with uncertainty but with a potential threat. The fact is that if under certain circumstances negative outcomes are inevitable these situations cannot be called risky. Therefore, a more accurate definition of risk is “Risk is the probability of a negative outcome under the conditions of uncertainty”.

It is vital to assess and predict risks in order to determine an appropriate management concept under the conditions of a changing external environment.

In high risk environments, a person in charge needs to find an alternative way to solve a problem.

Risk management includes the following components (Fig. 1).

Fig. 1: Components of risk management

The authors of the article proposed two approaches to risk management that can be applied by local governments.

According to a process approach, risk management includes a number of stages:

1) research and policy analysis with a focus on risk management;

2) risk analysis.

It is vital not only to assess the existing risks but also to analyze what brings about these risks. However, it turns out that under the same conditions the outcomes can be different. It is crucial to

form a specific system to mitigate or eliminate risks. The final stage of risk management involves risk prediction and taking measures to compensate for losses.

According to a system approach, the main components of risk management at the regional level are:

- elimination of negative consequences;

- distribution of powers and responsibilities;

- completion of work ahead of schedule;

- data analysis;

- effective interaction;

- balance of income and expenses.

These components should be included in the job description of a civil servant. A competency-based approach which is used to assess a civil servant's performance is based on these requirements.

According to V.V. Verna, a special technology should be used to develop a competency framework. This technology includes a set of specific methods, techniques and tools [5].

E.A. Galiy and her co-authors consider the assessment of competencies as a process of determining the priority qualities a civil servant should have to efficiently perform his/her duties.

A.A. Gorbunova and her co-authors claim that assessment of competencies of a civil servant is a process of evaluation of knowledge, skills and abilities of a civil servant and his/her capability to apply them in practice. Moreover, within this process his/her personal qualities and behavior are analyzed.

N.V. Tsurgan defines "competency assessment technology" as a set of organizational measures and a system of methods and tools which are used to assess the knowledge, skills and abilities of the personnel, and their capability to apply their knowledge, skills and abilities to solve practical problems they have to deal with when performing their professional duties.

Thus, in modern economic conditions and high-risk environments it is advisable to develop a civil service competency framework and introduce a system of assessment of civil servants' competencies.

Methods

In their works many researchers analyze the use of a competency-based approach in the civil service system. As for the methodological basis of this study, the authors applied a system approach to assess the competencies of civil servants. Studying a civil service competency framework, the authors concluded that project activities should be taken into account in the job description of a civil servant.

The authors carried out this research in a comprehensive manner (McClelland, Boyatzis and other authors). The first part of the study is devoted to the assessment of competencies in the context of project management. The authors published the results of this research in their previous works. The second part of the study is based on a general methodology; the competencies of civil servants have to be assessed under the conditions of high-risk environments. To develop the tools for assessing the competencies of a civil servant, the authors conducted the following analyses:

- document analysis. It was required to study instructions and regulations in order to obtain information about the specifics of the work of a civil servant;

- content analysis. Using the method of "brainstorming", the researchers analyzed the information obtained in the process of developing a civil service competency framework. Apart from that, the researchers analyzed the results of the survey (the competencies were ranked by order of importance).

The authors studied the specifics of the activities of the regional administration, the organizational structure of the executive bodies, the staffing table and the functions of structural divisions. The process of developing tools for assessing competencies consisted of several stages.

At the preparatory stage the authors interviewed the leading HR specialists of the civil service department, personnel administrators and award specialists. The goal of the researchers was to develop a civil service competency framework. The researchers identified the employees who deal with the personnel and are involved in the process of developing a competency framework (a leading specialist and a chief specialist of the HR department and a chief consultant). The researchers analyzed the documents required to develop a competency framework of a civil servant. Finally, the authors investigated the regulations for administration and structural divisions (departments), regulations on competitive selection of civil service staff, regulations on the formation and training of a reserve of managerial personnel.

At the second stage, a working group of specialists was formed. It included the specialists from the HR department - a leading specialist, a chief specialist and a chief consultant. The members of the working group were informed about the objectives of the project and expected results. In the course of this stage, the authors also examined the competency framework of the administration - the highest executive body in the region. In the course of the discussion, the brainstorming technique was used: based on their experience all the members of the working group spoke on the problem of the development of a competency framework and came up with their own ideas.

At the third stage, the researchers carried a content analysis of the information and developed a questionnaire on competencies (it included 10 core competencies civil servants should master) (Fig. 2).

Fig.2: Competencies civil servants should master to work in high-risk environments

The members of the working group were asked to fill in the assessment sheet and rank the importance of the competencies using a 5-point rating scale (Table 1).

Table 1: assessment sheet

№	Competence	Competency characteristics (abilities)	Importance
1	Analytical thinking	Ability to identify priority goals for yourself and analyse possible difficulties in achieving it	
		Ability to analyse problems and draw systematic and logical conclusions	
		Ability to predict developments, anticipate possible problems, develop specific ways to solve them	
2	Result Orientation	Ability to make efforts and remain active to achieve goals and objectives	
		Ability to clearly represent the outcome and strive to achieve it	
		Strive to meet or exceed established standards	
3	Resistance to stress	The ability to control your emotional state, not lose activity and performance when in a stressful situation	
		The ability to work efficiently for a long time, solving monotonous or time-consuming tasks	
		Ability to cope with frustration, failure, and keep moving forward	
4	Initiative and innovation	The desire to propose ideas and solutions aimed at improving performance. Support other initiatives	
		Desire to make additional efforts, go beyond their functional responsibilities to actively influence the improvement of the efficiency of the work process	
		Initiatives and innovations, ability to measure their effectiveness based on objective indicators	
5	Communication skills	The ability to easily build relationships with different people	
		Ability to persuade, argue, defend their ideas	
		Ability to choose the optimal communication style in various business situations	
6	Conflict Management	Ability to prevent conflict situations without compromising one's own interests	
		The ability in interpersonal or group conflict to constructively and productively build tactics of interaction with the opponent, aimed at achieving their own goals without compromising the needs of the other party	
		Ability to competently get out of conflict situations	
7	Ability to work in a team	Ability to work on a common result by creating a common information field	
		Commitment to discharge their responsibilities responsibly, respect other team members and agreements reached among themselves	
		Willingness to assist and support team members in addressing emerging issues	
8	Leadership	The ability to inspire, encourage others to act. Motivation and persuasion without administrative pressure	
		Ability and desire to educate and transfer knowledge to others, develop their subordinates	
		Ability to form a strong team	
9	Making management decisions	Ability to make effective decisions and willingness to take responsibility	
		The desire to achieve the maximum possible result, to make additional efforts for this.	
		Ability to take responsibility for the results of their team, provide professional support and	
10	Personal effectiveness	Focus on the development of professional knowledge and skills, regularly monitor recent changes, current state of affairs in their professional field	
		The desire for self-development, the use of several ways of learning: passing trainings, studying literature	
		Pursuit of excellence and career advancement	

Rank the competencies using a 5-point rating scale (unimportant - 1, highly important - 5).

At the fourth stage, based on a qualitative analysis of the results of the questionnaire, the researchers identified the five key competencies which were ranked as the most important. At the same stage, the researchers and the head of the HR formed a competency framework.

Results and Discussion

Based on the results of the implementation of the third and fourth stages of the study, the authors identified the competencies a civil servant should master in high-risk environments (Table 2).

Table 2: the competencies a civil servant should master in high-risk environments

Competence	Competency characteristics (abilities)	Behavioral indicators
1. Analytical thinking	Ability to assess the current situation and predict risks that are potentially likely to arise	- in solving problems, identifies gaps in information, finds possible sources and formulates precise questions for obtaining it; - determines the relationship of individual parts of the problem, finds the causes of its occurrence; - considers the situation in a broad context, takes into account the influence of the maximum number of factors and the likelihood of risks; - accurately predicts the development of events and assesses how its decisions are reflected in others (people, organizations, regions), including in the long term; - offers solutions aimed at preventing possible problems and taking advantage of future opportunities; - is guided by strategic objectives and determines the most effective ways to achieve them
2. Communication skills	The ability to organize the work of the team, which will ensure the integrated identification and leveling of risks	- communicates with others in a respectful and friendly manner; - establishes and maintains long-term partnerships with other people inside and outside the organization, broadens the range of contacts; - takes into account the needs of other people, develops mutually beneficial solutions, shows willingness to compromise; - consistently and logically state its position in the form and scope necessary for the interlocutor; - shows confidence in communication with different people, knows how to clearly distribute instructions; - arguably explains his point of view to others; - influences and enlists the support of others to promote ideas, solutions, projects.
3. Personal effectiveness	Ability to effectively organize your own work and efficiently allocate efforts to achieve maximum results	- ensures performance of the work within the established time frame; - faced with obstacles, persevere and continue to work until the result is achieved; - offers new ways to improve the performance of duties; - considers ideas and proposals of others to increase the efficiency of performance of official duties and implements them; - switches from one task to another in a short time; - does not reduce the quality of work if it is necessary to perform several tasks
4. Leadership	Ability to manage subordinates, effectively plan, organize and monitor work	- clearly sets and monitors tasks; - distributes tasks among subordinates, taking into account their individual characteristics and current load, performs effective control; - encourages subordinates to learn and develop professionally. - demonstrates confidence in the successful resolution of the problem, inspires others with its actions and enthusiasm for the best performance and achievement of a common goal
5. Making management decisions	Ability to quickly make and implement management decisions	- promptly makes decisions at its level of responsibility, complying with the established decision-making procedure; - decisions are taken in a balanced manner taking into account possible risks; - builds a motivation system based on transparent and understandable indicators; - is responsible for his decisions and actions, as well as for their consequences.

Developing the tools for assessing the competencies civil servants should master in high-risk environments, the authors analyzed the procedures for personnel selection, certification, qualification examinations and probationary period (interviews, questionnaires, group discussions, individual work of the candidate, testing, observation, case solving, 360 degrees Performance Appraisal, Assessment Center).

The researchers came to the conclusion that the method for assessing competencies depends on the goals and objectives of the organization (institution), as well as the contents of the competencies. For example, Table 3 shows the methods for assessing competencies.

Table 3: мethods for assessing some competencies of the personnel

Competence	Valuation methods						
	Interview	Observation	Case / Work	Case Resolution	Panel Discussion	360 Degree	Testing Evaluation Center
1. Analytical thinking	+		+	+	+	+	+
2. Communication skills	+	+	+	+		+	+
3. Personal effectiveness	+		+			+	+
4. Leadership	+	+	+	+		+	+
5. Making management decisions	+		+		+	+	+

To test the proposed tools for assessing the competencies civil servants should master in high-risk environments, the following measures were implemented:

- the levels (indicators) and contents of competency were determined (incompetency, development, experience, skills);

- the optimal assessment method was selected (a competency-based interview);

- an assessment sheet was developed to make it easier for the staff to give answers. The interviewees were asked to indicate which structural unit they worked in and the position they held (Table 4);

Table 4: competency-based Interview Assessment Sheet

№	Competence	Notes and comments	Competency level of candidate from 1 to 4
1	Analytical thinking		
2	Communication skills		
3	Personal effectiveness		
4	Leadership		
5	Making management decisions		

- The schedule and location of the interview were approved. The employees of the regional administration departments were selected (the department of administrative work and contract service; Department of State, Municipal Service and Anti-Corruption; Department of State and Municipal Services, Information Technology, Communications and Document Management; Department of Public Relations and Information Policy; Law department.

A competency-based interview was conducted (it is a type of structured interview which is conducted according to a pre-developed scenario. During a competency-based interview, real situations that a candidate had to face in the past are considered). There were three sets of questions on each competency. If there was a need, additional clarifying questions were asked (Table 5).

Table 5: list of procedures for assessing the competencies civil servants should master to work in high-risk environments (a partial list)

Competence	Competency Levels	Competency Assessment Issues
Making management decisions	**1 - Level of incompetence.** He does not know how to make decisions on his own, is not able to take responsibility for making a decision. Not ready to take the risk. When discussing alternatives, he demonstrates conformism, does not seek to defend his own position. Own actions do not agree with the actions of other people. **2 - Level of development.** Attempts to analyze the situation. In conditions of uncertainty, he prefers not to take risks. When making a decision, it takes into account the opinion of more experienced colleagues. Takes responsibility for the decisions made in case of full confidence in their correctness, in other cases strives to share responsibility among all members of the team. **3 - Level of experience.** Capable of making programmed decisions on its own, for which it has experience in making. Takes risks in exceptional cases. The presence of experience in decision-making uses as an argument in their favor when defending their position before management. Takes responsibility for a specific area of work. **4 - Skill level.** Performs a detailed analysis of the problem situation and the consequences of making a decision. Demonstrates risk preparedness if necessary. Regularly aligns his own actions with those of other people. When defending his own decisions, he is convincing, uses logical and understandable reasoning. Capable of coordinating the efforts of subordinates, demonstrates responsibility, controlling the timing and conditions of work.	Describe the situation in which you were responsible for the management decision you made? Have you been held responsible for the irrational actions of your subordinates? Give a concrete example from your own experience when it was difficult for you to make a decision? How did you come to this decision and what was the result?
Analytical thinking	**1 - Level of incompetence.** Decomposes the problem into a number of simpler tasks or actions without prioritizing them. Forms a set of tasks without establishing the order of their solution. It does not take into account the consequences of its decisions and the nature of their impact on the work. **2 - Level of development.** Establishes a causal relationship between different aspects of the situation. It can classify these elements, classifying them into one of the categories according to the criterion "for" and "against." **3 - Level of experience.** Identifies multiple causal relationships; sees a set of potential causes of the phenomenon, as well as a number of consequences of the action. Analyses the relationships between the components of the problem, foresees possible barriers to solving the problem, predicts the development of the situation. **4 - Skill level.** Carries out comprehensive planning and analysis. Uses a variety of analytical methods and procedures. Generates a number of possible alternatives to solving the problem and compares them according to the value criterion.	What are your personal goals for the coming year? How do you estimate the probability of their achievement? What are the barriers to achieving your goals? Give an example of the ineffective decision you have made? What are the reasons for making the wrong decision? What are the consequences of making the wrong decision? In the event of a similar situation, would you change your own actions in any way? Describe your own experience of successful performance of complex or urgent work in conditions of interference (lack of time, resources, inefficient work of subordinates or team members). What helped you to succeed and solve your problems?

Conclusions

Management activity is constantly associated with risk. Risk can be numerically measured. It is a potential possibility of an unfavorable outcome. It is vital to assess and predict risks in order to determine an appropriate management concept under the conditions of a changing external environment.

The authors of the article proposed two approaches to risk management that can be applied by local governments. According to a process approach, risk management includes a number of stages:

1) research and policy analysis with a focus on risk management;

2) risk analysis.

It is vital not only to assess the existing risks but also to analyze what brings about these risks. It turns out that under the same conditions the outcomes can be different. It is crucial to form a specific system to mitigate or eliminate risks. The final stage of risk management involves risk prediction and taking measures to compensate for losses.

According to a system approach, the main components of risk management at the regional level are:

- elimination of negative consequences;

- distribution of powers and responsibilities;

- completion of work ahead of schedule;

- data analysis;

- effective interaction;

- balance of income and expenses.

These components should be included in the job description of a civil servant.

Abstract

Nowadays organizations are facing a tremendous wave of change due to various factors such as globalization, technology development, unstable economic environment and specialized workforce. In this context, managers need a series of instruments for obtaining performance in the organizations they are leading, while at the same time, answering to the external and internal factors of change. In order to be able to harmonize these variables, continuous improvement (KAIZEN™) became a performance approach in the economy and motivated all the organizations to think about innovative ways of developing their activities. In this concern, organizations managed to adapt and evolve as customer demands are changing constantly by using continuous improvement techniques at all the levels of the organization on one hand and by keeping in mind that improving processes is a core value of their business on the other hand. Based on literature review and empirical evidence, the aim of this study is to provide an overview of the most used methodologies in continuous improvement, as well to describe the specific characteristics of a project approach within an organization, in order to develop a management system scheme for continuous improvement projects. The method used for this paper is a qualitative one and the purpose of the study is to contribute to an increased understanding of the benefits of such methods and techniques. The paper could be perceived as an initial step in continuous improvement implementation and thereby as a basis for further research studies.

Keywords: Continuous Improvement, KAIZEN™, Evolution, Performance, Management

Introduction

The sustainable success of an organization is supported by its own ability to meet the needs and expectations of all stakeholders: customers, shareholders, employees, and society in a long-term and in a balanced way. To develop such capabilities, it requires vision and leadership from the management team, but also the application of a coherent set of management tools that involve the entire organization in the continuous improvement of results.

Process analysis and identification of improvement opportunities, along with streamlining these processes, are essential steps that must be followed by all the companies that want to achieve operational performance, efficiency and profit.

Considering the above aspects, two research questions that are connected were designed:

RQ1: Which are the steps that need to be accomplished by a company in order to implement a continuous improvement process and,

RQ2: Which are the most used tools and techniques of CI that can be applied by companies?

Cite this Article as: Nicoleta CHICU And Andrei RADUTU "Overview of the Continuous Improvement Methodologies used in Organizations" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

To answer these questions, the authors used the literature as a support. The present paper aims to present an overview of the techniques and tools used in the continuous improvement processes in companies, to define the steps that such a project must contain, as well as the decision matrix through which an improvement initiative qualifies for implementation. Furthermore, the benefits of using continuous improvement techniques will be enumerated and how they can determine a competitive advantage of company in the market.

Literature Review

KAIZEN™ or continuous improvement (CI) or is a well-known way of achieving performance that is focusing on obtaining profit, while reducing costs of an organization or company (Imai, 1986). At the same time, Bessant and Caffyn (1997) is outlining that CI is a wide focused and sustained process that will bring innovation in organizations. Other scholars draw attention to the fact that CI aims to eliminate waste from all the processes and systems of an organization in order to carry out the activity more easily (Bhuiyan and Baghel, 2005). The same authors describe continuous improvement as a never-ending process that occur in every organization and which involves some or all of the company's employees by using specific methods and techniques in order to develop easier ways of working, eliminating waste from the process and leading to innovation.

Until now, KAIZEN™ has been implemented in fields of activity related to production and manufacturing (Gieskes and Broeke, 2000), but also in services (Emiliani, 2004), being considered a key to organizational competitiveness. The results obtained can be underlined in multiple ways by reducing the defect rates, response time, by increasing the delivery commitments, productivity, by involving the customer into product, by improving quality performance, employee commitment and motivation and by reducing costs (Hamid et al., 2018).

Through the CI methods, companies use their skills for achieving better results, build a culture of performance and also a personalized management system. While designing the start of their continuous improvement projects, the organizations are required to have a project plan which include a various information such as: the goal, procedure and process map, the people involved in the project and their function, the documentation needed.

Rus (2008) identifies the steps that a CI process must pursue, being composed of 4 main phases: phase 1: data collection, phase 2: identification and documentation of processes, phase 3: permanent supervision and adaptation and phase 4: process management and improvement. The last phase of the process (phase 4) will be developed in the figure 1, involving the following elements: monitoring the performance of success; determining the needs for improvement; launching and leading actions for improvement; formalization and generalization of savings. In this phase, it is necessary to constantly consider the feedback and the performance matrix, so that the process is carried out correctly. Moreover, it is important to mention that the improvement of a process can take place when it has the following characteristics: it is stable, standardized, has few or no exceptions and its improvement have not affected its performance.

Fig. 1: Generic steps for CI projects. Source: Rus, 2008

The present model was extended by adding the following information (Figure 2) – after determining the needs of improvement, it is necessary to collect the opportunities of improvement. The next step added to the model is the evaluation of the CI idea – solution, estimating the terms and savings, and the type of the project are determined.

Fig. 2: Generic decision matrix for CI implementation. Source: Rus, 2008

The following step is to analyze and prioritize – use a specific tool for tracking the progress and allocate the necessary resources. Going further, the team and the plan is created – identification of the project manager and project sponsor, assigning a CI coordinator and setting the execution times. Next, communication with stakeholders – discussion with impacted teams, with the process experts and teams are performed. The next step consists in implementation of the project – application of specific KAIZEN™ techniques, coaching, project monitoring and communication with stakeholders. The next phase is about control and calculation of actual savings – financial savings, savings as per volume of work divided by the total number of employees (FTE) and the quality check. The last step consists in closing the project and report the optimization – approvals from the project sponsor and financial analyst, closing the project in the system used for tracking.

Principles and tools of continuous improvement

While the need of a continuous improvement system in companies and organizations is essential, the road for obtaining performance is rather a more challenging way and it not necessarily follows a straight line, as the change process itself.

Most companies and management teams which are deciding to follow this path are encountering a certain problem or constraint, while not being able to identify other ways in which to reach their objectives. There are also few visionary managers, who understand the benefits of continuous improvement methods and techniques on the long term and their impact on their company's performance. They would rather choose to implement them for further developing the organization from top to bottom, while "developing the people for developing the organization" (Imai, 2012).

Therefore, in order for the change ("Kai" in Japanese) for the better ("Zen" in Japanese) to begin, as KAIZEN™ methods and techniques to be applied by everyone, everywhere and every day (Imai, 2012), the companies must be aware of the importance of a series of a series of principles and concepts. These will be further detailed and their application within every workplace, process and organization-wide represents the fundamentals for the continuous improvement implementation of methods and techniques.

"*Quality first"* represents an approach related to both quality as a result, but also a process. While in the first one, the quality of a product or a service could be very well measured, considering the external client requirements, the quality as a process is referring to every activity as a result of internal client-supplier relationships. Basically, it can be stated that the quality as a process implies that within all the actions necessary to build a product or a service, every person involved respects the following rules:

- ✓ "Do not accept a problem" – because in that specific workplace, the person performing the activity is an internal client for the previous activity or process, therefore she has certain requirements for the product or service in question
- ✓ "Do not create a problem" – it will not create any value
- ✓ "Do not pass a problem on" – the next workplace is an internal client and the product or service will have to also respect a series of requirements. Passing it on will involve additional costs and time for fixing it.

By following these rather simple rules, an organization could have a more in-depth focus on the quality, both from the result and process perspectives (Imai, 2012), (Kaizen Institute Romania, 2020).

"Gemba Orientation" is a principle involving the practical application of any continuous improvement method within the real place where the value is added ("Gemba" in Japanese), such as the production floor, in case of a manufacturing company, or the office in case of services company. In fact, the Gemba orientation principle represents the way to act in case any problem appears. The first step consists in establishing a KAIZEN™ Team and objective for that specific situation. Next step is going to Gemba and see for yourself the effects of that situation, not trying to solve it from a conference room, because it is not relevant and efficient. The third step is to verify data from the aspects that could have an influence on that matter. Continuous improvement methodologies recommend checking the causality with five factors: manpower, materials, methods, machinery, environment. Practically, a potential cause related to any of the 5 factors involved is very easy to be seen, simply by observing and collecting data. The fourth step of this principles is represented by the identification of any wastes ("Muda" in Japanese), variability of the process ("Mura" in Japanese) or excess ("Muri" in Japanese) that could be observed in the place the problem appeared. Finally, the fifth step consists in applying KAIZEN™ methods and techniques for taking the necessary measures

to solve the problem and add value for the internal and external client (Imai, 2012), (Kaizen Institute Romania, 2020).

"Waste elimination". Both a principle and a fundamental method of continuous improvement, waste elimination (Muda) creates a high degree of awareness regarding the client's requirements, by splitting the activities that a company has in two categories: value-added and non-value-added ones. As Taiichi Ohno – father of the Toyota Production System, where KAIZEN™ has its origins, stated, "the client is not willing to pay for any activity", the value-added activities are defined as the ones that the clients are willing to pay for and are generically represented by the ones which are transforming the product or service, considering their requirements (Ohno, 2013). All the other ones are non-value added and their costs are assumed by the company. At their turn, the latter could be perceived from two perspectives: activities which are clearly wastes for the company and should eliminated (e.g. waiting time, defects, etc.) and activities which although do not add value, there are necessary for the current process, depending on a series of factors. In time, by in-depth analysis, all activities can be improved, the objective being to have as much value-added as possible, in order to increase the organization's performance (Imai, 2012), (Kaizen Institute Romania, 2020).

"PDCA and SDCA Continuous Improvement cycles". Known also as "Plan – Do – Check – Act" and "Standardize – Do – Check – Act", the two improvement cycles are complementary and can be used by any team at every organization level. While the PDCA improvement cycle has as purpose to make a performance improvement of a process in time, the SDCA improvement cycle aims to eliminate the process variability and standardizing the best, simplest and safest method of operating, while also communicating and performing trainings to the team for everybody to apply it. Although most teams would think that it is essential to start with the improvement actions (using a PDCA cycle), the recommended way of considering to improve a process is actually to standardize the existent practices (by applying a SDCA cycle), in order to reduce variability and have a solid fundament to improve, rather than scattered performances with various root causes and solutions. After the process is standardized, when a team considers that it identified a better way of operating, it should implement a PDCA cycle, followed by a standardization of that specific best practice (SDCA) and the two are following each other without a limit (Imai, 2012), (Kaizen Institute Romania, 2020).

"Process and results" principle consists in the fact that organizations should acknowledge the fact that their performance could be perceived from two perspectives mentioned. Management teams of any level should be aware that every result is the effect of a process, and every process conducts to a result. Therefore, it is not sufficient to control just one of them, but to have an in-depth analysis of both perspectives, for having stable processes and therefore, good results (Imai, 2012), (Kaizen Institute Romania, 2020).

"*Integral system approach*" principle represents an overview of the activities, processes, and objectives perspective. The main benefit of the companies which are implementing continuous improvement methods is the focus on so-called "total system", rather than on "functional approach". In the latter one, activities and objectives are not very well linked between the departments and directions of the company, not following the client-supplier logic, the problem solving not being systematically approached and solved. The total system approach follows a very clear organizational objective in which every department knows exactly the specific activities and KPIs with which they could contribute, the problems are seen as opportunities and solved in multi-disciplinary teams, by involving all the specialized parties involved and more than that, the performance of the organization is always more important than the individual one (Imai, 2012), (Kaizen Institute Romania, 2020).

"*Developing the organization through people development*". This principle also implies an approach which is very common especially in Japan, where the "respect for people" represents still a central value of the country and of Toyota. As the main glance, a management team would be tempted to develop first the organization and after that being oriented to the people. In this concern, it could be stated that any company has to essentially focus on people development, and together with them to develop a performing organization (Imai, 2012), (Kaizen Institute Romania, 2020).

Results approach and performance

Once the awareness regarding the benefits of applying the principles aforementioned has been created within the management teams of the organizations, there are a series of continuous improvement methods that could be implemented, depending on the specifics of the problems encountered.

In order to maximize performance and create a culture of continuous improvement, a company could use various methods and techniques, which can lead also to building its own personalized management system.

Probably some of the most important ones that manages to solve around 80% of the problems of an organization, once they are used organization-wide are the "*Daily KAIZEN*™" ones (Kaizen Institute Romania, 2020). These methods are related to shop floor management and include the following:

- ✓ "*Waste Identification and Elimination (Muda)*": this method manages to make the teams aware of the wastes that they have within their workplaces and processes. There are 7 types of Muda, each of them being easy to observe and quantify: over-production (worst type of Muda because more products than necessary are manufactured or in a shorter time than needed, which leads to other types of Muda); inventory (stock of raw materials, WIP products, etc., or in other words costs that are blocked until the sale); waiting time (for a person or a machinery, which is leading to waiting time alongside the process); motion (people searching for various instruments, information, or who encounter heavy movements for operating the product); transportation (various transportation times and distances within the company and not towards the client); over-processing (more operations than necessary are performed, which involve additional costs or unstable process, which causes variability) and defects (any quality parameter that is not respected leads to additional costs, rework, etc.) (Imai, 2012), (Kaizen Institute Romania, 2020).

- ✓ "*Problem Solving Story*": represents the approach of solving problems in a systematic way. In this concern, every team learns how to identify, understand, search and successfully recognize the root cause, create a specific action plan to eliminate it, while also thinking ahead for preventing the problem to reappear (Imai, 2012), (Kaizen Institute Romania, 2020).

- ✓ "*5S Method*": being represented by 5 logical steps, the method is actually a management tool for optimizing the workplace. Its benefits could be seen in a greater quality, productivity, a better space organization, a more visual approach meant to identify any product, tool or information in a very short time and also in an increased moral and motivation for the team, which has the opportunity to optimally project its workplaces. Also, one of the most important benefits is the trust given by the 5S implementation to every client, partner or employee, due to the standardized and stable process. 5S is also a method which is the fundament for implementing other more complex continuous improvement tools (Imai, 2012), (Kaizen Institute Romania, 2020).

- ✓ "*Standardization*": is represented by the implementation of best, simplest and safest way to perform actions (e.g. operating, quality, communication, etc.). Therefore, standards assure the performance by being the fundament for training, operating and eliminating the variations within the processes (Imai, 2012), (Kaizen Institute Romania, 2020).

- ✓ "*Visual Management*": in accordance with the way people perceive information (over 70% being visual), this continuous improvement technique improves the way in which information, progress, KPIs and so on are communicated on three levels: workplace, process and system (organization). In order to optimally implement it, it is necessary to adapt the information for every level, in correlation with the information needed by the beneficiaries. Another characteristic of this method is that the content should be very easy to read and

understand (e.g. graphics, pictures, tendencies, color codes, etc.) and at the same time to manage the process with the data illustrated (Imai, 2012), (Kaizen Institute Romania, 2020).

- ✓ "*Team Management*": this method adds some best practices for team organization, defining the roles and responsibilities for every team member, what subjects should be communicated and under what specific format, etc. This technique also involves some other elements from the previously mentioned methods, such as a team board where the meetings takes place, standards, visual management aspects, specific to the teams (Imai, 2012), (Kaizen Institute Romania, 2020).

Subsequently, the more complex problems that companies encounter could be solved with some other categories of techniques such as: TFM (Total Flow Management) – a series of techniques studying the sequence of activities, operations and processes that a product or service goes through, from the moment of the raw material is received within the company until the delivery to customer (e.g. Value Stream Design, Levelling, etc.); TPM (Total Productive Maintenance) – methods used for monitoring, improving and operating the company's equipment and machinery, as an indicator of the efficiency and effectiveness (e.g. Planned Maintenance, Autonomous Maintenance); TQM (Total Quality Management) – techniques which ensure a good control of the quality and of the operations through which a product or a service is realized, as well as the measurement of the quality requirements of the internal and external customer, customer complaints analysis, etc. (e.g. Auto-Quality Matrix); TSM (Total Service Management) – continuous improvement methods having as aim to increase sales, marketing, innovation, etc. Of course, in order for the company to be competitive also in the future, it is essential to have a strategic and operational management orientation, by defining its mission, vision for 3 or 5 years, the strategic objectives, as well as specific KPIs for every department and leadership development (Imai, 2012), (Kaizen Institute Romania, 2020).

Conclusions

Coming back to the two research questions stipulated in the beginning of the paper, one could argue that implementation of a continuous improvement project and methodologies is rather a complex process, which requires changing the mentality, attitude, paradigms and habits of the entire organization, starting from the top management until the operators level. The continuous improvement techniques should be implemented after a Gemba evaluation, in which it needs to be established the real needs of the company, with a focus on improving the value-added activities.

As Masaaki Imai (2012), founder of Kaizen Institute stated: "There are three key factors to successfully implement KAIZEN™: Management commitment, Management commitment, Management commitment.", the top management teams should understand their essential role in leading the change towards a culture of performance and guide their teams to obtaining it.

Acknowledgment

The authors would like to thank to the project members and to the anonymous reviewers and editor for their valuable contribution. This work was co-financed from the European Social Fund through Operational Program Human Capital 2014-2020, project POCU/380/6/13/125015 "Development of entrepreneurial skills for doctoral students and postdoctoral researchers in the field of economic sciences".

Abstract

The development and improvement of new technologies are leading companies to re-think their methods, processes, and practices in several areas. In human resources management, this trend is also present. Despite this growing trend of integrating new technologies in human resources management, there is no systematic information on what is being done, how, and with what results.

This paper tries to fill this gap by presenting the results of a systematic literature review about the use of virtual and augmented reality in human resources management and development.

The results show that the use of these technologies is still in a very early stage, requiring more in-depth research, but the results so far are promising, namely in terms of the impact that this technology can produce in some human resources management and development processes. Future paths of research are also pointed out.

Keywords: Virtual Reality, Augmented Reality, Human Resources Management, Systematic Literature Review

Introduction

The current social and economic conjuncture, impacted by growing globalization and technological advances, demands more qualified and competent people. The ability to face constant changes in a market characterized by innovation is one of the most prominent demands. This context has consequences for organizations, especially for Human Resources Management and Development (HRMD), pressured to develop innovative tools and processes capable of guarantee higher levels of productivity and competitiveness (Oliveira and Oliveira, 2011; Stone and Deadrick, 2015).

Cite this Article as: Pedro FERREIRA, Viviana MEIRINHOS, Ana Cláudia RODRIGUES And António MARQUES "What Do We Know About Virtual and Augmented Reality Applications in Human Resource Management and Development? A Systematic Literature Review" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The growing movement for integrating new technologies in management processes is well illustrated by what has been called as industry 4.0 (Hecklau et al., 2016; Sivathanu et al., 2018; Shamim et al., 2016). It's well documented the importance of preparing human resources management processes for the integration of new technologies, such as Internet-of-Things, Big Data, and artificial intelligence in order capable of automating HR processes, thus promoting more efficiency.

Despite the growing volume of research on the topic of industry 4.0 with a focus on the role of technologies in management processes, there is still no systematic analysis of literature on specific technologies, such as virtual reality (VR) and augmented reality (AR), and human resources management.

As such, this work aims to contribute to the systematization of what has been studied and researched about the use of VR and AR in the area of HRMD, with a special focus on the potential application and impact of these technologies on HR processes. In detail, this research work aims to accomplish the following goals:

- Organize scientific knowledge already produced about the use of VR and AR in HRMD;
- Understand the potential use and impact of VR and AR in HRMD;
- Understand the process of applying VR and AR in HRMD;
- List the benefits of using VR and AR in HRMD.

To accomplish these goals a systematic literature review was conducted. The option for this method is mainly related to the need to identify, evaluate, select, and systematize the scientific available information about the topic.

VR is a computational technology, generated by one or more multisensory devices, that the user can control, manipulate and explore, interactively and in real-time, allowing the user to have an immersive experience in a different and alternative environment (Aguinis, et al ., 2001; Tori and Kirner, 2006). Through the use of 3D graphics or 360° videos, users experience an authentic computer-generated environment, creating a sense of presence that allows experiences such as walking on the surface of Mars, flying an aircraft, or observing the frescoes in the Sistine Chapel, without actually being there (Aguinis, et al., 2001).

Currently, VR systems have three main characteristics: navigation, interaction, and immersion. These systems allow users to move through three-dimensional computer-generated images, such as a walk through the corridors of a virtual museum, enjoying the exhibitions. But they also allow navigating through the environment, interacting with it, touching, lifting, manipulating, or moving objects (Kirner and Kirner, 2011). VR systems are often, but not always, immersive: immersion refers to the perception that the user is surrounded by the virtual environment, in which the stimuli of the physical environment are blocked through devices, such as the HMD, directing human senses to images, sounds, and objects to create a realistic virtual environment (Aguinis, et al., 2001).

While VR can be defined as a dynamic and reactive system with the virtual environment produced by a computer, transporting the user to a virtual environment (Choi, et al., 2005), AR is achieved when the user, inserted in the real world, interacts with elements registered three-dimensionally (Kivrak, et al., 2013). As such, AR makes use of real and virtual elements, allowing the creation of interaction between the real and the virtual environment.

In recent years, AR has registered a more accentuated growth, since it is used in different contexts, including but not limited to the training of technicians for complex tasks such as equipment repair and maintenance; the visualization of constructive elements or hidden objects; signaling environments or consulting complementary information in real environments; the prospection and graphical visualization of data by estimation in real environments; the consultation of data enabling their interaction and analysis; simulation; conferences with participants in remote meetings; entertainment and games; archeology with the possibility of total reconstruction of the object from the fragment found; teaching with the insertion of complementary or relevant information to the theory taught (Cardoso, Lamounier Jr, Kirner, and Kelner, 2007).

VR and AR are types of technology that offer several benefits to their users: the multisensory characteristics allow the visualization of objects in three dimensions, enhancing the experience of "being there"; this three-dimensional observation allows a better assessment of objects in terms of size, shape, and texture concerning the two-dimensional projection where it's harder to determine those same characteristics (Anthes, et al., 2016; Ausburn and Ausburn, 2014).

This type of technology is also advantageous for simulating dangerous tasks or jobs, avoiding compromising the person's safety, such as training in special rescue operations, training in work at height or with hazardous materials, and training in tasks involving expensive equipment or material; it is also useful to know or manipulate objects and products that do not exist or are hard to find (Bennett, 2009).

Time reduction is seen as another advantage in using this technology. Hou, et al. (2015), who dealt with the use of VR and AR in the industry, guarantee that the decrease in production time is directly related to the increase in companies' profits. Also Baird and Barfield (1999) show that the use of AR positively influenced the time needed to complete equipment assembly tasks when compared with the use of instruction manuals.

The use of VR and AR enables the reduction of errors, for example in the assembly actions done manually by the operators. The reduction of manufacturing errors makes it possible to reduce the time and resources needed to recover defective products and also resources and time spent on the manufacture of irrecoverable products (Hou et al., 2015). In 2017, Doshi, Smith, Thomas, and Bouras carried out a study to assess the possibility of increasing precision in tasks such as welding; the test was carried out in an industrial environment, in the automotive sector, with a significant increase in the precision of spot welding, using AR instead of traditional methods.

In HR, the advantage of using this technology can be useful in several processes: it can promote the company and the job with immersive experiences, allowing to change the way a job interview is conducted, immersing the candidate in different situations so that their behaviors can be observed and assessed (Muhanna, 2015; Van Krevelen and Poelman, 2010). VR also makes it possible to conduct a non-face-to-face interview, allowing the company to save time, reduce travel costs for the candidate (Van Krevelen and Poelman, 2010), as well as presenting the business environment, values , and culture of the company in an interactive way; it can also assist in the training of tacit knowledge among employees; to promote a more complete, simple and practical induction process, with information accessible at any time; and finally, it can promote the company's culture by enabling employees to relate and commit to the organization (Muhanna, 2015).

Bennett (2009) argues that the use of VR or AR makes HRMD processes more efficient, such as training, recruitment and selection, and the integration of employees, as it allows them to save time, material, and human resources management. Aguinis and colleagues (2001) add that the use of this technology can also have advantages over the traditional methods, made of questionnaires or interviews because the realism created by the software allows a realistic simulation of the work environment; the more immersive, interactive, and navigable the selection techniques, the greater the consistency and predictability of the candidate's performance in the job (Bennett, 2009).

On the other hand, there are some disadvantages to the use of virtual and augmented reality. Although nearly residual, Aguinis et al., (2001) and Anthes et al. (2016) refer to some physical problems reported by users after the immersive experiences such as blurred vision, headaches, disorientation, balance problems, drowsiness, excessive sweating, loss of appetite, nausea and vomiting. Despite being increasingly accessible and cheap, this type of technology still has a somewhat high cost. The initial investment in hardware and software and the need for constant updating requires some financial which is not within the reach of all companies (Aguinis, et al., 2001).

Method

The study consisted of a Systematic Literature Review (SLR) intending to identify, critically evaluate, and organize a synthesis of results and scientific evidence of available and relevant studies, related to the use of VR and AR in HRMD. As a previously planned method, SLR aggregates results from primary research using strategies that limit bias or random errors. (Cook, Mulrow, and Haynes, 1997; Kietchenham, 2007).

This method became relevant and popular primarily in Health studies since it allows researchers and practitioners to be up to date with the advancements in scientific knowledge, the direction of their main conclusions, and even future lines of research (Sampaio and Mancini, 2007). The method is used in scientific disciplines other than Health, since it is particularly useful for integrating information from a set of studies carried out separately on a specific issue, pointing out comparisons between coincident or opposite results, as well as identifying areas that do not yet have scientific evidence allowing exploration in future research (Moher, Liberati, Tetzlaff, and Altman, 2009; Sampaio and Mancini, 2007).

The SLR research protocol used in this study was based on the Cochrane Handbook for Systematic Reviews of Interventions (Higgins and Green, 2011) with a few adaptations as a result of the specificities of the area of this study. The protocol includes six steps: 1) formulation of the research question; 2) definition of objectives for the systematic review; 3) definition of inclusion criteria; 4) research strategy; 5) selection procedure; 6) procedure for data extraction and categorization, which are summarized in the following table:

Table 1: Summary of the SLR protocol

Research Question	How do VR and AR are being used in human resource management processes and practices?	
Goals for the SLR	Organize scientific knowledge already produced about the use of VR and AR in HRM and D Understand the potential use and impact of VR and AR in HRMD Understand the process of applying VR and AR in HRMD List the benefits of using VR and AR in HRMD	
Search strategy	Databases	Web of Science and Scopus
	Keywords	virtual reality AND human resources (and variations with initials) augmented reality AND human resources (and variations with initials)
	Parameters	Full-text; Years (all); Type of output (article or conference paper)
Selection procedure	Based on PRISMA Statement	
Data extraction and categorization	General data of the outputs were registered on an Excel database. Several categories of analysis were also defined and information collected: 1) publication year; 2) geographic location of the first author; 3) authors; 4) keywords; 5) type of study; 6) methods used; 7) impact of the technology; 8) development; 9) implementation; 10) assessment; 11) HR process; 12) resources used	

The selection process (stage 6) used in this study was based on the PRISMA Statement model (Preferred Reporting Items for Systematic Reviews and MetaAnalyses). PRISMA emerged as an evolution of the original QUOROM, to support researchers in improving, organizing, and presenting

meta analyzes, including SLR (Liberaty, et al., 2009). PRISMA consists of a checklist and a four-phase diagram that objectively and accurately materialize SLR (Liberaty, et al., 2009).

The categories used in the analysis can be divided into two groups. The first group reports categories related to the document description, such as publication year, keywords, type of study, and methods. The second group is related to the specific goals focused on the potential use and impact of VR and AR in HRMD.

Figure 1: Steps of the selection procedure

Findings

The final set of documents includes 21 research studies. The reduced number of results already reveals that this research topic is still understudied. Since 2007, the year of the first publication, this means that an average of 1.75 studies was published each year. However, when looking at the number of publications per year (figure 2), it is possible to identify a general growing trend, although not very consistent given the small number of publications. The year 2013 seems to mark the relatively steady growth of publications in this area.

Figure 2: Articles by year of publication

In SLR, keywords used by authors to categorize published research can also offer some clues on what is relevant in a specific research area (table 2). Not surprisingly, the research in this area is dominated by the keywords "virtual reality" (n=9) and "augmented reality (n=5), with some evidence of human resources management related keywords.

Table 2: Frequency of most used keywords

Keyword	n	%
virtual reality	9	7.6
augmented reality	5	4.2
virtual environments	2	1.6
human resources	2	1.6
knowledge management	2	1.6
smart glasses	2	1.6
countainers terminal	2	1.6
production	2	1.6

The geographical distribution of the studies was defined using the first author affiliation. Europe seems to show a greater interest in this area (n=10). However, this data should be taken carefully, since, except for 3 published studies, most research was published by several authors with different affiliations (table 3).

The categories "type of study" and "research methods used" offer an idea of the research approaches more common when studying the use of VR and AR in HRMD (table 3). The research is mainly empirical and qualitative in the approach. Even though mixed methods is a common option. Most studies focus on the application of some kind of solution to a specific context (e.g. 3D simulation as a training tool, VR-based firefighting training, or augmented reality applications in construction project

activities) which help to explain the empirical nature of studies. For the same reason, the preference for the qualitative approach may be anchored on the small scale nature of the context where the application was made.

Table 3: Descriptives of main categories

	n	%
Geo-distribution of documents		
Europe	10	47.6
America	5	23.8
Asia	5	23.8
Africa	1	4.8
Type of study		
Theoretical	6	28.6
Empirical	15	71.4
Type of methods		
Quantitative	2	9.6
Qualitiative	12	57.1
Mixed	7	33.3
Type of technology		
Virtual reality	17	80.9
Augmented reality	3	14.3
Both	1	4.8
Resources used		
Hardware	13	61.9
Software	3	14.3
No mention	5	23.8

Finally, the type of technology and the resources used. Virtual reality is the most common type of technology (n=17). Only one study used both technologies. This might mean that researchers find more potential in the application of virtual reality to HRMD than augmented reality. As to the resources used,

the large majority uses some kind of hardware. This may be explained by the fact that most studies are focused on virtual reality (which most of the times demands the use of some kind of hardware).

Figure 3: Most mentioned HRMD processes

The second part of the analysis aims to offer information about the focus of the research. Specifically, the HR processes that were involved and the connection of VR and AR with those processes.

Regarding the HR processes that were the focus of the research, "learning and development" is by far the preferred target of the connection between HR processes and VR and AR (figure 3). This preference may be explained by the long tradition of studies in the area of formal education and training (Psotka, 1995), but is also supported in the positive results that simulation, immersion, and virtual worlds have on learning outcomes (Merchant et al.i, 2014). In a lesser extent, other HR areas were also the focus of previous research, such as "health and safety", "stress management" or "performance management".

6The final group of data is related to the conclusions reported by the research. For this study, the information was grouped into four categories: development, implementation, assessment, and impact (table 4). The reason for these categories is related to the goal of this systematic literature review, namely understanding the process of applying VR and AR to HR, its use, and its impact.

Most studies report information about development, implementation, and assessment. Nevertheless, considering that the nature of the topic involves assessing if and how VR and AR can be an efficient solution in several HR processes, the number of studies that show no evidence of development, implementation, or assessment is quite high.

Finally, the large majority of the studies (n=17) offer information about the impact of VR and AR, which is evidence of the relevance of the study, to improve and expand the knowledge produced. Within the studies reporting information on impact, there is a consensus that VR and AR produced a positive impact on the HR process, with just one study reporting a negative impact.

Table 4: Information reported on the connection between HR processes and Virtual & Augmented Reality

Category of Analysis	Category definition	n
Impact	Evidence of the relevance of the study, with the aim of improving and expanding the knowledge produced	Positive n=16
		Negative n=1
		No evidence n=4
Development	Indicates whether the study reports on the detailed presentation of an application or project	Yes n=11
		No evidence n=10
Implementation	Indicates whether the study reports on the actual practice of an application or project	Yes n=13
		No evidencen=8
Assessment	Indicates whether the study reports on the verification of an application or project	Yes n=13
		No evidencen=8

Conclusions

The results of this systematic literature review point to several conclusions, alongside with some suggestions for future research in the field of the use and impact of VR and AR in HRMD. The results show a field of research that can be characterized as (1) under-explored, (2) immature, and (3) inconsistent.

The reduced number of publications (n=21) in the past 12 years with less than 2 publications per year, is a manifest low number when compared with other systematic literature reviews (see as an e.g. Macke and Genari, 2019; Tariq et al., 2016). Thus, the low number of publications reveals an under-explored field of study.

The field can be also characterized as immature. The year 2013 seems to mark the relatively steady growth of publications. This means that the study of VR and AR use and impact on HRMD is quite recent, still in its first steps. Also, the majority of studies are empirical and qualitative. The empirical studies under analysis are more concerned with assessing if the technology serves the purpose of HR processes or not than the development of the theory that supports future studies in the field. The preference for qualitative instead of quantitative studies is the result of the focus on the application of some kind of VR or AR solution to a specific context. However, it also reveals some immaturity in the field since the reduced number of quantitative studies prevents the generalization of results to a larger scale.

Finally, the study of the use and impact of VR and AR in HRMD can also be characterized as inconsistent. The number of publications, although with a relatively growing trend since 2013, is inconsistent with no publications in 2 years in a row (the years of 2011 and 2012. But more importantly, the imbalance between studies that focus on VR and AR technology's impact is quite pronounced.

Although this result is consistent with Tori, Kinner, and Siscoutto (2006), namely the use of VR hardware equipment on HR processes, the fact is that the field of study as a whole grows imbalanced.

The larger number of studies on training and development, alongside the lack of study of several HR processes, is another argument that supports some inconsistency in the field of study. Muhanna (2015) and Van Krevelen and Poelman (2010) described the HR processes where VR and AR can be applied, including recruitment and selection, induction and integration, training, employer branding (promoting the company's brand), organization culture and mission. This study revealed that only four processes were the focus of published research. Training and development stand out, followed by far by health and safety processes, performance management, and stress management.

The number of studies that show no evidence of development, implementation, or assessment is quite high, but the number of studies that report some kind of impact is quite high. We believe that this is a sign of under-exploration and immaturity of the area. The lack of information about development, implementation, or assessment reveals that there is no focus on developing and test new AR and VR solutions, but simply use what already exists and test if it works on the context of HR processes. This argument is further supported by the fact that papers are mainly empirical, looking to report the impact of VR or AR on some kind of HR process.

Tavares (2010) stresses that the search for new methods and strategies for organizations to differentiate themselves are increasingly important in the current job market. The use of VR and AR in HR processes can be considered one of those methods, due to their characteristics of immersion and interactivity. At first sight, the results of the systematic literature review could seem discouraging, showing an uninteresting scenario. However, this scenario offers several clues for future research.

Being an under-explored area, but with a high level of receptivity, particularly among practitioners, the novelty of possible solutions will certainly be welcomed in the scientific as in the practitioner communities. Nevertheless, it is important to offer robust studies, with a high degree of generalization and consistent results. This demands more quantitative studies, using larger samples. Additionally, it may be useful to introduce quasi-experimental studies allowing to compare the results of HR processes with and without the use of VR and AR solutions. This kind of approach will allow us to isolate the variables induced by the characteristics of the technology, and thus a better understanding of the real effectiveness of VR and AR in HR processes.

As seen in the introduction, VR and AR have some distinctive characteristics, offering different potential benefits. As such, it is important to develop a balanced understanding of both types of technologies. Another important research path is the comparative understanding of both technologies as alternative and complementary solutions.

The reduced number of studies reporting development, implementation, and assessment of VR and AR solutions shows one of the most important paths of future research. There is a need for the development of VR and AR solutions adjusted to the reality and constraints of HR processes. Although assessing the impact of existing solutions is crucial and a major contribution, the development of software that can take advantage of VR and AR technologies, without losing sight of the characteristics of HR processes is of utter importance.

Finally, there is much more in HR than learning and development. This is not to say that L and D is not a set of important HRMD processes. But from a holistic, integrated, and balanced perspective it is important to understand how VR and AR can be used in other less obvious areas. This path of research will certainly encourage more disruptive and innovative thinking and solutions, thus furthering knowledge in the effective application of VR and AR in HRMD.

Abstract

The purpose of the study is to generalize and systematize Russian management practice based on false scientific theories. The authors have analyzed such destructive influence processes as orientation of organizational policy towards post-industrialism, inefficiency of monetization of the economy, application of liberal theory, which led to reduction of state regulation of socio-economic processes and excessive openness of the national economy. It was identified that these concepts and ideas were brought to Russian state practice from the outside (in particular, they were recommended by the International Monetary Fund (the IMF). The authors have revealed that introduction of these false concepts weakened Russia's national potential.

Keywords: Management Practice, Post-Industrialism, Monetization Of The Economy, Liberal Theory, State Regulation Of Economy

Introduction

We follow the statement that destructive concepts introduce to the country's intellectual environment false scientific theories, paradigms, strategies that affect its public administration towards weakening defence-important national potentials (Rusrand, 2014). The introduction of a false theory leads to wrong management practices and destructive state policies that can affect country's potentials in negative way.

A destructive state policy in modern Russia can be illustrated by the following examples: orientation towards post-industrialism as the general direction of structural policy; inefficiency of the monetization process, application of liberal theory, which led to reduction of state regulation of socio-economic processes and excessive openness of the national economy. These concepts and ideas were brought to Russian state practice from the outside. In particular, they were recommended by the International Monetary Fund (the IMF).

Research Material and Methods

The purpose of the study is to generalize and systematize Russian management practice based on false scientific theories.

RASPOPIN "Impact of Implementation of Destructive concepts in Public Administration" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain

The theoretical basis of the research was formed by the conceptual provisions related to various aspects of public administration and presented in the works of Gillis M., Perkins D.H., Roemer M., Snodgrass D.R. (1996), Meier G.M. (1992), Ray D. (1998), Hess P., Ross C. (1997), Singer H. (1964), Skarstein R. (1997).

During the research process, there were used the following research methods for studying complex social objects: analysis, synthesis, comparison, analogy.

Research Results

In December 1990, the International Monetary Fund, the World Bank and the Organization for Economic Co-operation and Development prepared a report with the recommendations to the USSR towards taking a course of transition from a planned economy to a market economy (Rambler News, 2019).

According to George W. Bush's speech delivered in 1992

"… the revolution in these new States is a defining moment in history with profound consequences for America's own national interests. The stakes are as high for us now as any that we have faced in this century. And our adversary for 45 years, the one nation that posed a worldwide threat to freedom and peace, is now seeking to join the community of democratic nations … But if this democratic revolution is defeated, it could plunge us into a world more dangerous in some respects than the dark years of the cold war…"

In April 1992, the British Chancellor of the Exchequer and G-7 finance minister Norman Lamont raised the similar idea, 'If we miss this opportunity, then everyone will regret it later. The reform process in Russia must be made irreversible.'

The IMF proclaimed the end of the 'cold war' between East and West and the formation of a 'new partnership'. Russia became a member of the IMF on June 1, 1992. In 1992-1999, the IMF in total directed USD 22 billion to support economic reforms in Russia. The granting of loans was accompanied by the setting of conditions for the liberalization of the Russian economy. It was developed the Washington Consensus, an economic stabilization program and a radical structural reform. The Washington Consensus assumed privatization of public enterprises, introduction of market pricing, liberalization of foreign economic activity (requirements to eliminate export taxes on gas and oil; to abandon mandatory pre-customs examination of exported goods; to reduce import taxes), free convertibility of currencies, liberalization of international capital flows, and removal of currency restrictions, radical land and agricultural reforms. Information transparency became a prerequisite for Russia's admission as a member into the IMF (the IMF was provided with information about the Russian economy, its balance of payments, gold and foreign exchange reserves, etc.) (Smyslov, 2010).

The following foreign advisers played an active role in practical implementation of the economic policy developed by the IMF in Russia: A. Aslund, L. Balcerowicz, M. Dabrowski, J. Sachs., etc. Whenever Russia failed to fulfill the requirements, the IMF blocked the next tranche. The implementation of the Washington Consensus's prescriptions led to disastrous consequences, comparable to the consequences of the revolution and the civil war. The GDP in 1922 relative to 1913 was 57%, and then in 1998 its level was only 60% of the 1991 level. Even during the Great Patriotic War, the economy of the RSFSR grew at an average rate of 4.7% due to the relocation of industry beyond the Urals and the construction of new enterprises. During the Great Depression, the USSR demonstrated fantastic growth rates of 13-14%. In 1998, the production decline amounted to 46% of the 1990 level (Odintsov, 2017).

If starting from 1990 the average GDP growth rates had remained at 3%, the GDP would have reached USD 1625 billion by 2015 (its actual value for this period is USD 1176 billion). Thus, the total loss of GDP (we are talking about underproduction of GDP) is about USD 10.5 billion. I.

Lavrovsky gives a similar estimate of the damage – USD 8-10 billion. It was established about 43,320 enterprises during the Soviet epoch from 1922 to 1984, and about 30,000 were closed at the Yeltsin Era (Odintsov, 2017).

A theory of postindustrial society surfaced in the 1960s under the impact of development of post-industrial spheres of activity (Minakova, 2019). However, despite the emergence of postindustrial theory, in the United States, unlike in Russia, the growth of industrial production continued. The fact is that developed countries have moved their production to the territory of developing countries. This opened up the opportunity to freely use a low-cost labor and resources of developing countries, thus reducing production costs. However, in general, the material production of developed countries, redistributed throughout the world, not only did not decrease, but increased. It is the level of industrial development that largely determines the potential of the economy, the efficiency of using natural, material and labor resources.

It is no coincidence that, according to statistics, the countries with the largest GDP are at the same time the leading industrial powers (Table 1) (Visasam, 2020).

Table 1: Industrial production in 2016-2019

Industrial Production in 2016 (USD, million)		Industrial Production in 2017 (USD, million)		Industrial Production in 2019 (USD, million)	
China	8057	China	8414	China	8414
Taiwan	402	Taiwan	411	Taiwan	411
Hong Kong	30	Hong Kong	30	Hong Kong	30
the EU	4718	the EU	4873	the EU	4873
the USA	3500	the USA	3601	the USA	3601
India	2375	India	2590	India	2590
Japan	1332	Japan	1356	Japan	1356
Russia	1214	Russia	1250	Russia	1250
Indonesia	1176	Indonesia	1221	Indonesia	1221
Germany	1173	Germany	1210	Germany	1210
Saudi Arabia	777	Saudi Arabia	796	Saudi Arabia	796
Brazil	761	Brazil	757	Brazil	733

In terms of industrial production, China is an undisputed leader, its industry accounts for more than 40% of the modern economy. China's share in global ship production is 45%, mobile phones – 71%, footwear – 63%, personal computers – 91%, air conditioners – 80%, energy-saving lamps – 80% (Visasam, 2020). As for Russia, there has been a decline in industrial production. Moreover, in the 1990s some liberal-minded representatives of economy related ministerial offices stated the absence of necessity for industrial policy at all for a market economy. In particular, according to A.B. Chubais, a First Deputy Prime Minister of the Russian government (in his interview to 'Expert' magazine in August 1997), noted that 'we are not rich enough to have an industrial policy' (Viperson, 2003).

As a result, in 1999 Russia's industrial production index in comparison with 1991 decreased by almost two times (by 48%). In 1992-1999, the average decline was about 7% per year (Newsruss, 2000).

Inefficiency of the monetization process

Inefficiency of monetization of the economy has become a consequence of monetary policy of Russia. Material production must be provided with financial support. All other things being equal, the higher the level of monetization, the higher the rate of economic growth (Mirkin, 2011). In the Russian economy, the monetization coefficient is much lower than in developed and dynamically

developing countries (Japan – 1,184.87%, China – 198.04%, France – 91.96%, Germany – 89.06%, Russia – 43.22%) (Kravchenko, 2020).

In Russia, the demonetization of the domestic economy is carried out in order to suppress inflation. However, this statement is true only in relation to monetary inflation, which is impossible in Russia due to not having enough money in circulation. Unlike developed countries, where the money supply is excessive, Russia needs a remonetization of the economy, which would stimulate economic development.

The theory of radical liberalism, promoting reduction of state's share and excessive openness of the economy. To measure state participation in the regulatory processes of socio-economic system, the indicator of government spending as a share of GDP can be used (Fig. 1) (Kravchenko, 2020). At the same time, government spending becomes the main source of investment and stimulation of business activity. It has a special importance during the economic slowdown, when government spending serves as a lever for stimulating development.

In addition, countries with a high government spending as a share of GDP actively provide financial assistance to the social and cultural sector, environmental activities.

Fig. 1: Government spending as a share of GDP, %

There is a correlation between life expectancy and government spending as a share of GDP.

High life expectancy has been registered in countries with a high government spending on health care, development and implementation of population health programs.

Government spending has a direct impact on the state's human resources: with a share of government spending in GDP of 50-55%, the human development index reaches 0.82, with a share of government spending in GDP of 30-35%, the human development index does not exceed 0.59 (Sulakshin and Kravchenko, 2016). Countries with a high government spending provide their citizens with the best living conditions: standard of living, education, health care, law enforcement, recreation, etc. Given the fact that long-term economic growth and human capital have a strong correlation, cuts in public expenditure are unacceptable.

As for the excessive openness of the economy, it has increased the dependence of the modern Russian economy on exports, determined, first of all, by the sale of oil and gas. So, in 2019, mineral

products accounted for 53% of all Russian exports (Ru-Stat, 2020). Such a pronounced monospecialization of Russian exports leads to dependence on the global situation in the hydrocarbon market.

Conclusion

The results of introduction such wrong management practices as orientation towards post-industrialism, inefficiency of the monetization process, application of liberal theory have led to a significant lag of Russia from the leading countries in terms of GDP. Long before the emergence of neoliberalism as an economic school in 1944, K. Polanyi warned about the possible catastrophic consequences of the dogmas of market fundamentalism

"… to allow the market mechanism to be sole director of the fate of human beings and their natural environment, indeed even of the amount and use of purchasing power, would result in the demolition of society."

Abstract

This research, especially on the financial aspects, will be of particular interest in Russia, which, half a century after the USA, has faced the need to develop a rational transport policy, including the choice of adequate fiscal instruments for its implementation. The aim of this article is to trace the history of American twentieth-century transportation policy-making and financing. This study relies on methods of historical research and logical analysis. The general trend that determined the US transport policy in the twentieth century - the primacy of the automobile - remained more or less stable throughout the given period. However, the creation of a trust fund for more efficient and better targeted financing of road construction can definitely be regarded as a positive experience to learn from. Throughout the twentieth century, in their choice of priorities, American policy-makers almost always focused on the car as the dominant mode of travel. The priority goal of the transport policy was to provide traffic congestion relief. Unsurprisingly, this problem was addressed through heavy investment in road space expansion. To summarize the above analysis, we can point out the following three periods: 1920-1960s – Mass automobilization, conditions highly conducive to car use; 1960-1990s – Growing car dependence, suburban sprawl, conditions conducive to car use; 1990s – Development of multi-modal transportation, growing constraints on car use.

Keywords: Transport Policy, Transport Taxes, Trust Fund, Conducive to Car Use.

Introduction

The US was the first to encounter the challenges of mass automobilization, therefore, the development of its transport policy can greatly contribute to our understanding of state management of the transport sphere (Mayburov, 2017). This research, especially on the financial aspects, will be of particular interest in Russia (Mayburov, 2016), which, half a century after the USA, has faced the need to develop a rational transport policy, including the choice of adequate fiscal instruments for its implementation.

The car has become synonymous with American lifestyle and throughout the twentieth century the country's transportation policy was predominantly oriented towards car ownership (Congress, 1994). In short, its main priority was to ensure self-sufficiency of citizens and businesses in fulfilling their transportation needs. This, however, resulted in the population's growing car dependency while mass transit was deemed of secondary importance (Lyle, 1964). In this light, public transport came to be seen as an obligatory social service for low-income and vulnerable categories of citizens, socially useful but able to be kept fully self-sustaining through passenger fare revenues.

To gain a more in-depth understanding of the US transport policy and its fiscal instruments, we need to look at it in historical perspective. Historical analysis will bring to light the factors behind Americans' attachment to private car ownership and the far-reaching implications of this situation.

The aim of this article is to trace the history of American twentieth-century transportation policy-making and financing.

Our hypothesis is that the system of transport taxes in the USA evolved for a long time as a part of the general transportation policy.

Literature Review

There is a vast body of research on US transport policies. Most of these studies adopt the urbanist perspective on this problem. Those written in the first half of the twentieth century emphasized the advantages of mass automobilization and road expansion, although some of them also brought to light the problems associated with these trends and ways of counteracting their negative effects (Leontyeva, 2016).

The network of interstate highways connected the major metropolitan areas and made the country's territory better suited for automobiles, which soon started to be perceived as the only means of transport. This process also contributed to the deterioration of downtown areas and had a detrimental impact on the human character of the city (Vuchic, 1999).

It should be noted that the above-described negative effects resulted from the simplified approach to transport planning: highway engineers gave priority to cars and failed to recognize the growing significance of public transport in city life during the period of mass automobilization. This approach was based on the famous methodology developed by Wilbur Smith (1961), who helped design and build major parts of the Interstate Highway System. He argued that construction of interstates would guarantee a stable flow of positive effects and would have virtually no negative effects. All the parameters used in planning road infrastructure (number of lanes, capacity of parking lots, etc) were set through simple extrapolation in proportion to the ever-increasing car traffic. Laying bus routes along overhead roads was deemed infeasible because in the general traffic flow the bus could not compete with the car in virtually all of the parameters. According to Wilbur Smith, the only mode of public transport that could compete with the car was the metro or the underground railway system, which was planned and designed separately.

Only in the 1990s did the expert community become aware of the drawbacks of this simplified approach (and others similar to it). Anthony Downs, an expert from Brookings Institution, pointed out that in the USA, most transport experts were more interested in the benefits of further development of high-speed road networks in agglomerations rather than their disadvantages. The main accent in these studies was placed on predicting the growing traffic volume of motor vehicles. Mass transit was considered as rudimentary, as something that should be excluded from the general volume of transport work within the highway construction projects. Unsurprisingly, in this kind of planning, little attention was paid to the relative efficiency of alternative transport modes (Downs, 1992).

Moreover, some studies (Rendell, 1994; Burchell, 1999) pointed out the following repercussions of the policies adapting cities to car travel: downtown areas ceased to attract investment and there was an outflux of more affluent residents to the suburbs. As middle-class urbanites moved to the periphery, they were followed by businesses and trade centres. As a result, the value of the property in city centres fell dramatically. In contrast to wealthy suburbs, downtown areas started drawing poor, vulnerable and marginalized groups, which led to increased crime and disorder and deterioration in the quality of health care and school education (Cisneros, 1993). Consequently, downtown areas lost some of their tourist attraction.

It should be noted that the fiscal policy played an important role in the urban sprawl process. For a long time, owners of single family housing were entitled to a variety of tax credits and reliefs: they could deduct mortgage interest and property tax payments as well as certain other expenses from their federal income tax (Pucher, 1994).

Another group of noteworthy studies deal with the technological initiatives aimed at alleviating the problem of congestions. Since 1990, the US government has been spending massive funds (in total 40 billion dollars over a 20-year period) on the program 'Intelligent Transportation Systems' (ITS). One of the key figures behind ITS research and deployment was D. Gazis (1972). The purpose of this program is to increase the awareness of road traffic participants and improve the efficiency and safety of the whole traffic system with the help of information and communications technologies. Despite the obvious benefits of this program, it still tends to prioritize private vehicles since what it increases the traffic capacity of the road network, which leads to an increase in the total car traffic. At least these are the outcomes of the ITS program described by American researcher Harmut H. Topp (1995). In his critical review, he showed that the solution to major transport problems lies not in the sphere of high technologies as many hope but in the creation of intermodal public transport systems.

Methodology

This study relies on methods of historical research and logical analysis. We studied the evolution of transportation-related taxes in the US, described the key trends in the development of the US transport policy and drew general conclusions about the transformations in the funding of this policy.

In this paper we are not going to look into the specifics of transport financing in individual states but will consider the national trends in the transport policy throughout the twentieth century. Our study is based on the analysis of the relevant research literature and US legislation.

Results

Development of the US federal transportation policy

In the US, the rise of automobile ownership and production started in the 1920s: while in 1920 there were 33 vehicles per 100 households, in 1930, this figure grew to 77. By 1955, there was one vehicle per household. The Report of The Federal Electric Railways Commission compiled by Delos Franklin Wilcox dealt with the reasons behind the crisis in the transportation sector and stated that in the period of mass automobilization in the 1920s and 1930s, authorities on all levels concentrated on creating policies and patterns which favoured car use over other transport modes. The provision of public transportation was at the same time passed to private hands.

After World War II, the US transport policy became even more focused on road construction.

The Highway Trust Fund (HTF) was established in 1956 and served as a source of funding for the National System of Interstate and Defense Highways consisting of a federal grid network of one-way freeways. Although in the beginning the HTF was not supposed to provide financing for public transportation, the situation changed in 1970, after the Urban Mass Transportation Act was adopted. Another significant event happened in 1966, when the first freeway revolts occurred in major urban agglomerations as people became aware of the disastrous effect that the transport policy was having on their local neighborhoods.

Faced with the public protest, the government had to adjust the plans for constructing new highways in cities like San-Francisco, Boston, Philadelphia, and Washington and to make freeways bypass these agglomerations rather than cut through them. Moreover, the federal government recommenced financial support for public transportation projects. In the 1980s, Ronald Reagan cut the public transit budget significantly and all the revenues from the Fund were again allocated or road construction.

A dramatic shift in favour of intermodal surface transportation systems happened in the 1990s (Intermodal Surface Transportation Efficiency Act of 1991 – ISTEA. Public Law 102-240). The HTF provided regular funding for road construction projects on a cumulative total basis while public transportation systems had been starved for funding until the 1990s - these projects received funding only occasionally, in certain time intervals.

It should be noted that as a result of the fundamental change in the sentiments of the American elite in the 1990s, public transport started to be given more consideration. The Intermodal Surface Transportation Efficiency Act of 1991 (Public Law 102-240) and the Transportation Equity Act for the 21st Century adopted in 1998 (Public Law 105-178) were the two key laws, which reflected a serious shift in experts' and public opinion in favour of mass transit and in particular intermodal transport systems (Vuchic, 1999).

Development of Financing Mechanisms for The Transportation Policy

The mechanisms for financing road construction were established by the two related laws adopted in 1956: The Federal-Aid Highway Act and the National Interstate and Defense Highways Act. The Federal-Aid Highway Act authorized the construction of a 66,000 km-long network of interstate and defense highways and, to begin with, allocated 25 billion dollars from the funds of the Ministry of Defense. These funds were directed to the Highway Trust Fund (HTF), established by the second law. The Fund drew on the following key sources of revenue: the federal excise tax on gasoline (since 1993, it has been 18.4 cents per gallon on gasoline (4.86 cents/litre) and 24.4 cents per gallon for diesel fuel (6.45 cents/litres) along with taxes on tires and heavy highway trucks. Highway construction was financed according to the 90:10 federal-aid formula, where 90% came from the HTF and the states contributed only 10% of the total cost of road construction on their territories.

State fuel taxes were not abolished and continued to be used as a source of revenue for respective states. The average fuel tax rate for all American states is 31.04 cents per gallon of gasoline and 31.01 cents per gallon of diesel fuel. By and large, the federal and local fuel taxes turned out to be acceptable for car owners (13 cents per litre) and did not have a significant impact on the car usage decision.

The HTF proved to be a steady and predictable institutional structure, existing for more than a half of a century without any significant change. In 1982, within the HTF, two separate accounts were established – one for funding road construction and other surface transportation projects and the other, 'Mass Transit Account', for supporting public transportation (this account has a fixed source of revenue - 1 cent per gallon from the gas tax).

The system of trust funding of road construction led American car owners to perceive highways as a common good, maintained and developed exclusively at the expense of car owners themselves. This resulted in utter rejection of any other kinds of fiscal instruments which were seen as limiting access to this good.

The Interstate Highway System was declared complete in 1992 (the initial goal was to build the highway network in 10 years). The System comprises 77.5 thousand kilometers of road. With the initial cost of the project being 25 billion dollars, the final cost of the project was estimated as 114 billion (in the prices of 2018, 521 billion dollars). One of the reasons why the construction of interstates became so costly was the faulty (from the modern point of view) design choices made back then as highways cut through central cities instead of bypassing them. As a result, 20% of the network cut directly through the core of virtually every big city, which entailed further costs such as the costs of buying out urban land, construction of interchanges, and having to reconstruct the cities' central parts (the most illustrative in this respect are the examples of Seattle, Hartford and Huston). In many cases these changes were initiated by states and municipalities themselves, which were eager to reconstruct the downtown areas in their cities at the federal expense.

After the main network was officially completed in 1992, the project was continued and plans were made to widen lanes, expand and reconstruct the existing network. Most interstates remain toll-free (car owners pay for the use of the roads by contributing via the gas tax). The exception is a small share of toll roads (about 4.700 thousand km, or only 6% of the total network), which had been built prior to 1956 and were incorporated into the network in the late 1950s.

Parking pricing appeared when the first meter was installed in 1935 and underwent significant transformations throughout its history. It gradually transitioned from subsidized parking (the costs of

parking were covered by the territorial community, employer, seller, etc) to the system of parking fees paid by car owners themselves. Paid on-street parking was first introduced in downtown areas in the 1960s, which decreased the number of car trips to the centre of the city since the number of parking places was considerably lower than the demand for them and the price elasticity of demand was high (it was -0.52 for trips to work and -0.62 for other trips) (Lehner, 2019).

The disproportion between supply and demand led municipal authorities to increase the number of parking spaces. Eventually, municipal authorities in many American cities started to enhance the paid parking capacity of the downtown areas by building comfortable multi-level parking facilities. In the majority of large cities this caused a delayed negative effect as the car traffic to the centre increased. This happened because large parking lots created stable behavioral patterns as people started to associate car trips to the city centre with easy parking.

To sum up, the evolution of the US transport policy went hand in hand with the growth in car ownership although in different periods the transport and infrastructure system was to a greater or lesser extent conducive to the use of private vehicles. To summarize the above analysis, we can point out the following three periods/

Figure: Development of the transport system and financing in the USA

The general trend that determined the US transport policy in the twentieth century - the primacy of the automobile - remained more or less stable throughout the given period. However, the creation of a trust fund for more efficient and better targeted financing of road construction can definitely be regarded as a positive experience to learn from.

Conclusion

Throughout the twentieth century, in their choice of priorities, American policy-makers almost always focused on the car as the dominant mode of travel. The priority goal of the transport policy was to

provide traffic congestion relief. Unsurprisingly, this problem was addressed through heavy investment in road space expansion. In residential areas with dense housing such expansion inevitably led to changes in the structure of urban land use. Expanding freeways threatened the urban spaces meant for other purposes, primarily, for recreation (boulevards, parks and other green spaces). Downtown areas were drowning in car storage as garages and multi-level parking lots sprouted across the cities, arterial highways sliced through the middle of the cities, accompanied by multi-level junctions and roundabouts. The number of cars grew together with the increasing traffic capacity of the highway network. The construction of urban freeways spurred suburbization as more affluent urbanites fled to the suburbs, which also changed the cities' business and cultural landscape. The relocation of economic, cultural and social activity from the historical centre to the periphery further intensified the processes of suburban low-rise sprawl.

Consumer Attitudes Towards the Causes of Food Waste in Poland

Urszula SAMOTYJA

magdalena.ankiel@ue.poznan.pl

Abstract

Consumers attitudes toward food waste, which is an emerging challenge around the world, are affected by several factors and mechanisms. Recognizing them is key in order to implement effective preventive actions. The main aim of the study was identification, analysis and evaluation of consumer behavior on the food market in the context of wastage in households in Poland. The research method used was a direct individual questionnaire interview. The surveyed population constituted of consumers purchasing food products (N = 1145). The main cause of food waste (51%) is shopping without proper planning, which causes consumers to buy too many food products that are not consumed by the expiry date. The perception of excessive needs is also pointed out as a significant cause of food waste during shopping (37%). Moreover, consumers say that food waste is favorable when there is so-called 'buying just in case', which also leads to an excessive amount of food in households that is ultimately not consumed (23%). In the opinion of consumers in Poland, buying large packages of products also contributes to throwing away food (due to the unavailability of smaller packages or the economic benefits resulting from large capacity, 22%). The phenomenon of food waste (due to non-consumption) is obvious and acceptable to 11.2% of the Polish consumers. This study was supported by the National Science Centre (Narodowe Centrum Nauki), Poland [grant number 2017/27/B/HS4/00805].

Introduction

According to the Goal 12.3 of the Sustainable Development Goals (SDG) halving per capita global food waste at retail and consumer levels by 2030, and reduce food losses along production and supply chains, is an emerging challenge for the forthcoming decade (United Nations, 2015). The reason for this call as well as for other several interventions undertaken is the alarming data about the scale of food wasted around the world (FAO, 2019; Kim et al., 2019; Schanes et al., 2018; Parfitt et al., 2010).

Food waste at consumer level is affected by several factors and mechanisms (Schanes et al., 2018). In comprehensive literature review, Principato (2018) presented 'the household food waste journey' of which every phase including planning, provisioning, storing, preparing, consuming, and disposal is affected by psychological, social, situational, and demographic and socio-economic factors which influence wasteful behaviours. Gaiani et al. (2018) on the basis of a survey performed in Italy identified and described seven consumers' profiles related to food waste behaviour: (1) the conscious-fussy type, who wastes because food doesn't smell or look good; (2) the conscious-forgetful type, who forgets what is in the fridge or on the shelves; (3) the frugal consumer who tends not to consume fruits and vegetables and declares to waste nothing or almost nothing; (4) the exaggerated cook, who overbuys and overcooks, (5) the unskilled cook, (6) the confused type and (7) the exaggerated shopper. The study revealed that food waste is a complex and multi-faceted issue.

Wansink (2018) specified three distinct stages in which food is wasted by consumers: after purchasing (food was bought and never used), after preparation (food was prepared but never served) and after serving (food was served but never consumed). Consumers' practices and routines play a significant role in the wasting process. According to Bilska et al. (2020), arranging products in a refrigerator or cabinet in such a way so that products with closest expiry date are placed closest to the door is not commonly practiced in Polish households. One quarter of Italian consumers admitted that they make errors at the shopping planning stage. Moreover, 48% and 42% pointed to expiration and spoilage as a cause of food waste; 37% reported that food was in the fridge or cupboard for too long; some of them reported a lack of sensory attractiveness as a reason for discarding food (Gaiani et al., 2018). In the McCarthy and Liu study (2017), 34.4% and 19.9% of respondents discarded food because it has passed the 'use by' and 'best before' dates. According to Lanfranchi et al. (2016), the main reasons for food waste in Italy were leaving food out for too long (23%) and buying or preparing excessive amounts according to the needs (23%). Spoilage or expiration was often pointed out as a result of not consumption of food at the proper time (Bilska et al., 2020; Aitsidou et al., 2019; Lanfranchi et al., 2016; Quested, Ingle and Parry, 2012). Excessive safety concerns, uncertainty about product safety and date labelling or problems with finding or understanding information were also reported (Williams et al., 2020; Wilson et al., 2017).

It was proved that having high intentions to reduce food waste do not go in pair with waste reducing behaviour (Stancu et al., 2016; Visschers et al., 2016). This weak relationship between the intension to reduce food waste and acting upon it was described as the 'attitude-behaviour gap' (Vermeir and Verbeke, 2006). On the other hand, consumers consider throwing away food as improper behaviour which is associated with feeling guilty and uncomfortable (Waitt and Philips, 2016; Graham-Rowe et al., 2014; Radzymińska et al., 2016). It is probably because of this reason that they tend to provide underestimated values when asked to self-assess the extent of food waste in households (Falasconi et al., 2019). In In a study of Gaiani et al. (2018), 90% of respondents reported that they consider food waste a serious issue and would like to be more informed about its consequences, whereas 78% affirmed that they are worried about food waste. Nearly 58% of them would discard smaller amounts of food if they were charged a fee for wasted food, 35% – if they were informed about the monetary value of wasted food, 26% and 20% – if they were informed about the environmental and social impact (respectively). Reynolds et al. (2019) found that the majority of current interventions achieve only a 5–20% reduction in food waste. There is a need to gain more knowledge about the drivers of food waste at the consumer level. Recognising consumer attitudes is necessary in order to implement effective actions and best practices (Caldeira et al., 2019).

The main aim of the study was identification, analysis and evaluation of consumer behavior on the food market in the context of wastage in households in Poland. The specific research objectives concerned the behavior and attitudes of consumers with regard to the problem of food waste in households, in particular:

- identification and assessment of consumer attitudes in Poland towards the causes of the problem of food waste in households;
- identification and analysis of the relationship between consumers' attitudes towards the causes of the problem of food waste and segmentation variables such as gender, education, income level and the number of people in the household;
- analysis of the relationship between consumer attitudes towards the problem of food waste and the frequency of throwing it away in households in Poland.

The results of the study are part of an advanced research project on food waste in households and a continuation of publications in this thematic scope (Ankiel and Samotyja, 2020; Ankiel and Samotyja, *accepted paper*).

Materials and Methods

The empirical research on consumer behavior in the context of food waste was conducted using the face to face interview method in the period from April to May 2019. The research tool was an

interview questionnaire prepared and verified in piloting. The interview questionnaire contained 20 questions divided thematically into sections related to the determinants of consumer purchasing behavior on the food market in Poland, the perception and consumers' understanding of information on shelf life of food, consumer behavior related to food waste in households, as well as the perception of the health risk of food in the context of its waste in households. In addition, the interview questionnaire contained questions allowing for the identification of respondents in terms of demographic, economic and social characteristics (including sex, age, place of residence, material status, education, number of people in the household, and number of children in the household). Nominal and ordinal scales were used in the questionnaire, including the Likert scale, i.e. a bipolar interval scale, used mainly to measure consumer attitudes. The correctness and reliability of the construction of the questionnaire was verified by the Alpha-Cronbach test (the coefficient α oscillated between 0.7 – 0.9).

The research population was consumers declaring the systematic purchase of food products. The selection of the research sample (N = 1145) was carried out by the quota method (selection criteria: sex, age, and place of residence), which met the demand for maintaining the relative representativeness of the research population. In the process of the empirical data analysis, the IBM SPSS Statistics tool was used, which allowed the analysis of the results of the statistical description. The detailed structure of the research sample was presented in Table 1.

Table 1: Structure of the research sample

Variables		Percentage

Results and Discussion

Food waste is a major economic, ethical and social problem affecting the world community, and has been the subject of numerous social campaigns in recent years, especially in the context of malnutrition and hunger. According to the United Nations Food and Agriculture Organization (FAO), more than 820 million people across the globe are suffering from hunger (Fan et al., 2020). In this context, an interesting research problem is the identification of the frequency of food wastage by consumers in Poland and their attitudes towards the problem of wasting food in households (in particular towards the reasons for throwing away food that has not been consumed). The results of the study are presented in Figure 1.

Fig. 1: Frequency of throwing out purchased food in the households

Source: own research

As indicated by the results in Figure 1, the vast majority of consumers surveyed in Poland admit to having thrown out purchased food (88.5%). Only 11.5% of consumers declare that they do not throw out purchased food. A relatively high percentage of the surveyed consumers throw away non-consumed food with high frequency, at least once a week (25.2%, including 1.3% of those who throw food away every day). 31.5% of consumers in Poland waste food several times a month, and 31.8% only a few times a year. Therefore, it can be concluded that the vast majority of consumers Polish households do not consume food by throwing it away, and a quarter of consumers do so very frequently (i.e. at least once a week), which is highly worrying. It can be assumed that consumers who discard food are not able to plan shopping rationally, buy too much food in relation to consumer needs, and also have low awareness of the importance of the food waste problem (Ankiel and Samotyja, 2020). In turn, the reasons for wasting food in households in Poland indicated by the respondents are presented in Table 2.

Table 2: The reasons for wasting food in the opinion of consumers in Poland (%)

Reasons for throwing out food	**Total***	**Women***	**Men***
lack of thought / planning in shopping	51.0	51.1	50.8
we succumb to the illusion of 'excessive needs' when shopping	37.0	37.8	35.8
we buy more just in case	23.3	23.9	22.4
it is normal that some of the purchased products are not used	11.1	10.6	11.6
smaller packages are not available	8.0	7.0	9.3
larger packages seem to be more cost-effective	13.8	13.7	14.0

Source: own research

* values do not add up to 100% due to the possibility of choosing several answer variants

The surveyed consumers in Poland indicate '*lack of thought / planning shopping'* (51.0%) as the main reason for wasting purchased food in households. This means that ½ of consumers in Poland are aware that they do not plan their purchases properly, perhaps they do it under time pressure or impulse (low prices, sales promotions, etc.). The first step to changing habits (in this case leading to excessive, unplanned shopping) is to become aware of the problem, so it can be concluded that a large percentage of consumers are aware of irrational purchasing behavior leading to food waste. The second reason indicated by the respondents for wasting food is '*succumbing to the illusion of excessive needs when shopping'* (37.0%). During shopping (especially in large-format stores, with a self-service form of sales such as hyper, supermarkets or discount stores), buyers are subjected to the influence of various stimuli, such as price reductions, discounts, sensory marketing activities (aromas, colors, light), food products images (or their packaging) that influence their purchasing decisions (often irrational). Impulse buying results in up to 62.0% of supermarket sales and 80.0% of all sales in some categories of consumer products (Luo, 2005). Unplanned shopping increases the chances of impulse buying by 20% (Gaille, 2014). Additionally, research shows that consumers who purchase food under the influence of hunger buy more than they need (de-Magistris and Gracia, 2017). Bushong, King, Camerer, and Rangel (2010) found that the physical presence of an appetite for food items triggered hungry people to be willing to pay more for them. De-Magistris and Gracia (2016) pointed out that hungry participants were willing to pay a higher price premium for products when they predicted being both hungry and satiated in the future. Therefore, a rational approach to

the purchase of food products is particularly important, because – as shown by the results in Table 1 – consumers realize that they are under the delusion of excessive needs, which leads to excessive purchases, which in turn lead to non-consumption of the purchased food, i.e. waste.

Another major cause of food waste is '*buying more food just in case'* (23.3%). Consumers often buy food in bulk (in particular those on the run, under time pressure or consumers who prefer to make larger purchases less frequently); additionally they buy it in case of unexpected circumstances. It turns out, however, that such conduct leads to excessive stocks, failure to consume food within its use-by date and ultimately leads to it being thrown away, and thus wasted. This problem has become extremely common in the time of the global crisis caused by the COVID-19 pandemic. In most countries where COVID-19 cases have started to appear, consumers begin 'panic buying' products, including food products (especially products such as rice, pasta, jarred meals, flour) (Arafat et al., 2020). It can be assumed that if the study were conducted in 2020, the discussed cause of food waste would be indicated by a much larger percentage of the surveyed consumers. '*Buying food in larger packaging, which seems to be most cost-effective',* is another reason indicated by consumers for throwing away purchased food (13.8%). Large food packages (e.g., mayonnaise, ketchup in a 500 ml jar, 2 kg meat, 1 kg cakes) is an increasingly popular shopping option appearing in the portfolio of many food market companies. It should be clearly emphasized that the assumption of large packaging is profitability for consumers – the per 100 g price of a product in large packaging should be lower than the standard size packaging (Coelho do Vale et al., 2008; Ghosh, 2017). Consumers in Poland admit that they do not consume food in large packages in full – only ¼ of consumers declare that they consume the entire product. This is a very alarming phenomenon that leads to food waste (Authors, *accepted paper*).

It is highly disturbing that 11.2% of the surveyed consumers in Poland indicate that '*it is normal that some of the purchased products are not used'*, which means that the phenomenon of food waste (due to non-consumption) is obvious and acceptable to them and taken into account in the purchasing process. Although the percentage of consumers with such views is not high, nevertheless, in light of the malnutrition problem in the world, and also in regards to the implementation of the principles of sustainable development (including minimization of food and packaging waste), this percentage should be minimal. The smallest percentage of consumers in Poland claim that the reason for throwing away the purchased food is due to purchasing it in large packages, but because of an objective reason, namely: *'smaller packages are not available'*. It can be assumed that consumers decide to buy large food packages under the pressure of a strong need (e.g. the product is necessary to prepare a specific dish) and in the absence of a standard or smaller package. Perhaps they are not aware that the remaining food product can be used in a rational way (frozen, given to others) and not thrown away. When analyzing the indicated causes of food wastage depending on gender by consumers in Poland (Table 1), it can be noted that gender does not determine the opinion of consumers – the differences in the percentages of indications are less than 3 percentage points, therefore within the statistical error.

In summary, according to consumers in Poland, the main reason for throwing away, and thus wasting food, is the lack of planning the shopping and – which is related to this – being under the illusion of excessive needs when shopping. Additionally, consumers buy food in bulk, just in case. Thus, it can be concluded that irrational, excessive shopping is the key determinant of food waste by consumers in Poland. The current situation with the COVID-19 pandemic shows that there is no need to stockpile excess food. Unfortunately, from the point of view of both producers and trade intermediaries, striving to maximize the volume of purchases made by consumers is the primary motivator for their actions.

On the other hand, consumers should increase their awareness of the problem of food waste, or more precisely, strive to reduce the throwing away of food they have purchased rather than consumed by sharing food with others, processing or freezing food. Such behavior would reduce the problem of food waste even in the case of excessive shopping. The attitudes of consumers are a big problem, as they a priori recognize that it is normal that some of the purchased food products are not used. The above realizes how important it is to educate consumers, the aim of which would be to make them

aware of the problem of food waste in the world, and thus convince them that the priority should be consuming the purchased food in its entirety, and if that is impossible, implementing the principles of the sharing economy, i.e. giving food to others (friends, family).

In the context of identifying, analyzing and assessing consumer attitudes in Poland towards the causes of food waste, an interesting issue is their analysis in relation to the frequency of discarding non-consumed food. The results are presented in Table 3.

When analyzing the results included in Table 2, it can be noticed that:

- in the segment of consumers who agree that *''lack of thought/planning in shopping'* contributes to food waste in households, 56.6% discard non-consumed food with high frequency (daily, 2-3 times a week, once a week and several times per month) and 43.4% only throw away food a few times a year or not at all;
- in the segment of consumers who agree that *'we succumb to the illusion of 'excessive needs' when shopping'*, which contributes to food waste, 59.0% discard food very frequently, and 41.0% only throw it away a few times a year or not at all;

Table 3: The reasons for wasting food in the opinion of consumers in Poland, and frequency of throwing out food (%)

Reasons for throwing out food	**Frequency of throwing out food**					
	everyday	2-3 times a week	once a week	several times a month	several times a year	it doesn't happen
lack of thought / planning in shopping	1.4	7.7	15.1	32.4	31.2	12.2
	56.6				43.4	
we succumb to the illusion of 'excessive needs' when shopping	1.2	8.5	18.1	31.2	31.3	9.7
	59.0				41.0	
we buy more just in case	1.5	9.2	16.1	34.1	30.7	8.4
	60.9				39.1	
it is normal that some of the purchased products are not used	4.0	7.3	16.9	37.9	29.0	4.9
	66.1				33.9	
smaller packages are not available	0.0	6.8	11.4	30.7	38.6	12.5
	48.9				51.1	
larger packages seem to be more cost-effective	1.3	7.2	18.3	30.7	30.1	12.4
	57.5				42.5	

Source: own research

- among consumers who say that we *'buy more just in case'*, which contributes to food waste in households in Poland, 60.9% discard food frequently, and 39.1% do not throw away food at all or only a few times a year;

- in the consumer segment, according to whom 'it is normal that some of the purchased products are not used', as many as 66.1% of consumers throw away food very often / frequently, and only 33.9% throw it away several times a year or not at all;
- in the group of consumers who agree with the statement that *'smaller packages are not available'* (so they buy larger ones without consuming the whole product), less than half (48.9%) discard food very frequently, and 51.1% don't do it at all or only a few times a year;
- in the segment of consumers who agree that *'larger packages seem to be more cost-effective'* (so we buy them without consuming the entire product), 57.5% throw away food every day, 2-3 times a week, once a week or several times a month, and 42.5% only throw food a few times a year or not at all.

In conclusion, the largest percentage of consumers discarding non-consumed food is in the group that agrees that it is normal that the entire product is not used (66.1%). This is highly disturbing; meaning that this segment of consumers is unaware of the importance of food waste and malnutrition / hunger in the world. This segment requires education in terms of both increasing the awareness of the problem of food waste and changing consumption habits in households. On the other hand, the least often (or not at all) are consumers in the segment agreeing to the opinion that sometimes large packages are bought because smaller ones are not available – as many as 12.5% of consumers in this segment do not throw away food at all, and 38.6% only a few times a year. Interestingly, and at the same time definitely worth following – in the analyzed segment, none of the consumers throw away food every day.

Conclusions and Recommendations

The results of the study on consumer attitudes, opinions and awareness about the causes of food waste in households in Poland allowed us to draw many interesting conclusions, as well as formulate important recommendations. Half of polish consumers are of the opinion that the main cause of food waste is shopping without proper planning, which causes consumers to buy too many food products (in relation to both the types of products and the quantity of individual products) that are not consumed by the expiry date. According to consumers, the perception of excessive needs is also a significant cause of food waste during shopping (especially in self-service stores), which is actually related to the lack of proper shopping planning. Consequently, household consumers possess excessive amounts of food that they do not consume but throw away, generating waste. In addition, consumers say that food waste is favorable when there is so-called 'buying just in case', which also leads to an excessive amount of food in households that is ultimately not consumed. In the opinion of consumers in Poland, buying large packages of products also contributes to throwing away food (due to the unavailability of smaller packages or the economic benefits resulting from large capacity).

When analyzing the views of consumers on the causes of food wastage in households in Poland, the most disturbing fact is that about 11% of respondents admit that it is normal not to use all of the purchased food products, and therefore it is normal to waste this food. While in the case of poorly planned purchases or purchasing larger packages, it can be assumed that the excessive amount of food (which will not be consumed) results from unintended, unplanned, often impulse actions of the consumer. The attitude which assumes that not consuming some of the products is the norm is alarming. In view of the above, it is very important to take actions aimed at individual consumers in Poland, which, on the one hand, would increase their awareness of the problem of food waste, and on the other hand, would affect the purchasing habits (more rational, well-planned purchases) and consumption habits (not throwing away the purchased food – consumption in time / issuing to others).

As far as the causes of food waste are concerned, an interesting conclusion is that education significantly determines the attitudes and opinions of consumers. Consumers with lower education more often agree with the statements that the reason for throwing away food is to buy it in large packages and to buy larger amounts 'just in case'. On the other hand, consumers with the highest level of education agree to a greater extent with the statement that wasting food in Poland results from the lack of planning of purchases and succumbing to the illusion of excessive needs when

shopping. Thus, presumably, the least educated consumers may waste food, despite being guided by economic determinants of purchase (large, more profitable packaging); educated consumers, on the other hand, are not always driven by economic determinants, but they can waste food by making irrational, impulse purchasing decisions. Similar conclusions can be drawn by analyzing the attitudes of consumers towards the problem of food waste and the level of their income. As it turns out, consumers in the poorest households most agree with the statement that large packages appear more affordable (and unfortunately for this reason, non-consumed food is thrown away); in turn, consumers from the richest households support this view the least. Therefore, it can be assumed that the least educated, the poorest consumers waste food without really planning, guided by economic reasons. On the other hand, the most educated, well-off consumers in Poland waste food by making rash purchasing decisions. When analyzing the relationship between the size of a household and consumers' views on the causes of food waste in Poland, no clear, obvious relationships are noticed (only the most numerous households are partially distinguished by clearer attitudes towards the causes of the problem in question). On the other hand, when analyzing the attitudes of consumers towards the causes of food waste in relation to the frequency of throwing it away in households, it can be concluded that the largest percentage of consumers throwing away non-consumed food are those who agree with the statement that it is normal that the entire product is not used. As already stated, the above means that this segment of consumers is not aware of the importance of the problem of food waste in Poland and in the world.

In view of the above conclusions, it is worth formulating a few recommendations for consumers in Poland in the field of food waste. First of all, education is of key importance and should reach the consumer through various available communication channels (television, press, Internet, education in educational institutions, education through play in kindergartens) and make consumers aware of the importance of this problem. Additionally – points of sale should conduct information campaigns with the help of banners, displays, leaflets communicating the proper handling of the product, so as not to let it expire (which will involve the necessity to throw it away). In addition, manufacturers could use food packaging to convey content that increases consumer awareness of food waste. Social media are currently one of the key communication channels, so they should be used as sources of information on both the problem of food waste itself, but also ways of reducing this phenomenon (e.g. making rational purchasing decisions and proper handling of food in households so that the products do not expire, and ultimately are consumed).

The conducted research may be a starting point for further, in-depth research of households in Poland (e.g. ethnographic research), which would show not only consumer declarations, but also actual behaviors contributing to increasing or reducing the problem of food waste in relation to various product categories.

Abstract

Identifying consumer behavior related to the consumption of long and short shelf life foods as well as recognizing consumer preferences regarding purchases of food with different shelf life dates is important for effectively tackling the goals of sustainable development. In the article, the authors presented the results of a study on consumer behavior on the food market in Poland, with particular emphasis on preferences in the purchase of perishable and shelf-stable food with long and short shelf life dates. The research method used was a direct individual questionnaire interview; the surveyed population constituted of consumers purchasing food products (N = 1145). The results of the study indicate that in the case of shelf-stable foods, consumers prefer the ones with a long shelf life, and in the case of fresh food, consumers prefer the ones with a short shelf life. Moreover, consumers in Poland are characterized by a positive attitude towards discounted food with a short shelf life, only if they are convinced that they will manage to consume it on time. The research conclusions are a contribution to the discussion on the relationship between consumer preferences in the studied area and their handling of purchased food with short shelf lives in the context of sustainable development and reducing food waste. This study was supported by the National Science Centre (Narodowe Centrum Nauki), Poland [grant number 2017/27/B/HS4/00805].

Keywords: Consumer Behavior; Purchase Decisions; Food Labelling; Shelf life Labelling; 'Use By' Date; 'Best Before' Date; Food Waste

Introduction

Labeling plays an important role in communicating information about food products along the food chain. Food labels contribute to fair competition on the producers market and are one of the essential mediums through which consumers get knowledge about a food product and its properties. Thus, food labeling enables consumers to make informed choices, helps them formulate opinions or shape preferences, and influences consumer behavior (Bryła, 2020; Latiff et al., 2016; Ankiel-Homa, 2012). Most of the information supplied on food packaging is served on a mandatory basis. These include:

a) information about the identity, composition, mass or volume and other characteristics of the food product,
b) nutritionally relevant information – declaration of energy value and content of nutrients,
c) information related to the protection of consumer health and the safe use of a foodstuff, such as information on substances causing allergies or intolerances, alcohol content, special conditions of storage and use, and shelf life dating (Regulation (EU) No. 1169/2011).

It has been shown that information on shelf life is important for the consumer. The declared shelf life is one of the main functional attributes of food products considered at the stage of purchasing

decisions (Kumar and Kapoor, 2016; Ababio et al., 2012). The fact that the information occurs becomes the basis for building the trust of the buyer towards the product and the producer. The results obtained in the study of Djekic and Smigic (2016) show that the shelf life of products is the most important information on labels for Serbian consumers. The same observation was made in relation to Polish consumers (Olejniczak et al., 2016).

According to art. 2 Regulation of the European Parliament and of the Council No. 1169/2011 of 25 October 2011 on the provision of food information to consumers, food placed on the market should be labeled (with some exceptions) with the 'use by' date or the minimum durability date ('best before'). 'Use by' date generally is applied to fresh, perishable, microbiologically unstable products – consuming the product after its expiry date is associated with a health threat for the consumer (Regulation (EU) No. 1169/2011). In turn, the date of minimum durability indicates the date until which the food product retains its properties, provided that it is properly stored. After exceeding this date, the product does not become dangerous to the health of the consumer. In the case of many food products, exceeding the minimum durability date is only associated with quality losses, e.g. deterioration of the smell or texture, while the product is still safe and edible. Some foods are exempt from the need for shelf life labeling; these include fresh fruit and vegetables, vinegar, sugar, salt, and some alcohols.

Several studies proved that date information influences behavior at the point of purchase and consumption. Based on the label, buyers can select proper food products according to their preferences regarding shelf life. On the one hand, consumers prefer fresh and low-processed products, and on the other hand, they are looking for convenient food which can be stored for a long period of time or used under various conditions (Hertz and Halkier, 2017). Consumer preferences differ in this area (Stranieri et al., 2017). The study of Liem et al. (2016) showed cross-cultural differences in how consumers perceive short and long shelf life milk. Australians preferred the taste of pasteurized milk over the taste of UHT milk. This was in opposition to Chinese participants, who preferred the taste of UHT milk over the taste of pasteurized milk. Contradictory, they had a higher liking for any milk that was labeled 'short shelf life milk'.

It was shown that freshness dating determines consumer attitudes toward food which manifests itself in its acceptance or rejection. Based on freshness dates, consumers gain insight on how much time is left before the product's expiration. They are less willing to pay for perishable foods as they approach the end of their shelf lives and the perceived risk of a loss of freshness increases. It was found that consumers sort foodstuffs according to the remaining shelf life, causing the older product to remain on the shelf (Newsome, 2014; Chung and Li (2013). The results show that short shelf life is one of the main causes of food waste in the retail sector because there are problems with the sale of short-dated products resulting in their expiration (Bilska et al., 2018; McCarthy and Liu, 2016; Garrone et al., 2014).

This data is in line with a previous study conducted in Poland, where it was proved that the most common reason milk and milk products were wasted in retail was due to their exceeded shelf life (78% loss). It was found that the length of shelf life is the factor that most differentiates wasted products (kefir, pasteurized milk, buttermilk, cream, yogurt) from those which have a low waste share (e.g. packaged rennet cheese) (Wrzosek et al., 2014). As consumers are unlikely to purchase perishable foods with a shorter remaining shelf life if the price is the same as of those with a longer remaining shelf life, several strategies were developed (Aschemann-Witzel, 2018). Chung and Li (2013) suggest that food retailers can enhance customer satisfaction by offering an earlier but lower discount, and increasing it as perishable food items approach their expiry date, rather than a higher discount when the expiry date is imminent.

After-purchase freshness information also influences the consumer's value of the product and willingness to either consume or reject. Van Boxstael et al. (2014) noticed that consumers are more willing to reject food at the purchase decision than in a situation when the food had already been paid for. In the study of Altintzoglou et al. (2012) and Østli et al., (2013) freshness dating influenced the acceptability of cod fillet. In the study of Wansink and Wright (2006), dates influenced overall

acceptability, perception of freshness and healthfulness of yogurt. The contextual influence was showed in the study of Samotyja (2015) where freshness dating affected the overall acceptability of potato snacks, perception of crispness and oxidative flavor. These attributes were rated less favorably when the label suggested post-expiration. Rejection of food was reported not only after passing the date of minimum durability date (Williams et al., 2020) but also due to the forthcoming 'use by' and 'best before' dates. The strong effect of the freshness dating on the consumer decision was shown by Alongi et al. (2019). When the expiry date of salad stored was communicated, rejection increased from 12 to 27%. A lack of knowledge and consumer awareness, misunderstanding of the information on the label and excessive health concern were among the reasons cited (Zielińska et al., 2020; Gaiani et al., 2018; Manzocco et al., 2016).

The food market in Poland offers many product categories, which include both fresh products labeled with the 'use by' date and products marked with the minimum durability date (milk, convenience food, fruit, and vegetable products). It can be assumed that consumers do not correctly interpret the way these products are labeled with shelf life dates, which may result in wasting food labeled with the minimum durability date if the date indicated on the packaging is exceeded. Therefore, it seems reasonable to recognize consumer preferences regarding purchases of shelf-stable and perishable food and to identify consumer behavior related to the consumption of these products in terms of food waste. Most of the studies conducted in the past have presented shares of wasted foods regarding food categories but without making a distinction between perishable or shelf-stable ones. In order to design effective food waste prevention strategies, it is also important to recognize the influence of remaining freshness on the willingness to purchase food products with short and long shelf lives.

The main aim of the study was the identification, analysis, and evaluation of consumer behavior on the food market in the context of wastage in households in Poland. The specific research objectives concerned consumer behavior and attitudes regarding food products labeled with different shelf life dates, more precisely:

- analysis and evaluation of the frequency of food purchases by consumers in Poland;
- analysis of consumer preferences in the field of long and short shelf life foods;
- identification of consumer attitudes towards perishable and shelf-stable foods, including products that will soon expire and are therefore discounted.

In this study, long and short shelf life food was considered in two dimensions as presented in Fig. 1.

Fig. 1: The concept of long and short shelf life food

Source: own elaboration

According to microbiological stability, food products are represented by perishable and shelf-stable foods; this is reflected in different types of labeling ('use by' and 'best before' dating). Within each date type, there are products that are going to expire soon and others, with longer remaining shelf lives. We examined consumer behavior in the entire area presented in Fig. 1.

Materials and Methods

Empirical research on consumer behavior in the context of food waste was conducted using the face to face interview method in the period from April to May 2019. The research tool was an interview questionnaire prepared and verified in piloting. The interview questionnaire contained 20 questions divided thematically into sections related to the determinants of consumer purchasing behavior on the food market in Poland, the perception and understanding of information on shelf life of food by consumers, consumer behavior related to food waste in households, as well as the perception of the health risk of food in the context of its waste in households. In addition, the interview questionnaire contained questions allowing for the identification of respondents in terms of demographic, economic, and social characteristics (including sex, age, place of residence, material status, education, number of people in the household, number of children in the household).

The research population was consumers declaring the systematic purchase of food products. The selection of the research sample (N = 1145) was carried out by the quota method (selection criteria: sex, age, and place of residence), which met the demand for maintaining the relative representativeness of the research population. In the process of empirical data analysis, the IBM SPSS Statistics tool was used, which allowed for the analysis of the results of the statistical description. The results were presented in the form of structure indicators and position measures (mean, mode and median).

Results and Discussion

Consumer preferences in Poland in terms of shopping for long and short shelf life foods

The frequency of purchasing food products is related - as it can be assumed - not only with the frequency of consumption of these products, but it can also be assumed that it directly influences consumer behavior in terms of reducing / increasing food waste in households. An interesting research issue related to the possible disposal of purchased, not consumed food is the identification of consumer attitudes and preferences regarding the purchase of long and short shelf life foods. As you know, food products can belong to the short or long shelf life categories. In the case of products with a short shelf life, their timely, current, regular consumption is important in order to avoid throwing these products away due to (1) excessive purchases (2) expiry due to lack of consumption. Throwing out fresh food products as a result of not consuming them on time contributes to increasing food waste in households, which is a major ethical, economic and social problem. Therefore, it is important to diagnose consumers' preferences with regard to the purchase of long and short shelf life foods.

The results of the survey on consumer preferences in the above-mentioned scope in total and in terms of gender are presented in Table 1.

Table 1: Consumers' preferences regarding long and short shelf life foods (%)

Product categories	Consumer preferences when purchasing long and short shelf life foods	Overall	Women	Men
grain products	I purchase those with a long shelf life	24.3	26.3	21.7
	I purchase those with a short shelf life	26.2	28.4	23.5
	I purchase those with both a long and short shelf life	31.8	30.9	32.8
	I do not pay attention	16.0	21.2	11.6
	I never purchase	1.7	0.8	2.7
dairy	I purchase those with a long shelf life	24.6	23.6	25.4
	I purchase those with a short shelf life	31.6	28.7	33.9
	I purchase those with both a long and short shelf life	33.0	32.9	33.1
	I do not pay attention	7.9	5.3	11.1
	I never purchase	3.0	2.3	3.7
meat, lunch meat and fish	I purchase those with a long shelf life	21.5	21.8	21.4
	I purchase those with a short shelf life	39.9	42.0	37.0
	I purchase those with both a long and short shelf life	27.5	28.6	26.1
	I do not pay attention	6.8	4.4	9.9
	I never purchase	4.3	3.2	5.6
fruits and vegetables	I purchase those with a long shelf life	12.4	12.1	12.5
	I purchase those with a short shelf life	39.1	41.9	39.1
	I purchase those with both a long and short shelf life	25.8	26.2	25.8
	I do not pay attention	21.1	19.6	23.4
	I never purchase	1.6	0.2	3.3
fats and oils	I purchase those with a long shelf life	34.0	37.8	29.6
	I purchase those with a short shelf life	4.1	4.6	3.8
	I purchase those with both a long and short shelf life	27.0	26.8	26.9
	I do not pay attention	31.0	33.3	28.9
	I never purchase	3.9	6.4	1.9

Product categories	Consumer preferences when purchasing long and short shelf life foods	Overall	Women	Men
sweets	I purchase those with a long shelf life	26.5	28.8	23.6
	I purchase those with a short shelf life	2.4	2.9	1.8
	I purchase those with both a long and short shelf life	22.0	21.5	22.3
	I do not pay attention	40.2	40.0	40.6
	I never purchase	8.9	6.8	11.7
snacks	I purchase those with a long shelf life	22.9	25.5	19.7
	I purchase those with a short shelf life	4.5	5.2	3.7
	I purchase those with both a long and short shelf life	19.1	18.3	19.5
	I do not pay attention	38.9	38.5	39.6
	I never purchase	14.6	12.5	17.5

Source: own research

The results included in Table 1 allow us to draw the following conclusions about consumer preferences in Poland in the field of long and short shelf life foods:

- consumer preferences regarding the purchase of long and short shelf life foods depend on the food category;
- in the identified consumer segments (women/men) there are no clear preferences for the purchase of long and short shelf life foods within the studied categories of food products;
- in the case of grain products, the highest percentage of consumers declare that they buy products with both a short and long shelf life (31.8%), and the percentage of consumers preferring products with a long shelf life and short shelf life is essentially the same (24.3% and 26.2%). Thus, it can be concluded that for grain products there are no clear consumer preferences for the choice and purchase of long or short-life products;
- in the 'dairy products' category, a greater percentage of consumers declare that they prefer to buy products with a shorter shelf life, although the difference is only 7 percentage points (24.6% prefer long shelf life and 31.6% prefer short shelf life). A relatively large percentage of respondents (30%) believe that they buy dairy products with both short and long shelf life, while 7.9% do not pay attention to shelf life;
- when analyzing consumer declarations in relation to meat, lunch meat and fish, it can be noticed that almost 40% prefer fresh products with a short shelf life (which seems obvious considering the way these products are sold in retail outlets, as well as their distribution), although it is surprising a relatively high percentage of consumers who prefer to buy meat, lunch meat and fish with a long shelf life. Perhaps such a high percentage of indications results from the fact that meat in self-service stores is offered partially cultured, preserved and wrapped, and therefore marked with a long shelf life. On the other hand, fish is often sold canned or frozen, and lunch meat are sliced and packaged. 27.5% of the surveyed consumers declare that they buy meat, lunch meat and fish, both with a long and short shelf life;
- fruits and vegetables are a product category where consumers in Poland (both women and men) prefer a short shelf life (39.1%). This is quite obvious considering the features and properties of these products, as well as the way they are displayed and sold (by weight). On the other hand, 12.4% of consumers prefer vegetables and fruit with a long shelf life (as it can be assumed, this

applies to partially processed products, e.g. preserved, dried or frozen fruits and vegetables). A relatively high percentage of respondents declare that they buy these products, both shelf-stable and fresh (25.8%), while as many as 21.1% do not pay attention to shelf life. In light of the law in force in the European Union, fresh fruit and vegetables which have not been peeled, cut, or similarly treated, do not need to have a shelf life label (Regulation (EU) No. 1169/2011);

- on the other hand, fats are products for which consumers in Poland prefer a long shelf life (34.0%). A similar percentage of consumers declares that they do not pay attention to shelf life (34.9%), and only 4.1% prefer short shelf life fats. Most of the fats offered on the Polish market are products with a long shelf life, so the results of the study in this regard are not surprising;
- sweets and snacks are – similarly to fats and oils – food products, where consumers in Poland prefer a long shelf life (sweets – 26.5%, snacks – 22.9%). The percentage of consumers who prefer products with a short shelf life is small (sweets – 2.4%, snacks –4.5%) and probably concerns fresh products (e.g. sweet and salty pastries), which are offered in bakeries, confectioneries and stands in self-service stores. Half of the surveyed consumers do not pay attention to shelf life of sweets and snacks. Taking into consideration such a high percentage, it can be assumed that consumers simply assume a priori that packaged products have a long shelf life, while products (mainly 'by the pound') offered in confectioneries, coffee shops and confectionery stands have a short shelf life.

Consumer attitudes in Poland towards food products with long and short shelf life

Considering the fact that in the case of the analyzed categories of food products, consumer preferences regarding the purchase of long and short shelf life products are varied, it is worth checking what attitudes are represented by consumers towards products with different shelf lives, including discounted products. In other words – it is interesting to analyze the attitudes and beliefs of consumers towards food products with long and short shelf lives because it may contribute to the discussion on linking consumer preferences with their attitude towards e.g. discounted food that will soon expire (Bilska et al., 2020; Aschemann-Witzel, 2018; Chung and Li, 2013). Consumers' attitudes towards statements related to foods with different shelf lives were assessed on the Likert scale. The values on the Likert scale were as follows: a value of 1 meant 'I disagree', a value of 2 ' I mostly disagree', 3 'It is hard to say', a value of 4 'I mostly agree', and a value of 5 'I agree'. The overall results are presented in Table 2 in the form of position measures, i.e. classical and positional measures represented by arithmetic mean, mode, and median. Such an approach will allow for a slightly different look at the obtained attitude ratings using the Likert scale.

Thus, the values of position measures presented in the table 2 show that in the case of the assessed statements 1 and 7, we can unambiguously accept their acceptance by the respondents. We can make a similar conclusion in the case of statements 3 and 5. However, the values of measures (arithmetic mean and median) for statements 2, 4, 6 show that the surveyed consumers do not have clearly defined opinions about their attitudes. Therefore, their actual purchasing routines may vary or depend on the situation at the time of making a decision (purchase necessity, time pressure, lack of product knowledge, etc.).

Table 2: Consumer attitudes towards long and short shelf life foods (average, dominant, median)

Statements about food products with varying shelf lives	$\bar{x}$	M_0	M_e
1. When choosing shelf stable foods (such as rice, jam), I prefer those with a longer shelf life	3.96	4.0	4.0
2. When choosing perishable food products (such as meat, delicatessen products), I prefer those with a longer shelf life	3.12	4.0	3.0
3. I sometimes buy food, where the 'use by' date will expire within a few days	3.49	4.0	4.0

Statements about food products with varying shelf lives	$\bar{x}$	M_0	M_e
4. I buy food, where the 'use by' date will expire within a few days only if the price is discounted	3.16	4.0	3.0
5. I sometimes buy food, where the date of minimum durability ('best before ') will expire within a few days	3.39	4.0	4.0
6. I buy food, where the 'best before' date will expire within a few days only if the price is discounted	3.14	4.0	3.0
7. I buy discounted food that will expire soon only if I know I can use it on time	3.70	4.0	4.0

Source: own research

In order to accurately verify the identified attitudes of consumers in Poland towards food products with a long and short shelf life, an analysis of the total structure indicators, dependent on the gender of consumers (percentages of responses) was additionally carried out. The results are presented in Table 3.

Table 3: Consumer attitudes towards long and short shelf life foods and consumer gender (%)

Statements about food products with varying shelf lives	Grade*	Overall		Women	Men
1. When choosing shelf stable foods (such as rice, jam), I prefer those with a longer shelf life	1	2.4	7.4	3.2	1.4
	2	5.0		4.0	6.3
	3	19.7		17.8	21.9
	4	40.3	73.1	38.4	43.0
	5	32.8		36.5	27.5
2. When choosing perishable food products (such as meat, delicatessen products), I prefer those with a longer shelf life	1	13.5	36.2	15.2	11.3
	2	22.7		25.0	20.5
	3	19.1		16.8	22.3
	4	27.0	44.6	26.5	27.1
	5	17.6		16.5	18.8
3. I sometimes buy food, where the 'use by' date will expire within a few days	1	5.8	19.2	5.3	6.3
	2	13.4		14.1	12.1
	3	18.8		17.6	20.5
	4	50.7	62.1	50.2	51.2
	5	11.4		12.8	10.0
4. I buy food, where the 'use by' date will expire within a few days only if the price is discounted	1	9.3	33.1	8.9	10.0
	2	23.8		24.6	22.3

Statements about food products with varying shelf lives	Grade*	Overall		Women	Men
	3	20.5		18.1	23.6
	4	34.6	46.5	36.5	32.2
	5	11.9		12.0	11.9
5. I sometimes buy food, where the date of minimum durability ('best before') will expire within a few days	1	5.8	22.2	5.0	6.6
	2	16.4		16.5	15.6
	3	20.7		20.4	21.7
	4	47.3	57.1	47.3	47.5
	5	9.8		10.8	8.6
6. I buy food, where the 'best before' date will expire within a few days only if the price is discounted	1	8.7	33.9	8.1	9.8
	2	25.2		26.4	23.4
	3	21.6		20.4	22.9
	4	32.1	44.5	32.5	31.6
	5	12.4		12.6	12.3
7. I buy discounted food whose shelf life will expire soon only if I know that I can use it on time	1	6.5	16.7	5.3	8.0
	2	10.2		10.2	10.2
	3	18.4		16.0	21.1

	5	27.9		30.5	25.2

**1 – I disagree, 2 – I mostly disagree, 3 – It is hard to say, 4 – I mostly agree, 5 – I agree*
Source: own research

In conclusion, the detailed distribution of responses in the case of assessments according to the Likert scale of the formulated statements are presented in Table 2. In our opinion, they fully confirm the conclusions presented on the basis of the positional measures obtained for each of these statements (Table 3). The confirmation of the above may be the cumulative percentages of responses in the case of the value 4 (I mostly agree) and 5 (I agree) for statements 1 and 7, as well as the cumulative shares for the values 2 (I mostly disagree) and 3 (It is hard to say) in the case of statements 2, 4, 6.

Conclusions and Recommendations

The results of the study on consumer attitudes and preferences in Poland, with regard to perishable and shelf-stable food products with a long and short shelf life (within the categories studied), allows for the formulation of several interesting conclusions, recommendations for food market participants, as well as for setting the directions of further research in the given subject area. When it comes to consumer preferences regarding the shelf life of the food they buy, it turns out that in the case of

grain and dairy products, consumers do not have clear preferences for shelf life – they buy both long and short shelf life products. In turn, in the category of meat, lunch meat and fish, and fruit and vegetables, the vast majority of consumers in Poland prefer products with a short shelf life, which in fact seems obvious considering the way these products are distributed and sold. Fats, sweets and snacks are food products for which consumers in Poland choose mainly those with a long shelf life. In the context of the above, it is worth paying attention to the fact that food products with a long shelf life belong mainly to the category of shelf-stable, marked with the date of minimum durability, therefore exceeding the shelf life in their case does not require the disposal of the product, but should prompt the consumer to process, consume or donate this product to reduce food waste. On the other hand, consumers who prefer products with a short shelf life, which usually belong to the fresh food category, should be aware that these products should be consumed within the shelf life, otherwise they should be disposed of (thrown away), which generates the phenomenon of food waste. In addition, consumers should also be aware that perishable food, after reaching the 'use by' date, should not be consumed due to high health risk. Therefore, an interesting research issue is the connection of consumer preferences in terms of food purchases with different shelf lives in the context of identifying the knowledge and awareness of consumers in relation to food labeling types, understanding the terminology related to food labeling and handling food after expiration. The above will be another subject of research undertaken by the authors. Referring also to the preferences of consumers in Poland in terms of shelf life of food in connection with selected segmentation variables (gender, household size), it can be concluded that gender does not determine consumer preferences, while the size of the household determines them to a limited extent. As already mentioned – in the case of most of the analyzed product categories, consumers from one-person households prefer shelf-stable products to a greatest extent, and consumers from 5+ households mostly do not pay attention to the shelf life of the food they buy (thus preferring neither of the two variants of labeling). The study of consumer attitudes towards shelf-stable and perishable food products with short and long shelf life (which may additionally be overestimated) provided highly interesting conclusions in terms of cognition and application. The analysis of the values of the position measures (mean, mode and median) and the analysis of the structure indicators (the percentage of indications) allows to draw the following conclusions:

- in the case of shelf-stable food, consumers prefer the one with a long shelf life;
- in the case of fresh food, consumers prefer the one with a short shelf life;
- in the category of shelf-stable food with a short shelf life and perishable food with a long shelf life, consumers in Poland do not have specific attitudes and beliefs;
- consumers are not fully convinced about the purchase of perishable and shelf-stable food products, which are discounted due to their short shelf life.

A summary of the analysis of consumer attitudes towards shelf-stable and perishable food with a long and short shelf life is presented in Figure 2.

Most consumers correctly expect a longer shelf life from shelf-stable foods. Previous research has shown that consumer expectations differ in terms of expected durability. Some customers value longer shelf life, are ready to pay more for it, while others have a bad perception of long-life products, fearing their high price, as well as the presence of preservatives (WRAP, 2007). Perishable foods may be associated with freshness and naturality, therefore consumers may prefer more short-term perishable foods. Consumers in Poland are characterized by having a positive attitude towards food with a short shelf life, which is discounted only if they are convinced that they will manage to consume it on time.

The formulated conclusions also provide recommendations for participants of the food market in Poland (mainly sales units and individual consumers).

FOOD PURCHASING PREFERENCES OF CONSUMERS IN POLAND		
PERISHABLE FOODS LONG SHELF LIFE	→	45% CONSUMERS
PERISHABLE FOODS APPROACHING EXPIRATION	→	62% CONSUMERS
PERISHABLE FOODS APPROACHING EXPIRATION AND REDUCED PRICE	→	47% CONSUMERS
SHELF-STABLE FOODS LONG SHELF LIFE	→	73% CONSUMERS
SHELF-STABLE FOODS APPROACHING EXPIRATION	→	57% CONSUMERS
SHELF-STABLE FOODS APPROACHING EXPIRATION AND REDUCED PRICE	→	45% CONSUMERS
APPROACHING EXPIRATION AND REDUCED PRICE + SOON CONSUMPTION	→	65% CONSUMERS

Figure 2: Consumer attitudes and preferences towards perishable and shelf-stable food with long and short shelf life

Source: own study

First of all, consumers should be educated about the specificity of the food category (perishable foods / shelf-stable foods). In particular, it is important that consumers are aware of how to properly deal with perishable / shelf-stable foods during the shelf life and after the expiry date. Due to the fact that consumers are not fully convinced about the purchase of perishable / shelf-stable foods, which are discounted due to the short shelf life, retail distribution channels (mainly large self-service stores) should conduct extensive promotional and educational campaigns to make consumers aware of the legitimacy of buying food with a short shelf life at a discounted price. Consumers should be aware that such action reduces food waste and generates less waste that must be disposed of. Additionally, buying short shelf life food at a promotional price is economically attractive and gives consumers a sense of savings. On the other hand, it is important that the promotional and educational campaign also raises awareness of the issue of differentiating food labeling systems with the use of durability dates, and thus indicates the right ways of dealing with products that will soon expire. In other words, consumers should be aware that perishable foods must be consumed by their 'use by' date and that shelf-stable foods may be consumed after their 'best before' dates) (it is highly unethical and irrational to throw them out). In addition, it is important that retail stores properly display and inform consumers about the possibility of buying food that has been discounted due to the very short remaining shelf life. Promotional information encouraging the purchase of discounted food should be placed next to store shelves with a given product category as well as directly next to the products. It is also effective to separate special promotional zones (e.g. store shelves) or baskets with discounted food, additionally supported by promotional messages encouraging to buy, not waste food. It can be assumed that for many consumers from the economically sensitive segment (e.g. seniors) such purchases may be an attractive product offer, as well as for consumers following the concept of 'zero waste' or the concept of sustainable development.

It should be emphasized that the conducted research and the conclusions drawn from it have limitations related to the adopted research procedure (declarative research) and do not describe the real purchasing behavior of consumers in Poland, but only their declarations regarding purchasing attitudes and preferences. Nevertheless, they provide valuable insights and recommendations, and fill the research gap in the field of consumer preferences as to food shelf life in Poland (the subject research on a representative research sample was not carried out earlier). In addition – as already mentioned – the results and research conclusions contribute to the discussion on the relationship between consumer preferences in the studied area and their handling of purchased food with short shelf life in the context of sustainable development, as well as the issue of reducing food waste.

Abstract

This paper presents an author's critical analysis of the existing electronic portfolios of university students for the availability of opportunities to implement the continuous development of a student and graduate. The authors provide a conceptual basis for further research in the field of student e-portfolio and its elements. This paper reveals approaches to the interpretation of the concept of "portfolio" and its main elements, reflected in scientific research and regulatory documents, and also provides the results of a desk study of approaches to the formation of electronic portfolios of 31 universities in the Russian Federation. The results of the analysis show the state of scientific knowledge about the context of the electronic portfolios use in universities. The authors conclude that it is necessary to study the student's reflective assessment of the stages of the formation and development of a portfolio. In addition, the implementation of the principle of portfolio continuity throughout professional life should become one of the priority tasks of future research. The authors also note the importance of organizing employers' access to portfolios as stakeholders of the educational process in higher education. As a result of the work carried out, the authors presented their vision of the structure of the student's electronic portfolio blocks with its possible integration into the digital competency platform.

Keywords: Higher Education, Student, E-Portfolio, Supra-Professional Skills, Employment.

Introduction

The modern world situation, economic instability, dynamics of technological development and sustainable development trends are reflected in the specialist's labor market. The professional community puts forward more and more serious requirements for job seekers. There are some contradictions between the preparation of students at the university and the requirements that employers impose on them. Confirmation is the foresight projects of the Agency for Strategic Initiatives "Education 2030" and "Competencies 2030", which provoke heated scientific discussions in the country (About the Education 2030 project, 2020; Luksha, 2012).

It should be noted that it is not only the availability of basic vocational education that makes a specialist competitive in the labor market, but also objective evidence of possession of certain skills in the educational and in the future professional sphere. This is about supra-professional skills. Experts point out that the difficulty of finding a job for students and graduates is primarily due to their lack of an adequate level of development of professional and supra-professional skills (Pereira, 2013). The importance of supra-professional competencies / soft-skills of modern graduates for the labor market is emphasized by researchers (Frey & Osborne, 2017; Pesha, 2020). Employers are interested in getting quick and transparent information about the applicant. That is why today the appendix to the resume is

relevant not only to social networks, but above all to the portfolio of a potential candidate.

Portfolio (English Portfolio - "portfolio"; French porter - to state, formulate, carry and folio - sheet, page) in the dictionary literature is defined as "a portfolio, a folder for important matters or documents" or "a collection of documents, samples of work, photographs that give an idea of the offered opportunities, services of the company or specialist. " Portfolios developed by students were first introduced in the 1960s. Later, researchers define it as a form of monitoring and assessing student achievement, its characteristics, evidence of progress in learning based on results, efforts made, materialized products of educational and cognitive activities, including self-esteem (Golub, Churakova, 2005). Portfolios in different countries of the World are part of the assessment of individual educational results of a student and a tool for broadcasting the achievements of graduates to future employers. Unfortunately, for a number of reasons, Russian universities have limited or no access to student portfolios for employers. These limitations act as an obstacle to the rapid and effective communication of the stakeholders of the educational process. In addition, a university student's portfolio can become an effective basis for the development and implementation of a continuous educational trajectory for a student, graduate and employee of the organization.

The key goal that the authors set themselves is to analyze the existing electronic portfolios of university students for the availability of opportunities to implement the continuous development of a student and graduate. The authors set themselves the task of developing a conceptual basis for further research in the field of a student's e-portfolio, as well as defining its basic elements as part of the future digital competency platform. In this article, the authors reveal approaches to the interpretation of the concept of "portfolio" and its main elements, reflected in scientific research and regulatory documents, and also provides the results of a desk study of approaches to the formation of electronic portfolios of 31 universities in the Russian Federation.

The approaches analysis to defining the essence and elements of students' portfolio

Conventionally, there are three types of portfolios in the scientific literature.

The first type is a paper or printed portfolio (traditional form) - a folder with supporting documents, and for creative professions these are photographs, sketches, drawings, etc. This type of portfolio has limited capabilities.

The second type is an electronic portfolio. It is assumed that all of the above is stored in digital format or recorded on an electronic storage medium.

The third type is web or network portfolio. This is a presentation of the applicant in the Internet space: social networks, personal website, business card website, etc.; assumes maximum availability of information and flexibility of the structure.

The portfolio system in Russian vocational education is no longer new. In Russian pedagogical practice, the portfolio began to be actively used in the late 1990s. New methods have come for the presentation of achievements. In connection with the transition to the Bologna system. In this system the emphasis is on the transparency and comparability of competencies, as well as on increasing the role of students' independent work and their activity. If earlier the portfolio was used by people of creative professions to demonstrate and confirm their professional level, now it is a mandatory attribute in almost any field.

Thus, today the portfolio is a multifunctional tool for external assessment and self-assessment of individual achievements of students, which allows you to consciously and reasonably predict and implement an individual educational route. For example, A.I. Masalskaya, N.G. Gomboeva, M.M. Dubtsova, I. V. Starchakova, N.V. Potekhina defines a portfolio as a form or component of authentic assessment of educational and scientific results in terms of a product created by a student (Gomboeva et al, 2017; Masalskaya, 2014). N.G. Gomboeva et al. (2017) Note that a portfolio as a career planning

technology contains a package of documents in electronic or paper form, which reflects the most significant achievements (personal, professional, social, etc.) of a student or specialist. The cumulative effect of the portfolio contributes to increasing the motivation of students to obtain educational, scientific, creative and sports achievements, which will further increase the competitiveness of the future graduate in the labor market. G.B Golub and O.V. Churakova introduces the concept of “model portfolio function”, which consists in building a model of an individual educational route for each student (Golub, Churakova, 2005).

Abroad, sufficient experience has been accumulated in using the portfolio, there are national and international organizations engaged in the study of electronic portfolio technology (the Euro Portfolio Consortium, based on EIfEL), the International Association for the E-Portfolio (International Coalition for Electronic Portfolio Research, and others) For example, the main goal of the Europortfolio Consortium is to increase the competitiveness of European education, the International Association unites specialists who study the impact of the e-portfolio on various aspects of the educational process and the educational achievements of students (Kravets, 2013, pp. 45-48). Abroad, the most often realized "portfolio of career advancement".

An electronic portfolio in world practice is a part of a promising strategy for the 21st century - e-learning. There is no unequivocal understanding today of the content of an electronic portfolio and the requirements for it. For example, the Instructional Management System Global Learning Consortium (IMSGLC) defines a portfolio as a collection of student personal data representing achievements, goals, experiences, and other personalized information that a student can provide to an educational institution, employers, and others. In this case, the portfolio acts as an “intermediary” between the student, the university and the employer.

A broader understanding of the e-portfolio is given by the European Institute for E-Learning (EIfEL) and defines as “a collection of reliable and diverse data, selected from a large archive, demonstrating the achievements of an individual (or organization) over a certain period of time, selected on the basis of reflective analysis and presented by one or several target audiences, depending on the specific goal pursued by the individual (or organization) ”(Ravet, 2007). It is based on a reflective assessment of the student's achievements, which are demonstrated to the interested party. So S. Ravet (2007) focuses on the reflective learner who develops a portfolio and uses or evaluates their assets in a specific context. However, it should be noted that back in the early 2000s, K. Zeichner & S. Wray urged to move away from the conclusion that the portfolio promotes more reflection, and to start considering the “nature and quality” of this reflection (Zeichner & Wray, 2001).

As M.M. Alajmi, e-Portfolios help students determine the results of their progress and give them a sense of their progress through comments received from faculty, administration or fellow students. This feedback gives students a clear understanding of their weaknesses and how to improve their work (Alajmi, 2019). D. Scully, M. O'Leary, M. Brown argue that study portfolios are suitable for the development and assessment of integrated cross-subject knowledge and general skills / attributes (e.g. critical thinking, creativity, communication, emotional intelligence) rather than focusing solely on disciplinary knowledge in specific subject areas. This is of particular interest in the higher education context, as universities and other parts of the sector face increasing demands to bridge the perceived gap between what students are learning and what is valued by employers (Scully, O'Leary & Brown, 2011).

The claim that today's college students are “digital natives” and therefore adapt easily to e-portfolio software, as argued by S. Bennett, K. Maton & L. Kervin (2008) and P.A. Kirschner & P. DeBruyckere (2017), is erroneous. Students need to be empowered to choose a convenient structure for portfolios, significant artifacts and learning outcomes, and they need personalized support in mastering the software (Bennet et al, 2008; Kirschner & DeBruyckere, 2017).

Bolliger D.U. & Shepherd C.E. in their study of the use of a portfolio in online programs, which involved creating an electronic folder for sharing documents, noted that 85% of students had an increased desire to learn (Bolliger & Shepherd, 2010). Working on the portfolio helped students assess

their own progress. Here it is necessary to note the point of view of D. Scully, M. O'Leary, M. Brown, who believe that high learning outcomes are achieved through competent integration of the content of an electronic portfolio into the educational context (Scully, O'Leary & Brown, 2011).

A. V. Korotun and Nikolaeva M.A. rightly note that "higher educational institutions must comply not only with the requirements of the state, which is undoubtedly reflected in the professional standard, the mission of which is to remove the contradictions between educational standards and the real requirements of the industry", but also they have to meet the labor market requirements (Nikolaeva, Korotun, 2018, P.70).

Today, each university collects information about its students in the format of an electronic portfolio. It is posted in the electronic information and educational environment of the university, but it is available only for internal use by the student himself, teachers and organizers of the educational process. To create an electronic portfolio, web technologies, learning management systems, and cloud computing technologies are used. Most often, in universities, the "Electronic Portfolio" service is developed on the basis of the LMS (Learning Management System) on-line training system, which is available through the student's personal account after preliminary authorization.

A portfolio is not only a modern effective form of self-presentation and self-assessment of the results of a student's educational activities, but also contributes to:

- strengthening of motivation for educational achievements;

- the formation of reflexive skills, the ability to objectively assess the level of their professional competencies;

- gaining experience in communication and business competition;

- development of professional competencies;

- increasing the competitiveness of the future specialist (Panyukova and others, 2013, p.5).

The electronic portfolio is placed in the electronic information and educational environment of the university and is one of its elements. For example, L.A. Ivanova defines an e-portfolio as a web-based resource that reflects the continuous growth of educational, scientific or professional achievements of the owner and is based on hypertext technologies that make it possible to implement links between the components of cross-references (Ivanova et al, 2009, p.69).

The classical structure of the electronic portfolio of a university student consists of the following sections:
- educational activities,
- research and design activities,
- cultural and creative activities,
- social activities,
- sports activities,
- personal and professional development.
Sometimes the portfolio also includes an autobiography, which is filled in by the student in a free narrative form. The autobiography describes the main stages of life, interests, hobbies, characteristics and strengths of the character, the main achievements of the student.

The data of the electronic portfolio can be used for external analysis of the effectiveness and assessment of the quality of educational, research, creative and sports activities of the student, as well as act as a supporting base when submitting documents for the appointment of an increased scholarship, participation in youth competitions, shows, rallies, Olympiads, forums of various level and status.

Results

The local regulatory documents about electronic portfolios of the Russian Federation universities were analyzed with the purpose of our study (n = 31). In particular, the subject of analysis was the "Regulations on the student's electronic portfolio" and "Regulations on the student's portfolio". The results of this analysis lead to several conclusions.

1. The main term "electronic portfolio" by universities is interpreted ambiguously and rather diversely (Table 1). Common is the emphasis on the individual achievement of the learner. Therefore, the portfolio is a kind of vector that sets the direction for professional development and growth. Based on the intermediate and final results of mastering competencies, the student can build his further individual route of personal and professional development

Table 1: Approaches to the interpretation of the concept of "Electronic portfolio"

a set of documents, information, achievements ...	a personal account of a participant in the educational process ...
a package of documents, materials ...	a platform for the implementation of mechanisms of interaction between participants in the educational process ...
a set of electronic copies / documents ...	a way of recording, accumulating and evaluating ...
an individual electronic set of documents ...	an electronic resource ...
a form of self-assessment of performance results ...	an Information resource ...
the element of the Electronic Information and Educational Environment (EIE) ...	an information array ...
the basis for the rating of the university ...	a monitoring tool ...

2. The electronic portfolio of a university student is part of e-learning or an element of the electronic information and educational environment of the university, therefore, this element is integrated into the electronic journal. In an electronic journal, the teacher records the student's current progress. The content of the electronic portfolio includes mandatory control projects. These are abstracts, term papers, final qualification work, as well as all accompanying and supporting documents (reviews, reviews, defense protocols, and others).

3. 70% of universities analyzed by us implement e-portfolio on the Moodle e-learning platform. This allows you to implement the key principles of EIOS dictated by the Federal State Educational Standard of Higher Education 3 ++:

- access to curricula, work programs of disciplines (modules), practices, to publications of electronic library systems and electronic educational resources specified in work programs;

- fixing the course of the educational process, the results of intermediate certification and the results of mastering the main educational program;

- conducting all types of classes, procedures for assessing learning outcomes, the implementation of which is provided with the use of e-learning, distance learning technologies;

- the formation of an electronic portfolio of the student, including the preservation of the student's work, reviews and ratings for these works from any participants in the educational process;

- interaction between participants in the educational process, including synchronous and (or) asynchronous interaction through the Internet.

4. Approximately 70% of the normative documents analyzed by us indicate severe restrictions on access to the electronic portfolio - this is the student himself, the curator, the organizer of the educational process and the head of the educational program. In 10% of the Regulations, the student himself can assign the level of access to the materials of his portfolio. Compliance with the safety of students' personal data is one of the priority tasks of the university.

5. The university decides on the terms of keeping the portfolio. On average, terms range from one year to three years, in rare cases up to five years. However, some Regulations do not specify a time frame at all. The general practice of many universities shows that as soon as students finish their studies, their personal card goes into the archive, and with it the electronic portfolio. After graduation from the university, access to portfolio materials is limited for the student. The information can no longer be changed by the student independently.

The inability to update and manage the portfolio by a university graduate runs counter to the concept of Life Long learning and devalues the entire process and results of portfolio formation over several years.

6. 37% of provisions include obligatory reflection in the portfolio. It should be noted that the formation of a portfolio is carried out through the student's conscious independent activity. Consequently, special attention is paid to self-assessment of intermediate and final results, as well as the results of mastering certain types of activities (educational, research, project, social, etc.). At the same time, the creation of a portfolio is a creative process that allows taking into account the results achieved by students in a variety of activities: educational, research, sports, cultural and mass. The formation of a student's personal portfolio should teach him to regularly plan his professional and personal growth, to achieve the goals of this growth, should prepare him for professional self-promotion. Such self-monitoring should be systematic and regular.

7. The electronic portfolio is based on the principles of scientific and practicality, formalization, optimality, professional ethics and openness, aesthetics, integrity, reliability and thematic completeness of materials. All universities have specialists, curators who are responsible for the quality of filling the portfolio (data verification), reliability and timeliness, and their responsibilities include motivating students to work on a portfolio. At the same time, the main responsibility for placing and filling the portfolio is assigned to the student himself, who must systematically evaluate his own achievements. However, nowhere is it said what consequences or sanctions await a student who maintains a portfolio in bad faith or does not do it at all.

8. One of the goals of creating an electronic portfolio is to promote the choice of a conscious trajectory of individual development and successful employment of a student after graduation, as it can serve as a basis for drawing up a resume or further continuing education. The choice of a conscious trajectory of individual development is possible through a constant self-assessment of one's educational level and potential capabilities, through professional self-improvement and self-development. On the basis of the electronic portfolio, an objective resume is formed and subsequent successful employment. In this regard, a contradiction arises - the university restricts access to third parties to the materials of the graduate's electronic portfolio in accordance with the Federal Law of the Russian Federation of July 27, 2006 No. 152-FZ "On Personal Data". The employer needs to make a formal request to get permission to study the materials, which is very rare. Therefore, there is a break in the link: "Student - Portfolio - University - Graduate - Portfolio - Employer".

The portfolio is a powerful impetus for self-realization of the student's personality, which, according to N.V. Shramko, "is most effectively formed at the university." This desire "is due to the development of subjectivity, the individual's awareness of his place in the macro-environment of social relations in general and the educational environment of the university in particular" (Shramko, 2011, p. 38).

9. Each university independently determines the structure of the student's portfolio. As a result of the analysis, it was revealed that the portfolio loses its original purpose and is transformed into a student's

personal account, in which information is also recorded on the implementation of the curriculum in the field of training, an information about the student's incentives and the level of language and software products.

However, it should be noted that almost 60% of universities lack criteria for evaluating electronic portfolios in their normative documents, and about 25% have vague criteria. For example, the teachers of the Yelabuga Institute of the Kazan Federal University in 2015 make an attempt to reveal the content of the criteria for evaluating an electronic portfolio (Galimullina, 2015, p. 27-28). The authors distinguish the following groups of criteria: technical, ergonomics-design, content, presentation, reflective.

Despite the qualitative study of the content of these criteria, there is still a certain discrepancy between the learning process and the assessment of the portfolio content. We associate this tension with the lack of a common understanding of the content.

At the same time, today the content of an electronic portfolio is one of the most effective forms of self-assessment of the student's performance, which contributes to motivation in educational activities, the development of professional and supra-professional competencies, and an increase in the competitiveness of a future specialist in the labor market.

10. Unfortunately, to date, there is no clear distinction between learning outcomes and results that are presented in the portfolio. Hence, the question arises about the role of outcome evaluation and process evaluation. Wouldn't the demonstration style of learning outcomes assess the process itself be overlooked? A student's portfolio should not displace the learning process. In this regard, it is interesting to note A. Moores & M. Parks, who believe that a formal final assessment of a student's portfolio at the end of the semester can increase their motivation and level of involvement in the portfolio technology itself (Moores & Parks, 2010). At the same time, the researchers note the need for a personalized and holistic assessment of the portfolio, the presence of high-quality feedback. To date, the concept of software shells for personal educational environments (PLE - Personal Learning Environments) is actively developing, however, according to O.M. Karpenko, A.V. Abramova, M.E. Shirokova, V.A. Basov currently there is still no unified approach to what should be and what properties should be endowed with a personal educational environment (Karpenko et al., 2015, pp. 6-7). The desire to personalize education allows you to take into account the psychophysiological characteristics of the student and allows you to build an individual development plan more consciously and competently. Self-assessment of a student's capabilities and educational results is reflected through the maintenance of a continuous portfolio. However, certain "proofs" of the student's self-reflection are needed here. Demonstration of independence in work on a portfolio is the basis for students' understanding of lifelong learning.

The structure of the author's vision of an electronic portfolio within the digital competency platform is shown in Figure 1.

Fig. 1: Student e-portfolio structure concept

Conclusion

Research is needed that will be aimed at studying the student's reflective assessment of the stages of formation and development of a portfolio. The research data should include the learning process itself, which will in parallel correlate with the progress of the student during his studies.

Continuity should be a key characteristic of a portfolio. It needs because we are often faced with the fact that as soon as a student graduates from a university, portfolio management is "cut off". The portfolio is the basis for building a further individual development plan for the student. This basis not only within the walls of the university, but also after graduation. This is confirming the thesis of the continuity of education. In our opinion, the assessment of the portfolio is important not only on the part of the teacher, but also on the part of the future employer. Therefore, there is a need for communication support of the portfolio, for example, through the creation of chat rooms, the integration of social networks, as well as leading job portals.

A special training course (elective / elective course) or a discipline section is needed, where the technical and substantive aspects of creating and filling an electronic portfolio will be considered.

Students should be given autonomy in defining the content of the portfolio. Working on creating a portfolio is associated with maintaining high motivation of students, developing their ability to set goals, plan and organize their educational activities, develop skills of reflection and activities to assess their achievements. At the same time, the student's right to determine access to portfolio materials should not be limited by the LMS of the university.

The electronic portfolio of a university student is a modern tool for assessing educational results, which can be viewed as a response to the challenges of the digital economy. However, the closed nature of the university's IEE does not allow employers to organize interaction with potential candidates during

a student's training. The limited communication opportunities indicate the need for universities to revise the main regulatory provisions for access to an electronic portfolio. Communication between employers and students can be organized without access to students' personal data and an access algorithm can be written on a digital platform.

The expansion of the use of interactive web technologies and social media allows bringing the portfolio to a qualitatively new level through the creation and implementation of the Online competency platform, which will become a new educational philosophy.

Anarchy Potential Guarantor of International Security in Dynamic Context Generated by the New Hybrid Threats

Mihail PĂDURARU - PhD Candidate

University of Economic Studies Bucharest, Romania
mihail.paduraru@ccirom-tkm.ro

Abstract

The existence of the new Coronavirus "SARS-COV 2" was confirmed in early 2020 and then the rapid spread of the pandemic globally, generated major disruptions in communities, business and last but not least in political systems, putting considerable pressure on the affected countries.
In addition to affecting human health, coronavirus has also had a negative impact on economic, political and security activity with severe consequences worldwide, and its full effect has not yet been determined. In this context, the extent of the spread of the pandemic in most states exacerbates the existing socio-economic problems and dissatisfaction with the leadership, which puts significant pressure on political leaders in all states.The effectiveness of the actions taken by the authorities to combat the pandemic and the economic consequences of the health crisis will significantly influence the course of political regimes and not necessarily in a democratic direction. This paper aims to analyze in a realistic paradigm the implications generated by the existence of an anarchic international system and the inevitability of this state of affairs in the context of the current international situation caused by the pandemic caused by SARS-COV 2 virus. Comparative evaluation and introduction of The "dilemma of democracy" will seek to complement the overall picture of the anarchy.
"It is our suffering that brings us together. It is not love. Love does not obey the mind, and turns to hate when forced. The bond that binds us is beyond choice. We are brothers. We are brothers in what we share. In pain, which each of us must suffer alone, in hunger, in poverty, in hope, we know our brotherhood. We know it, because we have had to learn it. We know that there is no help for us but from one another, that no hand will save us if we do not reach out our hand. And the hand that you reach out is empty, as mine is. You have nothing. You possess nothing. You own nothing. You are free. All you have is what you are, and what you give."

Keywords: Security, International Relations, Anarchy, Democracy, Hybrid Threats.

Introduction

One of the fundamental points of realistic theory is represented by the premise of an international anarchic system. Anarchy must be understood not as a violent and unregulated chaos, but as a form of order with a horizontal, decentralized dispersion.

Anarchy is a competitive environment for states, which has negative connotations from a security perspective. Competition between states also determines their degree of international influence, although we cannot refer to the existence of a proper global hierarchy.

In *Theory of International Politics,* Kenneth WALTZ (1979) argues that there are times in the history of international relations when anarchy seems undesirable, the costs that a hierarchical order would impose, would be much higher and would affect all state actors.

In the anarchic system described by realistic theory, states have the opportunity to learn to rely on their own strengths and not to depend on an external authority for them to achieve the proposed goals. Thus, we notice that the anarchy postulated in realism is similar to that sustained even by the classical anarchist ideology and not a pejorative interpretation of it, as we can easily find.
The fundamental difference between the anarchy of the realists and that of the anarchists is generated by the degree of pacifism of each.

Classical anarchism suggests the state of anarchy as inherently peaceful (following a violent process of total state destruction) while realism associates the state of anarchy to the nature of pessimistic contractors like Thomas Hobbes (1651) argues in Leviathan, where each actor pursues his own interests and ensures security in every way possible.

Starting from the premises of the realistic theory of international relations, the present paper aims to argue the idea that the very anarchic order at the global level could be a sensitive guarantee of state security.

The Unlikely Extrapolation of Democracy

If in terms of order within a state we can conclude that democracy is the most appropriate regime, at the level of state actors the situation cannot be extrapolated without endangering the balance of power. Democracy require a well-established hierarchical model and necessarily a central figure of authority, an elected leader.

In the case of the international environment, the interests and vulnerabilities of the actors are felt much more acutely and have more dramatic repercussions, on a larger scale, than in the case of the relations between the citizen and the state.

The suppression of anarchy through the emergence of a possible world government would unbalance the fragile balance of power as Kenneth WALTZ (1979) argues in *Theory of International Politics*.

On one hand because control of the hierarchical system would become an end in itself and on the other hand because it would risk the outbreak of a widespread civil war being practically impossible to force all state actors to reach a common denominator regarding the chosen social system.

Democracy is also based on the trust given to the majority, at the level of the international scene this idea can be considered at least uninspired.

States cannot be treated as individuals (although in some situations there is the possibility of behaving as such) precisely because their status is not always permanent, as the consequences of wars prove.
In addition, democracy loses its meaning when it becomes an imposed regime, even with the best of intentions.

At the international level, a democratic and hierarchical regime would suppose the existence of a center that would completely destabilize politics at the global level as its role of administrator would be replaced by that of authority, the struggle for control over it becoming the new goal of the great powers. Centralizing power at the international level is not an appropriate strategy if a balance is to be maintained.

The anarchic system offers the possibility of avoiding this centralization, with the advantages and disadvantages arising from multipolar organization.

In the general contemporary sense, a democratic regime guarantees peace to some extent. Francis Fukuyama quoted in “Structural Realim after the Cold War” by Kenneth WALTZ (2000), argued that "a democratic state has never fought another democratic state". Based on this statement, a legitimate question could be about the vulnerability of democratic processes that can lead (and have done so many times) to completely undemocratic situations - a good example would be the election by democratic

vote of the German National Socialist Party in power in 1933, thus a democratic process reaching by force of events to create the premises for the establishment of a totalitarian regime.
Democracy, in any of its forms, is far from infallible. Advanced and industrialized democratic states do not necessarily tend to be attacked, but this does not rule out involvement in conflicts with undemocratic regimes.

If Kant's Rechtsstaat is the starting point of the idea of modern democracy, whether we refer to it as the rule of law or as a liberal democracy, then we can see that a restrictive definition of the democratic regime will have two possible consequences: it cannot be applied at the national and international level of improbability.

The understanding of democracy at the national level differs from the international one by the chronic lack of homogeneity in the international environment.

There are few cases in which a liberal democratic regime could prepare for war against another and the prevalence of democracy can only guarantee global peace if the causes of aggression are internal to the state, thus ignoring the conflicts of interest in relations between states.

However, relations between states cannot strictly involve the aspect of conflicts of interest, no matter how much this perspective would suit the realistic current.

In the international environment, the presence of a collaboration between states is also necessary, which often takes the form of an interdependence.

The interdependence of states is caused by the orientation of liberal democracies towards profitable peace, giving up the status of militarized power.

This type of economic and peaceful interdependence significantly decreases the situations in which armed conflict can be reached between states, but an overview is needed to indicate the corollary of this premise - an unequal interdependence in which relations become too close, between states with different capabilities and potential, can lead to tensions.

The closer the relationship, the more serious the consequences of interdependence.

In an anarchic order, competition and collaboration are equally expected, both of which can have a beneficial effect on the evolution of states and the cost-benefit ratio in terms of ensuring security at national and international level.

From a realistic point of view, there is no situation in which a factor cannot possibly degenerate into conflict, hence the preference of security studies for this paradigm.

Interdependence acquires different values depending on the political context in which it occurs.

In the contemporary international system, cooperation between states has a completely different impact and a much lower relevance, than in a situation like the Warsaw Pact member states, where dependence on the center (Soviet Union) was mandatory and collaboration between regimes with equal status or comparable status, were inevitable.

In anarchy (and in anarchism), any imposed, obligatory aspect gives rise to situations with potential violence.

Although difficult to accept as such, the desire for freedom often becomes a source of discord to a similar extent to the struggle for power.

States, as actors on the international stage, feel the situations they are forced to accept contrary to their will and identity as abuses and understand to treat them as such, hence most of the imbalances of inter-state dynamics.
We are taught to look reluctantly at totalitarian regimes, necessarily assuming them to be violent. However, if we can accept that (liberal) democracy cannot guarantee global peace, we could also accept that an authoritarian / totalitarian regime will not necessarily be aggressive in relation to other state actors.

The difference between a national regime approach and its application (or applicability) at the international level must be emphasized again.

If at the national level we can face both totalitarian and democratic regimes, but we cannot enjoy the freedom offered by an anarchic system, at the international level neither liberal democracy nor dictatorship works.

An alleged world government, viewed only at the conceptual level, will always lack legitimacy, which will also make it impossible to obtain it democratically.

The extrapolation of the democratic regime to the international environment will tend towards totalitarianism, the interest for maximizing the power of the big actors will cancel any other objective. Anarchy works as long as the Holy Grail of power is buried in no man's land.

Security and Conflict - The Dilemma of Democracy and the Illusion of Freedom

Security status can appear for a moment and can be felt by one state in the short interval between the increase of its military potential and the directly proportional reaction of another. This competition cannot last indefinitely, the war being often the deterrent.

On one hand, the conditions for a peaceful climate are complex and open to debate.

On the other hand, the conditions for the outbreak of war are simple: anything can trigger a conflict if the current interests of the actors involved demand it.

Returning to the Kantian perspective, where the natural state is that of war, the existence of international politics guarantees that at some point violent tensions will arise between states. However, it is hard to believe that the abolition of international relations in order to achieve security through isolation could be a viable solution.

A perfectly balanced behavior of a state would guarantee the absence of a threat from it only insofar as this behavior would be permanent, which is obviously a difficult goal to achieve.

The perspective of the minimal state, a libertarian vision proposed by Robert Nozick (1974) in *Anarchy, State and Utopia*, outlines the role of the central authority as being limited to law enforcement supervision.

In such a vision, the state loses its political role and can no longer influence the international environment to the same extent.

Libertarianism is theoretically close to anarchism, but it cannot yet imagine the total absence of the state.

There is no belief that the minimum state model could work at the international level in order to ensure a climate of security, but to some extent, international cooperation organizations and institutions end up playing a role similar to the minimum state on a smaller scale.

One of the most frequent criticisms of the realistic paradigm is skepticism about the efficiency and honesty of cooperation through international organizations.
From Kenneth Waltz point of view, a theorist of the structural realist current, this skepticism is perfectly justified.
The best example of this is provided by the North Atlantic Treaty Organization (NATO), whose goal theoretically ended with the Cold War. The extension of its existence confirms the principle according to which, an organization once created will always find something to do and will acquire its own identity, difficult to dissolve.

Realism argues that there is a subordination of international organizations to national interests, which leads to a lack of trust in the goals they set for themselves.
In the anarchic dynamics of the international environment, alliances between states can be multipolar, in which case, the participating powers are similar in capacity, bipolar, dividing spheres of influence and unipolar, centered around a single great power.

If military alliances have no purpose other than counteracting the threat that triggered their creation, sometimes finding new threats and imposing defensive behavior may justify turning alliances into security organizations centered around the actor or actors with the most decision-making power.

This state of affairs causes an imbalance of power at the international level which creates the need for counterbalancing which in turn creates the premises for tensions and conflicts.

Institutions can become useful tools for the great powers and have a greater share in changing the international environment than institutional liberalism considers.

Impregnating international institutions with a lush and complicated bureaucratic apparatus seeks to fill a void of legitimacy that the existence of that body feels.

At the same time, the bureaucratization of international institutions indicates the tendency to transform their image into a state-like one, bringing the hierarchy to the forefront to the detriment of the purpose for which they were created.

Again, the anarchic system can help balance the situation. The above-mentioned interdependence of states is a double-edged sword in any system of ordering authority, whether horizontal or vertical. The integration policy supported by the liberal current, highly appreciated in the international environment at the moment, can lead to an undermining of the identity of the states by the rapid propagation of the effects from the international, to the national.

A peaceful and ideal international system is utopian through the very inevitability of contact between states.

Max Stirner, the most ardent supporter of extreme individualistic anarchism, contemplated anarchist utopia in terms of total isolation of the individual, pursuing personal interests in the absence of cooperation with other individuals, concluding that self-preservation transcends all other goals that the individual would could propose.

At the level of interaction between states, isolationism is not really possible, although North Korea seems to be trying to disprove this premise, leaving itself anchored in an unconventional dystopia that determines the international environment to wait for the outcome in a manner proper to democracies.

Liberal democratic regimes in general, cannot refrain from spreading their enthusiasm to environments less conducive to their exuberance, at a time when history marks the emergence of liberal interventionist politics, a kind of forced benevolence under the legitimacy of the common good.

The liberal democratic regime should not, if we conform to its characteristics, engage in wars. Wars are the primitive manifestation of the failure of diplomatic relations and the decline of security and

have no place in the economy of the modern world that has retained the experience gained from two World Wars and one Cold.

Precisely because of this, democracy seems to be imposed on all state actors, of course, in order to ensure a safer international climate and fairplay competition between all state actors in the future.

When democracy needs to be imposed, it actually loses its democratic value. A state should, in a perfectly anarchic international system, be able to choose whether it wants to be a democracy or not.

The need for security of the other state actors, requires them to want a total uniformity on the types of regimes, in order to ensure against the unpredictable and undemocratic reactions of those with different visions.

Worryingly, the anarchy of the international environment is not really anarchic.

The basic principle of anarchy is freedom (also expressed by the refusal to accept a central authority). Freedom is not a viable option in an international system in which every action of a state causes chain reactions.

Modern democracies, although not fighting each other, create alliances to fight with others, repeatedly uniting in the face of threats to strengthen their enclave of democracy and profit-oriented pacifist spirit.

Thus arose the dilemma of modern democracy as a corollary of the security dilemma.

If a liberal democratic regime is also defined by its peaceful behavior, when it engages in a war aimed at imposing democracy where it does not exist, it loses its implicit democratic character.

If it does not, it risks further losing its democratic character by imposing stricter internal security policies to ensure its protection against the threats posed by undemocratic regimes.

Democracy at the national level, in terms of security in an anarchic international system, is the least harmful choice in the long run, but not the least expensive.

In addition, the emergence of the dilemma of democracy demonstrates that it simply cannot exist, it must be constantly maintained because competition for power in the international arena always follows authoritarian impulses.

If wars can be divided into crusades or crimes, those motivated by the uniformity of the democratic character of the international environment could fall into the subcategory of the struggle for security. Uniformity implies a greater degree of predictability and this in turn implies a lower risk from the security point of view.

Relative peace can be maintained in the current climate by corroborating internal and external restrictions, always keeping in mind that a higher power entails the desire to use it, while the lower powers will feel constantly threatened by it.

Even with the prospect of absolutely all states becoming liberal democracies, the anarchic system would continue to be the only one to function because it is unlikely to eliminate all cultural, economic and identity differences in order to achieve a classical democratic order in the international arena.

Conclusions: Criticism and Inevitable Anarchy

The thesis of this paper supports the anarchy as a potential guarantor of international security in an uncertain environment generated by the new hybrid threats - a comparative analysis, in a realistic paradigm.

Classical anarchy suppose absolute freedom, not just the lack of a leading figure. As stated in the previous lines, freedom in an anarchist sense does not exist in the international arena. Paradoxically, the states that can enjoy greater freedom are not the great powers, but the small and seemingly insignificant powers.

The great powers are on constant alert, trying on the one hand to maintain hegemony at the international level and on the other hand to maintain balance at the national level.

Where freedom appears, the feeling of insecurity also inherently arises. The limits of a state's freedom are unclear and their extent can only be tested by taking risks.

In classical anarchism, freedom cannot be combined with the idea of external limitation of the agent's will.

In the anarchy of the international environment, freedom is understood exclusively from the perspective of this type of limitation, the most important variable still being power.

Anarchy in realism is not equivalent to anarchy in anarchism. The anarchy postulated by realism suppose a mutual restriction of freedoms in the dynamics between states, determined both by the balance of power and by changes in polarity.

Anarchy from the perspective of anarchist theory suppose total freedom and implies only strictly necessary cooperation, abolishing the malignant character of politics.

A higher degree of security entails the restriction of freedom, but limited freedom is not a mandatory indicator of security.

The choice to be made between freedom and security perverts the meaning of anarchy, but even so, it remains inevitable due to the lack of an alternative.

During the paper, the reasons why democracy at the international level remains utopian (or dystopian, depending on preferences) were exposed, as well as the premises of a global totalitarian regime were excluded from the very beginning.

The model of the minimal state, laissez-faire, extrapolated to the international environment would probably achieve the same results that cooperation organizations currently achieve.

The tendency of states to form a coalition in the face of a threat, would translate into revolt against a global central authority.

In addition, it should be noted that, the classical anarchy is a pacifist concept by limiting the contact between individuals in the apolitical sphere and by abolishing the idea of power.

More than that, anarchy in the international environment, offers a sensitive guarantee of security precisely through the inevitability of contact between actors (which, as has been stated, implies both competition and interdependence) and through the pressure of history that reminds us all that the price of diplomacy is lower than the price of war.

Abstract

Capital market efficiency plays a major role in a country's economic development, as it affects capital formation, resource allocation and the distribution of wealth among market participants. This paper reviews previous studies to provide an understanding of the concepts of capital market efficiency. In addition to explaining the various forms of capital market efficiency, this paper discusses in depth the market efficiency of emerging economies, specifically in Malaysia. Prior studies show that accounting regulations, institutional infrastructure, quality of information disclosure are among factors that determine the extent of market efficiency. The paper further emphasizes that accounting information plays a significant role in determining market efficiency, especially in the Malaysian context which is scarcely explored by prior studies within the milieu of emerging markets.

Keyword: Capital market efficiency, stock price, earnings management, emerging economy, Malaysia.

Introduction

The efficient market hypothesis forms the basis of the modern financial theory, but its application is wide-ranging covering research fields such as economic, finance and accounting. The hypothesis was developed by Eugene Fama in the 1960s to explain the relationship between information and share price in efficient markets (Fama, Fisher, Jensen, & Roll, 1969; Beaver, 1981). The efficient market hypothesis by Fama (1970) suggests that stock prices immediately and accurately reflect all available information about firm's value at any time in an efficient market. According to the efficient market hypothesis, investors are not able to generate a risk-adjusted return in excess of the market portfolio by using selective trading strategies as all relevant information is accurately incorporated into the share price (Ross, Westerfield & Jordan, 2010). Thus, it is not possible to extrapolate future share prices or gain abnormal return in an efficient market through the analysis of past price data, i.e. technical analysis, and that instead share prices follow a "random walk" (Campbell, Hilscher, & Szilagyi., 2011).

Types of Market Efficiency

Capital market efficiency plays a major role in a country's economic development, as it affects capital formation, resource allocation and the distribution of wealth among market participation (Arshad, Rizvi, Ghani, & Duasa, 2016). Fama (1965) categorizes the market efficiency into three different forms, namely the weak form, semi-strong form and strong form of market efficiency.

(i) Weak Form Market Efficiency

The weak form market efficiency suggests that all information embedded in historical stock prices is incorporated into the current share price. In its weak form, the hypothesis claims that returns of the stocks are serially uncorrelated and show a constant mean, i.e. no systematic tendencies (Harrison & Moore, 2012). This suggests that trading rules based on historical price patterns, such as the ones

Cite this Article as: Intan W. OTHMAN and Maslinawati MOHAMAD "Market Efficiency, Accounting Information and Stock Prices" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

used in technical analysis, such as charting, are unable to predict future share prices and to systematically achieve a return in excess of the market portfolio (Jovanovic, Andreadakis, & Schinckus, 2016).
Factors such as inept accounting regulations, weak institutional infrastructure, low quality information disclosure and high information asymmetry generally feature the emerging markets (Al Janabi, Hatemi-J, & Irandoust, 2010). Within this scenario, some emerging capital markets are at best weakly efficient as they do not pass the requirements for higher grade efficiencies (Islam & Khaled, 2005; Rejeb and Boughrara, 2013). A regulatory framework that promotes market participation, ensure high accessibility to reliable and high-quality information and reduces institutional restrictions on securities trading help increase market efficiency (Antoniou, Ergul, & Holmes, 1997) to become at least weak-form efficient. For example, emerging stock markets in countries such as Saudi Arabia and Kuwait (1985-1989), Turkey (1992-1999); Uganda (1994-2012); the Organization of Islamic Conference (OIC) member countries (1998-2012) are found to be weak-form efficient (Butler & Malaikah, 1992; Buguk & Brorsen, 2003; Katusiime, Shamsuddin, & Agbola, 2015; Arshad et al., 2016). The stock markets of these countries are generally characterised by high volatility, low liquidity, high cost of fund, weak governance and legal framework and are found to be weak-form efficient.

(ii) Semi-strong form market efficiency

The semi-strong form of market efficiency suggests that current share prices reflect all past and present public information. The semi-strong form suggests that the market share prices are updated in response to any publicly announced new information. This means that all form of publicly available information such as information included in company reports, trading announcements and the business press will be instantly incorporated into stock prices. If this is correct, then, fundamental analysts which base their research on publicly available information will not able to gain an advantage over the investors (Jovanovic et al., 2016) in certain circumstances.

Both with regard to the weak and the semi-strong form of market efficiency, it is important to note that publicly available information might not necessarily be correct, e.g. due to mistakes, difficulties in predicting developments or opportunistic behaviour by managers. As a consequence, the release of new and updated information by the same or different sources is likely to lead to price adjustments. For example, Defond & Zhang (2014) document that bond prices incorporate most of the bad earnings news in the period leading up to and during earnings announcement. Nonetheless, a portion of the bad news impounded in the bond price reverses in the period following the announcement. This indicates that the market was aware of bad news, e.g. from press coverage of adverse economic or firm-specific developments, but that the firm's announcement revealed that the news was not as anticipated based on the previously available information.

The study by Al Janabi, Hatemi-J & Irandoust (2010) shows that the financial markets in the six Gulf Cooperation Council (GCC) countries; i.e. Qatar, Bahrain, Kuwait, Saudi Arabia, Oman and the United Arab Emirates are informationally efficient in the semi-strong form during the period 2006-2008. The study documents that practices of financial liberalisation, such as waiving barriers to the foreign capital influx and improving prudential policies and regulation, have stimulated growth in the countries' economic development and boosted up the trading activities in their stock markets. Cross-listing of equity securities further facilitated to improve over thin trading problem. This has led to high liquidity within the financial market, thus lowering borrowing costs for those entities having the aspire to raise equity funds. The imposition of high quality and transparency in financial reporting, improvement of corporate governance measures, and enhancing the application of international accounting standards and coherent enforcement of risk management measures may have further enhanced the efficiency of the GCC equity markets.

(iii) Strong Form Market Efficiency

The strong-form market efficiency assumes that all available information – public and private (i.e. insider information) - is reflected in the current market share price. This means that if new information is uncovered, it is immediately reflected in share prices. The random discovery of

information is expected to cause share prices to fluctuate unpredictably (Fama, 1970). This means that in markets with strong form market efficiency, it is impossible to earn or predict extra profit by applying technical trading rules. Even the application of insider information would be of no use since insider information is reflected immediately in the market price so that insiders are not able to make abnormal returns by trading on their information (Jovanovic et al., 2016). Strongly efficient market enables investors to ascertain the risk and return of their investments based on all currently available information, which means that there should not be undervaluation or overvaluation of assets (Jamil et al., 2020).

There are a number of assumptions which are crucial for the existence of a strong-form market efficiency by which the security price will "fully reflect" all available information (Fama, 1970). These conditions include (i) trading of securities at no transaction cost; (ii) information is available to market participants at no cost; and (iii) the implication of current information on current prices and the distribution of future prices of securities are agreed by all market participants. In practice, the assumptions for the existence of frictionless markets with freely available information and perfectly rational investors are unlikely to be ever met. Fortunately, the above three conditions are sufficient, but not necessary, for market efficiency (Fama, 1970). For instance, even with a high transaction cost may mean that prices may still "fully reflect" all available information when the transaction does take place, provided that all available information is taken into account by market participants in the process of price formation.

Capital Market Efficiency in the Emerging Market

Markets in the emerging countries tend to be less efficient compared to the developed ones (Griffin, Kelly, & Nardari, 2010). The nature of an emerging market makes it hardly possible to assume that all relevant information will be reflected in share prices (Samuel, 1981). The main reason for the weak information efficiency is due to poor capital market development resulting in weak regulations and control in the emerging markets (Gupta, 2006). Harrison & Moore (2012) further argue that the state of information inefficient are partially due to emerging markets being typically characterised with having a low level of liquidity and thin trading. Thin trading normally occurs in emerging markets because the opportunities for participating in the market is neither well understood nor well distributed among many investors. Moreover, the ill-informed investors sometimes have access to information that is less reliable. Lack of access towards reliable information arises due to the limited disclosure requirements among public firms (Harrison & Moore, 2012). Factors such as weak property rights protection, complex organisational structure, and regulatory distortions further contribute towards information opacity in the emerging market (Fan, Wei, & Xu, 2011). Changes in the accounting system alone may not improve financial opacity in the market since accounting rules enforcement relies on strong institutions which however are lacking in the emerging market (Ball, Kothari, & Robin, 2000). However, recent studies such as Arshad et al (2016) found that the market efficiency of the Turkish stock exchange has been gradually improving over time due to the informational advantage owned by the foreign investors who generally have high expertise, with local agents who concurrently help intensify their investments (Ciner & Karagozoglu, 2008). This suggests that foreign investors might be able to substitute or complement or add to markets' information efficiency due to them being highly skilled and knowledgeable and their market participation that increases market liquidity.

Excessive government intervention in commerce activities is another common attribute of the emerging markets (Fan, Wei, & Xu, 2011). However, political connection building and bribery become a significant behaviour distortion under the authority of low quality government. Prior studies document that managers and firm owners tend to have a close political connection or bribe bureaucrats who can easily influence the state banks to grant business privileges or loans to the firms (Sapienza, 2004; Charumilind, Kali, & Wiwattanakantang, 2006; Fan, Rui, & Zhao, 2008). Firms within these corrupted emerging countries are more likely to have poor transparency, complex organisational structure, and weak corporate governance. (Leuz & Oberholzer-Gee, 2006; Jiang, Lee, & Yue, 2010). High corruption coupled with weak corporate governance may, in turn, lead to

investment spending inefficiency and thus the instability of the emerging market's financial system (Radelet & Sachs, 1998).
Political and economic instability in the emerging markets may also cause high volatility in the stock market thus affecting the market efficiency negatively. For example, Egypt was generally found to be at the weak-form spectrum of market efficiency during the period 1998-2012 (Arshad et al., 2016). This was mainly due to certain catastrophic events such as the September 11 attacks, the Arab Spring and the global financial crisis causing volatility and high inefficiency within the Egyptian stock market. The stock market was impaired further by the frictions within the local trading process including limited information provision to market participants and limited financial intermediaries.

In general, due to the limited information efficiency within the emerging stock market, private information is often not captured in a company's share price (Fama, 1965). When the market does not have the information that is privately known among the managers, accounting manipulation can be used to influence and indirectly increase firm's share price (Efendi, Srivastava, & Swanson, 2007), which in fact can be misleading to the investors (Berkman, Zou, & Geng, 2009), causing them to lose on their investment. Louis (2004) argues that due to the many alternative ways of earnings manipulation, it would be improbable for the market to tell exactly how much the earnings have been managed. The existing anecdotal evidence such as the famously known case of Enron and WorldCom advocates that even the managerial incentive to deceive the market is evident; the act of earnings management can fool even the most sophisticated investor (Louis, 2004).

The Malaysian Capital Market

The key to an efficient market is the efficiency in resource allocation, i.e. where resources are channelled to their most productive uses (John & Senbet 1998). Prior research has tested and found that well-regulated emerging capital markets are generally semi-strong efficient, though they can also be subject to some weaknesses as possible sources of market inefficiency. Instances such as agency conflicts, imperfect information, and market imperfections such as taxes, weak regulatory enforcement and poor corporate governance structure impede the arbitrage process in the capital market, hence reducing the efficiency in resource allocation which then lead to market imperfections (Andres, Betzer, & Weir, 2007; Al Janabi et al., 2010; Rose & Søpstad, 2015).

The Malaysian capital market is generally well-regulated and highly liquid (Arshad et al., 2016). For instance, the survey by Credit Lyonnais Securities Asia (CLSA, 2006) showed that Malaysia recorded a scale of nine out of ten for instituting the most corporate governance rules and regulations. Furthermore, the national accounting standards in Malaysia comply with the International Accounting Standards whereby the International Financial Reporting Standards was fully adopted in 2012. While this might suggest that the Malaysian stock market has semi-strong form of market efficiency, prior research including Barnes (1986) (1975-1980), Laurence (1986) (1973-1978), Lim, Liew, & Wong (2005) (1990-2002) and Munir & Mansur (2009) (1980-2008) found that in the past the Malaysian capital market was only weak-form efficient. However, reforms of the capital market, corporate governance and accounting regulation in recent years is expected to have improved the information efficiency of the Malaysian stock market.

Malaysia has made a remarkable transition within a short span of 30 years, from a principally agrarian economy to becoming a productive middle-income economy (Randhawa, 2011). The Malaysian capital market is considered well-developed when compared to other East Asian economies (EAU, 2002). Malaysia macroeconomic stability and its business-friendly environment have sustained the inflow of foreign direct investment and contributed to a steady economic growth (Randhawa, 2011). In strengthening the Malaysian capital market, the Capital Market Masterplan (CMP) was implemented in 2004 that include initiatives to implement higher quality governance system, better supervisory and regulatory framework and improved market liberalization (Ibrahim, 2007). This is expected to improve market liquidity, better informational transparency and made Malaysia more integrated into the global economy (Poshakwale, 2020). With the launch of the Malaysia International Islamic Financial Centre (MIFC) in 2006 to promote Malaysia internationally

as a marketplace for Islamic finance, further allows Malaysia to be more integrated into the international financial system (Yusof & Bahlous, 2013).
In accordance with the objective to transform Malaysia into a high-income nation, the Capital Market Plan 2 (CMP2) being made effective in 2011, help to further improve the Malaysian economic growth through promoting capital formation and strengthening information infrastructure, among others. The CMP2 also puts a high emphasis on strengthening the governance system in ensuring that the capital market is well-regulated. This would include enhancing product regulation to manage risk, strengthening corporate governance and improving the regulatory framework according to the changes in the market landscape. In addition, Malaysia also has a sound financial reporting system which is in line with the General Acceptable Accounting Practices (GAAP) (Yeow & Mahzan, 2013). Concurrent with the global development of accounting standard, the Malaysian accounting standards have converged fully with all the International Financial Reporting Standard (IFRS) in the year 2012. The full adoption of the international accounting standards gives a significant contribution towards the Malaysian corporate disclosure practices.

Overall, it is contended that improvement in the Malaysian supervisory and regulatory framework, market liberalisation and betterment in the national accounting standards would contribute to increased market liquidity, better information transparency (and availability), hence higher degree of market efficiency (Qamruzzaman & Wei, 2019). Higher quality of governance system in place may also help ensure a higher standard of conducts are applied by business organisations which assist investors to be more well-informed and thus makes more rational decision making in ensuring that their wealth is maximised.

However, the information efficiency of the Malaysian capital market is still likely to be negatively affected by the poor legal enforcement and investor protection (Hasnan et al., 2013). These flaws arise due to the weak judicial system (which is subservient to the local political system), inadequate prosecutorial resources (Gunasegaram, 2007) and excessive political interference in the Malaysian economy that leads to cronyism (Muniandy & Ali, 2012). All these weaknesses hinder from an effective arbitrage process which then impedes efficient allocation of resources, hence limiting the information efficiency of the Malaysian capital market.

Efficient Market Hypothesis and Accounting Information

Some research assumes that capital markets are informationally efficient and that investors can "see through" any weaknesses in accounting data (Healy & Palepu, 1993). An example given by Stein (1989) is that firm's earnings are used by the stock market to make a forecast of firm value, whereby firm's current higher earnings will be associated with future higher earnings. Based on this view, managers tend to manipulate market signal by discretionarily inflating earnings to increase forecasted firm value. In an efficient market, investors will not be fooled by the manipulation. The well-informed investors will accurately conjecture that a certain amount of earnings is inflated and will regard this as part of stock price prediction.

It has long been documented that the reaction of stock price towards earnings announcement is relatively quick (Patell & Wolfson, 1984). This would mean in an efficient market, investors impound public and private accounting information efficiently and immediately adjust market prices. Nonetheless, it has long been criticized that accounting measures can be subject to managerial distortions due to manipulation e.g. of inventory valuation, depreciation policies, variation in the method of accounts consolidation, treatment of revenue and expenditure items, and outright deceit and fraud (Chakravarthy, 1986). Even if the market efficiency assumptions really holds, Bettis (1983) contends that firm's share price may change according to the information that managers choose to reveal to the investors, hence firm's share price does not essentially reflect its fundamental value. Bettis (1983) argues that the accounting standards only impose minimum information disclosure. Further information, such as product quality and management changes would be available in the process of doing business. Disclosure of such information depends on managerial discretion and if so, often done via public speeches, press releases, public interviews and security analysts briefing. This means that security price in an efficient market partially reflect the information that managers choose to reveal.

The implication intensifies in a market with limited efficiency where private information on managerial accounting malfeasance is not reflected in the company's share price due to information asymmetry. This may lead to the firm's share price being overvalued. For instance, managers might engage in earnings management activities to artificially boost earnings and enhance earnings growth expectations which eventually increases firm value, hence firm's equity overvaluation (Badertscher, 2011). This would result in failure of the capital market to differentiate between profitable corporations and unprofitable corporations (Watts & Zimmerman, 1986) and investors inability to appropriately determine the risk and return of their investments (Gupta & Basu, 2007). In view of this, it would be impossible to rely on the movement in share prices to predict aggressive or fraudulent financial activities in a market with limited efficiency.

Managerial opportunistic behaviour such as aggressive earnings management that precedes forced restatement typically cause volatility in firm's earnings (Dichev & Tang, 2008; Donelson, Jennings, & Mclnnis, 2011; Mayorga & Sidhu, 2012) which then lead to subsequent share price variability (Baginski & Whalen, 2003). Instances of volatile earnings due to opportunistic earnings management include firm's "big bath" and "cookie jar" reserving (Mohd Radzi, Islam, & Ibrahim, 2011; Dechow, Hutton, Kim, & Sloan, 2012). The big bath theory proposes that a firm experiencing from low earnings in any given year may choose to do discretionary write-downs to cut down current period's earnings even further (Jordan & Clark, 2011). The big bath practice makes it easier for managers to report higher profits in future years. This is based on the notion that the managers will not be penalised proportionately more due to boosting of earnings on the already depressed earnings (Jordan & Clark, 2011). On the other hand, "cookie jar" reserve is created by managers as hidden account used to expand earnings in later years when economic events unfold that led to actual losses to be realised (Levitt, 1998). This normally takes place when managers manage earnings slightly downward over a specified period of time to get the flexibility for upward earnings management in the future challenging period (Dechow et al., 2012).

In view of this, market signal via share price variability may then be used as an indication that firms' private information (opportunistic earnings management) is not fully impounded and reflected in share price. This is consistent with Ball (2009) who explains that in a perfectly efficient market, it is unnecessary to have future price reaction arising from a particular information because security price will adjust immediately to all available information. It would be thus unlikely for future price variability to happen in strongly efficient markets. In a different perspective, share price variability within the Malaysian limited efficient market may indicate that private information on manipulative accounting information may not be impounded by the market due to information asymmetry. It, therefore, seems appropriate for this study to utilize share price variability as a factor in predicting the likelihood of forced restatement.

Conclusion

Capital market efficiency plays a major role in a country's economic development, as it affects capital formation, resource allocation and the distribution of wealth among market participation (Arshad, Rizvi, Ghani, & Duasa, 2016). The general perception is that the developed markets are more efficient due to their long-term presence, increased maturity, and technological growth, in comparison to the emerging economy counterparts. The Malaysia capital market, more specifically, is found to have limited information efficiency (Barnes, 1986; Laurence, 1986; Lim, Liew, & Wong, 2005; Munir & Mansur, 2009). Factors such as poor legal enforcement and investor protection (Hasnan et al., 2013) as well as the pervasiveness of cronyism (Muniandy & Ali, 2012) are some possible weaknesses that might have contributed to the Malaysian limited market efficiency. Generally, the limited market efficiency may negatively impact the country's economic development due to inefficient resource allocation and inequality distribution of wealth among market participation (Arshad, Rizvi, Ghani, & Duasa, 2016). The limited information efficiency may cause investors not being able to detect and "see through" weaknesses in accounting data resulting in managers to take advantage and engage in opportunistic earnings management, earnings misstatement or even outright fraud with the purpose of rent extraction.

Abstract

Like other developing countries, Mergers and Acquisitions (M&A) has been emerging successfully in Malaysia. Despite being rich in resources, Malaysia is famous for its multiracial culture among foreign countries[ii]. As a result, there are high opportunities for foreign companies to expand. Malaysian company is said to be looking into M&A if they wanted to firm up their reputation in Malaysia before competing internationally (Kummer, 2012). This paper therefore addresses mergers and acquisitions in Malaysia as well as the main rules and regulations and the joint motive company involved in M&A. We extend our discussion on the motives of M&A in general.

Keywords*:* Mergers and Acquisitions, Malaysia, Regulations, Law, History, Motive

Introduction

Generally, mergers take place when two or more companies merged to become one new company or corporation, whereares an acqusition is when one company takes a controlling ownership interest in another firm. Many literatures described mergers and acquisitions (such, Horne and John, 2004; Gergios, 2011; Khan, 2011; Durga, Rao and Kumar, 2013) in various terms. Horne et al (2004) stated that mergers are legal activities in which two or more organizations merge to become a single company as a legal entity. Gergios (2011) stated that an acquisition may take places when large financial firms bought a small firm, whilst a merger is when two or more companies merged into becoming a single company. The concept of merger is when two or more entities merge and join one or more firms (Khan, 2011). However, according to Duksaite and Tamošiūnienė (2011) the distinction is not that important, since both definitions would have a similar effect, where two separate firms merge into one and these firms support each other.

In the Malaysian context, mergers and acquisitions (M&A) generally refers to the acquisition of shares of a company, consolidation of businesses or takeovers (Sankar and Yen, 2018). With the exponential growth of technologies and the worldwide wave of economic globalisation, M&As have been an effective way for businesses to discover and develop new opportunities. (Zhong, 2016). In other words, M&A is also a common corporate recovery strategy used by companies worldwide. However, according to Mah and Thomazios (2019), in Malaysia there are lack of companies that taking advantage of M&A incentives to boost growth. Aik, Hassan and Mohamad (2015) stated that an increase in the financial performance of target firms compared to the acquired firms is not statistically significant, it is inferred that there was no actual improvement in the financial performance of the merged firms after

Cite this Article as Nur Nashreen ZAKARIA, Maslinawati MOHAMAD, Intan Waheedah OTHMAN and Sutrisno "Mergers and Acquisitions In Malaysia" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

M&A practices. This has been identified by Malik (2019) that the performance of the merged firm is far more different as it is lower than the non-merged firm. According to Andreou, Louca and Panayides (2012), as cited in Rashid and Naeem (2016), firms involved in M&A are for synergistic reasons rather than expecting bonus consumption from the management. Therefore it is crucial for this study to provide an understanding on the key laws and regulations of M&A in Malaysia and the common motives on why companies involve in M&A activities.

This study was carried out as a systematic evaluation of previous literature. The findings of the selected research work have been classified, grouped and summarised in order to discern a meta-analytical view of the work carried out to date. M&A in Malaysia is in unfavourable states and is said to be softened following the Covid-19 pandemic due to business volatility (Zainul, 2020). The laws and regulations were therefore considered and organised in a way that would allow businesses to understand the act, code, rules and guidelines issued by the government. M&A 's motives are varied due to heterogeneous opinions as to why businesses are interested in M&A. They are known as synergy motives, agency motives and hubris motives. This paper summarises some of the key developments in M&A carried out over two decades in empirical studies in Malaysia. Study can help to recognise possible issues and set the agenda for future work.

This paper is organized as follows. Section II is the mergers and acquisitions (M&A) in Malaysia. Section III explains the rules and regulations of mergers and acquisitions in Malaysia. Section IV is the common motive of M&A and Section V is the discussion and conclusions.

Mergers and Acquisitions (M&A) in Malaysia

Malaysia is a country rich in natural resources, highly skilled labour at a relatively low wage scale and strategically positioned in the Asia-Pacific region[1], it is one of the largest concentration countries and economic traders in the South East Asia region, especially the Association of South East Asian Nations (ASEAN) (Tong, 2012).

The growth of the Malaysian companies are not only at the local arena, but also in ASEAN and internationally. This is shown when Malaysia is ranked third in ASEAN 's total trades of USD 466,642.8 million in 2018, while Singapore ranked one and Vietnam ranked two with total trades of USD 782,656.9 million and USD 480,567.6 million respectively. According to Tong (2012), Malaysian companies focuses into M&A before venturing overseas if they were to strengthen their foothold in Malaysia before competing internationally with another large company globally.

M&A began in Malaysia in the 1970s, where oil and rubber plantation companies were largely confined to business (Yusof, Hassan, and Jalil, 2000; Marimuthu, 2008), and the number of M&As continued to emerge with the industrial sector, coupled with a privatisation policy that encouraged many companies to become more competitive in diversifying their businesses (Ripain and Ahmad, 2014). However, the transactions have declined in recent years, as the number of completed M&A deals in Malaysia involving listed firms has decreased from 410 in 2015 to 227 in 2019[2]. According to The Star (2018), despite the slow down, the demand for M&A remained competitive in 2018, growth was led by a spike in high-value outbound sovereign wealth fund (SWF) transactions from Singapore, supported by domestic M&A activities in the area. M&A activities will remain robust into second half of 2020 and in year 2021 as a few companies have publicly made known their intentions to restructure, re-strategise and or deleverage (Shankar, 2020). However, the perception has turned differently because of the latest Covid-19 pandemic. Zainul (2020) recently reported in The Star News that merger and acquisition (M&A) activities are likely to slow down in the short term as market uncertainty contributes to the disparity in valuations.

The aim of this paper is therefore to provide further understanding on M&A, in particular on the typical legal agreements involved and the key laws and regulations in force in connection with mergers and acquisitions in Malaysia.

Key Laws and Regulations of Mergers and Acquisitions (M&A) in Malaysia

There are two types of companies that are involve in M&A which are the public and private listed companies. Public mergers and acquisitions in Malaysia are mainly regulated by the Capital Markets and Services Act 2007 (CMSA). The Securities Commission (SC) issued the Malaysian Code on Takeovers and Mergers 2016 and implemented in compliance with the CMSA. Malaysian Communications and Multimedia Commission (MCMC) emphasized that private and public mergers and acquisitions are typically regulated by the Companies Act 2016. According to Meng et al (2019), the parties are free to settle on the law regulating documents relating to transactions. However, the legal formalities and procedures for transferring shares, companies or properties will still be subject to Malaysian law.

CMSA (2007) requires the Commission to approve the acquisition or sale of an asset resulting in a significant change in the business direction or strategy of a listed firm, or any related M&A activities listed under the Act. Any failure to comply with the provision, the Commission shall have the right to refuse to accept the proposal.

In addition, there is also a public M&A code, the Malaysia Code for Takeovers and Mergers. This Code includes standards and rules regulating the conduct of all individuals or parties involved in the takeover bid, merger or compulsory acquisition, including the bidder, the offeror, the offeree and their officers and associates. The Commission shall prescribe the Code in compliance with the standards set out and may do whatever is appropriate or fair to provide best impact to the clauses of this Division and of the Code, without limiting the generality of the foregoing.

However, there are other key law and regulations that may be applicable for M&A as stated by Mah et al (2019) as follows:

- Financial Services Act 2013
- Offshore Companies Act 1990 (for Companies incorporated in Labuan)
- Bursa Malaysia Securities Berhad Listing Requirements 2010 (Bursa Listing Requirements)
- The Capital Markets and Services (Fees) Regulations 2012
- Contracts Act 1950
- Foreign Investment Committee Guidelines (administrative)

For both public and private M&A, Malaysian Communications and Multimedia Commission (MCMC) provide guidance and establish a process for assessing M&As that have been voluntarily notified to it, whether public or private M&A. These Guidelines also set out the procedures that the Commission would follow in the implementation of Chapter 2 of Section VI of the 1998 Communications and Multimedia Act (CMA) for mergers and acquisitions. MCMC (2019) defines M&A as capable of capturing a wider spectrum of corporate transactions, relating to any transfer or combination of ownership of two (2) or more businesses or business organisations. Such transactions include consolidation, tendering, asset purchases and acquisitions by management.

Despite the various codes, acts and guidelines provided by the Malaysian Government, there are lack of companies that took advantage of outbound M&A incentives to boost growth by moderating their earnings capacity (Mah et al, 2019). Recently, Zainul (2020) interviewed one of a member firm of Baker McKenzie International, who claimed that the policy and guidelines provided by the regulator should be more transparent in order to boost the M&A activity in Malaysia. He said again that the regulatory authority should improve the approval process and make it more timely and transparent.

This shows that regulators plays a vital role in improvising the numbers of M&A activity in Malaysia. Although there are rules and regulations on the activities but if the responsible players are not performing well, the bottom will inevitably fall. In addition, we will discuss the motive of companies involved in M&A.

Motives of M&A

There are various of motives that have been discussed by researches (Song, Ali and Pillay, 2005; Isa and Lee, 2010; Azevedo, Alves and Santos, 2016; Aggarwal and Garg, 2019). According to Song et al (2005), the reasons for M&A are always ambiguous and present a problem of classification. There is no common justification for a M&A, but rather a variety of reasons that often contradict and complement each other.

A. Synergy Motive

According to Al-Sabri and Nordin (2018), a number of studies have argued that synergy is one of the key motivations of M&A. Synergy typically means that the benefits that will be achieved when two businesses are engaged in M&A are greater than the combined benefits of the original two independent firms. (Tong, 2012). In a simple term, Ripain et al (2014) summarised their synergy as one plus one equal to three. There are three types of synergies, including financial synergies, organisational synergies and managerial synergies (Sudarsanam, 1996; Hitt, Dacin, Levitas, Arregle and Borsa, 2000). It is argued that these synergies can allow the merger of firms to achieve a positive net acquisition or boost performance (Song et al , 2005).

B. Agency motive

Agency motivation can also be referred to as Agency Theory and Empire Building Theory (Song et al , 2005; Tong, 2012; Al-Sabri et al, 2018). In comparison to the synergy motive, the Agency motive suggests that managers focus more on optimising their own income and resources than on maximising shareholder capital (as cited in Al-Sabri et al , 2018). By way of a simple example by Song et al (2005), if managers themselves are not properly diversified, they will diversify the assets of businesses in order to minimise the risk to their available capital, even though diversification provides little to no value to shareholders. The Agency Theory describes the presence of conflicting interests between managers and shareholders, which can induce managers to participate in such practises for their private benefit. These self-interest behaviours can lead to a decline in shareholder wealth.

C. Hubris motive

According to Al-Sabri et al (2018), hubris theory or motivation is another common theory used to describe the motivation of M&A. Hubris motive is also known as hubris theory, hubris hypothesis and process theory. Waal (2013) pointed out that the hybrid hypothesis is sometimes used to describe managerial overconfidence in mergers and acquisitions. The concept behind this hypothesis is that managers overrate their ability to determine future acquisition goals. As a result , the stock market responds adversely and the bidder firm's share price declines. This is similar to Rohra and Chawla (2015) which stressed out that acquisition managers make mistakes in assessing targets and lead to M&A where there are no synergistic benefits and thus overpayments made to the target business.

Discussion and Conclusion

M&A has been successfully emerging in Malaysia similar to other developing countries. Despite being rich in resources, Malaysia is famous among foreign countries with its multiracial culture. As a result, there are high opportunities for foreign companies to expand, as Malaysia has tremendous skilled labour from different races and low-wage ethnicity. In addition, M&A, which is generally owned in Malaysia, was the purchase of company stock, the sale of companies or the acquisition of assets. This type of operation benefits the business from growth, particularly at a low cost of purchase.

Although there are complete rules and regulations for public and private M&A to be followed as guidelines, it is believed that the framework or mechanism must be invented in order to strengthen the movement of M&A activities in Malaysia. Thus, companies planning to get involved in M&A are advised to study the real motive rather than jump into M&A activities and reach a complete failure in the future.

This study limitation is only to provide a great deal of insight and understanding on M&A in Malaysia, the rules and regulations for companies to follow, as well as the common motivation for M&A. Therefore, it is recommended for future research to study on the growth trend of M&A in Malaysia, potential effect of the current rules and regulations on M&A companies, the adoption of codes and guidelines provided by the government among public or private M&A in Malaysia or any further detail investigation is recommended.

Acknowledgment

The authors would like to thank the Ministry of Higher Education of Malaysia, the Research Management Institute (RMI) of Malaysia and Universiti Teknologi MARA, Malaysia, for their financial sponsorship and support in making this study a success.

A Study on Impact of Speed Radar and Red-Light Cameras on Drivers' Behavior in Abu Dhabi City

Khamis Salem ALNABHANI and Nor Hazana ABDULLAH

Faculty of Technology Management and Business, Malesia

Abstract

Traffic law enforcement is a main part of any road safety strategy and the only one that has quick and direct impact in improving driver's behavior. The main objective of this study is to investigate the impact of two new automated enforcement systems in Abu Dhabi (AD) city on drivers' behavior and overall road safety. These systems are speed and red-light enforcement cameras. Two types of data sets are used: crashes and traffic violations data for six years and self-reported questionnaire survey data. Crash data analysis showed that as increasing the number of speed camera devises the number of speed-related crashes decreases. Regarding the red-light camera systems (RLCs), the analysis showed that the number of red-light running crashes was decreased by 47.2% after implementing RLCs. More understanding of the driver's behavior and response towards the enforcement camera systems were investigated from 600 participants in a questionnaire survey. The main findings indicated that significant number of drivers tend to reduce their speed only at the speed camera sites. Drivers always comply with the speed limit when they feel that they under camera detection. Well known locations and visible cameras pushing drivers to such behavior. In addition, drivers who think that they can avoid camera detection and who prefer high speed limit were involved in speed-related crashes more than others. Finally, about 83% of participants believe that speed and red-light cameras have significant impact in improving road safety. The findings of this study are very helpful for road safety authorities in developing effective road safety action plans.

Keywords: Speed Camera; Red-Light Running Camera; Drivers' Behavior; Traffic Enforcement; Self-Reported Questionnaire

Introduction

Based on World Health Organization report (WHO-2015), about 1.24 million people die every year as a result of traffic crashes and more than 90% of road traffic deaths occur in low- and middle-income countries. People aged between 15- and 44-years account for 48% of the global road traffic deaths which made the issue of road safety more dramatic. Currently, significant efforts are being carried out in most countries to improve road safety level and achieve strategic targets of road crash fatality rates such as zero-vision strategies in some European countries.

Emirate of Abu Dhabi (AD), the capital of the United Arab Emirates (UAE), has an increasing population growth rate accompanied by an increasing number of vehicles and, in turn, increasing number of driving licenses. more than 200 different nationalities are living in AD with different cultures and road safety background that put the road safety authorities in a real challenge. Traffic crashes escalated, putting an economic burden on the country. Thus, the main concern of the traffic police is to enforce road users to follow traffic law in order to improve road safety level. The strategic target of Department of Transportation DOT in UAE is to reach 3.0 fatalities per 100,000 inhabitants by 2023. In addition, AD traffic police department has a zero-vision strategy for traffic crash fatalities by 2030. To achieve this target, the traffic police of AD has established two types of traffic enforcement systems; speed and red-light cameras during last eight years. The human error accounted for about 97.2% of the severe crashes in AD during the past years. Thus, improving drivers' behaviors is the core of the road safety strategy of AD traffic police. However, drivers'

Cite this Article as: Khamis Salem ALNABHANI and Nor Hazana ABDULLAH "A Study on Impact of Speed Radar and Red-Light Cameras on Drivers' Behavior in Abu Dhabi City" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

response and the impact of the implemented enforcement cameras on drivers' behavior and overall road safety still need more. therefore, the main objective of this study is to investigate the impact of the speed and red-light camera systems on the driver's behavior and road safety and to understand driver's response and attitude towards these two systems.

Literature Review

Human errors are considered as the lead cause of traffic crashes in the majority of crash reports over the world (Karscasu and Er 2011). Early study, Treat et al. (1979), found that "human errors and deficiencies" were a definite or probable cause in 90-93% of crashes. More updated report by NHTSA's (2008) stated that human error is the critical reason for about 93% of crashes. That findings prove the significant impact of improving drivers' behavior on improving road safety level. Traffic enforcement is the most powerful toll that enforce drivers to follow traffic rules and drive by a safer way. The main purpose of traffic law enforcement is to push/encourage drivers to comply with traffic rules, and it is traditionally underpinned by the principles of deterrence theory that the behavior of human beings can be modified by making them fearful of the consequences of committing illegal acts (Homel, 1988).

Recently, automated traffic enforcement devices are widely used, especially speed and red-light running camera systems. Wilson et al., 2006, reviewed some prior studies that tacked the impact of the speed camera on road safety. The reviewed studies concluded that speed camera leaded a reduction in crashes frequency by a range from 14% to 72% and a reduction in related fatalities by a range from 8% to 46%. Another study reviewed 14 speed camera sites (Pilkington and Kinra 2005) that proved a reduction in crash frequency from 5% to 69% and 12% to 65% in injuries and 17% to 71% in fatalities. In U.K., Gains et al., (2004) estimated a reduction of about 42% in fatalities and serious injuries as a result of the national safety speed camera program. In Europe, OECD 2003 pointed out a 50% reduction in fatalities of road crashes. Another study in U.K., belonging to the Department of Transportation, showed a reduction in speed-related fatalities by 65% at fixed speed camera sites and by 28% at mobile speed camera sites (Gains and Humble 2003).

Regarding the red-light camera systems (RLCs), many studies found that the RLCs reduced the overall number of crashes at signalized intersections (especially right-angle collision type) and related injuries and fatalities (Retting and Kyrychenko (2002); Hallmark et al. (2010); Wong 2014). In addition, Maryland (2001) investigated the impact of RLCs at 25 intersections in Howard County, MD. It was found that the right-angle collisions were reduced by 42% and 32% reduction in rear-end collisions and a reduction of 22% for other types of collisions. In U.K., Hooke, et al. (1996) evaluated the effectiveness of RLC in various sites in England and Wales covering 78 intersections. It was found that the total injuries of crashes at the studied intersections were reduced by 18% in average. Hu et al. (2011) studied many signalized intersections at 99 cities. It was found that RLCs decreased the overall fatal collisions.

Study Approach

The impacts of two automated traffic enforcement systems on the drivers' behavior and road safety are investigated in this study: speed camera and red-light camera systems. These two systems have been installed in the city of Abu Dhabi during the last decade and are still in increasing numbers.

Two approaches were applied to achieve the study objectives. The first approach is comparative statistics of road safety indicators such as number of crashes and number of related fatalities before and after the installation of the enforcement systems. The second approach relied on a self-reported questionnaire for a sample of licensed drivers in AD. The questionnaire survey aims to investigate AD drivers' behavior, response, and perception towards the installed enforcement camera systems. In addition, to know the awareness and education level of drivers regarding road safety aspects.

Data Collection

Two sources of data are employed in this study: 1) traffic crashes and violations data, and 2) interview survey data.

Crash and Traffic Violation Data

First data set is included the severe crash data during last six years from 2012 to 2017 that were extracted from AD traffic police database. A severe crash is the crash that resulted in at least one injury or fatality. The database includes all information about each crash (for example: location, road feature, crash cause, crash type, crash description, vehicle involvements information, etc.), and at-fault drivers' characteristics (such as age, gender, nationality, driving license information, years of driving experience, etc.). In addition, traffic rules violation records of all drivers were extracted from the traffic violation database of AD police, especially speed and red-light running. Traffic violations are classified based on the violation rule type and number of traffic violation points. The database has all information about the offender drivers' characteristics, location of the violation, and type of violation (face to face or through automated systems).

Survey Questionnaire Data

Second source of data was collected by conducting self-reported questionnaire survey. The questionnaire form included 42 questions to examine and understand drivers' behavior, attitude, education and reaction towards the new advanced two enforcement systems in AD. The questionnaire form was prepared in two different languages; Arabic and English. More than one thousand questionnaire forms were handed out among licensed drivers in AD in different public areas (such as governmental authorities, shopping malls, etc.). The sample of drivers is randomly selected taking into consideration the demographic characteristics distribution of licensed drivers in term of drivers gender and age to represent the real situation of drives population in AD. Finally, about 600 reliable and completed forms were selected to be used in the analysis process of this study.

Crash Data Analysis

The study methodology is mainly based on conducting comparisons between the traffic safety indicators in terms of number of crashes, crashes fatalities, and number of traffic rule violations before and after installing the automated enforcement devices (for both speed cameras and red-light cameras).

Impact of Speed Camera Systems on Speed-Related Crashes

Speed is one of the major factors contributing to traffic crash occurrence and severity. Many studies show that any small reduction in speed value can result in a significant reduction in road trauma. It was noticed that speeding violations make up about 81.7% of the total traffic violations record in AD. Statistics shows that male and young drivers being more likely to get involved in speed-related crashes than female and older drivers. Accordingly, road safety strategy that establish in 2011 focused in increasing the number of speed cameras for improving road safety in general and to achieve the strategic target to reach the fatality rate 3.0 fatalities per 100,000 inhabitants by 2023 from 10.7 fatalities per 100,000 inhabitants in 2011. Based on that the total number of the installed speed cameras has been increased from 422 cameras in 2012 to 1,450 cameras in 2017. During these years a significant reduction of speed-related crashes was observed.

Fig.1 illustrates the relationship between the number of the installed speed cameras and the frequency of the speed-related crashes over years. This figure clearly shows that as the number of speed cameras increases, the number of speed-related crashes decreases from 340 crashes in 2012 to 142 crashes in 2017 (i.e., about 58.2% reduction in speed-related crashes).

Fig. 1: Number of Speed Cameras Vs Speed-Related Crash Frequency

Fig. 2 shows the relationship between the number of the installed speed-cameras and the number of fatalities that resulted in speed-related crashes. This figure shows a reduction in fatalities of speed crashes from 77 fatalities in 2012 to 46 fatalities in 2017 (i.e., a reduction of 40.3% in fatalities that resulted in speed-related crashes).

Fig. 2: Number of Speed Cameras Vs Number of Fatalities Resulted in Speed-Related Crash

With increasing the number of speed cameras, the number of speeding violations is increased accordingly. Fig. 3 shows the relationship between the number of fatalities and severe-injuries that resulted in speed crashes in terms of total number of speeding violation records during last six years. The linear trend in this relationship shows the decreasing trend of fatalities and severe injuries as a result of increasing speed enforcement in terms of number of speed violation tickets that have been issued. all of the previous results reveal that increasing speed enforcement by increasing speed cameras led to significant reduction in speed-related crashes and fatalities.

Fig. 3: Speeding Fatalities and Severe Injuries

Impact of Red-Light Camera Systems on Red-Light-Running Crashes

Red-light running is considered one of the most prominent factors in urban crashes at signalized intersections and contributes to a rising rate of fatalities in recent years around the world. Based on the 2014 statistics in AD, about 60% of the total severe crashes at signalized intersections were due to red-light running violations. To decrease these numbers, red-light camera systems (RLCs) have been activated in the fourth quarter of year 2013 at 30 signalized intersections in AD city. To evaluate the impact of RLCs on road safety at intersections where the RLCs were installed, a before and after study was then conducted by investigating crash patterns in the four years before RLCs activation (i.e., from 2010 to 2013) and after the activation of the RLCs (i.e., from 2014 to 2017).

Fig. 4 shows the total number of crashes that occurred due to red-light running drivers at AD intersections from 2010 to 2017. This figure clearly shows a significant reduction in red-light crashes since year 2014 (i.e. after activation of the RLCs) compared to the period before. By aggregating the total crashes of red-light for the four years after and before RLCs, it was found the reduction in red-light related crashes have been reduced by about 47.2%. Furthermore, Fig. 5 shows the number fatalities that resulted in red-light crashes during last eight years. this figure shows a significant reduction of fatalities at intersections that resulted in red-light runners since 2014. By aggregating the total crashes of fatalities due to red-light running crashes during the four years after and before RLCs, it was found the reduction in the fatalities that resulted in red-light crashes have been reduced by about 53.6%.

Fig 4. Crashes due to Red-Light Runners

Fig 5. Crash Fatalities due to Red-Light Runners

By analyzing the crashes that occurred at the 30 intersections where the RLCs were installed, it was found that the total number of crashes at these intersections was decreased by a range of 25% to 88% during the four years after RLCs installation compared to the four years before with average reduction in all intersections of 52.5%. In addition, the total crashes that occurred due to red-light was decreased by a range of 11% to 100% with average reduction in red-light crashes of 57.0% at the 30 intersections.

Questionnaire Survey Data Analysis

As mentioned before, about 600 self-reported questionnaire forms are used in the analysis for more understanding the driver's behavior and response to speed and red-light camera systems. The first 5 questions in the survey form was about drivers' characteristics including gender, age, nationality, experience and education level. Fig. 6 shows the percentage of the sample participants of drivers and the licensed drivers' population in AD in terms of gender and age. The Chi-Square test showed that the sample of drivers is significantly represent the drivers' population.

Fig 6. Drivers' Characteristics in the Sample and Population

Due to the limitation of this paper length, Table 1 shows results of some key questions of the survey. It shows that about 16.1% of drivers have more than 5 speeding violations during the last year. About 11.8% of drivers feel no enough speed enforcement and 10.5% reported that they can avoid speed camera detection. About 32.1% of drivers prefer high speed limit values and 11.4% admitted that they intentionally like to violet the speed limit. A significant percentage of drivers (73.2%) reduce their speed when they recognize a speed camera ahead. one third of the drivers directly reduces their speed just when see a speed camera without checking their current speed value. Such a behavior of reducing speed just to see the radar should be investigated given the seriousness of this behavior on traffic safety.

Regarding the location of the cameras, 53.1% of the drivers are familiar with the enforcement camera locations and 61.5% of drivers easily recognize the camera locations. That may interpret their behavior of reducing speed at camera locations. In addition, the percentage of drivers who reduce their speed when they recognize a patrol car stopping on the road side is higher compared to speed cameras. Finally, a significant percentage of drivers (89.6%) admitted that the existence of speed camera systems led them to comply with the speed limits. Most drivers (about 83.0%) believe that automated enforcement camera systems improved road safety level.

The survey data analysis showed that almost three-fourths of the drivers (73.6%) who were involved in speed-related crashes had at least two speeding violation tickets during the last year. This confirms the fact that the majority of the drivers who frequently violate the speed limit are more likely to be involved in speed-related crashes. Furthermore, it was found that male drivers tend to drive much faster, have more repeated speeding violations, and prefer higher speed limit values compared to female drivers. Most drivers tend to violate speed when they feel no enough speeding enforcement on the roads; the respondents who feel there isn't enough traffic monitoring were the most reckless where about 70.4% of them had at least two speeding violations during the last year.

Some alarming results were that 76.7% of participants claimed that they usually exceed the speed limit when they feel no speed camera around, about 88.2% reduce their speed when they approach speed camera locations, and 52% know well the speed camera locations. Moreover, about 78% of drivers got at least one speed violation ticket and 37% of them got more than 4 speed tickets during the last year. It is important to mention that about 33.7% of the respondents feel the existing number of speed limit signs isn't enough, which is a percentage that can't be overlooked since about 75.5% of them had no less than two speeding tickets last year.

Table 1: Participants' Responses to some Questions

Question No.	Variables	Categories	Freq.	Percentage
Q6	How many speed violations tickets did you get during the last year?	- Nothing	129	21.7%
		- One only	95	16.0%
		- 2 ~ 3 violations	152	25.5%
		- 4 ~5 violations	123	20.7%
		- More than 5	96	16.1%
Q8	What are the main reasons that make you exceed the speed limit while driving?	- Low values of the posted speed limits	199	33.2%
		- I feel no enough monitoring and enforcement	71	11.8%
		- I can avoid the radar easily	63	10.5%
		- I was in a rush and try to save time	253	42.2%
		- I enjoy high-speed driving	14	2.3%
Q10	Are the existing speed limit values on external roads satisfactory for you?	- Yes	351	63.1%
		- No, I prefer higher speed limit	180	32.4%
		- No, I prefer lower speed limit	25	4.5%
Q12	Do you prefer removing the existing speed limits?	- Yes	88	15.3%
		- No	488	84.7%
Q13	Do you always comply with speed limit signs?	- Yes	513	88.6%
		- No	66	11.4%
Q14	Do you adjust your speed when you approach the speed camera?	- Yes	429	73.2%
		- No	157	26.8%
Q15	What is the action you take when you watch a speed camera?	- Reduce my speed directly	72	32.9%
		- Look at my current speed to decide whether to reduce my speed or not	127	58.0%
		- Do nothing	20	9.1%
Q16	Are you familiar with the locations of existing speed and red-light cameras on the roads that you frequently use?	- Yes	297	53.1%
		- No	262	46.9%
Q17	Do you easily recognize the	- Yes	347	61.5%

Question No.	Variables	Categories	Freq.	Percentage
	locations of fixed radars when you drive on any road?	- No	217	38.5%
Q19	Is the value of fines for speeding violations deterrent for you?	- Yes	486	83.2%
		- No	98	16.8%
Q23	Are the existences of enforcement cameras leading you to comply with the speed limits?	- Yes	527	89.6%
		- No	61	10.4%
Q24	Have you faced a speed-related crash before?	- Yes	178	30.0%
		- No	416	70.0%

One interesting result was that 15.5% of the participants prefer to have roads with no speed limit. Fig. 7 shows that drivers who prefer removing the speed limits completely had slightly more speeding violations (65.9%) than others (62.9%). However, they had a remarkably higher speed-related crashes involvement (50.0%) versus (26.6%) for those who prefer roads with clear speed limit regulation. These findings prove the importance of defining a speed limit for all roads and the speed limit signs should be visible and clear.

Fig. 7: Speeding Violations and Speed-Related Crashes Regarding Speed Limits Approval

As for the drivers' opinions regarding the efficiency of the automated enforcement camera systems, Fig. 8 points out that a lower percentage (60.9%) of drivers who believe that automated enforcement camera systems improved road safety level got speeding violations compared to those who think enforcement camera systems have no impact on road safety (70.0%). Moreover, almost half of drivers who thought that enforcement camera systems did not improve safety were involved in traffic crashes versus 26.0 % of drivers who thought that enforcement camera systems have a significant impact in improving road safety.

Fig. 8: Impact of Drivers' Opinion towards Enforcement Cameras Efficiency

It was found that the drivers who are unaware about the margin value between posted and enforcement speed limits were involved in speed related crashes more than others. The merging value between the posted speed limit and enforcement speed camera limit is 20 kph in AD. about 45.3% of drivers who thought the merging speed value is more that 20 kph were involved in speed crashes and hove higher speed violations compared to 25.4% of drivers who know the correct value. A positive finding in the survey is a significant number of drivers (about 83% of participants) believe that the recently implemented speed and red-light camera systems actually improved the road safety level in AD.

Fig 9. Impact of Drivers' Knowledge on Violations and Speed-Related Crashes

Conclusion and Recommendations

This study investigated the impact of the two automated traffic enforcements systems: speed and red-light camera systems on road safety and driver's behavior in Abu Dhabi city. Two sets of data were used to achieve the study objective; crash and traffic rule violations data during last six years and self-reported questionnaire survey data. About 600 reliable and completed forms were selected to be used in the analysis process of this study.

Crash data analysis showed that the total number of the installed speed cameras has been increased from 422 cameras in 2012 to 1,450 cameras in 2017. As a result, the number of speed-related

crashes decreases from 340 crashes to 142 crashes during the same period (about 58.2% reduction in speed-related crashes). In addition, the resulted in fatalities in the speed-related crashes were decreased from 77 fatalities to 46 fatalities (about 40.3% reduction in fatalities in speed-related crashes). The relationship between speed violation records and crashes showed that by increasing speed violations tickets the speed-related crashes decreasing.

Regarding red-light camera system RLCs, by comparing four years before and four years after RLCs installation, the analysis showed that the total crashes that occurred due to red-light running at all signalized intersections in Ad were reduced by 47.2% and RLCs installation. In addition, the red-light running related crashes were reduced by about 52.5% at the intersections where the red-light cameras were installed and the resulted in fatalities of these crashes were reduced by 57.0%.

The questionnaire survey data analysis showed a lot of information regarding drivers' behavior and response towards enforcement cameras. Male and young drivers tend to drive and violate the speed limit more than female and old drivers. About 53.1% of drivers are familiar with the locations of speed and red-light cameras. The majority of drivers reduce their speed at speed camera sites to avoid camera detection. The analysis proved that drivers who prefer high speed limit and who have more than two speeding violation tickets were involved in speed-related crash more than others. The analysis also showed a weakness in the road safety education for drivers. Drivers who do not know the true margin value between the posted and enforcement speed limits are more likely to be involved in speeding violations and speed-related crashes. Finally, about 83% of participants believe that speed and red-light cameras have significant impact in improving the overall road safety level in AD.

It is expected that the findings of this study will be very helpful for road safety authorities in Ad to improve road safety programs and action plans. in the light of these findings, it is recommended to continue in the installation of speed and red-light cameras due to its positive impact of road safety and driver's behavior. It should be taken into consideration when installing the speed camera to combine between the visible and hidden speed camera sites to reduce the local impact of the visible cameras and feel drivers that they can be detected at any time. In addition, more effort towards increase the drivers' education regarding speeding behavior and general road safety aspects in Ad should be done through awareness campaign especially for young drivers.

Acknowledgment

The authors would like to thank Abu Dhabi traffic police for providing the data used in this study.

Abstract

The preferences of customers in the restaurant and hospitality industry strongly depend on national characteristics, fashion and the spread of certain behavioral patterns. Therefore, it is important to reveal how the increase in the popularity of pro-ecologically oriented ideas and healthy food can affect some industries. It is sociological legitimate to select the population of people from Generation Z as a research group that is currently entering the market with new ideas and new needs.

The specific aims of this paper are: (1) to explore the Generation's Z attitude to eco food and green restaurants; (2) to conduct a comparison between representatives of Generation Z in three Middle and Eastern European countries: Poland, Bulgaria and Ukraine, concerning this attitude. The article describes the main characteristics of the Generation Z. This study presents a discussion on the results of empirical research covering the attitude of Generation Z to pro-ecological activities and lifestyle, green food and projection of consumer behavior towards the creation of green-food restaurants.

The contribution of this paper is as follows:

- Comparative analysis was done on the basis of the answers of the representatives of Generation Z from three different post-communists countries, which has not been done till now by other authors;
- Innovative is the idea to outline the relation between Generation Z's attitude to eco-food and the entrepreneurial intentions for setting-up eco-restaurants as own business;
- The current level of pro-ecological consciousness of the representatives of Generation Z in the three countries was revealed.

Introduction

Young people are more and more important segment of the tourist market. The annual value of the tourist market of that group of customers was estimated at 190 billion dollars in 2009 and 286 billion dollars in 2014 (Richards, 2016). The people constituting that segment possess the features crucial in tourism. What distinguishes them are relatively high amount of free time, mobility and curiosity. At the same time, they are eager to learn about new cultures, be close to nature and local communities. These features make the young an important group of customers of the tourist industry not least because they also have at their disposal significant financial measures, which is a result of the financial aid from their parents and the fact that they are not bound by the necessary expenses

Cite this Article as: Denka ZLATEVA, Mariya VELEVA, Maciej DEBSKI and Antoni KOLEK "Generation Z's Attitude to Eco Food as Determination Factor in Setting Up Eco Restaurants" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

characteristic of older generations. It is also believed that the importance of this group is going to increase fast in near future (Buffa, 2015). At the same time, it is argued that the tourist industry is the industry of the future (Vukic, Kuzmanovic and Stankovic, 2014). Understanding the specifics of consumption of a given market segment, the expectations, and the sources of satisfaction, is crucial for successful sales. Taking into account the growing importance of the group and the increasing number of young people as customers of the tourist industry, the study of their behavior seems fully reasonable.

At the same time, the question of sustainable development is a significant notion in the development of the modern tourist industry (Tzschenke, Kirk and Lynch, 2004), and it has become an important topic of analyses (Berezan, Milar and Raab, 2014). Tourists' interest in sustainable holiday experience has been pointed out as a global trend (Buffa, 2015). Its key aspect is ecology and care for environment, which in many places is endangered by the excessive development of tourism. It is green concept itself is identified as one of the most crucial tasks facing the modern tourist industry (Han, Kim and Kiatkawsin, 2017). It is underlined that the concept and the need to follow its rules are especially noticeable in the hospitality industry (Mousavi, Oskara, Woosnam, 2017). Its dynamic growth inevitably means high impact on the environment (da Rosa and Silva, 2017). It is obvious that the rapid growth of the hotel services and venues is closely related to the growing number of young tourists and the growing demand for culinary services.

Understanding the motives behind purchases and the sources of customers' satisfaction is of key importance for effective sales based on adding value for consumers. That is why it is worthwhile to analyze various groups which determine the demand on the tourist market. One of such groups of ever increasing importance is the group of young people. Their behavior has undergone numerous analyses, but such studies are mainly focused on the Generation Y (Buffa, 2015; Jang, Kim and Bonn, 2011) while the Generation Z remains examined insufficiently studied. Bearing this in mind, it seems only reasonable to analyze their attitude to pro-ecological behaviors among entrepreneurs in the context of using such behaviors in building company's competitive advantage. For the purpose of this research, the following hypotheses are set:

1) The environmental protection is important to generation Z;
2) The eco food is important to generation Z;
3) Generation Z perceives „being green" as competitive advantage, and it makes sense to establish „green restaurants" as part of their green lifestyle.

In order to gain a broader perspective, a comparative analysis is carried out. The analysis includes groups of students coming from three Middle and Eastern European countries: Poland, Bulgaria and Ukraine. It yields yet another fourth question: Can any differences between the representatives of the three nations in question regarding ecology and eco food be observed?

The Generation Z – General Characteristics

In the literature concerning the subject, young people are defined according to different criteria. The authors of this study focused on the people belonging to the so-called Generation Z, assuming that it comprises people born between 1995 and 2010 (Lazanyi and Bilan, 2017; Vallone et al., 2016; Ivanyi and Biro-Szigeti, 2019). Those who are underage have been excluded from the present study as they appear far more difficult to examine (Sauthgate, 2017). This situation results in the insufficient number of analyses, especially those of the empiric character which describe purchasing behaviours of the Generation Z including those regarding tourism (Cini, Leone and Passafaro, 2012). At the same time however, the literature accentuates the need for studies concerning the behaviours of the representatives of different generations (Li, Li and Hudson, 2013).

Some of the analyses point out the fact that the young people from the Generation Z are independent (Desai and Lele, 2017), expect fast access to information and instant answers to their questions (Opris and Cenusa, 2017). This should be seen as an important premise for those employees of organisations who are responsible for communication with the young. What is not surprising is the

high level of using the available online tools for tourism-related consumption, which itself is the subject of numerous researches (Hamed, 2017; Ip, Lee and Law, 2012; Rudez and Vodeb, 2015). This generation is even characterised as more online than offline. Another characteristic feature is their use of smartphones to gain access to the internet (87% of them) when compared to older generations (Ivanyi and Biro-Szegeti, 2019). Not only does it show their need for fast access to information but also the need for various applications used for tourist consumption. The easy use of such applications results in them, being used for finding and booking tourist products on the way to work, at work or during lunch breaks (Wang, Xiang and Fesenmaier, 2014). The young do it also while travelling (Tan et al., 2017), waiting for „last minute" offers or other „limited-time-only" offers.

Hence, the features characteristic of the tourist consumption by the young should not be surprising. According to the literature, they are as follows (Baltescu, 2019):

- Proneness to last-minute decisions;
- Constant search for bargains and options;
- Use of word-of-mouth recommendations while making tourist decisions;
- Ever growing use of low-cost services.

It is worthwhile to consider the young's attitude to ecology. The environment and the need to protect it have been named as one of the main factors determining the growth of the tourist market. Moreover, the significance of this factor is still rising (Dwyer et al., 2009). The literature points at eco-tourism, nature-based tourism, responsible tourism or green tourism (Buffa, 2015). As early as in 2010, over 60% of Europeans voiced their concerns about air pollution and 50% feared the negative impact of food on health (Food-related risks, 2010). It is observed that a lot of people implement often radical changes to their lifestyles in order to limit the impact on the environment (Bostrom and Klintman, 2011; Zalejski and Faszczewska, 2012). Sidali, Huber and Schamel (2017), in turn, present an analysis which reveals different attitudes to the ecological issues depending on the respondents' age. Other sociological factors such as sex, level of education or level of income do not seem to generate any significant differences. Hence, it is worthwhile focusing on specific age groups, including the young ones. Han et al. (2017) present the results showing that young people do care about the environment and are eager to undertake pro-ecological actions. Similarly, in Poland it is the young who are most committed to pro-ecological actions. (Zalejski and Jaszczewska, 2012).

Green Restaurants for Green Consumers

Nowadays consumer behavior is strongly influenced by environmental or "green" values. According to Doszhanov and Ahmad (2015) and Mohd (2013) these values influence their consumers 'needs and attitudes, or in other words, what people buy and what they want to consume in the restaurants. 'Green' consumers are usually defined as consumers who apply consumer practices that are viewed as environmentally-friendly (Connolly and Prothero, 2008).

In the widest sense the 'green customer' is a person who is interested in the environment. According to numerous authors, the occurrence of green consumers is obvious worldwide. For example, in the USA, health-aware people prefer green restaurants, since they offer local, organic and healthy food (Namkung and Jang, 2017). A typical stereotype of the 'green customer' is that they implement green practices at home (Di Pietro et al., 2013), they are mid-high income earners, female (Han et al., 2011) and youths (Baltescu, 2017). This new trend results in a new market with an environmental conscience and new competitive advantages for the companies. In the same time, rising environmental and health concern about the current food production systems has contributed to increasing number of people considering the purchase of ''eco-friendly'' food (Mohd, 2013). Baltescu (2017) surveyed 264 students in Brasov. The results showed that although only 34% were aware of the green restaurant concept, 95% consider themselves as highly environmentally concerned. To young adults, an ecofriendly restaurant attributes are: use of renewable energies, attention to the use of ingredients, avoiding of frying procedures, and the use of organic ingredients (Baltescu, 2017).

Jang et al. (2011) defined a green restaurant as one that implements green practices. According to some authors, green practices that can be widely applied in restaurant businesses include employing energy-and water-efficiency equipment, using locally-grown and organic food, offering healthy menus, forbidding disposable cups and to-go containers, training employees to adopt green practices, recycling and disposing of cooking oil, and reducing pollution (Gázquez-Abad et al., 2015; Schubert et al., 2010).

La Vecchia (2008) points out, that in general, organic, locally and sustainably grown food can be considered as green food. It could be suggested that food-focused green attributes such as organic or locally-grown food ingredients may appeal to customers, especially health-conscious ones, who tend to prioritize their health and form their purchasing decisions based on such principles (Jang, Kim and Bonn, 2011). In their analysis, Hu, Parsa and Self (2010) confirmed that people who care more about their health are more likely to purchase green products.

Kwoka and co-authors (Kwoka, Huang and Hu, 2016) study what really matters to the consumers, why they should prefer a green restaurant. Based on the results of the survey, the authors make the following suggestions: restaurants should highlight what they have achieved in terms of environment-focused green attributes on their websites, advertisements, and other marketing materials. Green restaurants should develop menu items or special events tailored to female consumers, who tend to view green attributes to be more important than males. But according to the findings of the study green restaurants should be very cautious about charging higher prices, since most consumers indicated that they would make only marginal efforts to dine at a green restaurant. Consumer demand for environmentally friendly food has risen quickly over recent decades. Establishment of new environmental regulations has increased individuals' environmental awareness. A study conducted by Harris Interactive shows that 63% of consumers would spend more for organic food or locally grown food.

That's why increasing consumer interest in eco-friendly food caused a number of changes to the restaurant industry. Young people have become a challenging market in the restaurant industry. There are lots of studies concerning Generation Y consumers' behavioral intentions concerning green restaurants (Yoon, Woo and Mark, 2011), but studies for Generation Z are yet insufficient. That's why, in order to successfully market to this generation, restaurateurs need to understand how to satisfy this market segment of consumers.

Methodology

Sample and data collection

The study took place in December 2019 and January 2020 and included a group of students. of Generation Z in three Middle and Eastern European countries: Poland, Bulgaria and Ukraine. The survey addressed to respondents was named "Generation Z's attitude to eco food as determination factor in setting up eco restaurants". Its purpose was to obtain answers enabling the determination of attitudes and values related to organic food and the will to establish organic restaurants.

The research is directed to Generation Z - people born between 1995 and 2010. Having in mind their age, it was considered appropriate to hold it among university students. The survey is addressed to 18-26 years old respondents at University of Social Sciences - Lodz (campus Warsaw, Poland), and University of Economics - Varna, Bulgaria (Bachelor and Master degree students). The respondents were asked voluntarily to fulfill the survey questionnaire and to present them directly to the survey administrators. 600 questionnaires were distributed, as 55 of them were incomplete or invalid. 545 questionnaires were processed.

Questionnaire Development

Questions to be answered by respondents were established in accordance with the social research methodology aimed at limiting the interviewer's influence (Babbie, 2008). The respondents' knowledge of the issue also allowed questions to be predicted about future behavior and motivations (Schwarz, 2007). The survey questionnaire consisted of 15 questions that were directed to 195 Poles, 204 Ukrainians, and 146 Bulgarians.

The questionnaire was created in accordance to the research hypotheses, stated in this paper. It consists of several parts: the first one reveals demographic information like gender, age, and socio-professional groups of respondents; the second part concerns their attitudes towards pro-ecological actions, and behaviors implemented in their everyday life; the third part studies their perceptions of eco-food and green restaurants. Also there is a question concerning the relation between their green life-style and their intention to establish a green restaurant as a start-up or future business.

All the answers were measured using a nominal scale.

Data Analysis

The statistical analysis procedures used in the research are descriptive statistics as well as factor analysis. First, descriptive statistics such as simple frequencies and average values were used. Then analyzes were made detailing socio-demographic characteristics, as well as international comparisons.

The comparative analysis used in the article is an element of the study consisting in listing objects distinguished due to a common factor and observation of other differentiating aspects. The differences in the perception of eco food and eco business revealed as a result of the study have revealed the specifics of perception of this industry in different countries.

Limitations of the study and research methods used

This study included in the research is not free from limitations. First, the populations of young people studied in different countries may be an imperfect representation. Secondly, the respondents' attitudes may change over time and it may be interesting to repeat the test after a year or two. Among the limitations of the study, we can also mention the diverse level of knowledge about eco food and eco business. This means that people who are more aware of healthy attitudes may behave differently.

Results and Discussion

Respondents' Profiles by Gender and Age

According to gender criteria, out of 545 respondents, 361 are female and 184 - male. Among the different nations included in the research, the percentage between male and female respondents is as follows (table 1):

Table 1: Profile of the respondents based on gender

Gender of the respondents	**Results by nationality of the respondents**		
	Ukrainians	*Poles*	*Bulgarians*
Female	70%	59%	69%
Male	30%	41%	31%

Source: own research

More women than men took part in the study. The largest percentage of women can be found in the group of Ukrainians (70%) and Bulgarians (69%). In the case of Poland, the proportion was 59% to 41%.

People between 18-26 are considered as Generation Z. In according to this, and the age criteria, 156 of the respondents are 18-20 years old, 248 from them are 21-23 years old, and 141 are 24-26 years old. Table 2 shows the distribution of the respondent groups by age and nationality as follows:

Table 2: Profile of the respondents by age

Age of the respondents	**Results by nationality of the respondents**		
	Ukrainians	*Poles*	*Bulgarians*
18 – 20 years old	54%	23%	1%
21 – 23 years old	38%	51%	48%
24 – 26 years old	5%	26%	51%

Source: own reserach

Respondents by Social Groups

Among the surveyed people social groups related to the status on the labor market and participation in education were distinguished: 156 are students, 4 are working, and the biggest group is of the working students - 385 respondents. Table 3 presents the percentage of people by nationality and socio-professional groups:

Table 3: Profile of the respondents by social groups

Socio-professional groups of respondents	**Results by nationality of the respondents**		
	Ukrainians	*Poles*	*Bulgarians*
Student	25%	18%	48%
Working	1%	1%	0%
Working student	74%	81%	52%

Source: own research

Summing up the demographic features of the surveyed populations, it can be said that responses can be classified as the Generation Z, and the conducted research maintains the diversity of the population due to gender, age and socio-occupational group.

Attitudes towards pro-ecological actions, and behaviors implemented in their everyday life

Among the examined issues a question arose regarding the attitude towards pro-ecological actions and products. According to the conducted research, as much as 62% of Bulgarians believe that this is important and always pays attention to the environmental performance of products. In this case, only 22% of Ukrainians surveyed and 12% of Poles surveyed said that they always pay attention to it. This is shown in Table 4:

Table 4: Attitude towards pro-ecological actions and products

Pro-ecological actions	Results by nationality of the respondents		
	Ukrainians	*Poles*	*Bulgarians*
It is important, I always try to act in line with ecology	22%	12%	62%
I try to act according to ecology, but I do not always succeed	64%	67%	38%
I'm indifferent	7%	13%	0%
I follow the rules of ecology only as long as it is in line with my interest	5%	7%	0%
It is a waste of time	2%	1%	0%

Source: own research

The results show that young people, in all three countries, pay attention to the pro-ecological idea but with varying degree of awareness. The fact that all respondents from Bulgaria indicate the first or second answer speaks of a naïve attitude, rather than of strictly following the ecological way of life. The concept of ecological lifestyle is relatively new to the Bulgarian society and is not yet deeply understood by the young people there.

Among the Ukrainians and Poles surveyed, the largest is percentage of the respondents who try to act according to the ecological idea but do not always succeed. For Bulgarians it is approximately one third of the respondents. 13% of Poles and 7% of Ukrainians surveyed are indifferent and 1% of the Poles and 2% of the Ukrainians say that, being pro-ecologically oriented is a waste of time. It is disturbing that more than 8% of all respondents are still not aware of the importance of pro-ecologically oriented lifestyle. On the other hand, they are still young and it could be presumed that in nearest future they may become more ecologically oriented.

The answer "I follow the rules of ecology only as long as it is in line with my interest" was indicated by 7% of Poles and 5% of the Ukrainians. This position reveals the more selfish-oriented values, which is more or less typical for the young people of 21st century.

In order to indicate what the everyday life of respondents related to environmental protection looks like, they were asked what activities and behaviors they perform. Table 5 presents the results based on the result referring to measures: definitely yes - 0, rather yes - 1, rather not - 2, definitely not – 3. According to the respondents' answers, the most frequently implemented action among Ukrainians is to take the empty glass bottles to recycle-collection point; to avoid plastic packaging and to use biodegradable packaging. Among Poles, sorting garbage and switching off lights are the most important things. Also they usually use own shopping bags in order to avoid disposable plastic one. It is well known that they are non-degradable and are considered as one of the biggest environmental threads. In the case of Bulgarians, the most common form of pro-ecological activities is also delivering empty glass bottles to recycle / collection point, to carry own shopping bag, and sorting of garbage.

Table 5: Everyday actions/behaviors implemented in respondents' life

Everyday behavior of respondents	Results by nationality of the respondents		
	Ukrainians	*Poles*	*Bulgarians*
I sort my garbage	1,58	1,14	1,92
I save water cutting down its use	1,52	1,26	2,38
I carry my own shopping bag so that I don't need to buy disposable plastic ones	1,69	1,20	1,66
I use biodegradable bags	1,12	1,31	2,82
I save electricity cutting down its use	1,68	1,36	2,58
I try to buy and eat healthier foods	1,89	1,47	2,66
I pay attention/react to unnecessarily switched-on light	2,42	1,19	2,49
I take empty glass bottles to recycle/collection point	0,52	1,93	1,65
I avoid plastic packagings	0,9	1,65	2,65

Source: own research

The results in Table 5 indicate that for the different nations the same everyday activities have different impact to their ecologically oriented lifestyle. For example, avoiding plastic packaging is measured by 0.9 points for Ukrainians, 1.65 for the Poles, and 2.65 for the Bulgarians. The points for the use of bio-degradable bags vary from 1.12 (for the Ukrainians) to 2.82 (for the Bulgarians). On this base it could be suggested that the reason is still that there is still no generally accepted idea for ecological behavior by all countries.

Perceptions of Green-Food and Green Restaurants

Restaurants, oriented to green practices could establish a new niche for environmentally responsible customers and potentially sustain long-term profits. Such green restaurants could gain advantage over common restaurants on the base of implementing green policy. According to Kassinis and Sotiriou (2003), this could not only attract new customers and form higher satisfaction, but also could lead to increased loyalty and long-term increased sells.

Usually the prices at green restaurants are higher, and according to other researchers (Jang, Kim and Bonn, 2011) it could be a factor for some of the consumers to avoid this type of restaurants, regardless of their green orientation. According to Hannas (2007), even the consumers that are most committed to the green idea do not choose all the time green restaurants.

In our research to the question "Are you willing to pay more for a restaurant, following a pro-ecological policy (green restaurant)?" we received the answers presented in Table 6:

Table 6: Paying more for a restaurant following a pro-ecological policy

Possible answers	Results by nationality of the respondents		
	Ukrainians	*Poles*	*Bulgarians*
Definitely yes	8%	3%	29%
Rather yes	47%	44%	68%
No opinion	18%	28%	1%
Rather not	25%	21%	2%
Definitely not	2%	4%	0%

Source: own research

Almost 2/3s of the respondents (63.4%) are willing to pay more, but only 11.7% of them gave the answer 'Definitely yes", while 51.7% said 'Rather yes". It can be seen that the percentage of those who are firmly ready to pay is approximately low - 11.7%. Similar results are presented by other researchers too (Manaktola and Jauhari, 2007) - they found out that despite of the positive attitude towards green practices, only 15% of the respondents were willing to pay extra for environmental initiatives. Dutta et al. (2008) found out that around half of the respondents are ready to pay up to 3% more than regular menu prices if the restaurant is green, and almost 15% of the respondents would pay as much as 10% more.

On the other hand, almost 20% of the respondents are not willing to pay more even though they realize the advantages of the green idea. If we try to distinguish the national attitude - it can be seen that approximately half of the Ukrainians and Poles would pay more for green food, while for the Bulgarians the percentage is considerably higher (above 90%). Probably it is due to the fact that in Bulgaria, especially out of the capital, there are still not enough green restaurants. So, maybe some of the respondents do not have a real idea about the price differences between green and common restaurants.

In recent years, green food consumption became a global issue and it could be assumed that, as income increases consumers tend to pay more for high-quality food. Food safety and sustainability are two important factors for food quality. That is why green food with less chemical residuals has become more preferable across the world.

In this study, in order to examine whether green food is important for respondents from the generation Z, they were asked if they were willing to pay more for green food. The results are shown in Table 7:

Table 7: Paying more for eco-friendly food

Possible answers	**Results by nationality of the respondents**		
	Ukrainians	*Poles*	*Bulgarians*
Definitely yes	10%	7%	37%
Rather yes	59%	53%	60%
Rather not	26%	32%	3%
Definitely not	5%	8%	0%

Source: own research

The vast majority of respondents (73.2%) in general, are willing to pay more, but there are shaped two segments: definitely ready to pay more (16.14%), and consumers, rather willing to pay more (57.06%). The last ones are prevailing in the answers of all the three nations examined.

The results are similar to the ones of other researchers (Xiaohua, Zhifeng and Yinchu, 2014). In their study they conclude that younger people are willing to pay more for green food. A possible explanation for this could be that they have a longer life expectancy and because of this they prefer food of high quality to gain health benefits.

Almost 27% of the answers belong to the group which is not willing to pay more for eco-friendly food. The possible reasons could be: they are not willing to change their willing habits; insufficient financial resources and because of this - re-arraignment of spending priorities; insufficient awareness of green food benefits. Probably, the regional difference between the big and small cities could be also a reason for these results - the green food benefits awareness is more spread in the big cities than in the small ones.

In addition to economic behavior, an attitude towards health-related qualities of food is also of an interest. Despite that generation Z prefers snacks and street food they are also ready to try new kinds

of food. That is why they are open towards to 21st century trend of green food. According to Mc Sweeney (2019) the majority of generation Z is looking for food that fits in with their values - green, sustainable, and the locally produced.

The respondents of our study were asked to answer the question: "Do you pay attention to health-related qualities of the food you consume?". Results are presented in Table 8:

Table 8: Paying attention to health-related qualities of food

Possible answers	**Results by nationality of the respondents**		
	Ukrainians	*Poles*	*Bulgarians*
Definitely yes	18%	26%	76%
Rather yes	54%	60%	34%
Rather not	26%	11%	0%
Definitely not	2%	3%	0%

Source: own research

Almost 85% give positive answers (36.5% - definitely yes; 48% rather yes). Nevertheless that all the respondents origin from post-communist countries, the national eating patterns have impact on their attitude towards health-related aspects of food.

Relatively low (1.9%) is the percentage of those who definitely does not pay attention to health benefits of food.

In order to examine which specific characteristics of the food our respondents define as green, we asked: "Which of the following statements are true regarding green food?". The possible answers were: always - 0; sometimes - 1; never - 2; no opinion – 3. The presented results (Table 9) indicate that respondents attach great importance to the healthy aspects of food products. Among the main symptoms of healthy food, the most important were: low calorie, production doesn't harm environment, product has short expiry date, or product doesn't contain preservatives. Result is shown in Table 9.

Table 9: Perceived characteristics of green food

Characteristics of green food	**Results by nationality of the respondents**		
	Ukrainians	*Poles*	*Bulgarians*
Is less calloric	1,94	1,46	1,5
Tastes good	2,22	1,33	1,46
Has short expiry date	2,23	1,09	1,11
Its production doesn't harm environment	2,35	1,18	1,02
Is not genetically modified	2,23	1,21	1,01
Is not highly processed	1,89	1,12	1,05
Looks attractive	1,96	1,39	1,46
Is more nutritious	2,15	1,07	1,02
Doesn't contain preservatives	2,2	1,15	1,05

Does not cause allergies	1,98	1,34	1,56
Is very healthy	2,34	1,07	1,03
Has no distinctive feature except high prices	1,54	1,48	1,04

Source: own research

The results presented in the table indicate differences in green food characteristics perception among the respondents, based on their nationality. For Poles, the following features are most often related to green food: it is more nutritious; it is very healthy, while most rarely the following statements are considered true: it is less caloric; it has no distinctive features except high prices.

The Bulgarians consider the answers "it is not genetically modified"; "it is more nutritious"; "its production doesn't harm environment"; "it is very healthy" as most related to the green food. The least related ones are: it does not cause allergies; it is less caloric; tastes good; looks attractive.

Ukrainians differ in their opinion - most often, they associate green food with the statement "it has not distinctive feature except high prices". Next in importance are: "it is not highly processed"; "it is less caloric"; "looks attractive". As least important ones they point out: "its production doesn't harm environment". Comparing the values listed in Table 9, similarities of perceptions of green food for Poles and Bulgarians can be seen, while the opinion of the Ukrainians differs. For example, the statement "it is more nutritious" is among the most important for Poles (1.7) and Bulgarians (1.02), while for Ukrainians it is considered less important (2.15).

According to Schubert, F., et al (2010) the pro-ecological policy of restaurants includes three aspects: environmental, health, and social. The various groups of consumers rank these aspects in a different way while creating the image of pro-ecological restaurant in their minds.

In order to reveal how our respondents estimate the value of restaurants following a pro-ecological policy (or using green-food), a question was included in the survey. Results are presented in Table 10:

Table 10: Value of restaurant following a pro-ecological policy (or using green food)

Possible answers	**Results by nationality of the respondents**		
	Ukrainians	*Poles*	*Bulgarians*
Definitely yes	16%	13%	52%
Rather yes	60%	46%	44%
No opinion	17%	29%	3%
Rather not	6%	10%	1%
Definitely not	1%	2%	0%

Source: own research

Almost 75% of all respondents state that they would value higher such restaurants. It is worth to compare these results to the ones, presented in Table 6, where 63.4% are willing to pay more to visit a restaurant following a pro-ecological policy. Obviously, some of the respondents value higher this kind of restaurants, while they are not able to pay more for them.

17.6% do not make difference between pro-ecological and common restaurants. 7.5% do not see the advantages of pro-ecological ones.

As mentioned above, one of the aspects of the pro-ecological policy of the restaurants is the environmental one. The most common practices related to this aspect are: energy and water efficiency equipment; recycling of cooking oil; pollution reducing; forbidding disposable caps, etc.

A question related to this was set in our questionnaire: "Do you think that the establishment of more restaurants following a pro-ecological policy could support the idea for ecologically clean nature?". The results are presented in Table 11:

Table 11: Relation between establishment of restaurants following a pro-ecological policy and ecologically clean nature

Possible answers	**Results by nationality of the respondents**		
	Ukrainians	*Poles*	*Bulgarians*
Definitely yes	22%	18%	95%
Rather yes	48%	52%	5%
No opinion	22%	16%	0%
Rather not	7%	12%	0%
Definitely not	1%	2%	0%

Source: own research

Less than 10% give a negative answer, while 78% are confident that implementing these practices can help for cleaner nature. Presented by nations, the results are as follows: 70% of the Poles, 70% of the Ukrainians, and all of the Bulgarians support this idea.

In order to obtain a prognostic knowledge about the tendency and willingness to establish a pro-ecological restaurant as a startup for own business by the respondents, a question whether they would like to establish such a restaurant was asked. The results are presented in Table 12:

Table 12: Intentions for establishing a pro-ecological restaurant as a start-up for own business

Possible answers	**Results by nationality of the respondents**		
	Ukrainians	*Poles*	*Bulgarians*
Definitely yes	18%	9%	60%
Rather yes	43%	18%	39%
No opinion	17%	23%	1%
Rather not	16%	33%	0%
Definitely not	6%	17%	0%

Source: own research

From the table it is obvious that 26.2% of all the respondents answer "definitely yes", as in this quota prevail the answers of the Bulgarians (60% of the Bulgarian respondents). 33% of all answers are "rather yes". In this case prevailing is the quota of the Ukrainians (43% of the Ukrainian respondents). Almost 60% of the young people belonging to Generation Z, included in the survey, have entrepreneurial intentions and would start their own business (answers "definitely yes", and "rather yes"). .

The biggest is the share of the Bulgarians, followed by the Ukrainians, and the Poles. It is difficult to define the exact reason for these results. Nevertheless, it could be suggested that most of the young Bulgarians believe that through establishing their own business they could gain financial independence and self-managed professional development.

26% of the respondents are not interested in establishing their own pro-ecological restaurant, at the same time, 14.8% state that they have no opinion.

Conclusions

The presented research demonstrates that young people, in all three countries, pay attention to the pro-ecological idea, although - with varying degree of awareness. For the young people of the three nations presented in the study, the same everyday activities (sorting garbage, saving water, using bio-degradable bags, avoiding plastic packaging etc.) have different impact to their ecologically oriented lifestyle, but they do apply them.

Most of the respondents from Poland, Ukraine and Bulgaria, are willing to pay more for a restaurant following a pro-ecological policy and they believe that such restaurants could help to protect the environment, because of the pro-ecological practices implemented. Green food consumption becomes trendy for the generation Z and it is not just because it turns out to be a fashion, but also because they pay attention to the health benefits of green food and healthy lifestyle too.

Almost 75% of the respondents estimate higher the value of restaurants following a pro-ecological policy which highlights their ecological consciousness regardless of nationality, and consider it as a competitive advantage. There is a strong bond between their ecological awareness and the level of their intention to establish a pro-ecological restaurant as a start-up. However, a difference could be seen among the representatives of the three countries studied. A large number of respondents representing generation Z believe that such restaurants could help to protect the environment.

The research hypotheses adopted for the purpose of this study have been confirmed by the results and thus - should be considered as correct. The contribution of this paper is spread in few aspects:

- Comparative analysis was done on the basis of the answers of the representatives of Generation Z from three different post-communists countries, which has not been done till now by other authors;

- Innovative is the idea to outline the relation between Generation Z's attitude to eco-food and the entrepreneurial intentions for setting-up eco-restaurants as an own business;

- The current level of pro-ecological consciousness of the representatives of Generation Z in the three countries was revealed.

This study could be considered as a starting point for further analysis related to Generation Z's attitude towards pro-ecological life-style.

Abstract

In modern times, the process of making a decision on whether to invest in education or not is complicated. When a person decides to invest in education and continuing education, his expectations regarding his future income play a significant role in this matter. Since the results of investment in education appear in the form of higher wages, it is possible to conclude if the investment was profitable and efficient. The main practical problem is associated with the lack of scientific tools which determine the relationship between the competencies formed at the training stage and the results that are obtained by the both sides interested in the development of intellectual resources. Along with the transition to the digital economy, significant changes are taking place in the labor market. The demand for professions that are associated with the performance of repetitive formal operations is decreasing. Instead there is a growing demand for specialists who can deftly use digital technologies for the benefit of business, competence profiles are changing; new professions continue to appear, the requirements for staff flexibility and adaptability are increasing as well as the need to obtain supra-professional skills ("soft skills"). In this regard, the purpose of the article is to create a measuring toolkit for assessing the results of investment in the development of intellectual resources. The proposed toolkit allows for a more accurate setting of educational tracks on the basis of technical specifications of employers' enterprises and allows accelerating the process of paying off the investment in the development of intellectual resources. The authors attempted to describe mathematically the relationship between the competencies formed at the training stage and the results achieved by the participants in the development of intellectual resources. A particular feature of the proposed economic and mathematical tools is the ability to quantitatively measure the relationship between competencies and wages. At the same time, the authors note down that this method is developing in the direction of paying attention to the formation of professional competencies and personal qualities in the development of intellectual resources.

Introduction

In recent years, the development of the digital economy has been driven by large-scale technological, demographic and geopolitical trends.

During this time, the mechanisms of human involvement in economic activity have changed, along with the transition of the economy from one type to another. The era of mass digitalization is no exception, and it also leads to dramatic changes in people's lives.

Labor productivity and competitiveness of companies are growing, jobs are being created. Humanity is now connected by technological devices and each person is given the opportunity to find and buy goods from anywhere in the world. Linguistic, religious and racial borders and barriers are being erased.

So, the electronic economy is no longer limited to the e-commerce business, but affects absolutely all aspects of life. All this is due to the growth of the digital space.

Therefore, first of all, this term refers to an economy based on the use of digital information and communication technologies.

Mostly, it characterizes the field of electronic goods and services. But it also affects production, which uses the latest Internet technologies. These include, for example, "Industry 4.0", "Smart Factory", etc. Human resources serve as the carrier of information and knowledge, which in turn affects the business environment. During this period of digitalization, the importance of control over the technological processes which are associated with the accumulation and use of human capital should be noted.

Thus, the purpose of the article is to create a measuring instrument for assessing the results of investment in the development of intellectual resources.

Literature Review

Although human capital as an economic category appeared for the first time in the 17th century, William Peter was the first who tried to measure it quantitatively. So, by human capital he meant both a person and his useful properties. He believed that it was this factor that contributed to the increase in national wealth more than all the others [1].

Adam Smith proceeded in conducting the research on this topic and wrote ‘A Study on the Nature and Causes of the Wealth of Nations’ (1776). There he noted that in order to achieve productivity growth, it is necessary to improve the skills and abilities of a worker and only afterwards to upgrade and renovate the machines and tools. The cost of it is tantamount for property capital investments and are paid off over the course of a working period. To sum up, education is an investment in a person's ability to earn money in the future. Therefore, it must be accessible to the population [2].

In the modern world, given the growth and infusion of the digital economy, information and knowledge are becoming even more significant factors of production. Now, when the competitiveness of an enterprise is being determined, it is not so much the materials and resources that are assessed as intellectual resources [8].

Therefore, the latter, as well as fixed and circulating assets, are considered the welfare of an enterprise and are a key factor in its development.

Despite the fact that the authors all over the world carried out research on this topic, modern economic science still gives no clear interpretation of the concept of "intellectual resource".
T.A. Stewart is the first to use the term "intellectual capital". He explained this concept as useful knowledge, information and intellectual property assigned to a company and used to produce more valuable property. Intellectual resources are used to form intellectual capital [3].

Statement of the problem

Analysis of the literature [4,7,12,13] has shown that in modern conditions the choice of whether to invest in education or not is becoming more complicated. When a person decides to invest in education and continuing education, his expectations regarding future income play a significant role in this matter. Since the results of investment in education appear in the form of higher wages, it is possible to say whether the investment was profitable and efficient.

The main practical problem is associated with the lack of scientific tools which determine the relationship between the competencies formed at the training stage and the results that are obtained by the both sides interested in the development of intellectual resources.

Theoretical part

Along with the transition to the digital economy, significant changes are taking place in the labor market:

- the demand for professions that are associated with the performance of repetitive formal transactions is decreasing;
- there is a growing demand for specialists who can deftly use digital technologies for the benefit of business;
- competence profiles are changing;
- new professions continue to appear;
- the requirements for flexibility, adaptability and the possession of supra-professional skills (“ soft skills ”) of personnel are increasing [9].

According to UNESCO, an international research showed that the level of income depends on the level of education by 60%. The following trends were distinguished:

- the wages of the people who received better education are higher than those with a worse quality education;
- the more experienced and older the employee is, the higher his salary is;
- the better the education is, the later the marginal revenue is reached.

Therefore, when a person decides to invest in education and continuing education, his expectations about future income play a significant role in this issue [10]. Since the results of investments in education are manifested in the form of higher wages, the high earnings prove that the investments showed themselves as profitable and effective.

In these conditions, the process of making a decision regarding investment in education becomes more complicated. This is due to the lack of scientific tools for determining the relationship between the competencies formed at the training stage and the income received at the stage of labor activity [11].

The development of intellectual resources consists in the constant improvement of human abilities, competence and motivation [15].

The formation of individual resources includes the following stages:

1. Primary socialization. A child gets the basics of world picture, culture, some primitive knowledge, skills and abilities, norms of human interaction. Psychomotor reactions and stability of the nervous system are also formed [14].

2. Basic intellectual. A child goes to school and gets basic knowledge in the field of natural, humanitarian and social sciences [16]. Also, his talents, abilities, creativity, individual needs and interests are identified and formed out.

3. Professional and educational. At this stage, a person gets high education, receives basic professional training and forms intellectual potential. Thanks to theoretical and practical training, the professional competencies of the individual are developed. They are consolidated with advanced training, industrial training and retraining.

4. Accumulation and implementation of intellectual capital. At this stage, a person receives and updates his knowledge in institutions of higher education and postgraduate education, attends various extra trainings, courses and seminars. All this contributes to the development of professional and personal competencies.

The time of using human capital can be extended by investing in health care and social security of citizens [17], as well as in disease prevention, social insurance, leisure and sports. Also, the improvement of living conditions contributes to the improvement of the quality of life, reduction of morbidity, mortality and extension of working capacity.

5. Return and depletion of intellectual capital. This is the final stage at which social, labor and creative activity decreases. The person loses some professional skills and retires. Both the person and the organization reduce the investments in the person's education, but the help and support of the family and the state are required [18].

The realization of intellectual potential at each of these stages changes in scale, subjects of financing and cost characteristics.

So, on one hand, the development of the use of intellectual resources is accelerating thanks to the digital economy. It makes it possible to acquire knowledge without interfering in the work process, e.g. via distance learning, consulting general cultural and professional information resources, free consulting services on educational forums, blogs, Internet reference books, encyclopedias and other resources [19].

However, on the other hand, the person needs a sufficient number of high-quality personnel for full development [20]. Therefore, most enterprises are trying to adapt to new conditions taking into account the values of the new generation and changing the tactics of hiring, retention and remuneration of employees.

All the work of the future is expected to be team work. Employees must interact with each other and complement each other. Instead of narrow specialists there should be a team of people and over time their roles in the team will be changing. The project changes and so do the requirements for the skills of employees.

The most demanded will be the employees who have a whole range of competencies and other qualities that go far beyond the scope of highly specialized training and also those who are versed in several areas at once and can transfer knowledge and technological solutions from one industry to another.

Also it is important to note that any organization has specific strategic goals. In order to achieve them, you need personnel with the appropriate knowledge, skills and abilities. No financial investment can ensure the viability of an organization if it does not have talented and experienced employees.

The company, in turn, uses a remuneration system, motivates employees and focuses their attention on solving certain problems. This system should be valuable to the employee and satisfy his needs.

In practice, there are several main approaches to the development of a remuneration system:

1. based on the assessment of the value of labor (workplace);
2. based on the assessment of labor results;
3. based on the assessment of competencies.

Considering the development of the digital economy and the intellectualization of education, where a person receives not just an education, but a set of certain competencies, the remuneration based on a competence-based approach deserves more attention and meets modern requirements.

In this case, for each position, a list of competencies is formed which includes a full set of characteristics (knowledge, skills, abilities) and behavior indicators necessary for the employee to successfully perform his functions. The value of remuneration of staff will depend on the level of competence required.

In the case when these competencies are designated, the personnel have goals and motivation that orient them towards achieving a significant level of competence in a particular area of activity.

The main advantage of competency-based pay is its developmental component. The introduction of such a system will be more successful in organizations with a sufficiently high level of general education, in a corporate culture, which has great values of self-development and competence.

Some authors proposed to use the model which links the wages of workers of a certain category with their levels of general, professional and general cultural competence.

For the sake of simplicity, we will consider 4 categories:

1 - workers
2 - employees
3 - specialists
4 - leaders.

The model for each category of personnel will be the dependence of workers' wages on the level of competencies required.

Let's introduce the notation:

i - personnel category $(i=\overline{1,4})$

P_{ij} - general professional competencies for the i category of personnel $(i=\overline{1,4};\ j=\overline{1,\ell_i})$

p_{ij} - professional competencies for the i category of personnel $(i=\overline{1,4};\ j=\overline{1,m_i})$

The salary level for each category will be considered as a function of competencies

$$Z_i = f_i(\overrightarrow{P_i}, \overrightarrow{p_i}, \overrightarrow{k_i})$$

Where $\overrightarrow{P_i} = (P_{i1}, P_{i2}, ..., P_{i\ell_i})$

$\overrightarrow{p_i} = (p_{i1}, p_{i2}, ..., p_{im_i})$

$\overrightarrow{k_i} = (k_{i1}, k_{i2}, ..., k_{in_i})$

The type of function can be selected taking into account specific data on the enterprise.

The general requirements for functions are the following: non-decreasing in the interval of changes in its arguments and capable to pass through the origin.

Let us consider a model of the competence of the personnel of an enterprise using the example of an economist (settlement and economic activity) of an enterprise.
For example, in the enterprise an economist y (i = 3) is required to have the following competences:

General professional:

- the ability to analyze data and be able to justify research results (P_{31}) ;
- the ability to collect, analyze and process the required data (P_{32}) ;
- the ability to solve problems connected with professional activity (P_{33}) ;
- the ability to make managerial decisions and the willingness to take responsibility for them (P_{34}).

Professional:

- the ability to analyze the financial and economic activities of the enterprise (p_{31}) ;
- possesses the skills with software reference of the Economic and Financial Statements (p_{32}) ;
- the ability to perform the calculations necessary for drawing up the economic sections of plans, justify them and present the results of work in accordance with the standards adopted in the organization (p_{33}).

General cultural:
- the ability to communicate in oral and written forms in Russian and foreign languages (k_{31}) ;
- to be active and creative regarding the work (k_{32}) ;
- the ability of self-organization and self-education (k_{33}).
For example, consider the linear form of the function:

$$Z_i = \sum_{j=1}^{\ell_i} a_{ij} P_{ij} + \sum_{j=1}^{m_i} b_{ij} p_{ij} + \sum_{j=1}^{n_i} c_{ij} k_{ij}$$

For the sake of convenience while describing the example, let us assume that the competences within one group have the same coefficients, i.e.

$$Z_i = a_i \sum_{j=1}^{\ell_i} P_{ij} + b_i \sum_{j=1}^{m_i} p_{ij} + c_i \sum_{j=1}^{n_i} k_{ij}$$

Where

$i=3,\ \ell_i = 4\ ,\ m_i = 3\ ,\ n_i = 3$

We will introduce a scale of competencies indicating the levels that describe the quality of behavior. The level scale can be different. For example, 4 levels:

0 - competence has not been demonstrated;
1 - the level of basic development;
2 - the level of confident possession of competencies in standard situations;
3 - skilled level.

A university graduate who has mastered the bachelor's program possesses the competencies provided by it.

General professional competences:

– the ability to solve standard problems based on information and bibliographic culture, using information and communication technologies and taking into account the basic requirements of information security;
– the ability to collect, analyze and process the data necessary to solve professional problems;

– the ability to choose tools for processing economic data in accordance with the task, analyze the results of calculations and substantiate the findings;

– the ability to find organizational and managerial solutions in professional activities and the willingness to bear responsibility for them.

Professional competences (settlement and economic activity):

– the ability to collect and analyze the initial data necessary for calculating economic and socio-economic indicators characterizing the activities of economic entities;

– the ability to calculate economic and socio-economic indicators characterizing the activities of economic entities on the basis of standard methods and the current regulatory framework;

– the ability to perform the calculations necessary for drawing up the economic sections of plans, justify them and present the results of work in accordance with the standards adopted in the organization.

General cultural competences:

– the ability to use the foundations of economic knowledge in various fields of activity;

– the ability to communicate in oral and written forms in Russian and foreign languages for solving problems of interpersonal and intercultural interaction.

– the ability to work in a team, being tolerant to social, ethnic, confessional and cultural differences;

– the ability for self-organization and self-education.

Comparison of these competencies with the enterprise competency model shows their only partial correspondence. Assuming that a graduate has a basic level of competencies, we will have:

$P_{3j} = (1, 1, 1, 1)$; $p_{3j} = (1, 0, 1,)$; $k_{3j} = (1, 0, 1)$

Table 1: economic effect of investing in education according to the requirements of federal standards

Period (year)	First . expenses	Cash income	Cash expense	Cash flow	Net cash flow	Net Present Value (NPV)
1	116400	-126637	-243037	-243037		0

14	10000	469800	10000	459800	2018092	1174768
15	10000	522000	10000	512000	2530092	1412770
Total:						1 628 739

Initial data for the calculation:
tuition fee is 116.4 thousand rubles, annually for 4 years
discount rate = 4.25%
lost wages while studying is equal to the minimum wage
the annual expenses for the acquisition / improvement of competencies are 10 thousand rubles.
the acquisition / improvement of competencies leads to an increase in salary according to the competency model.

With this initial data taken into account, training costs will pay off in the fifth year of operation.

If a university prepares a specialist paying attention to the requirements of the enterprise beforehand, the graduate is already more prepared to work in the enterprise. In this case, all the competencies included in the model can be considered as having a level of confident competence in standard situations for a graduate.

In this case, the starting salary is 40 thousand rubles (table 2).

Table 2: The economic effect of investing in education in accordance with the requirements of federal standards and TK of the employer enterprise

Period (year)	First . expenses	Cash income	Cash expense	Cash flow	Net cash flow	Net Present Value (NPV)

Total:						11898639

In this case, the training costs will pay off in the third year of work. It can be seen that the second model has a significant advantage over the first. A characteristic feature of the proposed model for the development of intellectual resources based on the formation of standard competencies and competencies ordered by employers is the possibility and necessity of enhancing cooperation between educational institutions and employers. This relationship provides an independent request of society, students and employers for quality education.

Results

It should be noted that a more accurate setting of educational tracks based on the technical specifications of employers' enterprises allows accelerating paying off the investment in the development of intellectual resources. In this article, an attempt was made to describe the mathematical relationship between the competencies formed at the training stage and the results that are obtained by the both sides interested in the development of intellectual resources. A characteristic feature of the proposed economic and mathematical tools is the ability to quantitatively measure between competencies and people's salaries. At the same time, the authors note down that this method is developing in the direction of paying attention to the formation of professional competencies and personal qualities in the development of intellectual resources.

Abstract

The paper is devoted to the analysis of the potential influence of teamwork on Information System(IS) success. The study concentrates on IS success and its influence on organizational performance. It is assumed that teamwork is one of factors potentially influencing that relation. Empirical research is conducted to verify formulated hypotheses based on results obtained from more than 1000 organizations from two business contexts (Poland and Switzerland) in order to determine whether teamwork is a moderator of the relation between IS success and organizational performance.

Keywords: Information System success, organizational performance, teamwork

Introduction

On dynamical and competitive markets the Information Systems are the elements of socio-technical organizations which enables their business activity and would made their competitive advantage (Ives and Learmonth, 1984). They are enough relevant to become the business strategy entity (Wilson, 1989; Bergeron and Crotau, 2001). Implementation and servicing of IS are also a big share in companies' budget and its failure exposure the for the risk often threatening its existence. That means the success of IS is significant to organizational effectiveness and may determine its performance (Delone and McLean, 1992) but this relation was limited to some benefits (Delone and McLean, 2003; Seddon, 1997).

In 1992 Gordon studies it was showed: the 82% of North American companies with over a hundred of employees are organized in a form of work teams. In the middle of 1990s approximately 70% of Fortune 1000 companies involves teams and plans their use of teams in the future (Chen and Barshes, 2000). Teams are the basement building of most organizations (McGrath, 1997) and team effectiveness is the significant factor of organizational performance (Gladstein, 1984; Hackman, 1987; Magpili and Pazos, 2018; Bieńkowska, 2019; Bieńkowska & Ignacek-Kuźnicka, 2019). This is why teamwork become important construct effecting this performance(Salas, Cooke and Rosen, 2008; Delarue et al. 2008). Teamwork as the socio-technical phenomena is studied in context of shared cognition (Salas and Fiore, 2004; Salas, Cooke and Rosen, 2008) and quality of work life (Pearce and Ravlin, 1987; Hackman, 1987; Campion, Papper and Medsker, 1996) and these factors may strengthen relation between IS Success and organizational performance.

So far, many research were conducted according to team effectiveness and organizational impact. In 2008 there were over 130 models explaining team performance (Salas et al. 2007) . Many of them were concentrated on teamwork (Salas, Sims and Burke, 2005). Moreover, there many developments and modifications of IS success models. In 2011 there were over thirty ongoing or finished research in area of IS success model (Müller and Urbach, 2011). Thus, this study does not focus on the statement, that IS success and teamwork influences organizational performance. The main approach of is to verify if teamwork is a moderator of the relation between IS success and performance. If it turned out to be true

it might mean that the role of teamwork in organizational performance and the IS success is bigger than it is currently understand.

Literature Review and Hypotheses Development

Teamwork in organization

Teamwork as the way of organization structure impacting its performance comes from socio-technical systems theory (Trist, 1981). Researchers assume various approaches to explaining the term 'team'. There is no unambiguous approach to the term itself, as it is interchangeably (seldom without proper explanation of differences) used as: self-managed team or autonomous team (Delarue, et al. 2008; Muller, Procter and Buchanan, 2000; Guzzo and Dickson, 1996) or even group or working unit (Benders and Van Hootgem, 1999). In this article, the term team will be understood as: ' (a) two or more individuals who (b) socially interact (face-to-face or, increasingly, virtually); (c) possess one or more common goals; (d) are brought together to perform organizationally relevant tasks; (e) exhibit interdependencies with respect to workflow, goals, and outcomes; (f) have different roles and responsibilities; and (g) are together embedded in an encompassing organizational system, with boundaries and linkages to the broader system context and task environment' (Kozlowski and Ilgen, 2006).

Teamwork can be defined as the set of specific and inter-correlated knowledge, skills, and attitudes (KSAs) letting the team for effective work in terms of coordination and adaptiveness (Campion and Stevens, 1994;Cannon-Bowers et al. 1995; Sims, Salas and Burke, 2005).

The essence of IS success

Information System (IS) success model (Delone and McLean, 1992) was positively verified by many researchers (Petter and McLean, 2009). User satisfaction is general factor of IS success (Zviran and Erlich, 2003) basing on three dependent variables : IS quality , information quality and service quality (Delone and McLean, 2003).

Fig. 1: Delone and McLean IS success model

IS success may be measured by dependent variables in reference to Delone and McLean model, by four items:

- Service Quality : The fulfillment of the given SLA.
- IS intention to use: The willingness of use of IS by employees.
- Quality, Information Quality : The correctness of information received from IS
- Quality, Usefulness : The performance of employees enhanced by the use of IS

In this article IS usage is not taken into consideration because the relation between IS use and IS user satisfaction is not clear enough (Bokhari, 2005) and was replaced by usefulness (Seddon and Kiew, 1996; Seddon, 1997).

Teamwork , IS success and organizational peformance – hypotheses development

In a time perspective, IS success depends on user involvement from the very early stage of system definition (requirements definition), through the development, implementation, ending on IS servicing. User involvement plays key role in IS success, but this role needs further research (Bano and Zowghi, 2015; Alam, 2002). Moreover, teamwork quality (TWQ) is a crucial construct building software teams effectiveness understood as IS quality (Gemuenden and Hoegl, 2001). High TWQ influences high IS quality as the output of teamwork and may lead to IS success. User involvement as the participant of the development teams (Bano, Zowghi and de Riminmi, 2016) leads to better user satisfaction and IS Success. It can be noticed especially in Agile teams involving customers (system users) (Lindsjørn, et al. 2016) and in innovative projects (Gemuenden and Hoegl, 2001). It allows to assume that teamwork improves such IS success factors as user satisfaction and may impact usefulness and IS intention to use at the stages from definition to implementation.

Teamwork is also a basement determinant of service quality in IS (Wattson, Nel and Pitt, 1993). Service quality is the factor of IS user satisfaction and effects on IS success. Doll and Torkzadeh (1988) consider IS user satisfaction in term of system quality and information quality. IS user satisfaction finally impact on IS success and may impact on its usefulness. It leads to the second assumption that at the at the stage of IS servicing teamwork relates positively to IS success.

Basing on these two assumptions: teamwork supports IS success during the development, implementation and servicing phases of IS lifecycle , afore mentioned hypothesis can be formulated:

H1a: There is a positive relation between teamwork and IS success.

Teamwork effectiveness and building high performance teams in relation to organizational performance is still matter of research (Salas and O'Neill, 2017; Jones, 2017; Turner et al. 2020). Influence of a teamwork and TWQ on organizational performance is not well defined, but support of hypothesis about positive impact of teamwork on organizational performance as the standalone variable or with other constructs can be found (Kozlowski and Ilgen 2006; Guzzo and Dickson, 1996; Salas, Sims and Burke, 2005; Magpili and Pazos, 2018).

There are many attempts to team effectiveness basing on input-process-output (I-P-O) McGrath (1984) models (Gladstein, 1984; Pearce and Ravlin, 1987; Hackman, 1987; Yeatts and Hyten, 1998) and its variations. This models are often considered in multi-level approach. Team effectiveness is related to individual, team or organizational level but still there is no consent about the impact of team effectiveness on organizational performance. It is because organizational performance indicators varies the same way the organizations varies and because team performance output structures differs according to differences in models and differences in teamwork effectiveness theories. It brings the idea of research the relation between the teamwork and organizational performance as the way of finding simpler and more general dependence.

Hypothesis below can be formulated on the conceptual framework with independent teamwork and transmission values : attitudinal and behavioral outcomes and structural changes and dependent organizational performance variable was presented by Delarue et al.(2008).

H1b:There is a positive relation between teamwork and organizational performance

More field study research should investigate and incorporate organizational impact measures (Delone and McLean 1992) . Verification of the Delone and McLean model becomes disputable the relation between usage and user satisfaction as well as measurement of usage (Downing, 1998). Also the usage, as the variable in this model, is questionable and it was replaced by usefulness factor (Seddon and Kiew, 1996; Seddon, 1997). The attempt to test the construct of IS success which includes usefulness and excludes usage lets for verification this construct.

After many verifications, Delone and McLean (2003) model don't explains the impact the IS user satisfaction and intention to use on organizational performance. Instead of it, the net benefits variable is introduced. Moreover user satisfaction and use may not be alternative to measuring IS performance directly (Youthas and Yong, 1997). Further investigations of new construct of IS success influencing the organizational performance directly are needed. Usefulness of the IS defined as 'the degree to which a person believes that using a particular system would enhance his or her job performance' (Davis, 1989) lets for researching direct impact of the IS success construct on organizational performance and it makes to legitimate verification of hypothesis below:

H1c:There is a positive relation between IS success and organizational performance.

Individual level is a level the IS success factors impact the organization (Petter and McLean, 2009.). Teamwork supports employee performance on the same level (Manzoor et al. 2011).Team effectiveness output is partially defined in many models by the elements of quality of worklife (QWL) (Pearce and Ravlin, 1987; Hackman, 1987; Campion, Papper and Medsker, 1996). On the other side, QWL satisfaction influences IS success through IS user satisfaction (Garrity and Sanders, 1998). That means the QWL may be factor which make resonate the teamwork and IS success. Additionally, elements of QWL can be transitional mechanism between teamwork and organizational performance (Delarue et al. 2008). This make legitimate question about relation between IS success and organization performance in the context of teamwork moderation variable at the individual level.

Mental models play important role in IS influence on organizational performance, because they are positively influencing on IS learning and IS user performance (Staggers and Norcio, 1993). Shared cognition is the central matter of teamwork (Salas ,Coke and Rosen, 2008). Shared mental models as the shared cognition is linked to teamwork performance (O'Connor, 2004) . It lets for the assumption the shared metal models may improve of IS performance better than individual mental models and teamwork may be a moderator between IS success and organizational performance.

H2: In organizations based on teamwork, the influence of IS success on organizational performance is stronger than in organizations not based on teamwork.

An overview of all formulated hypotheses is presented in Figure 2 and is aligned with the main aim of this article: the verification of teamwork as a moderator of the relation between IS success and organizational performance.

Fig. 2: Teamwork as a moderator of the relation between IS user satisfaction and Organizational Performance

Research Methodology and Results

In order to verify the proposed hypotheses, the empirical research based on a survey method (gathered using CAWI method) was performed.. The main survey was preceded by the pilot survey conducted in late 2018 among the group of 50 managers (acting as competent judges). According to obtained results, the ambiguous questions were rewritten in order to obtain more informed response and it was established that proposed questions are understood by respondents as it was intended by researchers (which is a prerequisite for establishing a questionnaire as a valid measurement method (Czakon, 2019). The main research was conducted in early 2019, among organizations located in Poland and Switzerland, which was the only condition limiting the sample (organizations were surveyed regardless of size, industry or type of business etc.), using CAWI method.

The obtained sample covered 349 organizations operating in Poland and 288 organization operating in Switzerland. The selection of those specific countries was intentional and responses from both countries were treated as one sample to ensure proper distribution over the entire scale of responses. The distribution of the organizations across all sizes was satisfactory and allowed to assume that the obtained sample can be representative for all organizations (see Table 1).

Table 1: Organization sizes and countries

	Time of operations				**Total**
Organization size	**Poland (local organization)**	**Poland (branch of a global organization)**	**Switzerland (local organization)**	**Switzerland (branch of a global organization)**	
Micro (below 10 people)	24	58	40	3	125
Small (11-50 people)	30	68	66	6	170
Medium (51-250 people)	15	86	89	13	203
Large (above 250 people)	12	56	63	8	139
Total	81	268	258	30	637

Source: Bieńkowska et al., 2020

Variables overview

The following variables were used to verify the proposed hypotheses:

IS success was measured based on 4 items covering four areas of IT operations, which are crucial for building its proper support for organization. The scale was based on a 5-point Likert scale (from I strongly disagree, to I strongly agree with a middle point: I have no opinion).

Organizational performance was measured based on Balances Scorecard concept (Kaplan and Norton, 1996), being the framework that allows to draw together multiple measures aimed at financial performance, internal business processes, customer perspectives, and innovation and learning. 10 items were rated on the 5-points' Likert scale (from well below expectations to well above expectations with the middle point: as expected).

Research Results

The first step of the analysis was the correlation analysis between IS success, teamwork and organizational performance. The r-Pearson correlation analysis was used and the results presented in table X show that all correlations are strong and statistically significant. Therefore, those results are a basis for positive verification of hypothesis H1a, H1b and H2 initially confirming that *there is a positive relation between IS success, teamwork and organizational performance*.

Table 2: Correlation analysis between the IT reliability, IS success and organizational performance

	IS success	teamwork
teamwork	r(629)=0,677**, p<0,001	1
Organizational performance	r(629)=0,864**, p<0,001	r(629)=0,706**, p<0,001

Source: own work

The relation between IS success and organizational performance was analyzed in the context of *teamwork* to verify whether teamwork is a statistically significant moderator of the relation, which existence is verified above. Regression analysis with moderator was used to determine that. The results of the analysis are presented in table 3.

The statistical reasoning was based on the linear regression analysis with moderator. In every case, as a first step, new variable – moderator – is introduced. The moderator variable is built as a product of two standardized independent variables. As a second step, 3 regression models are built (the analysis was performed using Process macro for IBM SPSS Statistics). The first model is built as a base model for comparison, only independent variables are added as predictors. The second model is built using independent variables together with the moderator as predictors to verify whether the moderating influence is occurring in sample. To confirm that, the third regression model is built using only one independent and the moderator as predictors.

Table 3: Regression models' statistics.

Model description	R^2	*Delta* R^2	*Moderator coeff.*	*Standard error*	*t Stat*	*P Value*
IS success, teamwork, Moderator *dependent v.: organizational performance*	0,776	0,022	0,037	0,014	2,514	0,012

Source: own work.

The obtained models clearly show that teamwork is a moderator of analyzed relation. The delta R2 and obtained model are statistically significant ($F(3, 629) = 728{,}762$, $p < 0{,}001$). Therefore, obtained results are the basis for positive verification of hypotheses H2 confirming that *teamwork is a moderator for the relation between IS success and organizational performance.*

Discussion

Teamwork has positive impact on organizational performance. Study confirmed previous research and many theoretical models found in literature. Team effectiveness models are complex constructs aimed at explaining the dependence between team characteristics, processes and the output effects of teams in the organization, but in this study direct relation was confirmed on the more general level. This means the teamwork and high TWQ leads to better performance on every organizational level.

Teamwork has also positive impact on IS success. Chance on IS success grows up by building the teams that involves users at the every stage of IS lifecycle. IS success is also complex construct this research confirms the direct relation more generally. Further studies are needed to explain the relation between IS success factors and work team. Especially relation between IS user satisfaction and teamwork requires further investigations.
IS success has no strong positive effect on whole organizational performance. This results were described in previously in literature. Exchange between usage and usefulness factors didn't bring expected expansion the organizational net benefit into organizational performance.

The main focus of this research was to verify whether the effect of IS success on the organizational performance due to IS Success impact is stronger in organizations performance with teamwork and weaker in organizations without teamwork. The obtained results confirm adopted assumptions and underline the role of teamwork as the moderator strengthening the effect. Teamwork improves QWL and lets for building shared mental models which are the basis of IS performance, but it remains the presumption. This study confirms general moderation supportive role of teamwork but further research on QWL and team effectiveness factors and their particular share of supporting between this two constructs are required. Especially metal models and transitive memory requires further research as the factors of teamwork influence (direct or indirect) on performance (Kitaygorodskaya, 2006).

Theoretical studies were performed with additional foundations. The quality is measured only in reference to data quality and usefulness because some studies founds the quality effect on data quality and system usefulness (Bergeron and Raymond, 2008; Hasan et al. 2013). Quality of service was measured by SLA fulfillment (Marciniak 2013; Yoon and Im 2008). This additional foundations don't change the generality of the results but they may be consider as the theoretical limitations.

Conclusions

Currently, teamwork is a basis for many companies and organizations determining their operational performance(Kroupa, 2007). Also, information system becomes the critical factor effecting organizational performance or even shaping business strategy(Bergeron and Crotau, 2001).

The obtained results clearly showed that also in case of IS success, there is a positive, statistically significant correlation between teamwork and SI success also between teamwork and IS success and organizational performance. Moreover, they showed that teamwork is a moderator of the relation between IS success due to organizational performance. Therefore, it confirms that teamwork plays a fundamental role in IS design, implementation and usage and effects IS success leveraging organizational performance.

Performed empirical study is conducted with certain limitations. Only two countries were selected for comparisons, so in future it is worth to consider the verification of formulated hypotheses in organizations operating in other countries. However, the obtained results seems to be a solid first step in the analysis of teamwork and IS lifecycle, establish directions for further research.

Supporting Entrepreneurship from Public Funds during the Major Economic Disruptions: Polish Evidence

Justyna ZYGMUNT

Opole University of Technology, Opole, Poland
j.zygmunt@po.edu.pl

Abstract

This paper uses a data set for the Polish economy covering the early months of the COVID-19 pandemic (March-August 2020) to examine how the economic downturn has been responded in Poland through establishing "first aid" supporting programs to entrepreneurship. The focus is on the usage of funds that have been granted to Poland within the EU financial framework 2014-2020, and which have been re-directed to answer the urgent needs of enterprises. In particular, this paper addresses the following questions: (i) what were the phases of supporting entrepreneurship in Poland during the COVID-19 economic disruption from funds within EU financial framework 2014-2020, and (ii) what was the nature of that support? The study makes a contribution to the entrepreneurship literature by providing a useful evidence of the approach towards supporting entrepreneurship during a major economic downturn. In particular, this paper finds that policy actions in Poland to support entrepreneurship from the EU funds within financial framework 2014-2020 have been two-tier, with the nationwide tier more likely to support medium enterprises and the regional tier focused primarily on supporting micro and small enterprises. It has been also observed that although the policy actions to respond to the COVID-19 effect on enterprises have been considerable, they remain relatively undifferentiated in terms of sectors and the regional specificity.

Keywords: Entrepreneurship, Economic Disruptions, Public Support, COVID-19, European Union, Poland

Introduction

Entrepreneurship is commonly acknowledged to be pivotal to economic growth (Audretsch and Keilbach, 2008) and has relevant consequences for structural changes (Zygmunt, J., 2020a). However, entrepreneurship tends to be contingent on the business cycle (Davidsson and Gordon, 2016) and notably vulnerable to the major economic disruptions (Cowling et al., 2015). The impact of such disruptions on entrepreneurship is mixed. On the one hand, it is argued that many enterprises are likely to employ a variety of flexible responses and are disposed to apply adaptive behaviour (Smallbone et al., 2012), including pivoting to take advantage of the crisis-induced opportunities (Morgan et al., 2020). On the other hand, economic downturns may entail serious distress for enterprises as they may be substantially constrained, which may lead to dramatic alternation in business dynamics (Naudé, 2020) with significant decrease in new business registration (Klapper and Love, 2011), severe prevention the existing ones from expanding (Paulson and Townsend, 2005), and strong growth in the likelihood of bankruptcy (Kliestik et al., 2018). While the scale of crisis-driven business failures may be huge, conducing to high social and economic costs, a question arises of whether enterprises should be supported from public funds during the major economic disruptions, and if so, what policy actions should be taken to mitigate crisis fallouts.

The issues of supporting entrepreneurship from public sources have attracted growing attention of scholars in recent years, and public grants are increasingly considered to be an important vehicle for enterprises survival and growth (e.g., Pergelova and Angulo-Ruiz, 2014; Dvouletý et al., 2020). However, until recently, only a few studies provide evidence of how public grants may be applied to moderate the blowbacks of the major economic disruptions on enterprises (e.g., Brown et al., 2020;

Hale et al., 2020), and still little is known about the ways in which entrepreneurship may be fostered during economic crisis. Therefore, the goal of the paper is to address this gap in the literature by examining how the major economic disruptions have been responded in Poland through establishing supporting programs to enterprises from public funds. More specifically, this paper contributes to the literature on entrepreneurship by using the recent COVID-19 downturn as the empirical setting to investigate the ways in which the European Union (EU) funds that have been granted to Poland within the EU financial framework 2014-2020 have been used to support entrepreneurship during the economic downturn.

The rest of the paper is organized as follows. The next section provides the research background. Data and research method are described in the second section. Third section presents the empirical results. Conclusions are provided in the fourth section.

Theoretical background

As claimed by Naudé (2020), entrepreneurship is "reflected in the start-up of new firms and the growth of existing firms, particularly SMEs" (p. 1). Numerous dimensions have been recognised as being significant for entrepreneurship (e.g., Maj, 2017; Zygmunt, A., 2017; Kubiciel-Lodzińska and Solga, 2019; Zygmunt, A., 2020; Zygmunt, J., 2020b), and it is increasingly suggested that the success or failure of entrepreneurial firms may be strongly dependent on the economic adversity (e.g., Lai et al., 2016). Alongside this perspective there is a growing school of thought which indicates that there are differences in how economic disruptions impact small and large firms (e.g., Smallbone et al., 2012). Smaller firms are regarded as more flexible to adapt their behaviour to a recessionary environment (Osiyevskyy et al., 2020), however they are vulnerable to large decline in the demand for goods and services (Cowling et al., 2015). They are more likely to perform worse during crisis conditions due to "liability of smallness" (Aldrich and Auster, 1986) and crisis-induced resource scarcity, as e.g. disconnected supply chains and logistic channels (Morgan et al., 2020), deficient internal financial sources and limited access to external ones (Brown, 2020), which may strongly affect liquidity and day-to-day operations in particular.

There is a broad consensus that the major economic disruptions are inevitable, however their seedbeds, intensity, and duration are tough to predict (e.g., Knudsen, 2019). It is argued that the current COVID-19 pandemic has generated an economic downturn that is likely to exceed the effects of previous ones, even those caused by global financial crisis in 2007-2008 (e.g., Brown et al., 2020; Sułkowski, 2020). This pandemic caused an unprecedented situation with the lockdown of large parts of society and enforced closure of some economy sectors, mostly services, for a certain period. The consequences of the COVID-19 pandemic for the economy have been elusive, with preliminary estimations forecasting a deep global recession, increase in unemployment and in bankruptcies (OECD, 2020). Hence, it is understandable that policy attention in many countries concentrates on mitigating the impact of the COVID-19 downturn through supporting entrepreneurship. As argued by Naudé (2020), such support should be directed to constrain entrepreneurial exits and to mitigate large decrease in consumer demand. In general, it is possible to distinguish two main forms of that support: (1) direct financial (e.g., grants, loans), and (2) non-direct (e.g. advisory services, trainings) (Dvouletý et al., 2020). It seems that whilst many enterprises temporarily diminished or even ceased trading because of the lockdown, particularly direct financial support would be sought-after. In other words, the nature of that particular support – almost immediate to apply and more disposed to yield results at short notice – may be pivotal in determining the "first aid" support to ease liquidity constraints and to hinder the threat of closure.

As the means of support for enterprises are generally government funds and, in the member states of the EU, structural funds. While the EU funds were thus far principally aimed to enable enterprises to enhance their performance and increase their growth (Le Gallo et al., 2011), the recent major economic downturn has caused an unprecedented situation. More specifically, while it is expected that the current COVID-19 recession is going to be highly deep, it seems that mitigating the economic and social blowbacks only from government funds may be highly insufficient. That is a key reason why the European Commission urgently shifted its policy and for an unseen scale re-

directed its funds to respond to COVID-19 economic disruption. In particular, the €81.4 billion SURE instrument has been approved to financially support some of the member states, and in terms of the current EU financial framework 2014-2020 transfers between these funds, their categories and policy objectives have been allowed, with simplified administration and eased procedures of their allocation (European Commission, 2020). However, the extent to which these particular funds have been directed to support entrepreneurship in respective member states during the COVID-19 crisis has been left to distinct decisions and policy actions of each member state. Therefore, while it is argued that government responses to COVID-19 downturn varies significantly (Hale et al., 2020), and given the need for more rapid insights into how entrepreneurship may be supported during major exogenous shocks, this paper is focused on the following research questions: (i) what were the phases of supporting entrepreneurship in Poland during the COVID-19 economic disruption from funds within EU financial framework 2014-2020, and (ii) what was the nature of that support?

Materials and Method

The research approach used in this paper was an analysis and review of relevant policy documents at both the EU and Polish levels. First step was to identify legal acts related to COVID-19 pandemic published by the European Community and by Polish authorities. In next step, those legal acts were selected that relate to supporting entrepreneurship during the COVID-19 downturn in Poland from that funds within the EU financial framework 2014-2020 which have been re-directed to answer the urgent needs of enterprises. Then, while the analysis of these documents led to the identification of additional data sources which may provide extensive data on policy actions, especially in terms of their implementation, further data were sourced from the following official websites of Polish government and non-governmental organisations: the Ministry of Development Funds and Regional Policy, Bank Gospodarstwa Krajowego, Polska Agencja Wspierania Przedsiębiorczości, as well as from the European Commission website and also from European Funds Portal which reports about the usage of the EU funds in Poland. Next, the findings were synthesized and the results of analysing process have been reported.

Research period starts from March 2020 when the COVID-19 lockdown was announced in Poland and finishes at present (August 2020), covering different phases of policy actions.

Findings

The first case of the COVID-19 infection in Poland was registered in early March 2020. With the growing number of infected, starting from 12 March nurseries and kindergartens were closed, and schools and universities started remote teaching. Restrictions were introduced in the operation of shopping centres. Border traffic was closed for non-Polish citizens and two-week quarantine for Poles returning from abroad was mandatory. Physical distance has been introduced as 2.0 metres, and as of 16 April face masks have been required indoors (in public places) and outdoors. From 30 May to onwards (late August 2020) face masks are still obligatory in some indoor areas (e.g., shops, public transport, churches) and from 25 July physical distance has been reduced to 1.5 metre. Border traffic opened at 13 June for the EU citizens without mandatory quarantine.

The stages of the lockdown and its easing in Poland were as follows:

- stage I (24 – 31 March 2020) – first stage of the lockdown – movement restrictions, client limits in shops, large area DIY stores closed Saturdays and trade Sundays, passenger limits in public transport
- stage II (1 – 19 April 2020) – second stage of the lockdown – temporary suspension of some business activities, mostly from the services
- stage III (20 April – 3 May 2020) – first stage of the lockdown easing – more people allowed to do the shopping at the same time, loosening in movement restrictions, outdoor recreation acceptable

- stage IV (4 – 17 May 2020) – second stage of the lockdown easing – hotels and similar accommodation reopened, large area DIY stores reopened Saturdays and trade Sundays, museums, libraries, art galleries reopened, therapeutic rehabilitation reopened
- stage V (18 – 29 May 2020) – third stage of the lockdown easing – beauty and hair salons reopened, all shops in shopping centres reopened, eating out allowed, sport events allowed in open space for up to 50 people without the spectators, loosen passenger limits in public transport
- stage VI (30 May – 24 July) – fourth stage of the lockdown easing – solariums and massage parlours reopened, cinemas and theatres reopened, sport events allowed indoors, ease in restrictions on the number of people in shops, restaurants, etc.
- stage VII (25 July – 7 August 2020) – fifth stage of the lockdown easing – increased numbers of spectators allowed on sport events, as well as on swimming pools, conferences, trade shows, exhibitions (up to 50% of places), removal of restrictions on taking alternate seats during indoor entertainment events and in the amphitheatres
- stage VIII (8 August 2020 – onwards) – the zone lockdown – reversion to some restrictions of limited number of people in shops, restaurants and cafes, entertainment events, limits in public transport in areas with a growing number of COVID-19 cases. Such areas have been divided into "red" and "yellow" ones with more strict restrictions comparing to the other areas (gov.pl, 2020).

Following the lockdown, policy actions have been taken to mitigate the impact of the COVID-19 crisis. A Polish aid scheme has been developed promptly, and early April it has been approved by the European Commission (European Commission, 2020). Particular attention has been given to supporting entrepreneurship. Business population in Poland is dominated by micro, small and medium companies – almost 99% of Polish enterprises fall into these classes, with the predominance of micro companies (96%), and the 58% of total workforce. Hence, their survival and adoption to the COVID-19 crisis environment seem to have a great consequence for social and economic conditions in Poland.

As a part of that support, the following direct financial vehicles have been launched by now: liquidity loans, working capital subsidies, exemption from paying social security contributions and health insurance, compensation for the loss of turnover from business activity, covering of remuneration costs for employees with relevant social security contributions, etc. (gov.pl., 2020). These support vehicles have been backed from the government funds, as well as from the re-allocation of funds that Poland has at disposal within the EU financial framework 2014-2020. Also, Poland has been granted late August €11.2 billion financial support from the EU under the SURE instrument in the form of loans on favourable terms to respond self-employment drop in particular (European Commission, 2020).

Within the EU financial framework 2014-2020 Poland has been granted €82.5 billion and 81.1% of this amount has been already allocated to the end of 2019 (gov.pl., 2020). With the acceptance of the European Commission some of remaining funds, notably from the European Regional Development Fund and the European Social Fund, have been mobilised to address the effects of COVID-19 downturn (European Commission, 2020). The analysis of the relevant policy documents provides evidence of the two-tier approach towards supporting entrepreneurship in the research period. More specifically, nationwide and regional tiers have been identified, as it has been observed that enterprises' location matter in securing support. Given the nature of supporting entrepreneurship across each tier, it has been recognised that it has been mainly similar, with liquidity loans and working capital subsidies as the major vehicles. That finding indicates that when it is estimated that the economic shock is going to be extremely steep, the main focus of policy actions, regardless of the range (nationwide, regional), is primarily on business survival objectives, most notably to ease liquidity constraints. This observation supports the view that as financial distress may strongly affect entrepreneurship (Cowling et al, 2015) short-term policy actions directed to "injecting liquidity" (Brown, 2020, p. 11) to the enterprises are recommended.

Table 1 presents the summary of support means directed to the enterprises at the nationwide tier,

which have been backed from the re-allocation of funds that Poland has at disposal within the EU financial framework 2014-2020.

Table 1: The vehicles of support entrepreneurship from the re-allocation of funds that Poland has at disposal within the EU financial framework 2014-2020 – a nationwide tier

Liquidity loans for micro, small and medium enterprises from any sector
The amount of support for enterprise the possibility to take several loans for a total amount up to PLN 15 million (approx. €3.40 million) *Support conditions* (a) the amount of total support should not exceed: (i) 25% of the enterprise's total turnover in 2019, or (ii) double value of the annual wages, including the costs of employee benefits in 2019 or in the last year for which data are available, and (b) enterprise faces financial difficulties or is at risk of it due to the COVID-19 pandemic and before 31 December 2019 was not in financial difficulties *Support details* payback period up to 6 years, interest rate 0%, no commissions and fees, grace period up to 6 months
Working capital subsidies for medium enterprises from any sector
The amount of support for enterprise determined as the product of special coefficient related to enterprise's workforce and the number of months for which support is applied (up to three months) – max amount is PLN 0.42 million (approx. €0.09 million) when enterprise employs 249 people and applies for three months support *Support conditions* (a) enterprise faces financial difficulties at the day of being supported as a result of the COVID-19 pandemic, or (b) enterprise faced at least 30% decrease in turnover in any month after 1 February 2020 in relation to the previous month or the same month in previous year *Support details* non-repayable, except when enterprise discontinues business activity in period for which support is granted

Source: Own elaboration based on data sourced from BGK, 2020; PARP, 2020; European Funds Portal, 2020.

At the nationwide tier, funds re-allocated within EU financial framework 2014-2020, have been used in Poland, in early months of the COVID-19 economic shock, to provide liquidity loans and working capital subsidies for enterprises nationwide. Interestingly, the analysis shows that this support has been company-size oriented. More specifically, at this tier liquidity loans have been offered to micro, small and medium enterprises that have been affected by the COVID-19 economic disruption, while only medium enterprises have been eligible to apply for working capital subsidies. It has been also observed, that although some sectors have been particularly influenced in Poland by the lockdown commence, any sector has not been privileged with targeted means at the national tier, and the rules for securing support remained the same for any enterprises.

Second tier represents all regions in Poland which implement their regional operational programmes. These programmes have been approved by the European Commission in regions' action plans aimed to achieve the Cohesion Policy goals on their territories by the use of the EU funds. Consequently, supporting entrepreneurship at the regional tier is highly location dependent. It means that the vehicles supporting entrepreneurship may differ regionally in terms of their nature, value, and rules for securing them, and are directed only to enterprises from a particular region. The analysis indicates

that there has been a considerable policy activity at the regional tier in responding to COVID-19 crisis and supporting entrepreneurship by the re-allocation of funds that Poland has at disposal within the EU financial framework 2014-2020. While it is beyond the ambition of that paper to discuss in details the regional differences in the amount and conditions of support directed to enterprises, it should be emphasised that the nature of that support remains relatively undifferentiated among regions. In particular, the analysis provides evidence that in each region liquidity loans for micro, small and medium enterprises have been channelled, and complementary to the nationwide tier, working capital subsidies have been directed only to micro and small enterprises. However, it should be emphasised that support for enterprises at that tier has been wider compared to the nationwide in terms of its nature. More specifically, with only two types of the support vehicles at the nationwide tier (liquidity loans and working capital subsidies), co-financing of remuneration costs from funds within EU financial framework 2014-2020 has been offered as the vehicle to support enterprises at the regional tier. Some regions have also have channelled further support in the form of e.g., investment microloans or loans to help changing the business model. Moreover, as compared to the nationwide tier, predominantly any preferences have not been given in terms of sectors. Only three regions have taken a different approach and directed their working capital subsidies to the enterprises from these sectors that have been strongly affected by the lockdown commence (e.g., tourism and related services, accommodation, gastronomy).

While the COVID-19 downturn has caused liquidity shortages in many enterprises, the immediacy of providing support seems essential to prevent massive bankruptcies. The analysis provides evidence that support for entrepreneurship from the re-allocation of funds that Poland has at disposal within the EU financial framework 2014-2020 has been available in different phases. Specifically, at the nationwide tier first phase of supporting entrepreneurship started early May 2020, that is during stage IV of the lockdown and its easing in Poland, when first liquidity loans for micro, small and medium enterprises have been accessible. At first PLN 0.4 billion (approx. €0.09 billion) have been channelled, however due to great demand the amount of support has been raised in three waves up to total PLN 2.15 billion (approx. €0.48 billion) at the end of August. More than 1,000 enterprises have been already granted with the process still pending (end of August 2020). That was followed by the second phase starting early June, that is during stage VI of the lockdown and its easing in Poland, when working capital subsidies for medium enterprises have been accessible at the nationwide tier. That particular support has been channelled in the seven waves (to 11 August 2020), with the number of supported enterprises ranging from 88 to 872 in respective waves. In total, PLN 2.5 billion (approx. €0.56 billion) have been channelled for working capital subsidies to 42% of all medium enterprises in Poland. A slightly different picture emerges from the analysis of the regional tier when various means of supporting entrepreneurship from funds within the EU financial framework 2014-2020 have been available disparately depending on the regions policy actions, but not earlier than middle of July, that is stage VI of the lockdown and its easing in Poland.

Conclusions

This paper has looked at the how public funds may be applied to moderate the blowbacks of the major economic disruptions on entrepreneurship. Using a data set for the Polish economy covering the early months of the COVID-19 disruptions (March-August 2020), this paper offers some exploratory insights into how that downturn has been responded in Poland through establishing “first aid” supporting programs to entrepreneurship from the re-allocation of funds within the EU financial framework 2014-2020. The findings provide evidence that, while the COVID-19 downturn is still ongoing, the two-tier approach towards supporting entrepreneurship from these funds has been adopted as of now: nationwide and regional. It has been also observed that the nature of that support is generally liquidity loans and working capital subsidies. Such support’s nature seems appropriate given the stage of the crisis and the necessity of policy actions to respond to enterprises’ urgent need to alleviate liquidity constrains and to ensure continuity of employment. Various phases of supporting entrepreneurship have been identified, with support at the nationwide tier available more promptly than at the regional tier. The findings provide empirical support to the ongoing research discussion on relevant policy actions related to supporting entrepreneurship during the major economic disruptions.

Several policy insights can be drawn from the findings of this paper. While foregoing support is predominantly provided to any sector, enterprises from these sectors that have been profoundly affected by the lockdown commence may need to be especially targeted when constructing policy actions. Similarly, there may be crucial to ensure the necessary support for these enterprises that are considered to be of regional significant. Support should also not only provide "first aid" to enterprises but also be focused on the long term objectives, as e.g. fostering high growth enterprises and increasing innovation.

Some limitations of the paper should be acknowledged. First, although the paper covers some policy actions that have been directed to date to support entrepreneurship since the COVID-19 lockdown in Poland, there is not sufficient knowledge about the ways the pandemic would proceed and how it may affect entrepreneurship *in spe*. Further research should therefore focus on examining which vehicles may be adequate to support entrepreneurship during the COVID-19 pandemic changing dynamics and economic downturns arising from that. Second, while this paper illustrates how some public funds may be used to support entrepreneurship under the environmental volatility, such as during the major economic disruptions, the outcomes of this support are not regarded in this paper. This is because not much time has elapsed since the analysed support has been directed to enterprises. While it takes time until the effects of supporting policy become visible in empirical data, another possible avenue for research is to evaluate wherever policy responses were appropriate both for individual enterprise and economy.

Business Environment Institutions in Rural, Urban-Rural and Urban Municipalities in Poland As Subjects Supporting Development of Entrepreneurship

Agnieszka ŻOŁĄDKIEWICZ-KUZIOŁA

Nicolaus Copernicus University in Torun, Torun, Poland
a_zoladkiewicz@umk.pl

Abstract

The present article strives to provide answers to the following research queries: (1) Within Polish municipalities, are there disproportions regarding the number and type of business environment institutions functioning on their territories? (2) Is there any, and if yes, what type of support is granted to business environment institutions by municipality? The article presents the results of the author's survey study which was conducted from September to December 2018. The research tool used was a survey questionnaire in electronic form which was sent directly via email to all 2478 municipalities in Poland. In the research, the division into rural, urban-rural and urban municipalities was taken into consideration. The results have shown that there are significant disproportions in the number of business environment institutions functioning in municipalities in Poland. The smallest saturation with business environment institutions was reported in rural municipalities whereas the largest in urban municipalities. Among researched institutions, the largest group in the case of rural and urban-rural municipalities were information centres while in the case of urban municipalities investor service centres. Rural municipalities provide support to business environment institutions mainly in the form of advisory service, urban-rural municipalities provide access to premises and urban municipalities offer financial support.

Keywords: Entrepreneurship, Business Environment Institutions, Support of Entrepreneurship, Municipalities.

Introduction

Entrepreneurship is perceived as the engine of economic growth (Acs, Szerb, 2007, p. 112; Farayibi, 2015). Foremostly the development of enterprises from SME sector, play an important role in the state's economy: they create new workplaces, boost production of goods and services as well as increase the income of citizens, the budget of local government units and the state. Moreover, they have a positive impact on the development of infrastructure, improve the quality of natural environment, but also the knowledge, qualifications and new skills of the society (Żołądkiewicz, 2016, p. 357; Żołądkiewicz, 2019, p. 118; see more Keskin, Senturk, Sungur, Kiris, 2010; Kruja, 2013; Hu, 2010).

The development of SME is determined by numerous varied internal factors connected with the entrepreneur and specific character of the enterprise as well as external factors associated with the environment of the enterprise (Kamińska, 2011, p. 53). Enterprises from SME sector when handling difficulties require mainly operational and strategic support from the so-called business environment institutions (BEI) (Filipiak, Ruszała, 2009, p. 75). Such institutions are also referred to as institutions supporting entrepreneurs, back office institutions, institutions supporting business, institutions from business environment (Dorożyński, Urbaniak, 2012, pp. 202-203), or market environment institutions (Lizińska, Marks-Bielska, Serocka, 2014, p. 68), support infrastructure (Lisowska, 2016, p. 87), non-commercial business environment (Fabińska, 2013, p. 72).

Cite this Article as: Agnieszka ŻOŁĄDKIEWICZ-KUZIOŁA " Business Environment Institutions in Rural, Urban-Rural and Urban Municipalities in Poland As Subjects Supporting Development of Entrepreneurship" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

As Krajewski, Śliwa (2004) observe, development of enterprises, including those from SME sector, is conditioned by the number and type of business environment institutions located in the closest neighbourhood, such as municipality which forms a basic unit of local government. Hunt (2015, p. 5) in the work on the role of business environment institutions is close to assume that 'the more, the better'. Even though business environment institutions provide support to entrepreneurs, they also need support from other subjects so that they can exist and function in a particular area. Therefore, it is crucial to verify the number and type of business environment institutions functioning in a particular area, but also the level and form of support granted to them by the local government.

The article strives to provide answers to the following research queries: (1) Within Polish municipalities, are there disproportions regarding the number and type of specific business environment institutions functioning on their territory (business incubator, local development agency, loan guarantee fund, loan fund, entrepreneurship support association, information centre, investor service centre, technology park, industrial park)? (2) Is there any, and if yes, what type of support is granted to business environment institutions by the municipality?

Theoretical Framework

In literature on the subject one may find various definitions of business environment institutions. For instance, the European Commission defines business environment institutions (BEI) as subjects offering services supporting entrepreneurship, i.e. ‘services, originating in a public policy initiative, that aim to assist enterprises or entrepreneurs to successfully develop their business activity and to respond effectively to the challenges of their business, social and physical environment' (Commission of the European Communities, 2001, p. 7).

In the Regulation of the Minister of Regional Development of 20 May 2009 on granting support for boosting the potential of business environment institutions within the scope of regional operational programmes, such institutions are defined as 'a micro-entrepreneur, a small or medium entrepreneur, but also other type of entrepreneur, regardless of their legal form, who does not operate for profit or allocates profits for statutory goals and conducts activity which is aimed at creating beneficial conditions for development of entrepreneurship'.

In Burdecka's opinion, business environment institutions are 'non-profit institutions which do not operate for profit or allocate profit for statutory goals specified in the statute or similar document, and operate on the territory of Poland'. Subjects owning material, technological basis, human resources and competences necessary to offer services for SME sector' (Burdecka, 2004, p. 5).

On the other hand, for Dorożyński, business environment institutions are 'subjects which offer various forms of services which support operation of business activity. This support may be granted against payment or free of charge to people who conclude business activity or already functioning enterprises in order to stimulate their development' (Dorożyński, 2013, p. 137).

Concluding, taking into consideration all presented definitions one may state that the notion of business environment institution includes almost all types of subjects which are directly or indirectly linked to the creation and functioning of enterprises.

These institutions have impact on the investment attractiveness of the region as well as its level of competitiveness. Moreover, they also contribute to the development of high tech industry, regional economy's innovativeness and help to shape a knowledge-based economy (Dominiak, 2013, p. 44). They also play a significant role in the development of entrepreneurship, particularly SME sector, by offering information, advisory, technical, coaching, organizational, legal and financial support (Dominiak, 2016, pp. 100-101, Lisowska, 2016, p. 86). Additionally, they offer assistance in networking with foreign counterparties (Glabiszewski, Grego-Planer, Liczmańska-Kopcewicz, 2018, p. 580). Support is directed to those who initiate business activity as well to those who already operate an enterprise (Mempel-Śnieżyk, 2014, p. 53).

Business environment institutions can be divided in many ways. For instance, with regard to the type of undertaken actions, target group of recipients or necessary competences of the staff, business environment institutions may be classified into three basic categories (Bąkowski, Mażewska, 2014, p. 8; Matusiak, 2011, p. 182):

- centres of entrepreneurship (e.g. business incubator, training and advisory centre): their role is to promote and incubate entrepreneurship, direct support services to mainly small enterprises, activate the development of peripheral regions or those affected by structural crisis,
- innovation centres (e.g. technological park, technology transfer centre, academic business incubator): their role is broad promotion and incubation of innovative entrepreneurship, technology transfer and providing pro-innovative services, activation of academic entrepreneurship and cooperation of science with business,
- para-banking financial institutions (e.g. business angels networks, seed capital): their role is to reduce financial discrimination of newly created and small enterprises without credit history, provide financial services adjusted to the specifics of new business ventures.

The most complex catalogue of business environment institutions functioning in Poland compiled for work purposes by the Polish Agency for Enterprise Development encompasses such institutions as (Domańska, 2019, p. 32-22):

- central administration units with their reporting units, including foremostly the Polish Agency for Enterprise Development,
- local government units,
- regional development agencies,
- research and development units, including centres of excellence and centres of advanced technologies,
- employer associations,
- trade chambers and associations,
- training-advisory or consulting institutions,
- higher education units,
- institutions supporting entrepreneurship, including employment agencies, business incubators, industrial parks, foundations and associations realizing programmes supporting entrepreneurship,
- financial institutions, such as banks, Bank Gospodarstwa Krajowego, investment funds, loan funds, business angels networks, venture capital funds,
- subjects listed in the Database of Development Services, compiled by the Polish Agency for Enterprise Development.

In further part, the focus is on only 9 business environment institutions, i.e. business incubator, local development agency, loan guarantee fund, loan fund, entrepreneurship support association, information centre, investor service centre, technological park and industrial park.

Business incubators are organized economic units which encompass a broad group of isolated and real estate based centres. They are targeted at assisting newly created and small/medium enterprises, foremostly by facilitating sufficient venue area for business activity, creating a positive atmosphere for undertaking business activity and realizing innovative ventures, but also support in the form of legal, financial, patent, organizational, technological services as well as assistance in acquiring funds (Sosnowska, Poznańska, Łobejko, Brdulak, Chinowska, 2003, p. 53; see more Salem, 2014).

Local development agencies are institutions the operation of which is aimed at counselling and organization of trainings for SME enterprises, but also local and regional government units or non-governmental organisations. They also play the role of an intermediary between the public authorities and the business. Very frequently they conduct other business environment institutions (Krajewski, Śliwa, 2004, p. 93-94).

Loan guarantee funds and loan funds are para-banking institutions. The role of loan guarantee funds is to provide guarantees for mainly small and developing enterprises which do not have a sufficient credit history or collateral required by the bank (Mażewska, 2011, p. 85). The scope of activity of loan guarantee funds includes support for entrepreneurs while preparing loan applications as well as popularization of knowledge regarding the acquisition of EU funds (Kogut-Jaworska, 2008, p. 111). On the other hand, loan funds grant capital support by providing loans mainly for micro and small enterprises. Financial support is directed also to the unemployed who initiate business activity (Szydłowski, Wojtowicz, 2019, p. 75).

Another type of business environment institution taken into account in the research is entrepreneurship support association. Their main goal is popularization of the idea of entrepreneurship and self-employment, active cooperation with local government administration as well as private and non-governmental organizations (Mempel-Śnieżyk, 2014, p. 56).

Municipal information centres function in a complex way. Their services are directed mainly to the unemployed, students and graduates of upper-secondary schools, employers and those who wish to start their own business. Their activity concentrates on assisting job search, compiling recruitment documents, informing of available courses and trainings, counselling with respect to labour law and networking employers with job seekers (Zespół ds. Współpracy Regionalnej, 2015). Investor service centres are units which usually function within the structure of big city administration, their purpose is mainly promotional activity and offering services to new investors, both Polish and foreign (Grycuk, Russel, 2014, p. 69).

Technological parks are sets of isolated venues with technical infrastructure which were created in order to facilitate exchange of knowledge and technology between scientific units and enterprises. Industrial parks, in turn, encompass industrial areas equipped with proper infrastructure aimed at entrepreneurs who wish to operate a business activity in them (Grycuk, Russel, 2014, pp. 69-70; see more Hunjet, Ivetić, Kozina, 2018).

Research Methodology

So as to realize the research goal, in the article one presents the results of author's survey study which was conducted in the period from September to December 2018. Research tool used is a survey questionnaire in electronic form which was sent directly via e-mail to all 2478 municipalities in Poland. In the study the division of municipalities into rural (1548 units), urban-rural (628 units) and urban (302 units) was taken into consideration. During realization of the study research data was obtained from 394 rural municipalities, 188 urban-rural and 114 urban municipalities. Rural municipality is the area without a town in its area, it has only villages. Urban-rural municipality contains both rural urban areas. Urban municipality is contained within the administrative boundaries of a city. Moreover, urban municipality may also be a city with county rights (Kozłowski, Zadworny, 2016). In the conducted study the queries regarding business environment institutions concerned selected nine types of institutions, i.e. business incubator, local development agency, loan guarantee fund, loan fund, entrepreneurship support association, information centre, investor service centre, technological park and industrial park.

Research Result

The major aim of the conducted study was to indicate which business environment institutions listed in the survey questionnaire function in their municipalities, and also which institutions are planned to be established in the nearest future.

In rural municipalities, business environment institutions are rare (see Fig 1). Despite that, the largest share are information centres which conduct their activity in 21 rural municipalities; that constitutes only 5% of all studied rural municipalities. Next are investor service centres which function in 17 rural municipalities, local development agencies (14 rural municipalities), loan funds (13 rural municipalities), entrepreneurship support associations (12 rural municipalities), loan guarantee funds

(11 rural municipalities) and business incubators (10 rural municipalities). The smallest group are industrial parks which were indicated by 3 rural municipalities and technological parks functioning in one rural municipality. Also, a small percentage of rural municipalities plan to establish business environment institutions in their area in the nearest future. Only 6 rural municipalities declared to create a business incubator, 4 rural municipalities declared an information centre, 3 rural municipalities an entrepreneurship support association, investor service centre and industrial park and finally, 2 rural municipalities plan a technological park.

Fig. 1: Business environment institutions functioning on the territory of rural municipalities
Source: own compilation based on the author's research results (n=394).

Similarly to rural municipalities, urban-rural municipalities pointed most frequently information centre among business environment institutions functioning on their territories (see Fig 2). Nonetheless, such choice was characteristic of only 11% urban-rural municipalities. The smallest group were industrial parks (6 urban-rural municipalities) and technological parks (4 urban-rural municipalities). Also, as in rural municipalities, the authorities of urban-rural municipalities declared to create a business incubator (5 urban-rural municipalities), information centre (4 urban-rural municipalities), investor service centre (2 urban-rural municipalities), entrepreneurship support association (1 urban-rural municipality) and industrial park (1 urban-rural municipality). Yet, in the nearest future urban-rural municipalities do not plan to create a technological park, loan fund, loan guarantee fund or local development agency.

Fig. 2: Business environment institutions functioning on the territory of urban-rural municipalities
Source: own compilation based on the author's research results (n=188).

In the case of urban municipalities, the situation of municipalities with selected business environment institutions functioning on their territory is definitely better in comparison to rural or urban-rural municipalities (see Fig 3). The most frequently pointed by urban municipalities were investor service centres. These institutions operate in as many as 52 municipalities, which constitutes nearly 46% of all

urban municipalities which replied to the query. The second most frequent indication was a business incubator (38 urban municipalities), then information centre (37 urban municipalities), loan fund (36 urban municipalities), local development agency (35 urban municipalities), loan guarantee fund (34 urban municipalities) and entrepreneurship support association (31 urban municipalities). Similarly to rural and urban-rural municipalities, the smallest group of institutions indicated by urban municipalities was industrial park (29 urban municipalities) and technological park (24 urban municipalities). Only 2 urban municipalities declared to create a business incubator and another two information centre, whereas one municipality declared an entrepreneurship support association and another one investor service centre.

Fig. 3: Business environment institutions functioning on the territory of urban municipalities
Source: own compilation based on the author's research results (n=114).

Having analysed the replies to queries regarding the functioning of business environment institutions provided by municipality authorities, one may evaluate the degree of saturation with specific subjects (see Table 1). It may be observed that mostly rural municipalities (84.77%) are deprived of business environment institutions. Second are urban-rural municipalities (70.74%). As for urban municipalities, only 32.46% of them do not have a functioning business environment institution on their territory. Among rural municipalities with functioning business environment institutions, the majority are those with only one such subject. Moreover, there are no rural municipalities with 7, 8 or 9 functioning business environment institutions. A similar result can be observed in the case of urban-rural municipalities. Nonetheless, the case is different for urban municipalities as one may indicate local government units where as much as 9 business environment institutions function on their territory.

Table 1: The number of business environment institutions functioning on the territory of municipalities

The number of business environment institutions	Type of municipality					
	rural		urban-rural		urban	
	number	share	number	share	number	share
0	334	84.77	133	70.74	37	32.46

In further part of the study, the subjects were to evaluate their scope and type of support (facilitating access to premises, financial support, advisory services) provided to specific business environment institutions.

In general it may be stated that rural, urban-rural as well as urban municipalities demonstrate great commitment to creation and functioning of business environment institutions (see Table 2, 3, and 4). Almost in all cases, the percentage of subjects declaring support exceeded 60%. Rural municipalities provided a lot of support for information centre in the form of advisory services whereas the smallest support was offered to industrial park, where only one municipality declared advisory services. Urban-rural as well as urban municipalities declared most support for investor service centres in the form of facilitating access to premises. In the case of urban municipalities, the smallest support was provided to technological park. In turn, among urban-rural municipalities the smallest support was provided to loan fund. Moreover, among rural municipalities support in the form of advisory service seems to dominate among all indicated business environment institutions. Urban-rural municipalities declare support mainly in the form of facilitating access to premises whereas urban municipalities offer financial support.

Conclusions

The study has shown that the distribution of business environment institutions (BEI) in municipalities in Poland is uneven. One may observe significant spatial disproportions between rural, urban-rural and urban municipalities. Among others, Ładysz (2020, p. 109) aptly notes that significant disproportions in the number of functioning business environment institutions affect the attractiveness of particular areas for entrepreneurs planning to start their business. Additionally, in the case of municipalities with the lowest number of business environment institutions, their development opportunities also decrease.

The lowest saturation with BEI was reported within the area of rural areas. 84.77% of studied rural municipalities do not have a functioning business environment institution within their territory. In addition, among rural municipalities with functioning business environment institutions, the majority are those with only one such subject. Such situation is highly unfavourable. The results of numerous studies (e.g. see Bieńkowska-Gołasa, 2015, p. 9-10) indicate that the level of entrepreneurship in rural municipalities in Poland is lower when compared to urban-rural and urban municipalities. Consequently, a small number of business environment institutions in rural municipalities may have a negative impact on the development of entrepreneurship in those areas.

On the other hand, urban municipalities have the largest number of functioning business environment institutions. These are mainly investor service centres. Only 32.46% of urban municipalities do not have any active business environment institutions. Moreover, unlike rural or urban-rural municipalities, among urban units one may list areas where as many as 7, 8 or even 9 business environment institutions function. Among all studied institutions, the largest group in the case of rural and urban-rural municipalities are information centres whereas in the case of urban municipalities investor service centres.

The number of business environment institutions may result from the commitment of local authorities into their creation and functioning. Also, the results of the study show that urban, urban-rural and rural municipalities provide support to business environment institutions in the form of facilitating access to premises, financial support and advisory services. Nonetheless, certain discrepancies may be observed. Rural municipalities provide support mainly in the form of advisory services, urban-rural in the form of facilitating access to premises while urban municipalities offer financial support. Thus, in order to improve the situation regarding the number of business environment institutions, rural municipalities, in the fashion of urban municipalities, ought to engage in financial support of such institutions.

Due to the role of particular business environment institutions in entrepreneurship development, changes in the policy of supporting entrepreneurship are necessary. There is a need to a.o. systematize the rules regarding location of business environment institutions which would reduce the disproportion

in the number of such institutions. The research conducted by DEG's has shown that improvement of business environment is significant not only for enterprises, but also for the whole society (Skibbe, 2018).

Abstract

This paper defines the roles of spatial policy tools protecting the space understood as a public good. Space protection in this approach must be implemented through specific spatial policy tools. The paper verifies the real scope of such protection. An attempt was made to translate approaches and dilemmas regarding public goods into conditions related to the spatial management system.

Keywords: Public Goods, Space, Spatial Order, Planning and Spatial Development.

Introduction

Issues related to the protection of spatial order and proposing the optimal spatial management system can be undertaken from various perspectives. The perspective of institutional economics undoubtedly remains one of them. In the context of current problems occurring in the spatial management system, it is worth developing the approach to space as a public good. The aim of the paper is to indicate functions that spatial policy tools at local level should fulfill while protecting the space understood as a public good

Space management and malfunction of public authorities

A specific feature of the public good is that its unit can satisfy more than one consumer. Furthermore, an additional consumer does not reduce the amount of public good available to others. Thus, individual consumption of a good by one person does not exclude individual consumption of this good by others (Samuelson 1954, Samuelson 1958). A. Kargol-Wasiluk links the occurrence of public goods with the occurrence of collective needs. Examples include national defense, public safety, sanitary protection, street lighting, and the use of public roads. A. Surdej distinguishes between competitive goods in consumption (private goods and goods for shared use) and non-competitive goods in consumption (club goods and pure public goods). Excluding from consumption is a separate element (private and club goods are excluded). The author indicates that the criteria of consumption non-competitiveness and non-exclusion from consumption are met by small number of goods - pure public goods (Surdej 2006). According to W. Gaczek, all goods, except private goods, can be roughly treated as public goods. It is the authorities (central, regional, local), who determine how much public funds will be allocated to public goods [Gaczek 2003]. Thus, the authorities shape these goods. This approach can be largely agreed, especially in the context of special treatment of public goods themselves; first of all, due to the fact that in practice there are no public goods that fully meet all textbook attributes assigned to them. It should also be noted that, according to E. Ostrom, with every institutional solution aimed at regulating access to goods that are jointly owned in

a way that achieves multiple purposes, this requires prior answers, among others, to the following questions:

- how is the issue of multidimensional links between different levels of action to be solved?
- how is the unforeseen accident to be resolved?
- how will the rules set out over time change in response to ongoing internal and external changes (Ostrom 2012, Ostrom 2005)?

R. Stiglitz points out that one of the most important public goods is the quality of state management. The model-managed state has the characteristics of public goods in this approach. (Stiglitz 2004). The above principle can also be applied to issues related to spatial planning. The initial assumption would be that the external effect is the quality of space management and: guaranteeing such solutions that will sufficiently protect spatial order and related environmental and natural conditions. Therefore, public interests related to spatial management are inseparably connected with the category of public goods. They are understood as all products of human activity of every citizen's interest, to which access on equal terms is guaranteed by public authorities of all levels in accordance with their real competences and possibilities of the economy (Markowski, Drzazga 2015). In other words, it can be stated that public goods are:

- space shaped according to the spatial order,
- access to environmental and natural values of space,
- clarity regarding the rights of individual entities in the field of spatial development,
- related opportunity to the implementation of projects important from the perspective of individual investors (Nowak, 2017).

Functions of spatial policy tools

As part of these considerations, reference was made to two key spatial policy tools at the local level, i.e. studies of spatial development conditions and directions, as well as local spatial development plans. The analysis should, however, be started from the basic framework, possibilities and limitations of local spatial policy. W. Gaczek, among features of the active way of conducting spatial policy mentions, among others:

- emphasis on implementing the agreed spatial policy objectives,
- taking preventive actions that do not allow restrictions on the development of the commune,
- taking active measures to combine various external sources of financing in the implementation of spatial development programs (Gaczek 2003).

Among the main problems, T. Markowski includes:

- introducing optional local planning,
- basing the issuing of location decisions on pathological and corruption-generating principles,
- strengthening the traditional approach to spatial planning at supra-communal levels,
- orientation of local governments only towards internal matters and excessive intergovernmental competition (Markowski 2011).

There is no doubt, therefore, that there is a serious gap between the goals and expectations of spatial policy and real possibilities. This should also be taken into account when assessing the function of the study and local plans (Bąkowski, 2018, Śleszyński, Stępniak, Mazurek 2018, Zawadzka 2017) . The assumption of creating the current spatial management system was that the study of conditions and directions of spatial development is to constitute a basic spatial document in the commune. J.M. Chmielewski emphasizes that the study by means of specific principles can define the future desired spatial structure without falling within the impassable framework for freedom of planning local (Chmielewski 2010). In accordance with the assumptions underlying the spatial management system in Poland, a key document at the local level should be local spatial development plans (Mickiewicz, Nowak 2019, Nowak 2015, Kowalewski 2019, Izdebski et al 2018). M. Feltynowski even indicates

that the adoption of local plans significantly determines the effectiveness of spatial policy in the commune (Feltynowski 2009). Their most important role can be reduced to the following elements:
- determination of land use,
- delimiting the areas for various purposes,
- defining a building ban for specific plots,
- defining the rules related to environmental and nature protection.

The scale of the problem is illustrated by results of the research. As part of the author's previous publication, spatial policy in 299 communes (from voivodeships throughout Poland) was analyzed, including the use of spatial policy tools.

Table 1: Application of spatial policy tools in selected communes

Area of communes covered by local plans (%)	Number of communes meeting the criteria related to the area covered by the plans	Percentage share of communes in which building conditions are not denied at all - in a given group
0	26	57,6
0,1-20	117	25,6
20 – 50	25	24
More than 50	121	39,7

Source: own study based on (Nowak, 2017)

In Table 1, attention was paid to the planning coverage of communes and issuing decisions on building conditions dependent on that coverage (a tool replacing the local spatial development plan in the absence of it in a given area). In the whole country, slightly more than 30% of the area is covered by local spatial development plans. The results contained in Table 1 show that the area of communes covered by local plans is varied and very often depends on random circumstances from the perspective of the main spatial policy framework. It is rare that the local plan covers a space recognized as e.g. the most important public good in a given commune (from this perspective). Rather, local plans cover areas designated for specific buildings – thus, it is primarily about meeting the individual needs of individual space users. A broader tendency to order the space can be found only in the communes covered by local plans in the scope exceeding 50%.

Conclusion

Repairing the indicated problems should be as follows:
- creating a broader system basis for adopting the local spatial development plans (or their equivalents), while consistently maintaining, for example, tendency analysis related to the protection of space values that can be associated with recognizing them as public goods,
- integrating development planning, also (or rather above all) in the spatial dimension - in addition to achieving other goals, this will allow for a broader view of space in the context of public goods.

Specific actions taken by communal authorities and space users have a dimension directly related to the economic context. Failure in considering this context will lead to significant losses in the long term. This is fully inscribed in the context of the problems undertaken, among others, in publications by E. Ostrom. And it is her proposed focus on the analysis of issues related to public goods that finds full application in the spatial management system.

Abstract

The goal of the study was twofold: (i) To verify the effect of 3 variables – self-evaluation of performance, evaluation of direct superiors and evaluation of organization – on acceptance of smart work monitoring systems, and (ii) To distinguish predictors that increase readiness to have such monitoring systems installed, in exchange for a small monthly salary bonus for the monitored employees. A questionnaire study was conducted in Poland, on a group of 130 respondents, of which 55 were immigrants from post-Soviet Union countries. Low levels of each of these three variables were found to significantly decrease acceptance of smart work monitoring systems. A logistic multivariate regression analysis showed that – of the five potential predictors studied – only desire for promotion within the organization (a measure of attitude towards the organization) and evaluation of direct supervisor were significant.

Keywords: acceptance of electronic monitoring systems, work monitoring system, monitoring, privacy calculus decision model

Introduction

Monitoring work performance and its outcomes is a standard managerial activity. Its origins reach back to pre-industrial times and over-the-shoulder observation of employees by supervisors (Thiel, MacDougall, & Bagdasarov 2019). Developments in telecommunications technology have led to a proliferation of the means of carrying out monitoring activities, and the creation of new tools and innovations in performing and analyzing these observations has caused a sudden spike of practical and research interest in the topic of work monitoring (Ravid et al. 2020; White et al. 2020).

Recent solutions in this area involve the Internet of Things, or the capacity to transmit information between various objects at any moment, anywhere, and in any way (Lu, Papagiannidis, & Alamanos 2018). The Internet of Things carries with it, among others, the ability to gather current data about the events around a given item or person, at practically no expense. As a consequence of this ability, electronic performance monitoring tools (and the so-called smart work monitoring systems) are being developed and used to gather, process, preliminarily analyze, and report monitoring data, which then serve as the basis for (mostly automatic) decision-making. However, although new ways of monitoring emerge, there is currently a dearth of scientific data about their reception by employees. Moreover, their improper use can lead to substantial losses (Ravid et al. 2020).

The goal of the current study was twofold: to measure how acceptance of a simple kind of smart work monitoring system is influenced by three factors related to the context of its implementation: an individual characteristic of the monitored employee (self-assessment of own performance) and their subjective, context-dependent self-reports of attitudes towards their supervisor and towards their organization. Additionally, an attempt was made to distinguish the predictors of increasing this

Cite this Article as: Alicja BALCERAK And Jacek WOZNIAK "Reactions to Employee Work Monitoring Systems: Preliminary Considerations and Pilot Study" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

acceptance by offering the employees a small financial bonus for their consent to being monitored. A recent review of the literature on individual differences influencing the reactions to electronic performance monitoring highlights the need for further studies combining individual differences with the characteristics of monitoring and the workplace context (White, Ravid & Behrend 2020: 58). Our study took such a direction.

The article is organized in the following way: The first part describes monitoring, and presents factors that influence its perception by employees. Part 2 introduces the premises of the study and the research hypotheses. Part 3 discusses the results, conclusions and further research needs.

Monitoring and Employee Attitudes

For the purposes of the current study, we defined monitoring as „the observation, examination, and/or recording of employee work-related behaviours, with and without technological assistance" (Stanton 2000: 87; Thiel, MacDougall & Bagdasarov 2019: 20). Such a definition distinguishes monitoring from the ways of utilizing monitoring data, particularly for performance assessment, the ways of communicating this assessment to the employees, as well as the resulting corrective behaviors. This definition focuses on work performance behaviors rather than strictly on performance outcomes. Thus, the definition does not specify the type and frequency of observations, allowing for observations that a given employee is both aware and unaware of.

Defined this way, monitoring also includes a range of behaviors only distantly related to work, such as, for example, observing employees' physical activity during their free time, as this activity indirectly influences employee health, which, in turn, influences attendance and retention. This definition of monitoring thus does not involve issues related to the rights and permissions of the monitoring institution, the privacy risks, nor the ways of implementing these solutions legally and acceptably for the employees. Although in modern organizations monitoring refers chiefly to security and performance, in the current study we focused rather on monitoring behavior, placing us within an older, Taylorian rather than Druckerian, tradition of thinking about work management (Woźniak 2020).

Monitoring can be realized through various techniques of data gathering which are separate from the ways and techniques of analysis used for reporting. Traditional monitoring, for example, CCTV recordings or observation cards filled out by observers, were mostly used for creating very simple reports consisting of counting the number of observed occurrences of a given event. The second area has recently begun incorporating not only simple reports based on frequencies and graphs showing the occurrence of the appropriate behavior types, but also analyses created via artificial intelligence and machine learning methods, mostly used for Big Data analyses. On the one hand, this results from the large volume of data obtained from behavior observations via the Internet of Things. On the other hand, this is due to the character of this data, which is no longer unform and directly related to work performance, but increasingly often serve as potential sources of varied indices, often of weak prognostic validity and reliability. For example, webcam feeds, eye tracker monitors, and keystroke trackers provide a constant stream of observations which – as any kind of Big Data, that is, data which is heterogenous with respect to type and reliability, extensive, and potentially with high value (Lee 2017) – require extensive analyses in order to yield managerially useful information. However, implementing new technological solutions which replace traditional, human-supervised monitoring with artificial intelligence analyses of the gathered data can also become a new, separate source of employee concerns.

The current interest in monitoring is related to new technologies which not only allowed for the expansion of monitoring beyond those business sectors which traditionally used it since the 1980s such as call centers, but also lowered the costs of data gathering. The best example is the constant data gathering via CCTV cameras, which have become a well-understood possibility, analogous to the (more difficult to imagine) possibility of monitoring via the Internet of Things. Thus, although smart monitoring usually refers to monitoring systems based on the Internet of Things (Princi &

Krämer 2019), that is, in the simplest cases, systems using the RIFT technology for data gathering (Lu et al. 2018), we define smart monitoring systems for the purposes of the current study as those methods of data gathering, storage, processing, preliminary analysis, and reporting which utilize ICT capabilities. Research shows that specific solutions in the sphere of the aim, invasiveness, temporality, and transparence of electronic monitoring systems influence their reception by the monitored individuals (Ravid et al, 2020). Attempts to explain the reactions of specific individuals to specific types of system usually refer to the privacy calculus decision, that is, the estimation of costs and benefits, particularly the costs, related to a partial loss of privacy due to such monitoring (Princi & Krämer 2019; Bhave et al 2020).

However, as has already been underscored by Stanton (2000), the characteristics of the monitoring system are only one of the factors influencing its perception, as it can also be analyzed similarly to the perception of any new procedure within an organization. Stanton pointed towards an array of workplace-related contextual factors which determine this perception – from the consequences of monitoring and the arguments used to justify its implementation to the specific conditions of a given position (such as employment security, workload, and the ability to control it). Stanton also noted that different reactions to the same (technologically and organizationally) monitoring system should be expected based on employee individual differences, both psychological and demographic, such as trust in the supervisors or in the organization as a whole (Stanton 2000: 89). This served as the starting point of the current study.

Developments in monitoring technology which took place at the beginning of the 21st century and the new wave of interest in electronic performance monitoring systems has resulted in a recent publication of several literature reviews (Ball 2010; Das 2019; Ravid et al 2020). However, they are based on data from studies on electronic monitoring systems, that is, systems employing humans for data analysis and interpretation, carried out chiefly in call centers in English-speaking countries. The current study, carried out in a different social context (opinions of employees of various business branches in eastern Europe, also about the beginning of smart monitoring systems) is complementary to the aforementioned analyses. Additionally, it represents a step towards a better understanding of Stanton's analytic model, which has yielded inconclusive empirical results.

Assumptions of the Research and Hypotheses

The goal of the current study was twofold: to measure how acceptance of a simple kind of a smart work monitoring system is influenced by three factors related to the context of its implementation: an individual characteristic of the monitored employee (self-assessment of own performance) and their subjective, context-dependent self-reports of attitude towards their direct supervisor and towards their organization. Additionally, an attempt was made to distinguish the predictors of increasing this acceptance by offering the employees a small financial bonus for consenting to being monitored.

The research hypotheses were formulated on the basis of the model of interdependence of the respondents' reactions to monitoring systems and their attitudes towards the organization and their direct supervisors, proposed by Stanton (2000). We assumed that a positive relationship with the direct supervisor (operationalized here as rating one's supervisor as better than average) and a positive attitude towards the organization (operationalized here as a desire for promotion in the organization) as well as low fear of performance evaluation (operationalized here as a high self-assessment of own performance) will facilitate – ceteris paribus – a positive attitude towards smart work monitoring systems.

Research carried out thus far on electronic monitoring systems has yielded disparate results concerning the simultaneous and independent influence of the three factors distinguished in Stanton's model.

Some research confirmed that trust in the organization is a moderator of the influence of the attitude towards the monitoring system on the effects of its implementation, measured by changes in attitudes,

retention behaviors (Alder, Noel & Ambrose 2006), or ratings of systems using the Internet of Things (Princi & Krämer, 2019).

Trust in the supervisor – as opposed to trust in the organization, and thus in contrast to Stanton's model which highlighted the importance of both those factors – was revealed to have no effect on the reaction to monitoring. This has been interpreted as an effect of treating monitoring as an organizational procedure rather than a line manager's choice (Alder et al 2008: 493). On the other hand, another study showed that trust in the manager moderated the relationship between assessments of fairness of electronic performance monitoring system use and its consequences for workplace attitudes and performance (McNall & Roch 2009).

We expected high self-assessments of own performance quality to facilitate greater readiness to accept performance monitoring on the basis of results from experimental studies showing that self-efficacy is related to positive effects of electronic performance monitoring systems implementation (Laird, Bailey & Hester 2017). Literature reviews concerning electronic monitoring systems do not indicate that trust in the quality of one's performance has been directly studied as a factor in acceptance of monitoring.

The following hypotheses were posed:

H1. The higher the self-assessment of own performance, the higher the acceptance of smart work monitoring systems.

H2. The more positive the attitude towards one's supervisor, the higher the acceptance of smart work monitoring systems.

H3. The more positive the attitude towards the organization (measured as a desire for promotion in the organization), the higher the acceptance of smart work monitoring systems.

A second goal of the study was to verify some predictors affecting the consent for being monitor by smart work monitoring systems in exchange for a small salary bonus. The predictors taken into account in the current study were: acceptance of smart work monitoring systems, gender, and nationality (immigrant status).

The following hypothesis was put forward:

H4: Readiness to consent to the implementation of smart work monitoring systems in exchange for a small salary bonus will be facilitated by the positive self-assessment of own performance, supervisor's evaluation, desire for promotion in the organization, immigrant status, and male gender.

Thus, we indirectly refer to the results of Princi & Krämer (2019) who showed that the individual privacy calculus can be an explanatory model for the level of acceptance for performance monitoring systems basing on the Internet of Things. In that study, costs were measured with a scale of privacy threats related to a given type of monitoring. On the basis of this model, it can be assumed that individuals with a more positive attitude towards monitoring would rate the costs of being monitored as lower. Alternatively, they could rate the subjective value of the salary bonus granted in exchange for being monitored as higher. For this reason, the direction of our hypothesis on immigrant status is based on a premise that the subjective value of money would be greater for immigrant employees than for native Polish employees as there is wide disparity between wages in Poland and in the immigrants' country of origin.

Taking into account gender as a predictor was based on the study by Ball, Daniel, and Stride (2012) who showed that women are more concerned about maintaining privacy in their work environments. This means that they value their privacy more, which should result in expectations of a higher

financial bonus to balance the costs of monitoring in their subjective cost/benefit analyses. In case of a predetermined amount of compensation for monitoring, women will thus be less likely to consent to it, as they will judge privacy loss as more significant.

Method

Participants

The sample consisted of 130 currently employed subjects, over 50% of respondents had higher education, and 32% were still studying. 43% of respondents were younger than 25. We would like to thank Mr. M. Yakovlenko, a Ukrainian engineer working in Poland in a large energy company, for sharing data obtained for the needs of his MA thesis, written under the supervision of one of the authors. The data for the study was collected using the "snowball" method. Hence, most of the respondents worked as technicians in technology companies.

Measures

Acceptance of a smart work monitoring system was measured by the question: "Assess whether you accept supervision of your work with the use of ICT software which observes and registers the behavior of the working person", assess on a 7-point Likert-type scale.

Readiness to consent to the implementation of smart work monitoring systems in exchange for a small salary bonus was measured by a question: "Would you consent to your employer using any observation tools of his choice to collect information about what you do during the working day, in return for an additional monthly bonus of 100 PLN?" [c. 25 $]. Participants responded on a 7-point Likert-type scale. As frequencies on low levels were small, the variable was recoded as binary: 1. Agreement, 2 – Disagreement.

Self-evaluation of own performance was measured by the statement *"Assess your work effectiveness"* on a 5-point Likert-type scale. As nobody assessed their performance negatively, only 3 levels of the variable were used: Average, Rather higher than average, Higher than average.

Evaluation of supervisor was measured by the statement: "Assess your supervisor (boss)", on a 5-point Likert-type scale. (1 – Lower than average; 2 – Rather lower than average 3 – Average; 4 – Rather higher than average, 5 – Higher than average). As frequencies on low levels were small, the variable was recoded to 3 levels: Average or lower, Rather higher than average, Higher than average.

Desire for promotion in the organization was measured by a direct question, with responses on a 7-point Likert-type scale. As frequencies on level 1, 2 and 3 were small, the variable was recoded to 3 levels one: Not present or weak, Present, Strong.

A detailed description of smart monitoring systems preceded the questionnaire. IBM SPSS Statistic software (v.25) was used to conduct all statistical analyses. Statistical significance was set for a 0.05 level.

Results

Hypotheses 1-3

As the *Acceptance of smart work monitoring* systems did not pass tests of normality (Shapiro-Wilk statistic = 0.843; $p<0.001$), hypotheses 1-3 were tested with Kruskal-Wallis-test followed up by pairwise comparisons with the Bonferroni corrections for multiple tests. The results are summarized in tables 1, 2 and 3 below.

Table 1: Comparisons of acceptance of smart work monitoring systems across three levels of Self-evaluation of performance – results of Kruskal-Wallis test

Null hypothesis	Ranks			Kruskal-Wallis test		
	Self-evaluation of performance	N	Mean Rank	H	df	Sig.
The distribution of Acceptance of smart work monitoring systems is the same across categories of Self-evaluation of performance. (Rejected)	Average	39	46.81	17.41	2	0.000
	Rather higher than average	57	68.53[A]			
	Higher than average	34	81.87[A]			

Notes: Ranks with the same superscripts are not significantly different at p<0.05. The Bonferroni correction for multiple comparisons was applied.

Table 2: Comparisons of acceptance of smart work monitoring systems across three levels of Supervisor's evaluation – results of Kruskal-Wallis test

Null hypothesis	Ranks			Kruskal-Wallis test		
	Supervisor's evaluation	N	Mean Rank	H	df	Sig.
The distribution of Acceptance of smart work monitoring systems is the same across categories of Supervisor's evaluation. (Rejected)	Average or lower	45	45.77	20.25	2	0.000
	Rather higher than average	56	74.74[A]			
	Higher than average	29	78.28[A]			

Notes: Ranks with the same superscripts are not significantly different at p<0.05. The Bonferroni correction for multiple comparisons was applied.

Table 3: Comparisons of acceptance of smart work monitoring systems across three levels of Desire for promotion in the organization – results of Kruskal-Wallis test

Null hypothesis	Ranks			Kruskal-Wallis test		
	Desire for promotion	N	Mean Rank	H	df	Sig.
The distribution of Acceptance of smart work monitoring systems in the same across categories of Desire for promotion. (Rejected)	Not present or weak	38	43.33	19.76	2	0.000
	Present	58	74.72[A]			
	Strong	34	74.56[A]			

Notes: Ranks with the same superscripts are not significantly different at p<0.05. The Bonferroni correction for multiple comparisons was applied.

As we can see, Acceptance of smart work monitoring systems is significantly lower on groups with the lowest levels of *Self-evaluation*, *Supervisor's evaluation* and *Desire for promotion*. Differences among higher levels are however insignificant. Hypotheses 1-3 may therefore be taken to be partially supported.

Hypothesis 4

For the verification of H.4., only data from respondents who gave a definite answer to the question: "Would you consent to your employer using any observation tools of his choice to collect information about what you do during the working day, in return for an additional monthly bonus of 100 PLN?" was used. Eliminating the "don't know" response reduced the sample to 112 people. Descriptions of the variables and their significant correlations are shown in Table 4.

In order to find the significant variables that influence the *Readiness to consent to the implementation of smart work monitoring systems in exchange for a small salary bonus*, a backward stepwise binary logistic multivariate regression analysis was performed. The model was specified as follows: dependent variable: FB_cat; predictors: Nationality, Gender, Desire for promotion, Supervisor's evaluation, Self-evaluation. The elimination threshold was set at $p > 0.1$.

Table 4: Descriptions and significant correlations of variables used in logistic regression analysis

Variable (short name)	Description	Mean (SD)	Correlations significant at the 0.05 level
FB_cat	Readiness to consent to the implementation of smart work monitoring systems in exchange for a small salary bonus 1 – Agreement (n=76); 0 – Disagreement (n=36)	0.68 (0.47)	Desire for promotion (0.32) Supervisor's evaluation (0.28) Self-evaluation (0.24)
Nationality	Nationality 1 – Immigrant (n=47); 0 – Pole (n=65)	0.42 (0.50)	Desire for promotion (0.19) Supervisor's evaluation (0.21)
Gender	Gender 1 – Male (n=45); 0 – Female (n=67)	0.40 (0.49)	Desire for promotion (0.22) Supervisor's evaluation (0.21) Self-evaluation (0.26)
Desire for promotion	Desire for promotion 1 - Not present or weak (n=31); 2 – Present (n=52), Strong (n=29)	1.98 (0.73)	FB_cat (0.32) Nationality(0.19) Gender (0.22) Supervisor's evaluation (0.39) Self-evaluation (0.52)
Supervisor's evaluation	Supervisor's evaluation 1 - Average or lower (n=36); 2 – Rather higher than average (n=49), Higher than average (n=27)	1.92 (0.75)	FB_cat (0.28) Nationality (0.21) Gender (0.21) Desire for promotion (0.39) Self-evaluation (0.48)
Self-evaluation of performance	Self-evaluation of performance 3 - Average (n=31); 4 – Rather higher than average (n=49), 5 - Higher than average (n=32)	4.01 (0.75)	FB_cat (0.24) Gender (0.26) Desire for promotion (0.52) Supervisor's evaluation (0.48)

The iteration for the logistic regression analysis terminated at step 4 leaving two parameters in the model i.e. *Desire for promotion* and *Supervisor's evaluation* (Table 5). The Hosmer-Lemeshow test revealed good fit with a value of 8.34 ($p = 0.304$).

Table 5: Logistic regression test results

Variables in the Equation							
		β	Standard error	Wald	df	Sig.	Exp(β)
Step 4	Desire for promotion in the organization	0.814	0.330	6.069	1	0.014	2.256
	Supervisor's evaluation	0.627	0.328	3.661	1	0.056	1.873
	Constant	-1.937	0.738	6.898	1	0.009	0.144

The values of Exp(β) indicate that as *Desire for promotion in the organization* and *Supervisor's evaluation* increase, the odds of the *Readiness to consent to the implementation of smart work monitoring systems in exchange for a small salary* bonus increase.

Nagelkerke R2 value is 0.186, which means that *Desire for promotion in the organization* and *Supervisor's evaluation* explain only 18.6% of the dependent variable's variability, and consequently that there are other factors influencing *Readiness to consent to the implementation of smart work monitoring systems in exchange for a small salary bonus*.

Discussion of Result and Conclusions

The first aim of the study was to ascertain the way that positive assessment of own work performance, of direct supervisors, and of own organization (measured by the desire for promotion) affects the acceptance of smart work monitoring systems. The verification of H1-H3 showed statistically significant differences in acceptance between people who rate each of these three variables as low, or higher. This constitutes a partial confirmation of Stanton's arguments, translated into a different type of monitoring, that both individual differences as well as attitude towards the organization and the direct supervisor influence the acceptance of smart work monitoring systems. The lack of statistical significance for the medium and high levels of acceptance might suggests that from a certain level upward, positive attitudes towards the organization and the direct supervisor, as well as a positive assessment of own performance do not additionally influence the acceptance of new organizational procedures.

Such an interpretation, which requires further studies, disproves the validity of using the privacy calculus decision model for explaining the acceptance of smart work monitoring systems, provided we assume a strong monotony of the dependence of subjective value of the potential losses on the increase in the risk of privacy threat in the sphere of workplace behaviors. This suggests that low levels of trust facilitate high estimations of privacy threat, whereas trust levels above a certain threshold (on three separate dimensions) do not decrease the estimation of privacy threat. Such threshold effects of attitude-related factors are not atypical, especially for factors which are hygienic in Herzberg's sense.

The second aim of the study was to verify which of the considered factors facilitate consent for being monitored by smart work monitoring systems in exchange for a small salary bonus. An analysis of predictors (H4) showed that from among the five included factors, only the desire for promotion in the organization and evaluation of the direct supervisor were statistically significant, explaining 18.6% of the dependent variable's variance. This relatively low amount of explained variance should not be surprising as it should be expected that the factors related to trusting the direct supervisor and the organization are not the only factors influencing the decision to consent to being monitored in exchange for a small financial remuneration.

However, it is notable that the remaining factors were not included in the model, which suggests the necessity for further research on the actual determinants of the decision to consent to being monitored in exchange for a small salary bonus. From the perspective of the privacy calculus model, a salary bonus lowers an individual's subjectively perceived costs of accepting a given solution. This was the basis of H4 in the current study. The fact that not every predictor was revealed as statistically significant suggests that, in the situation of consenting to such a procedure in exchange for money, other factors change the value of protecting one's privacy (or the subjective value of money), on which H4 was founded. Studies on the consequences of including extrinsic rewards in situations where a decision was intrinsically motivated have yielded examples in which small financial bonuses lowered the readiness to accept certain solutions which would be negative for the individual, for example, locating a uranium waste landfill near one's place of residence (Woźniak 2012). Further research is needed to establish the factors, as well as their interactions, that would facilitate such a change in the context of consent for smart work monitoring systems.

The current study had a preliminary character, which does not allow for drawing practical conclusions about the predictors of "buying acceptance" for smart work monitoring systems. More than 80% of the dependent variable's variance remained unexplained. Rather, the current results should be treated as an argument showing the limitations of the privacy calculus model as the basis for explaining the process of giving consent for smart work monitoring systems, especially in light of large individual variability in attitudes towards privacy protection revealed by prior studies showing that only around 55% of participants can be considered "privacy pragmatists" ready to negotiate equivalents for giving away their own privacy (Bhave et al 2020: 142). However, the confirmation of the factors in Stanton's model has practical use, since it suggests that, when considering the implementation of smart work monitoring systems, the supervisors' activities should first focus on increasing their employees' trust and a sense of that their performance is appreciated.

It must be noted that the current study was carried out on an incidental sample gathered via snowball sampling, which resulted in a greater than average proportion of participants with technical education and – potentially – varied attitudes towards ICT-based solutions. Second, the study involved questionnaire responses, which can be treated as indices of real decisions only to a limited extent. In this sense, the current results should be treated as preliminary, stimulating further research. In particular, further studies should focus on the issues of the threshold effects of the three factors in Stanton's model, which, in the current exploratory study, were measured with a single self-report question each. However, each of the attitudes in Stanton's model has a multifaceted character and further studies, even if questionnaire-based, should employ a more detailed operationalization. This should be the case especially with regard to operationalizing the attitude towards the organization: The current study measured it as the desire for promotion, which, however, is only an indirect index of a positive emotional attitude.

Development of Theory and Practice of The Knowledge Management System as A Component of The Digital Economy

Olga V. RUZAKOVA

Ural State University of Economics, Ekaterinburg, Russian Federation
rov@usue.ru

Abstract

This article considers the development of the theory and practice of knowledge management as a component of the digital economy. The relevance of the article is due essentially to the powerful development of the digital economy and its impact on all areas of the state's economy. The purpose of the study is to develop theoretical provisions on the strategy, organization, and economics of the knowledge management system as a component of the enterprise management system as a whole. The strategy of the knowledge management system and methods of its formation are determined. The structure of the knowledge management system has been developed with the definition of three main outlines and their description. This structure can be used in practical work on modeling the components of the system. The technological and methodological components of the organization of the knowledge management system are determined. In the course of the research, the author determined the economy, including the budget and the formation of the system's profit, and also considered the method of multi-tier cost accounting for the functions of ABC (Activity Based Costing) and its practical application. The work uses some methods of system analysis (structuring, classification, modeling, analogy, and graphic methods).

Keywords: Knowledge Management System, Organization of Knowledge Management, Strategy of Knowledge Management, Knowledge Economy, Business-Process.

Introduction

The modern economy is often defined as a knowledge economy. This term refers to an economy that creates, disseminates, and uses knowledge to ensure its growth and competitiveness. Knowledge is something that many businesses increasingly produce, sell and acquire, and this drives the development of advanced knowledge and the most effective use of it. In this regard, at present in the theory and practice of enterprise management, the direction "Knowledge Management" has become widespread (Abdikeev and Kiselev, 2011).

At present, according to many experts, the company's intangible assets - the secrets of production, ideas, technologies and other know-how - all that make up its knowledge become the main competitive advantage. In the world's leading companies, the share of intangible assets reaches 30-80% of the value of assets (Marinicheva, 2008). The quality of knowledge at the enterprise directly affects the effectiveness of the following processes: the adoption of managerial decisions in strategic, tactical and operational management; innovation activity; continuous professional development of employees; providing partners with access to counseling and training; use of internal knowledge of the company's business processes and the accumulated knowledge of consulting companies; control and workflow of the company.

Neither resource planning of production, nor general quality management TQM (Total Quality Management) nor reengineering of business processes BPR (Business Process Reingeneering) will not be able to provide a large company with relevant market positions and development in the future. Obviously, knowledge management (Knowledge Management) today is a requirement of time. The

RUZAKOVA " Development of Theory and Practice of The Knowledge Management System as A Component of The Digital Economy" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

knowledge market is gradually beginning to play a major role, outstripping the development of the market of material goods (Ruzakova, 2010).

Gartner Group defines knowledge management as an area of activity that provides an integrated approach to the collection, organization, access and use of the organization's information resources, which include databases, information and documents describing rules and procedures, and explicit and implicit knowledge in heads of employees of organizations (Labotsky ,2006).

The most progressive, according to the author, is the view of the collective of Russian authors under the direction of B.Z. Milner on the management of knowledge at the enterprise as "a way of thinking, a system of views and principles that focus on the development of intellectual resources and innovation activity" (Milner, 2003).

To expose the content of the modeling of knowledge management systems, the analysis objects proposed by Ronald Maier (Maier, 2007), which include the strategy, organization, technology and economy of the knowledge management system, were taken as a basis. In turn, these four aspects touch upon a wide range of issues: the rationale for a competitive positioning strategy for the company's activities, the structure of the information model of the knowledge management system, the description of the device for system design technology, the rationale for choosing a methodology for modeling business processes, the methodology for static and dynamic modeling of business processes, formalization of the component methodology of the organization of knowledge management systems, formalization of the solution of the problem of configurations a comparative analysis of problem domain modeling, a description of the syntactic (object) level of the knowledge management system, a description of the semantic (conceptual) level of the knowledge management system, a description of the pragmatic level (application level) of the knowledge management system, the business process modeling toolkit of the management system knowledge, the method of cost analysis of the organization of business processes, the methodology of multi-level accounting of costs by function (ABC - Activity Based Costing), dynamic an Liz performance of business processes.

Knowledge Management System Strategy

When analyzing and organizing the four components of the knowledge management system, it should be noted that knowledge management in the enterprise has its own structure, which, according to one of the first researchers in this field, K. Viga consists of three interrelated levels of management: business, management, practical actions (Dresvyannikov, 2006), presented in Table 1.

Table 1: Knowledge management structure

Level of knowledge management	Practical exercise of each level			
Business level	Planning a corporate strategy to best manage knowledge	Planning, creating, and implementing new products based on better knowledge	Business reorientation for the creation, deployment, and operation of knowledge assets	Creation of joint ventures and attraction of outsourcing projects0
Management level	Creation of knowledge, its acquisition, preservation, transfers, and use	Monitoring knowledge management and linkage practical functions	Policy of knowledge management and actions	Identify actions and resources associated with relevant knowledge
Level of practical actions	Analysis of certain and available	Formation of human resources through education	Support of projects and other research	Combining knowledge with expert networks

Level of knowledge management	**Practical exercise of each level**			
	knowledge	and training	programs	and consultations
	Creation of knowledge accounting system	Maintenance of educational programs	Creation and deployment of soft applications	Applying knowledge to working objects

Knowledge management strategies are aimed at creating a new value realized in products, people and processes through the rational formation and use of knowledge in organizations. The main goal of these strategies is to increase the efficiency of using all available resources of the organization, introduce innovations, improve customer service, and reduce losses from unused intellectual assets (Gaponenko and Orlova, 2008).

The knowledge management system strategy includes a description of the goals, objectives and factors that influence the strategy. Among the many methods for forming a strategy, one can single out the following:

- Rationale for the competitive strategy for positioning activities.
- Methods of identification of business processes.
- Heuristic method of strategic planning based on the SWOT - analysis method.

The rationale for a competitive strategy for positioning activities is based on the analysis of the "AND-OR" graph of the tree (Fig. 1). We will consider the formation of the method " Rationale for the competitive strategy for positioning activities" in two directions:

- life cycle of the system.
- characteristics of the organization's potential.

Fig. 1: Graph "AND-OR" analysis of the competitive positioning strategy of the company's activity

The characteristics of the first direction are presented in Table 2. "System life cycle" in detail. The second direction can be defined as: production and marketing capabilities of the enterprise, competitive opportunities and the financial condition of the enterprise. Financial condition can be presented through indicators of assessments of liquidity and assessments of financial stability.

Table 2: Life Cycle

Characteristic	Life Cycle Stage			
	Launching on the market	**Growth**	**Maturity**	**Decline**
Definition	Weak competition, consumers - new lovers, sales growth rate - weak	Constantly growing competition, consumers - a mass market, the rate of sales growth - fast-growing	Big competition, consumers - a mass market, the rate of sales growth - slowly growing	Decreasing competition, consumers lagging behind, growth rate of sales falling
Strategic efforts	Expansion of the market	Penetration deep into the market	Defending the market share	Minimization of costs
Competitive strategies	Focusing on the target segment	Leadership over costs. Focusing on costs	Wide differentiation. Optimal costs	Focusing on costs. Focusing on differentiation
Profit	Negligible	Maximum	Falling	Low or zero
Price	High	Somewhat lower	Lowest	Increasing
Product	Main option	Advanced version	Differentiated variant	Increased profitability

Organization of a knowledge Management System

The organization of a knowledge management system is a structure of knowledge management, a description of methodology and technology. The structure of knowledge management can be divided into three main contours: the synthetic (object) level, the semantic level (ontology), the pragmatic level (the level of applications). In turn, each of these levels consists of a number of components. For example, the synthetic level includes different knowledge bases, and the semantic level includes a hierarchy of relations of concepts. The pragmatic level of the management structure contains applications that are the result of the work of the two above levels (Fig. 2).

Fig. 2: Structure of knowledge management systems

Synthetic level (object) is responsible for storing in the specially developed categories of indexed knowledge. The semantic level (ontology) contains the ontology of the upper level (metaontology),

the ontology of the domain and the ontology of the problems. He defines the conceptual model of knowledge. The pragmatic level (applications) is the choice of the company's development goals, the choice of activities and the rationale for the structure of business processes. At this level, the goals and objectives of the issues under consideration are formed for the knowledge management system.

The syntactic (object) level

It presumes the storage of annotated categories of sources of knowledge annotated with a specially developed system and their indexing (Telnov, 2004, p.105). Each base of this level can include, for example, the knowledge base of best practice, the following sections:

- performance metrics.
- methods of organizing business processes.
- precedents.
- reference materials.

Semantic (conceptual) level

The definition of a conceptual model of the structure of knowledge common to all sources of knowledge, that is, the development of ontology.

The structure of ontology knowledge should show the paradigmatic relations of concepts (synonymy, homonymy, polysemy) and syntagmatic relations of concepts (axioms, logical rules).

Pragmatic level (application layer)

At the application level (pragmatic level), each task is addressed in the following areas:

- Formulation of the problem.
- Selection of relevant sources of knowledge.
- Understanding the selected material.
- The solution of the problem.
- Verification of the feasibility of the solution of the problem.
- Decision making and monitoring of its implementation.

It should be noted that all levels of the knowledge management system are of fundamental importance for its construction and functioning. However, it is necessary to especially highlight the semantic level, which provides the possibility of interpreting user requests to the knowledge management system through the use of ontology, which in turn determines the set of concepts of the domain and relations between them.

Metaknowledge systematizing and creating provides an opportunity of using individual parts of ontology as construction material for constructing new ontologies or extension of existing ones. Regardless of kind of business metaontology may be unified. Its purpose is to describe general concepts: essence, object, subject, function, feature, event etc. It is necessary to have control under syntactic constructions, which are used at the next level — ontology of subject area (Telnov, 2013).

The semantic level of the knowledge management system (ontology) provides a number of significant advantages of a virtual organization in the field of electronic retail financial services, namely: an accurate understanding of the knowledge of the situation and the client through the recognition of implicit knowledge; as close as possible to the vocabulary and understanding of the client's financial situation and the corresponding commercial offers; the possibility of gaining additional knowledge by the knowledge management system in the process of solving specific problems through a dialogue with the user.

The methodology and technology of the organization of the knowledge management system includes:

- Apparatus for the design of systems.
- Justification of the choice of methodology for modeling business processes.
- Component technology for organizing business processes using a knowledge management system.
- Methods of static and dynamic modeling of business processes.
- Formalization of the component methodology of the organization of the knowledge management system.
- Formalization of the structure of ontology.
- Formalization of the solution of the task of configuring the company's business processes.

The formalization of the component methodology of the organization of a knowledge management system can be based on the definition of the "S" system given by Yu. F. Telnov, which is a generalization of definitions by L. Fon Bertalafi, V.N. Volkova, F.I. Temnikova, A.I. Uemova, Yu.I. Chernyak and others (Telnov, 2004, p.123) in the form of a tuple:

$$S = \{G, E, En, T, F, R, Z\},$$

where S is the system; G - a set of goals for the functioning of the system, determining the purpose of the functioning of the system, which are measured using reachability criteria; E - a set of elements of the system as entities that are converted using functions (created, consumed, used, saved); En is the set of elements of the external environment as entities of the system environment that influence the performance of system functions; T is the set of periods of time characterizing the frequency of reproduction cycles of the elements of the system; F - a set of functions (types of activities, processes, operations) that carry out the transformation of the elements of the system; R is the set of relations of the system components that determine the constant interrelations and dynamic interactions of the system components; Z is the set of regularities (strategies, methods) of the functioning of the system, determining the structure of the system and its relationship with the external environment.

Considering knowledge management as a process, according to Newman and Conrad, knowledge management consists of four main processes: the creation, storage, transfer and use of knowledge (Milner, Rumyantseva, Smirnova and Blinnikova, 2006, p.91). However, this process can be expanded, namely, to include collection, storage and accumulation, processing, transfer and use of knowledge. For example, the process of storage and accumulation includes methods of spiral-like knowledge building and software such as Data Warehouse, Data Mart, OLPT systems. The processing process is based on the methods of artificial intelligence, the method of justifying a competitive strategy for positioning activities, the method of analyzing critical success factors, the method of searching for the optimal supply of products and services, and uses the Business Intelligent software: OLAP, Data Mining. (Ruzakova and Zvyagintsev, 2015). Note that semantic networks, according to experts, are the most common way of representing knowledge in the space of possible states, and their use in the formalization of knowledge occurred earlier than other methods.

Economics of Knowledge Management System

The economy includes a description of the budget and profit generation of the knowledge management system, and includes:

- methodology of cost analysis of business process organization (break-even point analysis method).
- The methodology of multi-tier cost accounting for the functions of ABC (Activity Based Costing).
- method of dynamic analysis of business process performance.

The method of cost analysis of the model (Medynsky and Ildemenov, 1999), based on the analysis of the breakeven point, allows to determine the break-even sales volume, the critical level of the implementation price and fixed costs, as well as the appropriateness of management decisions on

technology and product line change. Also, it involves multi-tier accounting of costs, i.e. the cost of a product or service in terms of the value of the functions performed, rather than the traditional cost elements.

The method of multi-tier cost accounting for the functions of ABC (Activiti Based Costing) includes a description of the costs by functions proposed by Yu. F. Telnov (Telnov, .2004. p.188): determination of total costs for performing functions by business units, assigning costs to value objects in terms of the functions used (Fig. 3).

It should be noted that this technique requires a precise definition of all the functions used in the chain of basic and auxiliary business processes.

Fig. 3: Two-stage cost accounting by functions

It should be noted that when carrying out a cost analysis of business processes in a retail banking, it is necessary to take into account that various operations and services represent a very definite value for clients. A well-known reorganizer of banks Paul H. Allen believes that "bank managers need to get away from the practice of pricing based on costs and a benchmark against competitors. This approach should give way to the natural method for retail business - the determination of prices based on the subjective value of the service for the consumer" (Allen, 2002).

Conclusion

The description of the main components of the knowledge management system allows us to conclude that the construction of a knowledge management system is a complex process, requiring the formalization of implicit knowledge, the dynamic analysis of multidimensional business models, but at the same time necessary for building up the competence of the company, and hence its future development. Managing knowledge, the organization seeks to create and consolidate its competitive advantages.

In the near future, one can reach the creation of knowledge bases, in which the best examples of the use of modern management technologies in state enterprises and institutions, as well as consulting companies, are concentrated.

A broad range of tasks which are solved by systems and based on knowledge allows to make a conclusion of possibility to make management decisions using the publication data of such systems on the level of experts' conclusions.Knowledge management process can be extended around information processing, storage and collecting the methods of artificial intelligence, methods of searching the optimal offer of products and services etc.

Report

According to the Federal state educational standard of higher education in the learning process of students the competence-based approach should be implemented. It means that it is necessary to be able to determine the level of formation of students' competence in different subject domain. The purpose of the article is to describe the methods of levels determination of students' competences formation as a result of the development of the discipline, allowing them to assess, using a level approach (low, medium, base, high). The competence of the student of concrete subject domain is understood as his theoretical knowledge and abilities in the studied subject domain and practical experience of their application. The main stages of the proposed methodology: the input diagnostic test before studying the course, the final pedagogical testing after the course, the defense of the project which is independently executed by the student. The criteria of Kruskal-Wallis and Bartlett were used for an assessment of the results homogeneity of pedagogical testing, and the criterion of Pearson's Chi-squared was used for the level evaluation of students' experience in project developing. The algorithm of application of the methodology is presented in specific numerical data. The technique can be used during studying disciplines, which are ending by independent development of students' projects, such as: term paper, final qualification work, a thesis project, master's dissertation, etc.

Keywords: Digitalization of The Economy, Engineering Training, Statistical Processing of The Results of Pedagogical Testing, The Level of Competence Formation.

Introduction

In accordance with the Federal State Educational Standard of higher education, a competency-based approach must be implemented when preparing students. At the same time, in the context of the transition to the digital economy, new requirements are imposed on graduates, according to which the graduate must possess, in addition to key professional competencies, called hard skills, a certain set of non-specialized, career-relevant supra-professional skills that are responsible for successful participation in the work process, high productivity and are not related to a specific subject area, called soft skills.

According to modern research in the field of professional training, the professional competence of a student in a specific subject area is understood as his theoretical knowledge and skills in the subject area under study and practical experience in their application. This means that it is necessary to be able to determine the level of competence of students in a particular subject area.

RUZAKOVA " Challenges of The Digital Economy: Assessing the Level Of Competence of Technical Universities Graduates Based on Pedagogical Testing" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Thus, the *problem of research* is determined by the current state of engineering training of students, which requires the implementation of a competence approach, and insufficient development of methods for determining the levels of formation of professional competence of students.
This fact determines the *relevance of the article*, which consists in the fact that there is an objective need to develop a methodology for determining the level of formation competence of students in the field of engineering training.

The main idea of the publication is to expand the understanding of the possibility of evaluating the levels of formation of professional competence of students using the results of pedagogical testing and their subsequent statistical processing.

The purpose of the research is to develop a method for determining the levels of formation of professional competence of students. *The purpose of the publication* follows from the purpose of the research and is to develop a methodology for determining the levels of competence formation of students as a result of mastering engineering training disciplines based on statistical processing of the results of pedagogical testing.

Object of research: the process of engineering training of students in modern universities. *The subject of the research* is to determine the levels of students ' competence formation in the field of engineering training based on statistical processing of the results of pedagogical testing.

Literature Review

The researches of Bolotov V. A. (2003), Bordovskaya N. V. (2002), Zeer E. F. (2007), Zimnyaya I. A. (2006), Pak N. I. (2006) and others is devoted to the theory of competence approach. The implementation of the competence approach is based on a level approach to the empirical assessment of the formation of a student's competence in the field of engineering training. The level approach to the estimation of empirical values has been known for a long time, and its use in pedagogical measurements is based on the works of Bloom B. (1956), Bespalko V. P. (1969) and others. Questions related to the application of this approach to the experimental assessment of professional competencies are reflected in the research of Serdyukov V. I. (2007), Kozlov O. A. (2017), Starichenko B. E. (2004) and others. Based on their research, the formation of knowledge and skills is evaluated in the framework of a taxonomic approach, which involves identifying the levels of formation of a student's competence in the field of engineering training. At the same time, the professional competence of a student in the field of engineering training will be understood as a set of theoretical knowledge and skills and the availability of practical experience related to the development of engineering projects.

The analysis of Federal state educational standards of higher education has shown that the competence approach requires the search for new methods for determining the levels of formation of students ' competence in a particular area. One of them is pedagogical testing. According to research on the levels of learning material assimilation of Bloom B. (1956), Bespalko V. P. (1969), to assess the competence of students, it is advisable to use a level approach that assumes the presence of four levels: reproductive (low), adaptive (medium), heuristic (basic) and creative (high).

At the reproductive (low) level, the student distinguishes, recognizes objects of knowledge when re-perceiving previously studied material, performs actions with them, but "with a hint", copies educational information. At the adaptive (medium) level, the student independently reproduces and applies information in the previously considered typical situations. At the heuristic (basic) level, the student uses the acquired knowledge and skills in atypical situations, gets new knowledge by acting on a pattern. At the creative (high) level, the student acts in unexpected situations and creates new algorithms, rules, actions, that is, subjectively new information.

The analysis of scientific publications has shown that in accordance with the competence approach in education (Zimnyaya I. A., 2006), which involves the identification of theoretical and practical aspects of the educational process based on the formation of a set of knowledge, skills and experience

of various activities, the student should be able to demonstrate their skills in practice. Then you can evaluate the level of competence achieved by students in a particular field on the basis of a separate assessment of their knowledge and skills in the field of theoretical foundations of the discipline studied by means of pedagogical testing (Dakhin A. N., 2009) and the levels of experience in applying this knowledge and skills in solving practical problems (for example, when defending an independently completed project).

Method

As part of the method for determining the level of students ' competence in a particular subject area, we will consider the theoretical training of students in one of the engineering disciplines, which ends with the defense of a project completed by the student independently. You can evaluate the level of initial knowledge for the development of a new subject area based on the results of the input diagnostic test. The content of the input diagnostic test is determined by the subjects of those disciplines, the development of which is necessary for the formation of competence in a new subject area.

Since the article will consider a specific calculation method, for the convenience of further calculations, we will assume that the input diagnostic test contains 50 main questions on the courses passed by students, determined by the training curriculum. The results of a test task are traditionally evaluated on a dichotomous scale: 1-the answer is correct, 0-the answer is incorrect. Thus, the maximum possible score for all correctly answered questions in the input diagnostic test is equal to the number of test questions (in our case, 50 points). According to research of Bespalko V. P. (1969), allocate the level of initial knowledge and skills of students in the field of studied disciplines required for the development of a new course: from 70% to 100% of the maximum number of points received for a diagnostic test (35 to 50 points), and a low level, insufficient for the development of a new course with scores less than 70% of the maximum (0 to 34 points).

You can evaluate the level of theoretical knowledge and skills in a particular engineering discipline based on the results of the final pedagogical testing. The volume of the final test should include a number of questions that fully cover all the learning material studied by students. Let's assume that the final test for the engineering discipline studied by students contains 60 test tasks that fully cover all modules of the engineering discipline and are adequate for its thematic planning. The result of each test task is also evaluated on a dichotomous measurement scale (Zimnyaya I. A., 2006). In our example, the sum of possible values of dichotomous variables obtained by students based on the results of the final test will be measured on a 60-point scale, which can be divided into four non-intersecting intervals: [1; 15], [16; 30], [31; 45], [46; 60], each of them corresponds to a low, medium, basic and high level of theoretical material assimilation, respectively.

To assess the level of formation of experience in implementing methods of activity in a particular engineering discipline, you can use the results of a student's defense of an independently completed project. The student project also scores on a dichotomous scale. The presence of relevant experience is assessed with 1 point, the lack of experience-0 points. To evaluate the results of the project, you need to develop a table that is divided into four intervals: [0; 2], [3; 4], [5; 6], [7; 8], corresponding to low, medium, basic and high levels of formation of experience in applying the acquired knowledge and skills in a specific engineering field. This table will be used by members of the Commission who evaluate the result of project protection. The content of the assessment table is determined by the specifics of the subject area and requires serious preparatory work of the subject teacher, who needs to describe in detail all the practical requirements for the student project that meet each level of formation of student experience.

The described method is divided into 3 stages. At the 1st stage, we form groups of participants who will determine the level of competence formation. Then the input diagnostic testing is performed. At the 2nd stage, the theoretical development of the engineering discipline is carried out, which ends with the final testing and defense of the project completed by the student independently. At the 3rd stage, statistical processing of the results of the method is performed.

As part of statistical processing of research results, the following steps must be performed:
3.1. Check the homogeneity of the sample with the results of the input diagnostic testing.
3.2. Check the homogeneity of the sample with the results of the final pedagogical testing after mastering the theoretical course of engineering discipline.
3.3. Check the homogeneity of the sample with the results of student project protection.

The Results of Research and Discussion

Stage 1. As an example, the level of competence of students will be checked during 4 academic years, one academic group per year (group 1-21 students, group 2-23 students, group 3-29 students, group 4-25 students).

The results of the input diagnostic test for the studied disciplines are presented in tables 1-4.

Table 1: Results of group 1 students performing the input diagnostic test

Sum of points	42	41	41	41	40	40	40	40	39	38	38	37	

Let's perform consecutive steps of statistical processing of the results of pedagogical testing.

Checking for homogeneity of samples containing the results of input diagnostic testing

Since the conclusion about the level of competence in the field of engineering training will be made on the basis of combining four groups into one, first of all, it is necessary to check the homogeneity of four groups of students based on the results of the input diagnostic testing.

We show that the samples containing the results of input diagnostic testing are homogeneous. To do this, we use the Kruskal-Wallis criterion (Levin D. M., Stefan D. et al., 2004).
Statistics of the Kruskal-Wallis test for testing the H_0 hypothesis that there is no shift in the position parameters of the compared samples have the form:

$$H = \frac{12}{N(N+1)} \sum_{i=1}^{k} n_i \left(\overline{R}_i - \frac{N+1}{2} \right)^2,$$

where $\overline{R}_i = \frac{1}{n_i} \cdot R_i;\ R_i = \sum_{j=1}^{N} R_{ij}$, N is the volume of the combined sample, i is the sample number, and n_i is the volume of the i – th sample.

The use of Kruskal-Wallis statistics requires combining the four samples under consideration, presented in tables 1, 2, 3, 4, into one, sorting its elements in ascending order and assigning them ranks.
Algorithm for applying Kruskal–Wallis statistics:
Step 1. Write down the attribute values for each of the studied groups.
Step 2. Arrange the overall selection in ascending order.
Step 3. Calculate the sum of R_j ranks of each sample with volume n_i.
Step 4. Calculate the H_{calc} statistics.
Step 5. Find $H_{tabl} = \chi 2\ (\alpha, k\text{-}1)$ for $k \leq 4$ and $nj \leq 5$ using a special table for small k and n_j.
Step 6. The H_0 Hypothesis is accepted if the $H_{calc} \leq H_{tabl}$.
If $n_j > 5$, an approximation of the Kruskal–Wallis statistics is required.
If there are groups of repeated ranks, then modified statistics must be calculated.
Let's perform all the steps listed in the algorithm sequentially, using the data presented in tables 1, 2, 3, and 4.

Step 1, 2. Rank together all the x_{ij} scores (i-sample number). The result of this step is shown in table 5.

Table 5: Combined sample of input diagnostic test results

Score	35	35	36	36	37	37	37	37	37	37	37	37	38	38

Rank	85	86	87	88	89	90	91	92	93	94	95	96	97	98

Step 3. From the table 5 let's make table 6, in which R_{ij} is the rank of the j-th score in the i-th sample. Matching scores are averaged.

Table 6: Values of sample points and their rank

I	X_{ij}	R_{ij}	I	X_{ij}	R_{ij}	I	X_{ij}	R_{ij}	I	X_{ij}	R_{ij}
1	35	1,5	2	39	27	2	42	52	3	46	73,5
2	35	1,5	2	39	27	3	42	52	1	47	79,3

3	38	17,5	1	41	45,5	2	45	68,5	3	50	93,5
3	38	17,5	3	41	45,5	3	45	68,5	3	50	93,5
3	38	17,5	3	41	45,5	4	45	68,5	4	50	93,5
4	38	17,5	3	41	45,5	1	46	73,5	4	50	93,5
4	38	17,5	4	41	45,5	2	46	73,5	4	50	93,5
1	39	27	4	41	45,5	2	46	73,5	4	50	93,5
1	39	27	4	41	45,5	3	46	73,5			
2	39	27	1	42	52	3	46	73,5			

According to table 6 we calculate R_i и $\overline{R}_i$:

$$R_1 = \sum_{j=1}^{98} R_{1j}$$

R_{1j}=1,5+3,5+8,5+8,5+17,5+27+27+36,5+36,5+45,5+45,5+52+57+63+63+68,5+
+73,5+79,5+79,5+85+93,5=972

$$\overline{R}_1 = \frac{972}{21} = 46,28$$

$$R_2 = \sum_{j=1}^{98} R_{2j}$$

R_{2j}=1,5+3,5+8,5+8,5+8,5+17,5+17,5+27+27+27+36,5+36,5+52+57+63+63+68,5+
+73,5+73,5+79,3+79,3+93,5+93,5=1016

$$\overline{R}_2 = \frac{1016}{23} = 44,17$$

$$R_3 = \sum_{j=1}^{98} R_{3j}$$

R_{3j}=8,5+8,5+17,5+17,5+17,5+17,5+17,5+17,5+27+27+27+36,5+36,5+45,5+45,5+45,5+
+52+63+63+63+68,5+73,5+73,5+73,5+79,3+85+88+93,5+93,5+93,5=1458

$$\overline{R}_3 = \frac{1458}{29} = 50,27$$

$$R_4 = \sum_{j=1}^{98} R_{4j}$$

R_{4j}=8,5+17,5+17,5+27+36,5+36,5+36,5+36,5+45,5+45,5+45,5+52+52+57+57+
+57+68,5+79,3+85+85+85+50+50+50+50=1405

$$\overline{R}_4 = \frac{1405}{25} = 56,2$$

Step 4. Substitute the found value $\overline{R}_i$ in an expression for calculating Kruskal-Wallis statistics:

$$H_{calc.} = \frac{12}{98 \cdot 99} \cdot (21(46,28 - 49,5)^2 + 23(44,17 - 49,5)^2 +$$

$$+29(50,27 - 49,5)^2 + 25(56,2 - 49,5)^2) =$$

$$= 0,0012 \cdot (217,77 + 653,2 + 17,11 + 1122,5) = 0,0012 \cdot 2010,58 = 2,41$$

In the case of the use of statistics Kruskal–Wallis test, if $n_i \geq 5$ (in our case $n_1 = 21$; $n_2 = 23$; $n_3 = 29$; $n_4 = 25$), an approximation is required.

The approximation of the Kruskal–Wallis statistics is defined as follows (Levin D. M., Stefan D. et al., 2004):

$$M = \frac{N^3 - \sum_{i=1}^{k} n_i^3}{N \cdot (N+1)}$$

$$\nu_1 = (k-1)\frac{(k-1)(M-k+1) - V}{\frac{1}{2}MV}$$

$$\nu_2 = \frac{(M-k+1)}{k-1}\nu_1$$

$$V = 2(k-1) - \frac{2\left[3k^2 - 6k + N\left(2k^2 - 6k + 1\right)\right]}{5N(N+1)} - \frac{6}{5}\sum_{i=1}^{k}\frac{1}{n_i}$$

Then statistics $F = \frac{H(M-k+1)}{(k-1)(M-H)}$ will have an F-distribution with ν1 and ν2 degrees of freedom.

Compute an approximation of the Kruskal–Wallis test:

$$M = \frac{98^3 - (21^3 + 23^3 + 29^3 + 25^3)}{98 \cdot 99} = \frac{879750}{9702} \approx 91$$

$$V = 2 \cdot 3 - \frac{2 \cdot (3 \cdot 4 - 6 \cdot 4 + 98 \cdot (2 \cdot 4 - 6 \cdot 4 + 1))}{5 \cdot 98 \cdot 99} - \frac{6}{5}\left(\frac{1}{21} + \frac{1}{23} + \frac{1}{29} + \frac{1}{25}\right) =$$

$$= 6 - \frac{1616}{48510} - 0,199 \approx 6$$

$$\nu_1 = 3 \cdot 2 \cdot \frac{(3 \cdot 88 - 6)}{91 \cdot 6} = 2,8$$

$$\nu_2 = \frac{88}{3} \cdot 2,8 = 82$$

$$F_{calc.} = \frac{2,41 \cdot 88}{3 \cdot 93,41} = 0,756 \cdot$$

Given that in the calculations q=15 groups with matching ranks (t_1 =2; t_2 =2; t_3 =8; t_4 =10; t_5 =9; t_6 =10; t_7 =8; t_8 =5; t_9 =5; t_{10} =7; t_{11} =4; t_{12} =6; t_{13} =6; t_{14} =5; t_{15} =10), find the modified Kruskal–Wallis statistics using the formula:

$$H^*_{calc.} = H\left[1 - \left(\sum_{j=1}^{q} \frac{T_j}{N^3 - N}\right)\right]^{-1}$$

where $T_j = t_{j3} - t_j$; t_j is the size of the j-th group of identical ranks, q is the number of groups of identical ranks. For $n_i \geq 20$ (this is our case), the approximation of the distribution of statistics by the H χ^2 – distribution with f = k-1 degrees of freedom is valid, i.e. the null hypothesis is rejected, if H* ≥ $\chi^2_{\alpha(k-1)}$.

Calculate the modified statistics H*.

$$H^*_{calc.} = 0,756 \cdot (1 - E)^{-1}, \text{ где } E = \sum_{j=1}^{q} \frac{T_j}{N^3 - N} = \sum_{j=1}^{15} \frac{T_j}{N^3 - N},$$

$T_1 = t_1^3 - t_1 = 8-2=6$; $T_2 = t_2^3 - t_2 = 8-2=6$; $T_3 = t_3^3 - t_3 = 512-8=504$;
$T_4 = t_4^3 - t_4 = 1000-10=990$; $T_5 = t_5^3 - t_5 = 9^3 - 9=720$; $T_6 = t_6^3 - t_6 = 10^3 -10=990$;
$T_7 = t_7^3 - t_7 = 8^3 - 8=504$; $T_8 = t_8^3 - t_8 = 5^3 - 5=120$; $T_9 = t_9^3 - t_9 = 5^3 - 5=120$;
$T_{10} = t_{10}^3 - t_{10} = 7^3 -7=336$; $T_{11} = t_{11}^3 - t_{11} = 4^3 - 4=60$; $T_{12} = t_{12}^3 - t_{12} = 6^3 - 6=210$;
$T_{13} = t_{13}^3 - t_{13} = 6^3 - 6=210$; $T_{14} = t_{14}^3 - t_{14} = 5^3 - 5=120$; $T_{15} = t_{15}^3 - t_{15} = 10^3 -10=990$.

$$E = \frac{1}{941094}(6 + 6 + 504 + 990 + 720 + 990 + 504 + 120 +$$
$$+120 + 336 + 60 + 210 + 210 + 120 + 990) = 6,2 \cdot 10^{-3}$$

$$H^*_{calc.} = 0,756 \cdot \left(1 - 6,2 \cdot 10^{-3}\right)^{-1} = \frac{0,756}{0,9938} = 0,76 \cdot$$

Step 5. Tabular value χ^2 for the significance level α=0,05 with the number of freedom degrees k-1=3 is 7,82.

Step 6. If $H^*_{calc.} < \chi^2_{tabl.}$ (0,76 <0,82), then the null hypothesis about the absence of shift in the studied samples is accepted as plausible, which means that the samples with the results of the input diagnostic test are homogeneous.

Next, we show that the set of sample variances containing the results of input diagnostic testing will also be uniform. To do this, we use the Bartlett criterion to compare several sample variances with different volumes (Mironova L.I., 1997). Table 7 shows the variances of the original samples.

Table 7: Values of variances of initial samples of results input of diagnostic testing

Number Samples I	Length Samples N	Variance Selections D_i
1	21	D_1 = 18,13
2	23	D_2 = 20,58
3	29	D_3 = 18,89
4	25	D_4 = 18,32

We introduce the notation:

$$N^* = \left(\sum_{i=1}^{k} n_i\right) - k$$

$$D = \frac{\sum_{i=1}^{k}(n_i - 1)D_i}{N^*}$$

$$V = 2{,}3026 \cdot \left(N^* \cdot \lg D - \sum_{i=1}^{k}(n_i - 1) \cdot \lg D_i \right)$$

$$C = 1 + \frac{1}{3 \cdot (k-1)} \cdot \left(\sum_{i=1}^{k} \frac{1}{n_i - 1} - \frac{1}{N^*} \right)$$

The calculated value of the Bartlet criterion is determined by the formula B_{calc} = V/C.

Calculate N* = 98-4 = 94

$$D = \frac{20 \cdot 18{,}13 + 22 \cdot 20{,}58 + 28 \cdot 18{,}89 + 24 \cdot 18{,}32}{94} = 18{,}98$$

V=2,3026·(94·lg(18,98)-20·lg(18,14)+22·lg(20,58)+28·lg(18,89)+24·lg(18,32)))=0,107

$$C = 1 + \frac{1}{3 \cdot 3}\left(\left(\frac{1}{20} - \frac{1}{94} \right) + \left(\frac{1}{22} - \frac{1}{94} \right) + \left(\frac{1}{28} - \frac{1}{94} \right) + \left(\frac{1}{24} - \frac{1}{94} \right) \right) = 1{,}014$$

B_{calc} = 0,107/1,014 = 0,105

We compare the calculated value of the Bartlett criterion with the critical value taken from the distribution table χ^2 in accordance with the significance level α=0,05 and the number of degrees of freedom ν = k-1. As mentioned above, the table value of χ^2 for the significance level α=0,05 with the number of freedom degrees k-1=3 is 7,82.

Since the calculated value of the Bartlett test is less than the table value (0,105<7,82), the hypothesis being tested that the variances of samples with the results of input diagnostic testing are uniform can be taken as plausible at the significance level α=0,05 and the number of freedom degrees k = 3.

Thus, the verification of the homogeneity of the initial samples with the results of the input diagnostic testing using both the Kruskal–Wallis criterion and the Bartlett criterion gave identical results, which allowed us to accept the hypothesis of the homogeneity of the initial samples as plausible at the significance level α = 0,05 and the number of freedom degrees k =3.

Checking for homogeneity of samples containing the results of final pedagogical testing after mastering the theoretical course of engineering discipline.

At this stage of statistical processing, it is advisable to use the Pearson consent criterion χ^2. The Pearson agreement criterion χ^2 is used to compare distributions of objects of several aggregates based on the state of a certain property based on measurements on the scale of names of this property in several independent samples from the considered population (Serdyukov V. I., 2007, Starichenko B. E., 2004). The essence of the method is to check the degree of discrepancy between the observed and expected frequencies – the greater the discrepancy, the greater the value of χ^2.

The following is an algorithm for applying the Pearson consent criterion χ^2:

Step 1. Formulate the null statistical hypothesis H_0.

Step 2. Set the level of significance of the hypothesis, which is that the probability of making an error of the first kind, that is, to accept the hypothesis H_0 as plausible, while it is not. In pedagogical research, as a rule, the significance level is chosen 0,05. Then, if the null statistical hypothesis is rejected, the probability of making an error of the first kind is 5%, and the probability of making a correct conclusion is 95%.

Step 3. Determine the number of freedom degrees.

Step 4. Calculate the value of the χ^2 criterion using the formula:

$$\chi^2_{calc.} = n \cdot \left(\sum_{i=1}^{k} \sum_{j=1}^{l} \frac{n_{ij}^2}{n_i \cdot n_j} - 1 \right),$$

where n is the total sample size (in our example n=98);
k – the number of levels of formation of knowledge and skills based on the results of the final test k=4;
l – number of groups (l = 4);
i – group number (i = 1,2,3,4);
j – level number (j = 1,2,3,4).
n_i – the number of students who have reached the i-th level of knowledge and skills formation;
n_j – the number of students who have reached the j-th level of knowledge and skills formation;
n_{ij} – the number of students of the i-th group who have reached the j-th level of knowledge and skills formation.

Step 5. The calculated value of the criterion is compared with its table value.

Step 6. Formulate a conclusion that if the calculated value of the criterion χ^2 is less than the table value, then the null statistical hypothesis is accepted as plausible. Otherwise, it is rejected and an alternative hypothesis is accepted.

Based on the fact that the described method is used on students who successfully coped with the input diagnostic test, a null statistical hypothesis H_0* is put forward that all four groups are homogeneous according to the results of the final pedagogical testing for the studied course of engineering discipline, which is checked by the Pearson agreement criterion χ^2 at the significance level $\alpha = 0{,}05$.

Based on the results of the final pedagogical testing, we make table 8 for calculating the criterion χ^2.

Table 8: Results of final pedagogical testing of 1, 2, 3 and 4 students groups in engineering discipline

The results of the final of pedagogical testing					
Level in points	**Group 1**	**Group 2**	**Group 3**	**Group 4**	**Total by level**
Low 1÷ 15	3	2	2	1	8
Medium 16÷ 30	4	3	4	3	14
Basic 31÷ 45	6	8	10	9	33
High 46÷60	8	10	13	12	43
Total students	21	23	29	25	98

According to table 8 we calculate the value of the criterion χ^2:

$$\chi^2_{calc.} = 98 \cdot \left(\frac{3^2}{21 \cdot 8} + \frac{2^2}{23 \cdot 8} + \frac{2^2}{29 \cdot 8} + \frac{1^2}{25 \cdot 8} + \frac{4^2}{21 \cdot 14} + \frac{3^2}{23 \cdot 14} + \right.$$
$$+ \frac{4^2}{29 \cdot 14} + \frac{3^2}{25 \cdot 14} + \frac{6^2}{21 \cdot 33} + \frac{8^2}{23 \cdot 33} + \frac{10^2}{29 \cdot 33} + \frac{9^2}{25 \cdot 33} +$$
$$\left. + \frac{8^2}{21 \cdot 43} + \frac{10^2}{23 \cdot 43} + \frac{13^2}{29 \cdot 43} + \frac{12^2}{25 \cdot 43} - 1 \right) = 3{,}53$$

Let's calculate number of freedom degrees (NFD) for table 8. It is known that the number of freedom degrees for the matrix consisting of m rows and n columns and equal (m – 1) (n – 1) -1, then NFD= 3*3 -1 = 8. The table value of χ^2 with 8 degrees of freedom at a significance level of 0,05 is 15,5.

The calculated value of Pearson's χ^2 is 3,53. the Table value of the criterion for NFD = 8 is $\chi^2_{0,95}$ = 15,5. Since the calculated value of the criterion χ^2 is less than the table value, the hypothesis H_0* can be accepted as plausible and combine data from four samples based on the results of the final

pedagogical testing into one. Analysis of the total sample data allows you to determine how many students have mastered the engineering discipline at the high, basic, medium and low levels.

Checking for homogeneity of samples containing the result of the students projects protection

Table 9 shows the results of student projects protection in groups 1,2, 3, and 4.

Table 9: Results of student project protection in groups 1, 2, 3 and 4

The result of the protection projects						
Level		**Group 1**	**Group 2**	**Group 3**	**Group 4**	**Total**
[0,2] low	0	0	1	1	1	3
	2	1	1	2	1	5
[3,4] medium	3	1	2	2	2	7
	4	2	4	3	1	10
[5,6] basic	5	6	5	5	5	21
	6	7	6	6	5	24
[7,8] high	7	2	2	7	6	17
	8	2	2	3	4	11
Total students		21	23	29	25	98

Based on the results of testing the statistical hypothesis H_0*, a null statistical hypothesis H_0** is put forward that according to the results of project protection, the four experimental groups are homogeneous. To check its plausibility, we calculate the criterion statistics χ^2 based on the project protection results shown in table 9. Since each level of experience assessment represents an interval, to improve the accuracy of calculating the Pearson criterion, we will allocate sublevels within each interval corresponding to the lower and upper bounds of the interval, so we have 8 levels of experience in project development. The project protection results matrix consists of 8 rows and 4 columns. Then the number of freedom degrees for this case will be NFD = 7*3-1 = 20.

$$\chi^2 = 98 \cdot \left(\frac{1^2}{21\cdot 5} + \frac{1^2}{21\cdot 7} + \frac{2^2}{21\cdot 10} + \frac{6^2}{21\cdot 21} + \frac{7^2}{21\cdot 24} + \frac{2^2}{21\cdot 17} + \frac{2^2}{21\cdot 11} + \right.$$
$$+ \frac{1^2}{23\cdot 3} + \frac{1^2}{23\cdot 5} + \frac{2^2}{23\cdot 7} + \frac{4^2}{23\cdot 10} + \frac{5^2}{23\cdot 21} + \frac{6^2}{23\cdot 24} + \frac{2^2}{23\cdot 17} +$$
$$+ \frac{2^2}{23\cdot 11} + \frac{1^2}{29\cdot 3} + \frac{2^2}{29\cdot 5} + \frac{2^2}{29\cdot 7} + \frac{3^2}{29\cdot 10} + \frac{5^2}{29\cdot 21} + \frac{6^2}{29\cdot 24} +$$
$$+ \frac{7^2}{29\cdot 17} + \frac{3^2}{29\cdot 11} + \frac{1^2}{25\cdot 3} + \frac{1^2}{25\cdot 5} + \frac{2^2}{25\cdot 7} + \frac{1^2}{25\cdot 10} + \frac{5^2}{25\cdot 21} +$$
$$\left. + \frac{5^2}{25\cdot 24} + \frac{6^2}{25\cdot 17} + \frac{4^2}{25\cdot 11} - 1\right) = 9,2$$

The calculated value of the Pearson criterion is 9.2. the Table value of the criterion for NFD = 20 is equal to $\chi^2_{0,95}$ = 31,41. The calculated value of the Pearson criterion is less than the table value, which makes it possible to accept the H_0** hypothesis as plausible and combine data from four samples based on project protection results into one. Analysis of the combined sample allows you to determine the number of students who defended projects at the high, basic, medium and low levels.

Then, based on the results of testing the null statistical hypotheses H_0* and H_0**, combined named sample of students from four experimental groups is compiled, including data on the results of their final pedagogical testing on the theoretical course and the protection of student projects. The analysis of the named sample allows us to determine the number of students who have achieved high, basic,

medium and low levels of competence in the field of engineering course development as a result of training.

Conclusion

The article considers a method that allows you to determine the number of students who have a certain level of competence in the development of engineering discipline, which involves the formation of theoretical knowledge and skills and the ability to demonstrate them in practice during the preparation and protection of an independently completed project. The method is based on the application of a level approach to the empirical assessment of competence formation in the field of engineering disciplines development. It is shown that evaluation of the level of formation competence of the student in studying an engineering discipline consists of two private empirical estimates: an empirical assessment of student theoretical knowledge and skills in the field of engineering disciplines and empirical assessment of a student's experience of independent project development and protection.

In the framework of statistical data processing, the Kruskal – Wallis rank criterion was used to prove the homogeneity of samples to determine the equality of the medians of the compared samples, the Bartlett criterion to compare the variances of several samples with different volumes, and the Pearson agreement criterion.

Analysis of the levels of competence formation of students after studying a particular engineering discipline will allow, in the case of insufficiently satisfactory results, to make corrective pedagogical actions, thereby improving the quality of engineering training of students.

Soybean Production - Actual Statement and 2020-2024 Forecast in Romania

Agatha POPESCU

University of Agricultural Sciences and Veterinary Medicine, Bucharest, Romania
E-mail address: agatha_popescu@yahoo.com

Abstract

The paper analyzed the dynamics of soybean cultivated area, production and yield in Romania in the period 2010 -2019 and established the estimates of sown area and seeds output for the 2020-2024 horizon. Both the soybean cultivated surface and production registered a high development in the last decade, so that in 2019, in Romania, 158,149 ha were harvested from which there were obtained 415,942 tons of seeds, meaning 2.8 times more than in 2010. Yield had a slight increase of only 12% and accounted for 2,630 kg/ha in 2019, which proved that surface extend had a more important influence on production growth than yield. The decision to chose the quadratic trend model having the formula $Y = 581.53\ x^2 + 6{,}834{,}4\ x + 51{,}174$ for the cultivated area and $Y = 3{,}841.7\ x^2 - 2{,}863{,}9\ x + 122{,}867$ for production for setting up the estimates for the next five years was taken based on the results obtained for R^2, $\bar{R}^2$, RMSE, MAE, and MAPE criteria which offered a higher accuracy. In 2024, it is expected that Romania to produce 844,291 tons soybean seeds from 284,534 ha cultivated with this crop. Farmers are interested to increase the cultivated areas and production, as a response to the subsidies offered by the EU according to its new Green CAP policy reform regulations and Danube Soya Program aiming to grow protein output from certified non GMO crops like soybean.

Keywords: soybean production, trends, growth models, forecast, Romania

Introduction

Soybean is an important oilseeds crop for its many uses as food, feed, raw material for processing industry, a high value plant in crop rotation, and a valuable resource for achieving bio-fuels, reducing pollution and preserving environment as mentioned by Bilteanu and Birnaure (1989) and Popescu Agatha (2012a).

In the EU-28, soybean is not so much produced, as long as imports are cheaper, but during the last years the need of protein crops certified as non GMO has determined the EU to sustain farmers to extend production within a new CAP policy focused on Green Reform started since 2013 (European Parliament, 2013, Regulation No.1307/2013) and the establishment of the Danube Soya Program (Austrian Development Agency, 2020).

Romania is ranked the 6th in the EU for its production after France, Germany, Poland, and Czech Republic (EU, Crop Market Observatory, 2018). Soybean finds good conditions in Romania to express its production potential among the oil-seeds crops, coming on the 3rd position after sunflower and rape as affirmed by Popescu Agatha (2010, and 2012b), Surca (2018), and Popescu and Dinu (2020).

The areas suitable for soybean cropping are: the South and South Eastern Romania (Zone I), West (Zone II), the Sub-Carpathian area (Zone III), East Moldova and North West (Zone IV) and small areas in North East and the Central part (Zone V) (Popescu Agatha, 2018a, and 2018b).

Cite this Article as: Agatha POPESCU "Soybean Production - Actual Statement and 2020-2024 Forecast in Romania" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The increased demand on the domestic and foreign market is also a reason to intensify the cultivation of soybean on larger surfaces and carry out a higher production, for reducing imports and stimulating exports as attested by Preda (2017) and Popescu Agatha et al. (2019).

"Growth models" such as: linear, quadratic, logarithmic, cubic, exponential, power etc are largely used for analyzing and forecasting as described by Pindyck and Ribinfeld (199l0, Karim et al. (2010), Habib et al. (2013) and Nazir et al. (2016).

Researchers are interested to carefully select the best fitted models which are going to be used to estimate the future levels of a variable. For this purpose, different models should be tested, compared and selected depending on the measure in which they assure the highest precision of the actual image of the growth scenario in a time series.

The selection criteria for a growth model could show: (a) either the highest prediction precision judged by means of coefficient of determination (R^2) and adjusted R square ($\bar{R}^2$), taking into consideration that, the higher the R^2 and $\bar{R}^2$, the higher the prediction accuracy; (b) or the lowest deviations and errors in estimating mean, judged by means of Root Mean Squared Errors (RMSE), Mean Absolute Deviation (MAD), Mean Absolute Error (MAE), Mean Absolute Percentage Error (MAPE), Akaike Information Criterion (AIC), Bayesian Information (BIC) etc; (c) or a mix of these criteria as affirmed by Pindyck and Ribinfeld (199l), Karim et al. (2010), Habib et al. (2013) and Nazir et al. (2016).

In this context, the purpose of the paper was to identify the best fitted model to design soybean production forecast in the next five years in Romania taking into account the analysis of the dynamics in the 2010-2019 decade.

The paper is structured as follows: *Introduction,* which briefly presents the results regarding the importance of soybean in the EU and Romania, justifying why it is needed to increase production and the main diagnosis tools which could be used to comparatively test various trend models in order to chose the best one which assure the highest accuracy of the prediction. *Materials and methods* present the sources of data, the trend models selected for soybean production forecast, and the criteria chosen to test them. *Results and Discussions* provide the obtained results, comments and interpretations, and *Conclusions* present the main ideas resulting from this research work.

Materials and Methods

Data collection

The data used in this study refer to soybean production carried out in Romania in the period 2010-2019, the empirical data being provided by the National Institute of Statistics.

The studied indicators were: (i)cultivated area with soybean, (ii)soybean seeds production and (iii) production.

Methodological aspects have been:
Dynamics analysis based on the formula of Fixed basis Index: $I_{FB(\%)} = (Y_n/Y_1)100$, where: Y_n is the value of the variable in the year n and Y_1, the value of the variable in the year 1.
Average annual growth based on the formula: $\overline{\Delta y} = (y_n - y_1)/(n - 1)$.
Trend models, as follows: (a) linear fit model, having the formula: $Y = bx + a + e_i$, and (b) quadratic fit model, with the formula: $Y = ax^2 + bx + c + e_i$.

The criteria used for testing the accuracy of the trend models have been: R^2, $\bar{R}^2$, RMSE, MAE, and MAPE.

The results were tabled and graphically illustrated, being accompanied by comments. The conclusions pointed out the main aspects regarding the future of soybean production in Romania according to the best fitted forecasting model.

Results and Discussions

Present situation regarding soybean crop performance

Soybean cultivated area has almost tripled its size in 2019 compared to 2010. If ten years ago, in Romania there were cropped only 63,948 ha with soybean, in 2019, the surface sown with this crop reached 158,149 ha, meaning an average annual growth of 10,466.7 ha (Table 1, Fig. 1 and 2).

Table 1: Dynamics of soybean cultivated area, production and yield, Romania, 2010-2019

	Cultivated area (ha)	Production (Tons)	Yield (kg/ha)
2010	63,948	149,940	2,345
2011	72,056	142,636	1,980
2012	79,793	104,330	1,308
2013	67,672	149,931	2,216
2014	79,910	202,892	2,539
2015	128,156	262,061	2,045
2016	127,266	263,380	2,070
2017	165,143	393,495	2,383
2018	169,422	465,609	2,748
2019	158,149	415,942	2,630
2019/2010%	293.15	277.40	112.15
Average annual growth, $\overline{\Delta y}$	10,466.7	29,555.7	31.6

Fig.1: Dynamics of soybean cultivated area based on linear trend model, 2010-2019, Romania (thousand ha)

Source: Own design based on the data from National Institute of Statistics, 2020.

From a statistical point of view, spreading the data on the graph, two trend line models were considered suitable for reflecting the evolution of the cultivated area with soybean: the linear one and the quadratic one. However, analyzing R square value, we may easily notice that in case of the linear model $R^2 = 0.867$ while in case of the quadratic model $R^2 = 0.8769$, therefore a little higher, meaning that the last trend line model assures a higher precision in estimating the tendency of soybean cultivated surface in the studied interval (Fig. 1 and 2).

The increase of the cultivated area with soybean was determined by higher and higher interest of the farmers for this crop, stimulated by the subsidies per surface unit coming from the EU and also from the Romanian Government for producing more seeds rich in protein from crops certified as non GMO, and by the higher acquisition price compared to the one for other crops.

Fig.2: Dynamics of soybean cultivated area based on quadratic trend model, 2010-2019, Romania (ha)

Source: Own design based on the data from National Institute of Statistics, 2020.

The EU market has a high requirement of protein, and soybean is the crop whose seeds have the highest content in protein. Due to the difficulties in assuring the import of non-GMO soybean meal from America, the EU-28 decided to reduce the imported amounts by 50% and to start producing soybean in the member states till 2025, as a first stage, and then to continue to develop soybean production only in the community for assuring the independence of food security.

The European Protein Independence Plan encourages farmers to extend the soybean cultivated area and use modern technologies to grow seeds production, as long as soybean proved to be highly efficient crop (Paybou, F., 2018). The price difference between the non-GM and GM soybeans (and derivatives) is high and looks to widen significantly in the coming years (Brookes, G. et al, 2005).

For the cultivated area with soybean, Romania comes on the 2nd position in the EU-28, after Italy, and being followed by France, Croatia and Hungary. About 14% of the EU-28 cultivated area with soybean is in Romania (Eurostat, 2018).

In Romania, the share of soybean in the cultivated area with oil plants increased from 4.5% in 2010 to 8.8% in 2019. The largest percentages were achieved in the last years, reflecting the increased importance of soybean among the oil seeds crops (Popescu Agatha, 2018b).
At present, soybean is cultivated in the following regions and zones of favorability: Oltenia, Muntenia, Dobrogea and South of Moldova regions (Zone I), Banat region (Zone II), West Moldova, North Muntenia and North Oltenia in the the Sub-Carpathian area (Zone III), East Moldova and North West Crisana (Zone IV) and small areas in North East Moldova and the Central part of Transilvania (Zone V) (Fig. 3).

Fig.3: The regions and zones of favorability where soybean is cultivated in Romania

Soybean seeds production

As a result of the extend of the sown area with soybean in Romania, seeds production increased 2.77 times in the analyzed interval from 149,940 tons in 2010 to 415,942 tons in 2019, meaning an average annual growth rate of 29,555.7 tons (Table 1).

The trend models suitable to characterize the dynamics of soybean production are again the linear and quadratic models as presented in Fig. 4 and 5.

The quadratic model offers a higher accuracy in estimating the trend of soybean production as long as $R^2 = 0.9075$, a little higher than $R^2 = 0.8547$ in case of the linear model.

Fig. 4: Dynamics of soybean production based on linear trend model (Thousand tons)
Source: Own design based on the data from National Institute of Statistics.

Soybean production increased because of the implementation of modern technologies, based mainly on the use of the new high breeding value hybrids offered by various companies to farmers. Along the soybean chain to the final product: soybean meal, the importance of the crushing factories in seeds processing increased and their capacity was correlated with the seeds supply.

Fig. 5: Dynamics of soybean production based on quadratic trend model (tons)
Source: Own design based on the data from National Institute of Statistics.

From the total oils seeds production achieved in 2019 by Romania, which accounted for 4,792 thousand tons, soybean production of 416 thousand tons represent only 8.6%, but more than 6.3% in 2010 as mentioned by Popescu Agatha (2020).

Romania is among the most important soybean seeds producers in the EU-28, being ranked the 6th for its production after France, Germany, Poland, and Czech Republic (EU, Crop Market Observatory, 2018; EU, Oilseeds and protein crops, area and yield, 2020).

However, the demand of crude protein for feed market is much higher in the EU. The feed market absorbs about 93% of crude protein production and the main sources of oilseeds meals are: rapeseed, sunflower seeds and soy beans; pulses: beans, peas, lentils and lupines. As the internal production of the EU is much smaller than the requirements, about 75% of protein supply is assured by imports, especially from the USA, Brazil and Argentina. Soybean is on the top position among the imported amounts of oilseeds (USDA GAIN Report, 2018).

Soybean Yield

In comparison with the high increase in the cultivated surface and production, in Romania, soybean yield registered just a slight growth of only 12.15% in the last ten years, from 2,345 kg/ha in 2010 to 2,630 kg/ha in 2019 (Table 1).

Average production is still at a low level in Romania, because of the deficiencies in choosing the best varieties with high production potential and adapted to the local conditions of soil and climate, in assuring the proper farm inputs and in managing the modern technologies, aspects with which many farmers, especially owning smaller farms, are facing.

Another reason why soybean yield did not increase too much in Romania is linked to climate change, especially in terms of high temperatures and long periods of drought in the years 2012, 2015 and 2016 as mentioned Popescu Agatha (2018a).

Romania's position in the EU-28 for soybean cultivated area, production and yield

According to Eurostat crops statistics, 2018, and Chancellor (2018), regarding the situation of soybean crop performance in the EU-28 main producing countries in the period 2008-2017, Romania came on the 2nd position after Italy for the cultivated area in 2008 with 49.9 thousand ha, representing 18.3% of the EU-28 cultivated area, while in 2016, Romania was ranked also the 2nd after Italy, for 126.7 thousand ha.

For soybean seeds production, in 2008, Romania came on the 3rd position after Italy and Croatia for 90.6 thousand tons, and in 2016, the country was also ranked the 3rd after Italy and France for 261.9 thousand tons.

But, for soybean yield, Romania was 1,816 kg/ha in 2008, a level which situated the country on the 6th position after Italy, Croatia, Austria, France, Hungary, and in 2016, the country was ranked also on the 6th position for 2,067 kg/ha soybean seeds after Italy, Croatia, Austria, Hungary and France.

However, the figures reflected the development of the soybean sector in Romania's agriculture in 2016 versus 2008 in the as long as the cultivated area increased 5.2 times, seeds production 2.9 times and yield +13.8% (Table 2).

Table 2: Romania's position among the EU-28 top soybean producing countries in 2016 versus 2008

	2008			2016			2016/2008%		
	Area (Thou. ha)	Production (Thou. tons)	Yield (kg/ha)	Area (Thou. ha)	Production (Thou. tons)	Yield (kg/ha)	Area (Thou. ha)	Production (Thou. tons)	Yield (kg/ha)
EU-28	273.0	764.2	2,799	817.1	2,490	3,047	299.3	325.7	108.8
Italy	107.8	346.2	3,211	288.1	1,081.3	3,753	267.2	312.3	116.8
France	21.8	63.1	2,894	125.1	293.7	2,348	573.8	465.4	81.1
Romania	49.9	90.6	1,816	126.7	261.9	2,067	524.8	289.1	113.8
Croatia	35.8	107.6	3,005	76.0	239.0	3,145	667.6	222.1	104.7
Hungary	29.0	74.1	2,555	61.3	181.3	2,958	211.3	244.7	115.8
Austria	18.4	54.1	2,940	49.8	152.6	3,064	270.6	282.1	104.2

Source: Own calculation based on the data from Eurostat, Crops Statistics, and Chancellor, 2018.

Descriptive statistics reflects that in the last ten years, in Romania, the average sown area with soybean was 111,151.5 ± 43,043.40 ha, with a variation coefficient of 38.72%, showing a high deviation of the variable in the chronological series from the mean as the values are heterogeneous and the mean is not representative.

The average soybean production in the 2010-2019 interval accounted for 255,021.6 ± 128,961.18 tons, with a high coefficient of variation (CV = 50.56%) reflecting the heterogeneous data and the lack of representativeness of the mean.

The soybean yield registered an average level of 2,226.4 ± 412.70 kg/ha and the variation coefficient was, CV = 18.53%, reflecting a relative homogeneous series of data and that the mean could be accepted as representative (Table 3).

Table 3: Descriptive statistics for the studied indicators

	Mean	St. Dev.	Coeff. of variation (%)
Cultivated area (ha)	111,151.5	43,043.40	38.72
Production (Tons)	255,021.6	128,961.18	50.56
Yield (kg/ha)	2,226.4	412.70	18.53

Source: Own calculation based on the data from National Institute of Statistics.

Future Production Scenario

Based on the results obtained by processing the primary, there were established two mathematical growth models which are suitable to reflect the dynamics of the soybean cultivated area and production as follows:

For the cultivated area:

(a)Linear trend model, whose determined formula is $Y = 13{,}231.2\ x + 38{,}379.8$
(b)Quadratic trend model, whose obtained formula is $Y = 581.53\ x^2 + 6{,}834{,}4\ x + 51{,}174$

For soybean seeds production:

(a)Linear trend model, whose determined formula is $Y = 39{,}394.96\ x + 38{,}349.26$ and
(b)Quadratic trend model, whose obtained formula is $Y = 3{,}841.7\ x^2 - 2{,}863{,}9\ x + 122{,}867$.
The resulted values for the selection criteria used to chose the best fitted forecasting model are presented in Table 4.

Table 4: Selection criteria for testing the trend models

	Criteria				
	R^2	$\bar{R}^2$	RMSE	MAE	MAPE
Linear fit	0.867	0.851	14,939.08	12,906.76	0.01358
Quadratic fit	0.8769	0.8615	14,329.01	11.976.22	0.01168
Results for soybean production					
Linear fit	0.854	0.836	46,520.83	42,078.7	21.65
Quadratic fit	0.907	0.895	37,553.88	32,449.5	14.23

Source: Own results.

Comparing the results for the two fit models, one may easily notice the differences for each criterion.

Both in case of the cultivated area with soybean and production, R^2 and $\bar{R}^2$ have higher values in case of the quadratic model versus the linear one. Therefore, from this point of view, the better fitness model is the quadratic one, as long as R square for tells us that 87.69% of the cultivated area and 90.7% of production depends on the time variation and the remaining on other factors.

RMSE, MAE and MAPE have registered lower levels in case of the quadratic model compared to the linear one: $RMSE_Q < RMSE_L$, $MAE_Q < MAE_L$, and $MAPE_Q < MAPE_L$.

This means that the quadratic model is better than the linear fit yielding smaller forecasting deviations and errors both in case of the cultivated area and soybean output.

Having in mind a clear picture of the results of the use of the diagnosis tools, one may recognize that the best fitted model for forecasting soybean production in Romania for 2020-2024 horizon is the quadratic trend model.

The forecast of soybean cultivated area and production is presented in Table 5.

Table 5: Soybean production forecast for 2020-2024 horizon (tons)

	2020	2021	2022	2023	2024
Soybean cultivated area	196,718	216,927	238,300	260,836	284,534
Soybean production	556,210	641,705	734,884	835,746	944,291

Source: Own results.

In 2024, it is expected that soybean sown area with soybean to reach 284,534 ha and seeds production 944,291 tons. This means that the cultivated area will be by 80% higher and production by 127% higher than in 2019.

Conclusions

Both the soybean cultivated area and production proved a high dynamics during the period 2010-2019. The results attested a high growth rate in soybean production and a strong increasing trend in the last decade (+177.4%), so that, in 2019, soybean output accounted for 415,942 tons.

The production growth was influenced in a higher proportion by the increased cultivated surface and in a smaller proportion by yield due to many technological factors and climate change.

For forecasting soybean cultivated area and seeds production with a high precision in Romania in the period 2020-2024, two models have been tested: the linear model and the quadratic one.

Taking into consideration the results for the criteria R^2, $\bar{R}^2$, RMSE, MAE, and MAPE, it was drawn the decision that the quadratic model assures a higher accuracy in forecasting soybean sown surface and output for the next five years.

Based on this, it was estimated that in 2024, Romania is expected to produce 944,291 tons soybean seeds from a cultivated surface of 284,534 ha, meaning an average production estimated at 3,318 kg/ha by 26% more than in the year 2019.
The extend of the cultivated area with soybean and the growth of seeds production have led to the increase of the value of the agricultural output and the farmers' income and, also, created new opportunities for oilseeds exports on the EU market.

The use of the diagnosis tools named growth determinist models in selecting the best fitted model to set up the future level of a variable is compulsory as researchers to be sure that their results are accurate and conclusions are pertinent. They have to pay attention to the forecast period, having in mind that the longer the forecast horizon, the higher the forecast error. Therefore, a short-term scenario is more recommended than a long-run forecast.

Contribution of Agriculture to Romania's Gross Domestic Product

Agatha POPESCU

University of Agricultural Sciences and Veterinary Medicine, Bucharest, Romania
E-mail address: agatha_popescu@yahoo.com

Abstract

The paper analyzed Romania's GDP and GDP produced in agriculture in the period 2008-2019 pointing out the changes by resources and in the territory, and also in agriculture by micro regions. Descriptive statistics, and trend regression functions, correlation and determination coefficients were used to process the data. In 2019, Romania achieved Euro 222 Billion GDP, almost double than in 2008. Trade, transportation, tourism, Industry, and Public services have the highest contribution to GDP. More than 50% of GDP is achieved by three regions: Bucharest- Ilfov, North West and South Muntenia. Agriculture carried out Euro 11.08 Billion GDP in 2019, by 55% more than in 2008 and contributes by 5% to GDP. Agriculture GDP has a more balanced growth in the territory. The dynamics from the last decade and the positive connection between GDP in agriculture and Romania's GDP ($r = 0.731$), $R^2 = 0.534$, and the regression model, $Y = 19.820 x + 29.423$, reflects that agriculture will continue to be an important sector of the economy in the future. If in case of GDP per capita Romania accounts for 69% of the EU-27 average (Euro 31,000), and occupying the 24th position, for GDP created in agriculture, Romania is ranked the 5th in the EU after France, Italy, Spain, and Germany. It is expected that in the future Romania's economic growth to continue and GDP produced in agriculture to increase much more.

Keywords: agriculture, Gross Domestic Product, trends, Romania.

Introduction

Agriculture is an important sector of the economy as it supplies primary agricultural products, most of them essential to nourish the population and also to assure the raw materials for processing industry.

Agriculture is the main activity in the rural areas where over 50% of Romania's population is living (Popescu, 2013, Popescu and Condei, 2015, and Popescu et al., 2018). It offers jobs, but also has an indirect impact in other sectors such as: food processing and machinery industry, transportation, trade etc along the agricultural products chain.

Agriculture is an opportunity for rural population for business development in order to assure farmers' income and the living standard for their families, and also plays an important role in landscapes and biodiversity preservation and environment protection.

Romania's has a high agricultural production potential and performance, coming on the eight position in the EU-28 for the value of agricultural output which in 2018 accounted for Euro 18.6 Billion, representing 10.51% of the EU-28 agricultural output. Other EU countries have a higher contribution such as: France (43.6%), Italy (32.2%), Germany (30%), Spain (29.5%), United Kingdom (16.8%), the Netherlands (15.5%) and Poland (14.1%) (Eurostat, 2020).

In order to characterize the dimension of the economy of a country, the contribution of various sectors to the economy, and to compare the economic development of different countries, the most commonly used indicator is Gross Domestic Product (GDP).

Cite this Article as: Agatha POPESCU "Contribution of Agriculture to Romania's Gross Domestic Product" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

GDP is "equal to the sum of gross value added (GVA) achieved in production, plus taxes on products and minus subsidies on products. GVA is given by the difference between output and intermediate consumption"(Eurostat, Glossary GDP, 2020).

An increase in GDP reflects that the economy is performing well, having a good impact on jobs availability, salaries increase and consumers' spending on goods and services.

GDP has various types, but two of them, real GDP which is an inflation-corrected indicator and nominal GDP at current prices (with inflation). For this reason, nominal GDP is higher than real GDP and for calculating real GDP, nominal GDP is divided to a deflator.

GDP is usually analyzed in its dynamics for various intervals of chronological series of data provided by the official statistical institutions, the approach being made either regarding GDP as a whole at the country level, as well as by its resources and uses, and also in the territory by regions of development (Russu, 2014, Popescu and David, 2015 and 2017, Sfetcu, 2016, Popescu, 2017b, 2018a).

Specific econometrics models and methods are commonly used to analyze GDP dynamics and its factors of influence (Anghelache and Anghel, 2017).

The analysis of GDP of a country involves many approaches referring to: (a) the main production factors which participate to the creation and growth of GDP as macroeconomic indicator: fixed, human and financial capital (Popescu, 2011, Burgen et al., 2012, Popescu and David, 2015) and (b) the uses of GDP for consumption, gross capital formation, stock variation and net export (Bobinaite et al, 2011, Anghel et al., 2018).

Romania's GDP accounted for Euro 180 Billion GDP in the year 2017, meaning Euro 9.232 per inhabitant (current prices). (Amariei, 2016, European Commission, 2018).

The main resources contributing to GDP in Romania are: services (32%), industry (23%), trade (18%), financial transactions (Popescu and David, 2017). Also, in Romania, GDP is much more influenced by final consumption than export and gross fixed capital (Popescu, 2018a).

In the territory of Romania, the discrepancies regarding the contribution of the eight micro regions of development to GDP reflect a divergent trend and an unbalanced economic growth (Popescu, 2017b). Having in mind that GDP is the key indicator reflecting the health of the economy, in this study it was approached both GDP produced in agriculture and GDP at the country level, in order to evaluate the contribution of agriculture in the economy of Romania.

GDP in agriculture results from "the difference between the value of agricultural output and the value of the expenses spent to assure goods and services inputs which are required to sustain production process and, finally, all these are adjusted for taxes and subsidies on products" (Eurostat, 2020).

In Romania, GDP created in agriculture is deeply influenced by agriculture peculiarities connected to: farm structure where subsistence farming is dominant, small farm size, low technical endowment and investments, labour force aging and low education level (Popescu, 2015a and 2015 b), the climate change impact on agricultural technologies, low productivity and high risk caused by meteorological phenomena (Popescu, 2015c, Popescu, 2016a and 2016b), and product quality (Popescu, 2018b, Popescu, 2019a and 2019b).

Due to this, Romania produces only Euro cents 0.21 added value per kg of raw materials consumed in agriculture compared to Euro 1.58 added value - the average in the EU-28 which shows that GVA produced in Romania is seven times smaller than in the EU (Boghean and State, 2013, Enache, 2014, Novotna and Volek, 2016, Popescu et al., 2016).

Agro-food export plays an important role in increasing GDP, but Romania's agro-food trade balance is still a negative one, despite that the general trend in imports is a declining one (Popescu, 2017a and 2017c).

In this context, the purpose of the paper was to analyze both the evolution of Romania's GDP by its resources at the national level and in the territory, and also GDP created in agriculture at the country level and in the micro regions of development in the period 2008-2019, in order to evaluate in what measure agriculture, forestry and fishing contributed to the economic growth.

The paper is structured as follows: *Introduction,* which briefly presents the results regarding the importance of agriculture in the economy and its contribution to GDP as well as the main results in studying GDP in relation to its resources and uses and determinant factors. *Materials and methods* present the data sources, and the main methodological aspects used to process them. *Results and Discussions* provide the obtained results, comments and interpretations, and *Conclusions* present the main ideas resulting from this research work.

This section should follow keywords. This section should provide background of the study and highlight research motivation.

Materials and Methods

Data collection

The data used in this study refer to GDP both at the national level and in agriculture, forestry and fishing in Romania in the period 2008-2017 were taken from the data base of the National Institute of Statistics.

The studied indicators were:

(i)Romania GDP in its dynamics as whole and by economic activities contributing to its achievement, and also its territorial distribution by micro-regions of development;
(ii) GDP created in agriculture, forestry and fishing its dynamics and also its territorial distribution by micro-regions;
(iii)The relationship between Romania's GDP and GDP created in agriculture, forestry and fishing in terms of correlation coefficient and dependence quantified by a regression model.

Methodological aspects have been:

Dynamics analysis was carried out using the Fixed basis Index: $I_{FB(\%)} = (Y_n/Y_1)100$, where: Y_n is the value of the variable in the year n and Y_1, the value of the variable in the year 1.
Average annual growth was calculated using the formula: $\overline{\Delta y} = (y_n - y_1)/(n - 1)$.
Trend models were used to characterize the general tendency in the evolution of GDP both at the national level and in agriculture, forestry and fishing. For this purpose, it was used the quadratic model having the formula: $Y = ax^2 + bx + c$.
Descriptive statistics involved the calculation of mean, standard deviation, kurtosis, skewness, minimum and maximum values, coefficient of variation.
The correlation coefficient was calculated using the well known Bravais-Pearson's formula.
The determination coefficient, R^2 was used to establish the measure in which the variation of the dependent variable, Romania's GDP is caused by the variation of the independent variable, GDP created in agriculture, forestry and fishing.
Linear regression model having the formula: $Y = bx + a$ was used to calculate and interpret the dependence relationship between the two types of GDP.
The results were tabled and also illustrated in a few graphics, which were accompanied by comments. The conclusions emphasized the main ideas resulting from this research work.

Results and Discussions

Romania's Gross Domestic Product (GDP) increased by 95.22% from Lei 539.8 Billion (Euro 146.6) in 2008 to Lei 1,053.8 Billion in 2019 (Euro 222 Billion), the average annual growth in the studied interval 2008-2019 being Lei 46.7 Billion (Euro 10.65 Billion). These figures reflect that Romania's economy is developing well having a continuous ascending trend (Fig .1).

Fig. 1: Romania's GDP dynamics, 2008-2019 (Lei Billion)

Source: Own design based on the data from National Institute of Statistics, 2020

The GDP growth was determined by the contribution of all the economic activities in various volumes and proportions. According to the empirical data available at present, in 2017, the highest contribution to GDP was given by Trade, transport, hotels and restaurants which produced Lei 158 Billion GDP, Industry came on the 2nd position with Lei 137.6 Billion, Public administration and defense, education, health and social assistance occupied the 3rd position with Lei 105.7 Billion. In the decreasing order other economic activities came as follows: Real estate transactions with Lei 68.8 Billion, Professional, scientific, technical and administration activities with Lei 64.6 Billion, Information and communication with Lei 46.9 Billion, Constructions with Lei 44.2 Billion, Agriculture, Forestry and Fishing with Lei 37 Billion, and Cultural activities with Lei 26.6 Billion. Compared to the year 2008, in 2017 it was noticed that almost all the economic activities increased their contribution to GDP, except the field of Buildings (Table 1).

Table 1: Romania's GDP by activities in 2017 versus 2008

	Activity	GDP by activity (Lei Billion)		2017/ 2008 %	Share of the activity in GDP (%)	
		2008	2017		2008	2017
	Romania's GDP	**539.8**	**857.9**	**158.9**	**100.0**	**100.0**
1	Agriculture, forestry, fishing	34.0	37.0	108.7	6.3	4.3
2	Industry	137.2	137.6	100.3	25.4	16.0
3	Constructions	61.3	44.2	72.0	11.3	5.1
4	Trade, transport, hotels and restaurants	97.3	158.0	162.4	18.0	18.4
5	Communications and information	23.4	46.9	200.4	4.3	5.5
6	Financial transactions and insurance	11.3	21.0	185.9	2.1	2.4
7	Real estate transactions	35.8	68.8	192.1	6.6	8.0
8	Professional, scientific, technical and administration	21.6	64.6	298.7	4.0	7.5
9	Public administration, defense, education, health, social assistance	50.2	105.7	210.4	9.3	12.3
10	Cultural activities	12.0	26.6	221.9	2.2	3.1
11	Gross Value Added	484.2	776.6	160.3	87.9	90.5
12	Tax per products	57.6	81.2	141.0	10.6	9.5

13	Rights on imports (Customs tax)	0.9	2.6	266.6	0.2	0.3
14	Subsidies per product	-3.0	-2.6	85.3	0.5	0.3

Source: Own calculation based on the data from National Institute of Statistics, 2020.

The highest growth rate in the analyzed interval was registered by Professional, scientific, technical and administration sector (+198.7%), Cultural activities (+121.9%), Public administration and defense, education, health, and social assistance (+110.4), Communication and information (+100.4%), Real estate transactions (+92.1%), Financial transactions and insurance (+85.9%), Trade, transport, hotels and restaurants (+62.4%),
GDP produced in Agriculture, forestry and fishing increased by 8.9%, while in the field of industry the growth rate was the lowest one, just 0.3%.

An important aspect which has to be mentioned is that Gross Value Added created in the economy increased by 60.3% from Lei 484.2 Billion in 2008 to Lei 776.6 Billion in 2017 (Table 1).

The structure of GDP by activity in the economy in 2017 reflects that the highest share in GDP belongs to: Trade, transport, hotels and restaurant (18.4%), Industry (16%), Public administration and defense, education, health and social assistance (12.3%) and the lowest shares to Agriculture, forestry and fishing (4.3%), Cultural activities (3.1%) and Financial transactions and insurance (2.4%).

Also, we may notice that in 2008 compared to 2017, the percentage contribution to GDP declined in case of the following activities: in Agriculture, forestry and fishing from 6.3% to 4.3%, in Industry from 25.4% to 16%, and in Constructions from 11.3% to 5.1%, and raised in case of all the other activities (Table 1).

The increase of GDP in Romania was the result of the economic efforts and performance achieved by the eight micro-regions of development in the studied period.

Over 50% of GDP is created in three micro regions: Bucharest-Ilfov, North West and South Muntenia. In 2017, the highest GDP accounting for Lei 233 Billion was carried out by Bucharest-Ilfov, their contribution being by +64.4% higher than in the year 2008. On the 2nd position came North West micro region which produced Lei 104.9 Billion GDP, by 70.2% more than in 2008, and on the 3rd position was South Muntenia micro-region with Lei 101 Billion., a level which was by 49.6% higher than in 2008. The other micro-regions registered a lower GDP, but enough to sustain the economic growth at the national level.

Compared to 2008, the contribution to GDP increased in all the eight micro-regions at least by 50%, the highest increase being +70.2% in North West and the lowest one accounting for +49.6% was registered in South Muntenia. The percentage contribution to Romania's GDP by micro-region, in the descending order was the following one in 2017: Bucharest-Ilfov 27.1%, North West 12.2%, South Muntenia 11.8% Center 11.35%, North East 10.45%, South East 10.25%, West 9.5% and South West Oltenia 7.5% (Table 2).

Table 2: The contribution of the eight micro-regions to GDP in the year 2017 versus 2008

	GDP by micro-region (Lei Billion)		**2017/2008 %**	**Share of micro-region in GDP (%)**	
GDP Romania	**538.9**	**857.8**	**158.9**	**100.0**	**100.0**
North West	61.6	104.9	170.2	11.4	12.2
Center	60.0	97.0	161.6	11.1	11.3
North East	57.2	88.9	155.4	10.6	10.4
South East	56.3	88.0	156.3	10.4	10.2
Bucharest - Ilfov	141.7	233.0	164.4	26.2	27.1

South Muntenia	67.5	101.0	149.6	12.5	11.8
South West Oltenia	42.0	64.0	152.3	7.8	7.5
West	53.5	81.0	151.4	10.0	9.5

Source: Own calculation based on the data from National Institute of Statistics, 2020.

Gross Domestic Product in Romania compared to other EU countries

In the period 2009-2019, the EU-27 registered an average annual GDP growth rate of 1.6%. Romania achieved 3.1%, coming on the 7th position among the countries which had a higher economic growth rate than the EU average, it is about: Ireland (6%), Malta (5.7%), Estonia (3.7%), Poland (3.6%), Lithuania (3.5%), and Luxemburg (3.1%).

In 2019, the EU-27 GDP in PPS terms accounted for Euro 13,922 Billion, of which 60.7% was achieved by Germany, France, Italy and Spain which are the largest economies.

Considering PPS GDP in EU-28 = 1, in 2019, Romania recorded 2.48, being ranked the 7th after Hungary (205.03), Czechia (18.19), Sweden (12.78), Denmark (9.74), Croatia (4.79), and Poland (2.55) (Eurostat, PPP GDP, 2020).

Regarding GDP at current prices per inhabitant, reflecting the living standard of the population, the EU-27 average in the year 2019 was Euro 31,100. Considering it equal to 100, Romania came on the 24th position for 69% of the EU average GDP/capita, being followed by Greece (68%), Croatia (65%) and Bulgaria (53%), situated on the last positions. It is worth to mention that in the period 2009-2019, Romania moved from the 26th position to this 24th position as a consequence of the economic development. (Eurostat, 2020, National accounts and GDP).

Gross Domestic Product created in Agriculture, forestry and fishing had also a high dynamics in the interval 2008-2019, registering 154.89 % growth rate. In 2019, this economic sector produced Lei 52.6 Billion GDP (Euro 11.08 Billion) compared to Lei 34 Billion (Euro 9.23 Billion) in 2008, meaning an average annual growth of Lei 1,697.6 Million (Euro 387.43 Million) (Fig. 2).

Fig. 2:Romania's GDP dynamics in agriculture, forestry and fishing, 2008-2019 (Lei Billion)
Source: Own design based on the data from National Institute of Statistics, 2020.

As a result, the share of GDP created in Agriculture in Romania's GDP decreased from 6.3% in 2008 to 5% in 2019, but in the years 2012, 2014-2018, the percentage was even smaller, the lowest level being 3.66% in 2018, a year when agriculture output was deeply affected by climate change in terms of extreme phenomena (frozen periods at the end of winter early, huge rainfalls in spring, long and severe droughts in summer etc (Fig. 3).

Fig. 3: Share of GDP in agriculture, forestry and fishing in Romania's GDP, 2008-2019 (%)
Source: Own calculation and design based on the data from National Institute of Statistics, 2020.

The contribution of the micro regions to GDP created in agriculture, forestry and fishing is shown in Table 3. The micro-regions which are able to produce the highest GDP in the field of agriculture, forestry and fishing are: South Muntenia, which in 2017 achieved Lei 6.9 Billion, South East with Lei 6.7 Billion and North East with Lei 5.9 Billion.

The lowest GDP accounting for Lei 1.1 Billion was produced by Bucharest-Ilfov, where other economic activities are much better developed like industry, constructions, communications and information, financial transactions, real estate transactions etc.

The weight of the micro-regions in GDP produced in agriculture, forestry and fishing by region, in the decreasing order, was the following one in the year 2017: South Muntenia 18.5%, South East 18.1%, North East 15.9%, South West Oltenia 12.2%, North West 11.2%, Center 10.7%, West 10.5% and Bucharest-Ilfov 2.9%.

GDP achieved in agriculture, forestry and fishing increased in almost all the micro regions in the studied period 2008-2017, except North West and Central part, where in 2017 it was smaller than in 2008 by 6.9% and, respectively by 2.5%.

The highest growth was noticed in Bucharest-Ilfov region (+175%), South West Oltenia (+15.3%), South East (+13.5%), West (+11.4%) and South Muntenia (+11.2%), which are the regions which have the highest potential for agriculture, and the lowest growth was +3.5% recorded on North East (Table 3).

Table 3: The contribution of micro-regions to GDP created in agriculture, forestry and fishing (AFF), Romania, in the year 2017 versus 2008

	GDP in AFF by micro-region (Lei Billion)		2017/2008 %	Share of micro-region in GDP in AFF (%)	
GDP in AFF Romania	**34.0**	**37.0**	**108.8**	**100.0**	**100.0**
North West	4.4	4.1	93.1	13.0	11.2
Center	4.0	3.9	87.5	11.7	10.7
North East	5.7	5.9	103.5	16.8	15.9

Comparison between GDP created in Romania's agriculture to the one in other EU countries

Agriculture contributes to GDP by 5% in Romania and by 5.1% in Bulgaria, which reflects that this sector is of a high importance in the economy of these countries.

Also, the share of agriculture in GDP is enough high in Greece (4.1%), Hungary (3.9%), Latvia (3.9%), and Slovakia (3.8%).

In the largest economies in the EU, the share of agriculture in GDP is much smaller: Germany 0.7%, France 1.7%, Italy 2.1% and Spain 2.6%, which reflects that other sector such as services and industry have a higher contribution to the economic development.
However, taking into account the absolute values of GDP carried in agriculture, the top EU countries are: France, Italy, Spain, Germany, Romania, Poland, Netherlands, Greece, Hungary and Czechia. These ten countries produced PPS GDP Euro 209.97 Billion in agriculture, representing 76,22 % of the EU-27 GDP.

Therefore, Romania comes on the 5th position for PPS GDP Euro 20.95 Billion, representing about 8% of the GDP created in agriculture of the EU-27 in 2019. This confirm the fact that Romania has a powerful agriculture, a high potential to produce more and better, and to sustain economic development of the country (Table 4).

Table 4: EU-27 top 10 countries for GDP produced in agriculture in 2019

	PPS GDP (Euro billion)	PPS GDP in agriculture (Euro billion)	Share of agriculture in PPS GDP (%)
EU-27	**13,922**	**275.49**	**1.97**
France	2,214	37,63	1.7
Italy	1,785	37,49	2.1
Spain	1,331	34.6	2.6

Total Top 10	10,565	209.97	

Source: Own calculation based on Eurostat data, 2020, National accounts and GDP.

Comparing the increase of Romania's GDP with the growth of GDP created in agriculture, forestry and fishing by micro region, we may notice that at the country level GDP has a higher dynamics due to the large variety of activities, whose results do not depend on climate change.
Work in agriculture is deeply influenced by meteorological factors which could favor or not favor production in the vegetal and also in the animal sector, also the activity is running mainly in small farms of lower productivity, characterized by not sufficient endowment, modern technologies used just in a small percentage of agricultural holdings, high price for farm inputs and low acquisition price of agricultural products, most of farmers are over 60 years old, and only about 20% have a high training level in farm management.

At the national level, GDP increased by 58.9%, as a result of the growth of over 50% in each micro region, the highest growth being +70.4% in North West while the lowest one was +50% in South Muntenia.

In agriculture, the highest increase of GDP (+184.2%) was registered in Bucharest-Ilfov micro-region, but this aspect is less important as long as the value of GDP in agriculture is the smallest one. The lowest growth of GDP in agriculture was 2.4% achieved in North East. Also, in North West and Center, GDP in agriculture decreased by -6.4% and, respectively, by -0.9%.

However, it deserves to appreciate that in South West Oltenia, South East and South Muntenia, GDP produced in agriculture increased in the analyzed interval by +17.25, +13.4% and, respectively, +10.5% (Table 5).

Table 5: Comparison concerning the increase of GDP in Romania and of GDP in agriculture, forestry and fishing in the year 2017 versus 2008 by micro-region (%)

	GDP Romania	GDP in agriculture, forestry and fishing
At national level	**+58.9**	**+8.8**
North West	+70.4	-6.4
Center	+81.6	-0.9
North East	+55.3	+2.4
South East	+56.4	+13.4
Bucharest -Ilfov	+64.4	+184.2
South Muntenia	+50.0	+10.5
South West Oltenia	+52.6	+17.2
West	+51.4	+9.8

Descriptive statistics in terms of mean, standard deviation, kurtosis, skewness, minimum. maximum, and coefficient of variation for Romania's GDP and for GDP created in agriculture, forestry and fishing is shown in Table 6.

Table 6: Descriptive statistics for Romania's GDP and GDP created in agriculture, forestry and fishing

	Mean	St. Dev.	Kurtosis	Skewness	Min	Max	Var. coef.
Romania's GDP	704.8	183.8	-0.22	0.97	528.2	1,053.9	26.07
GDP in agriculture	34.0	6.78	5.36	1.93	26.4	52.7	19.90

Source: Own calculation based on the data from National Institute of Statistics, 2020.

The value of the variation coefficient is higher than 20% in case of Romania's GDP reflecting that the data in the chronological series 2008-2019 are relatively heterogeneous and the mean is not representative, while in case of the value of the coefficient of variation for GDP created in agriculture, forestry and fishing ranged between 10% and 20% reflecting a relatively homogeneous series of data and that the mean is representative (Table 6).

The dependence of Romania's GDP on GDP created in agriculture, forestry and fishing was studied by means of regression analysis, from which it resulted the following regression equation: $Y = 19.820 x + 29.423$, where: Y = Romanian's GDP, the dependent variable, and X = GDP created in agriculture, forestry and fishing, the independent variable.

The regression model reflects that if GDP created in agriculture, forestry and fishing will increase by one unit, GDP created in the whole economy will grow by 49.243 units.

The availability of the regression model is confirmed by F-stat = 11.484, whose value is higher than the F tabled value and also by the low risk degree, Sign. F = 0.0068.

The limits of the confidence interval, Lower 95% and Upper 95% have been the following ones for the parameters a and b of the regression model: - 422.4363 < a < 481.2840 and 6.7943 < b < 32.8467 (Table 7).

Table 7: The estimated regression model

Regression statistics						
Multiple R	0.7312					
R square	0.5347					
Adjusted R square	0.4882					
Standard error	131.54

x- variable 1	19.8205	5.8462	3.3903	0.00688	6.7943	32.8467

Source: Own results.

The value of the coefficient of determination, $R^2 = 0.534$, shows that only 53.4% of the variation of Romania's GDP depends on the variation of GDP created in agriculture, forestry and fishing, and the remaining depends on GDP created in other sectors. The fact that the correlation coefficient between Romania's GDP and GDP formed in the agricultural sector is r = 0.731 shows that between these two indicators it is a strong and positive relationship.

The predicted value of Romania's GDP, the value of the prediction error (residuals) and the standardized value of error are shown in Table 8.

Taking into account the points cloud in the graphical illustration of the relationship between X- the independent variable, that is GDP produced in agriculture, forestry and fishing and the residuals, we may conclude that the regression model is well chosen, because there is no correlation between the independent variable X and residuals, which reflect the value of the prediction error, in other words, the difference between the observed value and predicted value of Romania's GDP (Y) (Fig.4).

Conclusions

Romania's GDP followed a high ascending trend in the period 2008-2019 increasing by 95% and accounting for Lei 1,53.8 Billion (Euro 222 Billion) in 2019. This reflects the efforts made by all the sectors for the development of the economy. It is expected that in the future the economic growth to have the same ascending trend.

Taking into account the evolution in the last decade of trade, transportation, hotels and restaurants, industry, and public administration and defense, education, health and social assistance, in general services, it is expected that these economic activities will continue to develop and increase their contributing to GDP.

Bucharest- Ilfov, North West and South Muntenia regions will continue to produce over 50% of Romania's GDP and to keep their position of leaders in pushing upward of the economic growth.

GDP produced in Agriculture accounted for Lei 52.6 Billion GDP in 2019 compared to Lei 34 Billion in 2008, meaning + 55%. The decline to 5% agriculture share in Romania's GDP in 2019 is explained by the high growth rate of GDP in other fields.

Agriculture has a more balanced development in the territory as reflected by the contribution of the regions of development to GDP: South Muntenia (18.5%), South East (18.1%), North East (15.9%), South West Oltenia (12.2%), North West (11.2%), Center (10.7%), West (10.5%), except Bucharest-Ilfov which has the smaller contribution (2.9%).

The smaller GDP in Romania's agriculture compared to other economic sectors is caused by the reduced gross value added due created in this sector, determined by the specific features: the dominance of the small sized-farms, relatively low technical endowment, low productivity, farmers' aging and their low training level, high price for farm inputs and low acquisition price of agricultural products, and also by the fact that agricultural production is deeply influenced by climate factors which during the last decade have produced distortions in agricultural output affecting the agriculture contribution to the economic development and farmers' income.

Despite of these aspects, agriculture remain an important economic sector contributing to the economic growth, as proved by the correlation coefficient ($r = 0.731$) existing between GDP formed in agriculture and GDP at the country level and $R^2 = 0.534$, which shows that 53.4% of the variation of Romania's GDP depends on the variation in GDP in agriculture. The regression model, Y = 19.820

x + 29.423 proved that if GDP created in agriculture, forestry and fishing will increase by one unit, GDP created in the whole economy will grow by 49.243 units.

In the coming future, it is expected as Romania to produce more GDP in agriculture and to keep its 5th position among the major contributors to the development of the EU agriculture.

elzbieta.ociepa-kicinska@usz.edu.pl

Abstract

This article analyses the significance of smart specialisations in enhancing the innovative policy paradigm in the regions. Smart specialisations by definition should play a major role in stimulating innovativeness at the regional level, in particular with regard to enhancing the region's potential, its resources, key competences and competitive advantages while identifying the priority criteria. Thus, the concept should ensure a bigger growth of the regions attractiveness and their faster development. Smart specialisation is an approach implemented under the EU's Cohesion Policy, also in Poland. Smart specialisation in Polish regions is also known as an approach that combines the industrial, educational and innovative policies in order to identify and concentrate a limited number of priority areas for the economy. It is assumed that clearly identified smart specialisations in combination with appropriate management of public financial resources contribute to economic growth and improvement of the economic situation in Polish regions. The aim of this article is to present and characterise the assumptions for smart specialisations, and also to explore the process of intelligent specialisation and its role in the growth of innovativeness in Polish regions. First, the article presents the assumptions for introducing smart specialisation and characterises the smart specialisations identified by the individual regions in Poland. Next, the research assumptions are presented along with the results of the regional benchmarking based on the synthetic measure of development and on the analysis based on indicators for strategic horizontal objectives, describing the level of innovativeness and R&D advancement.

Keywords: Smart Specialisation, Regional Policy, EU Financial Policy, Innovation, Economic Development

Introduction

The concept of smart specialisation constitutes an overall (complex) approach to the issue of specialisation in the area of science, technology and economy in the European Union. The basic assumption of the smart specialisation concept is enhancing the innovativeness and competitiveness of regions via utilisation of their best assets and developing the most promising specialisation areas from the point of view of achieving competitive advantages on an international scale.

Pursuant to the assumptions of the smart specialisation strategies, each region has specific resources which, incorporated into global processes, become the key success factors. Taking into consideration the endogenous capabilities of the region, its resources, key competences and competitive advantages in the course of identifying the priority areas is to ensure a bigger growth of the regions' competitiveness and their faster growth.

Regional smart specialisations are a new instrument for regional growth, via which the European Union encourages the regions to develop the areas that have the greatest development potential. This

Cite this Article as: Magdalena KOGUT-JAWORSKA and Elżbieta OCIEPA-KICIŃSKA "The Significance of "Smart Specialisation" For the Regional Innovativeness Growth" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

is because the regional specialisations are to reflect the specificity, uniqueness and economic originality of each region. Consequently, the smart specialisations are to lead to creating areas and niches that enable durable and dynamic growth, preventing any duplicated investments, at the same time fostering the inter-regional growth.

Pursuant to the assumptions of the Cohesion Policy, in the years 2014–2020 the smart specialisation concept should be particularly important in the process of regional growth. On that basis, each of the voivodeships in Poland developed a regional innovation strategy containing the smart specialisation identified within the given area.

The aim of this article is to present and characterise the assumptions for smart specialisations, and also to explore the process of intelligent specialisation and its role in the growth of innovativeness in Polish regions. The main outcome of the analysis is presenting new research assumptions and the results of the regional benchmarking based on a synthetic measure of development and the analysis based on indicators for strategic horizontal objectives.

The article describes the role of smart specialisations and indicates their progress as well as the effects of their implementation in Polish regions. For the purposes of the analyses, a literature review was also completed, which included the analysis of major European and national documents, to show the conditions and constraints related to introduction of the smart specialisation concept to the regional policy. The pragmatic part concerns a short description of smart specialisations identified by the individual regions in Poland, and empirical identification and evaluation of progress in implementing the concept. The added value is outlining the effects of the innovative policy based on smart specialisation, and positioning of the Polish regions within a ranking based on the synthetic measure of development.

Conceptualisation of the idea of "smart specialisation" – background for the conducted research study

According to D. Foray, smart specialisation is "an entrepreneurial process of identifying the areas of science and technology, from among the specialisations, from which the given region may avail itself" (Foray, 2009). According to P. David, D. Foray and B. Hall, in turn, "a smart specialisation is both a concept inscribed in the innovation strategy and a tool applied for developing and building the current and future standing of the region or country in a knowledge-based economy" (Foray, David, Hall 2011). Smart specialisation holds an important place in the innovation and industry policy (Foray, 2016), as this concept is aimed at promoting an effective and efficient use of public investments in research, innovations and technological development. The idea is a determinant for prioritisation of allocating the public resources connected with innovations which are sensitive to the regional context.

The concept of smart specialisation offers a number of benefits in terms of designing a policy to stimulate innovations, while taking into account the diverse, evolutionary nature of regional economies. Smart specialisation may therefore be perceived as a result of the needed convergence between a regional development policy and an innovativeness policy (McCann, 2015). Even though the concept is nothing new in the EU's cohesion policy [i], its assumptions refer to the theories known for years in the area of economic thought, particularly with regard to regional growth, as e.g. the theory of: economic base, core product, industrial district, territorial production systems, cluster, "learning" region, or new economic geography. Smart specialisations have become a new philosophy for developing the innovation policy in the European Union, therefore they have been the object of numerous analyses and expert opinions as well as they have been referred to in the EU policy papers[ii]. The studies emphasise the congruity of the idea with the EU policy and indicate practical recommendations in the area of developing a regional policy focused on creating smart specialisations.

The concept of developing smart specialisations is an attempt to improve effectiveness of the innovation processes, particularly in the context of the public sector expenditure (Pessoa, 2014, pp. 5-8). The underlying assumption is that regions should not and cannot develop their activities simultaneously in all areas. They should be selective and choose the domains where they have the best developed resources, and should focus their scientific, research and innovative activities within their scope (McCann, Ortega Argiles, 2011).

Regional strategies of research and innovations for smart specialisation are in turn integrated and defined at the grass roots level economic transformation programmes, based on (Nowakowska, 2011):

- utilising the strengths and competitive advantages of a given region and its potential to achieve excellence, while taking into account any differences in economic capacities of individual regions in relation to innovations,
- full engagement of stakeholders and joint identification of the most promising areas of specialisation, as well as weaknesses that hinder introduction of innovations in any given region,
- focusing the public support in the area of the pursued policy and investments on key regional priorities which are manifested in trends, challenges and needs in the area of knowledge-based development, including any ICT-related activities,
- application of tools to encourage innovativeness and experimenting, to stimulate investments of private entities in research and development; to foster technological and practical innovations; to create a synergy effect,
- relying on evidence-based data and indicators as well as on a reliable system of monitoring and evaluation.

The difference between the smart specialisation concepts and the traditional concepts of innovation management is the process which can be defined as entrepreneurial discovery – an interactive process where the forces having an impact on the market and the private sector search for information about new, potential fields of activity, and governmental organisations assess the potential impact of any given areas on development of the region, and support the areas which have the greatest potential to achieve a competitive advantage in that respect (Wolniak, Hąbek, 2016). It should be noted that on the one hand the concept of smart specialisations requires a number of necessary conditions for its implementation, and on the other hand it is possible to identify many constraints affecting the policy as such, which was based on the concept. The major constraints are classified in the table below (Table 1).

Table 1: Conditions and constraints for a regional development policy based on implementing smart specialisations

Conditions	Constraints
– changing the traditional attitudes taken by the public to what is unknown, and stimulating pro-innovative behaviours, which includes elimination of stereotypes, fostering trust towards new solutions and stimulating social attitudes of being open to innovations – ensuring efficiency of the education system and the ability to adjust the education services to the market	– favouring the regions that are already developed, at the cost of underfinancing others, which would be in contradiction to the main principle of the EU's territorial cohesion – concentration of cutting-edge technologies development in the best developed regions, with concurrent marginalisation of less developed regions, which results in increased

needs, and adequate response to the social and economic situation in the region – stimulating pro-innovation attitudes among entrepreneurs, which includes encouraging them to implement innovations, especially those worked out in cooperation with the research & development sector – implementation of innovative ideas on the market via taking up activities aimed at reducing the level of risk involved in implementation of innovations – supporting research & development activities in research units and in enterprises, which is based on solid rules and legal regulations. This will make it possible for any engaged entities to prepare strategic planning of their actions in medium- and long-term time horizon. – ensuring effectiveness of allocating any means for research & development activities. This is to be fostered via supporting any R&D works aimed at introducing innovative ideas into the market. – increasing the number and quality of innovative ideas implementations, particularly those prepared on the basis of R&D works, while ensuring appropriate competences of any institutions engaged in the processes, as well as transparency of the intellectual property protection regulations – support for application of innovation and ICT technologies used in serving the public – ensuring access to the financial instruments that support innovation measures in various phases of development, including the latest solutions known worldwide in that respect – supporting the international cooperation and internationalisation of enterprises in order to enhance the competitive position and to increase the significance in international and global value chains – supporting the cooperation between the science and economy sectors via legal regulations encouraging the process participants to intensify their	polarisation – difficulties in anticipating which technologies in a long run will be developing at the fastest rate, which is due to the extremely fast progress of science – individual regions achieving the same or similar results in terms of priority rankings – too many regions select a few most popular technologies, predominantly ICT, nano- and biotechnologies, – the risk connected with wrong choices, resulting from excessive support provided to solutions that finally prove to be inefficient – constraints resulting from the unpredictable and complex nature of innovation, connected with application of technological solutions and results of research done in various areas, being applied in many fields which were not anticipated by innovators (e.g. pervasive IT technologies, new materials, nano- and biotechnologies) – a risk that the works in the region may be relatively easily dominated by traditional interest groups, which are more interested in retaining the *status quo* rather than restructuring the economy via innovations – reliance on single industries, which is particularly hazardous in case of regions and cities with a low level of development, with a small overall economic potential – attempts to create, on a top-down basis, clusters that constitute development policy instruments that may turn out to be a trap, both from the point of view of the chances for success and long-term effects, with regard to the types of activity that cannot rely on any traditions – ignoring the demand side represented by innovators, users and consumer interest groups, as well as any intermediaries with a knowledge-based and simultaneously market-focused perspective, i.e. settling for a traditional triple helix managerial model, assuming interactions between the academic world, public authorities and entrepreneurs,

activities, especially with regard to investments made by the enterprise in the area of innovation – developing the service offer of the institutions that support implementation of innovations and technology transfer, and ensuring easy access to their services	without the forth group of stakeholders representing a vast range of innovation users, as per the model described as a quadruple helix

Source: own study based on *M. Słodowa-Hełpa, 2013: Inteligentne specjalizacje polskich… Regionalna Strategia Rozwoju Inteligentnych Specjalizacji Województwa Zachodniopomorskiego 2020+ RIS3 WZ,* Zasady polityki innowacyjnego rozwoju … 2016 r 51.

Smart specialisation is based on a conviction that no country or region may be a leader in all areas of research and innovativeness, but each of them has its specific potential which makes it possible for them to attain a competitive advantage only in some specified areas. According to the European Commission, in a knowledge-based economy each region has its own role to play, on a condition that it is able to determine its competitive advantages, potential and ambition to achieve excellence in specific market sectors or niches

Innovative potential in smart specialisation strategies in Polish regions

Analysing the innovative potential in Poland, it is possible to distinguish a number of social, economic and spatial factors which affect the level of innovativeness. This is because the innovation processes on the one hand are heavily determined by the society wealth level and human capital resources, which is often manifested by open attitudes to innovative products. On the other hand, innovation development depends on the economy's technological capacity – understood in a broad sense as a level of technological advancement of industry and service sectors, the academic sphere that introduces innovations to the economy.

The processes of choosing smart specialisations in Polish regions were similar. Identification of the specialisation was mainly based on statistical data, predominantly on the level of GDP generated by a given sector, employment level and personnel with a given education profile. Another important element covered the comparative analyses performed in order to show the potential of key industries. Similarly, in each region, social consultations were carried out among the public, entrepreneurs, business environment institutions, and non-governmental organisations.

It should be noted that different levels of detail apply to smart specialisations in any individual regions, which made the comparison very problematic. In accordance with the comparative study methodology, in the course of distinguishing the specialisations, they were standardised according to industries, where specialisations were assigned to industry groups and then sectors made up of those groups. The categorising was aimed at determining in which direction the given industry is developing, on the basis of its more exhaustive description in the strategy document.

The study accounted for the significance level of a given industry in the smart specialisation strategy of a given region as a whole. Unfortunately, the level of detail for each voivodeship as well as the number of specified specialisations were not covered by uniform rules. The table below presents smart specialisations broken down into sectors and industries (see Table 2).

Table 2: Regional smart specialisations of Polish regions

Voivodeship	Smart specialisations
Dolnośląskie	Chemical and pharmaceutical industries Spatial mobility High quality foods Natural and recycled materials Manufacturing of machines and equipment, materials processing ICT
Kujawsko-Pomorskie	Safe foods Processing, fertilisers and packaging Medicine, medical services and health tourism Automotive industry, transport devices and industrial automation Tools, injection moulding, plastic products Information processing, multimedia, programming ICT services
Lubelskie	Bioeconomy Medicine and health Low-carbon power engineering IT and automatic control
Lubuskie	Green economy Health and life quality in the region Innovative (modern) traditional industry Business cooperation
Łódzkie	Modern textile and fashion industry (including design) Advanced building materials Medicine, pharmaceuticals, cosmetics Power engineering, including renewable energy sources Innovative agriculture and food processing Information technology and telecommunications
Małopolskie	Life sciences Sustainable energy ICT Chemicals Production of metals and products from metal and mineral non-metallic resources Electrical and mechanical engineering Creative and leisure industries
Mazowieckie	Safe foods Smart management systems Modern business services High quality of life
Opolskie	Chemical (sustainable) technologies Sustainable construction and wood-processing technologies Metal and mechanical engineering technologies Power engineering technologies (including RSE, improving the energy efficiency) Agricultural and food processing technologies, healthy food
Podkarpackie	Aviation and astronautics High quality of life ICT
Podlaskie	Agricultural and food sector

	Medical services sector Ecoinnovation sector Mechanical engineering
Pomorskie	Off-shore and port logistics technologies Interactive technologies in an information saturated society Eco-effective technologies in production, transmission, distribution and consumption of energy and fuels and in construction industry Medical technologies within the scope of civilisation diseases and ageing
Śląskie	Power engineering Medicine ICT Emerging industries Green economy
Świętokrzyskie	Resource-saving construction industry Metal and foundry industry Modern agriculture and food processing Health and pro-health tourism ICT Exhibition and trade fair business Sustainable energy development
Warmińsko-Mazurskie	Water economy High quality foods Wood and furniture
Wielkopolskie	Bioresources and food for conscious consumers Interiors of the future Industry of tomorrow Specialised logistic processes ICT-based development Modern medical technologies
Zachodniopomorskie	Bioeconomy (based on the region's natural resources and its economic and R&D potential) Maritime activities and logistics (including maritime technology – the industry which is nested in the region, but which must respond to current challenges) Metal and mechanical engineering industry (there are more and more companies operating in this sector in the region, there are more and more industrial parks, an additional advantage is the precious experience connected with the shipyard industry) Services of the future (the fast-growing ICT, IT KPO and creative industries) Tourism and health (making use of natural resources and cultural heritage)

Source: Own study based on the regional strategies of the 16 voivodeships in Poland.

The analysis of the indicated smart specialisations in the Polish regions has shown that the most popular specialisations – ICT and multimedia – were chosen by the voivodeships: Dolnośląskie and Wielkopolskie. Medicine and health tourism is supported as part of the regional policy in: Dolnośląskie, Lubuskie and Zachodniopomorskie. Smart specialisations within the scope of healthy food were indicated in the voivodeships: Dolnośląskie, Lubuskie and Opolskie. Bioeconomy is, in turn, promoted in Dolnośląskie, Lubuskie, and Zachodniopomorskie. Opolskie has focused its regional policy on power engineering, including renewable energy sources. Mechanical engineering and metal industry is another popular specialisation promoted in: Dolnośląskie, Lubuskie, Opolskie,

and Zachodniopomorskie. Business services are supported as part of the innovation policy in Zachodniopomorskie. Also, logistics and water engineering are valued in Zachodniopomorskie. Dolnośląskie, in turn, relies on chemical and mining industries.

Research assumptions

As part of carrying out the assumptions indicated in the article, the study was divided into two stages. During the first stage, the regions were benchmarked on the basis of the methodology found in the document: Regional benchmarking in the smart specialisation process: Identification of reference regions based on structural similarity (Navarro i in., 2014), according to which the key measures of the regional development level may be broken down into five[iii] groups:

1) geo-demography,

2) HHRR education level,

3) technological specialisation,

4) sectoral structure,

5) firm size.

Each of the groups contains from one to ten identified variables that describe a given feature (Table 3). The input data used in the calculations were derived from the Local Data Bank of the Central Statistical Office (Bank Danych Lokalnych, 2020) and pertain to the years 2008, 2013 and 2018. This selection of data made it possible to compare the levels of regional development before introduction and after the implementation of smart specialisations, and to compare the latest available data.

Table 3: The variables used in the study along with the weights assigned to them

Dimensions	Elements	Weight	Subtotal weight	Measure
1. Geo-demography	Population structure	0,2	0,05	Total Population
			0,05	Population >= 65
			0,05	Population <15
	Urbanisation		0,05	Pop. in urban and comm. areas
2. HHRR educ. Level	HHRR educational level	0,2	0,20	Pop. with upper secondary and tertiary ed.
3. Technological specialization	Technological distribution (patents)	0,2	0,05	Patents granted by the Polish Patent Office - total
			0,05	Patents granted by the Polish Patent Office - per 100,000 residents
	R&D		0,05	Share of persons employed in R&D in the economically active population
			0,05	Internal expenditure on R&D
4. Sectoral structure	Economy's sectoral distribution	0,2	0,02	Agriculture, forestry and fishing (A)
			0,02	Industry (except const.) (B-E)
			0,02	Construction (F)
			0,02	Wholesale and retail trade, transport etc. (G-I)
			0,02	Information and communication (J)
			0,02	Financial and insurance activities (K)
			0,02	Real estate activities (L)
			0,02	Professional, scientific and technical activities (M-N)
			0,02	Public administration (O-Q)
			0,02	Arts, entertainment and recreation (R-U)
5. Firm size	Firm size	0,2	0,20	Average firm size

Source: own work.

The diagnostic variables used in the study are expressed in different units of measurement, which made any direct comparison impossible. In order to make them comparable and additive, they were transformed by means of the zero unitarisation method based on the span between the maximum and minimum values of the feature in question. Obtained values of the variables are positive and fall within the range from 0 to 1, where "1" stands for the most beneficial, and "0" for the least beneficial value of the examined variable. It was assumed that when a high value of the diagnostic variable for a given phenomenon is associated with beneficial growth, the feature is considered Larger-the-better (LTB), whereas in a situation where a low value of the variable is beneficial for the phenomenon in question, it is deemed Smaller-the-better (STB). The standardisation was carried out with the use of the following formulas (Ziemiańczyk 2010):

LTB:

$$Z_{ij} = \frac{x_{ij} - min\, x_{ij}}{max\, x_{ij} - min\, x_{ij}},$$

STB:

$$Z_{ij} = \frac{max\, x_{ij} - x_{ij}}{max\, x_{ij} - min\, x_{ij}},$$

where:

Z_{ij} – diagnostic variable, falling within the range from 0 to 1,

x_{ij} – the feature value for a given region,

min x_{ij} – the lowest value of the feature among the examined regions,

max x_{ij} – the highest value of the feature among the examined regions.

Pursuant to one of the proposals of the authors of the methodology developed jointly by Orkestra – Basque Institute of Competitiveness and the S3 Platform (Navarro i in., 2014, s. 20), each of the indicated five groups of measures was assigned the same weight equal to 0.2, whereas the individual variables within the groups were assigned the partial weights of equal value in such a way so that their sum amounted to 0.2. Yhis approach is consistent with consistent with, inter alia, Grabiński (Grabiński, 1992), Sokołowski (Sokołowski, 1985), Klóska et al. (Klóska i in., 2020). The next step was calculation of the relative synthetic measure of development, expressed by the formula:

$$SMD_i = \sum_{j=1}^{k} \alpha_j z_{ij},$$

where:

W_i – relative coefficient of development,

k – quantity of variables considered in the study,

α_j – weight of the jth variable,

z_{ij} – values of the statistical features x_{ij} considered in the study, standardised by means of the zero unitarisation method.

It was assumed that a higher value of the aggregate formula is associated with a higher level of development. Thus, by means of the linear ordering method, the ranking of regions was obtained.

The basis for the second part of the research study was the five indicators selected for the strategic horizontal aims based on the analysis of the evaluation methods adopted by the regions (e.g. (Szmyt i in., 2016, s. 66)):

1) internal expenditure on R&D, relation to GDP (current prices),

2) PhD students per 10,000 population,

3) university graduates per 10,000 population,

4) people employed in R&D per 10,000 population,

5) expenditure on innovative activities in 2017 in industrial enterprises.

As for the first four indicators, its change over time was analysed, the fifth indicator was available only for 2017, however, in view of its great significance, it could not be ignored. At the last stage, the ranking of regions was presented on the basis of the most recent data – only the data for 2018 and 2017 were processed by means of the linear ordering method.

Results of own research

The analysis of the values of the synthetic measure of development made it possible to distinguish four groups of regions (Figure 1):

- the ranking leader – Mazowieckie voivodeship,
- three regions which, in different configurations, in each period took positions that ranged from the second to the fourth place (Śląskie, Małopolskie and Wielkopolskie),
- five regions which alternately took the last places in the ranking (Lubuskie, Opolskie, Świętokrzyskie, Zachodniopomorskie and Podlaskie),
- the remaining seven regions which were placed in the middle of the ranking.

Fig 1. Synthetic measure of development in Polish regions for 2008, 2013, 2018
Source: own work.

At the same time, over the 11 years covered by the analysis, the value of the synthetic measure of development calculated for the individual regions did not change much. The span computed for the values for 2008 and 2018 ranged from 0 to 0.1. The detailed values of the synthetic measure of development calculated for the individual voivodeships for the years 2008, 2013, 2018 are presented in Table 4.

Table 4: Synthetic measure of development in Polish regions for 2008, 2013, 2018

region	Synthetic measure of development		
	2008	2013	2018
mazowieckie	0,88	0,84	0,87
śląskie	0,65	0,60	0,63
małopolskie	0,60	0,59	0,64
wielkopolskie	0,60	0,60	0,62
dolnośląskie	0,53	0,55	0,49
łódzkie	0,54	0,46	0,45
pomorskie	0,45	0,45	0,45
kujawsko-pomorskie	0,43	0,42	0,41
podkarpackie	0,37	0,39	0,39
lubelskie	0,36	0,35	0,38
warmińsko-mazurskie	0,38	0,34	0,31
podlaskie	0,29	0,28	0,26
zachodniopomorskie	0,26	0,26	0,26
świętokrzyskie	0,27	0,24	0,22
opolskie	0,21	0,21	0,22
lubuskie	0,27	0,18	0,17

Table 5: Expenditure on innovative activities in industrial enterprises in 2017

region	Share of enterprises		
	grand total	innovation active	which incurred expenditures
dolnośląskie	100,0	20,4	15,2
kujawsko-pomorskie	100,0	18,6	12,7
lubelskie	100,0	23,2	13,8
lubuskie	100,0	15,8	12,0
łódzkie	100,0	17,3	12,2
małopolskie	100,0	23,5	17,3
mazowieckie	100,0	21,4	15,3
opolskie	100,0	23,1	17,5
podkarpackie	100,0	21,2	15,9
podlaskie	100,0	18,6	13,2
pomorskie	100,0	20,2	15,1
śląskie	100,0	20,8	15,0
świętokrzyskie	100,0	20,8	15,8
warmińsko-mazurskie	100,0	16,0	11,2
wielkopolskie	100,0	19,4	15,1
zachodniopomorskie	100,0	20,9	14,4

Source: own work.

The analysis of the values of strategic horizontal objectives has shown that the Małopolskie and Mazowieckie voivodeships are characterised by the highest values of internal expenditure on R&D, PhD students per 10,000 population and university graduates per 10,000 population. The Małopolskie voivodeship also shows the highest level of expenditure on innovative activities in industrial enterprises. At the same time, it may be surprising to note the low ratio of the employed in R&D per 10,000 population in these voivodeships (8th and 9th place in the ranking). In this category, the Dolnośląskie region is the leader. It should also be noted that the Śląskie voivodeship which managed to attain the second/third highest value of the synthetic measure of development, is placed in the bottom half of the ranking in Graphs 2 – 5 and in Table 5. The Lubuskie voivodeship, in turn, takes the last position in categories such as: internal expenditure on R&D, university graduates per 10,000 population, and expenditure on innovative activities in industrial enterprises in 2017.

Summary and conclusions

To conclude the deliberations regarding the significance of smart specialisations in enhancing the paradigm of the innovative policy in the regions, it should be stressed that in Poland only in the few regions the level of structural conditions which are relevant for innovation-driven development and the strategic horizontal objectives are consistent (e.g. Małopolskie, Lubuskie). We should also note the rising level of all strategic horizontal objectives: internal expenditure on R&D, PhD students, university graduates, the employed in R&D, expenditure on innovative activities in industrial enterprises in 2017, which may confirm the increasing role of innovativeness, consistent with the smart specialisation assumptions presented in the theoretical part.

When comparing the effects of the analysis performed with the branch specialisations selected based on the strategies of smart specialisations for particular Polish regions, it needs to be said the leading branches are those which focus on development of innovative companies production and service, and ensure proper ways of cooperation between the production sector and the research potential. In case of Mazowieckie and Małopolskie regions, they are the branches of the ICT, energy, electronics, advanced services for business, as well as the branches which improve living standard of the population. In case of Dolny Śląsk (Lower Silesia), the specialisations are mainly concentrated around the modern, industry-based economy. For some regions, e.g. Podkarpackie, the path of development is obvious and the smart specialisations follow the traditional, historically conditioned branches, however, for some other regions, the identification of the specialisations seems to be difficult to perform and to compare with other regions (especially where modern branches of economy became the choice). Broad assessment has to be applied in order to conclude which particular branches are the key factors for success in implementation of innovative processes. In conclusions, it needs to be added that the level of specify of the identified specialisation areas is diverse in particular regions of Poland. Similar conclusions can be drown regarding the number of branches or sector found within the process of smart specialisation defining, for every region features a different number of endogenous advantages sectors and branches which decide about development of innovations in a given region.

Summing up, it should also be pointed out that regional smart specialisations are a new instrument of regional development in Poland, and that currently the country is still paving the way to create areas and niches to enable sustainable and dynamic development of regions. Taking into account the current implementation stage of smart specialisations, we can also assert that constraints for a regional development policy based on implementing smart specialisations, which are presented in the article, in view of the results of the completed analyses of the synthetic measure of development based on the indicators for strategic horizontal objectives, will be gradually becoming less important, whereas the benefits resulting from introducing the smart specialisation concept will be increasing and will be more visible in terms of development of innovativeness in Polish regions.

An interesting issue in that regard may be a detailed evaluation of the smart specialisation implementation process in the individual regions, and even though it is not consistent with the assumptions of this study, it may constitute an interesting point of reference for further studies on effects of implementation of the smart specialisation concept in Poland.

Acknowledgment

This research was funded by the program of the Minister of Science and Higher Education under the name “Regional Excellence Initiative” in the years 2019–2022; project number 001/RID/2018/19; the amount of financing: PLN 10,684,000.00.

[i] The concept was worked out in connection with the implementation of the Europa 2020 strategy by an expert group headed by Janez Potočnik, European Commissioner for Science and Research Knowledge, whose deputy was Prof. D. Foray. The outcome of the works carried out by the Group was the report: Knowledge for Growth. European Issues and Policy Challenges (European Commission, 2008).

[ii] The following studies are particularly important for understanding and implementing the concept (Nowakowska, 2011): Regional Policy Contributing to Smart Growth in Europe 2020 – this document describes the role of the regional policy in implementing the Europe 2020 Strategy in the area of smart growth, in particular with regard to implementing the "Innovation Union" flagship project (COM 2010, p. 553), Connecting Smart and Sustainable Growth through Smart Specialisation – this document specifies the ways to connect smart specialisations with sustainable economic growth (European Commission 2012), Guide to Research and Innovation Strategies for Smart Specialisation RIS 3, which shows the ways of designing smart specialisations and instruments of implementation (Foray et al. 2012).

[iii] The source methodology also includes 2 more groups of measures, i.e. openness (trade openness), measured as total exports (% GDP) and institutions & values determined by multilevel government, social and institutional capital (quality of institutions, feeling of safety of walking alone in the local area after dark, most people can be trusted or you can't be too careful) and entrepreneurial / innovative attitudes, which in the case of analysing the regions being part of one country do not seem relevant. Moreover, for some of them the values are not updated, and as a result the Benchmarking Regional Structure tool is based on e.g. the outcomes of a study pertaining to a given feature, which was conducted back in 2008.

Stakeholders Training Strategy as a Key Factor of Project Costs Estimation

Abstract

The authors of this article took up the subject of an incorrectly planned training strategy in projects and the consequences of this phenomenon in economic and organizational practice. As the research objective, they adopted indicating the critical role of training planning in project management. Based on literature research, case studies, and direct interviews with representatives of the military, IT, banking, logistics, and financial and development/construction industries, carried out in 2018-2020, they proposed the original method ("STOP costs"). The method of multidimensional analysis, which is a combination of well-known techniques and management tools (i.e., Stakeholders Mapping, Training Needs Analysis, Objects maintenance and Goals Management, Project Life Cycle), can be used to eliminate the problem of underestimating the training costs in project management and minimizing the negative consequences of the lack of appropriate training in all phases of the project.

Keywords: Trainings, Development, Project Management.

Introduction

Project management is a field that has been explored for many years by theoreticians and practitioners, who represent not only management science. However, it turns out that it is still possible to identify research and management gaps in this field (i.e., related to the planning and implementation of projects in social or economic life).

The authors of the article paid particular attention to the overly routine and even disrespectful approach to the issue of training in projects, which in turn leads to real threats related to their implementation and functioning of the project subject in the post-project phase. The thoughtless duplication of cost items related to training in the budgeting of subsequent projects was considered routine, while it is disrespectful to reduce or omit these costs knowingly, for example, to increase the attractiveness of a commercial offer or convince the management board that it is appropriate to undertake design work. Therefore, the article aims to present the critical role of training planning in project management.

Moreover, an additional goal is to present the proprietary method of multidimensional analysis of the sources of identification of training costs in the project, given the working name "STOP costs." In the first phase of works, the following research problems were formulated: 1 / underestimating the training costs related to a given project may adversely affect all project dimensions, i.e., budget, implementation time, and requirements; in particular, it is related to the risk of exceeding the project budget, generating considerable costs in the post-implementation / exploitation phase, failure to implement the project, untimely implementation of the project, lack of improvements/results expected in connection with the project implementation; 2 / the underestimation of training costs in

Cite this Article as: Katarzyna CZAINSKA and Kazimierz KOWALSKI "Stakeholders Training Strategy as a Key Factor of Project Costs Estimation" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

projects results from a narrow perception of the subject of training, target group, methods and forms of training, lack of synchronization of training activities with the project life cycle.

Therefore, a research question was asked: how to avoid the problem of underestimating the costs of training in project management? Empirical research was preceded by literature studies (in-depth desk research); then, case studies of military projects were carried out. The obtained results were additionally confronted with the experts' statements (i.e., project managers and members of project teams) from the IT, banking, logistics, financial, and development/construction sectors. The research was conducted in the years 2018-2020. The preliminary analytical work results allowed for the following hypothesis: there is a possibility of eliminating the problem of underestimating the costs of training in project management by using the multidimensional analysis of "STOP costs." The hypothesis will be verified in the course of further research aimed at determining the effectiveness of the tools as mentioned above in business practice.

Theoretical Framework

One of the paradigms of modern management is building a company's competitive advantage based on strategic management of employees' competencies (Moczydłowska, 2018; Skrzypek, 2016). Moreover, it has been stated that employee development carried out by an appropriate training program is one of the main foundations of sustainable human capital management, i.e., the leading idea of modern organizations (Kuźniarska, 2018). In the 2018 study, Nogalski and Niewiadomski confirmed that the main factors lowering the "excellence" of a company include, among others, inadequate employee training system; despite the understanding of the idea and the need for training in enterprises by top management and executive employees, the number of training courses is significantly reduced. The main reasons for such a situation included the lack of time for participation in training (mainly caused by numerous professional duties) and the lack of funds allocated for this purpose (Nogalski, Niewiadomski, 2018).

The above conclusions were also formulated about such an extensive management field as project management (Clark, 2010; Lee-Kelley, L., Blackman, D., 2012). Unfortunately, the observation made by Ramazani and Jergeas still holds true that *the expenses devoted to training, certifications, and project methodologies are enormous; however, the failure rate is still high, and the gaps between expected and actual results are still there* (Ramazani, Jergeas, 2015).

When searching for the causes of the existing situation, it was decided to adopt a process approach and analyze the various phases of the project life cycle regarding the mismatch between the demand and the supply of knowledge. As research in the field of project management did not lead to a single and widely accepted model of the course of project implementation, due to the subject of this article, the model developed by Trocki was adopted as the starting one because it takes the aspect of stakeholder participation in individual phases of the project life cycle into account (Figure 1).

Besides, that model is universal enough to correspond to traditional and the newest project management methods (e.g., agile, scrum). On the other hand, the assumption of analyzing the problem from the point of view of stakeholders is consistent with the strategic approach, where the organization's environment (including the project's environment) is understood as a unique and dynamic configuration of diverse groups of stakeholders. To properly recognize the problems of an organization, it is first necessary to identify key players, i.e., stakeholders. Project stakeholders are the direct participants and affected people of the projects (Guide, 2001), but not only the project members (i.e. owner, consultant, contractor, suppliers), but also those from the project environment (i.e. customers, government, local community, public media etc.) (Institute, 1987). Moreover, stakeholder analysis has been conducted in different branches to help researchers to study on various project related problems from perspectives of stakeholder influence, stakeholder concerns, stakeholder expectations, and public participation. Xue, J., Shen, G.Q. and Yang, R.J., et al. (2020) presented the results of bibliometric research in which they showed that the identification of

stakeholders is a key process of project management; stakeholder identification should be carried out differently, depending on the industry/branch and project characteristics.

When examining the issues of training in projects, Globerson and Korman (2001) pointed to the necessity of two approaches to planning and implementing training, namely standardized and just-in-time training (JIT-T). Standardized type of training concerns general, shared, and repeatable topics for many projects. JIT-Ts should be tailored to the project specifics and compatible (in terms of time and subject) with the problem they concern and, above all, carried out for stakeholders who need the knowledge.

Fig. 1: Project life cycle model

Source: based on Trocki, Grucza, Ogonek, 2003, pp.32

An essential issue in project management, at every stage, is the identification of competency and training needs (Tam, Moura, Oliveira et al. 2020; Wiewiora, Chang, and Smidt 2020). The competency needs analysis is of long-term importance and is performed to: 1/ identify specific areas for improvement; 2/ obtain support from the management staff to conduct efficient training and development activities; 3/ determine the costs and benefits of training and development programs; 4/ establish the necessary data resource useful for the evaluation of development programs in the future (Juchnowicz, 2016, pp. 275-276).

The analysis of training needs is a set of activities that define the target group of training participants, its subject, scope, and forms (Serafin, 2011). However, the training need might be ongoing (regarding the currently performed tasks), adaptive (allowing for additional tasks), and developmental (related to the anticipated changes in the scope of work in the future) (Jasiński, 2005). Thus, further dimensions arise that should be considered in the design training strategy.

Therefore, a vital aspect of identifying training needs will also be the inclusion of object maintenance in the post-project phases, i.e., operation and withdrawal. Such analysis is crucial in any case when the project object/result is to be used for a certain period after the project ends, especially when the end-users are people who are not the project team members. Thus, one can notice the consistency of the design process and analyses of stakeholders and training needs. Therefore, the training strategy is aimed at reducing the costs arising in the individual phases of the project related to non-performance or improper implementation of this project.

Methodology and Research Process

The decision to undertake research was made after identifying a significant problem in economic practice, consisting in diminishing the importance of training in projects. The research work took three years (2018-2020) and is still being continued. The research process was organized according to generally accepted principles and consisted of the following phases: formulation and development of research assumptions (questions, scientific problems, hypothesis); literature review (in-depth desk research); selection of research methods and tools; selection of respondents; qualitative and empirical research; data analysis; inference; development of the "STOP costs" tool.

Table 1: Specification of the analyzed projects

Industry	Goal of the project	Research method	Respondent (-s)	Period of the study
Military	the acquisition of military equipment	case study	Project team members	2020
IT, banking, logistics, financial	transition	face-to-face interviews	Project managers	2018
Information Technology	software	face-to-face interviews	Project managers	2020
			Project teams members	2020

Source: own study

The tool testing stage and the transfer of knowledge to economic and organizational practice remain to be implemented.

The Impact of Training on Project Implementation - A Case Study

The implementation of projects aimed at the acquisition of military equipment (SpW - equipment specially designed or adapted for military needs and intended to be used as a weapon, ammunition, or war measures) is one of the most expensive and time-consuming projects in the military sector. It should be mentioned that the projects aimed at acquiring SpW are not only the purchase of new SpW but also the modernization (modification) of the already used SpW, or the implementation of development works. Their importance for the Armed Forces is demonstrated, among other things, by the functioning of the Defense Acquisition University, a higher education institution educating

personnel (both civil and military) in the field of procurement and services for the United States Department of Defense.

Training of stakeholders in military projects related to the acquisition, operation, and disposal of military equipment is carried out its life cycle including the phases of identification, analysis and concept, implementation, operation, and withdrawal (Decision No. 141 / MON, 2017; Decision No. 161 / MON, 2018). In the Armed Forces of the Republic of Poland, the training of personnel involved in the acquisition of firearms, as part of standardized training, includes post-graduate studies "Management in the military equipment acquisition" and a specialist course "acquiring military equipment".

The training personnel, in the above-mentioned manner, is recommended by the key stakeholder in the system for obtaining SpW, namely the Department of Defense Policy of the Ministry of National Defense (powers - civilian employees) and by the Human Resources Department of the Ministry of National Defense (powers - soldiers). It happens that the second of the afore-mentioned institutions sends to the course not always according to the needs for projects but taking account of the individual development needs of the staff - further career).

As part of the above-mentioned of training, the staff acquires general, common, and repeatable knowledge for the implementation of many projects in the field of the system of acquiring, operating, and withdrawing SpW of the Armed Forces of the Republic of Poland, the life cycle of SpW, project management in the organization, team management, arms cost accounting, the armaments market and defense technologies, logistic systems and processes, the system of obtaining the foreign assets in NATO and the EU, the quality management system in accordance with the AQAP requirements in the process of acquiring foreign resources, Prince 2 Foundation. Each member of the project acquiring SpW should be a graduate of the above-mentioned courses. The reality indicates a 50% implementation rate for this postulate.

The main stakeholders of the military equipment acquisition subsystem (identification, analytical-conceptual and implementation phase) are the Minister of National Defense, the Secretary of State in the Ministry of National Defense responsible for technical modernization, the Chief of the General Staff of the Polish Armed Forces, the Director of the Armament Policy Department, Organizers of Functional Systems, the Chief of the Armament Inspectorate, the Chief of Inspectorate for the Armed Forces Support, SpW Chief executives (a unit or an organizational unit of the Ministry of National Defense, as well as an internal unit responsible for defining the directions of the SpW development in the Armed Forces of the Republic of Poland, as well as organizing the implementation process and determining the operation, including combat use, and specific withdrawal processes), central logistic authorities (COL - a unit or organizational unit of the Ministry of National Defense, and their internal unit, responsible for organizing operation processes and training technical specialists for specific types of SpW), the Director of the Military Center for Standardization, Quality, and Codification, and the Heads of District Military Representations.

The above-mentioned stakeholders decide on sending participants of SpW acquisition projects to the standardized and JIT-T pieces of training. SpW Chief xecutives (user training) and COL (operator training) play a special role in the needs of JIT-T.

The cost structure of acquiring SpW includes the costs of the logistics package and the training package. As part of the logistics package, technical personnel's training is provided. However, as part of the training package, user training is most often carried out. Training costs most often include expenditures on training users and operators, trainers, stands, simulators, and IT systems. Competency and training needs, and training costs, are strictly dedicated to individual projects.

As part of the acquisition of the high-mobility medium-capacity vehicle Jelcz 442.32 (950 items), the training of technical personnel (at the instructor level) was carried out in plants producing key vehicle components (including MTU - engine, Axeltech - drive axles, ZF - gearbox, transfer case, steering

gear, WABCO - brake system). Five people who participated in the above-mentioned trainings received the qualifications of certified instructors (currently there are two remaining in the service, who can train other instructors).

The training of mechanics in the field of construction and operation of vehicles in the number of 2 mechanics for each 40 vehicles delivered is carried out comprehensively once a year; it lasts for 4 days at the Logistics Training Center and 5 days at Jelcz Sp. z o.o. On the other hand, user training (8 hours at the manufacturer's) is carried out as part of each delivery / transfer of the vehicle with 1 person (driver) for each vehicle. Drivers, most often users of the Star 266, report postulates to extend this training due to the much greater design and technological complexity of the vehicle.

The Impact of Training on The Implementation of Projects - Results of Direct Interviews

Face-to-face interviews took place in the years 2018-2020. The long period of research resulted from the fact that the interviews were conducted separately in various industries and were always one of several segments (threads) of complex research related to human capital management.

In October and November 2018, the Association of Business Services Leaders (ABSL) made it possible to conduct a study, which covered six managers of transition projects from the IT, banking, logistics, and financial sectors. Projects of transition in business are seen as projects related to the establishment of Business Process Outsourcing Centres (BPO), Shared Services Centres (SSC), IT Centres or Research and Development Centres (R&D).

The respondents pointed out that the key factor of the success of the transition is the training tailored to the individual phases of the project and the entities involved. The training topics included issues of employees' resistance to changes, negotiations, conflict resolution, building commitment and trust, counteracting professional burnout, and multicultural management. Training courses for employees (both on the part of the acquired entity and the acquiring entity) regarding the essence of the transition and the consequences of its implementation, i.e., direct impact on employees and the way they perform their work, were also significant. Training in the so-called hard competencies related to the subject of the transition, i.e., legal, financial, organizational, and IT matters, etc. was essential as well. Competency gaps were noticed mainly on the side of transition managers, who were expected to acquire soft and subject hard competencies, as well as hard skills related to project management.

Based on the analyzed investments an expert in the development (construction) industry indicated the relationship between the training system and the project implementation effectiveness. In the enterprise he runs, all employees are systematically trained every four months in the field of quality standards operating in the organization. Such a system counteracts potential defects on the construction site, and also contributed to the reduction of the number of complaints by 70% and made it possible to reduce the staff of the warranty service. According to the respondent, the main beneficiaries of trainings should be site managers. However, the scope of training must include both soft skills (especially organizational and negotiation skills) and traditional technical training in strictly construction knowledge and skills. In practice, both types of training are often delivered together as complementary or as a result.

Eight board members of development companies, who participated in the focus study organized in 2018, formulated similar conclusions (Rostkowski, Kawecki, 2018). Managers of real estate development companies decided that the trainings constitute a strong element of the employee motivation system. Unfortunately, the 2019 quantitative study on a group of 96 site managers and 24 board members of 18 development companies listed on the Warsaw Stock Exchange proved that in practice 22% of companies do not train employees, which translates into an increase in the number of defects reported by customers (Kawecki, 2019).

The IT industry seems to be the best experienced and trained industry in project management. Nonetheless, also there the respondents (project managers) indicated shortcomings. First of all, the trend of managing projects using new methods, e.g., scrum, turned out to be a trap. The threat results from the inept use of these methods, and above all, team members' lack of knowledge about them. The project manager is often the only person who knows the assumptions of the method; unfortunately, it happens that even he/she has no experience in this field. Therefore, a problem begins when the team members do not understand the style of work. What is worse, the methods of cooperation are also not understood by external entities (e.g., employees of the client or subcontractors).

The new project management methodology is also related to the IT system for project implementation monitoring. The respondents (members of project teams) indicated that in the crowd of work, employees forget about training in the use of these systems, they do not explain the rules of document circulation (especially creating and archiving project documentation) and the related rules in the field of internal (in the project team) and external (with entities outside the team) communication.

The respondents (both project managers and team members) pointed to a gap related to a very important element of the project, which is the valuation of individual works (tickets); employees at various stages of the project are asked for this quote. Although the valuation affects the price offered to the contractor, it is often performed under time pressure and by an employee who does not know the rules that should be followed when estimating labor costs. Employees who evaluate tasks (tickets) under the agile methodology have a similar problem.

From the point of view of employees, the neglected competency gap is the ongoing updating of specialist substantive knowledge, for example, resources are not foreseen for a) renewing employee certificates or acquiring new ones, b) participation in industry conferences, c) subscription to magazines, reports, and industry channels, etc. A substantial neglect in the project life cycle is narrowing down the thematic training of end-users or limiting the preparation of manuals (instructions) to those available in paper and/or electronic form. Unfortunately, it also happens that a help desk is appointed; however, due to staff shortages or cost reduction, the people employed there are not specialists but also use instructions.

Multidimensional Analysis of "STOP Costs"

The training strategy is classified as functional; hence it should be related to the general strategy of the enterprise. In addition, it was assumed that, in accordance with the applicable rules and best strategic management practices, the training strategy should contain goals and directions that will become the basis for creating operational plans specifying such elements as the subject of the training, defining the target group (training entities), time and place of training, forms, methods and tools, training assessment indicators, and evaluation of training outcomes.

However, any work on the strategy should be preceded by a strategic analysis, and in the case of a training strategy, an analysis of competency gaps and training needs (existing and potential). When designing a tool for multidimensional analysis of potential competency gaps, the authors used a combination of methods and tools known in management sciences, namely **S**takeholders Mapping, **T**raining needs analysis, **O**bjects maintenance, and **P**roject Life Cycle. The working name of the tool "STOP" was created using the first letters of the above-mentioned elements. Since the tool is designed to reduce and/or eliminate costs in projects, the above-mentioned the name "costs" was added.

The tool takes the form of a matrix (Table 2), which is the basis for a detailed analysis of the needs of its individual cells (fields of intersection of matrix dimensions). The procedure of using the tool consists of twelve stages, referring to indication of: project phases, stakeholders, competency gaps, training needs, groups of topics, agendas, syllabuses, cost estimation, division of responsibility,

training activity, monitoring, training evaluation, training efficiency evaluation. The first and at the same time key step is the specification of the project phases, i.e., adjusting the number and naming of phases to the specificity of the project. One can leave the names presented in the formula (Table 2) but due to the fact that individual industries may use a different language, appropriate verification is recommended for better communication in the project team and the project environment. It is crucial to include the pre and post-project phases in the project life cycle. The level of detail is left to the tool users. The second stage of the procedure is listing the stakeholders of the project; in the initial phase of creating the list it should not be assumed that all the indicated persons are to be trained. A heuristic approach resulting in a suitably complete list of entities is recommended.

The third step is to analyze the competency gap in individual cells of the matrix. Each cell of the matrix is tested. A cell can be assigned a value equal to 0, which means that: a) a given stakeholder does not participate in the indicated phase of the project; b) no competency gap was identified. The fourth step is to decide which gaps are to be closed by supplementing or updating knowledge, i.e., training needs are identified. To avoid duplication of training for several stakeholders, in the fifth step the needs is rationalized by grouping them in terms of thematic and time. The training is then introduced into the overall project schedule to keep it in sync with other project tasks. Simultaneously, work can already be carried out on the development of syllabuses, which mainly define the subject of training, group size, methods, techniques, and forms of training.

The requirements specified in the syllabuses should form the basis of the training valuation. It is also recommended to separate funds for JIT-T. An essential stage in creating a training strategy (especially in the case of projects realized with entities or for external entities) is to specify who is responsible for organizing individual training, and most importantly, who will bear the cost, while maintaining the requirements specified in the syllabuses. An indicated person(s) who is a member of the project should monitor the quality and timeliness of training organization. Monitoring is to be carried out during the project duration, not after its completion. Organizational monitoring should be supplemented by efficiency monitoring, i.e., checking whether training participants acquire competencies and, more importantly, perform the tasks entrusted to them in the project.

Table 2: The exemplary matrix of training needs diagnosis of including project key stakeholders

Phase of a project / Stakeholder	Analysis 1	Performance 2	Implementation 3	Exploitation 4	Withdrawal 5
DM - Decision makers	DM_1	DM_2	DM_3	DM_4	DM_5
PM - Project manager	PM_1	PM_2	PM_3	PM_4	PM_5
PTM - Project team members	PTM_1	PTM_2	PTM_3	PTM_4	PTM_5
PCS - Project control staff	PCS_1	PCS_2	PCS_3	PCS_4	PCS_5
C - Coach / mentor	C_1	C_2	C_3	C_4	C_5
SFU - Support of final users	SFU_1	SFU_2	SFU_3	SFU_4	SFU_5
MS - Maintenance staff	MS_1	MS_2	MS_3	MS_4	MS_5
FU - Final users	FU_1	FU_2	FU_3	FU_4	FU_5

Source: own study

Conclusion

The presented research results indicate the relationship between the training of project stakeholders and the effectiveness of the project implementation. The need for training and acquiring competencies should be determined and implemented in accordance with the phases of the project life cycle. Training should be provided to all stakeholders, not only project managers, to ensure a holistic approach to the project, which may, for example, eliminate the reduction of project implementation costs by reducing the cost of training needs (frequent practice in acquiring SpW). The tool determining the competency and training needs of the project stakeholders should be programmed in accordance with the suggested steps in the procedure for using the "STOP costs" tool. The "STOP costs" tool should be implemented collectively, with the participation of PM and selected team members, including external companies. As part of the project task fulfillment, it is necessary to create conditions for knowledge sharing, knowledge transfer, and creating teams of internal trainers or mentors.

In order to continue the research work related to determining the effectiveness of the above tool in economic practice, the following hypothesis was formulated: it is possible to eliminate the problem of underestimating the costs of training in project management through the use of multi-dimensional "STOP costs" analysis. The hypothesis will be verified in the course of further quantitative research.

Abstract

The article develops methodological aspects of managing innovative activities in networked production systems, including: identifying the challenges of transforming the infocommunication nature of managing modern production systems in the digital economy; the conceptual apparatus of the innovation management system in networked production systems has been expanded; a comparative analysis of project management in non-network and network production systems is carried out, as well as the distinctive features of the categories "production and trading networks" and "network production systems" are shown; revealed the features of material and technical support in traditional and network production systems; the characteristics of the prospects of networkization of the production system of an industrial holding are given on the example of enterprises of the radio-electronic industry.

Keywords: Network, Production System, Digital Economy, Ecosystem, Infrastructure, Freedom, Competition.

SNEGURENKO "Methodological Aspects of Innovative Activity Management in Network Production Systems" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Introduction

The digital economy is qualitatively changing the nature of interfirm relations, as well as the model of relations between producers and consumers. Modern companies strive to create smart production systems that operate on the principles of a networked economy. At the same time, the global market is considered as consumers and suppliers of resources. The network becomes an ecosystem for the formation of consumer values, which creates conditions for a plurality of goal-setting systems. This leads to a shift in emphasis from the competition of innovative products to the network competition of innovative management models [1]; the need to operate with very large data; a radical acceleration of the change of technological orders; the emergence of new consumption patterns; desire to have a high level of personal freedom.

The need to take into account the plurality of goal-setting systems leads to a contradiction of traditional models of innovation management with modern market demands for the ways of organizing human interaction and the need to create fundamentally new organizational structures that allow working in conditions of multi-parameter and multifunctionality of interaction between innovation participants.

The purpose of the article is to develop methodological aspects of innovation management in networked production systems in the context of digitalization of production management processes and the development of new consumption patterns.

Objectives of the article:

1. Identify and characterize the challenges of transformation of the infocommunication nature of the management of modern production systems in the digital economy.
2. To expand the conceptual apparatus of the innovation management system in networked production systems.
3. Conduct a comparative analysis of project management in non-network and network production systems, as well as show the distinctive features of the categories "production and retail networks" and "network production systems".
4. Identify the features of logistics in traditional and networked production systems.
5. To characterize the prospects for the networkization of the production system of an industrial holding.

Research Part

Modern production is characterized by extremely heightened competition, the expansion of markets far beyond the borders of one state or even a continent, significant volatility in demand and heterogeneity. The effective use of the heterogeneous market and resource advantages of individual industries and their digital management as an interconnected production system in geographically distributed production centers, united by a single network, is becoming an imperative today for most large manufacturers of goods and services. Applying the concepts of manufacturing networks in practice allows you to structure globally dispersed operations and combine them into a single structure that ensures the creation of customer value. This leads to the transformation of the infocommunication nature of modern industries and, as a consequence, the development of networked production systems. The network is understood as scattered production with matrix connections, where individual production centers influence each other, and therefore cannot be controlled in isolation [3]. All these complex multifactorial processes increase competition in the markets, expand the boundaries of competition to a global scale and present manufacturers with modern challenges, ignoring which can lead to partial or complete loss of market share in which the company can operate with confidence at the moment.

According to the author, the most significant challenges of transformation of the infocommunication nature of the organization and management of modern industries are the following [2]:

1. Development and active use of smart grids and control systems, which, at the global level, transform the conditions for the implementation of economic activities by business entities.
2. Formation of a new technological order in the global system of industrial relations, based on the widespread use of automation and intellectualization of production facilities, including: big data; internet of things; 3D printing; printed electronics; quantum computing; distributed ledgers (blockchain); autonomous robots, etc.
3. Creation of new methods and technologies for organizing production, based on additive technologies, involving a fundamentally different principle of shaping based on layer-by-layer production. This approach allows you to create an unlimited number of variants and types of products and ensure a level of zero waste in production.
4. Development and widespread use of artificial intelligence in production processes, which changes the usual perception of human functions in almost all areas of his activity.
5. Digitalization of production leads to the blurring of the boundaries between Bio, Social & digital reality, which is expressed in the rapid development of Internet of Things (IoT) technologies, which radically transforms the nature of production and economic relations.

In this regard, in the modern world, the competition of goods and services is inferior to the competition of production ecosystems. In other words, production systems today and in the future must be able to create new meanings for completely different categories of consumers. Manufactures become personalized and at the same time their technologies and formats of interaction with consumers are unified.

The format of the relationship between producers and consumers, aimed at the continuous formation of new consumer meanings through the interactive involvement of resources of the internal and external environment in this process, in the author's opinion, can be provided by network production systems that are more focused on collecting and analyzing information about consumers, the formation of personal commercial offers for various categories of clients, and also have the technical capabilities to effectively organize mass creativity, including consumers in the creative process.

The use of the intelligence of society can be considered as a significant reserve for increasing the efficiency and flexibility of the functioning of networked production systems. At the same time, the intelligence of the network society depends on the social intelligence of the network participants, as well as on the level of development of the ecosystem of open network production. The definitions of the expansive differences of the proposed terms characterizing networked production systems are presented in Table 1.

Table 1: definition of expansive differences of the proposed terms characterizing networked production systems

Term	Definition
1	2
Network effect	Results jointly created by network participants for each other when using network products or services, which ensures changes in the levels and degrees of their network freedom
Network freedom of participants	Freedom of participants in networked production systems in choosing the parameters of interaction with each other in the network with the ability to determine and accept the associated risks and obligations
Number of degrees of network freedom	The minimum number of independent variable parameters required for a complete description of the state and movement of the network subject
Social intelligence of network participants	Abilities of a participant in a networked production system, which determine the success of network and off-network interaction with other participants, including systems of the external environment.
Intelligence of a networked society	The collective intelligence of the network, allowing to find the most effective solutions to the problems of networked production systems.
Network culture	The activity of network subjects in various manifestations, including all forms

	of self-realization and self-development, the accumulation of social intelligence and their integration into the intelligence of the network society.
Network space	Part of the global information space within the communication boundaries of networked production systems.
Network Infrastructure	A subsystem of the network economy that provides general necessary and equally accessible conditions for the functioning of networked production systems.
Ecosystem of networked innovation	An open production network communication material-field environment that has the properties of self-organization, self-regulation and self-development, which allows you to create competitive value propositions for market participants.

The networkization of production systems is based on the formation of the intelligence of a networked society, which ensures the implementation of the key values of participants in networked production systems in the freedom of self-development and self-realization. The rate of development of social intelligence of participants in a network depends on the ecosystem of networked productions, which generate fields that attract or repel the networked society. Thus, social intelligence is a substance, and the ecosystem of networked productions is a field, which together form a material-field force aimed at creating the intelligence of a networked society.

The development of production technologies is aimed at the active involvement and use of the intelligence of the network society in production systems, the integration of which occurs, including through the collection, storage and processing of big data (Big Data technology). Large companies actively use big data to form and implement their business strategies, as well as at the level of making standard operational decisions. This fact is confirmed by studies of Russian and foreign analytical centers. So, according to the statistical analytical collection "Indicators of the Digital Economy: 2019", which is published by the HSE Research University at the end of each year with the participation of Rosstat and the Ministry of Communications. In addition, according to the results of the activities of the Cornell Research University Consortium, INSEAD - the School of Technological Bidness and the World Organization for Intellectual Property Management, the volume of the global big data market in 2018 was already estimated at 38 billion US dollars, and by 2025 this figure will reach 132 billion. US dollars. At the same time, the global volume of digital data will amount to 175 zettabytes by 2025. By comparison, the global digital data volume in 2018 was 33 zettabytes. According to the above-mentioned analytical center, the drivers of the world big data market are the growth of information transfer speed and an increase in the capacity of information storage facilities; reduction in data storage costs; lowering barriers when using cloud services for data processing; increased interest in educational tracks on big data theory and, as a result, an increase in the number of specialists in this area; a radical increase in the amount of available data, including unstructured data; a sharp increase in the number of objects of the Internet of things. The speed of change in the global manufacturing field forces manufacturers to constantly use new knowledge, including those based on big data analytics, in order to maintain their presence in the markets and develop new directions.

The key competence of managers in a network production system is the ability to organize the mass creativity of interested, neutral and disinterested people, whose purposeful mental activity forms the intelligence of society.

As a rule, a project-based approach to managing the development of an organization's innovations is implemented in networked production systems [4]. A characteristic feature of project management of innovation activities in networked production systems is peer-to-peer simultaneous interaction on the principle of "many-to-many", establishing links on a short-term basis without the cost of maintaining them, high speed of information dissemination, availability of a large number of resources, the ability to share costs between participants, flexibility and stability of the production system, constant communication with the consumer, a sharp reduction in the number of management links, a decrease in the cost of promoting innovative products, the presence of a higher probability of interaction, a sharp decrease in barriers to interaction, including psychological (Table 2).

Table 2: Comparative characteristics of project management in offline and networked production systems

Comparison criteria	Off-grid production system	Networked production system
Number of potential participants in innovative projects	Determined by the classic controllability rate, usually up to 10 participants	Directly proportional to the square of the number of network nodes according to the law of network economy
The likelihood of implementation of innovative projects	It is determined by the product of a limited number of centers of activity by their level of their innovative activity	It is determined by the product of the expanded number of activity centers by their level of their innovative network activity
Number of initiated innovative projects	Determined by a variety of interests, intellectual experience and social intelligence of individual participants in the system	Determined by a variety of interests, intellectual experience and intelligence of the network society
Quality of initiated innovative projects	Limited by the financial capabilities of the initiator of the innovation and his ideas about quality	Increased by pooling financial resources of network participants, quality is determined by general requirements
Probability of creating market value in demand	Depends on the level of predictive abilities of the participants of individual participants in the system	Increases proportionally with the growth in the number of network participants
Company risk level	Increases sharply if the demand of the target group changes	Decreases sharply depending on network scale
Asset utilization rate within the framework of innovation implementation	Work under uneven load conditions with peak voltages and sharp drops	Load balancing occurs due to the network resource and the connection of other network participants
Distribution of risks in the implementation of innovations	Weak uneven distribution with concentration of risks in separate elements of the system	The concentration of risks in individual elements of the network production system is excluded
The number of assets used in innovative projects	Determined by the capabilities of a limited number of participants in innovative activities	Increases dramatically due to the expansion of the volume of resources involved in innovation activities
The nature of interaction in the field of innovation	Multi-rank interaction with a strict delineation of rights and powers in decision-making	Peer-to-peer interaction with the differentiation of rights and powers in decision-making based on chaos management methods.

The highlighted properties of networked production systems create conditions for the formation of flexible organizational structures with such characteristics as: a large number of participants; heterogeneity of participants; the goal-setting systems of the participants are not always consistent with each other, they may contradict each other; difficultly predictable activity of participants in time and in network space; the object of management is a whole group of homogeneous or heterogeneous processes; many decision-making centers that affect many directly unrelated processes at once; a high degree of interconnectedness and interdependence of decisions from each other.

Networked forms of innovative project management provide some competitive advantages for manufacturers who want to obtain additional production effects through the use of network resources. The Internet is becoming a limitless platform and field for implementing innovations in the digital

economy; competition is shifting to the sphere of digital competencies for managing innovative technologies.

At the same time, the concepts of production and trading networks and network production systems should also be separated. Manufacturing and distribution networks are sprawling and geographically standardized manufacturing systems. The emergence of networked production systems is associated with a qualitative change in production and economic relations on the basis of: high liberalization of participants and consumers; a decrease in the role of administrative management, replaced by artificial intelligence; transformation of the notions that production is the totality and concentration of the production capacities of a company and its personnel located in certain territorial areas into the idea that the information space on the Internet can be a platform for placement and effective functioning, which can connect isolated and independent subjects who have objects and / or means of labor in the ownership or on other conditions, as well as having the necessary competencies to perform specific production tasks on a temporary basis. Comparative characteristics of the categories production and trading networks and network production systems are presented in Table 2.

Table 3: comparative characteristics of the categories "production and trading networks" and "network production systems"

Characterizing feature	Production and retail chains	Networked production systems
State of the art	Have received rapid development in the past few decades in connection with	They are actively developing in areas, the effectiveness of which significantly depends on information technology
Development potential	The development potential of production and retail chains has been largely exploited, the development is aimed at intellectualizing production management	There is significant potential for the development of networked production systems, due to the development of the digital economy
Distinctive feature of the network	Active use of informatization of production processes to improve manageability	Active use of artificial intelligence for automatic network management
The nature of network management	Organization and optimization of production processes in the network based on the collection and analysis of information in the form of big data	Creation of conditions for the development of the network as a self-adjusting and self-governing system, where big data is a necessary condition for the operation of artificial intelligence
Degree of freedom of participants	The network participants work in a hierarchical system under conditions of fairly strict administrative control	Network members have a high degree of limited freedom, restrictions on entry and exit of their network and the schedule of working in the network are reduced

Business digitalization leads to acceleration of production processes with a significant simplification of the availability of information [5]. The formation and development of network production involves the formation of a new economic entity that provides a platform for interaction between network participants in order to form and distribute network values. It is difficult to imagine a modern company that has achieved high results in production and economic activity, as a result of the hard work of many employees who work to create corporate success, whose plans do not include the development and expansion of the market presence and increase in market capitalization. As a rule, such companies are building strategies for the development of their representative offices in the form of network formations. So, the most active distribution of network forms of production and economic relations were in the areas of trade, as well as various services, including banking. According to the author, there are reasons to believe that real production spheres are prepared for networkization,

which allows predicting the spread of network technologies and models of network business development. This is largely due to the rapid development of automated company management tools, the possibility of switching to 3D printing of material objects, the use of a large amount of data when the company operates in the markets, the modernization of the company management model, the creation of unique materials, etc.

The high degree of openness of the networked production system provides access for a large number of suppliers, performers and consumers to the network. In this regard, the restrictions on the use of certain types of resources existing in traditional production systems can be lifted provided effective and creative methods of their involvement in the network. The network model of the organization of production requires a wide variety and availability of various types of resources, including information, financial, labor, intellectual and others. This is a distinctive feature of network production, which provides them with a competitive advantage compared to offline production and leads to increased efficiency of resource use.

Continuity of production requires timely supply of resources of the required quality and in the right quantity for various consumers [6]. In traditional production systems, continuity is achieved by diversifying suppliers. For this, a long-term contractual relationship is established. At the same time, a high probability of deliveries is ensured as a result of acquiring a certain experience of interaction with suppliers. To increase the likelihood of supply and guarantee of sale, interaction with an unlimited number of suppliers, performers and buyers is carried out. At the same time, the probability of obtaining the required amount of resources from a separate supplier, performing work by a separate performer or making purchases to individual buyers can be quite low. However, the overall probability increases due to the fact that the number of subjects in the network is much wider than in the out-of-network form of organization of production. Features of the characteristics of logistics in traditional and networked production systems are presented in Table 4.

Table 4: features of logistics in traditional and networked production systems

Specifications	Traditional production system	Networked production system
Link types	One with many	Many with many
Interchangeability of resources	Limited interchangeability for certain types of resources	Polyresource - mandatory interchangeability of a wide range of resources
Diversification of suppliers	Increases the likelihood of supplying resources	Provides a high probability of supply of resources due to networkization of suppliers
Sales diversification	Increases the likelihood of product sales	Provides a high likelihood of product sales due to networked buyers
Interchangeability of products	Interchangeability at the whole product level	Interchangeability at the level of product parts

The hallmark of logistics in networked production systems is the sophisticated type of fast many-to-many links that require high speed transitions from one resource to another, as well as providing a wide product line for shoppers with dynamic customer requirements. This makes it possible to increase the reliability of interaction and the stability of material and technical support and the speed of updating technologies in the network production system through the use of organizational resources of the external environment, ahead of setting higher standards of interaction, as well as increasing the mobility of production.

One of the striking examples of the formation and development of its own network production system is the innovative activity of Russian enterprises of the radio-electronic industry, which are united by the vertically integrated company Joint Stock Company "Concern of Radio-Electronic Technologies" (hereinafter referred to as the concern). The concern includes more than 70 Russian industrial enterprises engaged in the development and production of radio-electronic products for both military

and civil purposes. Today, the enterprises that are part of the concern supply their products to various countries of the world, the total number of export destinations is more than 30 countries.

The digital economy opens up new opportunities for the group to collaborate in the field of innovation with other enterprises of various sizes and scales of activity. In this regard, the chain is considered by the concern as a factor in maintaining the existing market share and developing new segments. Based on competencies in the current segments of its presence, the Concern will enter the most important segments for the state and implement additional market opportunities based on network development and integration of its production systems.

Analysis of the dynamics of the development of the Russian radio-electronic industry showed that the concern is switching to a network organizational structure for managing production systems, which involves two directions of networkization of production:

1. Network as a more perfect control structure, featuring increased flexibility, stability and robustness;
2. Network as a new form of accelerated collaborative creation of new values that meet modern market trends.

The first direction allows to increase the flexibility and stability of the company management system. A characteristic feature of networked organizational structures for managing production systems is a high degree of adaptability of production subsystems to changes in the internal and external environment of the company. The network organizational structure of management may not enter into a rigid contradiction with the existing hierarchical management structure, but harmoniously fit into the practice of managing production processes due to the fact that network forms of interaction do not require constant expenditures of resources to maintain communication channels.

The second direction of networkization of the processes of creating and managing innovations in production systems provides, in the author's opinion, the possibility of solving the problem of single-product and narrow specialization of production systems of the Russian radio-electronic industry, as well as reducing the dependence on direct budget financing within the framework of the state defense order.

In this regard, the concern forms a network-centric business model based on a set of such parameters of production and economic activity according to the C4ISR principle, which assumes the effective organization of digital management of the production system, control, communication, collection and computer processing of information, surveillance and intelligence. Networkization is manifested in the fact that today conditions are being formed for the implementation of joint activities of enterprises of the radio-electronic industry with companies operating in various industries and types of economic activity.

Conclusion

The main conclusions of the research presented in the article are as follows:

1. The most common critical challenges of transformation of the infocommunication nature of management of modern production systems have been identified: active use of smart grids and control systems; the formation of a new technological order in the global system of economic relations; creation of new methods and technologies for organizing economic systems; development and widespread use of artificial intelligence; digitalization of production, which leads to blurring the boundaries between Bio, Social & digital reality. It has been established that the key competence of managers in a network production system is the ability to organize the mass creativity of interested, neutral and disinterested people, whose purposeful mental activity forms the intelligence of society. The maximum manifestation of the intelligence of society is possible in the conditions of liberalization of network relations in which the manifestation of the talents and abilities of network participants is organized in a tolerant network environment. It has been established that the

networkization of production systems, including on the basis of co-branding projects with leading world corporations, makes it possible to strengthen the role of domestic companies in the international division of labor in the implementation of projects for computer engineering of production.

2. The definitions of the broad differences of the proposed terms characterizing the network production systems are given, including: network effect; network freedom of participants; the number of degrees of network freedom; social intelligence of network participants; the intelligence of the network society; network culture; space of a networked production system; network production system infrastructure; ecosystem of networked innovation. It has been proven that networked production systems provide a wider range of opportunities for creating a qualitatively different production ecosystem aimed at maximizing the involvement of participants in the process of creating new values, including those that are exclusively characteristic only for networked forms of cooperation - networked values.

3. The characteristic features of the project management of innovative activities in non-network and network production systems have been identified by such characteristics as: the number of potential participants in innovative projects; the likelihood of implementing innovative projects; the number of innovative projects initiated; the quality of initiated innovative projects; the likelihood of creating a demanded market value; the level of company risks; the degree of asset utilization in the framework of the implementation of innovations; distribution of risks in the implementation of innovations; the number of assets used in innovative projects; the nature of interaction in the field of innovation. For networked production systems, a characteristic feature is highlighted - the presence of active open digital platforms for automatic or semi-automatic production control in the network.

4. The features of resource management of innovation activity in networked production systems operating on the principle of "many with many" are revealed. It has been established that network interaction can improve the reliability of interaction and the sustainability of organizational and resource support for innovation in networked production systems, increase the rate of technology update through the use of organizational resources of the external environment, ahead of setting higher standards of interaction, as well as increasing the mobility of production.

5. Using the example of the Russian radio-electronic industry, the advantage of network cooperation in such areas as: transport, health, safety, etc. is shown. For this, the integration of enterprises of the radio-electronic industry takes place on the basis of a network organizational structure of management, which involves two directions of network of production: the network as a more perfect structure control, characterized by increased flexibility, stability and robustness; network as a new form of accelerated collaborative creation of new values that meet modern market trends.

Abstract

The digital economy makes new demands on the models of company management, demands from them fundamentally new approaches to innovation, including in the field of innovative entrepreneurship. Among the important prerequisites for the network transformation of the innovative activity of modern production systems in the digital environment, the author attributed the following: the emergence of new technological structures; the emergence of new models of innovation management based on the development of organizational and communication mechanisms; expanding the availability of resources in the digital environment and increasing the economic freedom of participants in innovative activities.

Keywords: Network, Production System, Digital Economy, Ecosystem, Infrastructure.

Introduction

The network production system involves the formation of an ecosystem of generation and resource support for innovation in the network. The critical element of the ecosystem is the following

GAREEV "Conceptual Aspects of Innovation Management in Offline and Networked Production Systems" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

functionality: methodological and instrumental support for innovation; high-quality examination of projects; involvement in the network of people and resources necessary for specific projects; organization of effective interaction of subjects of innovation. The quality of the ecosystem is essential to ensure the efficiency and continuity of the networked production system and innovation within its framework. Among the important functions are the following: formation of a personnel reserve of innovative activities in networked production systems; the formation of a social lift for participants in innovative activities in the network; ensuring flexibility of motivation of participants in innovativeactivities based on identifying and supporting the talents of each; the ability to localize resources within the framework of the implementation of individual stages of projects in terms of time and volume; navigation of personnel and resource support for innovation in networked production systems.

According to the author, the key characteristics of networked production systems are the following parameters for organizing innovation in a networked format:

1. The number of potential participants in innovative projects.
2. The likelihood of implementing innovative projects.
3. The number of innovative projects initiated.
4. The quality of initiated innovative projects.
5. The likelihood of creating a market value in demand.
6. The level of company risks.
7. The degree of asset utilization as part of the implementation of innovations.
8. Distribution of risks in the implementation of innovations.
9. The number of assets used in innovative projects.
10. The nature of interaction in the field of innovation.

Research part

One of the most important distinguishing characteristics of network innovation in production systems is the number of participants involved in network innovation and the number of potential participants who can be involved in it. The principal position of the author is that there is much more opportunity in the network to involve human capital in network innovation, which makes it possible to increase the likelihood and efficiency of using the intelligence of the network society for the purpose of innovative development of the company. Outside the network production system, the number of participants is determined by the classical norms of controllability; completely different laws work for the network. So, according to Metcalfe's law, the number of potential participants in innovative activity in a network production system is proportional to the square of the number of nodes in the network. Increasing the efficiency of innovation in the digital economy, according to the author, is associated with an increase in the number of network participants, as well as the creation of a system for motivating network participants to innovative activities. The formation of competitive advantages of production systems in the digital economy is directly related to the use of technologies for integrating the social intelligence of participants in innovative activities in the network and the maximum realization of the intelligence of the network society for the qualitative growth of the parameters of innovation.

Another important parameter of innovation in the network in production systems is the likelihood of initiation and implementation of innovative projects aimed at increasing the innovative activity of production systems. In the author's understanding, in non-network production systems, the probability of initiating and implementing innovative projects is determined by the product of a limited number of activity centers by their level of their innovative activity. At the same time, the probability of initiation and implementation of innovative projects in networked production systems is determined by the product of the expanded number of activity centers by their level of their innovative network activity. The author relies on modern studies of network formations, which made it possible to identify one of the most important characteristics of innovation in networked production systems, which is that the active use of network resources can create a fundamental opportunity for initiating innovative projects, improve the quality of solutions in the field of innovation, and accelerate implementation processes. innovative projects through the use of digital management technologies.

Increasing the likelihood of generating innovative projects by enhancing the innovative activity of network participants creates additional opportunities for the growth of the number of innovations. The number of ideas that can form the basis of innovation determines the innovative activity of production systems. At the same time, it is not at all necessary that all these ideas end with the implementation of production and other innovations. In some companies, on the contrary, as a measure of the effectiveness of innovation, they use such criteria as: the number of their own ideas that did not stand up to criticism; the amount of working time used to implement the employees' own ideas, etc. The increase in innovative ideas creates the basis for creating a database of directions for innovative development. The use of scientific approaches to the analysis of information, such as addition, product, division, difference, hybridization and others, allows you to create an unlimited number of innovative projects, as well as create conditions for the implementation of human capital in the production system. The involvement of artificial intelligence resources increases the speed and ability to make informed management decisions in the implementation of the innovation strategy. The author's approach is based on the assumption that in non-networked production systems, the number of initiated innovative projects is determined by the diversity of interests, intellectual experience and social intelligence of individual participants in the system. At the same time, the number of initiated innovative projects in networked production systems is determined by the variety of interests, intellectual experience and intelligence of the networked society.

An important element of innovation in networked production systems is the quality of initiated innovation projects. In the author's vision, the network format of innovation activity allows using the intelligence resource of the network society to improve the quality of the company's innovative activity. At the same time, the basis of a networked society can be completely diverse network participants, including people involved and not directly involved in the networked production system.

The stages of quality assurance initiated by innovative projects in networked production systems are shown in fig. 1.

Fig. 1: Stages of quality assurance initiated by innovative projects in networked production systems

The quality of ideas and the ecosystem for the realization of the intelligence of a networked society form the basis of the innovation activity of the networked production system and characterize the innovative potential of the networked production system. Ensuring the quality of initiated innovative projects requires the formation of a system consisting of the following stages: chaotic generation of innovative projects; intellectual selection of innovations; network testing of innovations, digital implementation of innovations in production and economic activities; operation of products of innovative activity, including on the principles of a joint economy; eco-efficient utilization of innovations in networked production systems.

To ensure quality, initiated projects in networked production systems is the stage of generating innovative ideas. A characteristic feature of this stage, according to the author, should be the removal of restrictions on the creative activity of participants in the innovation process. Formation of a base of innovative ideas, which can later be formulated as innovative projects, should be carried out in a controlled chaos. Thus, a significant increase in the number and quality of innovative projects can be achieved. To improve the quality of testing innovative projects, scientific institutions also acquire special importance as subjects of their own opinion regarding networked production systems and their innovative activities.
At the second stage, innovative projects are selected. As a rule, most of the generated projects at this stage do not stand up to constructive criticism. However, the ideas underlying innovative proposals can work to improve the quality of projects that have been selected. Information technology can make the selection process intelligent by using the resources of artificial intelligence.

At the next - third stage, network testing of innovative projects takes place, with the maximum involvement of the social intelligence of network participants. The production system creates conditions for accelerated and semi-automatic testing of innovations. Innovation activities in a networked production system can take place in research teams that can migrate across the network. The research team becomes an independent subject of innovation, which becomes more mobile in the network. Competition of innovative projects in the network is ensured on the basis of openness and increased availability of information. This significantly improves the quality of testing innovative projects and innovative products. The quality of testing can be improved by allowing network innovators to test the outcome of innovation in different roles. At the same time, in the networked production system, according to the author, there should be a reasonable structure of participants performing appropriate functions in innovation. Thus, the following classification of the roles of participants in innovative activities in the network is proposed : generators of innovative projects; critical analysts of innovative projects in the network; realists who carry out a balanced and comprehensive assessment of projects. At the same time, testing projects should involve evaluating projects based on a set of criteria. An excessive desire to evaluate projects solely on commercial criteria can cut off important projects that have significant potential for strategic development of the network production system.

The most important stage in ensuring the quality of network and innovation activities is the implementation of innovative projects. The network form of innovation makes it possible to increase the flexibility of the networked production system due to the fact that during the implementation of projects the set of project quality parameters can be adjusted, and the implementation can take place in conditions of unclear goals and results. At the same time, a high proportion of projects implemented in the network production system can be used as one of the criteria for the effectiveness of innovation in the network production system. In addition, an important element of ensuring the quality of innovation in the network production system are such parameters as: the quality of selected innovative projects; quality of elaboration of innovations; the quality of project management systems in the network, the quality of project implementation in the network, and others. Scaling up the implementation of projects can be carried out through the active use of digital technologies, which provide significant advantages to the production system. Digital is becoming a key element in ensuring the quality of networked innovation in companies.

The exploitation of products of innovation, including those created in networked production systems, is also an element of ensuring the quality of innovation in the network. The system for collecting information on the course of operation of products of networked innovation is of particular importance . The main characteristics of quality assurance of network innovation are the quality level of collection, storage and analysis of big data on the course of operation of innovation products. The information obtained during the registration of events related to the operation of the products of innovation is used to improve the quality of innovation in the future.

The environmental friendliness and efficiency of disposal of products created or created within the framework of innovative projects determines the quality of the organization of innovation activities within the network of production systems. Modern business, in our opinion, cannot but take into

account the ecological component of the created products, which is a characteristic of its social responsibility. In the author's vision, the utilization of the results of innovative activities should be without costs or with their minimum amount. The decision to dispose of products created as a result of innovative activities should be made as soon as possible. The ideal end result of such a system for recycling spent or ineffective elements of the ecosystem of innovation in networked production systems is an independent, if possible, forced exit of obsolete products and technologies from the system.

The author's approach is based on the proposition that in non-networked production systems, the quality of initiated innovative projects is limited by the financial capabilities of the initiator of the innovation and his ideas about quality. At the same time, in networked production systems, the quality of initiated innovative projects can be significantly increased by pooling the financial resources of network participants, the quality is determined by general requirements.

The network production system makes it possible to implement the concept of a joint economy to a greater extent, which ensures a higher degree of utilization of the company's assets that are involved in innovation. Joint investment in innovation, joint exploitation of resources in the field of the company's innovation and rational distribution of the effects of innovation, provides a significant increase in the efficiency of asset use and a significant increase in the return on equity of individual participants in network and innovation activities. In off-grid production systems, work is carried out under uneven load conditions with peak voltages and sharp drops. At the same time, load balancing occurs in networked production systems due to the network resource and the connection of other network participants.

The joint economy in the field of network innovation, in our opinion, makes it possible to reduce the overall project risks, and most importantly, to reduce the risks of individual participants in innovative activities. Reduction of risks for individual participants is ensured by reducing the volume of initial investment per participant, a higher level of utilization of labor resources and resource efficiency, as well as due to the increased flexibility of the network production system in the organization of the company's innovative activities. In non-networked production systems, there is an uneven distribution with a concentration of risks in individual elements of the system. At the same time, in networked production systems, the concentration of risks in individual elements of the networked production system is excluded.

The network provides, in the author's opinion, an expanded involvement of resources in the company's innovative activities. In this regard, fundamentally new opportunities appear for project participants and new horizons for specific projects open up. Such opportunities appear due to the wider involvement of resources in the company's innovative activities, including through such tools as crowdfunding , crowdsourcing , sharing costs , volunteering and volunteering, and others. In non-networked production systems, the number of assets used in innovation projects is determined by the capabilities of a limited number of innovation participants. At the same time, in networked production systems, the number of assets used in innovative projects increases sharply due to the expansion of the volume of resources involved in innovative activities.

A characteristic feature of innovation in networked production systems, according to the author, is the possibility of constructing a model of interaction between participants of innovation activity, possessing th th possibility of providing increased freedom of members of the network. Off-grid production systems have a relatively rigid structure for managing processes in the implementation of projects, including innovative ones. In non-networked production systems, as a rule, the multi-rank principle of communication is used. Under the authority of the author, the rigidity and hierarchy of the organizational structure of innovation management reduce the speed of processes in the implementation of innovative projects. The peer-to-peer communication model implemented in the network allows to increase the speed of generation, selection, testing and implementation of innovative projects. In non-networked production systems, the nature of interaction in the field of innovation involves multi-rank interaction with a strict delineation of rights and powers in decision-making. At the same time, in networked production systems, the nature of interaction in the field of innovation involves peer- to -

peer interaction with the differentiation of rights and powers in decision-making based on chaos management methods.

Comparative characteristics of project management in non-network and networked production systems are presented in Table 4.

Table 4: comparative characteristics of project management of innovative activities in non-network and network production systems

Comparison criteria	Non-network production system	Networked production system
Number of potential participants in innovative projects	Determined by the classic controllability rate, usually up to 10 participants	Directly proportional to the square of the number of network nodes according to Metcalfe's law
The likelihood of implementation of innovative projects	It is determined by the product of a limited number of centers of activity by their level of their innovative activity	It is determined by the product of the expanded number of activity centers by their level of their innovative network activity
Number of initiated innovative projects	Determined by a variety of interests, intellectual experience and social intelligence of individual participants in the system	Determined by a variety of interests, intellectual experience and intelligence of the network society
Quality of initiated innovative projects	Limited by the financial capabilities of the initiator of the innovation and his ideas about quality	Increased by pooling financial resources of network participants, quality is determined by general requirements
Probability of creating market value in demand	Depends on the level of predictive abilities of the participants of individual participants in the system	Increases proportionally with the growth in the number of network participants
Company risk level	Decreases sharply depending on network scale	Decreases sharply depending on network scale
Asset utilization rate within the framework of innovation implementation	Work under uneven load conditions with peak voltages and sharp drops	Load balancing occurs due to the network resource and the connection of other network participants
Distribution of risks in the implementation of innovations	Weak uneven distribution with concentration of risks in separate elements of the system	The concentration of risks in individual elements of the network production system is excluded
The number of assets used in innovative projects	Determined by the capabilities of a limited number of participants in innovative activities	Increases dramatically due to the expansion of the volume of resources involved in innovation activities
The nature of interaction in the field of innovation	Multi-rank interaction with a strict delineation of rights and powers in decision-making	Peer-to-peer interaction with the differentiation of rights and powers in decision-making based on chaos management methods

Thus: the characteristic features of project management of innovative activity in non-network and network production systems have been revealed by such characteristics as: the number of potential

participants in innovative projects; the likelihood of implementing innovative projects; the number of innovative projects initiated; the quality of initiated innovative projects; the likelihood of creating a demanded market value; the level of company risks; the degree of asset utilization in the framework of the implementation of innovations; distribution of risks in the implementation of innovations; the number of assets used in innovative projects; the nature of interaction in the field of innovation.
The following features can be attributed to the characteristic features of project management of innovative activity in non-network production systems : the number of potential participants in innovative projects is determined by the classical norm of manageability, as a rule, up to 10 participants; the probability of implementation of innovative projects is determined by the product of a limited number of centers of activity by their level of their innovative activity; the number of initiated innovative projects is determined by the variety of interests, intellectual experience and social intelligence of individual participants in the system; the quality of initiated innovative projects is limited by the financial capabilities of the initiator of the innovation and his ideas about quality; the probability of creating a demanded market value depends on the level of predictive abilities of the participants of individual participants in the system; the level of company risks decreases sharply depending on the scale of the network; the degree of asset utilization within the framework of the implementation of innovations; work under conditions of uneven load with peak voltages and sharp drops; distribution of risks in the implementation of innovations weak uneven distribution with a concentration of risks in individual elements of the system; the number of assets used in innovation projects is determined by the capabilities of a limited number of innovation participants; the nature of interaction in the field of innovation involves multi-rank interaction with a strict delineation of rights and powers in decision-making.

The following features can be attributed to the characteristic features of project management of innovative activity in non-network production systems: the number of potential participants in innovative projects is directly proportional to the square of the number of network nodes according to Metcalfe's law; the probability of implementation of innovative projects is determined by the product of the expanded number of activity centers by their level of their innovative network activity; the number of initiated innovative projects is determined by the variety of interests, intellectual experience and intelligence of the network society; the quality of initiated innovative projects is increased by pooling the financial resources of the network participants, the quality is determined by general requirements; the likelihood of creating a demanded market value increases proportionally with an increase in the number of network participants; the level of company risks decreases sharply depending on the scale of the network; the degree of asset loading within the framework of the implementation of innovations, load balancing occurs due to the network resource and the connection of other network participants; distribution of risks in the implementation of innovations, the concentration of risks in individual elements of the network production system is excluded; the number of assets used in innovative projects increases sharply due to the expansion of the volume of resources involved in innovative activities; the nature of interaction in the field of innovation involves peer- to -peer interaction with the differentiation of rights and powers in decision-making based on chaos management methods.

Conclusion

It has been established that the network forms of organizing innovation activities are non-alternative in the digital economy, due to the shift of competition between companies in the sphere of rivalry between management models and the desire of manufacturers to form and distribute network effects.

Formation of the systemic foundations of project management of innovation in networked production systems requires the development of scientific tools that allow identifying and measuring the parameters of interaction between innovation participants in the network, as well as creating conditions for the effective implementation of innovative projects in networked production systems. It should be noted the importance and possibility of ensuring a higher level of quality of innovation in networked production systems through, for example, the implementation of the proposed stages of ensuring the quality of project management of innovation. Thus, an increased level of quality of innovation in the network in production systems is ensured, in the author's opinion, can be ensured through the possibility

of using an expanded composition of participants in the testing process and innovations implemented within production systems. In this case, an open system of testing innovations in the network is assumed, which allows using the intelligence of the network society in the organization of innovative activities. Improving the accuracy of assessing the results of innovative activities provides, according to the author, to target the development of innovative products and predict the demand for them.

Abstract

The purpose of the study is to analyze the conditions for the development of the online education sector as the basis of the digital economy in rapidly developing countries (Russia, China, Brazil), as well as to assess its current state and growth prospects. The authors identified the advantages of online education in comparison with traditional education forms, also revealed the specifics of the development of online education in Russia, China and Brazil. The authors determined that China is the leader in the field of online education among the countries studied, and it is ahead of the world's leading countries in the development of certain segments of the online education sector. Russia shows a steady growth of online educational platforms and online higher education programs, however, the country faces a number of problems in terms of institutional, technical, personnel and methodological support. Brazil is characterized by rapid growth of online education in the higher education system (due to the removal of institutional restrictions and affordability), the share of students enrolled in online programs has reached almost 30% of the total number of students, while the number of applicants is also increasing. It is concluded that the development of online education in developing countries can be a tool for forming the intellectual basis of the digital economy.

Keywords: online education, developing countries, digital economy, human resources, e-education, MOOCs, educational platforms.

Introduction

Rapidly developing countries such as Russia, China, and Brazil (a leading part of the BRICS Association) are now seen as likely leaders in digital development on a global scale. Their potential is

Cite this Article as: Arthur A. MAKSAEV, Nurmagomed S. SURAKATOV, Tatyana G. SOBOLEVSKAYA, Sofia L. LEBEDEVA And Evgeniya K. KARPUNINA "Online Education in Developing Countries: A Comparative Analysis of the Development of the Sector in Russia, China and Brazil" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

quite high, and the level of development of information and communication infrastructure contributes to the effective dissemination and processing of information (Antipova and Rodionova, 2016). And given the slowdown in economic growth in most of the world's mature economies, experts predict a redistribution of the global landscape in the near future (United Nations, 2019b).

Education is fundamental to the digital economy development. Intensive generation and use of digital technologies is possible if there is a reliable basis in the form of a competitive education system, high-quality educational services that ensure the formation of specialists required for the digital economy, as well as the expansion of educational opportunities. However, such parameters of the education system are not available in every country.

However, in the context of digitalization, the development of the online education sector can probably become a real tool for increasing the educational and intellectual potential of developing countries. At the very least, the rapid growth of this sector (according to Statista (2020b), the global online education market will amount to 243 billion US dollars in 2022), the confidence and support of teachers and students around the world (more than 60% of teachers around the world support digital education models, and 92 % of students around the world are interested in personal support and information support for the degree process), as well as the large investments of companies in online educational services (in 2015 alone, more than $ 2.2 billion was invested in the development of more than 300 companies) emphasize the importance of online education in the processes of increasing the educational and intellectual potential of countries, as well as the level of their digital development (Education International, 2020).

Therefore, the analysis of the demand for online educational services, the current state of this sector, as well as the problems and prospects for its growth in rapidly developing countries require special research attention.

Methodology

The purpose of the study is to analyze the conditions for the development of the online education sector as the basis of the digital economy in rapidly developing countries (Russia, China and Brazil), assess its current state and growth prospects.

Research objectives:

1) identify the advantages of online education in comparison with traditional forms of education;
2) reveal the conditions for the development of online education in rapidly developing countries;
3) determine the current state of the online education sector in Russia, China and Brazil;
4) assess the prospects for the development of the online education sector as the basis of the digital economy and the possibility of overcoming existing growth constraints.

The topic of online education development is revealed in the research of Yuan and Powell (2013), Bauder (2012), Keegan (2013), Kentnor (2015), Vishneva (2019), Mozhaeva (2013).

Approaches to assessing the ICT infrastructure and technical equipment of educational institutions are presented in the works of Van Deursen and Van Dijk (2014), Vega et al. (2019).

The specifics of the use of modern digital technologies in the educational environment in different countries are presented in the publications Luckin et al. (2016), Rizzotto (2017); Greenspan (2015), Blaschke and Hase (2015).

The object of the study is a set of online education programs implemented in developing countries such as Russia, China, and Brazil.

In this study, online education is understood as the organization of educational activities at all levels of education using information technologies (computer-based learning technologies, interactive

multimedia, web-based learning, online learning), as well as technical means, including telecommunications networks that provide the necessary information through communication channels, interaction between students and teachers, who may be located in the same educational institution, or in different cities and countries. Methods of online education make significant changes in the generally accepted approaches to the educational process, as well as determine the removal of restrictions and increase the availability of education (Bolkunov, 2016).

Research methods: theoretical analysis method, comparative analysis method, economic analysis method, system approach.

Results

1) What are the advantages of online education over traditional education? Why can it be considered as a tool to increase the country's educational potential and create a basis for digital development?

First, online education allows to personalize the educational process and provide adaptive learning (in contrast to traditional educational institutions) (Kalyuzhny, 2017). This is possible thanks to the selection of suitable content and its adaptation to the abilities of each person.
Second, online education uses more interactive technologies and advanced media tools (tablets, screens, etc.), as well as augmented and virtual reality technologies.
Third, the cost of online education is lower than the cost of traditional education, which makes it more accessible to a larger population (Uvarov and Frumin, 2019).
Fourth, online education allows you to overcome geographical boundaries and meet the educational needs of different groups of the population, regardless of country or race.
These advantages have provided a rapid growth of the Learning Management System (LMS) market since 2012 (when the boom of educational startups in the world began), by 2019 the market size reached 198 billion US dollars (Vishneva, 2019), by 2022 it is projected to grow to 243 billion US dollars.

Today, 77% of American companies use online education resources to train staff, which provides them with an increase in revenue of up to 26% and a reduction in costs of up to 70%. According to the results of international surveys, the use of online learning technologies is supported by more than 65% of teachers (65% of them use open educational resources in the learning process, 37% - MOOCs, 63% - learning technologies based on competencies) (Statista, 2015a).

The demand for online training courses from students is also high: according to 2015 data, 49% of students surveyed worldwide have completed at least one online training course in the past year (Statista, 2015b). 63% of the surveyed US University students note an increase in the effectiveness of learning through the use of online learning technologies, 53% say they have increased confidence in their knowledge of the material, and 34% confirm an improvement in their ability to cope with non-academic tasks (Statista, 2016). Thus, these facts confirm the advantages of online education.
2) Let’s reveal the conditions for the development of online education in Russia, China, and Brazil.
Opportunities for online education are primarily determined by the development of digital infrastructure, i.e. free access to the Internet, the availability of technical means for access, as well as the speed of data transfer and the affordability of connecting both organizations providing educational services and the population receiving them (table 1).

Table 1: The state of digital infrastructure in Russia, China, and Brazil as a basic condition for online education

Country	Fixed broadband connections per 100 people	Active mobile broadband connections per 100 people	Average data transfer rate, MB / s	Cost of fixed and mobile broadband connection, $US PPP	Percentage of Internet users from all citizens	Percentage of households with a computer
Some rapidly developing countries						
Russia	21,4	80,8	11,8	10,1	76,0	74,4
China	28,0	83,6	7,6	16,1	54,3	55,0
Brazil	13,7	90,2	6,8	29,9	67,5	46,3
Developed countries						
USA	33,7	133,1	18,2	66,1	94,9	89,2
Euro-28	33,8	81,5	12,5	32,5	92,1	83,2

Source: compiled by the authors based on OECD (2018), ITU (2018).

The table shows that in some positions Russia, China and Brazil are not inferior to European countries with mature economies and the United States. For example, the level of mobile broadband connection usage in the countries studied is very close to the average European level. The number of households equipped with computers in Russia is high (74.4%), approaching the level of European countries (83.2).

The average data transfer rate in Russia is 11.8 MB/s, which is comparable to the European average of 12.5 MB / s. China has a high value of "fixed broadband connections per 100 people" - 28.0 (in Europe-33.8, in the US-33.7). However, Russia and Brazil have a significant lag in such indicators as the level of fixed broadband connections, the share of Internet users from all citizens, which, to a greater extent, determine the opportunities for online education.

The analysis of composite indices of human development in the studied countries shows the existing need to improve the General level of education and literacy of the population (table 2).

Table 2: Composite indices of human development in Russia, China, and Brazil

Country	Average duration of training, in years	Skilled labour	Education index adjusted for inequalities	Human Development Index
Some rapidly developing countries				
Russia	12,0	96,4	0,807	0824
China	7,9	71,4	0,573	0,758
Brazil	7,9	64,1	0,525	0,761
Developed countries				
USA	13,4	96,4	0,849	0,920
Euro-28	11,7	90,72	0,879	0,890

Source: compiled by the authors based on United Nations (2019a)

These tables show that China and Brazil are clearly lagging behind developed countries in terms of education, average training duration, labor force qualifications, and human development index. In contrast to Russia, whose indicators are almost comparable to the average European level.

According to the United Nations (2019), countries with higher broadband access and higher levels of human development tend to have advantages in higher education and increase their leadership in these areas over time.

Thus, first of all, in China and Brazil, and second-in Russia, there is a need to increase the level of education of the population, which makes it necessary to develop the online education sector.

3) Let's analyze the state of the online education sector in Russia, China, and Brazil.

Online education sector in Russia

In terms of the online education development, Russia lagged significantly behind developed countries until 2014. For example, in the United States in 2012, there were 277 online universities, while in Russia there were only 2 (Makhmudov, 2016).

By 2014, there were more than 50 major projects in Russia that attracted tens of thousands of listeners, and the population's interest in self-education was reflected in the growth of this market segment by 70% in the period 2013-2014 (Mozhaeva, 2013). Most of the population during this period used the potential of online education to learn a foreign language, prepare for the unified state exam, and develop programming skills on a paid basis (Andreev, 2014).

Since 2015, the opportunities for online education, regardless of the requirements for the basic level of education in Russia, have expanded due to the implementation of the open education project at the country's leading universities (MSU, HSE, SPBU, MISIS, etc.) on a free basis (Npoed, 2020).

In addition, the free educational project “Universarium” has created a network of inter-university platforms for pre-professional training and targeted specialized training (Universarium, 2020).

An online learning platform “Uniweb” together with leading universities in the country, develops online educational products for the distribution of high-quality business education in Russian, both on a paid and free basis (Univeb, 2020).

The “Lectorium” project, which has more than 105,000 students, cooperates with the Ministry of education and science of the Russian Federation, leading universities and schools in Russia and Europe, as well as professional associations and companies (Lektorium, 2020).

Since 2016, the growth of online education programs (e-learning) and learning based on distance educational technologies has begun in Russian universities (table 3).

Table 3: Number of programs using e-learning and distance learning technologies in the total number of higher education programs (bachelor's degree, specialty, master's degree)

Educational programs of higher education	2016	2019
The total number of educational programs of higher education, units	41112	46496
Number of educational programs using e-learning, units	8441	12133
The number of educational programs using distance learning technologies units	4090	6485

Source: compiled by the authors according to the Ministry of education and science of the Russian Federation (2020)

In the period 2016-2019, the total number of programs implemented using e-learning increased by 30%, while the number of programs implemented using distance learning technologies increased by 37%. Accordingly, the number of students enrolled in online higher education programs has increased (table 4).

Table 4: Number of students enrolled in online higher education programs in Russia in 2019

Name of educational programs	Number of students-total, people	Number of students enrolled in e-learning programs	Including using exclusively e-learning	Number of students enrolled in programs using distance learning technologies	Including the use of exclusively distance learning technologies
Bachelor's degree programs	2814179	610114	14026	396312	35236
Specialist's degree programs	753393	112129	576	59702	685
Master's degree programs	531673	117632	2641	78423	4098

Source: compiled by the authors according to the Ministry of education and science of the Russian Federation (2020)

However, Russia is characterized by the problem of staffing online higher education due to the reduction of the teaching staff of Russian universities by 26.1% in the period 2013-2018, as well as the low level of digital competence formation among teachers and the lack of material incentives for improving competencies.

However, online educational programs are implemented not only at the higher education level. They also take place in the sphere of preschool and school education. For example, an increasing number of students use the "Ya-klass" simulator for schoolchildren, platforms for preparing for the unified state exam, as well as projects in the field of human cognitive improvement (HCI). However, this market segment is not sufficiently developed.

Online education sector in China

The online education sector in China is one of the fastest growing. In 2018 179 million people participated in online educational programs, and the sector grew by 63% compared to 2015 (International Education News, 2019). This was due to the growth of public financial investments in educational technologies at all levels (growth dynamics since 2011), the implementation of the plan to modernize the education system, as well as attracting investment from interested companies (Solovyov, 2019).

The development of the online education sector provides revenue growth (in 2018 - 251.76 billion yuan, or 25.7% of the sector's growth), as well as increasing the level of acceptance of online education among users and improving the online learning experience.

In China, there is a segmentation of the online education market: the primary and secondary online education sector (including homework and English language training on the platforms of companies such as 17ZuoYe, Vipkid, etc.); the test-oriented sector (preparation for tests, civil service exams and international exams TOEFL, IELTS, for example, on the platforms of Koolearn, GEDU); the vocational education and training sector (for example, from the companies FenBi, huatuEducation).

The fastest-growing segment in 2018 was the primary and secondary online education sector, by 2022, it is expected to grow further (to 27.7%), against the background of a reduction in the segment

of higher online education from 61.8% in 2012 to approximately 40.8% in 2022 (IResearch Global Group, 2019). According to iResearch estimates, the adult population is the main consumer of online education services, which is due to the stable dynamics of the development of the professional online education sector (table 5).

Table 5: Structural dynamics of the online education sector in China, 2012-2018

The sector of online education	2012	2013	2014	2015	2016	2017	2018
Primary and secondary online education sector	9,0	10,1	11,6	11,6	12,6	14,9	17,6
Higher online education sector	61,8	61,0	59,6	60,2	60,9	57,3	53,3
Vocational online education sector	25,7	25,5	25,3	24,3	22,6	23,7	24,8

Source: compiled by the authors according to IResearch Global Group (2019)

It should be noted that China has a problem of staffing online education, which is successfully solved by attracting teachers and specialists from all over the world.

The online education sector in China is demonstrating its investment attractiveness. In 2018, more than 50% of the total capital of venture EdTech companies around the world was invested in Chinese startups (Solovyov, 2019). In 2013, the volume of investment in the Chinese education industry was only 54 million US dollars, by 2018 this figure has increased to 2573 million US dollars (Deloitte, 2019).

In addition, in 2018, experts note a characteristic trend for China – the rapid development of 97 “unicorn” companies in the online education sector. According to CB Insights, in February 2019, the six largest EdTech “unicorns” were of Chinese origin (17zuoye has more than 60 million users; Vipkid serves 200,000 paid students from 32 countries; DaDaABC English language learning system; world leader in educational solutions STEAM Makeblock; o2o educational service Changing Edu) (Solovyov, 2019).

The rapid development of the online education sector in China is also due to cultural factors and the social values that are being implemented, which are the basis of the emerging digital economy.

Online education sector in Brazil

Brazil is showing growth in the information and communication technology sector, including through ICT collaboration with developed countries (Perminov, 2019). In 2016, there were 9820 registered IT companies in Brazil focused on software development, service delivery, and commercialization of third-party products. The total number of employees in the IT sector, according to the Brazilian Association of computer technology and telecommunications companies (BRASCOM), is 1 million 500 thousand people, of which 600 thousand people work directly in IT companies, and 900 thousand-on the side of customers from commercial and government structures (Igate, 2016).

However, the country has a high level of illiteracy - 9.7% in 2010 (Saraiva, 2011). Thus, the number of young people with higher education in 2009 was 14.4%, while in other Latin American countries this figure is much higher: in Argentina- 40%, Venezuela- 26%, Bolivia-20.6%, Chile-20.6% (Perminov, 2019). At the same time, inequality in obtaining higher education remained due to the high cost of education: only 5.6% of young people had a monthly income that allows them to get higher education(the minimum wage in Brazil as of January 1, 2017 is 937 reais, which is equal to US $ 300. The minimum wage was $ 282 in 2016 and $ 253 in 2015).

Only 28% of 345 thousand university teachers have a doctorate, 38% have a master's degree, 34% of teachers work without a degree, and only 78% of 2 million teachers have a higher pedagogical education (Popova, 2018). The main reason for this situation is the lack of resources invested in education.

Therefore, the development of the online education sector in Brazil is one of the most pressing issues. Currently, the Brazilian Government is trying to stimulate the country's innovative development, select and train qualified workers, strengthen the research base and create a modern scientific and technical infrastructure.

Currently, total spending on education in Brazil is about 6% of GDP, which is higher than in Argentina (5.3%), Colombia (4.7%), Chile (4.8%), Mexico (5.3%) and the United States (5.4%) (Wenr, 2019).

Starting in 2003, the Brazilian Ministry of education launched a program to modernize public schools under the “ProInfo” project: providing public secondary schools in Brazil with computer equipment, communications, and free software. As part of the project, 95.24% of the entire fleet of school computers was updated, two thousand schools are connected to the Internet, have a network infrastructure and use digital learning technologies. In 2009, the number of laboratories and educational institutions equipped with Linux systems was 53,000. They provide Internet access to 52 million students, as well as opportunities to use projectors, central processors, and group content in the educational process.

There are more than 2,000 universities in Brazil, 78.5% of which are private. Many of them successfully implement online learning programs, including for international students. According to a 2019 survey, almost half of Brazilian Internet users said they had completed an online course: about 52 percent completed a free course, and 24 percent successfully completed a bachelor's degree program via the Internet (Statista, 2020a).

The growing demand for education and the increasing use of the Internet to deliver educational content are driving the development of online education in Brazil. Since 1996, universities have been allowed to supplement existing full-time programs with bachelor's and master's programs implemented online and remotely.

In 2018, about a million students were enrolled in technology education programs, almost half of them using online learning technologies. In general, in the period from 2007-2018, the number of students enrolled in online education in technology-related programs increased by 586 percent (Wenr, 2019).

In 2018, 24 percent of all undergraduate students were enrolled in online education, 92 percent of them in private universities. In 2018, the number of available places for online education exceeded the number of available places in traditional teacher training programs for the first time.

In the near future, even more growth in online education is expected: private institutions are allowed to set up 250 online learning centers per year in several locations, and online learning programs are subject to the same accreditation standards as traditional programs. In this way, online learning contributes to increasing the opportunities for people in rural and remote areas to access higher education.

Brazil is one of the countries (including Chile, Colombia, Argentina, Mexico, Norway, Turkey) that do not have the resources to create and maintain national educational platforms and use the capabilities of leading platforms where universities publish MOOCs in the national language. Thus, the country uses MOOCs in the educational process of its universities, without investing financial resources in the creation of a national platform (Semenova et al., 2018).

Currently, Brazil is implementing the SP Stars program, which selects startups whose representatives participate in training sessions and receive online advice from expert mentors representing large high-tech companies. An example of such a startup is the private business school in Sao Paulo, which offers free online courses to teach Brazilians professional development through entrepreneurial value. To date, about 70,000 students have completed online courses and almost 2,000 have paid for a six-month program.

Conclusions

Thus, the analysis allows the authors to identify China as a clear leader in online education among rapidly developing countries. The level of development of the online education sector in China, as well as its growth prospects, will undoubtedly provide a reliable intellectual foundation for the digital economy development.

Online education is a relatively new phenomenon for the Russian reality, which faces a number of development problems in terms of institutional, technical, personnel and methodological support. So, the main problems of online education development in Russia are: lack of criteria and general standards for the quality of electronic content and educational materials, problems with copyright protection and institutionalization of online education as one of the legally established forms of education, lack of financial resources to support the processes of creating web resources, filling them and storing data, as well as staffing problems (Lapchick, 2014; Bolkunov, 2016).

The general problems of the development of the education system in Brazil do not allow the authors to talk about segmentation of the online education sector yet. The use of digital technologies helps to optimize the educational process in school education, but the segment of online education for primary school children in Brazil is poorly developed. However, the rapid growth of online education is typical for the higher education level (due to the removal of institutional restrictions and affordability), where the share of students enrolled in online programs has reached almost 30% of the total number of students, while the number of applicants is also increasing. Thus, the analysis confirms the authors ' assumption that the development of online education in developing countries can contribute to the formation of the educational and intellectual potential of their digital economy and provide long-term advantages in digital development.

Personal Brands in The Networked World

Wioleta KUCHARSKA

Gdansk University of Technology, Gdańsk, POLAND
wioleta.kucharska@pg.edu.pl

Abstract

This conceptual paper is focused on the theoretical considerations concerning the role of personal brands in the process of value creation in a network economy. Based on the literature review, the author points to the growing, dynamic and awareness of the importance of personal brands, and draws attention to the fact that the key resources of the modern economy, such as knowledge (especially tacit), skills (professional & social), relations, are inherent to humans. So, individuals aware of their assets consciously shape their personal brands and participate in the process of value creation by entering into alliances concerning cooperation and integration of their key resources with entities and other prosumers. These alliances ensure the maximization of mutual benefits. As a result, we can observe how personal brands of human assets are dynamically moving from their place at the sidelines to the center of the modern economy.

Keywords: Personal Brand, Value Creation, Networked Economy.

Introduction

The "network economy" based on knowledge has significantly contributed to economic growth in recent years (Malik, Ali and Khalid, 2014, pp. 32–48). According to the World Bank estimates (Hamilton et al., 2005, pp. 61-70), intangible capital constitutes approximately 78% of the world's wealth. In developing countries, intangible capital accounts for 59% of assets, while in OECD countries it is approximately 80%. Intangible assets are the basis of the "new economy" (De, 2014, pp. 25-42; Crouzet and Eberly, 2018), and therefore brands significantly affect the condition of enterprises (Barwise, 1993; Bawise et al. 1989, 1990), and in the case of global brands - economies (Kucharska, et al., 2018). This contribution can be defined and considered in direct financial terms, but also in indirect and non-monetary terms, e.g., through the contribution to the improvement of the quality of life. The idea of the so-called meaningful brands (Hollis, 2013) is the concept of creating brands that gain a strong financial position through a significant contribution to the quality of life of their consumers. This contribution can and should be considered as the involvement of brands in pro-social activities within the meaning of the philosophy of corporate social responsibility (CSR), undertaken both by global and local enterprises, (Kowalczyk and Kucharska, 2020). But also, by strong personal brands that influence their social circles shaping attitudes. In the case of public figures and celebrities, the opportunities for social impact can be truly profound. In a networked economy, not only enterprises but also individuals are value producers. This is a kind of network economy phenomenon which has never been observed before. Knowledge workers, i.e. key producers of intangible assets, have transformed the importance of the role of an employee in relation to a corporation and its environment. Figures such as Bill Gates, Mark Zuckerberg, Richard Branson, and Steve Jobs perfectly showcase the importance of individuals and their personal brands in a networked economy. Importantly, virtual social media have created a communication channel that enables promoting every personal brand regardless of its position in the real world. Consciously, every user of a network automatically functions as a personal brand and his or her media presence is nothing more than a broadly defined branding. Naturally, social media do not determine how people function as brands, they are only a (or the) global communication channel available "for everyone". Social media are both 'only a' and 'the' global communication channel, 'only a' communication channel because the opportunities (e.g. their reach and tools) do not determine the ability of individuals to effectively create their own brand, but they are also 'the' global communication channel because the opportunities offered by such a wide reach and tools for measuring that reach and the

power to foster involvement in the posted content capture the imagination and build awareness of the importance of the communication activities undertaken by given individuals within the network, thus creating space for new activities and proposals for "new value bundles". Therefore, the knowledge of a person, namely the knowledge worker, the ability to create intangible assets, which are key in the modern economy, and also because of the fact that in the network economy every person, and, in particular, the user of the social network, regardless of whether he or she wants it or not, and whether he or she is aware of branding processes or not, has a personal brand; and, therefore, it is necessary to include personal brands in the considerations on the influence of brands on the creation of value in the network economy.

In the recent decade, the network economy has changed and continues to change in a special way the models of value creation through brands. Social media and specifically online brand communities (Kucharska, 2019b) significantly contribute to e.g., the new business models. Personal brands are an important part of this process alongside corporate brands on a global and local level. It is therefore important to explore the role of personal brands in the value creation process in the network economy. This conceptual paper aims to do this and identify key research areas worth to be more in-depth examined.

Value Creation in the Networked World

The concept of value in the perspective of the network economy is quite dynamic. The dynamics of the business and social environment leads to continued redefining of this concept. The network is both an infrastructure and a modern form of market process coordination. New infrastructure and resources not only generate new methods of value creation, but also a new perspective on how it is perceived and defined. In the network economy, the internet is a key business infrastructure, while in line with the S-DLogic resources are both tangible and intangible bundles of benefits in the form of skills and knowledge, as well as relations, among others. S-DLogic, service-dominant logic (Vargo, Lush, 2004) is the idea that all providers on the market are service providers. A service in this context is the use of a given resource to generate benefits. Resources are owned by both consumers and producers. Therefore, in line with this idea, producers provide a resource-production service that is used for generation of bundles of value. As a consequence of this approach, the generated benefit is a special form of experiencing meanings which becomes a value determinant in this context. The beneficiary's perspective is crucial for the assessment and measurement of value. In this context, every "bundle of benefits" is a "value proposition" that is subject to constant evaluation in the process of integration with the potential beneficiary, which gives it its current meaning. This meaning is an indicator of value. The meaning transfer affects the concept of value. This transfer is based on existing relations.

Regarding the R-A theory proposed by Hunt and Madhavaram (2014), the relation itself is also a resource, so it is a kind of value proposition. The weight of this resource in the process of networked value creation has significance. Therefore, the key competence in the context of networked value creation is the configuration of an effective system of networking which is capable of integrating the resources available within the network, i.e. co-creation and meaning transfer. Relationship networking, supported by modern communication technologies, is a transfer infrastructure. According to the idea of S-DLogic, it is only the interaction and integration of resources, including relations, in a configured network that gives value to a given bundle. The relationship capital (Perechuda, 2007) becomes a significant intangible asset of an enterprise. The network economy forces building relationship capital beyond the transactional level to configure an effective value network. In this context, the value becomes more important, if understood not only as a simple function of money (financial benefits) but also as a function of relations and integration (social benefits).

in line with the idea of prosumerism, the network economy is based on the cooperation of individual creators based on a value network instead of a hierarchical structure; it also promotes a symmetrical exchange of benefits between co-creators (Powell, 2003). Individual value creators, understood as

sources of intellectual capital, can independently of corporate hierarchies, for instance, distribute the generated value in a selected, existing network, or they can configure a network themselves. As a source of value in the network economy, the intellectual capital is generated outside any hierarchies.

Considering the above, it can be concluded that value in the network economy is created through the co-creation and cooperation of members of a consciously configured value network. The more conscious and careful the configuration of the network, the greater its value generation efficiency. An organization can create value both within the internal and external network, similarly generated values can be dedicated to the external or internal network of beneficiaries. Common to all these cases is the overriding need to generate value for the shareholders of enterprises in the long term, through the ongoing generation of value dedicated to specific beneficiaries under the adopted business model. According to the aforementioned idea of S-DLogic (Vargo et al., 2008), both suppliers and recipients of values are not only parties to the transaction, but they are also integrators of resources available within the network (tangible and intangible in the form of specific competencies or knowledge , for instance). Each innovation as a "bundle of potential benefits" is, in this context, a "value proposition" that is subject to continuous evaluation in the process of interaction and integration with the potential beneficiary. Therefore, the perspective of the beneficiary is essential for proper assessment and measurement of the value (Vargo et al., 2008). An interesting research thread concerning the definition and creation of value in the network economy is the prosumer perspective, i.e. a conscious consumer oriented towards his or her own personal brand.

Personal Brands

The research aim considered in this paper is centred upon determining the role of personal brands in the process of value creation in the network economy. Based on the definitions proposed by Shepherd (2005) and Khedher (2014), personal branding is a planned process in which conscious prosumers try to promote themselves (Kucharska and Mikolajczak, 2018). The concept of personal brand was first introduced by Peters (1997). In the initial stage of formulating this concept, the idea of self-marketing appeared to concern mainly celebrities, politicians and business leaders (Schawbel, 2009; Shepherd, 2005; Nolan, 2015). Over time, it has proved to be of value for other groups as well, such as broadly understood managers (Evans and Hempstead, 2017; Kang, 2013), scientists, university lecturers (Gander, 2014; Kozinets, 2017), footballers (Kucharska et al., 2020), knowledge workers (Mládková et al., 2015; Kucharska, 2019a), librarians (Ahmad et al., 2016) and students who are in the early stages of their careers (Lee and Cavanaugh, 2016; Merdin, 2011). The rapid development of social media has significantly contributed to the increasing importance of the competencies of building a personal brand among the so-called "average" social media users, regardless of profession or age (Labrecque et al., 2011; Schawbel, 2009). Dutta (2010) suggested that under present conditions all people should become specialists in their own branding and consciously protect their reputation and personal network. Kucharska and Dąbrowski (2016) pointed to personal brand building as a strong motivation for sharing knowledge. Knowledge workers want to be seen as experts; they can gain such a reputation by sharing their knowledge, so indirectly, by building their own brand they can also significantly influence the creation of value of enterprises or economies. Similarly, artists and footballers develop specific sectors of the economy related to their activities by building their own personal brands (Kucharska et al., 2020). The indicated publications fill a research gap concerning the importance of personal brands in the value creation process in the network economy. Specifically, they point to the impact of personal brands on the performance of individuals and businesses, as well as the economic sectors they represent.

An important element in considering the contribution of personal brands to value creation in the network economy is the context in which the online brand community operates. Social media are an important communication channel. In 2019, 72.4% of the world's online population had access to social networks, compared to 69.6% in 2016 (Statista, 2020). This denotes a rapid development of this communication channel open to "all". This increase justifies the continually growing interest of scientists and practitioners in virtual communities' power of integrating people. Virtual communities, and especially online brand communities, are a special type of consumer communities defined as specialised, geographically unrelated human relations that are part of a structured set of social

relations between brand enthusiasts (Muniz and O'Guinn, 2001). The relations between members of virtual communities and brands, as well as the resulting community identification, are continually evolving and therefore are an exciting object of research (e.g., Zaglia, 2013; Wolter et al., 2016; Tuškaej et al., 2013, 2018; Manchanda et al., 2015, Coelho et al., 2018; Pedeliento et al., 2020). The key issues requiring exploration, in the context of creating value with the participation of the brand community, are mechanisms regarding the identification of consumers with the particular brand online and their influence on loyalty to this brand, and the mechanisms shaping relationships between consumers who join the same online brand community (Millán and Diaz, 2014). It is therefore important that research on online brand communities explains one of the most important motivations for joining online communities, supporting the thesis that consumers associated with a group are less radical in rejecting brands than those independent of a social group (Escalas and Bettman, 2005). In fact, brand enthusiasts simultaneously perceive social identity together with the brand community and its environment (Zaglia, 2013). In addition to social networking with community members and brands, previous research has shown that another important motivation for using social media is the self-presentation of network members (Seidman, 2013; Teichmann et al., 2015). In support of this claim, the findings of Orehek and Human (2017) suggest that social media platforms can be a useful outlet for self-expression, which is a form of self-affirmation, as originally defined by Ashfort and Mael (1989). The mechanisms of these relations are crucial in determining the intensity with which consumers identify themselves with a given brand (Millán and Diaz, 2014). Therefore, it is important to understand how these two dimensions affect the creation of value in social networks, to understand the motives that lead consumers to join online brand communities. Kucharska (2019b), and Confente and Kucharska (2020) indicated that the users' personal brands are an important part of the social media value creation process. These publications empirically verify both the motives and effects of user identification with online brand communities. Specifically, the authors have proven that users make use of commercial brands online to create their own personal brands, and this is, according to Ajzen's theory of "planned behaviour" (1991, 2002), the key motive for identifying a personal brand with a commercial brand online. The importance of this finding is all the more significant because it leads to a deeper understanding of the brand-consumer relationship in the social network, which is vital for optimising business models developed in this environment.

The new trend in the design of value circulation in the economy favours the development of the so-called sustainable models, which make it possible to create, analyse, manage, provide and communicate propositions of the value generated by enterprises to customers and other stakeholders by using the social capital of customers and other stakeholders so that the model is fed, in a way, by the involvement of all parties potentially interested in it, i.e. customers and other stakeholders of a given value network (Neumeyer and Santos, 2018; Piyathasanan et al., 2015; Schaltegger et al., 2016). The idea of a sustainable business model involving all value stakeholders perfectly reflects the concept of "sharing economy"1 and "wisdom of the crowd", (Heinrichs, 2013) where value is both shared and co-created (Heinrichs, 2013). Sharing economy offers consumers the opportunity to "avoid waste" or at least delay it by exchanging, swapping, giving away, hiring, trading, lending, and sharing goods" (Piscicelli et al., 2015, p. 21). Therefore, with these trends in mind, enterprises are interested in establishing and maintaining close relationships with customers in virtual reality (Phillips, 2015). The concept of online brand communities provides favourable opportunities in this respect. There is little research on the identification factors concerning social media users and online brand communities for developing business models. Digitalisation offers new paths for business development. Social media are significantly changing social communication standards, becoming an important part of the new business system. Kucharska (2019b) proved that commercial brands can effectively create value in the social network if they consider in their models the need to create a user's personal brand in relation to their reference groups.

Moreover, Moulard et al. (2014, 2015, 2016, 2020) and Kucharska et al. (2018b, 2020) noted that the authenticity of the personal brand is one of the key factors influencing the ability to create value by the particular personal brand. Therefore, the personal brand authenticity factor should be also included in the theoretical model of personal brands contribution to value creation in the network economy.

Fig. 1: Theoretical framework

Further Research

The most promising directions for further research relate to the personal brands' contribution to value creation. Also, personal brand equity studies are needed, especially in the context of such drivers as personal brand growth (how to measure it?), contribution to human life by such personal resources as knowledge, relations, and skills - professional and social. How to operationalize it to measure it? Moreover, authenticity (true-to-ideal, true-to-fact, and true-to-self, following Moulard et al. 2020). Personal brands are a significant phenomenon worth to be more-in depth investigated.

Summary

The above considerations lead to the formulation of an initial theoretical framework (Figure 1) aimed at determining the role of personal brands in the process of value creation in the network economy. Personal brands of prosumers (e.g., consumers, professionals, or celebrities) as well as brands linked to businesses (e.g., a product, service, or organization), based on available resources, and through cooperation and integration of resources with other prosumers or businesses, generates a value proposition. This proposed value is then evaluated in each business context by its potential beneficiary. The key drivers (important factors in value evaluation) include perceived authenticity, perceived contribution to everyday life and the constant need for growth and development. All these elements together are significant in terms of the value creation process. Personal brands play a special and important role because their awareness and significance are rapidly growing. Moreover, key resources such as knowledge (especially tacit knowledge), skills (professional & social), and relations, which are inherently linked to given individuals, so individuals who are aware of their strengths consciously shape their personal brands and consciously participate in the process of value creation by entering into alliances concerning cooperation and integration of resources with businesses and other prosumers who ensure maximization of mutual benefits. As a result, we can

observe how personal brands of human assets are dynamically moving from their place at the sidelines to the center of the modern economy.

Energy Poverty in The Polish Village – Experts' Survey Report

Arkadiusz PIWOWAR

Wroclaw University of Economics and Business, Wrocław, Poland
arkadiusz.piwowar@ue.wroc.pl

Abstract

Poland faces serious challenges related to the provision of clean and affordable energy to its citizens, in addition, energy poverty is a significant problem, which most often affects the inhabitants of rural areas. In this paper, based on the analysis of primary data obtained through a survey of experts (agricultural advisors), the scope and causes of the phenomenon under study were identified. According to the research, almost half of the respondents assessed that energy poverty is a serious problem in rural areas in Poland. The research shows that the most important factor causing this problem is the cost of purchasing energy (the amount of energy price, distribution costs and taxes affecting the price). In experts' opinion, the problem of energy poverty is insufficiently emphasized in the media, in public and scientific discussions/debates.

Keywords: Energy Poverty; Rural Energy; Poland.

Introduction

The issue of energy poverty has been the subject of scientific considerations since the 1980s. Energy poverty has a multifaceted nature and in general it is the phenomenon of the inability of households to meet basic energy needs in their place of residence (i.e. an appropriate standard of heat and the possibility of supplying other types of energy to adequately meet the basic needs of household members) (González-Eguino 2015). The multifaceted nature of the studied phenomenon covers many economic, infrastructural, social equality, education and health problems (Bouzarovski and Petrova 2015; Middlemiss et al. 2019; Sareen et al. 2020). The issues related to energy poverty are an important element shaping the broadly understood quality of life (Maxim et al. 2016; Thomson et al. 2017; Zhang et al. 2019). The literature on the subject also emphasizes the existence of the so-called hidden energy poverty at the household level (Karpinska and Śmiech 2020). Due to material deprivation, problems related to technical infrastructure, etc., particular interest in the phenomenon of energy poverty occurs in the context of inhabitants of rural areas (Pereira et al. 2010; Kaygusuz 2011). The relatively high risk of exclusion covers farmers, retirees and pensioners living in the countryside.

In Poland, despite many positive socio-economic changes that have taken place in the last 30 years, the significant reduction of energy poverty remains a challenge in the field of social policy (Świerszcz and Grenda 2018; Chojnacka 2020; Sokołowski et al. 2020). Relatively low incomes, high and growing energy costs and low energy efficiency of buildings are the main causes of energy poverty in Poland. An additional problem with energy poverty is air pollution, which is mainly caused by heating homes with coal and other solid fuels (Rogus et al. 2019; Piwowar and Dzikuć 2019; Woźniak et al. 2020). The energy sector and energy policy in Poland must face fundamental changes in the near future related to climate change, security of supply and energy poverty (Ehrenhalt 2018; Kryk 2019; Piwowar and Dzikuć 2020). The problem of energy poverty within the countries of Central and Eastern Europe (CEE) does not only concern Poland (Kyprianou et al. 2019; Thomson et al. 2019; Teschner et al. 2020). The phenomenon of energy poverty in this area is not marginal, but it is often underestimated and treated superficially (Lenz and Grgurev 2017; Neacsa et al. 2020).

In Poland, the problems of energy poverty are mainly dealt with by independent research institutes, mainly the Institute for Structural Research (IBS) and the Institute for Sustainable Development (Szpor and Lis 2016; Rutkowski et al. 2018). The data from 2018 shows that this problem affects

Cite this Article as: Arkadiusz PIWOWAR "Energy Poverty in The Polish Village – Experts' Survey Report" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

approx. 10 percent of households in Poland (3.35 million people). The reports of the Institute for Structural Research show that in 2016, 12.2% of the Polish population suffered from energy poverty. Therefore, this is a real problem, more and more often discussed, but still not sufficiently recognized, especially in relation to households of farmers. To date, there is no detailed research at the microeconomic level in the literature on the subject, which would attempt to characterize the energy poverty of this group of households. However, the results of previous studies of the general level of energy poverty indicate that in Poland this problem mainly affects inhabitants of rural areas. The available IBS reports show that every fifth person living in the countryside is struggling with energy problems. This is related to economic reasons (lower incomes of population in the countryside compared to city dwellers), and also to the fact that the villagers live in single-family houses, often of large square metrage and low energy efficiency. In addition, many people living in rural areas have no access to the heating and gas networks.

The issue of energy poverty is one of the most important challenges of contemporary economic and social policy in Poland (Piwowar 2020). However, the problem of energy poverty in the context of rural areas has not been of particular scientific interest so far. The necessity to carry out the research covering this area has been signalled in many studies (Świerszcz et al. 2019; Piwowar and Dzikuć 2020). The aim of this study was to find out the position of people specialized in a particular field (agriculture) regarding the problem of energy poverty in rural areas in Poland, including in particular the scope and causes of the studied phenomenon.

Material and Research Methods

This article uses the results of own research carried out as part of a research project financed by the National Science Centre in Poland. The project included three-stage empirical research based on original questionnaires:

- quantitative surveys of farmer's households (size of the test sample – 480 farmers' households, surveys representative in the scale of Poland);
- qualitative research (size of the test sample – 60 farmers' households, surveys among the holdings from the first stage);
- qualitative expert's studies (size of the test sample size – min. 30 experts).

The primary data was obtained by means of a survey research conducted by direct interview with the use of a questionnaire. The questionnaire contained a total of 22 questions, of which 7 demographics and 15 substantive questions. The demographics questions were aimed at assessing and verifying the experts, including their education, experience and knowledge regarding the research problem. The substantive questions concerned opinions, declarations and assessments of various aspects related to the phenomenon of energy poverty. Responses were made on nominal or ordinal scales (usually 5-point). Some of the questions were open-ended, in which experts were asked to write down their opinions on a particular topic. Selected results from this study are presented in this paper.

This study was based on a survey conducted among 31 experts (agricultural advisors), including at least four experts dealing with low-emission agriculture in each of the six Macroregions in Poland. Due to the nature of the research, the time range of analyses was related to 2018-2025. The structure of the respondents was dominated by women (19 people), and 24 people had higher education related to agriculture (agronomy, animal husbandry, agricultural technology). Taking into account professional experience, it is worth emphasizing that 20 respondents could boast over 20 years of professional experience in the field of agriculture and rural areas.

The research technique and the method of sampling (random selection within all macro-regions in Poland) ensured in-depth analysis of the issue under study, taking into account the spatial diversity of

rural areas in Poland. Agricultural advisers who were experts in the studied subject matter know very well the behaviour and actions of farmers. Employees of the centres support farmers with their advice, respond to the information needs of agricultural communities and the main priorities of rural and agricultural development.

Results and Discussion

The research has undertaken, among others, the problem of the occurrence of energy poverty in Poland. The respondents were asked for their opinion on the existence of the problem of energy poverty in three areas: in Poland in general, in rural areas in Poland and in farmers' households (Fig. 1).

Fig. 1: The respondents' declarations on the problem of energy poverty in Poland

Source: own study based on questionnaire surveys (N=31)

As the analyses show, positive answers ("definitely yes" and "rather yes") were most often related to rural areas in Poland (48.4% of the answers in total). Slightly less, according to the respondents, this problem occurs among farmers' households (45.2% in total). According to 38.7% of respondents, this problem occurs throughout the country.

It is worth emphasizing that a similar percentage of positive answers was recorded when asked about the problem of energy poverty in rural areas, which the respondent represented and/or knows its conditions in terms of agriculture. 15 positive answers were given, 16 people answered "no".

The respondents were also asked about the main causes of energy poverty in rural areas in Poland (Fig. 2). The respondents were asked to rank the factors according to the degree of importance, assigning them numbers from 1 to 5, where 1 is the most important factor and 5 the least important.

1	The amount of energy prices, distribution costs and taxes affecting the price
2	Technical condition of residential buildings
3	Technical condition of livestock buildings
4	The usable floor area of a dwelling
5	Family
6	Increasing dependence on electricity related to, among others, the growing number of electrical appliances
7	Low energy class of devices consuming electricity in household equipment
8	Low energy class of devices consuming electricity on farm equipment
9	No actions (activities) in households for energy saving
10	No actions (activities) on farms for energy saving

Fig. 2: Respondents' declarations on the main causes of energy poverty in rural areas in Poland

Source: own study based on questionnaire surveys (N=31)

According to the respondents, the most important factor is "the amount of energy prices, distribution costs and taxes affecting the price" (weighted average was 1.41). The technical condition of residential buildings (weighted average was 2.5) and livestock buildings (weighted average was 2.76) were also classified as important causes of energy poverty in rural areas in Poland. Moreover, the respondents pointed to the increasing dependence on electricity related to, among others, the growing number of electrical devices (this factor was the third most important factor in the opinion of the respondents, the weighted average in this case was 2.68).

The respondents were also asked whether the issues related to energy poverty in rural areas in Poland were sufficiently emphasized in various forms of communication and discussions. The results of this part of the analysis are presented in Tab. 1.

Table 1: Experts' declarations on the sufficient emphasis on the topic of energy poverty in rural areas in selected media

Specification	**Definitely yes**	**Rather yes**	**Hard to tell**	**Rather not**	**Definitely not**
	[%]				
Legal regulations	0	19	26	42	13
Scientific publications	3	29	19	39	10

Training programs for farmers	10	29	6	45	10
Discussions, public debates	3	23	16	48	10

Source: own study based on questionnaire surveys (N=31)

In almost all of the above-mentioned media, the respondents agreed that in public discourse, scientific and popular science works, etc., the studied phenomenon is not emphasized enough. Experts marked the most positive answers ("definitely yes" and "rather yes") during training courses for farmers (39% of answers in total).

Summary

The study was based on the analysis of data using the direct interview method among experts working in agricultural advisory centres. This approach attempts to explore and describe the scope and causes of energy poverty in rural areas in Poland. One of the first conclusions that can be drawn from the analysis of the information obtained from the survey is the fact that almost half of the respondents considered the problem of poverty in rural areas in Poland as existing (9.7% answered "definitely yes"; 28.7% answered "yes"). The percentage of positive answers was definitely higher than to the question about the overall occurrence of this problem in Poland. According to experts, the biggest problem of maintaining an adequate heat standard and supplying other types of energy to adequately satisfy basic needs occurs in rural areas.

On the basis of the conducted interviews, the main reason for this phenomenon can be distinguished – the amount of energy prices, distribution costs and taxes affecting the price. Moreover, three other factors turned out to be important: the technical condition of residential buildings; increasing dependence on electricity related to, among others, the growing number of electrical appliances and the condition of livestock buildings. According to the respondents, considerably less importance was attributed to factors such as: the size of the family; no action (activity) in households/farms for energy saving; usable floor space of a dwelling; low energy class of electricity consuming devices for household/agricultural equipment.

Summarizing expert opinions on the subject matter under study, it is worth emphasizing that, according to experts, these issues should be subject to a wider public debate. Conducting a deeper public debate and better shaping the social policy are undoubtedly challenges in the studied subject matter. Furthermore, the expected increase in prices of CO_2 emission allowances, the COVID-19 pandemic and the related economic crisis may aggravate the problem of energy poverty in Poland, which will require additional programs and funds to support people (families) affected by energy exclusion.

Acknowledgment

This study was conducted and financed in the framework of the research project "Socio-economic, environmental and technical determinants of the energy poverty in rural areas in Poland", granted by the National Science Centre in Poland, program OPUS, grant No. 2018/31/B/HS4/00048.

Abstract

The purpose of this article is to provide a compliance monitoring solution in an unmanned aerial traffic management system (UTM), using fuzzy logic. Fuzzy logic, which is based on the theory of fuzzy sets, allows the linguistic description of the laws of command, operation and control of a system. In working with complex and nonlinear systems it can often be observed that with the increase of their complexity a diminution of the significance of the details in the description of the global behavior of the systems is observed. A detailed description of the behavior of a system is often not only unnecessary, but even counterproductive. One of the consistent arguments for approaching by the methods of sets and vague logics the description of the laws of command and operation of systems is that of the ease of use of linguistic expressions, of the use of words. Finally, we will propose a TMU architecture for the control of the trajectories of unmanned aircraft vehicles (UAS).

Keywords: Unmanned Aircraft Vehicle, System Traffic Management, Fuzzy Logic, Trajectory Monitoring

Introduction

In recent years, the use of drones / unmanned aircraft system (UAS) has increased significantly in all directions - commercial and personal applications, with millions of aircraft registered in Europe and the United States alone. Predictions show a steady increase, with FAA estimates suggesting that the number of unmanned aircraft registered could double by 2025 [1]. This rapid increase in the traffic of unmanned aircraft used more and more frequently in the commercial area due to the COVID-19 pandemic, brings new challenges. As airspace capacity is limited [2] and increasing the level of use of unmanaged air traffic can lead to insecurity and potential critical situations. For these reasons, it has become necessary to develop unmanned aerial traffic management system (UTM) architectures in order to ensure the maximization of the use of airspace, but also the safety of Critical Infrastructures [3].

The principles that currently apply to radio-electronic (radar) research can also be applied to UTM. Actions of detection, interception, analysis of communications and electromagnetic radiation and especially the ability to determine the trajectories of drones evolving at high speeds in an uncontrolled environment, measurements can often be severely disturbed and unable to provide relevant data to UTM systems. . The use of classical methods, based on Boolean logic, which are not able to operate with imprecise notions, can provide erroneous data, which can jeopardize the success of detection

actions. Therefore, it is necessary to use methods that allow great flexibility in describing input variables, that exceed the limitations imposed by Boolean logic and that allow logical reasoning with multivalent logic variables capable of taking any value in the range [0,1].

Fuzzy logic, which is based on the theory of fuzzy sets, allows the linguistic description of the laws of command, operation and control of a system. In working with complex and nonlinear systems it can often be observed that with the increase of their complexity a diminution of the significance of the details in the description of the global behavior of the systems is observed. A detailed description of the behavior of a system is often not only unnecessary, but even counterproductive. One of the consistent arguments for approaching by the methods of sets and vague logics the description of the laws of command and operation of systems is that of the ease of use of linguistic expressions, of the use of words.

Although such an approach may seem inappropriate, it often proves to be superior and much less laborious than a rigorous mathematical approach. The main argument in favor of fuzzy set theory, which is a generalization of classical set theory, is to excel in operating with vague, vague notions.

In classical set theory, a clear distinction is made between the notion of belonging and the notion of non-belonging of an object to a given set. Thus, there is no partial membership in a set and no means of expressing such a situation. For example, a tree may belong to a set called the "biosphere," while a rock may not belong to that set. We will continue to call such sets crisp sets. The theory of vague sets highlights the fact that there are extremely few rigid sets. For example, defining a rigid set called the "biosphere" may have difficulty including the notion of "coral," which is often considered a lifeless limestone. The fuzzy approach to such a problem is not an exception, by eliminating the paradoxes that may arise from the dichotomy of strict membership or non-belonging to a certain set. Fuzzy logic admits the partial belonging of an object to a set; thus, the gradual transition between total membership in a given set and total non-membership in the same set is allowed. Partial membership in a certain set simultaneously implies partial non-membership in that set.

Figure 1: Representation Fuzzy logic that allows partial membership in the defined set, being characterized by the gradual transition from "low" to "high".

The generalization characteristic of the classical set theory is given by the fact that the fuzzy set theory allows both total membership and total non-membership (of course, not simultaneously). It is obvious that we can use fuzzy logic to implement rigid systems (determined by rigid sets), but the benefit of such an approach would be negligible. The force of fuzzy systems is manifested in transition situations, in the areas of partial belonging of an element to a certain set. Traditional logic recognizes only complete membership and complete non-membership and requires that an assertion be either true or false. Fuzzy logic allows the existence of partial truth or falsehood. Figure 1 illustrates the difference.

Given the premise that the transition from false to true must be gradual and that an assertion can be both partially true and partially false, a different way of approaching command and control issues must be constructed. We agree, in principle, that the world around us cannot be perceived only in "white" and "black." In fact, in most cases, the surrounding world presents itself in a multitude of shades of "gray", which, however, in practice, we assimilate with two values: "white" and "black". Fuzzy logic not only accepts shades of "gray", but also provides us with powerful tools to operate with these shades in a proper way.

Proposed Solution

Following the collaboration between the departments of Engineering and Management for Transports and the Department of Telematics and Electronics for Transports, the Faculty of Transports within University “Politehnica” of Bucharest (UPB), resulted a UTM system, based on distributed fuzzy logic control.

Currently, drone detection systems are in full development, using acoustic fingerprint [4], [5], [6], radar detection [7], [8], radio communication detection [9] and video detection [10], [11], [12]. For drone trajectory management systems, GPS detection can be used, as well as anonymous detection of communications used by the drone on Wi-Fi, by detecting the MAC address specific to each drone [13], [14].

Rapidly growing interest in the development of intelligent systems a led to the multiplication of sensor types, which ensures an increasingly rich perception of the surrounding reality, allowing the description and solving some of the most varied problems. Use of new types of sensors and actuator leads to better quality, productivity, and safety of processes. The general trend is a rapid increase in the number of measurements and actions in controlling complex processes. Therefore, processing power it must also grow. Developing a processor that perform all measurements, make all decisions, and perform all actions control is no longer a realistic approach. Thus, data collection and control of actions must be both logically and spatially distributed. This one solution raises new problems in sharing information or finding solutions cooperation. The distribution of components should, as far as possible, ensure decentralization of computing capabilities without substantially reducing reliability global system. In particular, communication between components should limited; otherwise the performance could decrease dramatically. The use of communication buses ensures the endowment of intelligent components with the possibility of digital communications, which can be considered as a first level of intelligence. In addition, smart components must be able to to process locally the data addressed to them. This second level of intelligence is needed to reduce the exchange of information as long as smart tools produce increasingly complex data. This one the approach should reduce the flow of data between various components and in at the same time, it should ensure a uniform and homogeneous treatment of the data that they come from various sources. Thus, distributed tools must be able to perform complex functions, but they must also communicate and communicate. work with other equipment. These capabilities are called interoperability and collaboration between systems. To achieve the concepts described above, access to means is necessary which allow the integration of intelligence at lower levels. Due to the ability to represents gradual information in a way familiar to human thinking, fuzzy logic is a powerful tool for integrating intelligence. In particular, the way the connection between linguistic terms and numerical quantities allows implementation of high-level functions, such as data fusion and processes of complex decision.

Most implementations of *distributed fuzzy systems* are based on interacting distributed components that have a fuzzy and rules base which communicates with other components by numerical values. The most classic solution for coding a fuzzy system is the use of a high-level language. Another solution is to use dedicated hardware such as fuzzy processors. None of the solutions provide an easy way to implement the systems fuzzy: the first because it does not have methods for distributing applications in many processors, and the second because the hardware solutions require enough long time for development.

The problem is to define distributable fuzzy components, such as fuzzy sensors or fuzzy inference components that are connected to a bus communication. Depending on the configuration, a fuzzy component implements one or several combinations of fuzzy processes, known as real-fuzzy transformation (TRF), inference and fuzzy-real transformation (TFR).

Theoretical Aspects on Fuzzy Components

Tracking of targets represents the forecast of the possible trajectories of the target as a function of its previous positions. The prediction accuracy depends on how much precisely the previous and current positions of the object were measured. Unfortunately, due to parasitic echoes generated on the radio locator screen, the limitations of algorithms related to processing the signals coming from different sensors, the position of the targets can be determined with approximation. The values measured can enhance multiple variable features and may be constrained by different initial conditions depending on the flight angle and on the position of the target towards the radar.

Research presented in articles [15] and [16] on the use of fuzzy logic to track the trajectory of a target has had a major impact on research and academia. The stability of the fuzzy controller plays an important role and has been thoroughly investigated.

In [16] we presented the mathematical algorithms for tracking the trajectory using fuzzy logic, below we will present only the results obtained by demonstrating the superiority of fuzzy logic over the Kalman filter. In the first situation (figure 2), a target accelerates rapidly and executes rapid turns. As it can be observed, the Kalman filter performs several erroneous actions in series, which increases the displacement between the current position and the predicted one by accumulating the errors from one scan to another. This low rate of response to unexpected changes in the dynamic of flight is due to the time required by the Extend Kalman estimator's response (usually during a few scans). For the target executing a 360° turn over six scans, a delay of two scans may represent a 120° angular deviation. Thus, the tendency of the Kalman system to overestimate the next position of the target is not surprising, thus resulting in loss of the target.

Figure 2: Kalman filter estimation (red – real target position, blue – estimated target position) left image and Fuzzy filter estimation (red – real target position, blue – estimated target position) right image.

Figure 3 show the performances of the two systems in another situation. A target is being tracked on an approximate linear trajectory with constant speed. There are no significant losses of the target. It can be noticed that the predictions of the Kalman system are placed on a curve in a zig-zag pattern. The system is thus dependent of noise, even if the noise level is minimum.

Figure 3: Kalman filter estimation (red – real target position, blue – estimated target position) left image and Fuzzy filter estimation (red – real target position, blue – estimated target position) right image.

Application with Fuzzy Sensors Distributed for Measurement Distance

Using the results presented above [15], [16], in this article we propose a new algorithm for estimating the trajectory using *distributed fuzzy control*.

The problem is to obtain a symbolic description of the position of an object, based on two distance measuring sensors, c1 and c2, as in figure 4. The goal is to characterize the object detected by its position and orientation toward a direction through via two fuzzy subsets. The sets of linguistic terms

are respectively {close, quite_close, quite_far, far} and {left, front, right}. To obtain the distances d1 and d2, two intelligent sensors with ultrasound. Each smart sensor is equipped with two transducers the same resonant frequency. The detection principle is based on modulation linear of the transmitter. The receiver transducer receives a signal modulated in frequency. The difference between the transmitted frequency and the received one, marked with a face, is proportional to distance. This difference is obtained after multiplication the two signals and the application of a filter goes down. To obtain the distance, the frequency must be obtained fa. For this, a measurement was implemented of the signal period using microprocessors.

Smart sensors can be turned into fuzzy sensors by simply applying FACCT language, without the use of additional hardware. Every The fuzzy distance sensor describes its measurement as a fuzzy subset over lexical set {close, medium, far}. A third cell is used to perform the aggregation of the two distances, which leads to obtaining a virtual sensor for obstacle detection. The aggregation is performed by two different sets of rules (see figure 5), one being associated with the position, and the other orientation. The configuration of fuzzy cells is described in figure 6. For fuzzy cells 1 and 2 no specificity issues. They are based on the same text files FACCT configuration. Each cell first performs the fuzzy symbolic transformation of the measurements. The resulting fuzzy subsets are transmitted cell 3, whose I2C address is 96.

Figure 4: Description of the position of an object, based on two distance measuring sensors.

THE BASIS OF RULES FOR POSITION

	POSITION	CLOSE	MEDIUM	FAR
d2	CLOSE	CLOSE	QUITE_CLOSE	QUITE_FAR
	MEDIUM	QUITE_CLOSE	QUITE_FAR	FAR
	FAR	QUITE_FAR	FAR	FAR

THE BASIS OF RULES FOR GUIDANCE

		d1		
	ORIENTATION	CLOSE	MEDIUM	FAR
d2	CLOSE	FRONT	RIGHT	RIGHT
	MEDIUM	LEFT	FRONT	RIGHT
	FAR	LEFT	LEFT	FRONT

Figure 5: The aggregation is performed by two different sets of rules.

For example, suppose d1 = 90 m and d2 = 230 m. By definition to the linguistic variable distance in figure 5, their respective fusions are:

j2 (d1) = {0.3 / Close, 0.7 / Medium, 0 / Far}
and
j2 (d2) = {0 / Close, 0.2 / Medium, 0.8 / Far}

The proposed operators give for h and i:

h = {086 / Left, 0.14 / Front, 0 / Right}
i = {0 / Close, 0.06 / Quite_close, 0.38 / Quite_far, 0.56 / Far}

Figures 6: Configuration of fuzzy cells system.
As in the previous example, these results illustrate only the functionality offered by fuzzy cells.

Conclusion

After explaining the concept of distributed intelligent control, the concept of fuzzy components and their definition in terms of hardware and software was presented. The simple way to implement fuzzy cell-based systems has been described. The configuration of the cells in the network is done by a specific language, called FACCT. FACCT files can be compiled by fuzzy cells using a resident

compiler. The cells are implemented on the structure of an INTEL C100 microcontroller. The advantages of using a network of fuzzy components do not consist only in those offered by distributed systems. It is found that fuzzy cells are easy to configure, but at the same time provide high-level functions, such as fusion and decision-making processes. The network also allows the addition of components to increase system performance. The added components do not necessarily have to be fuzzy components, because the network supports several types of data. There is also the possibility to create virtual components, where cell 3 can represent a virtual position sensor.

Abstract

The general objective of the project, presented in this article, is to create a hardware and software platform to provide support in substantiating decisions and coordinating activities in crisis situations. Thus, the main objective is to make a prototype module for "agent-based modeling and simulation of pedestrian crowds in panic situations", to which will be added modules for "Detection of the escape route from a scene using Deep Learning and Voronoi networks" and "remote monitoring system of the physiological parameters of the intervention teams". To achieve this support system for making strategic decisions, we propose the implementation of a complex hardware and software architecture of C5ISR type (command and control, communications, computers, cyber, intelligence, surveillance and reconnaissance).

Keywords: strategic decision systems, panic situation, pedestrian crowds' model, Voronoi cell.

Introduction

In the study of the design process of strategic decision support systems, the notion of system is essential. A system is a set of interdependent elements (components) between which a dynamic interaction is established, based on predetermined rules, to achieve a certain goal [1]. According to systems theory, any military body is a system. Depending on how detailed the analysis is, a system has nine features [2], [3].

Each system accepts several inputs, processes the information provided by them and sends the results to the outputs and from here, in the environment in which the system evolves. The limits of the system separate it from the environment in which it manifests itself. Through the interfaces a system communicates with the environment. A system exists only in the environment that contains it and will interact with it through the data and information received.

A system is made up of components. These, also called subsystems between which various relationships are established, can consist of indivisible component elements or groups of aggregate elements. The design of the subsystems is very important because, if the system as a whole no longer functions properly, its "repair" should be possible by simply replacing the subsystem that caused the failure. System limitations refer to the constraints imposed by its parameters (eg storage capacity or speed) according to which the system must operate in order to achieve the purpose for which it was achieved.

There are some important notions regarding the study of the system. Decomposition is very useful when trying to understand how a complex system works. It will be broken down into simpler

Cite this Article as: Augustin SEMENESCU, Marius MINEA, Ilona Mădălina COSTEA and Ionut CHIVA "Strategic Decision Support - Integrated System for Support and Management of Crisis Interventions" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

subsystems, the structure of which can be analyzed and understood in turn, without taking into account interference between subsystems [4]. Modularity derives directly from decomposition and facilitates the process of troubleshooting the system. Coupling refers to the fact that the systems are interdependent although they should be as independent as possible. Thus, the failure of a subsystem would lead to the chain damage of all subsystems and, ultimately, the malfunction of the main system. If independence is ensured, only the defective component can be replaced, making the troubleshooting and repair process much shorter. Cohesion is the extent to which a subsystem can perform a single function [5].

The information system is based, as the name implies, mainly on information. It comprises all the internal and external information used within the organization as well as the data on which it was obtained, the procedures and techniques for obtaining information (starting from the primary data) and disseminating the information, as well as the staff involved in collecting, transmitting , data storage and processing. The information system refers not only to the way in which the tools provided by T&C are used but also to the way in which people interact with technology in an institution. In the military field, the information system ensures the connection between the decisional and the operational system. An information system can be represented as in figure 1:

Figure 1: The relationship between computer system and information system.

The functions of an information system are the following:

• to collect information from the operational and decision-making systems as well as the information coming from the external environment.
• to memorize this information as well as information resulting from its processing.
• to ensure the access to the memory in order to communicate the stored information.
• process information at the request of the operating system and the management system.

The notion of computer system is related to the computerization of the organization's activity, therefore to the use of hardware equipment and software products for organizing and managing information [6]. The use of computers in the information system (IS) of an organization leads to the definition of the Automated Information System (AIS) component - which includes only the work done with the help of computers. From this point of view, the SI - SIA relationship can be represented as in figure 2.

Figure 2: SI - SIA relationship.

An information system is an integrated user-computer system that provides information to support operational and management activities in an organization, using hardware and software, manual procedures, a database, and mathematical models for analysis, planning, control and decision making [7]. The main objective pursued by the introduction of an information system is to ensure the management with real and timely information, necessary for the substantiation and operative elaboration of decisions. The elaboration of the information systems imposes the modeling of the information system of the organization with the help of a formalism through which the reality within the information system can be represented as suggestively and faithfully as possible. For organizations of low complexity, computerization can mean the realization of a single computer application also referred to as a computer system [8]. Complex computer systems can be broken down into subsystems, which in turn can be broken down into applications for certain categories of users, which in turn can consist of one or more programs written in various programming languages as shown in Figure 3.

Figure 3: Computer system, subsystems, applications, programs.

Computer systems, subsystems and applications are called computer products and software products. A computer product consists of programs that access the database and the necessary documentation for the use and maintenance of the programs. These are based on methodologies and require the completion of stages starting with the specification of requirements and ending with their implementation,

operation, and maintenance [9]. The military information system is a structured set of functionally intercorrelated elements to automate the process of obtaining information and to substantiate decisions [10]. The information system is included in the scope of the information system if within the information system there will be a series of activities that cannot be automated.

Proposed Solution

Agent-based modeling and simulation of pedestrian crowds in panic situations
Motivation

The increasing occurrence of moments of panic during mass events motivated the study of the impact of panic on crowd dynamics and the simulation of pedestrian flows in panic situations. The lack of understanding of moments of panic continues to cause hundreds of casualties each year, not to mention methodological studies of panic behavior capable of predicting crowd dynamics [11]. Under these conditions, there are thousands of casualties and twice as many accidents caused by the crowd around the world, despite efforts to control the crowd and many security forces. Pedestrian crowd dynamics are generally predictable in high-density crowds, where pedestrians cannot move freely, self-propelled interactions develop between pedestrians. Although each pedestrian has personal preferences, the dynamics of the movement can be shaped as a social force of the crowd. The corresponding forces can be controlled for each individual and represent a different variety of behaviors that can be associated with panic situations [12], such as avoiding danger, crowding, and pushing[13]. In this software development, we use an agent-based model for pedestrian behavior in panic situations to predict collective human behavior in a dynamic crowd situation. The proposed simulations are a practical way to reduce fatalities and minimize evacuation time in panic situations. Moreover, we introduce a push behavior module, which will lead to an almost real pattern of crowd dynamics.

Theory and Approach

The proposed model will be presented as an extension of the work done by Helbing. The model proposed by Helbing is for a person who is part of a crowd and lives in a virtual world. This individual, who will henceforth be called the agent, is the element that will incorporate the intelligence of the system. Therefore, this approach is based on the collective behavior of individual intelligent agents, from whose interactions a group behavior and a dynamic of agents' self-organization will emerge.

Model proposed on agents

The microsimulation model proposed by Helbing, uses a mixture of physical and socio-psychological forces to simulate the dynamics of the crowd. Our goal will be to introduce (1) a panic parameter that affects agent behaviors, (2) a mechanism for spreading panic in crowds, and (3) auxiliary states for modeling push / push behaviors that do not belong to the Helbing model, being the contribution of the authors of the article [14], [15].

The novelty equation consists in planning two parts given by:

$$m_i \frac{dV_i(t)}{dt} = m_i \frac{V_i^o - V_i(t)}{\tau_i} + f_i$$

(1)

$$u_i(t) = m_i \frac{e_i(t)}{\tau_i}$$

(2)

where u_i(t) is the output of the control and m_i and τ_i are the mass and the constant agent, respectively. The interaction forces are given by:

$$f_i = \sum_{j(\neq i)} f_{ij} + \sum_w f_{iw}$$

(3)

where $e_i(t) = V_i0(t) - V_i(t)$ represents the error between the desired speed $V_i0(t)$ and the actual speed, $V_i(t)$. From eq. (2), we can see that the Helbing planning equation is the proportional representation of control.

Push / Push Pattern

The pushing or pushing behavior is one in which an agent tries to force a path through a crowd. This will require changing the modeling of the planning equation. To allow an agent to push, the planning part must overcome the interaction forces. To achieve this effect, we add an integrator to the planning part, resulting in a new acceleration equation that can be represented as a proportional integral control, this being represented in figure 4.

Figure 4: Speed control represented by the proportional values of the integrator.

In this context the equations are:

$$\frac{dV_i(t)}{dt} = u_i(t) + \frac{1}{m_i} f_i$$

(4)

$$u_i(t) = k_{pi} e_i(t) + f(P_i) k_{Ii} \int_0^t e_i(t) dt$$

(5)

$$f_i = \sum_{j(\neq i)} f_{ij} + \sum_w f_{iw}$$

(6)

$$e_i(t) = V_i^0(t) - V_i(t)$$

(7)

$$V_i^0(t) = \left(f(P_i) V_{i\,max} + (1 - f(P_i)) \left|V_i^0(0)\right|\right) \overrightarrow{V_i^0(t)}$$

(8)

where V_{max} is a scalar that represents the maximum speed that an agent can reach and $|V_i^0(0)|$ represents the initial speed (before panic) or the speed of the agent in relaxed situations. Moreover, $V_i^0(t)$ is a normal vector that represents the desired direction of the agent. The panic parameter $P_i \in [0,1]$ is also entered. The integrator is only active if $f(P_i)$ is nonzero. The increase of $f(P_i)$ increases the desire to push and cross the crowd. The function $f(P_i)$ has an exponential increase, mapping the panic parameter to a value ranging from zero to one, for example the appropriate function:

$$f(P_i) = \frac{1 - \exp(-P_i)}{1 - \exp(-1)}$$

(9)

The parameters kP_i & kIi, are integrative constants. The constants of proportionality and integration will determine the strength of the agent. In other words, they represent how fast an agent changes its status, the higher the constant, the faster the change. However, the interaction forces will be kept unchanged as described in the Helbing model. The repulsive forces will be active only if the agent j

was in the area surrounding the agent i, where the area of proximity for the force f_{ij} is defined by a circle centered at the position of the agent i with radius. In addition, there is a field of view, defined by a circle centered at the position of the agent i with radius rvi and used to activate fiw in a similar way.

Panic Behavior

"Herd" behavior is an essential reason for modeling panic behavior, in which individuals transfer their behavior to other agents. This leads to the spread of panic among other agents. In other words, the panic of individuals tends to cause social contagion, which leads to life-threatening blockage and overload. Each agent has P_i as a panic parameter, the value ranging from zero to one. The initial value of the panic parameter is always zero but increases due to sources of panic (fear) in the environment or could be acquired from the environment. In terms of dissemination, we use a model of consensus dynamics or dissemination with external input. Our model depends on the number of agents in the surrounding area and their level of panic [16]. The surrounding area is defined by a circle centered at the position of the agent with radius r_{si}. Panic behavior will also depend on the relative distances between agents. An agent will be more affected by agents who are at shorter distances. These factors result in the model:

$$P_i = c_i\left(z_i P_i + \sum_{j \in r_{si}} P_j w_j\right) + (1 - c_i) Q_i \tag{10}$$

$$\sum_{j \in r_{si}} P_j w_j + z_i = 1;\ w_j = \frac{(1 - z_i)/d_{ij}}{\sum_{k \in r_{si}} 1/d_{ik}} \tag{11}$$

where c_i is a constant, which is used to weigh the environmental effect of the influence of social behavior. Similarly, w_j is a constant used to weigh the influence of panic caused by agents in the area surrounding the agent. The constant z_i represents the personal confidence in the agent's own judgment on the generated situation.

For agents, the permissible values of control output $u\ t$) are limited. A level of saturation is used so that $|u(t)| < S_{ai}$. Panic sets in if the agent is stuck in the crowd and tries to open a path for himself, resulting in accumulation on terms of integration. This behavior is called windup. In other words, this occurs when the controller output can no longer affect the controlled variable (saturation), which leads to the accumulation of a significant error during this time in terms of integration. When the error $e(t)$ tends to zero, the control output $u(t)$ of the P_I is equal to the integration terms. To solve the problem, an anti-panic technique was used, involving stopping the integrator for periods of time until the response falls within an acceptable range. In our model, the integrator will be stopped if the control output $u(t)$ saturates, (shown in figure 5), reaches the pushing limit of the agent.

Figure 5: Control of the pushing speed of the agent when the panic is installed.

Detection of the escape route from a scene using Deep Learning and Voronoi networks

Motivation

Recently, Deep Neural Networks have been used to generate cutting-edge results in many subfields of the imaging industry. This category of algorithms can be used to extract a significant amount of information from many types of images or visual aids. Our activity focuses on training a neural network that accurately detects roads, analyzing images from an event. In the mapping industry, it is crucial to have detailed and accurate maps in order to be able to build accurate and quality travel route (evacuation) applications. The first step in achieving this goal is to detect all roads in a given area. Recent advances in aerial imaging technology make it possible for drones / satellites to provide high-resolution images that can be easily distinguished by anyone on the road. The goal is to build an intelligent system that, once it receives an aerial image, can accurately extract road topology. In technical terms, we need to generate a prediction for each pixel of the source image, namely the probability that that pixel is part of a path. Academic research calls this problem Semantic Segmentation because the image must be segmented into objects of interest. In the end, once the pixels are labeled according to the road, building the road network for later use becomes a relatively easy problem.

Theory and Approach

We briefly present as a first result a geometric solution to detect communities on graphs, based on Voronoi diagrams. This method is usually used to partition metric spaces into regions (Voronoi cells) around selected points (generating points), as illustrated in Figure 6 (black-red cell map representation). Each point in space belongs to the nearest generating point. We apply this solution in the case of graphs, where all the connections have a positive length and the distance between two nodes is equal to the shortest route between them, see figure 6 (green line) [17].

To introduce the clustering method, we first present the Voronoi partitioning method in 2D Euclidean space. Consider a set of points in a 2D plane, distributed to form local groups. We calculate the local density of the points inside the territories and select the generating points of the Voronoi cells inside their territory with radius r, as seen in figure 6 (the representation of the black-red cell map).

Each point in the plane is assigned to a Voronoi cell with the nearest generating point. As a result, the points are divided into groups by Voronoi cells [18]. To apply the previous theory to networks, we need to transform the graph into a metric space. First, we calculate a value of the distance between each two nodes, which is the length of the shortest route between them. The length of any route is equal to the sum of the lengths of the connections along the route, where we defined the length of the connection as the inverse of the grouping coefficient of the connections.

Once we have defined the distance, the next step is to determine the generating points. During the calculations we used a Voronoi generator point selection method based on the relative local density of the nodes. The best strategy for Voronoi partitioning, however, is to increase the r value and examine the quality of the clustering, for example by modularizing the cluster.

Figure 6: Automatic determination of the escape route (green line) from the event scene (background cell map) using Deep Learning and the Voronoi algorithm.

We tested our methods on real-world benchmarks and networks. We used benchmarking algorithms with a wide variety of settings of different parameters. I generated 100 graphs with different parameters. These graphs were partitioned by increasing the r values and the quality functions for our partitioning and for the communities predefined on the graph were monitored. For comparison we used the modularity function and the result of mutual information between our clusters [19].

When the method reached the maximum value of modularity, the values obtained from the mutual information were close to 1 (for the optimal value of r), indicating that the method successfully identified the original communities on benchmarks. However, it is noted that in some cases the structure of the communities is not very clear, since there are a lot of small groups.

Unlike benchmarks, in the case of real-world networks the grouping is more complicated. In this case we do not know the optimal structures of the communities, and the success of our method can be judged only by comparison with other methods already accepted [20]. We tested our algorithm on several real-world networks, with different structure and origin, and we compared the results with the results of five other algorithms used on a scale

range. We obtained that our method works well for relatively small values of the parameter r, and only if we have a pronounced mixing between communities, we do not find the right clusters.

Conclusion

Strategic decision support systems are integrated systems of policies, procedures, organizational structures, personnel, equipment, facility, and communications designed to support the exercise of the command and control process in all phases (states) of missions in the tactical field [21].

The strategic decision support system will ensure the transmission of information between the organizational structures (entities participating in the action) and the technical means of processing in the space related to the tactical field, beyond the visible and invisible horizon. The fundamental role of the technical decision support system is to ensure, in a timely manner, with maximum security, decisive and relevant information at the relevant levels to enable tactical forces to use it in achieving their objectives at all stages of the action. tactical. The missions that will be carried out by the strategic decision support system are:

1. Supporting command and control processes across the spectrum of tactical actions (providing decision-makers with the means to exercise authority and command of subordinate forces and those received in support to carry out the mission).
2. Support for planning, decision-making and rapid response in dynamically evolving tactical environments (rapid transition from offensive to defensive actions requires commanders to make frequent changes in conceptions and action plans).
3. Support for increasing the mobility of intervention teams and adapting them to different environments for carrying out specific actions.
4. Ensuring the exchange of information within the joint tactical actions, with the support of other participating entities.

Abstract

This article is focused on the analysis of information channels choosing preference during the self-study of teachers in the gender context for the decisive period from March to June 2020. Schools were closed worldwide in this period with the emphasis on communication with pupils via electronic platforms on the internet. Teachers were assimilated to completely new roles, within one week they had to adapt to this arisen situation and change the education in the sense of realised digital competence. The goal of the article is to find the scale of preferred information channels during the self-study of teachers and to compare the difference in preparations at men and women teachers in the three-month period mentioned above. We also wanted to know how the preference was changing according to the extent of the school residence where the online lessons were realised.

Keywords: COVID19, distant education, evaluation of teachers, pedagogy, self-study preference of teachers.

Introduction

The Czech Republic is the cradle of the tradition of education of the broadest levels of population. We file 94 % of people with higher secondary education in the age group of 25 – 64 years. As it can be seen in Figure 1, there are 150 thousand teachers (more precisely 150 592 in the period of January – February 2019) working in the level of pre-school, elementary and high schools in the Czech school system. According to [1] there is one quarter of men from this ground in the working process (more precisely 25,39 % in the period of January – February 2019). This situation is very imbalanced in pre-school education. Only a half percent of teachers are men (more precisely 0,68 % in the period of January to February 2019). Every tenth teacher is a man at secondary schools (more precisely 11,09 % men work at secondary schools in the period of January – February 2019). The older students study at schools, the more men work in the teaching staff. Nearly a third of men teachers work at lower-secondary schools (more precisely 31,90 % in the period of January – February 2019). High schools and colleges are already gender-balanced half on half (more precisely 49,94 % men teachers work here in the period of January – February 2019).

Fig. 1: Gender division of the number of teachers according to the type of school (Source: Own processing)

The state of ratio between female and male teachers in the Czech Republic is not rare at all on the global scale which illustrates Figure 2. In the theory of gender roles according to [2] there must also exist mechanisms of ways of behaviour in the question of preparations on work and self-study that are also expected from a person based on the gender. They blend with gender stereotypes and also participate on their creation. They can vary even in terms of one generation unlike the gender concept, that changes slowly. According to [3], [4], [5] the research points to the fact that the number of women in science, technology, mathematics and engineering (STEM) degrees are lower than the number of men. In addition, it has negative implication for closing gender gap earning because the STEM fields pay more than humanities and social fields, where women are majority Some authors consider the field of study choice as a relevant factor in the gender pay gap determination among graduates.

Fig. 2: Comparison of the gender balance in the pedagogical sphere between the Czech Republic and other countries [6]

The duty of further education when teachers renew, solidify and complete their qualification during their teaching activities is set by a school law that defines:

Forms of further education in the Czech Republic. Further education is realised:

- institutionally at universities

- institutionally in the facilities of further education of teachers (next marked in text and graphs as **FET**)
- **via self-study** [7]

There are 12 workdays set aside a year for self-study with varied selection of programmes and focuses for every teacher. This extent of time off corresponds to the time before breaking out of the COVID19 pandemic. During the distant education teachers had very little time for self-study of necessary technical competence. They also had limited resources when the state of emergency was declared. This period is often called the "big jump" period in the Czech Republic. Even conservative and elder teachers were forced to learn to work with new modern technologies as implements of their teaching communication with students and parents.

Methodology

The nationwide research to acquire necessary data was realised from March to June 2020 via the quantitative method of data collection with the participation of 211 experienced teachers (see Table 1). The whole research on the topic COVID19 in the school system for period mentioned above contained 42 questions and the recovery rate was 24 %. We choose the data relating to the objective of the contribution to this conference from the measured data.
The main objective of the research survey was to find the changes in preference in the question of self-study at female and male teacher before and after breaking out of the COVID19 pandemic.

The research question is: Which offered and used technologies and method do teachers see as great during the COVID19 pandemic, which were neglected and unused on the contrary?
We are going to reach the objective specified above via solving further particular problem marked **A**.

Problem A: Are there changes in preference of acquiring new knowledge and education trends in the area of using computers and multimedia in teaching before and after closing schools.
H1: The part of active self-study with a predominance of online publications, webinars, educational videos on YouTube etc. increased of one third among teachers in the period of COVID19 pandemic.
H2: There are differences in preference of using resources for self-study and teaching between male and female teachers.
H3: There is not a significant difference in preference of using resources for self-study and teaching between teachers from municipal and village schools.
The summary of the structure of the research sample is evident from following Table 1.

Table 1: demographic characteristics

Variables	Frequency	Percent		Variables	Frequency	Percent
Gender				**Age Groups**		
Male	34	15		18-29	11	5
Female	187	85		30-39	40	18
Magnitude of municipality where the school is				40-49	86	39
A municipality up to 2 thousand people	28	13		50-59	74	33
Small town 2001-10 000	74	33		60+	10	5
Middle 10 001-100 000	60	27		**Type of school**		
Big above 100 thousand	39	18		Elementary (1-5. grade)	97	44
Prague	20	9		Elementary (6-9. grade)	59	27
Teaching practice length (in years)				Elementary - special	4	2
0-2	14	6		Children's home with a school	1	0
3-5	16	7		A grammar school	12	5
5-10	33	15		Technical secondary school	31	14
10-15	29	13		Vocational school	5	2
15+	129	58		Another type of school	12	5
Education						
Complete University	218	98				
High school	3	2				

As visible in Table 1 shown below: Demographic characteristics, nearly 60 % respondents are teachers with experience of more than 15 years, only 6 % of the statistical unit can be considered as "beginning teachers".

Results

Problem A results: H1: The part of active self-study with a predominance of online publications, webinars, educational videos on YouTube etc. increased of one third among teachers in the period of COVID19 pandemic.

Fig. 3: Comparison of percentage preference of using information resources for self-study of teachers before and after the COVID19 pandemic (Source: Own processing)

Hypothesis H1 confirmed: 64 % respondents used covered opportunity of active study with a predominance of online publications, webinars and educational videos before breaking out of COVID19. During the online education it was 85 % which is a significant increase of 33,33 %. Preference in other areas like "trial-and-error" method, help from more experienced colleagues or family members remained the same. Organized accredited courses of FET recorded great fall of 23 %.

H2: There are differences in preference of using resources for self-study and teaching between male and female teachers.

Fig. 4: Comparison of percentage preference of using information resources for self-study of male and female teachers before and after the COVID19 pandemic (Source: Own processing)

Hypothesis H2 confirmed: Respondents answering these questions could use more answers to cover the area of their preferential interest of self-study more complexly. Male teachers use reading of special magazines more for their professional development in the area of new knowledge, educational trends, using computers and multimedia in lessons. We can see further differences in popularity of books for self-study. Male teachers started using the more during the period of COVID19 pandemic, it means it nearly doubled from 12 % to 21 %, on the contrary women stagnated on 9 %. Female teachers were more looking for support and advice in their families in this area. Female teachers used about three times more the "trial-and-error" method than male teachers.

H3: There is not a significant difference in preference of using resources for self-study and teaching between teachers from municipal and village schools.

The term "village" is obviously interpreted a little different in every country. In the Czech Republic we consider it a village when it is a township that has less than 2000 inhabitants.

Fig. 5: Comparison of percentage preference of using information resources for self-study of municipal and village teachers before and after the COVID19 pandemic (Source: Own processing)

Hypothesis H3 confirmed: We found that Czech village teachers have also great connectivity in terms of so many discussed differences between "villages" and "cities". The size of the facility (and particular absence of associated services) does not influence the way of preparation of teachers and their preference of choosing among particular types of self-study.

Conclusions

The continuity of education is one of the most important criteria of successful education. The transformation from contact education to online platform was realised successfully in the Czech Republic thanks to the change of preference of active self-study of teachers who were forced to change their usual forms and methods of teaching and upgrade their digital competence rapidly. The analysis of comparison of resource selection during self-study of teachers is also interesting according to gender and size of facilities. The results show that there are significant changes in preference of acquiring new knowledge and education trends in the area of using computers and multimedia in teaching before and after closing schools. The part of active self-study with a predominance of webinars, online publications, educational videos on YouTube etc. increased of one third among teachers in the period of COVID19 pandemic. Male teachers used to read special magazines and books more for their professional development in the area of new knowledge, educational trends, using computers and multimedia in lessons. Female teachers were more looking for support and advice in their families in

this area. Female teachers used about three times more the "trial-and-error" method than male teachers. Research shows here that active predominance of self-study using online publications and webinars creates the same conditions for education of teachers thanks to good connectivity in villages and it eliminates their preceding disadvantages related to the absence (or little variety) of available educational services in their surroundings. The closure of educational institutions due to preventive measures against the spread of COVID-19 has affected the education, well-being, and functioning of all parties involved in educational systems in the world.

The closure of educational institutions due to preventive measures against the spread of COVID-19 has affected the education, well-being, and functioning of all parties involved and benefiting from educational systems in the world.

The closure of educational institutions due to preventive measures against the spread of COVID-19 has affected the education, well-being, and functioning of all parties involved and benefiting from educational systems in the world.

Abstract

The aim of the article is to systematize knowledge of key managerial competencies in enterprises 4.0 as well as to learn about opinions on this subject expressed by the management staff from the enterprise sector. The first part of this paper presents considerations about managerial competencies. Next, the origin and essence of the concept Industry 4.0" were described. The aim of the empirical part is to solve the following research problem: what is the opinion of the senior management of large and medium-sized business entities about managerial competencies important in the context of changes resulting from the development of Industry 4.0? The article contains the results of research carried out using the desk research method and focus group interview (FGI). The empirical material allows for the conclusion that requirements for the competencies of the senior management are very high. Their broad, interdisciplinary knowledge of new technologies and the business opportunities that emerge from using them, must go hand in hand with communication skills and sensitivity to the needs of others. Impersonal analytical and strategic thinking must be supported by flexibility and creativity, commitment in building relationships (often virtual) and bold leadership in a dispersed team. Creating ambitious, bold visions of the enterprise development must be based on independence, mental resilience and self-discipline, but also on openness to various points of view. Due to the limitation of research to Polish managers, we treat their results as preliminary and requiring continuation.

Keywords: competencies, industry 4.0, senior management staff.

Introduction

Economy 4.0 – as it was in cases of the earlier industrial revolutions – constitutes the result of rapid technological changes coupled with changes in the social order, customs and behaviours of people. The main 'pillars' of Industry 4.0 include: the industrial internet of things, cloud-based production, smart factories, cyber-physical systems and social product development. The development of an industry based on digitization and new technologies generates challenges that can only be met by companies that are directed by managers equipped with competencies adequate to these challenges. Therefore, the study of key competencies in Industry 4.0 does not only have a cognitive dimension but also a utilitarian one because at the country level it allows for reorientation of the educational policy and at the organizational level it directs the selection of personnel and the policy of professional development of employees (Stock & Seliger, 2016; Sulich & Zema, 2020; Niemczyk et al., 2019).

The aim of the article is to systematize knowledge of key managerial competencies in enterprises 4.0 as well as to learn about opinions on this subject expressed by the management staff from the

enterprise sector. The article contains the results of research carried out using the desk research method and focus group interview (FGI). The interview was conducted among high-level managers (executive level) from selected industrial enterprises operating in Poland. These are the pilot studies whose results will be used to create tools for further, in-depth quantitative research.

Executive (managerial) competencies

For years, competencies were (and in many cases still are) equated with a formal right of a person to make decisions and take a position on the matter on behalf of the organization. The quality, effectiveness and efficiency of professional work were rather considered in the context of qualifications. Qualifications were mainly determined on the basis of formal education, knowledge and skills. Currently, it is assumed that the term *qualifications* has a narrower range and refers primarily to the results of formal education; replacing the term *qualifications* with the term *competencies* aims at reflecting changes taking place on the labour market, whereby in the process of performing work, routine manual work is replaced with activities definitely more intellectual (Assante et al., 2019, Moczydłowska 2009). It is also a manifestation of appreciating the importance of employees' abilities and talents as an element of their professional competencies.

T. Oleksyn (2006) is a supporter of a broad definition of competencies. While defining competencies, he lists a set of the following elements that create them:

- internal motivation,
- talents and predispositions,
- knowledge,
- education,
- experience and practical skills,
- health and physical condition,
- other psychophysical features important in work processes,
- attitudes and behaviours expected in the workplace,
- formal powers to act.

Competencies are additionally divided into universal competencies of the entire organization, universal competencies of managers and universal competencies of all employees. The universal competencies of the front line management include:

- ability to shape and effectively implement the mission, vision and strategy of the organization;
- ability to achieve the intended goals;
- knowledge and skills allowing for professional performance of all management functions;
- effective, rational and ethical management of all resources (human, financial, material) of the organization, skilful time and information management;
- competencies in the area of public relations and representing the organization in the external environment (Oleksyn 2006, pp. 25-30).

With regard to management staff, a distinction is also made between hard and soft competencies (Savanevičienė, Stukaitė, Šilingienė 2008, pp. 81-89). The first relate to knowledge and skills of the practical application of methods, techniques and tools useful in management, including mathematical, statistical, operational research, etc. Whereas soft competencies are mainly related to social and personal competencies, e.g. features of the management style, leadership or empathy (Ng, Kee 2018, pp. 252-257).

Researchers dealing with the issue of competencies determining the effectiveness of the manager's work often analyze them in three dimensions: attitude, managerial skills and knowledge (Dziekoński 2016, pp. 86-87; Kiełtyka 2018, p. 9). Each of them includes specific competencies, among which the dominant importance have:

- in the area of 'attitude': emotional intelligence, creativity, ability to show trust, consistency in action, ability to build authority, honesty, authenticity of behaviour, openness to diversity of

other people's attitudes, ability to deal with stress, establishing contacts easily, ability to work in a team, managerial awareness and courage;

- in the area of 'managerial skills': ability to make decisions under time pressure, responsibility, analytical thinking, ability to assess the effects of actions, ability to formulate goals, ability to organize the work of subordinates, ability to communicate effectively, ability to motivate team members, providing assistance in problem-solving, goal orientation, conflict-solving skills, negotiation skills;
- in the area of 'knowledge': extensive knowledge of determinants of effective management, including economics, psychology and sociology of organizations.

It will not be an overuse to say that managerial competencies are the most important among all resources of any organization. The quality of management is the result of the competencies of the management staff and motivation to use these competencies in practice. Without managers' professionalism it is impossible to create competency resources of an organization, diagnose these resources and transform them into a source of effective action. Moreover, the relationship between the competencies of the managerial staff and the professional competencies of employees should also be highlighted here (Sadowska-Snarska, 2014). Skills of managers, especially in the area of professional use of the human resource management tools, determine access to necessary competencies of individual employees. While making personnel decisions, managers are responsible for the quality of competency resources brought into the organization by its employees. By shaping and implementing incentive systems, managers are responsible for transforming employees' competencies into the desired and measurable results of their work. Therefore, it can be safely assumed that achieving management goals is impossible without a high level of managerial competencies of people performing managerial functions. These competencies are always assessed in a certain context, determined, on the one hand, by the framework of the organizational culture (Szydło 2018), and on the other hand, by the broad context of the global economy. Over the past few years, this broad management context has been dominated by changes known as Industry 4.0 (Economy 4.0).

Industry 4.0 – the origin and essence of the concept

Industry 4.0 is an indistinct and ambiguous concept. In the literature, it is referred to as an idea, concept, new corporate philosophy, industrial revolution, the result of this revolution, a new way of production, a new entrepreneurial paradigm, a new era of entrepreneurship and even as a 'specific label' used to describe the results of a research project financed by the German government (Białoń et al. 2018, pp. 84-85). The substitute term 'Economy 4.0' has also been adopted in Poland, where it has become a key element of the so-called Strategy for Responsible Development (Strategia ..., 2017) adopted by the Ministry of Economic Development. The authors assume that the term Industry 4.0 is a specific mental abbreviation used to describe a new way of manufacturing goods and services based on modern technologies and artificial intelligence, integrating the sphere of information and matter. At the same time, it should be clearly emphasized that due to the specificity of production systems in various branches of industry, the term Industry 4.0 cannot, as a rule, be generalized (Lasi et al. 2014, pp. 239-242).

The concept of Industry 4.0 was born as a result of the fourth industrial revolution (see Figure 1). The term 'industrial revolution' is attributed to A. Toynbee (after: Olender-Skorek 2017, p. 38), who identified the first of them in the beginning of 1760. Since then, four industrial revolutions have been described in economic sciences. Their common denominator was the introduction and publicity of an invention, which radically changed the production process and had an influence on the hitherto view about the structure of enterprises, work organization, used resources and efficiency. The 'key' words determining the understanding of the first three industrial revolutions are steam engine, electricity and computer (Mayer-Schönberger, Cukier 2013, p. 36). In the twenty-first century, changes in industry are advancing from electronic and information industrialization to next generation manufacturing systems (NGMS), also known as the intelligent ones (Drath, Horch 2014, pp. 56-58). They became the basis of the fourth industrial revolution known as Industry 4.0.

The genesis of Industry 4.0 is influenced by the cyclical nature of economic development and the emergence of crisis periods, in which appears an increased need to take risk and seek new technological solutions to ensure an increase in productivity of enterprises. The results expected

today are no longer achieved by economic activity performed by using methods characteristic of the paradigm of Industry 3.0 (i.e. electronic and information industrialization) from the second half of the twentieth century (Łapuńka, Marek-Kołodziej 2017, pp. 23-26).

Fig. 1: Industrial revolutions

It is assumed that the idea of Industry 4.0 is based on the vision of smart factories built of intelligent cyber-physical systems that are characterized by autonomy and have the properties of self-configuration, self-control and repair (Faller, Feldmüller 2015, pp. 88-91; Nosalska, Mazurek 2018, pp. 1000–1003). Germany is the birthplace of Industry 4.0 (Kagermann 2015, pp. 23–45). In 2011, in Germany, it was assumed that increasing global competitiveness by increasing the quality of products and reducing production costs would be only possible thanks to new production systems. These systems consist of an information system and autonomous numerically controlled machines using elements of artificial intelligence (Hermann et al. 2015, pp. 124-130; Lu 2017, pp. 6-10). A new technological generation in the area of production is heading towards designing manufacturing systems that integrate the information processing with the matter processing. This direction can be called 'digitization of the matter,' and its assumptions turn the smart factories controlled by CPS (Cyber-Physical Systems) into a reality in the Internet of Things environment. Probably for this reason, the terms Industrial Internet or Digital Factory are used alternatively to illustrate the changes described here under the name of Industry 4.0. The key process of the fourth generation can also be described as datafication, defined as the growing process of creating digital representations of subsequent areas of the real world and drawing value from the information obtained in this manner (Mayer-Schönberger, Cukier 2013, p. 36). Datafication also affects the way of functioning individuals in society since people have an access to an increasing amount of data that they can use to make life, professional and consumer decisions better suited to their preferences.

As mentioned before, the main goal of revolution 4.0 is to increase global competitiveness by increasing product quality and reducing production costs. A goal formulated in this way can hardly be considered innovative, but what is clearly new are the ways of achieving this goal. It is served by solutions in the area of smart factories and smart services, which increasingly will offer customers greater flexibility in operations and more efficient allocation of resources, paving the way for agile manufacturing and scalable logistics solutions. In the industry referred to as 4.0, computer networks

are integrated with the unified skills and real-time information exchange (Goliński 2013, pp. 37-43). Online process control makes it necessary to build an appropriate interface between humans, machines and technological devices, and as a result, defining their mutual interdependence. The Industry 4.0 concept describes the growing digitization of the entire value chain and resulting from this connection of people, objects and systems through real-time data exchange (Spath et al. 2013, p. 221).

Industry 4.0 is composed of three main parts. The first is IoT - Internet of Things and Cyber-Physical System. The second element of Industry 4.0 is associated with the progressive handling of a large amount of data and advanced analyzes (Ashton 2009, pp. 98-101). And the third part constitutes the appropriate communication infrastructure. Industry 4.0 is based on previously unknown combinations of technology, industry and digitization (Glas, Kleemann 2016, pp. 57-62). Moreover, the enterprise's system is not only a production system including machines and manufacturing devices, robots or industrial manipulators, but also a further environment, in the form of logistics systems, resources and customer service. All these elements, in accordance with the concept of Industry 4.0, should be highly integrated and connected, programmable, reconfigured, managed and flexible (Qina et al. 2016, p. 128). This leads to an increased demand for innovation in the area of new materials and technologies, innovative production processes as well as new business models. Therefore, it is no exaggeration to say that the new way of enterprise functioning, referred to as 4.0, has become a source of enormous, unprecedented challenges in the area of management, including new expectations regarding the competency resources of employees (Roszczyk-Kowalska 2018, p. 55). The analysis of the literature (Śledziewska, Włochy 2020, p. 171) shows that in enterprises 4.0 the following are of the key importance:

- Technological competencies that allow for a conscious and efficient interaction with technology in private and professional life. This group includes STEM (Science, Technology, Engineering, Mathematics) competencies, as well as advanced digital competencies in the area of programming and operating advanced IT systems. However, less advanced competencies, consisting in understanding the principles of functioning of machines and systems and controlling them by the use of intuitive interfaces, are becoming more important.
- Emotional competencies that allow for dealing with changes and uncertainty; these competencies facilitate teamwork and taking responsibility.
- Cognitive competencies including critical thinking, solving complex problems or creativity.

Competencies of a manager and challenges of Industry 4.0

In enterprise4.0, the management staff face the necessity to deal with complexity of data, complexity of problems and complexity of economic relationships between people, organizations, countries, and even cultures as well as between the entire human population and environmental conditions. Perhaps for this reason, cognitive competencies are indicated as the key competencies of managers of the Industry 4.0 Era. As Białoń and Werner (2017, p. 88) write, cognitive competencies are primarily composed of cognitive competencies in a narrow sense, i.e. ability to sensually perceive the world, use language, and thus also categorize sensory perception, ability to think, especially think creatively, and remember. In addition, cognitive competencies also include imagination or feeling emotions that do not belong to the traditionally understood cognitive competencies. The common product of these two groups is, for example, the ability to think with the help of metaphors and heuristics, extremely important especially in creative problem solving (Gigerenzer 2008).

One of the basic features of a manager in enterprise 4.0 is the awareness of benefits and risks of the idea of Industry 4.0 (Gudanowska et al. 2018, pp. 65-74). A manager who knows what his company is fighting for while implementing this concept will understand what he and his team must strive for and at what goals to direct the employees and the development of their competencies. And it is the word *development* that is of key importance in building a smart organization for a new era (Borowiecki 2016, pp. 9-16). Interdisciplinary and multidimensional development generate advanced competencies of employees who successfully combine technical skills with interpersonal skills (Jamka 2019).

Completely new technologies will require new technical skills. Examples include: integration of cyber-physical systems, advanced production management systems, advanced robotization, complex production data analysis systems, application of artificial intelligence algorithms in the production space (Schmidt et al. 2015, pp. 16-27). In an enterprise operating on the basis of cyber-physical systems, competencies related to ensuring cyber security move to the forefront. The success of modern projects also depends on good contact between employees at various levels of the organization and representing various specializations.

It should be emphasized here that the most modern technologies will not replace effective communication between team members and managers (Kinkel et al. 2017, pp. 323-330). This means that the ability to present complex technical problems in a simple and understandable way for representatives of other specialties assumes growing importance within the communicative competencies. Competencies such as flexibility of action, openness to changes and a positive attitude to the diversity of tasks as well as the ability to manage the time effectively and resistance to stress will still be highly valued. Managers cannot cope with the challenges of enterprise 4.0 without the ability to lead the project team, who will also operate differently than before. More and more often, remote communication with people from other cities, and even countries, with a different cultural background and speaking a different language will be at stake. Therefore, another key competency of the 4.0 era manager is intelligence and cultural sensitivity.

	professional	personal
conceptual	**cognitive**	**meta-competencies**
operational	**functional**	**social**

Fig. 2: Competency matrix

The authors, adopting the American definition of competency as a set of characteristics of a given person "which consists of elements characteristic for this person, such as: motivation, personality traits, skills, self-esteem related to functioning in a group and the knowledge that this person has acquired and uses"(Boyatzis 1980), propose that competencies of a manager in enterprise 4.0 should be presented in the form of a matrix (see Figure 2) covering both the dimension of personal competencies (manager as a person) and strictly professional competencies (manager as a task performer).

Based on the epistemological analysis, the authors of the article propose to assume that the key competencies of a manager in enterprise 4.0 are:

1. In the group of cognitive competencies: highly developed abstract and analytical thinking, highly developed spatial imagination, creativity, fluent thinking.
2. In the group of functional competencies: change management, project and process management at a high level of complexity, knowledge of modern technologies and their application, conflict management, commitment management.
3. In the group of social competencies: above-average ability to cooperate in a team characterized by a variety of competencies as well as generational and cultural diversity, managing relationships with all stakeholders of the organization, high level of mental maturity manifested by resistance to stress and emotional intelligence, authentic leadership.
4. In the group of meta-competencies: high self-awareness, managerial courage, openness, visionary approach to the enterprise's activity. Focus on continuous personal development.

Methodology and Results of The Research

The aim of the empirical part is to solve the following research problem: what is the opinion of the senior management of large and medium-sized business entities about managerial competencies important in the context of changes resulting from the development of Industry 4.0? In order to answer this question, the technique of focus group interview (FGI) was used. It is a research technique based on interviewing a group of people with similar experiences important in the context of the research subject. According to this methodology, the group of respondents is selected according to criteria such as age, gender or other important characteristics, for example, seniority in a managerial position (Barbour 2011). The group interview, the results of which are included in this publication, is based on the mechanism of introspection. The authors are aware that this method is perceived as the subjective one. Despite criticism from social science methodologists, introspective research basically constitutes the basis of all studies, and the use of their results in diagnosing the views of managers is based on the well-documented in the literature statement that an employee is the best source of information about the specificity of the organizational role and its determinants (Woźniak 2006, p. 706). Ten representatives of the senior management (6 men and 4 women) participated in FGI. The average time of their seniority in a managerial position was 11 years. At the time of research, all of them were performing a function of a director or board member. The discussion was moderated by the co-author of the article. The moderation was based on the experimental convention, according to which the moderator does not invite participants to take part in the discussion by calling individual participants to answer, but addresses the group as a whole (Lisek-Michalska, Lipiec, Olczyk 2012, pp. 207-211). The authors took care of the correct group dynamics assuming that it should have the following properties:

- an appropriate level of activity of individual participants – not too high to avoid monopolization of the discussion by individuals and not too low to prevent loss of information due to their withdrawal,
- domination of the subject – group relationship over the subject – moderator relationship, so as not to lose the character of a focus group interview in favour of individual interviews,
- the initiative of participants to engage in polemics with other participants or the initiative consisting in supporting the opinions of interlocutors with additional arguments,
- free expression of felt emotions,
- friendly attitude of participants taking part in the meeting towards other respondents, encouraging them to take part in the discussion.

The respondents' statements were recorded with their consent. The content analysis constituted the basis for drawing conclusions. The analysis of the message content is understood as "taking it apart into simpler elements (units of analysis) or distinguishing its features, properties and elements and then classifying them according to the adopted system of categories" (Worek 2001, p. 34). After B. Worek (2001, p. 36), it was assumed that the correct content analysis should have the following features: it should take into account only syntactic and semantic elements of the message, has to be objective and systematic, which means that a partial, biased analysis is unacceptable, in which only those content elements are selected that confirm the researcher's thesis.

Competencies mentioned by the managers were categorized (see Table 1), assuming the group division criterion presented in the theoretical part of this chapter. Additionally, a group of personal competencies was distinguished, which was not taken into account in the presented earlier typology of Delamare Le Deist and Winterton (2005, p. 40), and importance of which was emphasized by the participants of the research. The measurement of the amount of time the managers devoted to discuss individual groups of competencies shows that they talked about the importance of cognitive competencies for the longest time (approx. 30% of the time devoted to discussion), social competencies (also approx. 30% of the time), then functional competencies (20%), personal competencies (15%) and meta-competencies (5%).

Table 1: Groups of key managerial competencies in industry 4.0

Cognitive competencies	highly specialized professional knowledge, knowledge and understanding of the applications of new technologies, analytical and strategic thinking, openness to innovations, above-average creativity, flexible thinking	30%
Functional competencies	change management, project and process management, knowledge sharing, relationship management, customer orientation	20%
Social competencies	above-average ability to cooperate in a team, including a dispersed team, communicativeness, building a 'team spirit,' trust in colleagues	30%
Personal competencies	self-management, independence in thinking and acting, self-discipline, ability to work under pressure, work-life balance	15%
Meta-competencies	managerial courage, willingness to learn throughout life, life wisdom, ethical sensitivity.	5%

In the opinion of the managers, representatives of their profession in the era of Industry 4.0 must be very open to innovations and constant change. It requires constant learning and great flexibility as well as a kind of managerial courage. An example of such an approach is the statement: "In the chemical industry, which I represent, changes occur so quickly, product and organizational innovations are continuous, therefore only a person who is able to accept this pace or even stimulate it can effectively manage it. It must be a very creative, mentally strong and brave visionary."

According to the managers participating in the research, the senior management in enterprises 4.0 must have a very high level of interdisciplinary knowledge that goes far beyond the canons of traditional management. Basing your business on the latest technologies requires mastering the concepts used by their creators and understanding the possibilities offered by innovative solutions. According to the respondents, the role of a manager in the digital world of enterprise 4.0 is not to replace IT specialists and programmers, but to act as a link between experts in new technologies and those who will use them. As one of the manager noticed: "The most sought profession of the future will not be a programmer, but a person who will be able to understand it and precisely combine business and IT. This gap must be filled by managers of the new times." The multitude of managerial challenges in Industry 4.0 requires even greater analytical thinking skills, because paradoxically, despite the support of artificial intelligence, the amount and pace of data and information processed by managers is growing. During the group interview, the importance of strategic thinking was also commonly emphasized. According to one of the chairwomen, "despite the fact that in our daily work we focus on short-term results that guarantee our financial liquidity, we must not lose sight of the distant future and have a number of different scenarios of operation, depending on the dynamically occurring changes. A manager of the new times must be a strategist who plays in many fields at the same time."

In the course of the research, the importance of a specific managerial wisdom consisting in the ability to use the knowledge of colleagues has been highlighted. As one of the managers stated: "The worst that can affect us is an excess of ambition and a naive belief that we know everything better. Changes occur so fast, that even while still learning, we will not know everything. While managing enterprise 4.0, I must have an open mind and a lot of trust in my engineers, specialists and technicians."

According to the respondents, in enterprises 4.0 the value of social competencies will increase even more, including communication skills, team work, and ability to build authentic relationships. The following statement is an example: "The high mobility of employees, their dispersion, even on a global scale, means that the ability to communicate takes on a new dimension. It is not only communicating in different languages, on different cultural foundations, but most of all communicating remotely using various specialized languages. In addition, a link in the communication chain is more and more often the carrier of artificial intelligence. Therefore, it is no longer human-human communication, but human-robot-human communication. Managers have to

learn this and teach this in their organizations. The matter is further complicated by the fact that we will not get to know many of our close associates personally." Moreover, new challenges have been underlined that are associated with the fact that in the management process it is necessary to build a sense of commitment and employee-specialist bonds not so much with a specific employer, but with a 'flowing' project team. For that reason, an important managerial competency constitutes leadership understood as building a 'team spirit' and uniting very diverse employees towards a common idea.

The respondents also noted the ontological dimension of management in the era of Industry 4.0. A symbol of this discussion thread is the following statement: "Perhaps the most important competency of a manager is the healthy distance and criticism. You have to remember what is the point of the whole thing and for who it is to serve. There is always a risk that we may 'choke' on the possibilities offered by new technologies and forget that anyway the most important thing is the human being: the human being our employee, the human being our client." Another interesting statement is expressed in this trend: "Perhaps we will face a sad image of a business deprived of almost entirely authentic interpersonal relations." In this context, the specific humanistic sensitivity of a manager who must skilfully balance between the opportunities offered by new technologies and the needs of employees who often respond to these technologies with fear and a sense of progressive exclusion grows to the rank of an important competency.

In spite of the fact that during the focus group interview only 15% of the time was spent on expressing statements about personal competencies of a manager, the importance of such skills as working under time pressure, responsibility and taking care of your mental and physical well-being was strongly underlined. However, as pointed out by one of the participants of the research, "new technologies are also some kind of trap, which we also experience while managing our companies. We are available anytime, anywhere, and when a business partner forgets the time difference, we conduct teleconferences at three in the morning, neglecting our right to rest".

Summary

Implementation of the concept of Industry 4.0 causes far-reaching changes in the existing rules governing productivity and competitiveness. Enterprises must remove barriers between information and physical structures, which means the need for interdisciplinary thinking and putting into practice both technical and social competencies. Industry 4.0 requires modification of thinking about cooperation and changes organizational roles, forcing both the reorganization of process management and redefinition of the role of a manager.

The research shows that representatives of this professional group are aware of the challenges associated with management in enterprise 4.0 and competencies that enable them to cope with these challenges. They realize that the effectiveness of management, and thus the effectiveness of their work, requires the use of very diverse competencies. While analyzing the research results, the authors divided them into: cognitive, functional, social, personal and meta-competencies. The empirical material allows for the conclusion that requirements for the competencies of the senior management are very high. Their broad, interdisciplinary knowledge of new technologies and the business opportunities that emerge from using them, must go hand in hand with communication skills and sensitivity to the needs of others. Impersonal analytical and strategic thinking must be supported by flexibility and creativity, commitment in building relationships (often virtual) and bold leadership in a dispersed team. Creating ambitious, bold visions of the enterprise development must be based on independence, mental resilience and self-discipline, but also on openness to various points of view.

The results of the qualitative research presented in this article can be used as a basis for formulating hypotheses for further quantitative research. In addition, they can become the basis for constructing postgraduate managerial programs aimed at shaping and developing competencies important for people fulfilling the organizational role or preparing to fulfil it.

Abstract

The relevance of the research is determined by the Address of the President of the Russian Federation Vladimir Putin to the Federal Assembly in 2020, which forms profound and large-scale strategic changes in the constitutional, state and public construction for many years. The aim of the research is to provide an analysis of further improvement of the reformation and democratization of Russian society, which involves increasing the importance of civil society in a qualitatively new state and municipal management of socio-economic processes in the country, including processes in the socio-cultural sphere. The authors focus on the difficult conditions of the international situation, the consequences of coronavirus pandemic, with regard to which state and public institutions need to solve large-scale problems of socio-economic development without delay. It requires a new quality of state governance in accordance with direct dialogue with citizens.

Keywords: Address of the President of the Russian Federation, constitutional reforms, state governance, civil society, public oversight, socio-cultural sphere of society.

Relevance and Statement of the Problem

The most important feature of the Address of the President of the Russian Federation Vladimir Putin (2020) to the Federal Assembly of the Russian Federation in 2020 is the emphasis on the dialectical unity of the development of the processes of state and constitutional construction. It is in this harmony that many people see the future of the country. In this regard, the President of the Russian Federation delivered the Address to the Federal Assembly of the Russian Federation, saying that it is necessary to discuss "... state structure and domestic policy, which are defined by the Fundamental Law of our country – the Constitution of the Russian Federation. I keep getting these questions all the time …» (Presidential Address to the Federal Assembly, 2020).

It is well known that the adoption of the Constitution, more than a quarter of a century ago, was certainly a historic event because it stated, on the one hand, the change of political, socio-economic, ideological foundations of life of the country, and on the other hand, the birth of a new statehood, parliamentarism, Russian society, Federal, regional and local authorities, including the Presidency of the Russian Federation and the Constitutional Court, which had no parallel in the whole history of Russian society.

Extent of the Problem Elaboration

Over these years, the theoretical and methodological provisions of constitutional construction and the historical experience of its implementation in Russian society have been widely discussed by academic community. A number of articles, books, textbooks, monographs by such authors as A.N. Zuikov (Zuikov, 2008), V.A. Degtev (Degtev, 2005), A.N. Kokotov (Kokotov, 2010.) and V.D. Zorkin (Zorkin, 2018), N.A. Mikhalev (Mikhalev, 2010), Yu.I. Skuratov (Skuratov, 2007), M.A. Chekryga (Chekryga, 2010) were published.

Statements by the country's leading figures on this topic appeared in the media immediately before the constitutional anniversary of the new Russia. President Vladimir Putin addressed the theme of the anniversary of the Constitution of the Russian Federation repeatedly and emphasized the historical significance of the event. Federation Council Speaker Valentina Matviyenko gave an interview to Rossiyskaya Gazeta (Mislivskaya and Sadchikov, 2018), former Prime Minister Dmitry Medvedev published the article “25 Years of the Constitution of the Russian Federation: Balance between Freedom and Responsibility” in the journal “Zackon” (Medvedev, 2018), and the President of the Constitutional Court of the Russian Federation published the article “Letter and Spirit of the Constitution of the Russian Federation” in the Russian government newspaper (Zorkin, 2018).

State authorities and mass media drew public attention to the provisions of the Constitution of the Russian Federation as many citizens were not familiar with its content and history of adoption. Representatives of government bodies and citizens began to perceive the Russian Constitution in a new way, analyzing the processes in the country from a socio-political point of view, they were aware that our new Constitution is still imperfect. President of the Constitutional Court of the Russian Federation Valery Zorkin (2018) emphasized the fact that there are some shortcomings in the adopted laws, however they are quite correctable by certain alterations and further adjustment of the provisions of the Constitution of the Russian Federation to social and legal realities (Zorkin, 2018).

It is known that in accordance with Articles 83, 90, and 115 of the Constitution of the Russian Federation and existing legislation, the President of the Russian Federation has broad powers of presidential control in a diverse constitutional process. These powers are diverse, complex, dynamic and generally involve a high level of responsibility of the parties.

The event – the adoption of a new Constitution – takes place in a large country, in a difficult historical situation, therefore the President needs to have special political and legal powers and mechanisms that can be used to organize the functional activities of a modern law-based state. At the same time, the President exercises presidential control not only at the Federal level, but also at the regional and even municipal level, and the most important mechanism for such control is the Federal districts headed by representatives of the President of the Russian Federation. There are also representatives of the President of the Russian Federation in the Russian regions – the Chief Federal Inspector and his staff and the reception offices of the President of the Russian Federation; they maintain constant contact with the citizens.

In our opinion, academic community warmly and gratefully notes the fact that the historically specific experience of presidential control in our country – an integral part of the constitutional process of reforming and democratizing Russian society – has taken place during the execution of the duties of the President of the Russian Federation by Vladimir Putin. It is known that in March 2000, by all-Russian vote, Vladimir Putin was elected President of the Russian Federation, replacing Boris

Yeltsin, the first President of the Russian Federation, who, due to the prevailing objective and subjective circumstances, prematurely retired.

Vladimir Putin became the Head of State and guarantor of the Constitution of the Russian Federation at an exceptionally difficult time for the new Russia. At the cost of enormous efforts, relying on various branches of government, socio-political potential, and various social categories of the population, the President was able to implement a number of serious reforms in the country, including those that contribute to the democratization of Russian society, the unity of the people, and Russia's defense capability. It was V.V. Putin (2020) who managed to increase the role of the new Russia at the international level.

Thus, the Russian President, as the Head of State and guarantor of the Constitution, considering the established constitutional requirements, takes measures on protection of the Russian and shows initiative for its improvement. The President of the Russian Federation in his Address to the Federal Assembly and the people emphasized the need to introduce certain changes to the country's main law that will directly guarantee the priority of the Constitution of Russia (Presidential Address to the Federal Assembly, 2020).

The Address of the President of the Russian Federation to the Federal Assembly contains also the idea about the need to increase the place and role of civil society in the solution of large-scale socio-economic and technological challenges that require new quality of state governance, government's work, all levels of government, direct dialogue with citizens: "Our society is clearly calling for change. People want development, and they strive to move forward in their careers and knowledge, in achieving prosperity, and they are ready to assume responsibility for specific work. Quite often, they have better knowledge of what, how and when should be changed where they live and work, that is, in cities, districts, villages and all across the nation." (Presidential Address to the Federal Assembly, 2020). This change must be the result of "direct dialogue" with citizens and "they must be actively involved in this process" (Presidential Address to the Federal Assembly, 2020).

Research Results

Problems of political participation in state and municipal governance and public oversight carried out by civil society institutions, representatives of multi-party organizations, trade unions, public councils and associations require different ways of solution, as well as consideration of public opinion.

Some people believe that participation in public administration and control is hindered by paternalistic attitudes of a significant part of citizens, their dependency and a certain lack of self-confidence, which negatively affects the growth of their civic activity. This is also the fault of the media, which often do not contribute to improving the competence of citizens, especially at the regional and local levels (Molodov, 2015). Others note "the low involvement of a big part of population and civil society institutions in the form of real non-profit organizations in the implementation of public control. This is largely due to the low level of legal awareness, legal culture of citizens, and low level of trust in civil society institutions…" (Ibragimova, 2017). There is also an opinion that "the legal understanding of the subject of public control is higher than the level of knowledge of an ordinary citizen, which creates a barrier to the participation of ordinary citizens in the analyzed group of legal relations, and neither citizens nor public associations are yet fixed among the subjects entitled to carry out measures to implement public oversight in the law on public control" (Collection of Legislation of the Russian Federation, 2018).

The complexity of public control is determined by high significance and inaccessibility of certain authorities and management in society due to the closed nature of these institutions, while the implementation of public oversight requires the accessibility of their activities. A new concept of openness of executive authorities has recently started working: "expanding the opportunities for civil society participation in the development and expertise of decisions taken by executive authorities" (Vasilyeva, 2014). The emergence of "open government" and other measures of information

openness contributes to it, however, apparently, by inertia, there is a steady distrust of citizens to public organizations due to their lack of professionalism and social activity.

We think that the practical significance of the essence of public oversight is now understood ambiguously, however at the moment there is no alternative to it, and this movement continues to occupy an important place in the reformation and democratization of Russian society, and therefore in solving the most important tasks set in the Address of the President of the Russian Federation. Moreover, in accordance with the Address of the President of the Russian Federation, the role of civil society in the process of transformation is strengthening significantly, and there is a closer interaction of public control bodies with state and municipal authorities and other organizations and departments.

Much has been said and written about the concepts and definitions of public oversight, however we must keep in mind that there is a need to preserve and develop this movement (and we observe it at meetings of the President of the Russian Federation with residents of Moscow, St. Petersburg, Smolensk, Kirov, Ivanovo region, etc.). There is a need to have feedback from public, socially active citizens, and public institutions that, in accordance with existing norms, participate in the formation and development of Russian society, influencing the solution of current problems the state and the society are facing.

There are many other definitions of public oversight in the press. In general, this institution is a set of means and techniques by which society guarantees that the behavior of its members, individual public associations and social groups, will contribute to ensuring the legality of state and municipal governance, in accordance with the established norms (Semenova, 2011).

To improve the effectiveness of public control in modern conditions, civil society institutions should pay attention to the provisions of the new Constitution of the Russian Federation adopted on December 12, 1993, which became the starting point of legal public oversight at the stage of formation of reformation and democratization of Russian society. Part 1 of Article 45 and the legal relationship of Articles 2, 17, 18 refers to the need for public oversight over the activities of authorities and their representatives (Constitution of the Russian Federation, 2008). Article 4 of the Decree of the President of the Russian Federation No.601 “On the main Directions of Improving the System of Government Administration” (Official Internet Resources of the President of Russia, 2012), adopted on 7 May 2012, emphasizes that “activities of subjects of public control carried out in the course of monitoring the activities of state authorities, local self-government bodies, state and municipal organizations that exercise certain public powers in accordance with Federal laws, as well as for the purpose of public verification, analysis and public evaluation of regulations issued by them and decisions taken” (Official Internet Resources of the President of Russia, 2012).

The country's first Federal law No.212 of July 21, 2014 “On Fundamentals of Public Control in the Russian Federation” strengthens legal and regulatory framework for public oversight significantly (Collection of Legislation of the Russian Federation, 2018), it also uses the term “public control” for the first time. Attention is again focused on the need for participation of civil society institutions in the implementation of public control, and various forms and methods of this participation are defined, they are “aimed at ensuring the balance of integrity and effectiveness of the reformation, ensuring a positive effect of the ongoing state reforms” (Yarovaya, 2019).

In his Address to the Federal Assembly, the President of the Russian Federation encouraged civil society institutions to participate in state and municipal management and public oversight more actively, in particular in the implementation of demographic policy (Presidential Address to the Federal Assembly, 2020); in the implementation of the national project Russia – Land of Opportunity; in the sphere of the healthcare: “to monitor the provision of equipment, construction and repair of rural paramedic centres (Presidential Address to the Federal Assembly, 2020); in the development of education, creative work, implementation of social and cultural projects. The President emphasized the importance of “every creative initiative of our citizens, public associations, non-profit organizations, as well as their willingness to contribute to national development” (Presidential Address to the Federal Assembly, 2020); traditions of mutual assistance and respect for

older generations, the volunteer movement that unites schoolchildren, university students, and people of different generations and ages; the President encouraged to focus on the economic and social growth of our regions and interests of people, which "is possible only with the active participation of society, our citizens and, of course, ... all branches and levels of government" (Presidential Address to the Federal Assembly, 2020); to participate in improving the political system of society "... considering the maturity of our main political organizations and parties as well as the reputation of civil society, I believe these proposals are justified" (Presidential Address to the Federal Assembly, 2020).

About 100,000 civil society representatives are seeking to participate in the preparation and conduct of the upcoming vote on constitutional amendments. In the conditions of a critical situation – coronavirus infection (global pandemic) – institutions such as professional associations of doctors, nursing staff, social workers, business organizations, the media, the volunteer movement resolutely came to the aid of the country to protect our people, primarily children and older people, at the call of the government. Other representatives of civil society also provide irreplaceable support in this nationwide battle: parties, trade unions and other socio-political communities, professional and socio-cultural associations, numerous local formations.

The Russian President's initiatives to strengthen the country's defense capability and state security include, on the one hand, the creation of the main military and political directorate in the structure of the military department and the development of socio-political education of the personnel of Armed Forces, and, on the other hand, the interaction of the public with the leadership of the Armed Forces structures in solving this most important task.

Today, there are public formations under various branches of the Armed Forces. For teenagers there are clubs for young friends of pilots, tankmen, sailors, border guards, and cosmonauts. Military-technical centers, clubs and clubs work for military and pre-military age youth. At higher and secondary educational institutions there are search teams on the places of military battles of the Great Patriotic War. Representatives of the older generation of labor collectives, socio-cultural sphere are members of public councils under various defense agencies, law enforcement agencies and military-patriotic associations. As President of the Russian Federation Vladimir Putin emphasizes, this approach helps to strengthen the unity of these bodies and all categories of the population, makes their work more transparent and highly accountable to society» (Presidential Address to the Federal Assembly, 2020).

Some of these important issues of improving the civil society and developing its institutions in state and municipal management and public control are considered as part of possible amendments to the Constitution of the Russian Federation. The President emphasized that "public associations, parties, regions, the legal community, and Russian citizens will express their ideas. The broadest public discussion is needed." (Presidential Address to the Federal Assembly, 2020).

The issue of amendments to the Constitution of the Russian Federation was considered at the meeting with the working group chaired by Vladimir Putin. Distinguished representatives of the cultural community M. Petrovsky (2020), A. Kalyagin (2020), D. Matsuev (2020) proposed an amendment to the Constitution in the sphere of our national culture as the symbol of the nation is the DNA of the nation. Our national culture is famous in the world for such names as L. Tolstoy (1918-1986), F. Dostoevsky (1821-1881), P. Tchaikovsky (1840-1893), R. Shchedrin (1932), A. Solzhenitsyn (1918-2008), K. Malevich (1879-1935), V. Kandinsky (1866-1944), K. Stanislavsky (1863-1938), R. Gamzatov (1923-2003), F. Iskander (1929-2016), Yu. Temirkanov (1938), V. Gergiev (1953), D. Likhachev (1906-1999), D. Granin (1919-2017). This is an outstanding image of Russia, and it must be protected, therefore we propose an amendment to the Constitution of the Russian Federation that states that our national culture is supported and protected by law. Vladimir Putin approved this proposal and stressed that it is culture that makes us a multi-ethnic Russian people and shows our identity.

Proposals and Conclusions

As a result, the Law of the Russian Federation “On Amendments to the Constitution of the Russian Federation" in Article 68 states that “the culture of the Russian Federation is a unique heritage of the multi-ethnic people. Culture is supported and protected by the state” (Meeting of Vladimir Putin with the working group on drafting proposals for amendments to the Constitution, 2020) and Article 69 emphasizes that “the state protects cultural identity of all peoples and ethnic communities of the Russian Federation, guarantees the preservation of ethno-cultural and linguistic diversity”. Article 3 contains an important addition that “the Russian Federation supports compatriots abroad in preserving the all-Russian cultural identity” (Meeting of Vladimir Putin with the working group on drafting proposals for amendments to the Constitution, 2020).

Along with other proposals, the Commission's meeting in February 2020 adopted a proposal of members of the working group to define the place and role of civil society in the Constitution of the Russian Federation in the following words: “the State fully contributes to the development of civil society”. Following the discussion, Russian President approved the introduction of this provision in the new Constitution of the Russian Federation, and in the law of the Russian Federation on the amendment to the Constitution in Article 113 was written for the first time that the Government “Implements measures to support civil society institutions, including non-profit organizations and ensures their participation in the development and implementation of public policy” (Law of the Russian Federation on amendments to the Constitution of the Russian Federation, 2020). These measures also involve the volunteer movement and business.

Public institutions, as well as other state and municipal organizations, participated with interest in drafting their proposals for constitutional amendments. At the beginning of February, more than 220 proposals had been submitted, and by the end of the month, more than 900 amendments were under consideration by the working group. Russian President Vladimir Putin has repeatedly met with the working group to draft proposals for amendments to the Constitution of the Russian Federation. At the first meeting in February, Russian President Vladimir Putin emphasized that in working on proposals for amendments to the Constitution of the Russian Federation, “It is extremely important here to double-check every word, every letter, and every comma. But at the same time, we should not omit what was created with great effort of our people and enshrined in the current Constitution; we should not lose anything but, on the contrary, we must meet today’s challenges (Meeting of Vladimir Putin with the working group on drafting proposals for amendments to the Constitution, 2020). In the context of a democratic approach to the entire socio-political campaign, representatives of the non-systemic opposition, usually activists of individual parties, public organizations and movements, including those associated with liberal Western ideas and its aggressive ideology, also proposed their amendments to the Constitution of the Russian Federation. Even in these conditions, some of them partially support the proposed changes, and there are those who oppose some provisions of the Constitution and any amendments, however, in our opinion, it will not have a significant impact on positive people's movement because many people in Russia have long been aware that with all positive attitude to the Constitution of 1993, adopted in the difficult conditions of the initial stage of formation and development of Russian society, it does not fully corresponds with the essence of sovereignty and interests of the broad masses of the Russian population.

In this regard, we would like to draw attention to some aspects of the relationship between civil society institutions and other organizations and agencies. As for the attitude towards some aggressive pro-Western organizations, our attitude towards them as organizations of foreign agents is unequivocally negative. The proposed amendments to the Constitution of the Russian Federation offer a number of preventive measures concerning their representatives and their actions. Our attitude to other civil society institutions is another matter. We are not always attentive and caring in our daily life to public organizations. Unfortunately, there are still many regional and municipal government representatives, managers, business structures, entrepreneurs who sometimes, due to their busy life, underestimation of the place and role of civil society institutions in the socio-political process of municipal and regional organizations, sometimes show bureaucracy and indifference, do not pay due attention to their own numerous and quite diverse organizations and associations of civil society,

ranging from teenagers to veterans. As a result, there is often various signals of misunderstanding, critical assessments of their activities, and complaints to higher authorities as feedback, proving that civil society and its institutions, as well as regional representatives of state power and management, are an integral part of the socio-political system of Russian society. These organizations and agencies now need to think about the constitutional assessment of civil society and its institutions because for the first time in our history one of the amendments to the Constitution of the Russian Federation states the need to help civil society institutions, promote them and support them.

In our opinion, state and other organizations and departments should pay attention, first of all, to the huge creative potential of their civil society institutions, without which no problem can be solved in our society at any level – industrial, social, health, socio-cultural sphere, and especially public administration. However, to do this, it is necessary to strive for constant cooperation and interaction – to respect their status and not seek to manage these institutions themselves, avoid bureaucracy, and find the right methods of interaction, as Vladimir Putin, who heads various public councils, commissions and working groups under the President of the Russian Federation, demonstrates daily. He finds time to communicate with representatives of Federal, regional, and municipal civil society institutions. These meetings have become traditional and are a kind of effective feedback channel with citizens: "Most of all I trust the sentiments of average people as through their judgments, interest and sincerity, you can see the problems of millions of citizens" (Interview with Vladimir Putin, 2020).

Thus, the Address of the President of the Russian Federation to the Federal Assembly with a call to start solving large-scale socio-political, socio-economic problems in practice was, at the same time, an address to Russia's people. It aroused an unprecedented interest and desire of many citizens to be involved in improving the constitutional process and state building in the country. A new mechanism of state governance is emerging, which takes into account direct dialogue with citizens, strengthening the balance between the society and the state. This scientific-based approach in the Address of the President of the Russian Federation determines the viability of a democratic state designed to respond to modern socio-political, socio-economic and cultural challenges and threats in these difficult conditions of our life.

Abstract

In any organization, the performance of HC plays an integral role in organization success. Although human capital competencies vary widely, but they are crucial part in the workplace. The development of human capital is one of the pillars of success in most industries. Innovation is one of the elements that have transformed the business in recent decades. UAE has arisen as a country with a resilient awareness and encouraging approach towards innovation. The vision of UAE government is to become one of the most initiative governments by the year 2021. Therefore, this study is designed to analyze the current innovation practices by the government towards human capital development as well as innovation management and examined the direct relationships between these variables. To achieve this goal, quantitative methods were applied after the survey in The Ministry of Community Development (MOCD). The total number of population equal to 1230 individuals. Those individuals represent the staff working in MOCD. The outcome of this study revealed significant relationships between all variables. This research makes the following contributes: first, a valid factor structure for innovation and human capital development was formulated; second, measurement of the influence of these variables in public organizations was validated.

Keywords: Innovation Practices (IP), Human Capital Development (HCD), Innovation Management (IM), Human Capital (HC).

Introduction

Innovation is one of the elements that have transformed the business in recent decades. The concept of innovation has enabled both developing and developed countries to bring together extensive transformations among which some have been successful while other remained unsuccessful. If an innovation fails in the public division, it will have an impact on the citizens. Therefore, effective innovation in the public division is virtually indistinguishable, while a noticeable failure can put an end to brilliant career (Bain and Kleinknecht, 2016). It provides context in which companies, individuals and governments operate indicating the ability of a nation to attract innovative ideas and investments (Bason, 2010).

UAE seeks of developing environments which would enable and promote innovation through development of adequate regulatory framework, giving broad enabling services, improving technological infrastructure and warranting availability of incentives and investments. The key for success in innovative endeavors is the creation of right environment for innovation (UAE National Innovation Strategy, 2015). Human capital (hereafter referred as HC) forms the base of innovation as evident from the increasing concern of governments and companies over the world in recognition and promotion of innovative individuals and groups (OECD, 2014). Thus, the government of UAE, focuses

upon development of individuals who have high spirits of innovation. It aspires empowering nation for driving innovation through development of innovative people and their capabilities in technology, science, mathematics and engineering while equipping them with skills of 21st century (UAE National Innovation Strategy, 2015).

The question arises how to stimulate innovations has been extensively addressed in the strategic management field many studies in the past. However, the role of human capital in innovative development has not yet been explored fully. Scholars are still unable to provide a framework explaining how human capital development (hereafter referred as HCD) is linked to innovation management (Alsufyev, 2013). That is why the goal of the current study is to overview the literature body regarding the human resource development in order to differentiate it from human resource management and provide synthesis of diverse theories explaining the impact of innovation practices on HCD.

The aim of study

Many studies in the past have covered the topic of innovation and HCD. However, the question arises how to stimulate innovations from various perspectives towards HCD. The literature review shows that the role of IP to develop the workforce has not yet been explored broadly. While in UAE there are limited studies discussed the role of IM in public sector, this study aims to fill this theoretical gap and explain how IP and IM could enhance the skills of individuals. Scholars are still unable to provide a framework explaining how human resource development could be influenced by IP and management (Alsufyev, 2013). Despite there are lots of studies revealing that the development of HC will enhance innovation performance. But there are lack of empirical evidences on the contrary impact of innovation towards HC in many industries. That is why the objective of the current study is to overview the literature body regarding the human resource development in connection with innovation in order to differentiate it from previous research projects on this topic and provide synthesis of diverse theories explaining the impact of innovation on individual development. This study is designed to analyze current practices of government innovation in UAE towards HCD. The research problem is that there is no empirical evidence showing that a link between innovations practices (hereafter referred as IP) and HCD as well as the mediation role of innovation management in this model. Therefore, the research hypotheses were developed to determine the relationship between IP and HCD, and IP with innovation management (hereafter referred as IM), and finally between IM and IP in UAE. To achieve this goal, quantitative methods were applied to examine innovation practice in the Ministry of Community Development (MOCD). The total number of population equal to 1230 individuals. Those individuals represent the staff working in MOCD.

The concept of Innovation

Innovation refers to the successful implementation of a novel idea on the market and workplace (Steiber and Alänge, 2014). The advantages of this definition includes implicitly which emphasizes the difference between creativity and invention on one hand, from product development and implementation on another hand. It gives an aim and push to organizations by suggesting that creativity is not important without follow-through. The importance of this definition, is to move beyond classical boundaries of innovation idea generation and patenting (Benaim, 2015).

Simsit et al. (2014) stated that innovation is the continuous process through which productive resources are developed and utilized to produce higher quality with lower cost products than had previously been available. In the same context, Ilori et al. (2017) defined innovation as new knowledge incorporated in process, product, and service. The author also categorizes innovations according to technological development, marketing activities and organizational characteristics. Based on definitions mentioned above, innovation begins with sequential processes includes the recognition of a problem or discovery a novelty idea, then extends over the problem-solving and the creation of productive ability to the introduction of the creative product and service on the marketplace.

Previous studies showed that innovation have developed from the earliest times to today. For instance, from the 18th century there was some development in the innovation though not very much involvement

was done. It included the development of tractors, car engines and new machines. In the 19th century, the innovation improved to a more improved involvement including the application of the technology in innovation (Brown and Osborne, 2013). While in the 20th century the concept of innovation has continued to improve in all sectors including the development of the telephones, typewriters, power plants, manufacturing and many other industries. In the 21st century the concept of innovation has experienced a rapid advancement due to the advancement in information technology. For example, the development of super computers, smart phones and artificial intelligent (Baden-Fuller and Haefliger, 2013). The 21st century have really improved the communication industry in a way that innovation have aided communication effectiveness inside organizations. Innovation has grown prolifically over the past few decades, this has led to a great need for scholars to do a lot of research and try to come up with solid information on the same.

Innovation does not occur spontaneously. This is certainly true because in the case of the intensive competition in the global environment, the organizational authority is required to coordinate, facilitate, and decide to be innovative. Innovation depends on effective cross-functional orchestration. The purpose of this orchestration requires to organize the teams and dividing up responsibilities, roles, and powers to be part of the innovation challenge. Consequently, the organization must have a suitable organizational structure with explicit orientations and commitment to innovation (Nagano et al., 2014).

Innovation in UAE

UAE has arisen as a country with a resilient awareness and encouraging approach towards innovation. The UAE Government has exhibited a determination and holds the funds to capitalize the infrastructure, employment opportunities and HC to foster growth and innovation (Schilirò, 2015). Significant business has already been supported by the substantial investments that includes the oil and gas industry, semiconductor, green technology, aerospace and ICT in accordance with its approach towards becoming a prominent economy based on knowledge (Schilirò, 2015). UAE has arisen as a country with a resilient awareness and encouraging approach towards innovation. The UAE Government has exhibited a determination and holds the funds to capitalize the infrastructure, employment opportunities and HC to foster growth and innovation (Inkinen et al., 2015).
The vision of UAE government is to become one of the most initiative governments by the year 2021. In UAE, significant developments have been made by considering innovation as an important element for the growth and development in the country. The National Innovation Strategy (NIS) seeks taking innovation within UAE to great heights, where innovation culture will be implanted amongst companies, individuals and the government. Primarily it directs attention upon identified priority sector which will be driving innovation in future. Framework of national innovation strategy is structured around these key pillars:

i. Innovation Champions.
ii. Innovation-Enabling Environment.
iii. Innovation priority Service.

Moreover, the government of UAE has set out innovation strategies so as to reach the targeted position. There are three strategies set out for this namely creation of an enabling environment, innovation champions and by having innovation priority sectors. An enabling environment means setting out conditions that promote innovation. The government has formed innovation frameworks, improved on technology infrastructure and investment and incentives. All those companies trying to increase and focus more on innovation the government is setting out supporting measures to make sure their innovation reach a higher level without much financial constraints and by avoiding other challenges. But if an innovation fails in the public division, it will have an impact on all the citizens. Effective innovation in the public division is virtually indistinguishable, while a noticeable failure can put an end to an up to then brilliant career (Bain and Kleinknecht, 2016). Thus, NIS not only drives top international and national business towards investment in research and development but also aspires to building innovation and scientific research centers, sponsor innovative nationals, adopt advanced technologies, and launch award of national corporate (UAE National Innovation Strategy, 2015). NIS target innovative companies from all over the world and promote the reputation and role of UAE as

global center to test innovations across identified sectors of innovation. NIS appeals for improvement of specialized zones for specific sectors in line with Media, Industry, Renewable Energy, Internet and other specialized zones present within country (UAE National Innovation Strategy, 2015).

Innovation Practices

The concept of Innovation Practice (IP) is defined from the various perspectives in the literature. IP is defined as the representation of a process, usually an activity of developing a new service or a product, new process in technology, new organization, or improvement of the existing service or product (Deakins and Freel, 2009). Innovation has been appraised and considered to be necessary for individuals and organizations (Mehmet, 2016). Ideas are the raw materials for innovation, and they can have vital influence on the success or failure of IM (Fontana and Musa, 2017).

IP is the combination of overall organizational achievements as a result of renewal and improvement efforts done considering various aspects of firm innovativeness, i.e. processes, products, organizational structure, etc. Therefore, IP is a composite construct (Hagedoorn and Cloodt, 2003) based on various performance indicators pertaining, for instance, to the new patents, new product announcements, new projects, new processes and new organizational arrangements. Adams et al. (2006) observed that measurement of IP does not appear to take place routinely within management practice in organizations.

Martín-de et al. (2012) classified innovation by different categories, such as product, process, organizational, and marketing innovation. The measurement of innovation is regarded as a structured process rather than a hope-based strategy. It is evident that, innovation has traditionally focused on products and processes, and then it has attracted attention in other fields such as marketing and even organizational level. The new area of business will provide significant gains regarding innovation; however, the combination of product, process and distribution hasn't reflected the sufficient potential for organizational innovation (Doğan, 2017). Therefore, at the present, several types of innovations including the incremental product, radical product, incremental process, radical process, administrative innovation have been extensively studied (Kim et al. 2012). While this study is focused on four types of innovation (Product, process, marketing and organizational innovation). Marketing innovation is defined as implementing new marketing method that involve significant changes in the packaging, design, placement and product promotion and pricing strategy (OECD, 2005). While, Organizational innovation is defined as introduction of new practices of doing business, workplace organizing methods, decision making system and new ways of managing external relations (Polder et al., 2010).

Innovation Management

In order for innovation to take place, it depends on a complicated set of interactions between various elements of organization. Innovation require to establishing comprehensive system which are able to support innovation in a systemic way. The implementing of this system requires individuals should be dynamic and divisions interacting with each other, and emphasis to making decisions across organizational levels, which engage individuals in innovation activity, as well as improve the quality of the organization's relationship with the external environment (Nagano et al., 2014).

A large and growing body of literature has investigated the relationship between innovation and management, which is extensively seen as the heart of a competitive in contemporary economy. The literature includes evidence that successful competitive is dependent heavily upon capacity of an organization's management of the innovation process, also proposes factors that relate to effective management of the innovation process (Adams et al., 2006).

The review of literature shows that IM it is a multidimensional model explaining how innovation is influenced by human capital, culture, and strategy. To grasp innovation opportunities, all these dimensions must be managed. Organizations relying on innovation should be open to intelligent and creative ideas and should design a mechanism that begins with supporting human sources. In this context, innovative initiatives and the competitiveness of organizations will growth rapidly. Consequently, a managerial structure should be designed in a way to supports innovative tendencies.

Moreover, working conditions should be regulated accordingly to foster innovation strategy (Nagano et al., 2014).

According to Serpell and Alvarez (2014) these factors is useful for organization's management to improve their performance in innovation context as well enhance the competitiveness by helping the organizations in several industries to focus on best tools to manage innovation. Moreover, Serpell and Alvarez (2014) developed a measurement model of IM. These factors have emerged through identification of the best factors that can be used to measure IM found in literature. However, the focus in this study on three cultural and human capital factors as well as the strategy of innovation. According to Alex (2016) innovation culture characterized as an intangible source that contributes to increased levels of innovation through searching and acceptance of the diversity of opinions and provides a new horizon of thinking and a way of acting that supports innovation ideas, accepting the mistakes in order to growth, encouraging risk taking propensity, rewarding the success, flexibility of the management about work time and in problem solving, motivating the communication and acknowledgement of the work and of the team spirit. While strategic innovation usually involves a major adaptive change in the company's business model or the adoption of a new business model. They can sometimes be driven by innovations that occur within the organization, such as strategic change, product and process innovations or by innovations and external challenges. External strategic changes such as mergers are the most common manifestations of strategic innovations. In addition, strategic innovations focused internally generally involve structural reshaping (Doğan, 2017).

Human Capital Development

In any organization, the performance of HC plays an integral role in organization success. Although HC competencies vary widely, but they are crucial part in the workplace. For this reason, critical development has to be taken place to develop the performance of workforce. Several actions could be taken for achieving HCD such as training that equip HC them better skills for the job, also employment of individuals those who are qualified for the job (Martin et al., 2013).

The development of HC is one of the pillars of success in most industries. Islam, et al. (2011) made use of board statistics of 87 nations during the period from 1970 to 2004 to examine whether the involvement of HC in growth of productivity is reliant upon the structure of HC and the proximity to technological front. This research concluded that the impact of the growth augmentation by skillful HC rises as high and middle-income nations move closer to the technological innovation. Lengnick-Hall, et al. (2011) suggested that training, education and other proficient initiatives taken towards the enhancement of the levels of expertise, capabilities, values, knowledge and social assets of the workforce would result into employee satisfaction and improved performance and leading towards the enhancement in organizational. Many countries in the globe have put great emphases on the HCD in order to boost the economic progress by dedicating required time and efforts (Hanushek, 2013). Therefore, to step into the global arena of innovation, HCD is considered as one of the major solutions. Specifically, it is imperative for administrations to invest obligatory resources in HCD as it has a tendency to influence organizational performance (Marimuthu et al., 2009).

It is evident that HCD is a progressive approach that every organization need. When an organization is in its initial stages, it is always hard to have solidified on the best approach for that specific company and as such to form a concrete system requires better training and a good time for better outcome to be gained. Every organization has its own specific strategies for improvement and equipping better its staffs for a progressive development in this sector.

Martin et al. (2013) argued that HCD is a significance plan to foster innovative inside the organization. In particular, the organizations play an important role in refining the level of HC by explicit techniques that may include arranging formal training to enhance employee's proficiencies. This indicates that particularly in evolving economies, organizations could boost their innovative productivity by providing employees with the prospect to improve themselves.

According to Nankervis, et al. (2010), there have been a number of efforts being made in order to identify the path that leads to origin of the HCD. However, all these efforts have been specifically

limited to a specific era of the time and based on the experiences obtain by a certain region or the country. Starting with a very modest start as 'people's management' during the 1700s, HCD has transformed to turn out to be a necessary educational arena as well as exhibited an imperative operation in the administration of organizations (Rotich, 2015). While Baron (2007) suggested that investment in the human resource is the most valuable of all capitals. Therefore, it would be difficult to implement any innovation strategy without human capital having good level of skills and knowledge. In this regard, the development of human capital is necessary step before applying various innovation practices (Yashar and Maryam, 2016).

Human capital in UAE

Emiratis focusing on public sector jobs are largely determined by cultural and social traditions. It has been reported (Forstenlechner, 2010) that HC in public sector in UAE are not working like others in the private sector. In addition, it has been said that Emiratis see themselves as a middle class in the society of the UAE, and will not consider the possibility of filling jobs in the private sector that are believed to be less than their jobs in the public sector (Maurice 2005), or not seen as offering career development prospects (Nadir, 2013).

Today's age has no choice but a greater investment in human capital. To ensure this, countries are in search of innovation plans where such investment can be initiated. The huge flow of HCD such as training, exchange of talents, and attracting the talent is the main practice of UAE these days. Such cordial situations will equip UAE nationals with high exposure, flourish business at rapid pace and will become a central hub in this part of world (Nadir, 2013). The model of HCD comprises on two levels. First is individual level which will explain the parameters required for individual branding? This will justify the importance of branding at individual level and also put some reasons of UAE national's approach to adopt such sub parameters at individual level. Second is the model is about country level which means UAE approach to coordinate with other countries (Nadir, 2013).

However, elements of HC theory can be helpful in helping explain UAE employment patterns and the limited effectiveness of Emiratization so far. For example, from the perspective of new classical theories such as the theory of HC, a large number of foreign workers in a country's workforce can be interpreted as a result of the differences between countries in the supply and demand for work in assessing work in the UAE from a HC perspective money, it can be seen that Emirati citizens are in low demand because they have low levels of qualifications that employers do not need while their foreign counterparts are in high demand because they have the required qualifications that employers believe they will serve them well (Omar, 2012). Based on these evidences, this study concludes that Emirates human capital need acquiring certain skills, whereas innovation practices are strong determinants to HCD of Emirates workforce.

Previous studies revealed that the heavy dependence on large numbers of foreign migrants over time has distorted education and skills requirements in the labor market. For a long time, most of the high and low skills jobs in the UAE, and almost all of the jobs in the free market sector, were filled by expatriates, and there was little incentive for citizens to develop the expertise or skills needed for these jobs (Al Mutawa, 2007). This fact shows the importance of development plans to HC in public sector in UAE. Accordingly, this study surveyed the Emirates staff in MOCD in order to point out how innovation contributes to HCD in public sector organizations.

In the UAE, the concept of human resource management can be very important in contributing to understanding how to foster economic growth and competitiveness at the national level through appropriate investment in higher education and education. Vocational training that specifically targets the needs of employers and the economy in general (Ndubisi et al., 2015). This relates particularly to the context of the current Emiratization policy in the UAE, where the focus shifts somewhat from applying quotas to employing citizens to developing a local workforce equipped to meet the needs of employers in the private sector.

Innovation and human capital development

HC is supposed to be an important factor for innovation and economic development. However, the long-run impact of HC on current innovation trends and economic development is still a black box (Claude and Ralph, 2019). However, HC is a set of skills, knowledge, capabilities and attributes embodied in people, it is crucial to absorb and organize knowledge and to innovation (Helena et al., 2019).

A research conducted by Alawamleh et al. (2019) investigated the relationship between innovation and HC investment showed how the implementation of them leads to significant economic development. The findings of their study identified three main pillars required to support economic development and achieve a competitive advantage using the country's HC: (1) Habitation, (2) Opportunity, and (3) Entrepreneurship. The relevance of the questions dealing with the HC formation and functioning individualities in the innovative development conditions is provided by the fact that highly developed post-industrial economy, manufacturing and service sector cannot do without highly educated and skilled workers, that makes dependable the efficiency and competitiveness at the company level and the whole national economy (Snezhana et al., 2016). In other words, modern technology and all of its rapid changes is entirely driven by innovations originating in the human brain. Human cognition is intangible, yet it determines the creations of humans and the ways in which we perceive and interpret the world.

It is evident that skills development is one of factors of HC that is connected to innovation. In any organization when only skilled individuals are considered for the job its means that innovation will be higher. With HCD can work in given departments effectively and yield more results than the uneducated ones. Based on these arguments and the findings of previous studies, the following hypothesis will be examined in the empirical part of this study.

Hypothesis 1: Innovation practices has a significant effect on human capital development.

The creation of innovative ideas and technologies is considered uniquely human, and it is fundamental to advances in all sectors and aspects of human life (Marlin-Bennett, 2004). However, most organizations fail to utilize their human capabilities to the optimum extent, because they are focused on task-based execution approaches (e.g., the operation of equipment) rather than developing and deploying the resource of HC to foster innovation. Nevertheless, large organizations have long been alerted to the advantages of making the management of people their number one priority (Tan, 2014). Another aspect of HC investment views it as a sustainable, continually improved resource that delivers an innovative output leading to economic development through innovation and creativity (Alawamleh et al., 2019). HCD interventions can positively contribute to organization's innovation activities. HCD is also found to positively influence employee engagement, leadership, manager's motivation to learn, the promotion of a learning culture, and social capital development all of which are positively associated with innovation (Sheehan et al., 2014). Building on the findings of these previous studies, this research seeks to find connections and build relationships between IP and management with HCD and to find empirical evidences in which the implementation of these concepts leads to skilled HC in public organization in UAE.

It is evident that to formulate an effective IM through better strategy and innovation culture, an organization must understand that IP plays a huge role in how products or process are created (Mohammad, 2018). IM is a series of plans linked to IP used by an organization to achieve advancements in technology or services, usually by investing money in research and development activities. Based on these arguments and the findings from previous studies, the following hypothesis will be examined in the empirical part of this study.

Hypothesis 2: Innovation practices has a significant effect on innovation management.

In the same context De Rassenfosse et al. (2014) found a positive relation between HCD and innovation management. They concluded that the role of IM of organizations such as offering formal training and helping individuals to be innovated workforce. HCD involve at every stage of innovation journey: gestation, development, and implementation. However, there is still no model explaining the relationship between HCD and innovations (Alsufyev and Zavyalova, 2013). Foster (2006) proposed

some theoretical contribution to the exploration of the HCD-innovation phenomenon by providing suggestions on the role of HCD in innovation journey based on the model of the innovation process developed by Van de Ven et al. (1999). While Huasheng et al. (2018) claimed that without creative ideas from employees, there will be no innovation in the organizations. Moreover, he suggests that first organizations create ideas, secondly develop these ideas and finally implement them (Huasheng, et al., 2018).

The conceptualization in Figure 2 shows the relationship between HC and innovation at various. Based on these arguments and the findings from previous studies, the following hypothesis will be examined in the empirical part of this study.

Hypothesis 3: Innovation management has a significant effect on human capital development.

Results and Discussions

The analysis of hypotheses is based on various analysis methods including descriptive, correlations, factor analysis and regression. SEM analysis is used to validate the conceptual model which is an emerging statistical tool that is gaining popularity in the social sciences. In this chapter, the study examined the relationships between IP, IM, and HCD. To justify the direct relationships between variables the Critical Ration (C.R) is applied to validate each hypothesis as well as significance level of regression coefficients. C.R is formed by dividing an estimate by its standard error. The following two criteria are used to validate the hypotheses of this study. The C.R $\geq$ 1.96 or $\leq$ -1.96 for a regression weight. Then a hypothesis is true, otherwise the hypothesis should be rejected (Garson, 2005; Chen et al., 2010; Hair et al, 2010). The justification of each hypothesis is indicated in Table 1 shows that all values of C.R $\geq$1.96 and ranging between lowest value = 3.052 (IP-HCD) and highest value = 6.033 (IP-IM).Moreover, the level of significance $\leq$ 0.05 for all relationships indicated in Table 1. From this result it is concluded that IP (independent variable) influences two variables namely: IM (mediator variable), and HCD (dependent variable) in direct relationships. While IP affect HCD directly and indirectly through IM. In summary, the SEM analysis shows that Hypothesis 1, Hypothesis 2, and Hypothesis 3 are validated to be true and not rejected. In other words, there are significant and positive correlations (direct effects) between the three variables.

Table 1: Hypothesis Justification

Hypothesis	Hypothesis Statement	C.R	Result	Sig.
Hypothesis 1	Innovation practices has a significant effect on human capital development	3.052	Validated	0.002
Hypothesis 2	Innovation practices has a significant effect on innovation management	6.033	Validated	0.000
Hypothesis 3	Innovation management has a significant effect on human capital development.	4.157	Validated	0.000

Conclusions

The review of literature reveals that a good organization resource can be an essential factor in an organization's success. The deployment of unique skills of human resources is a major success of competitive advantage. Besides good and beneficial organization resources, another factor that may contributes to better development and high degree of success is innovation practices. Like any organization in the public sector, government institutions must foster innovation in the workforce and enhance innovated thinking among individuals to align with the sources of challenges, as innovation practices continue to evolve in parallel with the tremendous advancement of technology. The outcome of this study revealed that all hypotheses are validated within established criteria based on SEM methods also support the theory developed in this study. Moreover, the empirical evidences of this study revealed that all direct relationships between innovation practices, innovation management, and human capital development are significant. This research makes the following contributes: first, a valid factor structure for innovation and human capital development was formulated; second, measurement of the influence of these variables in public organizations was validated.

Abstract

Recent advancement in digital technologies has re-shaped the nature of entrepreneurship. The social media, for example, offers a platform for multiple actors to engage in entrepreneurial activities beyond their immediate environment. Therefore, the integration of technology in entrepreneurial activities has created huge potential for socio-economic outputs. The present study draws on the social cognitive theory to propose a model explaining the cognitive and social factors influencing individuals' engagement in entrepreneurial activities on the social media platform. The proposed model will be tested with data to be collected from youth within the Klang Valley area of Malaysia.

Keywords: Digital Entrepreneurship, Social Media Engagement, Socio-Cognitive Theory.

Introduction

Entrepreneurship plays a significant role in the economic development of nations through the innovativeness of people in harnessing diverse resources for economic activities (Bruton, Ahlstrom, & Obloj, 2008). An entrepreneur is "someone who specialises in taking responsibility for and making judgmental decisions that affect the location, form, and the use of goods, resources or institutions" (Hebert and Link, 1989). Successful entrepreneurial engagement depends on innovation as a dynamic process of adapting to changes and uncertainties in the market. Through carefully crafted policy and intervention, the government plays a central role in minimising uncertainty and transactional costs, yet entrepreneurial agency is essential to harnessing the potential opportunities. The tension between human agency and institution is well articulated in the paradox of embedded agency (Seo and Creed, 2002). The institution could create an enabling environment for several actors to engage in diverse activities, but the respective outcomes are dependent on how individuals make use of the available platform. This has become more evident in the modern economy where people have leveraged the internet and social media network for different outcomes.

The increasing accessibility to digital technologies like internet smartphones, tablets, computers and the associated products and platforms like Facebook, Instagram, Snapchat and Youtube has created a new trend in entrepreneurial activities (A. O. Ojo et al., 2019). Given the universality and collaborative platform of these technologies, the main assumptions of entrepreneurship uncertainty have been reversed. For example, entrepreneurial processes and outcomes have become less bounded, while the locus of the entrepreneurial agency has moved beyond the individual to include several actors. The multiple possible combinations of technology and entrepreneurship have resulted in a diversity of phenomena with different characteristics and socio-economic impact. In Malaysia, for example, a range of public and private initiatives have been taken to enable the younger generations to harness their awareness and capability in digital technologies for entrepreneurial purposes. The #mydigitalmarker programme was introduced by the Malaysian Digital Economy Corporation (MDEC) and the Education Ministry in attempt to expose the youths to the business opportunities available via the digital technologies platform (NST, 2018). Nevertheless, a recent world bank report

suggested that Malaysia should invest more in promoting digital entrepreneurship among the youth to spur economic growth and job creation (Worldbank, 2018).

Although there is a lack of generally acceptable definition of digital entrepreneurship, its significance in transforming the business landscape through the innovative use of digital technologies has been widely acknowledged (Nambisan, 2016). As Nambisan (2016) note, further to its impact in extending the boundaries of entrepreneurship, digital technology has also altered the underlying role of individuals in entrepreneurship. Digital entrepreneurship has facilitated interaction among multiple actors, thereby the context of individuals' engagement has become more central in the pursuit of entrepreneurial initiatives. Hence, the need to situate individual within the context of their engagement with digital technology has become imperative (Fichman et al., 2014).

Previous studies on youth entrepreneurship Malaysia has examined the adoption of ICT among younger entrepreneurs (Zaremohzzabieh et al., 2016), students' readiness for the implementation of entrepreneurship education (Othman et al., 2012) and perception of agro-based entrepreneurs on the application of mobile phone in agro-business (Shaffril et al., 2009; Ojo, 2017). However, the issue of youth engagement in digital entrepreneurship has been overlooked.

The main purpose of this study is to investigate how the cognitive and contextual factors shape the engagement of Malaysian youths in entrepreneurial activities on social media. The social cognitive theory (SCT) offers the appropriate theoretical basis for situating the individuals within their context of engagement (Pincus, 2004). Specifically, individuals' behaviour are shaped by their attributes and their interaction with the social environment. Therefore SCT is relevant in explaining the reasons why individuals adopt certain behaviour (Bandura, 1986). In line with this, we posit that youth's engagement in entrepreneurial behaviour on social media is associated with differences in their cognitive state and social interaction.

Theoretical Background

Social cognitive theory (SCT) is a meta-theory, which has been employed across discipline to explain the dynamics of human behaviour (Kock, 2004). Studies have validated its relevance in the adoption of technological innovation (Compeau & Higgins, 1999; Ratten & Ratten, 2007), e-government application (Loo et al., 2009; Rana & Dwivedi, 2015), social media (Khang et al., 2014), internet banking (Boateng et al., 2016) as well as internet use and gratification (LaRose & Eastin, 2004; Ojo and Raman, 2017)). The SCT posits that individual behaviour is shaped by expectation, as well as personal and external factors. These factors are expressed in terms of the triadic reciprocal interaction among individual's attributes (i.e., abilities, knowledge and skills), external environment and actual behaviour (Bandura, 1989; Benight & Bandura, 2004). Such interaction is facilitated through human agency, wherein the individual exhibits the power of choice over outcome and leverage on awareness to continually regulate her behaviour in tandem with the desired outcome (Bandura, 2001). This regulatory influence is enacted through the belief in one's capability to choose and control actions. Beliefs depend on the evaluation of one's cognitive ability, motivation and the availability of the resources to complete the task (Wood & Bandura, 1989).

SCT associates human behaviour with the concepts of reinforcement and observation, which are evident through the cognitive processing of human interaction. Individuals learn to do something by observing and imitating those who are already involved in such activities. Unlike in the Western context, where individuals exhibit a preference for personal identities and individual achievements, group commitment has proven to be salient to individual perception in the Eastern context (Hosfstede, 1980). Social identity theory suggests that individuals who are strongly attached to their group identity are likely to develop the social identity. This facilitates the alignment between their identity and the group norm, thereby enabling them to easily accept the intentions and behaviours of their group members (Chatzisarantis et al., 2009; Jiang et al., 2016).

Hypotheses Development

Drawing insight from the above, we posit that engagement in entrepreneurial activities on social media network is the outcome of choice made by the individuals. In line with this reasoning, individuals are expected to engage differently based on their beliefs as well as the perception of others behaviour. The link between social identity and individual perception is rightly emphasized in the SCT. Individual's learning process is enabled through the social context when one's behaviour is modelled by observing and interacting with other members of the group. Therefore, individual action could be shaped by the perception of the behaviour of those within one's social group (Bandura, 2001). In the following sections, we discuss the significance of personal beliefs in terms of self-efficacy and outcome expectations and the implications of social identity on such beliefs and behaviour.

Self-efficacy

Self-efficacy is the personal belief in the ability to attain a certain level of performance or desired outcome in situation that affect one's life (Bandura, 1997). It is strongly associated with individual engagement and the differences in outcome when people with a comparable level of skills are engaged in a certain activity (Shane et al., 2003). As a salient factor of individual differences, self-efficacy reveals how belief in one's ability could account for behavioural difference. When faced with similar challenges, the former perceive opportunities for action, while the latter perceives obstacles and risks, thereby justifying the lack of action. Self-efficacy could make people feel more competent to overcome perceived obstacles and achieve expected positive outcomes. Therefore, people high in self-efficacy are likely to persist when faced with challenges and uncertainty. Self-efficacy is relevant in differentiating the choice made by individuals in their engagement in entrepreneurial activities. Individual who perceives him or herself as being capable of using social media for entrepreneurial activity is more likely to demonstrate such behaviour by choosing to adopt the platform for entrepreneurial purposes.

H1. Self-efficacy positively influences the intention to engage in social media for entrepreneurial purposes.

Outcome Expectations

Lent et al. (1994) demonstrated the relevance of SCT in student's choice of an entrepreneurial career. The study suggests the interaction between students perceived self-efficacy and outcome expectations. Specifically, individuals who have confidence in their abilities to perform certain tasks would have a favourable expectation about the outcome (Bandura, 2001). Such expectation is a reflection of one's beliefs about the consequences of a particular choice of action. Therefore, outcome expectations are the behavioural incentives, which determine engagement in a given task. When the entrepreneur perceives the social media network to be useful for attaining certain desirable outcome, he/she will develop the intention to engage in the activity.

H2. Outcome expectations positively influence the intention to engage in social media for

Social Identity

Social identity suggests that an individual's awareness of his or her membership in a group and the extent of emotional attachment to such group shapes their sense of social identity (Jiang et al., 2016). This does not only influence personal identity but also one's perception and behaviour (Haslam et al., 2009). By identifying with a particular group, an individual's behaviour will be such that conforms to other members of the group. In other words, individual's will behave according to their in-group members, but different from their out-group members. Such behaviour evolves through interaction with other members of a similar group. Through social interaction with others, individuals express their attachment to various groups, and they develop their own identity to conform to the group's

image and reputation (Baker & White, 2010; Jiang et al., 2016). Therefore, people who are members of groups that promoting products on social media are likely to develop the intention to engage in entrepreneurial activities on social media network.

H3. Membership of commerce-oriented group on social media positively influences the intention to engage in social media for entrepreneurial purposes.

Entrepreneurial Capability

Entrepreneurial behaviour entails how an individual perceives innovative activity according to his/her level of autonomy and competitive aggressiveness. An important determinant of such is personal capability, which reflects the extent of an individual's innovativeness, proactive and risk-taking behaviour. Given that social media network is an innovative technology, which is characterised by some level of complexity and uncertainty, thereby individuals with high entrepreneurial capability are more likely to engage in the network for entrepreneurial purpose.

H4. Entrepreneurial capability positively influence the intention to engage in social media for entrepreneurial purposes.

Contextual Factors

Individual's engagement in entrepreneurial activities can be shaped through the contextual factors of the business and societal environments. Studies have confirmed the significant impact of educational background, perceived support and role model on individuals' decision to engage in entrepreneurial activities (Cooper and Park, 2008; Tran and Korflesch, 2016). Therefore, these contextual factors are also proposed as potential determinants of intention to engage in entrepreneurial activities on social media.

H5. Contextual factors (perceived support, educational background and role model) will positively influence the intention to engage in social media for entrepreneurial purposes.

Figure 1: Theoretical Model

Proposed Methodology

This proposed study will employ a survey method in the collection of data to test the hypothesised relationships. The data will be collected from individuals across the Klang Valley area. This is the most prosperous, developed and urbanised metropolitan area in Malaysia, thereby the youth populations are expected to be more exposed to digital technology (Ojo et al., 2019). Based on the recently passed bill in the Malaysian parliament, a youth is someone between the ages of 15 to 30 years (Zainuddin and Kaur, 2019). Therefore, the respondents for this study will be from the above age groups. The questionnaire will be self-administered following the intercept survey technique. This technique is relatively easy to implement and most appropriate for enhancing the response rate for respondents from diverse backgrounds (Boateng et al., 2016; Ojo et al., 2019). In implementing the intercept technique, two research assistants will be recruited and instructed to randomly administer the questionnaires to respondents in public places like train stations, malls, etc. The collected data will be analysed using the partial least square structural equation modelling method to test the hypothesised relationships.

Discussion

This study contributes to the entrepreneurship literature by drawing on the SCT to propose a conceptual model explaining the social and cognitive factors of youth engagement in entrepreneurial activities through the social media platform. In essence, the present study situates individuals within the context of their engagement in entrepreneurial activities. Beyond the personal attributes, we proposed the social and contextual factors that could shape personal intention and behaviour towards digital entrepreneurial activities. As a result, our study addresses the need for further research on the implications of social and situational factors on human behaviour towards digital technologies (Fichman et al., 2014).

The expected findings from this study will contribute to the national initiatives on encouraging digital entrepreneurship among youths, thereby offering insights on policy development for job creation and economic growth. The findings will also contribute towards enhancing the quality of life of youths in Malaysia by identifying the factors that are essential to cultivating digital entrepreneurial mindset.

kamil.bujak@avanta-audit.pl

Abstract

This research is a continuation from the earlier work of its authors on the requirements to identify and report key audit matters (further also referred to as "Key Audit Matters" or "KAM") in auditors' reports and its objective is to update, summarize and present the results of the work performed in respect of the key audit matters determined and communicated in the independent auditors' reports issued in conjunction with the audit of the 2017-2019 annual financial statements of DAX 30 and WIG 20 constituent companies. Research activities focused on reading of the reporting requirements in respect of key audit matters relating to audits of historical financial information as defined in the International Standards on Auditing (ISA) and examination of the auditors' reports issued in conjunction with the audit of the 2017-2019 annual financial statements of the DAX 30 and WIG 20 constituent companies listed on the Frankfurt Stock Exchange (Germany) and Warsaw Stock Exchange (Poland).

The main objective of the research was to confirm how the number and the nature of the Key Audit Matters for DAX 30 and WIG 20 constituent companies varied in the period covered by the research. For the purpose of the research it was tentatively assumed that both (1) the number and (2) the nature of Key Audit Matters identified and reported in conjunction with the audit of the annual financial statements of DAX 30 constituent companies for the financial years 2017-2019 would vary. It was further assumed that both (3) the number and (4) the nature of Key Audit Matters identified and reported in conjunction with the audit of the annual financial statements of WIG 20 constituent companies for the financial years 2017-2019 would also vary.

Keywords: Audit, Risk, Auditor's Report, Key Audit Matters.

Introduction

In accordance with the International Standards on Auditing the purpose of an audit is to enhance the degree of confidence of intended users in the financial statements. This is achieved by the expression of an opinion by the auditor on whether the financial statements are prepared, in all material respects, in accordance with an applicable financial reporting framework (ISA 200, *Overall Objectives of the Independent Auditor and the Conduct of an Audit in Accordance with International Standards on Auditing*, paragraph 3).

The financial statements subject to audit are those of the entity, prepared by management of the entity with oversight from those charged with governance (ISA 200, *Overall Objectives of the Independent Auditor and the Conduct of an Audit in Accordance with International Standards on Auditing*, paragraph 4).

In conducting an audit of financial statements, the overall objectives of the auditor are:

Cite this Article as: Grzegorz WARZOCHA and Kamil BUJAK " Analysis of Key Audit Matters in DAX 30 and WIG 20 Audit Reports" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

(a) to obtain reasonable assurance about whether the financial statements as a whole are free from material misstatement, whether due to fraud or error, thereby enabling the auditor to express an opinion on whether the financial statements are prepared, in all material respects, in accordance with an applicable financial reporting framework; and
(b) to report on the financial statements, and communicate as required by the ISAs, in accordance with the auditor's findings (ISA 200, *Overall Objectives of the Independent Auditor and the Conduct of an Audit in Accordance with International Standards on Auditing*, paragraph 11).

Risk Assessment

In accordance with the International Standards on Auditing the auditor is also required to identify and assess the risks of material misstatement, whether due to fraud or error, at the financial statement and assertion levels (ISA 315 (Revised), *Identifying and Assessing the Risks of Material Misstatement through Understanding the Entity and Its Environment*, paragraph 3).

As part of the risk assessment, the auditor shall also determine whether any of the risks identified are, in the auditor's judgment, a significant risk (ISA 315 (Revised), *Identifying and Assessing the Risks of Material Misstatement through Understanding the Entity and Its Environment*, paragraph 27). The auditor shall treat those assessed risks of material misstatement due to fraud as significant risks (ISA 240, *The Auditor's Responsibilities Relating to Fraud in an Audit of Financial Statements*, paragraph 27).

When identifying and assessing the risks of material misstatement due to fraud, the auditor shall, based on a presumption that there are risks of fraud in revenue recognition, evaluate which types of revenue, revenue transactions or assertions give rise to such risks (ISA 240, *The Auditor's Responsibilities Relating to Fraud in an Audit of Financial Statements*, paragraph 26).

Areas of higher assessed risk of material misstatement, or significant risks identified in accordance with ISA 315 shall be taken by auditor into account in order to determine, from the matters communicated with those charged with governance, those matters that required significant auditor attention in performing the audit (ISA 701, *Communicating Key Audit Matters in the Independent Auditor's Report,* paragraph 9).

Determination and Communication of the Key Audit Matters

The auditor shall determine which of the matters determined in accordance with paragraph 9 of ISA 701 were of most significance in the audit of the financial statements of the current period and therefore are the key audit matters (ISA 701, *Communicating Key Audit Matters in the Independent Auditor's Report,* paragraph 10).

In accordance with paragraph 10 of ISA 701, *Communicating Key Audit Matters in the Independent Auditor's Report* the auditor shall describe each key audit matter, using an appropriate subheading, in a separate section of the auditor's report under the heading "Key Audit Matters," unless the circumstances described in further paragraphs apply.

The purpose and the methods of the research

The purpose of the research was to examine how (1) the number and (2) the nature of Key Audit Matters determined and communicated in conjunction with the audit of the annual financial statements of DAX 30 constituent companies and how (3) the number and (4) the nature of Key Audit Matters determined and communicated in conjunction with the audit of the annual financial statements of WIG 20 constituent companies for the financial years 2017-2019 varied.

It was tentatively assumed that the number (hypothesis 1) and the nature (hypothesis 2) of Key Audit Matters identified and reported in conjunction with the audit of the annual financial statements of DAX 30 constituent companies for 2017-2019 would vary.

It was further assumed that the number (hypothesis 3) and the nature (hypothesis 4) of Key Audit Matters identified and reported in conjunction with the audit of the annual financial statements of WIG 20 constituent companies for the financial years 2017-2019 would vary.

The research focused primarily on the examination of the auditors' reports issued and filed in 2018-2020 in conjunction with the 2017-2019 annual audits of the financial statements filed by the DAX 30 constituent companies listed on the Frankfurt Stock Exchange (Germany) and examination of the auditors' reports issued and filed in 2018-2020 in conjunction with the 2017-2019 annual audits of the financial statements filed by the WIG 20 constituent companies listed on the Warsaw Stock Exchange (Poland).

To present the results of the research work Key Audit Matters were split in the following categories:

ACC – for KAM relating to accounting policies of the entity
ACQ – for KAM relating to mergers and acquisitions
IMP – for KAM relating to impairment
IFRS – for KAM relating to application of the IFRS and changes thereto
VAL – for KAM relating to valuation
PRO – for KAM relating to provisions
REC – for KAM relating to assets recoverability
REV – for KAM relating to revenue recognition
T&L – for KAM relating to tax & legal matters
OTH – for KAM relating to other issues

Given the empirical nature of the research, priority was given to the reading of the relevant International Standards on Auditing and analysis of the selected auditor's reports. Consequently, the study concentrates less on other theoretical aspects, references to professional literature or other publications.

Results of the Research Performed

Table 1 and Table 2 attached below summarizes the results of the research performed.

Evaluation of Results

All posed hypotheses (hypothesis 1, hypothesis 2, hypothesis 3 and hypothesis 4) were tested positively in the conducted research. This is however to note that:

For hypothesis 1 (the number of the KAM for DAX 30 constituent companies) the number of KAM did not vary significantly from year to year in the period of the research (105 KAM in 2017, 94 KAM in 2018 and 88 in 2019).

For hypothesis 2 (the nature of the KAM for DAX 30 constituent companies) the nature of KAM did vary for most of KAM and periods and did not vary for other KAM and periods.

For hypothesis 3 (the number of the KAM for WIG 20 constituent companies) the number of KAM did vary significantly from year to year in 2017 and 2018 and did not vary significantly in 2018 and 2019 (41 KAM in 2017, 65 KAM in 2018 and 62 in 2019).

For hypothesis 4 (the nature of the KAM for WIG 20 constituent companies) the nature of KAM did vary to different extent for the various KAM and research period.

Conclusions and definition of further possible research areas

Based on the results of the research the authors of this paper decided to continue their work on KAM determined and communicated in annual audit reports for DAX 30 and WIG 20 and to perform comparative study for other Stock Exchange constituent companies such us but not limited to CAC 40 or FTSE 100.

In addition to the above the authors of this paper plan to perform more detailed analysis of KAM and response to risk.

Abstract

This research is a continuation from the earlier work of its authors on the requirements to identify and report key audit matters (further also referred to as "Key Audit Matters" or "KAM") in auditors' reports and its objective is to update, summarize and present the results of the work performed in respect of the key audit matters determined and communicated in the independent auditors' reports issued in conjunction with the audit of the 2017-2019 annual financial statements of CAC 40 and WIG 20 constituent companies. Research activities focused on reading of the reporting requirements in respect of key audit matters relating to audits of historical financial information as defined in the International Standards on Auditing (ISA) and examination of the auditors' reports issued in conjunction with the audit of the 2017-2019 annual financial statements of the CAC 40and WIG 20 constituent companies listed on the Paris Stock Exchange (France) and Warsaw Stock Exchange (Poland). The main objective of the research was to confirm how the number and the nature of the Key Audit Matters for CAC 40 and WIG 20 constituent companies varied in the period covered by the research. For the purpose of the research it was tentatively assumed that both (1) the number and (2) the nature of Key Audit Matters identified and reported in conjunction with the audit of the annual financial statements of CAC 40 constituent companies for the financial years 2017-2019 would vary. It was further assumed that both (3) the number and (4) the nature of Key Audit Matters identified and reported in conjunction with the audit of the annual financial statements of WIG 20 constituent companies for the financial years 2017-2019 would also vary.

Keywords: Audit, Risk, Auditor's Report, Key Audit Matters.

Introduction

In accordance with the International Standards on Auditing the purpose of an audit is to enhance the degree of confidence of intended users in the financial statements. This is achieved by the expression of an opinion by the auditor on whether the financial statements are prepared, in all material respects, in accordance with an applicable financial reporting framework (ISA 200, *Overall Objectives of the Independent Auditor and the Conduct of an Audit in Accordance with International Standards on Auditing*, paragraph 3).

The financial statements subject to audit are those of the entity, prepared by management of the entity with oversight from those charged with governance (ISA 200, *Overall Objectives of the Independent Auditor and the Conduct of an Audit in Accordance with International Standards on Auditing*, paragraph 4).

In conducting an audit of financial statements, the overall objectives of the auditor are:

Cite this Article as: Grzegorz WARZOCHA and Kamil BUJAK " Analysis of Key Audit Matters in CAC 40 and WIG 20 Audit Reports" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

(a) to obtain reasonable assurance about whether the financial statements as a whole are free from material misstatement, whether due to fraud or error, thereby enabling the auditor to express an opinion on whether the financial statements are prepared, in all material respects, in accordance with an applicable financial reporting framework; and
(b) to report on the financial statements, and communicate as required by the ISAs, in accordance with the auditor's findings (ISA 200, *Overall Objectives of the Independent Auditor and the Conduct of an Audit in Accordance with International Standards on Auditing*, paragraph 11).

Risk Assessment

In accordance with the International Standards on Auditing the auditor is also required to identify and assess the risks of material misstatement, whether due to fraud or error, at the financial statement and assertion levels (ISA 315 (Revised), *Identifying and Assessing the Risks of Material Misstatement through Understanding the Entity and Its Environment*, paragraph 3).

As part of the risk assessment, the auditor shall also determine whether any of the risks identified are, in the auditor's judgment, a significant risk (ISA 315 (Revised), *Identifying and Assessing the Risks of Material Misstatement through Understanding the Entity and Its Environment*, paragraph 27). The auditor shall treat those assessed risks of material misstatement due to fraud as significant risks (ISA 240, *The Auditor's Responsibilities Relating to Fraud in an Audit of Financial Statements*, paragraph 27).

When identifying and assessing the risks of material misstatement due to fraud, the auditor shall, based on a presumption that there are risks of fraud in revenue recognition, evaluate which types of revenue, revenue transactions or assertions give rise to such risks (ISA 240, *The Auditor's Responsibilities Relating to Fraud in an Audit of Financial Statements*, paragraph 26).

Areas of higher assessed risk of material misstatement, or significant risks identified in accordance with ISA 315 shall be taken by auditor into account in order to determine, from the matters communicated with those charged with governance, those matters that required significant auditor attention in performing the audit (ISA 701, *Communicating Key Audit Matters in the Independent Auditor's Report,* paragraph 9).

Determination and Communication of the Key Audit Matters

The auditor shall determine which of the matters determined in accordance with paragraph 9 of ISA 701 were of most significance in the audit of the financial statements of the current period and therefore are the key audit matters (ISA 701, *Communicating Key Audit Matters in the Independent Auditor's Report,* paragraph 10).

In accordance with paragraph 10 of ISA 701, *Communicating Key Audit Matters in the Independent Auditor's Report* the auditor shall describe each key audit matter, using an appropriate subheading, in a separate section of the auditor's report under the heading "Key Audit Matters," unless the circumstances described in further paragraphs apply.

The purpose and the methods of the research

The purpose of the research was to examine how (1) the number and (2) the nature of Key Audit Matters determined and communicated in conjunction with the audit of the annual financial statements of CAC 40 constituent companies and how (3) the number and (4) the nature of Key Audit Matters determined and communicated in conjunction with the audit of the annual financial statements of WIG 20 constituent companies for the financial years 2017-2019 varied.

It was tentatively assumed that the number (hypothesis 1) and the nature (hypothesis 2) of Key Audit Matters identified and reported in conjunction with the audit of the annual financial statements of CAC 40 constituent companies for 2017-2019 would vary.

It was further assumed that the number (hypothesis 3) and the nature (hypothesis 4) of Key Audit Matters identified and reported in conjunction with the audit of the annual financial statements of WIG 20 constituent companies for the financial years 2017-2019 would vary.

The research focused primarily on the examination of the auditors' reports issued and filed in 2018-2020 in conjunction with the 2017-2019 annual audits of the financial statements filed by the CAC 40 constituent companies listed on the Paris Stock Exchange (France) and examination of the auditors' reports issued and filed in 2018-2020 in conjunction with the 2017-2019 annual audits of the financial statements filed by the WIG 20 constituent companies listed on the Warsaw Stock Exchange (Poland).

To present the results of the research work Key Audit Matters were split in the following categories:

ACC – for KAM relating to accounting policies of the entity
ACQ – for KAM relating to mergers and acquisitions
IMP – for KAM relating to impairment
IFRS – for KAM relating to application of the IFRS and changes thereto
VAL – for KAM relating to valuation
PRO – for KAM relating to provisions
REC – for KAM relating to assets recoverability
REV – for KAM relating to revenue recognition
T&L – for KAM relating to tax & legal matters
OTH – for KAM relating to other issues

Given the empirical nature of the research, priority was given to the reading of the relevant International Standards on Auditing and analysis of the selected auditor's reports. Consequently, the study concentrates less on other theoretical aspects, references to professional literature or other publications.

Results of the research performed

Table 1 and Table 2 attached below summarize the results of the research performed.

Evaluation of Results

In general, all posed hypotheses (hypothesis 1, hypothesis 2, hypothesis 3 and hypothesis 4) were tested positively in the conducted research. This is however to note that:

For hypothesis 1 (the number of the KAM for CAC 40 constituent companies) the number of KAM did marginally vary from 2017 to 2018 and it did not vary in 2018 and 2019 (136 KAM in 2017, 140 KAM in 2018 and 140 in 2019).

For hypothesis 2 (the nature of the KAM for CAC 40 constituent companies) the nature of KAM did vary for most of KAM and periods, but in general they did not vary significantly.

For hypothesis 3 (the number of the KAM for WIG 20 constituent companies) the number of KAM did vary significantly from year to year in 2017 and 2018 and did not vary significantly in 2018 and 2019 (41 KAM in 2017, 65 KAM in 2018 and 62 in 2019).

For hypothesis 4 (the nature of the KAM for WIG 20 constituent companies) the nature of KAM did vary to different extent for the various KAM and research period.

Conclusions and definition of Further Possible Research Areas

Based on the results of the research the authors of this paper decided to continue their work on KAM determined and communicated in annual audit reports for CAC 40 and WIG 20 and to perform comparative study for other Stock Exchange constituent companies such us but not limited to DAX 30 or FTSE 100.

In addition to the above the authors of this paper plan to perform more detailed analysis of KAM and response to risk.

Abstract

The involved staff is satisfied with the working conditions in the organization, loyal to its goals and values, and ready to take action to improve its business and organizational performance. The involvement of employees in the activities of any organization contributes to the high productivity of their work, which can have a positive effect on overall performance. The study of staff satisfaction, loyalty and involvement in higher educational institutions' process is of particular interest. In these organizations, the role of involvement is especially great, as it lets employees identify with the educational institution, as well as form both standards for their behavior and a sense of responsibility for their implementation. The aim of the study is to analyze the level of satisfaction with the work among educators of Russian higher educational institutions. The paper assesses tutors' involvement in comparison with other professions; the article gives analysis concerning the degree of satisfaction with the work of Russian teachers, their willingness to move to another job, preferences for wages.
The results of the study indicate a relatively high level of Russian educators' satisfaction with their work, which was proved by more than half of those teachers who were surveyed. There is a steady decline in the number of those who are ready to change jobs or stop working altogether. The share of such employees decreased from 33% in 2006 to 20% in 2017. Teachers' requirements for the level of salaries are also growing, which can stimulate their transition to another job with poor characteristics, compared to work at a university.

Keywords: Staff Satisfaction, Staff Loyalty, Staff Involvement, Human Capital, Staff Productivity, Commitment to The Profession.

Relevance and Problem Statement

World experience demonstrates that human capital is the key to the economic success of both national economies and individual organizations. Nowadays, it is evident that a highly qualified specialist in his or her field is the most important asset of any organization. However, the effectiveness of his or her work is influenced by many factors that depend both on the organization and on the employee himself/herself. Staff involvement, which is understood as a physical, emotional and intellectual state that motivates better performance of work, acts out as one of them. The involvement of employees in the activities of the organization contributes to the high productivity of their work, which can have a positive effect on overall performance.

The relevance of the problem of tutors' satisfaction with their work is increasing in the context of modern socio-cultural challenges to higher education, which require, among other things, the formation of a new type of relationship among the participants of the educational process. On the one hand, the

higher education system's institutions must fulfill their main purpose - to participate in the formation of students' human capital. On the other hand, higher educational institutions are rapidly turning into entrepreneurial structures which are forced to increase their efficiency and competitiveness, and it seems possible only if all scientific and pedagogical employees work effectively, and that demands their involvement.

The degree of the Problem Elaboration

The category of staff involvement attracted close scientific attention at the end of the 20th century and continues to hold it today. The first studies devoted to the problem of involvement were carried out by W. Ouchi (1981), R. Pascale and A. Athos (1981). The named authors, relying on the Japanese model of work, believed that the commitment of employees to the values of any organization favorably affects the level of their involvement, which acts out as the best way of motivation. One of the most fundamental works devoted to the mentioned problems was prepared by W. Kahn (1990). The scientist was one of the first who used the term "involvement" in scientific circulation. He interpreted involvement in terms of physical, intellectual and emotional properties and qualities of employees, which in any case can be reflected in the organization's activities. The works of such foreign scientists as T. Peters and N. Austin, M. Armstrong and A. Saks, F. Frank, R. Finnegan and C. Taylor are devoted to the study of staff involvement, as well as its essence and methodological tools to manage it. Involvement as a model of behavior for employees and their managers, in which the latter, demonstrating their leadership qualities, treat the former as equals, was studied in the works by T. Peters and N. Austin (1985). Considering theoretical and extensive practical experience, M. Armstrong (2006) proved that an employee, who is involved and who is participating in the process of the organization's activities forms an interest in the enterprise's success, which is undoubtedly acts out as an important condition for the organization's development. A. Saks (2006) researched employees' engagement, using the theory of social exchange (SET). He believed that such involvement is determined by those resources which any given organization represents, and it will be maintained until the rules of social exchange are violated (for example, the organization's management abandons the promised level of employee's support). F. Frank, R. Finnegan and C. Taylor (2004) interpreted staff engagement from the economic point of view, i.e. as the amount of effort which employees put into doing their job. They noted that the main reason for increasing involvement in any organization is the pursuit of additional profit.

It should be noted that the category of staff involvement is rarely mentioned in the Russian scientific literature, when it comes to study the labor relations' system. In the national scientific practice, the category of job satisfaction is widely used. The most in-depth studies of job satisfaction (staff involvement) were carried out in Russia by N. Alexandrova, M. Magura, M. Kurbatova and some others. In most cases, scientists have researched diagnostic tools and the ways to increase employee engagement. N. Alexandrova (2016) considers staff involvement as a result of increased satisfaction. Russian economists M. Magura and M. Kurbatova (2007) believe that it is the organizational commitment that combines such three components in its structure as identification (awareness of the organization's goals as one's own), involvement (the desire to contribute to the achievement of the organization's goals) and loyalty (emotional commitment to the organization). Interpretations of the involvement (engagement) category, which are given by V. Maslova (2012), T. Solomanidinova (2014), Yu. Melikhov (2014), are quite the same. The significant part of Russian specialists understand staff involvement as a motivation of a person to work, which is the result of internal incentive elements (needs, interests, value orientations), on the one hand, and environmental factors (external incentives that induce activity), on the other hand.

Research Results

According to the research by Gallup Institute, levels of engagement around the world can vary considering the type of job. Knowledge-based personnel, such as managers and specialists in various fields are more inclined to go about their jobs than those who are playing more routine roles, such as clerical or production workers. As it follows from the data in Figure 1, managers have the highest level

of involvement, which is about 28%. A high level of involvement characterizes the activities of specialists (doctors, lawyers, teachers, etc.), which is about 27%. The involvement level of the latter is more than double that of, for example, production and office personnel. This discrepancy is due to differences in workplace conditions that can affect engagement: the ability to speak up, expand your skills, and use a unique combination of them. For example, employees in the manufacturing or service sectors are not able to make significant changes to the working process, because their day is structured. In comparison, those employees who perform professional or managerial tasks can improve their work or their workplace more easily.

Figure 1: Staff involvement structure in some kinds of professions around the globe in 2017 (State of the Global Workplace, 2018)

The study of staff involvement in higher educational institutions is of particular interest. Emergences of a large number of higher educational institutions, their rapid transformation into entrepreneurial structures and, as a result, the growing competition between them determine the urgency of internal sources of their activities' efficiency. One of these sources is the involvement of tutors of higher educational institutions. In these organizations, the role of engagement is especially great, because it lets employees identify with the educational institution as well as form both standards of conduct and a sense of responsibility for their implementation.

The study of the tutor's attitude to his or her profession is dictated, on the one hand, by some professional standard requirements, and on the other hand, by motivation processes in the professional sphere. Engagement lets an employee "to realize commitment to the profession, to accept professional goals and values, to master the basic requirements of the profession to a person, to build a path of his or her professional development, etc." (Kalashnikov and Minyurova, 2017). Another variant of the work attitude can be the formation of professional marginalism, which manifests itself in the rejection of organizational values, the loss of a sense of commitment to the profession, the rejection of the socially acceptable professional morality for the given profession. The professional staff marginalism in some socially significant professions (educators, doctors, civil servants) is especially dangerous. In this regard, the study of the phenomenon considering the engagement of higher educational institutions' teachers is relevant and socially urgent.

Higher educational institution's staff involvement ensures the efficiency of its functioning and also fulfills its main purpose to contribute to the formation of the students' human capital. It is obvious that fulfillment of the indicators' array, by which the performance of higher educational institutions is monitored, can be difficult to provide without real engagement of scientific and pedagogical workers who supply both generation of new ideas and their practical implementation (Monitoring 2019, 2019). In this regard, the task of higher educational institutions is not only to search for eminent researchers and attract them to work, but also to support those who are already committed to the educational organization and profession, as well as to create a favorable environment for their initiatives' implementation. It should be noted that the involvement of scientific and pedagogical workers has a direct impact on the students' achievements and their attitude to the educational process. The involved tutors are dominated by values aimed at professional development, success and achievements. One of the results of tutors' activity is students' achievements. The specifics of teachers' professional activities allow them to have a significant impact on a wide segment of the society and the human capital's size.

Staff involvement, understood as a physical, emotional and intellectual state that motivates employees to work better, is one of them. Based on the increase in the of personnel's productivity, this engagement can be represented by an appropriate diagram (Fig. 2). Satisfaction means that an employee is satisfied with some or all of the working conditions in the organization and he or she intends to continue working there. Loyalty means that an employee accepts the working conditions in the organization, shares its goals and values. The staff involved is satisfied with the working conditions in the organization, loyal to its goals and values, and ready to take action to improve business and organizational performance.

Figure 2: The process of forming staff involvement

Research results indicate a high level of educators' satisfaction with their work (Philinkova, 2015). Tutors are most satisfied with such aspects of their work as pedagogical communication, teaching a favorite subject, and interaction with students. According to a 2017 study by the Higher School of Economics, 53.7% of tutors expressed satisfaction with their work. The highest level of satisfaction was demonstrated by educators of private Russian universities - 79.3%; the lowest level of job satisfaction was shown by employees of ordinary universities - 50.1% (Fig. 3). It should be noted that the level of satisfaction which exceeds the average university level, was recorded by HSE experts among tutors of Russian creative universities - 60.0%.

Figure 3: The level of tutors' satisfaction with the work considering the type of universities in 2017, % of the total number of educators who answered (Changes in strategies, motivations and economic behavior of students and tutors of Russian universities, 2019)

To our mind, it is important to consider job satisfaction among employees of higher educational institutions as a factor of their readiness to change jobs, since the problem of labor mobility of tutors has long ceased to be a problem of a specific educational institution, but has become a problem of state importance. The desire to change jobs should be seen as indirect evidence of dissatisfaction with it. According to the HSE, the share of full-time higher education's staff who is ready to change jobs or stop working altogether decreased from 33% in 2006 to 19% in 2014, in 2016-2018 it stabilized at the level of 20% (Fig. 4). Experts explain the attractiveness of academic employment, on the one hand, by its stability in the educational field, and by the growth of wages in this sector of the economy, on the other hand.

Figure 4: Willingness of tutors to move from work in the university to some other job or stop working altogether in 2006-2017, % of the total number of educators who answered (Changes in strategies, motivations and economic behavior of students and tutors of Russian universities, 2019)

Dissatisfaction with the work among tutors of higher educational institutions is associated with their willingness to look for a new job. At the same time, one group of educators understands the job change as a transition to another educational organization, and the other group considers it as a departure from the profession. It should be noted that there is a large proportion of those tutors who have not decided yet. If in 2010 they did not know, what kind of work 18.8% of tutors willing to change jobs, wanted to take, then in 2014 there was 15.2% of them, and in 2017 - 27% (Fig. 5). The share of tutors who understand a job change as a transition to another university is steadily growing: in 2010 it was 15.7%, in 2014 - 21.1%, in 2017 - 23.0%. This fact should, to our mind, be considered as evidence of the teaching profession attractiveness. However, a large proportion of educators are ready to leave the profession. Moreover, in 2010 and 2014, most of them sought to work in state institutions - 15.3% and 18.6%, respectively. According to the results of the 2017 study, only 6% of scientific and pedagogical workers gave preference to this field of activity. Non-teaching work in the private sector attracted 11.8% of tutors in 2010, 9.7% in 2014, and 10.0% in 2017.

Figure 5: Tutors' preference for a new job in case of leaving the university in 2017, % of the number among full-time university tutors wishing to change jobs (Changes in strategies, motivations and economic behavior of students and tutors of Russian universities, 2019)

A huge argument when choosing a profession and willing to stay in it is a salary. Undoubtedly, it is not the only, but a quite important factor which influences the dynamics of the number of educators. As the HSE study shows, the requirements of tutors considering the level of salaries are growing, which can stimulate them to move to another job (less attractive in comparison with the current). If in 2006 46.1 thousand rubles were enough for a teacher to move to a new place of work, in 2014 the sum was 101.9 thousand rubles, and in 2017 it was 108.0 thousand rubles (Average monthly nominal accrued wages of employees for a full range of organizations as a whole in the country of the Russian Federation in 1991-2019, 2019). As Figure 6 shows, a tutor working for a leading university can move to another

place of work, if his or her future salary is more than 136.0 thousand rubles. The employees' wishes of creative and ordinary Russian universities are significantly less - 82.0 thousand rubles and 90.0 thousand rubles.

Figure 6: What is the minimum wage level you agree to move to another job with a higher salary level than yours now, if it is uncreative, monotonous work with a tight schedule, not related to physical labor, does not require high qualifications and retraining? (2017)? (Changes in strategies, motivations and economic behavior of students and tutors of Russian universities, 2019)

Conclusions and Offers

Research and development of technologies for staff involvement has become a global trend for the management community over the past twenty years. Recently, not only economic effects of its growth have been calculated, but the main factors influencing employees' engagement have also been identified. The latest experience of foreign management proves that an efficient and high-performance labor level can be achieved in those organizations whose employees are satisfied with their working conditions, who are loyal to the goals and values of the organization and who are ready to take action in order to improve their business and organizational performance. The results of the study indicate a relatively high level of Russian tutors' satisfaction with their work, which was proved by more than half of those teachers who were surveyed. There is a steady decline in the number of educators who are ready to change jobs or stop working altogether. The share of such employees decreased from 33% in 2006 to 20% in 2017. Educators' requirements for the level of salaries are also growing, which can stimulate their transition to another job with unattractive characteristics, compared to work at a university.

Research and development of technologies for staff involvement in organizations have become a global trend for the management community over the past twenty years. In our opinion, increase in the job satisfaction among scientific and pedagogical workers should be facilitated by a number of factors, such as increase in the status of an educator and the prestige of the teaching profession; strengthening measures of tutors' social protection and resource provision of their professional activities; solving issues of their material incentives; development of corporate culture of higher educational institutions; formation of stable labor collectives, etc.

It is difficult to ensure fulfillment of all those indicators, which define the effectiveness of higher educational institutions' activities, if there is no real involvement of scientific and pedagogical workers, who provide both generation of new ideas and their practical implementation. The ongoing modernization of Russian education lets create any model, aimed at the development of educators' professional potential.

Abstract

As international cooperation has increased, problems related to the peculiarities of cross-cultural interaction are of importance. Significant differences between countries determine the relevance of studying the institute of corporate culture in Russia as an economic and socio-cultural phenomenon. According to domestic experts, the prerequisites for the formation of the institute of corporate culture in Russia emerged in the mid-1980s. Russian corporate culture is still being formed. Its rapid growth in our country is largely due to globalization and the desire of domestic corporations to become a part of the world economy. Russian researchers note that the formation of corporate culture in the country was influenced by and contains features of pre-revolutionary (pre-Soviet) corporate culture; the corporate culture of the Soviet period and contemporary foreign corporate culture. The research is aimed at analyzing the factors responsible for emergence of Russian corporate culture, identifying the stages of its development and defying its characteristics.

Keywords: Russian Corporate Culture, Soviet Corporate Culture, Pre-Revolutionary Corporate Culture, "Soft" Corporate Culture, "Hard" Corporate Culture, Leadership, Power.

Relevance and Statement of the Problem

Increased competition, larger amounts of information, the speed of its acquisition, as well as the rise in the role of human capital determine the importance of internal sources of efficiency of an organization. Corporate culture should be considered as one of such sources as it affects a company's operations and contributes to its ultimate success. A well-developed corporate culture encourages a rapid development of any organization. A poor corporate culture, on the contrary, can lead to crisis phenomena in companies, which can stem from a lack of necessary adjustments to the changing conditions of their internal and external environment (Annaev, 200).

Globalization processes have led to a growing interconnection and interdependence of countries. Today, countries are unlikely to remain unaffected by global economy. The increase in international cooperation (the emerging and functioning of multinational corporations that employ citizens of different states, international projects, etc.) has emphasized issues related to the peculiarities of cross-cultural interaction. There are significant corporate culture distinctions in countries.

Corporate culture in Russia cannot be considered finally-formed. Today, it is experiencing a rapid growth. Russian companies establish their own unique models of corporate culture, which differ from Western and Eastern ones, based on traditional relationships, the experience of Soviet period and demands of market economy. Current social processes emphasize the importance of studying the institute of corporate culture in Russia as an economic and socio-cultural phenomenon. Moreover, the

issue is of particular relevance taking into consideration the development of businesses in the context of globalization and mutual influence of national and business cultures.

Degree of the Problem Elaboration

Theoretical and empirical development of the problem of corporate culture has been developed in the works of both foreign and Russian scientists. There are a significant number of monographs, scientific articles, textbooks devoted to various aspects of corporate culture. Abroad, the process of understanding the role of corporate culture in the development of an organization began in the 1930s. For instance, M. Sherif (1936) in 1936 used the concept of social norm; K. Lewin, R. Lippitt and R. White (1939) used the idea of climate in the organization in 1939. According to E. Mayo (1933), along with organizational and economic factors, employees' behavior is influenced by other non-material factors. C. Barnard (1938) discussed organizational morality, considering it as an asset for integrating cooperative and individual components of an organization. H. Simon (1964) defined the concept of organizational goal. The research into corporate culture was continued in the 1950s. M. Dalton (1966) studied the process of natural emergence of cultures and subcultures. D. Hampton (1987) and H. Trice (1984) published works on companies' traditions, rites and rituals. Large-scale research of corporate culture began in the 1980s, when it was considered as a factor of business efficiency (W. Ouchi (1981), T. Peters and R. Waterman (1982)). K. Sholts (1995) considered corporate culture as a regulatory axiological system. Significant contribution to the study of corporate culture management problems was made by G. Hofstede (1984) and E. Schein (1988).

In Russian science culture was studied by A. Gastev (1924) within the framework of the concept of scientific organization of labor in the 1920s. According to Gastev, employees' relationships require certain "cultural conventionality" that contributes to a friendly internal environment. A. Alekseev (1990), S. Belanovsky (1988), and V. Olshansky (1968) wrote about the «culture of production and labor» and «quality of working life». Researchers studied the influence of factors such as ideology, psychological climate and leadership on labor efficiency. Russian scientists began to consider the concept of corporate culture in the early 1990s. The research of this phenomenon was implemented in the works of O. Vihansky, M. Ivanov, L. Kartashova, A. Naumov, A. Prigozhin, V. Spivak, V. Tomilov, D. Shusterman, V. Shcherbina. O. Vihansky and A. Naumov (2003) define organizational culture as a set of important assumptions that are accepted by members of an organization and expressed in the values declared by this organization, which sets guidelines for employees' behavior. According to A. Prigozhin (1995), a company's efficiency is determined by the ability to combine personal needs of employees and ways to meet them within the company through a corporate culture that was specially established and embedded in the minds of employees. L. Kartashova (2001) et al. distinguish two ways to establish corporate culture: spontaneous, when corporate culture is established under the influence of unmanageable factors and processes, and scientific, which is based on scientific methods and models of its formation. V. Tomilov (2009) considers corporate culture as a mindset that determines the internal life of an organization. M. Ivanov and D. Shusterman (2004) describe corporate culture as a variety of external manifestations that significantly affect the behavior of employees. V. Spivak (2001) argues that the approach to corporate culture based on the models of developed countries is irrelevant in the Russian reality and proposes to consider domestic approaches that had developed in the Soviet period. Y. Semenov (2004), E. Scriptunova and E. Svircova (2001), T. Solomanidina (2003), V. Yadov (1987) and others ontinued the study of corporate culture.

Research Results

In Russia the transition from planned to market economy was accompanied by significant institutional changes affecting both the structure of production and the structure of socio-economic relations. It was quickly realized that successful functioning of market economy requires not only an economic and organizational basis, but also the acquisition of a new culture. At that time the key problem of the Russian economy was and continues to be the improvement of general culture of socio-economic management through the formation of corporate culture. However, a comprehensive approach to the formation of corporate culture among Russian managers was just beginning to emerge at that time.

According to domestic experts, the prerequisites for the formation of the institute of corporate culture in Russia emerged in the mid-1980s, when domestic technologies of corporate events were developed. From this moment to the present day, they distinguish several stages in the development of Russian corporate culture (Fig. 1). It becomes clear that the vector of the development of Russian corporate culture corresponds to the vector of the socio-economic development of the country. Both Russian corporate culture and Russian economic model were formed under the influence of foreign experience and domestic practice. Thus, we can talk about the formation of a special model of relationships in Russian companies.

Figure 1: Stages in the development of Russian corporate culture (Govriakova, Vaganova, Vechkanova, 2015)

Russian researchers note that the formation of corporate culture in the country was influenced by and contains features of pre-revolutionary (pre-Soviet) corporate culture, the corporate culture of the Soviet period and modern foreign corporate culture (Sverdlikova, 2017). According to the study conducted in 2005-2006 by the marketing communications Agency Nextep Promotion and the PR Principle communication management Agency, it was found that during this period the main influence on the formation of the corporate culture of Russian organizations exerted foreign experience (55.8%). In many respects, the specifics of the Russian corporate culture were determined by the specifics of market relations that had developed in the country (32.6%). The traditions of Soviet corporate culture were in the third place in terms of impact (23.3%), however they did not lose their relevance. It should be noted that in Soviet times, our country had a rather distinctive corporate culture, which was based not only on the idea of working for the benefit of the state, but also on the idea of personal contribution to the formation of humane social relations and the promotion of socialist ideology in other countries. Unfortunately, the traditions of Russian business of the pre-Soviet era are hardly taken into account in the formation of modern corporate culture. And the business world of pre-revolutionary Russia had a lot of experience in building strong corporate culture and socially responsible business (Korobkova, 2015). Main factors that determined the formation of the Russian corporate culture is shown in the figure 2.

Figure 2: Major factors that have determined the formation of Russian corporate culture (Pervakova, 2012)

The Russian corporate culture is still being formed. Its rapid growth in our country is largely due to globalization and the desire of domestic corporations to become part of the world economy. According to Russian entrepreneurs, foreign business partners and consumers will consider them to be reliable partners if they have a healthy corporate culture in their companies. It should be noted that export-oriented companies and companies with foreign participation pay much more attention to corporate culture than other Russian organizations.

Today, there exist three models of corporate culture in Russia. The first model of corporate culture is characterized by the focus of top management on monitoring the employees' behavior. It is assumed that managing the employee behavior can increase their productivity and reduce risks. This model of corporate culture prescribes specific norms for each labor process. The weakening of monitoring the activities of staff entails the awakening of their true values and beliefs. The second model of corporate culture is based on a directive behavioral approach. The human resources management is based on the values of the organization formed by the owners and management of the company at the individual and collective level of employees. The third model of Russian corporate culture assumes that changes in the elements of the working environment determine changes in the system of values and behavior of personnel. The elements of the work environment that can transform the corporate culture of the organization include the transformation of office space, changing organizational principles, improving the motivational system etc.

Despite the recognition of the obvious role of corporate culture in the activities of modern organizations, the leadership of Russian companies does not always recognize this phenomenon and cultivate it. According to domestic management, the main reasons for this state of affairs are the lack of time and energy, as well as the lack of tools and good practices. The most disturbing reasons for the lack of desire to develop corporate culture are the reluctance to invest in the development of the organization and to make long term plans.

According to the study conducted by Oliver Wyman, a leading international company in the field of management consulting, in 2019, the management of Russian companies is aware of the importance of corporate culture in solving strategic tasks: 7.4 points out of 10 possible (Fig. 3). However, the attention paid by senior management of Russian companies to the development of corporate culture is relatively low: 6.4 points out of 10 possible.

Figure 3: Russian management on the importance of corporate culture and its cultivation in the organizationи (Corporate culture in Russia

Most Russian companies are currently working on the formation and development of corporate culture in one form or another. In this regard, it is important to understand what factors make domestic entrepreneurs pay attention to the corporate culture, what goals they want to achieve with it. There are main factors and backdrop factors that make Russian companies pay attention to their corporate culture (Fig. 4). The main factors are the main reason for the formation, development and transformation of corporate culture in the organization and they come from the strategy of its development. The role of backdrop factors is also quite large; however these factors are usually due to law, traditions, stereotypes, etc.

MAIN FACTORS	BACKDROP FACTORS
• Attracting and retaining promising staff. • Promotion of client-centricity. • Formation of the company's image. • Compliance with the new working conditions.	• The embodiment of the business founder's philosophy. • Ensuring work discipline, striving for cost optimization. • Focus on commercial success. • Fraud prevention and anti-corruption.

Figure 4: Main and backdrop factors that make Russian companies pay attention to their corporate culture (Corporate culture in Russia, 2019)

According to Oliver Wyman experts, the leadership model is one of the specific features of the Russian corporate culture. The image of the Russian leader differs significantly from the Western model. The Russian leader must combine authoritarianism with progressiveness. Employees of Russian organizations believe that authoritarianism is a mandatory trait of a leader. Authoritarianism is permissible even at the expense of fairness and consistency. However, a true Russian leader should combine authoritarianism with patronage and paternalism. The elder employees prefer a strong leader of the organization. It should be noted that the authoritarian leader looks less attractive only to young employees. They are more focused on such features of the leader as knowledge, experience, creativity, and communication skills, which is much closer to the world's common leadership model. Experts from Oliver Wyman stated that the ideal leader should combine traditional Russian authoritarianism with the role of a progressive public figure. In other words, the leader is expected to combine incompatible things consistently.

Russian researchers in the field of corporate culture agree that the “red” corporate culture is predominant in Russia. Experts of the Russian consulting company ECOPSY note that the culture of strength in domestic organizations is manifested both in its “negative” voluntary” type, and in the positive type, when it is a culture of feat” (Rosin, 2018). This type of corporate culture is justified in extreme conditions; however it is absolutely ineffective “in the age of digitalization, increasing the

speed of decision-making and the transition from competition by the quality of the product to competition by the quality of teams" (Zaitsev, 2020). This type of corporate culture is widespread in traditional industries and regions, and it is much less common in such industries as telecommunications, advertising, and IT.

The concept of spiral dynamics was proposed by management consultants D. Beck and K. Kovan (2006). According to this concept, people, collectives, organizations and entire countries go through typical stages in their development, when the higher ones resemble the lower ones from an evolutionary point of view, which makes it possible to speak of spiral movement. The spiral dynamics model is a color spiral, where each color represents a different value. The company's development is based on its corporate culture, which is understood as a certain set of values and priorities. The red corporate culture or culture of power is when the main value is power, and power acts as an engine.

Another distinctive feature of Russian corporate culture, according to the research by Oliver Wyman, is that the initiative in the Russian management system at all levels always comes from the management. The management of Russian companies does not encourage initiative on the part of ordinary employees. The Western willingness of management to give subordinates more freedom in their activities and initiate innovations is not applied in Russia.

It should be noted that the "red" corporate culture for business management always uses a hierarchical management model, a significant disadvantage of which is the low initiative of the staff. The value of any initiative under this management model is considered primarily in terms of policy (the interests of the leader), and not the effectiveness of the business. The "social contract" that has developed in the Russian corporate culture is as follows: management does not expect initiative from employees, and they, in turn, do not go beyond the official regulations.

According to Oliver Wyman experts, the low level of communication in Russian companies is also a distinctive feature of the Russian corporate culture. Vertical and horizontal communication channels are present in any organization. Vertical channels are responsible for transmitting the management information and feedback. Horizontal channels are used for communication between employees and structural divisions of the same level.

As we have already noted, the "red" corporate culture for business management always uses a hierarchical management model, the disadvantages of which include lack of communication with insubordination. According to the study by Oliver Wyman the level of development of vertical and horizontal communications in Russian companies is relatively low. The problem with vertical communications is the inability of the Russian leadership to convey management information to subordinates and get feedback from them. Each next level of managers acts as a filter. According to experts, Russian managers deliberately do not share information with colleagues and subordinates. As a result the top management of the organization receives significantly distorted information about the real state of affairs. The free movement of information requires trust, openness, and priority for corporate interests. In Russian companies, there is a "deliberate restriction of access to valuable information, its retention in order to increase competitiveness and significance of self in the organization", which is a big disadvantage of the Russian management model (Corporate culture in Russia, 2019). As shown in figure 5, employees of Russian organizations rated the communication process at 3.8 points out of 10, which is the lowest indicator in the entire study of corporate culture in the country.

Figure 5: Russian managers on the effectiveness of the communication process in the organization (Corporate culture in Russia, 2019)

Corporate culture is a collective phenomenon. This is particularly evident in the Russian corporate culture. Collectivism is a national trait. The collective spirit is formally embodied in ceremonial procedures (for example, a large number of corporate events). Russian employees show a greater propensity for teamwork than European employees. As shown in figure 6, relations between employees of Russian organizations are closer to trust (7.5 points out of 10) than to circumspection. It should be noted that this is the highest indicator according to the results of a study conducted by Oliver Wyman.

In general, experts from Oliver Wyman noted the growing awareness of the importance of corporate culture in Russian organizations. The previous disregard for corporate culture gives way to a willingness to form and develop it. In the modern world organizational changes are impossible without relying on corporate culture.

Figure 6: Russian managers on employee relationships (Corporate culture in Russia, 2019)

In early 2019, Superjob, an IT company that has been developing technology for recruitment and job search for more than 20 years, conducted its research on the corporate culture of Russian organizations. The organization's experts studied the types of corporate culture that are most common in domestic companies, and studied the commitment of professional groups to these types.

Different types of corporate cultures were divided into two main types – “soft” and “hard”. The “soft” type of corporate culture is characterized by honesty in relation to staff, suppliers, consumers and competitors; the model of behavior in the organization is determined by support, mutual assistance, and trust. The “hard” type of corporate culture is based on achieving goals by any means; the behavior model is based on competition, aggression, and power.

The survey by Superjob illustrated that 64% of respondents claimed that they work in organizations with a “soft” type of corporate culture; 16% – described the type of corporate culture of the company in which they work as “hard”; 20% – found it difficult to determine the type of corporate culture (Fig. 7).

Figure 7: What type of corporate culture characterizes your company?
(Aggressive type of corporate culture is preferred by directors and sales managers, 2019)

The survey by Superjob illustrated that the majority of respondents would like to work in organizations with a “soft” type of corporate culture – 83%; a “hard” type of corporate culture would suit 5% of respondents; 12% had difficulty with their preferences (Fig. 8). It should be noted that 89% of women and 76% of men prefer a «soft» corporate culture. A “hard” type of corporate culture attracts only 2% of women and 8% of men. Eighty eight percent of respondents with an income of less than 29.9 thousand rubles prefer a “soft” type of corporate culture, while a «hard» type is acceptable for only 3%. As the income of the respondents increases to 80.0 thousand rubles, we see a tendency that the number of employees who prefer a “soft” type of corporate culture decreases to 78% and the number of supporters of a “hard” type increases to 7%.

Figure 8: What type of corporate culture would You like to work with? (Aggressive type of corporate culture is preferred by directors and sales managers, 2019)

Of interest is the distribution of preferences for types of corporate culture among the 23 most popular professional groups. The "soft" type of corporate culture is preferred by architects, designers, and economists (more than 90% of all respondents). Sales managers and directors (more than 10% of all respondents) would prefer to work in companies with a "hard" corporate culture. Based on the conducted sociological research, Superjob experts claim that the "hard" type of corporate culture is preferred where there are more male employees (Aggressive type of corporate culture is preferred by directors and sales managers, 2019). The percentage of women who are supporters of this type of corporate culture is small for all professional groups. For example, among sales managers, 12% of men and only 3% of women are supporters of an aggressive corporate culture.

Conclusions and Proposals

The formation of corporate culture in modern Russia occurs against the backdrop of incomplete market transformations in the country and the ideas of social patronage that have persisted since Soviet period. However, we argue that foreign experience has a growing influence on the formation of the corporate culture of Russian organizations. This experience is of importance as market relations in Russia are relatively young.

The combination of both Western and Eastern features in the Russian national character explains paradoxical and contradictory nature of Russian corporate culture. In our opinion, its specific nature is determined by the dramatic history of the Russian state, the vast territory of the country and its multi-ethnic society.

The paper identifies a number of characteristics of corporate culture in Russia. First, specific features of Russian corporate culture are largely determined by the leadership model.

In Russia, the predominant corporate culture is a "red" corporate culture or culture of power that relies on a strong leader. Second, initiative in the Russian management system at all levels always comes from management, initiative of employees is not encouraged. Initiative is a quality that allows an individual to act creatively. It manifests itself consciously and intentionally and requires effort. Moreover, it manifests itself only if an individual is interested in changing the existing situation. And only the leader is responsible for creating the environment necessary for the initiative of the staff. Third, Russian corporate culture is also characterized by a low level of communication. At the same time, the efficiency of vertical communications is extremely low. Relations between employees of Russian organizations are characterized by a high degree of trust. In Russian companies, informal relationships between employees often dominate formal ones. Consequently, relationships in the organization are built in accordance with unwritten rules. Documents regulating the activities of employees are declarative in nature.

Because there are certain factors, such as unfavorable socio-economic situation in the country, spiritual crisis, high unemployment, insufficient financial incentives etc., the question of establishing a Russian model of corporate culture remains open. It should be expected that in the context of globalization the traditional Eastern model of Russian corporate culture will acquire features of Western capitalist business culture.

Abstract

Objectif : L'objectif de cet article scientifique est de comprendre l'impact de la capacité technologique sur la performance des entreprises dans un contexte de transformation digitale. Cette recherche repose essentiellement sur deux courants de recherche : Le premier fait référence à la théorie du management par les ressources permettant d'étudier l'impact des nouvelles technologies sur la performance des entreprises. Le deuxième, fait référenceà la théorie psychosociale et étudie le comportement des organisations et leur attitude face aux technologies de l'information. **Conception/Méthodologie/Approche :** Suivant une perspective hypothético-déductive, ce travail repose sur deux parties. Une partie théorique rédigée pour passer en revue les travaux antérieurs portant sur les variables du modèle conceptuel. Une partie empirique, développée pour présenter la méthodologie et les résultats des données recueillies via un questionnaire. L'étude empirique a été réalisée auprès d'un échantillon de 90 entreprises tunisiennes. Nous avons étudié la purification des échelles de mesure relative aux différents concepts en utilisant des analyses en composantes principales ACP à l'aide du logiciel SPSS 23 et effectuer une analyse confirmatoire avec l'approche PLS. Enfin, nous avons testé les hypothèses de notre recherche, expliqué les résultats obtenus et déduit un ensemble d'implications managériales qui intéressent notre sujet. **Résultat :** Les résultats ont montré que la capacité technologique à un effet positif sur la capacité marketing contrairement à la transformation digitale des entreprises qui n'a pas d'effet direct sur leurs performances sur le marché. De plus, l'étude a permis de vérifier que ces deux dernières variables ont un effet médiateur entre la capacité technologique et la performance sur le marché. **Implications Managériales :** D'une part, l'influence positive de la capacité technologique sur la capacité marketing montre que les nouvelles technologies aident les entreprises à améliorer leur performance et atteindre leur objectif commercial. D'autre part, nous pouvons constater à travers notre revue de la littérature que la transformation digitale n'est pas une mise à niveau logicielle ou un projet d'amélioration de la chaîne d'approvisionnement. C'est un choc numérique planifié pour ce qui pourrait être un système raisonnablement fonctionnel. Andriole (2017). De ce fait, avoir un site internet, une page facebook, nommer un community manager ou même un directeur du digital en entreprise ne suffit pas pour dire qu'une entreprise est digitale. En plus, nous pouvons également constater que la transformation digitale touche la culture même de l'entreprisepuisqu'elle met en évidence l'apportdes IT sur la structure organisationnelle, les routines, la circulation de l'information en entreprise. Li et al. (2017)

Originalité/Valeur : Dans certaines recherches plusieurs auteurs ont montré que les nouvelles technologies et capacités numériques continuent de dominer notre paysage économique, et que les organisations font face aujourd'hui à une surveillance accrue sur la façon dont la transformation numérique peut fournir le mécanisme d'innovation et de performance de l'entreprise. En effet, dans cette perspective, les auteurs ont montré que la capacité technologique est extrêmement utile pour les entreprises afin de connaitre une plus grande valeur commerciale au moyen d'une meilleure rentabilité, d'une meilleure productivité, d'une réduction des coûts d'exploitation, un avantage concurrentiel et d'autres mesures de performance des entreprises. Mais, des preuves pratiques indiquent qu'il est en même temps difficile et couteux d'intégrer la capacité technologique dans une infrastructure non IT. C'est autour de ces divergences que nous avons formulé notre problématique de recherche. En effet, nous cherchons à savoir :
Dans quelle mesure la capacité technologique influence-t-elle la performance sur le marché en considérant les effets médiateurs de la capacité marketing et de la transformation digitale de l'entreprise ?

Mots clés : Capacité technologique, transformation digitale, capacité marketing, performance, technologie de l'information (IT), management par les ressources (RBV).

Introduction

Massivement utilisées de nos jours, les nouvelles technologies ne cessent d'impressionner tout le monde grâce à leurs innovations aussi fréquentes et facilitant le quotidien. De facto, le changement est inévitable. Les organisations, les particuliers et leurs relations mutuelles changent. Plus que jamais, la primauté est accordée par ces deux parties aux technologies. Volle (2014) utilise le terme « iconomie » pour décrire la résonance avec cet accord technologique et sociétale actuel. Pour lui, l'«iconomie » est la société dont l'économie, les institutions et les modes de vie s'appuient sur la synergie de lamicroélectronique, du logiciel et de l'Internet. En effet, une prise de conscience des gains d'opportunités des technologies digitales se manifeste constamment, particulièrement par les organisations.

Etant un système ouvert sur son environnement, l'entreprise est supposée s'adapter aux changements fréquents du contexte dans lequel elle opère. En effet, depuis quelques décennies, les technologies d'Internet, puis le mobile et ainsi le digital ont complètement bouleversé tous les marchés. Quel que soit le secteur, les outils digitaux qui facilitent le partage de données et d'informations sont aujourd'hui au cœur des activités des entreprises. Cloud, intranet, plateformes et messageries collaboratives, solutions d'aide à la prise de décision, de relation clientèle, ERP, CRM et tant d'autres outils sont disponibles à tous managers et marketeurs. Ainsi, pour trouver des solutions pour les clients, de construire de nouveaux avantages concurrentiels, il est important d'envisager le digital non plus comme une forme d'équipement technologique mais comme une stratégie qui fait la différence. Toutefois, la diversité des opportunités du digital laisse place aux réflexions relatives aux choix et aux utilisations efficaces des solutions technologiques afin de créer de la valeur. Dans ce sens, pour Fayon et Tarter (2014), la performance d'une entreprise dépend de sa maturité digitale. Plus précisément, la réussitedépend de sa stratégie digitale clairement identifiée et de sa capacité à piloter les chantiers digitaux avec agilité et en concordance avec les marchés sur lesquels elle est implantée.
Tout en restant dans la logique du marketing digital qui se base sur les effets des nouvelles technologies, sur le comportement des consommateurs et utilisateurs de produits, notre recherche s'intéresse à étudier l'impact de la capacité technologique sur la performance sur le marché en considérant l'effet des deux variables médiatrices à savoir la capacité marketing et la transformation digitale des entreprises.

Une Revue De La Littérature Sur La Capacité Technologique

La capacité technologique décrit la capacité d'une entreprise à réunir et à déployer des ressources IT en combinaison avec les ressources d'autres entreprises (Bharadwaj, 2000). Certains chercheurs ont

soutenu que la capacité technologique est plus qu'une simple capacité qu'une entreprise possède, mais plutôt un ensemble complexe de technologie de l'information en relation avec les ressources, les compétences et les connaissances connexes qui permettent aux entreprises de coordonner les activités et d'autres ressources afin de produire les résultatssouhaités (Stoel et Muhanna, 2009).

Les entreprises ayant la capacité de planifier et d'intégrer leurs ressources en IT peuvent mieux saisir de l'information sur les clients, partager des connaissances et améliorer les processus opérationnels (Karimi et al., 2001 ; Mithas et al., 2011). Pour obtenir un bon rendement venant des ressources en technologie de l'information, les entreprises doivent créer une capacité technologique à l'échelle de l'entreprise en combinant l'infrastructure de l'IT, les compétences humaines en IT et les biens incorporels appuyés par les IT avec des ressources spécifiques a d'autres entreprises (Bharadwaj, 2000 ; Wade et Hulland, 2004). Jusqu'à maintenant, l'incidence de la capacité des technologies de l'information sur le rendement des entreprises a reçu beaucoup d'attention positive, et des études laissent entendre que les entreprises ayant une capacité technologique élevée ont tendance à surpasser leurs concurrents. (Bharadwaj, 2000 ;Mithas et coll., 2011). Dans le but de concilier l'évolution de la capacité technologique et son incidence, certaines études ont soutenu que l'avantage concurrentiel découlant de la capacité technologique dépend du fait que les entreprises tirent ou non pleinement parti de leur capacité technologique existante. (Bhatt et Grover, 2005 ; Rai et Tang 2010 ; Chen et al., 2014). Dans un environnement commercial de plus en plus digital, la capacité technologique est devenue un mécanisme important grâce auquel les entreprises peuvent créer des liens numériquesomniprésents entre les activités et les entités de la chaîne de valeur. La gestion stratégique et la littérature sur les SI indiquent que la capacité technologique est une variable latente comportant trois dimensions, à savoir la « capacité de l'infrastructure de l'TI », la « capacité de l'entreprise en IT » et la « position proactive de l'IT » (Lu et Ramamurthy, 2011). La capacité de l'infrastructure de TI désigne l'architecture, les services de gestion des données et les plateformes d'applications d'une entreprise. Cette capacité permet à une entreprise de construire un système de communication et d'intégration robuste à l'intérieur et au-delà des frontières organisationnelles. La capacité des activités en technologie de l'information est une mesure de la capacité d'une entreprise à envisager et à utiliser des ressources IT pour atteindre ses buts et ses objectifs opérationnels. L'approche proactive en matière de IT renvoie à la capacité d'une entreprise de chercher activement et constamment des façons novatrices d'utiliser les ressources IT pour cerner et créer de nouvelles idées et opportunités (Fichman, 2004).

La perspective adoptée dans la plupart des études est qu'une entreprise ayant une capacité technologique élevée devrait démontrer une capacité accrue dans chacune des trois dimensions.

Des recherches sur les systèmes d'informations continuent de remettre en question l'incidence directe de la capacité des IT sur le rendement des entreprises (Carr, 2003 ; Chen et al., 2014). Par exemple, Mithas et al. (2011) ont constaté que la capacité des technologies de l'information contribuait au rendement de l'entreprise en améliorant d'autres capacités de l'entreprise, comme la capacité de gestion de la clientèle, la capacité de gestion des processus et la capacité de gestion du rendement. En effet, les capacités informatiques permettent aux entreprises de créer un créneau de marché et de différencier leurs offres de produits dans un contexte commercial de plus en plus concurrentiel (Tan et Teo, 2000). De même, Bharadwaj (2000) a analysé le rendement des entreprises à l'aide d'une matrice de rendement fondée sur les profits et les coûts et a constaté que les entreprises ayant une capacité technologique élevée ont tendance à surpasser leurs concurrents. Ainsi, les entreprises ayant une capacité technologique plus élevée sont plus en mesure de mobiliser, de déployer et d'exploiter les ressources en IT avec d'autres ressources existantes pour obtenir un meilleur rendement.
Hypothèse 1 : La capacité technologique influence positivement la transformation digitale.

Une Revue De La Littérature Sur La Capacité Marketing

La capacité marketing a été schématisée dans la littérature en fonction de la capacité d'une entreprise à se servir des ressources disponibles pour effectuer des tâches de marketing de manière à obtenir les résultatsespérés (Morgan, Katsikeas et Vorhies, 2012). Par ailleurs, la littératuresuggère que les

capacités marketing sont particulièrementprécieuses, inimitable et non substituable permettant de créer un avantage concurrentiel durable et améliorer la performance de l'entreprise.
Selon Vorhies et Morgan (2005) la capacité marketing désigne la pratique, la routine et le mode de travail d'une entreprise qui utilise ses ressources pour répondre aux besoins du marché et renvoie également à des processus intégratifsconçus pour reconnaître, recueillir et appliquer les connaissances et les compétencesafin d'ajouter de la valeur dans le domaine du marketing (Su et al., 2009). En effet, la capacité marketing agit comme un moteur de connexion capable de gérer un portefeuille équilibré d'offres de marché, présenter des promotions intelligentes, faciliter une gamme appropriée de prix et exposer les produits au bon moment et au bon endroit. Ces efforts de marketing soigneusement configurés et déployés peuvent transformer le sens culturel organisationnel du marché en satisfaction de la clientèle, en croissance des parts de marché et en rentabilité.

Selon (Canine et Zou, 2009) les capacités marketing se composent de trois grands groupes : La capacité externe, comme la détection du marché et le collage des canaux, la capacité interne comme la logistique intégrée et le développement technologique et les capacités qui couvrent les deux approches, comme les nouvelles capacités de développement de produits et d'exécutiondes commandes des clients. Avec la demande continue du marché, le développement rapide des technologies de l'information raccourcit le cycle de vie de produit, cependant les chercheurs en marketing ont commencé à se concentrer sur la perspective dynamique pour examiner des capacités marketing.

En outre, la capacité marketing désigne le processus d'intégration par lequel une entreprise recueille et utilise ses connaissances et ses compétences pour gérer ses ressources internes et s'adapter à l'environnement externe (Su, Tsang et Peng, 2008 ; Teece, Pisano et Shuen, 1997). Aujourd'hui plusieurs entreprises intègrent des technologies numériques comme les médias sociaux, big data, l'analytique, le cloud et les technologies mobiles pour stimuler le changement. Grace à la capacité technologique et les technologies de l'information il est devenu donc possible d'accéder à l'information et faire face à la concurrence.

Étant donné que le marketing comprend l'établissement de relations avec les clients, les technologies de l'information et les capacités du marketing jouent un rôlecomplémentaire. Par exemple, la fonction marketing est chargée de communiquer sur les produits et services de l'entreprise afin de générer la demande des clients. La fonction informatique permet la fonction marketing en fournissant des informations sur les modèles de demande, les préférences des clients via la CRM, et peut utiliser l'analyse pour identifier les besoins latents.

Ainsi, les ressources associées aux capacités informatiques et de marketing peuvent avoir un effet d'interaction (Constantin et Lusch, 1994). Par conséquent, cela peut être la preuve de l'utilisation stratégiqueet de la combinaison inimitable de ressources que la RBV suggére conduire à un avantage concurrentiel (Barney 1991). Dans le contexte marketing, ERP conserve des informations sur l'ensemble des processus opérationnels d'une entreprise en intégrant plusieurs fonctions de gestion : solution de gestion des commandes, solution de gestion des stocks, solution de gestion de la paie et de la comptabilité, solution de gestion e-commerce, solution de gestion de commerce BtoB ou BtoC. Ces informations pourraient être avantageusement utiliséesultérieurement par l'entreprise pour mieux servir les clients et mieux servir l'activité marketing de l'entreprise.

Conformément à la RBV, le fait de tirer parti des capacités des entreprises en technologie de l'information peut permettre de tirer pleinement parti des capacités de marketing. Vickery et al. (2003) soutiennent que les systèmes d'information intégrés permettent à tous les services fonctionnels (la fabrication, les achats, le marketing, la R-D, etc.) de l'entreprise d'accéder à l'information et de la transmettre.

Hypothèse 2 : La capacité technologique influence positivement la capacité marketing des entreprises.

L'apport De La Transformation Digital En Entreprise

Selon Westerman et al, (2014) Les technologies numériques telles que analytics, big data, cloud, les médias sociaux, les plateformes mobiles et les solutions intelligentes sont des innovations remodelant les modèles d'affaires de conduite et réinvestissantla façon dont les organisations sont en cours d'exécution des opérations commerciales. Selon Libert et al. (2016) la transformation digitale se réfère à des changements et des transformations qui sont entraînés et construit sur la base de technologies numériques. Tandis que les organisations transforment et évoluent constamment en réponse à l'évolution du paysage des affaires, la transformation digitale représente les changements construits sur la base des technologies numériques, marquant le début des changements uniques dans les opérations commerciales, processus d'affaires et la création de valeur. Libert et al. (2016) ont fait la distinction entre mise à niveau digital, qui est l'utilisation des technologies numériques pour accroître l'efficacité des processus d'affaires d'une entreprise, et la transformation digitale, qui se produit lorsque les technologies numériques sont utilisées pour changer radicalement l'ensemble des opérations commerciales, la création de valeur et dans certains cas de nouvelles offres de produits numériques.

Grâce à la transformation digitale, les organisations sont en mesure d'intégrer les technologies numériques dans de nombreux aspects de leurs opérations et sont également en mesure d'engager les clients avec des innovations digitales émergentes (Aral et Weill, 2007).

Par ailleurs, À mesure que la transformation numérique augmente, les entreprises sont en mesure d'améliorerleurs offresgrâce à une plus grande personnalisation, à une plus grande satisfaction de la clientèle et à une réduction des coûts de vente (Mithas et coll, 2005;Brynjolfsson et Hitt, 2000). Des étudesantérieures sur les implications des technologies numériquessuggèrent que la numérisation influence positivement le rendement des entreprises. Les entreprises qui utilisent des processus opérationnels plus numériques obtiennent de meilleurs résultatsgrâce à leurs capacités en IT (Brynjolfsson et Yang, 1997).

Hypothèse 3 : La transformations digitale influence positivement la performance de l'entreprise

La Capacité Marketing Et La Performance De l'entreprise

De nombreuses études ont examiné les effets des capacités sur la performance, et de nombreuses études ont examiné les effets d'une capacité individuelle sur le rendement de l'entreprise. Toutefois, les gestionnaires doivent connaitre les effets de diverses capacités sur le rendement lorsqu'ils tentent d'affecter des ressources pour gérer l'ensemble des capacités pertinentes à la performance sur lemarché. Outre les capacités traditionnelles de gestion de la distribution, de gestion des produits, de gestion des prix et de gestion de la promotion, les gestionnaires doivent également tenir compte des capacités de leur entreprise en matière de collecte d'information ou de gestion de la recherche et de planification générale du marketing.

- **Capacité de distribution :**

C'est la capacité de maintenir derelations solides avec les membres des différents canaux de distribution. Cela peut aider à surmonter les problèmes typiques qui se posentquotidiennement dans le monde des affaires, les modifications apportées aux processus de distribution et les intrusions périodiques des concurrents. La gestion des relations de distribution repose principalement sur le développement et le maintien de la confiance que les partenaires de la relation distribuent équitablement les avantages et travaillent à la viabilité mutuelle (Samaha et al., 2011). Conformément au cadre des capacités dynamiques, la capacité des membres du canal de travailler ensemble pendant qu'ils s'adaptent aux changements dans l'environnement peut aider à maintenir les niveaux de rendement (Teece et al., 1997). Le fait d'être confiant que la flexibilité se traduira par des rendements

équitables peut aider à maintenir des partenariats et à améliorer les performances des canaux de distribution (Yu et al., 2013).

- **Capacité de développement de nouveaux produits :**

Il s 'agit d'élargir la perspective de l'orientation du marché. Han et al. (1998), ontconstaté que le développement de nouveaux produits génère une meilleure performance. Cette relation peut être le résultat d'un monopole temporaire détenu par l'entreprises la plus innovante (Schumpeter, 1942), ou tout simplement que le nouveau produit fonctionnellement surpasse les autres produits sur le marché (O'Cass et Sok, 2012). De nombreuses étudesréalisées ont ensuite étudié le lien entre l'innovation et la performance, en constatant la relation positive dans l'industrie des machines alimentaires (Bigliardi, 2013), dans l'industrie pharmaceutique (Sorescu et al., 2003), ainsi que dans de vastes contextes d'industries de haute technologie (Wuyts et al., 2004) et des industries de basse technologie plus courantes (Noble et al., 2002).

- **Capacité de tarification :**

Pour certaines entreprises, la capacité de négocier avec les distributeurs, les détaillants ou les clients commerciaux en ce qui concerne les contrats relationnels à long terme offrent la meilleure performance. Pour les autres entreprises, la capacité de prévoir la santé économique d'un marché offre les meilleurs résultats. Toutefois, le fait de pouvoir établir le prix des produits pour signaler la qualité, le prestige et la disponibilité par rapport aux concurrents donnera généralement les meilleurs résultats (Flatten et al., 2015). Cette capacité de comprendre la discrimination par les prix et la façon dont le marché réagira aux signaux et aux changements de prix est presque un art psychologique autant qu'il est comptable. On s'attend à ce que les entreprises dont les gestionnaires sont capables de comprendre les prix obtiennent de meilleurs résultats que celles qui sont plus performantes en finance ou en comptabilité.

- **Capacité de promotion :**

La capacité de promotion comprend toutes les communications entre une entreprise et ses marchés. Les recherches récentes dans ce domaine se concentrent sur la coordination et la cohérence des messages utilisant toutes les sources médiatiques de la télévision traditionnelle, de la radio et de la presse écrite jusqu'aux médias sociaux. Cette ligne de recherche suggère qu'une plus grande intégration de la capacité de communication en marketing améliorera l'efficacité de la promotion, le rendement de la marque sur le marché et le rendement financier (Luxton et al., 2015). L'uniformité qui accompagne la capacité augmente également la performance des nouveaux produits (Chen, 2011). En outre, une communication marketing plus efficace a permis d'accroître les performances globales de l'organisation (Jerman et Završnik, 2012).

- **Capacité de recherche en marketing :**

Narver et Slater (1990) soulignent l'importance de recueillir et de diffuser des informations sur le marché et sur les concurrents de l'entreprise. Des milliers d'études ont examiné la relation entre l'orientation du marché et la performance des entreprises, en tenant compte des principaux effets, des effets médiés et des effets conditionnels dans de nombreux contextes différents.

- **Capacité de gestion du marketing :**

Dans le monde de l'entreprise, les cours des actions changeront à mesure que les capacités de gestion de l'entreprise s'amélioreront ou se détérioreront avec l'ajout ou la perte de gestionnaires clés. Au-

delà des gestionnaires individuels, la documentation sur la prise de décisions de groupe laisse entendre que la diversité de la gestion améliorera la prise de décisions parce que la diversité apporte une variété de points de vue, tient compte d'autres options et permet d'établir des critères d'évaluation. Dans la documentation sur la gestion, la diversité des sexes a été associée à une meilleure performance financière (Opstrup et Villadsen,2015).

En outre, le plus grand capital intellectuel qui provient de la diversité des antécédents scolaires, de la diversité de l'industrie et de la diversité de l'expérience internationale au sein des équipes de gestion est étroitement lié à l'augmentation de la performance de l'entreprise (Díaz- Fernández et al., 2015). Même la diversité fonctionnelle au sein des équipes de gestion peut améliorer la performance (Cannella et coll., 2008). La raison d'être de la diversité et de l'inclusion de points de vue multiples est semblable à celle des équipes sportives qui ont des joueurs compétents à des postes précis. Chaque joueur peut éduquer l'équipe pour comprendre la perspective des joueurs de l'équipe du concurrent de la même position, et peut apporter la force spécifique de cette position à l'équipe de la maison. Les équipes, qu'elles soient sportives ou de gestion, avec les joueurs les plus compétents à chaque poste, seront probablement les meilleures dans la compétition.

Chacune des capacités de marketing se rapporte positivement à la performance du marché qui à son tour conduit à la performance financière.

Hypothèse 4 : Les capacités marketing, y compris la distribution, la recherche en marketing, le produit, la promotion, la gestion du marketing et les prix influencent positivement la performance sur le marché de l'entreprise.

Modèle Conceptuel

Figure 1 : La significativité des relations

Méthodologie

Cette recherche s'inscrit dans une perspective positiviste. Nous partons par un a priori théorique afin de vérifier des relations qui relient les différentes variables traitées.

Afin de répondre à notre problématique principale de recherche, nous avons suivi une démarchehypothético-déductive. Nous avons construit notre cadre conceptuel et proposer des hypothèses de recherche à partir des travaux de recherche passés.

Justification des échelles de mesures

Concept	Auteur	Source
Transformation digitale	Aral et Weill 2007	**IT Capability and Digital Transformation**
Capacité marketing	Morgan et al. 2009;Vorhies and Morgan 2005	**Big Data Resources,** [redacted] **Marketing Capabilities, andFirm Performance.**
Capacité technologique	**IT Business spanning** (Bharadwaj et al.1998 Mata et al. 1995)	**IT Capability and Digital Transformation**
Performance sur le marché	**IT Proactive stance** (Lu et Ramamurthy 2011 ; Weill et al. 2002)Morgan et al. 2009	**Big Data Resources,** [redacted] **Marketing Capabilities, andFirm Performance.**

Échantillon

Dans notre recherche, nous ne disposons pas une liste exhaustive des entreprises. Ainsi que notre recherche ne se limitera pas sur une régionprécise ou un groupe de personne précis, mais il inclut toutes les entreprises situées en Tunisie tout domaine confondu.

Le choix d'une méthode d'échantillonnagedépend de l'objectif de la recherche. Pour notre enquête, un échantillon non probabiliste est convenable.

Dans la branche de l'échantillonnage non probabiliste, nous avons choisi l'échantillonnage de convenance, comme son nom l'indique, il consiste à interroger la première personne rencontrée qui accepte de répondre et qui est capable de fournir des informations sur le sujet à étudier. Dans notre cas nous avons collecter les repenses auprès de 90 dirigeants d'entreprises située en Tunisie.

Étude Empirique

La partie empirique de notre recherche vise à présenter et discuter l'opérationnalisation empirique de notre modèle conceptuel qui a été testé sur un échantillon de 90 entreprises qui sont ou qui visent à

Figure 2 : Intensité des relations sur PLS

poursuivre une démarche de transformation digitale.

Pour ce faire, nous avons étudié la purification des échelles de mesure à travers l'usage de la méthode des équations structurelles, pour cela nous avons utilisé l'analyse en composante principale (ACP) via SPSS 23.

Enfin nous avons étudié la vérification des hypothèses de recherche, la validité des relations entre les différentes variables, et l'interprétation des résultats obtenus.

Après avoir utilisé la méthode PLS pour étudier l'intensité des relations entre les différentes variables,

Nous avons constaté que toutes les hypothèses de notre recherche sont validées sauf l'hypothèses 3 qui représente que la transformation digitale influence positivement la performance sur le marché et ce dû à plusieurs raisons :

- Selon Dubelaar et al (2005) les PME Africaine sont confrontées à de nombreux obstacles relatifs à leur développement, notamment en ce qui concerne la sécurité de l'information, en raison du manque de ressources humaines qualifiées. Partant de cette idée nous déduisons que dans un contexte de transformation digitale ce qui compte vraiment n'est pas seulement l'utilisation des ressources numériques, chaque entreprise qui vise à adopter une démarche de transformation digitale doit mobiliser des investissements dans les personnes, les processus et les technologies afin d'améliorer sa performance (Dehning et al., 2003). L'intégration des employés qui ne sont pas adaptés aux nouvelles technologies et ne maîtrisent pas les nouvelles tendances digitales, peuvent nuire à l'organisation et nuire à sa performance.

- Par ailleurs, la transformation digitale peut ne pas avoir un effet direct sur la performance de l'entreprise, mais, certes elle présente un effet stratégique permettant à l'entreprise d'être un Leader sur le marché. Avec l'utilisation des nouvelles tendances tel que big data, business intelligence, l'intelligence artificielle l'entreprise pourra mieux analyser la demande et mieux satisfaire sa clientèle.

- En outre, dans ce troisième argument qui explique la relation non significative entre la transformation digitale et la performance sur le marché nous mettons l'accent sur le concept de la maturité digitale des entreprises en Tunisie. Pour mieux expliquer cette idée nous allons présenter le constat de Cap Gemini (2013) sur la maturité des entreprises en matière de digital

Figure 3 : Cap Gemini (2013) : La maturité digitale

- En Tunisie, nous sommes encore dans la phase « débutants » non seulement sur l'axe des outils mais aussi sur l'axe des personnes. Ce qui explique la non validité de l'hypothèse 3 de notre recherche.

CONSTATIONS

L'analyse des données recueillies à travers l'étude quantitative a révélé plusieurs résultatsintéressants.

Premièrement, nous avons constaté la forte corrélation entre les variables du modèle conceptuel et l'intensité de l'effet de la capacité technologique sur la transformation digitale et la capacité marketing des entreprises et l'effet de cette dernière sur la performance sur le marché contrairement à la faible corrélation entre la transformation digitale et la performance sur le marché de l'entreprise.

Deuxièmement, nous avons pu étudier la significativité des relations et nous avons constaté à travers l'analyse multi groupe que seule la variable exportation est significative.

Pour résumer, ce présent travail de recherche présente certaines contributions sur le plan théorique et managérial.

- Apports théoriques

Sur le plan théorique, notre travail a permis un meilleur approfondissement du concept de lacapacité technologique. Nous avons pu confirmer l'influence positive de la capacité technologique sur la transformation digitale et sur la capacité marketing des entreprises. Nous avons égalementdégagé l'influence positive de la capacité marketing sur la performance des entreprises sur le marché. Enfin, nous avons constaté la non validité de l'hypothèse H3 en Tunisie, c'est-à-dire que la transformation digitale n'a pas un effet direct sur la performance sur le marché.

- Apports manageriaux

Tout d'abord, il faut savoir que la transformation digitale n'a pas un effet immédiat, elle vise plutôt le long terme. C'est un concept complexe qui nécessite toute une architecture IT adéquate afin d'améliorer le rendement des entreprises. Outre que son impact sur la performance sur le marché, la transformation digitale et l'utilisation de nouvelles technologies numériques, comme les médias sociaux, les appareils mobiles, les outils d'analyse ou les dispositifs intégrés, peuvent aussi apporter des améliorations importantes aux activités, comme l'amélioration de l'expérience client, la rationalisation des opérations ou la création de nouveaux modèles d'affaires.

En outre, les investissements en IT peuvent êtreconsidérer comme un avantage concurrentiel incontournable pour l'entreprise. Les entreprises ayant la capacité de planifier et d'intégrer leurs ressources en IT peuvent mieux saisir de l'information sur les clients, partager des connaissances et améliorer les processus opérationnels. Par conséquent, les entreprises dotées de ressources, de connaissances et de compétences en IT sont plus susceptibles d'évoluer et d'améliorer leur performance.

Par ailleurs, le marketing digital, rassemble à toutes les pratiques marketing employées sur les supports et les canaux digitaux. Les nombreuses disciplines du marketing digital ont pour principaux objectifs de développer la relation client. Tout cela a pour but d'améliorer la notoriété de son entreprise et améliorer sa performance sur le marché. Par ailleurs, le marketing digital permet la création d'une communauté, notamment sur les réseaux sociaux, qui est totalement acquise pour sa marque. Dans d'autres contextes, il est possible de se servir de cette influence pour déclencher un

besoin chez les clients potentiels. Pour améliorer ses chances d'atteindre ses objectifs, l'idéal est de mettre en place une stratégie qui a recours à de nombreux canaux numériques. Pour se faire, plusieurs sont les méthodesappropriées, notamment le SEO, Search Engine Optimization ou optimisation pour les moteurs de recherche, SMO l'acronyme de Social Media Optimization ou Optimisation pour les Médias Sociaux qui désigne l'intégralité des techniques et actions ayant pour but de développer la notoriété de l'entreprise sur les médias sociaux. Ainsi que, le web analyse ou web analytics qui se base sur l'analyse de comportement de son audience sur son site web, dans le but de déceler les points à améliorer ou à modifier. Tout cela, son oublier l'apport des canaux traditionnels et l'impact de ces derniers sur la performance de l'entreprise.

Limites De La Recherche Et Voies De Recherches Futures

Notre recherche a des répercussions sur le volet stratégique des entreprises. Plus précisément, ce travail de recherche sera d'une importance pratique pour les gestionnaires et les cadres qui luttent pour développer et intégrer les technologies numériques à leurs processus opérationnels. Cette étuderévèle que la capacité des IT est d'une part un moteur de la transformation numérique et d'autre part une source de performance. Cette étude comble le vide et révèle que la création d'une transformation digitale grâce aux capacités existantes peut stimuler la performance sur le marché. De plus, cette étude souligne la nécessité d'être conscient de l'empreinte numérique en entreprise.

Bien que cette étude apporte un certain nombre de contributions, comme toutes les autres études de recherche, elle a aussi des limites. L'étude a utilisé un petit nombre de variables qui peuvent avoir une incidence sur la performance sur le marché. Bien que la capacité technologique joue un rôle essentiel sur le rendement des entreprises, d'autres facteurs, comme les ressources, peuvent influer sur la façon dont ces entreprises utilisent et appliquent les technologies numériques. Des études futures complètes peuvent être nécessaires,il est important de ne pas limiter la transformation digitale contexte organisationnel tout en négligeant le contexte social dans lequel le système est utilisé.

Enfin, le concept de la capacité technologique dans cette étude a été expliquer sans prendre en considération la phase de maturité digitale de l'entreprise. Ce qui peut faire l'objet d'une recherche future.

Conclusion

La transformation digitale devient un sujet de prédilection pour les entreprises du monde entier (Von Leipzig et coll. 2017). On s'attend à ce que les entreprises qui ne sont pas en mesure de s'adapter au monde numérique soient sans aucun doute victimes du « darwinisme numérique », où les titulaires peuvent disparaître et seules les entreprises les plus adaptables, sensibles aux tendances technologiques, survivra pour rester sur le paysage concurrentiel (Schwartz 2001). En Tunisie, l'histoire des progrès technologiques des entreprises a été entachée de tentatives infructueuses qui se concentrent uniquement sur les technologies sans tenir compte des grands domaines de décisionstratégique. À l'heure actuelle, il existe de nombreux exemples d'organisations incapables de suivre le rythme de la nouvelle èrenumérique et les gestionnaires manquent encore de clarté sur les considérationsstratégiques dans leurs efforts de transformation numérique (Hess et al. 2016 ; Matt et al. 2014).

De ce fait, il est généralement admis que l'utilisation des capacités technologiques peut avoir un impact positif sur la performance sur le marché si l'entreprise prépare au préalable une bonne infrastructure IT qui regroupe les biens physiques constitués des technologies de l'informatique, l'infrastructure humaine qui comprend les routines, les expériences, les compétences, les engagements, les valeurs et les normes appliquées par la main-d'œuvre de l'organisation dans la prestation des produits et services (Henderson and Venkatraman , 1993; Byrd and Turner, 2000) et les biens intangibles appuyés par les IT qui comprennent la gestion des connaissances, l'orientation

des utilisateurs et la synergie entre les intervenants comme le gouvernement, les citoyens et les fournisseurs (Bharadwaj, 2000; Bakry, 2004; Grant, 2010)

Aujourd'hui nous entendons beaucoup discuter la transformation digitale. En réalité, La stratégie de transformation digitale est d'une part un plan directeur qui aide les entreprises à gérer les transformations découlant de l'intégration des technologies numériques, ainsi que dans leurs opérationsaprès une transformation (Matt et al. 2005).

D'autre part, La transformation numérique consiste à tirer parti des technologies numériques pour apporter des améliorations importantes aux activités, comme l'amélioration de l'expérience client ou la création de nouveaux modèles d'affaires. (Piccinini et al. 2015).

Par ailleurs, la transformation numérique englobe la numérisation des processus axée sur l'efficacité et l'innovation numériqueaxée sur l'amélioration des produits physiques existants grâce aux capacitésnumériques (Bekkhus 2016).

Enfin, la transformation numérique est la transformation profonde et accélérée des activités, des processus, des compétences, et des modèles pour tirer pleinement parti des changements et des possibilitésdécoulant des technologies numériques et de leur impact dans l'ensemble de la société de façonstratégique et prioritaire (Berghaus and Back 2016).

Abstract

While shareholder activism is most prevalent in United States, Asian region too is witnessing the rise in the activism count – driven prominently by the proliferation of global institutional investors stakes in Asian companies which support activist investors. However, since institutional investors all across the globe are much more dispersed and diversified than individual investors, hence, domestic institutional investors too could be as impactful as their foreign peers in steering targets' corporate governance agenda towards the direction that they considered ideal. Yet, despite deemed to be highly capable to force corporate governance change, the influence of institutional investors on their investees' corporate governance agenda may not be as cut and dry as it appears. Moved by this premise, this study proposes models for empirical investigations into the relationship between companies' lagged dividend payout level and their current dividend payout level. The study further proposes that the institutional shareholding would weaken the relationship between companies lagged dividend payout level and their current ones.

Keywords: Lagged Dividend, Shareholder Activism, Corporate Governance, Institutional Shareholdings

Introduction

Shareholder activism is exploding and as PwC (2018) claimed, their tactics and strategies are changing. In his writing, Breitinger (2017) shared that the activism could brutally damage the targeted companies since they may be forced to take an instant triggering positive share-price action, which potentially impair the wider organization. Though shareholder activism may be prevalent now than they were in the past, but, really, as stressed by Breitinger (2017) and Wolf (2017), shareholder activism is nothing fresh – it has existed ever since shareholders have had voting rights in the companies where they hold shares. However, Breitinger (2017) explained that the circumstances were different back then - shareholding was more concentrated and exclusive, and oftentimes, the shareholders would only exert influence behind closed doors.

Basically, according to PwC (2018), what draws shareholders' activists' interest in their targeted companies is the desire to steer the company towards the direction that they perceived right. For instance, the activists may shock awake their sleepy investors, management teams before they dive too far into deep sleep, which would be detrimental to the corporate life (PwC, 2018). In some other cases, the likes of Borges & Othman (2015) and Teng (2016) pointed out, shareholder activists may provoke their target(s) when, in their eyes, the interests of the corporate participants – particularly minority shareholders - have been deprived or taken lightly.

Cite this Article as: Nur Izni ZURNI and Norashikin ISMAIL "Lagged Dividend And Dividend Payout: Interacting Effect of Institutional Investors" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

While shareholders activisms are greatly linked with the United States, Summerfield (2018) emphasized that the statistics reported by JP Morgan (2018) demonstrate that activism is now gaining traction in other jurisdictions too. With reference to the report, there were 106 activist campaigns took place in Asia in 2017 – versus 94 carried out in 2016 and way far back in 2011, only 10 shareholder campaigns held. In Malaysia, as Ashrafi & Muhammad (2013) mentioned, particularly after the financial crisis back in the year 1997-98 of whereby the corporate governance mechanism was restructured, the brand-new structure has activated institutional shareholders' play in the market to uplift corporate governance system, intentionally. What is, as reported in Malaysian Reserve (2017), the urge from Minority Shareholders Watchdog Group – otherwise known as MSWG - to adopt the principles of non-compulsory Malaysian Code for Institutional Investors 2014 should somehow develop the interest of the institutional investors to exert their influences on corporate governance matters.

Typically, the setting of dividend level is typically referenced to the existing payout trend. However, this may be implicit to some. For instance, as reported in The Edge Malaysia (2017), there are companies that poorly regard - some even completely denied – the shareholders' dividend rights even with institutional shareholders around, in spite being in net cash positions, had been able to embrace various financial commitments and still have excess of funds. While institutional shareholders are claimed to be hugely capable to drive corporate governance change, which includes matter pertaining to dividend decision, yet, their influences on the dividend payout decision may not be as cut and dry as it appears. This is likely to be true especially when there is historic dividend payout level – let alone if there is already a deep-rooted and solid dividend payout trend in place. This gives rise to the research into this matter – the effect that institutional shareholding has on the relationship between lagged dividend payout level and the current ones. To reach the focal objective, there are two gatekeepers that need to be passed; to determine whether lagged dividend has relationship with current dividend and whether institutional ownership has any relationship with the dividend payout level.

The remaining parts of the paper are organised as follows: section 2.0 provides the literature review and thus covers relevant accounting theory underpinning the study, and other variables hypothesize to influence dividend payout. Section 3.0 gives the proposed empirical method of the paper which the sample source of data; model specification and the proposed estimation method. Section 4.0 presents the conclusion of the paper.

Literature Review

Agency Cost Theory

Developed by Jensen & Meckling (1976), this theory suggests that, since there is a separation of ownership and control, hence, both parties to the relationship – the shareholders (principal) and managers (agent) – are likely to defend their own interests. Their interests, according to Raviv & Harris (2010) and Shaftoe (2018), may be – oftentimes are – inconsistent. Depending on the magnitude of the disagreement between their interests, it is no surprise that while some companies may only face trivial conflicts, yet, as brought up by Raviv & Harris (2010) and Matsusaka (2017) in their pieces, there are shareholders and managers who are in a hostile corporate war.

Jensen & Meckling (1976) laid out several provokes to principal-agency battles. For instance, matters pertaining to the retention of earnings and cash accessible by the managers, which also agreed by some other recent scholars such as Chung, Firth, & Kim (2005) and Rahman (2008). It is worth to recall that, as described by Jensen & Meckling (1976), the incompatibility of both parties' interests aggravates the controversy around shareholders-managers' relationship. Hence, in aligning the interests so that companies can break free from agency crisis – if that is even possible – some of the control alternatives available includes dividend distribution as shared by Parikh (2007) and Picker (2018). Point taken from by Lo, Wu, & Kweh (2017) study suggested that institutional shareholders are competent agency-relationship's regulators and therefore, should be able to press agency cost as low as practically feasible

Signaling Theory

Signalling theory, Miller & Modigliani (1961) comes to presence primarily due to asymmetric information between managers and stakeholders, specifically outside stakeholders. Considering that dividend is one of the information transporters, hence, companies would send dividend off to the market Benveniste & Spindt (1989), Stoughton & Zechner (1998) and Aggarwal & Dahiya (2000). While the underlying message behind the issuance and non-issuance of dividends is abstract, nonetheless, Lacerda & Santa-Clara (2010) suggested it is tough to neglect the predictive power of dividend.

A consistent payout level of dividend is likely to circulate meaningful information about companies' performances. It is, therefore, fairly easy to comprehend why investors find dividend-paying companies with an uptrend payout record more eye-catching than the ones with descending payout movement. (Marquit,2011) Bhargava & Chen (2012) and Brito, Pereira, & Vareda (2016) suggested while many corporate information is kept confidential, however, the constructive ones like dividend payment, are better off to be dispensed to the market.

Besides that, this theory also proposed that another credible mechanism to transmit information to the market is by having institutional investors. Ajina, Lakhal, & Soughne (2015) in their France-based research revealed that the proportion of institutional investors has a positive and significant effect on stock-market liquidity. That is, institutional investors also are credible information transmitter, just like a dividend. It is widely testified that institutional investors play huge role in transmitting information, to the degree that, Ahmad & Jusoh (2014) stated that the existence of institutional investors or large shareholders mutes the necessity to hire other tools to trumpet companies' impressive performance.

Dividend Payout Level

Among well-known types of dividend policy is a residual payout ratio, which, as Harvey (2012) described as an approach of where the dividends are paid out of earnings left over. Especially when companies are not hugely profitable and/or are seeking to establish themselves, this is likely to be an ideal approach to a dividend payment. Generally, though many income-seeking shareholders tend to fall for companies that have high dividend payout ratios' records, however, Bergmann (2016) and Kennon (2017) punctured that popular idea with their argument – high dividend payers may over-glorify their financial footing. High payout ratios are rarely sustainable and it should warn the investors that on the horizon, there could be a disappointing dividend

Lagged Dividend Payout Level

Baker, Farrelly & Edelman (1985) and Goldberg (2016) held that, commonly, dividend stability dominates managers' dividend concerns as opposed to the simple dollar figure of dividends. While it may be irrelevant for some dividend-paying companies, Plaehn (2017) argued that in most cases, trimmed dividend payout, particularly the drastic ones, typically rings weakness. According to Aivazian, Booth, & Cleary (2003) and Klein (2014), in all rationality, companies would aim to project a rock solid image – which is the polar opposite of being weak. So, in plotting an ideal trend of payout ratio based on the premise of stability, Chemmanur, Hu, & Liu (2010) and Imran (2011) were in the opinion that, historical dividend payout level(s) is(are) ideal piece(s) of building block(s) to begin with.

Institutional Shareholding

Lang & McNichols (1997) and Venkat (2014) suggested that the term 'institutional ownership" signifies the ownership stake in a company that is held by institutional investors. These institutional investors, according to OECD (2017), are major collectors of savings and suppliers of funds to the financial markets. Institutional investors are loaded with a great deal of power, typically relative to individual investors. And for that, their presence, even in isolation of the shareholding, has granted them with what Mueller (2003) defined as "power without property". Hirschman (1970) stated that these investors can exercise control over their investees and lessen the management's moral hazard

through "exit and voice" behavior. Gillian & Starks (2000) described "Exit and voice" expression, as institutional investors' exertion of control over their investor's business decisions, which can stretch from the threat to sell off their shares (exit) to the active use of their voting rights (voice) in the shareholders' meeting.

Profitability

Profitability is one of the golden keys that unlock the access to a firm's overall health status (Maverick, 2016). When we look at profitability in isolation of other influential factors to the dividend payment decision, profit-rich businesses, have a financial advantage to spoil their investors.

In relation to dividend payout, Lintner (1956) and Boyte-White (2018) agreed that companies' profitability has long been regarded as the primary measure of the company's capacity to pay dividends. According to Biery (2014), companies that bagged large net margin, especially those that outperformed the broader market, are said to have a comfortable margin of financial safety.

Solvency

Solvency as defined by Bragg (2018), is a state of financial soundness which is influential to an entity's ability to clear their financial load as they fall due. One of the prevalent measurements of a company's financial leverage is debt-to-capital ratio. Speaking about debt, Nash (2016) and Tellefsen (2017) remarked that there is a popular myth about debt - it is narrowly considered 'evil' and would effortlessly take away its dependents' life. However, debt-financing can be beneficial, particularly when a company manages to subscribe to low-interest long-term loan. The running into insolvency does not flatly lie on debt - it lies in debt-capital structure. Normally, when a company carries a high debt relative to its entire capital base, they are said to be highly leveraged , and such structured, warned Garcia (2018) and Lawrence (2016), can be detrimental.

When companies acquire fund via external debt, Bergmann (2016), Cerini and Associates (2017) and Kisava (2017) raised that, by that time, new and fixed financial liability would be created since debt covenant binds debtors to their lenders. Logically, since the dividend is taken out of a company's wealth, hence, according to Abor & Fiador (2010), there is a chance that the collateral base which supplies the lenders with the confidence to lay the asked money in the hands of their borrowers, would collapse.

The Relationship between Lagged Dividend on Dividend Payout Level

The majority of former scholars conclude that current dividend payout models their seniors (Miller & Modigliani, (1961); Baker, Farrelly, & Edelman, (1985); Pruitt & Gitman, (1991); Naceur, Goaied, & Belanes, 2006). Yet, to replicate similar prediction can be inaccurate for multiple factors. First, these studies were conducted external to Malaysia territory thus there could be geopolitical factors that have sufficient weight to influence corporate decision, dividend distribution decision included. There is a strong mutual statement made by Aivazian, Booth, & Cleary (2003) and Klein (2014) on corporate image and dividend decision. According to them, in all rationality and under normal circumstances, companies would want to be known for their solid corporate reputation. To be able to serve the intended strong image, clear, rational and consistent dividend history is one of the corporate tricks that companies can dish out to the marketplace. So, in plotting an ideal trend of payout ratio with the ambition to accomplish such image, as cited by Chemmanur, Hu, & Liu (2010) and Imran (2011), past year's dividend payout ratio is an ideal piece of building block to begin with.

The Relationship between Institutional Shareholding on Dividend Payout Level

Institutional investors, as resourceful investors, at least compared to individual investors, advantage of economies of scale in information-gathering and analysis. Therefore, in the presence of

institutional owners, the corporation is less likely to use dividends as a means of reducing agency costs. In the case of where institutional investors hold a sizable amount of share – especially the holding size that grant them a scream rather than merely a whisper, it is sensible to predict that, when the size of institutional ownership expands, the level of dividend payout reduces.

The interactive Effect of Institutional Shareholding on the Relationship between Companies' Lagged Dividend and Dividend Payout Level

Institutional shareholders holding is projected to weaken the relationship between companies' current dividend payout level and their pasts'. One of the narratives that go into the prediction is that the presence of institutional shareholders, especially with sizable stake, can ease agency hiccups which activated by ownership-management split-up.

While it may be argued that institutional shareholders – especially ones that put forward huge investment size in their investee could perform active monitoring, and as a result, their investee would gain better financial returns, the argument is flawed primarily because financial benefit is not a promising outcome when institutional shareholders take active charge of monitoring roles.

Research Methods and Sample Selection

The STUDY adopts positivist research paradigm using a hypothetical deductive methodology through testing a set of hypotheses. The data is analysed using univariate and multivariate analysis involving ordinary least squares (OLS) regression with the estimation of equation as follows:

$$PAYOUT_{i,t} = B_0 + \beta_1 LAGGED_{i,(t-1)} + \beta_2 INS_OWN + \beta_3 ROFIT_{i,t} + \beta_4 LEVERAGE_{i,t} + \varepsilon_{i,t} \ldots\ldots\ldots (1)$$

The first model, it intends to provide answers to the question of whether to lag the dividend payout level and institutional ownership have any relationship with the current dividend payout level.

The second model to unearth the interacting effect that institutional ownership could have had on the relationship between lagged dividend payout level and the current LEVEL.

$$PAYOUT_{i,t} = B_0 + \beta_1 LAGGED_{i,(t-1)} + \beta_2 INS_OWN_{i,t} + \beta_3 LAGGED_{i,(t-1)} * INS_OWN_{i,t} + \beta_4 PROFIT_{i,t} + \beta_5 LEVERAGE_{i,t} + \varepsilon_{i,t} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (2)$$

The subscripts *i* and *t* denote firms and year, respectively. Payout denotes dividend in the current year. Dividend measured as total dividends paid over the number of shares outstanding, and expressed as ringgit Malaysia (RM) per shareholding. LAGGED denotes dividend payout in the previous period. INS_OWN_i denotes institutional ownership measured as percentage of shares owned by institutional shareholders that are listed on "Top 30 Shareholding List". PROFIT is measured as Net margin and calculated as net profit over sales while leverage is calculated as total debt over total equity.

Data and Sample Companies

The model tests the research hypothesis were estimated using a sample of companies listed on the main market of Bursa Malaysia that have made cash dividend payment in the year of study and in the prior year during the investigation year 2016 and 2017. The sample companies comprises of all industry sectors except finance, real estate investment and trusts (REITS), hotels, infrastructure project companies (IPC), mining and closed funds. The second criterion for inclusion in the final sample is that the company was continuously listed during the last five year period. The requirement that companies were continuously listed ameliorates the impact of Initial Public Offering (IPO) effects on the sample. Thirdly, international evidence supports the hypothesis that in the first year after listing, IPO companies manage earnings to meet the prospectus forecasts (Teoh, Welch & Wong, 1998). In particular, Ismail and Weetman (2008) document that Malaysian IPOs, in the first year of listing manage earnings in the direction of the forecast, so that the forecast error falls within

the limit tolerated by the regulations. Ismail et al. (2013) also provide evidence that IPO companies, managed earning to meet last year dividend payment. Therefore, newly listed companies were excluded from the sample. The model will be tested using multiple regression analysis.

Conclusion

The study proposes research models of the likely effect of lagged dividend and dividend payout level. The study further proposes that there is an interacting effect of institutional shareholders on the relationship between lagged dividend and dividend payout level.

The study hypothesize the institutional investors and their shareholding size have no influence over dividend payout level. It is assumed that the dividend-paying corporations that operate within a Bursa Malaysia regulatory environment leaves no space for their institutional investors To exert any force on matter pertaining dividend payout policy. While there are many explanations that drive to such assumption, yet the noticeable one could have been, while institutional investors' stake in their investees can be regarded as a valid signaling tool, but that fact does not replace, let alone take away, the credibility of dividend to signal corporate performance to the marketplace. Well, while dividend payout level may not necessarily give a correct reflection of the payers' financial being at all time, however, one the simplest ways for companies to communicate their financial well-being and shareholder value is by saying "the dividend cheQUE is in the mail and it is at par or even superior than we issued last year." Dividends may not be a perfect signaling tool, however, the prior studies suggests that, most dividend payers believe that building a resilient and durable payout trend could send a clear, powerful message about future prospects and performance.

Abstract

Green finance is an important area of tackling environmental threats, especially those associated with climate change. The Covid-19 outbreak has drawn additional attention to green finance as an economic mechanism for creating healthy living environments. The article examines the impact of COVID-19 on the financial industry, the involvement of green finance in the economic recovery after the pandemic, towards taking into account the Paris Agreement to reduce greenhouse gas emissions and improve sustainability. The authors put forward a provision on the presence of causal links between two concepts: "green" finance and "green" economy. The article substantiates the position that the global pandemic will have a long-term impact on the attitudes of investors, governments, and the public towards financing measures to protect the environment and prevent climate change.
The three-agent model proposed in the article makes it possible to analyze the behavior of green finance participants. By simulating their behavior, the mechanism of adaptation of both the system and agents to internal and external pressure is analyzed in order to preserve their functionality and increase the performance and efficiency of green financing.

Keywords*:* Green Finance, Green Bonds, Pandemic, Climate Change, Three-Agent Model.

Introduction

The outbreak of COVID-19 has demonstrated that society is not ready to respond quickly to global threats to both the environment in general and health in particular, and the economy (Guerriero et al, 2020). As uncertainties increase about protecting populations from disease and preventing climate change, it is important to make our society more resilient to both COVID-19 and long-term environmental challenges. This can be done by focusing on green finance - increasing its effectiveness and strengthening its position in post-pandemic economic recovery, which will bring significant benefits, both short-term and long-term, and increase societal resilience to shocks over time. The World Health Organization (WHO, 2019) ranks climate change as the biggest global health threat in the twenty-first century. Predicting future risks from climate change is not easy. An equally difficult task is to determine the response of the financial system to these risks, including insurance, as well as private and public financing of projects that contribute to their mitigation.

The suspension of habitual norms of life and activities during Covid-19 changed the way of life had a profound impact on the environment and attitudes towards health care. The pandemic has exacerbated many problems in the economy, increased risks, and increased uncertainties. Every week, the global economy loses $ 200-250 billion from the pandemic (COVID-19, 2020). When all attention is focused on the fight against the virus, climate problems and the risks associated with climate change are formally somewhat relegated to the background (Wyns, 2020). Against this background, there is a need to rethink attitudes towards green finance in order to clarify its place in economic development and track the ongoing transformation in green finance. These days, the

Cite this Article as: Igor K. KLIOUTCHNIKOV, Oleg. I. KLIUCHNIKOV and Olga A. MOLCHANOVA "Scrum Solo: Application in Projects with a Strong Integration Component" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

pandemic appears to be new opportunities for green finance and a green economy. Green growth, driven by green finance, could be a long-term megatrend winner rather than a niche zone.

A green focus in post-pandemic economic recovery will increase the resilience of society to pandemics and other emergencies, including climate change (OECD, 2020). Back in April 2020, at the initiative of the OECD General Secretariat, a document was prepared to discuss the post-pandemic economic recovery based on investments in improving the environment. The authors of the document propose "to increase resilience to pandemics with the help of environmental factors, which is a key component of measures to stimulate economic recovery, which are currently being developed by governments" (Cox and Piccolo, 2020). The transition to a green economy is necessary to achieve the goals set out in the Paris Agreement. During the transition, a system of regulation and measurement of investments is being created, the size of which is estimated at tens of trillions of dollars. All this requires a clear classification of green finance and the establishment of causal relationships, which will allow the transition to parameterization and assessment, comparisons, and targeted transformations of finance and the economy in a green direction.

Measuring the quality and depth of penetration of green finance into global markets, establishing causal relationships in this process, and determining the impact of investments on the preservation of the environment is a major challenge. The fact is that there are significant national and regional differences in their accounting and regulation. This problem can be fundamentally solved by standardizing green financial products and services, which makes it possible to move to their quantitative measurement, accumulation of statistical series, and their comparison between countries. In addition, in this way, you can move to the formation of proposals aimed at meeting the target demand of investors and preparing products for specialized markets (for example, green bond exchanges and markets where hydrocarbon emissions quotas are traded). This problem has attracted the attention of the UN and other international organizations. He has underpinned a number of initiatives, including the UNEP Positive Climate Change Initiative (UNEPFI, 2017), the UNEP Financial Centers Initiative for Sustainable Development (UNEP, 2017), the KIC climate finance initiatives, I4CE and PwC and UN PRI (2017-2018), as well as initiatives to create an environment for sustainable stock exchanges (UNPRI / UNCTAD 2009).

The article puts forward and develops the following provisions: (i) there are the following links (a) between climate change, pandemic, and green finance; (b) between the concepts of “green” financial and “green” economy: “green” finance is a mechanism for the formation (reasons) of a “green” economy (consequence); (ii) a narrow focus on coping with a post-pandemic recession can have adverse environmental and health consequences, as long-term effects cannot always be considered in the pursuit of short-term results; (iii) the effect of green finance can be greatly enhanced by changes in lifestyles, the behavior of people and companies, legislative initiatives and government decisions aimed at protecting the health and the environment. The aforementioned provisions are viewed from the point of view of at least two competing discourses, according to which, during the post-pandemic economic recovery, the New Green Deal (Schroeder, 2019; Cobb, 2019), which gained international circulation in 2018-9, will undermine the economy (Walden, 2020) or increase its resilience. According to the first statement, investments in environmental projects will be reduced, and according to the second statement, “climate” investments will help restore and restructure the economy towards increasing its resilience. Also, in the article, to analyze the relationship between the main participants in financing environmental projects and analyze their behavior, simulations are carried out using a three-agent model.

Literature and Framework

Much of the economic literature on the optimal financial response to climate change focus on the trade-off between direct costs and the potential uncertainties of long-term benefits of carbon investments (Giglio et al, 2015). At the same time, the discount rate and its parameters play a central role in this discussion, since even small changes in discount rates can dramatically change the present value of investments in the long term. Thus, in the long term, make investments in carbon reduction attractive or unattractive. In this regard, financing was considered in terms of solving two problems:

(i) climate change in the right direction (Mahsin et al, 2020; Campiglio, 2016), (ii) adaptation of economic systems (Birindelli et al, 2020; Kahn et al, 2019) and, above all, production and households to climate change (Pham and Huynh, 2020; Jones et al, 2020)

No less popular are futurological studies of a green future and the role of green finance in building it (Clapp, 2018). In this regard, there are various reviews and analysis of various aspects of green bonds: debt obligations associated with financing projects that claim environmental benefits (Anh, 2020; Jones et al, 2020; Banga, 2019). The role of finance in climate change mitigation is also widely explored (Painter, 2019; Kahn et al, 2019). There is a fairly large body of literature and research on the involvement of the green and environmental sectors in sustainable and socially responsible finance (Boubaker, et al, 2018; Alahbali and Nobanee, 2020; OECD, 2019). There are also studies on the link between green finance and the green economy (Klioutchnikov et al, 2018).

Policymakers, practitioners, and academics are just beginning to study the impact of COVID-19 on the financial industry, as well as its involvement in post-pandemic economic recovery (More, 2020). Overall, the link between climate change and the current pandemic (Sengupta, 2020) from a green finance perspective is a new topic.

Conceptual Approaches

Numerous organizations and institutions have developed their definitions of "green" finance. The G20 defines this concept as “financing investments that provide environmental benefits in the broader context of environmentally sustainable development” (G20, 2016). The OECD considers the term “stand-alone,” derived from a broader investment theme, or closely related to other investment approaches such as socially responsible investing (SRI); environmental, social, and government (ESG) investment, sustainable, long-term investment or similar concepts ” (Inderst et al, 2012). In general, the G20 and OECD represent “green” finance as a process aimed at achieving certain goals.

In 2016, the Committee on the Environment, together with the UN financial services, proposed to standardize the main definitions and concepts of “green finance” under the theme “Sustainable Financial System” (UNEP, 2016a). At the same time, the approaches to these concepts were analyzed, which operated in a number of intergovernmental organizations and countries. Approaches to this concept and its constituent parts of exchanges that trade in green bonds, banks that provide green loans, statistical bodies of a number of countries, investment companies, and others were also taken into account. As a result, schemes were developed for entering the green finance system of various clusters, as well as areas of its responsibility and actions - environment, social sphere, economy, and government. As a result, the following general approaches have been proposed for the following terms:

- “Climate finance” - within the framework of the UN Framework Convention on Climate Change, the concept is reduced to local, national, or transnational financing, which can be obtained from public, private and alternative sources. This concept serves both to denote solutions to the problems of reducing emissions, and to adapt countries to the adverse effects of climate change.

- “Green finance” is a broader concept than climate finance as it also includes other environmental goals and risks. It is used to characterize the greening processes of various investment projects (UNEP, 2016a). At present, a kind of consensus has been reached on the inclusion of health issues and the fight against the COVID-19 pandemic in this topic.

- “Green Banking” - describes the process of banks' participation in “green finance” (UNEP, 2016b). As part of this process, the role of central banks in supporting green finance has been identified (UNEP, 2017a).

The refinement of these concepts resulted in a roadmap for the formation of a sustainable financial system, which began to determine the main parameters and processes of stabilization of the financial system towards its “greening” (UNEP, 2017b). In October 2017, at the annual meeting of the World

Bank and the International Finance Corporation, together with Bloomberg, a mechanism for greening the financial system was considered and proposed, which included digital green finance (UNEP, 2018). Currently, a wide variety of information is generated, collected, transmitted, processed, stored, and used in digital form. Naturally, this process affected such areas as the environment and finance, which became the basis for the transition to digital "green" finance. The digital form of "green" finance has further contributed to the cross-border transformation of the "green" economy and is largely combined in the overall process of digitization of all assets of our time - from natural assets to knowledge and human capital, within which the digitalization of the environment among and the digitalization of management and recovery mechanisms it, including the digitization of green finance. Thus, green finance entered the digital sphere and gained significant development in it in a short period. It is associated with both digitized traditional financial services in green packaging and the use of blockchain technologies.

In 2018, the European Bank for Reconstruction and Development established that green finance covers the financing and risk management of projects in a clean economy, energy efficiency, energy conservation, rational use of water resources, waste recycling, green infrastructure, informatics, education, etc. social industries, as well as green building construction, green R&D (EBRD, 2018). Besides, it was suggested to define the level of zoning in 'brown' projects. Thus, the area of responsibility of green finance in society was expanded.

The International Finance Corporation has developed a methodology for defining green finance for bonds, loans, and investments (IFC, 2017). She approached the concept from the standpoint of project tasks (micro and macro data of the project, its result), location (borrower and investor, location of the project and its operator - legal registration and actual location), and supply and demand (including estimates and changes in economic indicators). This methodology allows you to cover the entire spectrum of financial activities and move from the bottom up. To this end, green is first determined at the project level, based on the intended use of the investment in the real economy, by applying estimates for the corresponding green share in the project. Then they move on to assessing the company as a whole, and then the numbers are aggregated at the industry and country level. These results can be compared with the need for green financing to identify problems and green points of action.

When calculating the Global Green Finance Index (GGFI, 2018), this concept refers to any financial instrument or activity in the financial services industry, including insurance, stocks, bonds, trading in commodities and derivatives, as well as analytical or risk management tools that lead to positive changes the environment and society in the long term, that is, create conditions for sustainability. This practice formed the basis for the development of the GGFI index (2018).

The most basic criterion for the "greenness" of a company, product, process, or project is the ability or contribution to reducing its greenhouse gas emissions. The past two decades have seen a surge in new financial instruments such as green bonds, and environmental markets such as carbon and forest markets or markets for water services and resources. In addition, there has been progressed in analytical methods and a shift to big data, which has fueled the development of green mechanisms in finance and economics and has drawn increased attention to these topics.

A differentiated approach to green finance in mature economies and emerging markets is often accepted. The latter is characterized by a concentration of green finance not only in areas such as clean energy, low-carbon transport, and energy-efficient buildings but also on financial support for industrial restructuring, including towards energy efficiency and environmental pollution control (Shultz, 2020). Probably, the post-pandemic economic recovery will also be associated with the widespread restructuring of industry in the above directions.

The GGFI classifies green finance as any financial instrument or activity in the financial services sector, including insurance, stocks, bonds, commodities and derivatives trading, analytical instruments, or risk management instruments, resulting in positive changes for the environment and society in the long term. The main criterion for the "greenness" of a company or project is that it

helps to reduce greenhouse gas emissions. Over the past two decades, the rise of new financial instruments such as green bonds, and environmental markets such as carbon, forestry, or water services, along with advances in analytical methods, has drawn increased attention to green finance.

The term "green" finance is quite significant in international policy debates, such as recent meetings at the World Economic Forum. For example, green finance is no longer seen as a limited activity but is a profitable and promising sector of financial markets that serve society and raise the status of financial centers within which the main financial processes unfold. The transition to a green economy is taking place within the framework of the goals set out in the Paris Agreement. It is backed by a global investment strategy valued at tens of trillions of dollars.

There are many definitions of green finance and opinions on how to move towards green investment, but they can be summarized as an approach to financial systems that mobilize finance for clean and sustainable growth.

A group of specialists from the International Banking Institute (St. Petersburg, Russia) at the 2019 seminar on green finance (Klyuchnikov, 2019) identifies three main options or approaches to green finance - narrow, medium and broader senses. In a narrow sense, green finance is limited to financial solutions to climate and environmental problems, and in the medium one, to the creation of environmentally friendly technological processes, products, and energy. In a broader sense, the concept borders on sustainable financing, which is necessary to ensure sustainable economic growth. Each option has its own set of both market and non-market activities, which can be classified into two groups: (i) supporting and stimulating the use of finance in the green direction, (ii) controlling and limiting investments in dirty technologies and production.

In the course of the current pandemic, under the influence of digitization and cross-border activities, changes in both the content and the organizational structure and management of green finance have accelerated. In general, the process of their management can be defined as a set of formal and informal rules and norms, following which people interact in the financial sphere for the effective accumulation, direction, and use of financial resources to solve various nature management tasks and prevent climatic and other natural threats. Modern societies adhere to a basic set of rules and regulations defined by national interests. Nation-states have physical boundaries; while the problems of natural resources users often have trans boundary dimensions and are not limited to national borders. The modern pandemic, on the one hand, has blocked states in solving internal problems of fighting the virus, maintaining infrastructure and the environment, and on the other hand, it has drawn attention to the trans boundary nature of epidemiological and climate threats and the need for joint actions to address these problems.

To summarize, green finance is usually classified as loans and investments aimed at improving the environment and preventing climate threats through a wide range of actions to solve social problems. From this point of view, they have many macroeconomic effects, and different lending and investment procedures, directions, and forms of organization may have different macroeconomic goals and properties. First, green finance often has a huge impact not only on a specific industry or region but also on global processes. The localization of capital investment is often associated with extraterritorial consequences. Consequently, green finance, even when solving local problems, does not have regional jurisdiction, since in most cases it has a broader and often global impact on the economy, that is, it has mega-economic and mega-social consequences and usually leads to the formation of a green economy in worldwide. In this case, their purpose - utility, value, and result - go beyond certain cost characteristics of the immediate effect. Understanding how value is created and accumulated in a green economy through green finance requires a new approach to defining the categories of cost, value, price, and utility. A new approach can only be formulated as a result of an interdisciplinary search and solution to this problem by combining many disciplines - from computer science, finance, and behavioral economics to management, psychology, political science, and even epidemiology.

The concepts of ‘sustainability’ and ‘green finance’ have both concrete and amorphous features. Both concepts cover many different practices that relate to natural, social and political-economic phenomena. In everyday life, stability is quite understandable. This concept is widely used to define the state of physical phenomena or natural ecosystems. The latter is often considered in connection with the desire to prevent them from destruction and the need to preserve them for posterity. As for green finance, most economists continue to consider them in narrow terms as a financial subsystem, the dynamics of which unfolds in the environmental direction of financing, that is, corresponding to the solution of problems of preserving the environment, primarily the prevention of climate change, processes, tools, and goals. However, an alternative approach to green finance can be offered. In this case, green finance includes a variety of subsystems - from economic to non-economic. The central link of the economic system in green finance is the relevant elements of the financial system that are associated with solving environmental problems. As for non-economic subsystems, they include political, social, and cultural phenomena and institutions that are necessary for the future survival of a person. Moreover, green finance (i) becomes an integral part of capital accumulation and the creation of a sustainable system of capital accumulation, (ii) ensures the stability of financial markets and the stability of the entire economy, and also (iii) acts as a financial mechanism for the life support of humanity and the preservation of the Earth's ecosystem.

Linking Climate Change to the Pandemic and Green Finance

The dominant schools viewed the environment (especially the climate) and finance as independent systems. As soon as the modern pandemic began to unfold, the shortcomings of this approach were immediately revealed. It turned out that the environment is directly related to finance. It's not just a shift towards social distancing during the COVID-19 pandemic that has impacted financial institutions' interactions with customers and fueled the rapid development of digital services. Important changes in financial liquidity were outlined and financial assistance programs were deployed, and the financial system began to prepare for post-pandemic economic recovery.

Traditionally, financial markets have been presented as an efficient system for allocating resources. They have been widely modeled and studied using general equilibrium models, game theories, in which agents behave rationally and maximize value. In this case, prices are determined using, for example, the Black-Scholes-Merton formula. In essence, it all boiled down to a linear approach. At the same time, optimization of the predictability of results was carried out under the strict control of two operators: the state and the market. However, first, during the 2008 crisis, the financial system showed its vulnerability. Internal misadventures turned out to be much stronger in their influence on the depth of shocks than external ones. Over the past twelve years, trends have emerged that may indicate new threats to the system, and this is not only a monstrous increase in debt and asymmetries but, above all, a gap in the balance between finance and the real sector. At the same time, the contradictions associated with the gap in the ratio between financial and natural capital are highlighted.

Another important circumstance is that the coronavirus pandemic could lead to a deeper understanding of the connections that bind people around the world. Well-equipped health systems are essential to protect people from health security threats, including climate change. Climate change has already paved the way for the spread of some infectious diseases. The current pandemic has shown that predicting future risks is not easy, but climate change is strongly affecting several areas that play a prominent role in when, where, and how pathogens appear. In this regard, changes in temperature and precipitation are of key importance. To limit the risk of infectious diseases, it is necessary to significantly reduce greenhouse gas emissions and limit global warming to 1.5 degrees. That is, to implement the Paris Agreement by increasing green financing for economic development.

In the baseline scenario of post-pandemic development, proposed by the experts of the World Economic Forum, the key condition for normalization of activities is an investment in the long-term development of human health and the environment towards building a green economy (IMF, 2020). Green finance acts as a tool for creating measures to preserve the environment and increase the resilience of the economy. In the new conditions, green financing will provide epidemiological

measures to protect people, which is extremely important for the effective reproduction of human capital. A green focus for economic recovery after a pandemic will increase the resilience of societies to pandemics and other emergencies, including climate change (Cox and Piccoli, 2020). In April 2020, at the initiative of the OECD General Secretariat, a document was prepared that discusses economic recovery after the pandemic based on investments in improving the environment (OECD, 2020).

Climate and environmental change, as well as the pandemic, have focused on leading players that can affect the future of society. Among them, finance, which determines future development, holds the palm. However, COVID-19 pandemic could be the biggest challenge for financial institutions. On the one hand, their involvement in economic recovery could potentially weaken the focus on climate bonds and environmental issues, but on the other hand, the pursuit of sustainable finance and investment in health and environmental improvements could also help raise awareness of green finance. These two tendencies will act simultaneously and in each case, the priority will be on the side of one or the other. As the economic impact spreads, green finance faces some big challenges. Their solution is associated with the choice of specific steps that are aimed at changing the position now, as well as associated with possible calibration for the future. In particular, the channels for raising capital are changing. There is growing interest in increasing their openness, despite the decrease in liquidity and the reduction in supply.

Post-pandemic financial institutions will contribute to unique solutions to finance environmental transformation. Already, various workarounds are being developed to eliminate bottlenecks, in particular, related to late payments, cancellation of fees, and the transfer of any investment decisions and changes in their directions.

Due to the pandemic, there have been several changes in cleantech funding:

1) The importance of the processes of monitoring financial flows has increased. The changes were associated with an increase in the impact on profit of changes in financing terms and balances on bank accounts, which was influenced by both lower interest rates and increased delays in debt and interest payments, changes in the conditions for raising capital, methods and priorities of working with clients as during pandemic and with subsequent recovery.

2) Investors' interest in financial products that have ESG criteria is growing.

3) There has been a change in the yield and liquidity of green bonds, as well as the demand for them. In the course of significant price fluctuations, demand was redistributed, attention to some green bonds declined, while others increased.

4) With a general increase in risk and uncertainty in the financial sector, green bonds and green loans tend to become more stable and therefore more attractive financial products.

5) The disruption of supply chains in all spheres of the economy caused a reorientation of attention and financial investments in this area. In particular, there have been changes in the financing chains for climate investments.

6) Information asymmetries have increased and information priorities have changed, leading to a change in the way financial institutions deal with climate information.

7) With the overall increase in business value, the flexibility of producers of environmental goods and services, as well as mechanisms for lending and investing in production chains, increases.

8) Under the influence of changes in the production and supply chains, an increase in inventories was required, which affected the structural changes in the cost of environmental products. There has been a revision of investment strategies and pricing of environmental investment projects, also related to a change in attitudes towards health and the environment as a result of cheaper money.

The coronavirus pandemic is contributing to a deeper understanding of the links that link society, the economy, and the environment. Well-equipped health systems are essential to protect people from threats to health security, including climate change. A stable financial system can financially withstand threats to the environment and human health.

Social interaction, as well as interaction with nature, can be considered as part of the human ecological environment. The growing popularity of investment strategies that incorporate ESG (Environmental, Social, and Governance) criteria is one of the main investment trends. More and more investors want their money to be invested sustainably or with positive effects, both socially and environmentally, and not harm the environment. Actions that can generate economic growth and prevent a new pandemic outbreak: (i) investing in public health, an early response to outbreaks and testing materials, and (ii) combating illegal wildlife trade Financial support for their implementation fits well with green financing". Besides, mitigation measures are intended to work in the same direction. For example, preventing deforestation (a major cause of climate change) can help (i) halt biodiversity loss and (ii) slow down animal migration, which also carries the risk of spreading infectious diseases.

Three-agent model of behavior in the green bond market

Green finance is complex systems exhibiting a wide range of non-trivial emerging phenomena, including extreme shocks, short and long-term memory, dynamics, and multifractality. Collective behavior in systems can be modeled using a variety of approaches, including complex dynamic models, agent-based models, or graph theory. One of the most important and complex tasks is to describe the collective behavior of interacting edges, the corresponding information flows between them, and also to determine the role of nodes in these interactions. This study proposes a three-agent model in which the nodes are (i) the issuer of the green investment project, (ii) the investor or underwriter, and (iii) the regulator. The model of behavior is considered on the example of issuing, placing, and regulating green bonds - innovative financial instruments (Bange, 2019).

Green bonds represent one of the most visible innovations in sustainable finance over the past decade. Their growing market reflects the growing interest of the financial sector in climate risks. There is no universal definition of green bonds, although there is growing consensus as to what they are for The Green Bond is defined as a fixed-income financial instrument to raise capital to finance or refinance related green projects (OECD 2017; ICMA 2017). Green bond issuance surged from $ 1 billion in 2007 to $ 259 billion. In 2019, with cumulative output for all years (since inception in 2007) $ 754 billion (Almeida, 2020).

In the Russian Federation, the green bond market is in its infancy. The first bonds were issued in 2018, and as of July 2020, there were only five issues. In 2016-18, a number of steps were taken at the government level to create a market for green debt instruments: the creation of a regulatory framework; determination of the principles of information disclosure by issuers; development of a procedure for opening and approving green bonds; compiling a list of areas in which green bonds can operate; creation of a commission that marks bonds and controls the sending by the issuer of funds received for the implementation of the declared project.

The Moscow Exchange has become the center for the issuance and placement of Russian green bonds (except the Russian Railways issued green bonds on the Irish Exchange) (Annual Report, 2020). It supports the development of the concept of sustainable development in Russia and in April 2019 joined the global initiative Sustainable Stock Exchanges (SSE). In 2019, the Sustainable Development Sector was created at the Moscow Exchange to finance projects in the field of ecology, environmental protection, and socially significant initiatives (Tuteeva, 2020). Within the sector, there are five issues of green bonds with a total issue volume of 7.55 billion rubles and 500 million euros (Table 1). In 2020, the exchange plans to expand the range of structural and green bonds, including the appearance of social bonds in the Sustainable Development Sector.

Table 1: Green bonds of Russian issuers (issues March 2017 - July 2020)

Issuer	Industry	Volume of issue	Placement year	Placement
JSC "Commercial real estate FPK" Garant-Invest	Commercial real estate, green technologies	RUB 500 million	2017	Moscow Exchange
LLC “Resource-saving” KhMAO	Housing and communal services, waste management	RUB 1.1 billion	2018	Moscow Exchange
PJSC CB “Center-Invest”	Renewable energy sources, environmentally friendly transport	RUB 250 million	2019	Moscow Exchange
JSC "Russian Railways"	Railway transport infrastructure	EUR 500 million	2019	Irish Exchange
JSC “OFO Rusol 1” (organizer of the placement Sovcombank)	Green energy, solar power plants	RUB 4.7 billion, RUB 900 million, RUB 100 million	2019	Moscow Exchange

The main purpose of the modeling is: (i) to show the main interactions of the three main participants; (ii) trace the flow of information between the three main participants in the issuance and placement of green bonds; (iii) consider the behavior of the participants. Entropy transfer can measure the movement of information; a model-free measure that determines the amount of information transferred from the source time series to the target time series. It can successfully describe complex systems with nonlinear interactions. The strongest flows are in the sectors associated with climate bonds (for example, the stock markets). On the other hand, outside the exchanges, much weaker information flows are demonstrated. This is because exchanges generate a significant transmission of information about marginal events, which becomes much more important in the transferred entropy picture (Korbel et al, 2019).

There are at least three major market participants involved in the issuance of green bonds (Figure 1), including:

1) The issuer or developer of the project who creates a "green" project. In the project document, the issuer describes the expected positive impact of its project on the environment. To avoid overestimating or underestimating such impacts, the project is audited in terms of its impact on the environment and compliance with the greenness criteria,
2) A regulator. The role of the regulator is to conduct a quantitative and qualitative assessment of the project:
a. Use of proceeds: Before issuance, the legal document must state how the proceeds of the bond will be used.
b. A technical assessment of the specific risks and opportunities associated with the project, as well as the creditworthiness of the green bond issuer.
c. Monitoring, Reporting and Transparency Requirements: Several reports are regularly published to monitor both the project and the use of proceeds to ensure that proceeds from green bonds are distributed in accordance with the Green Bond Principles, and
3) Underwriter. Green bond underwriter provides capital to the issuer for a specified period at a fixed or variable interest rate.
The tripartite process of issuing green bonds can entail significant transaction costs - which is one of the barriers to the development of green bonds.

Figure 1: Three-agent-based model

The logic behind the three-agent model is as follows:

- The issuer (I) prepares an issue prospectus that meets certain criteria for "greenness", which is controlled by R.
- A project that meets these criteria goes to the Investor (U).
- The investor, by placing bonds on the stock exchange, mobilizes the necessary capital, and transfers it to the issuer.
- In turn, the issuer makes coupon payments and pays the capital base to the underwriter.

The regulator moderates the process - it affects both the issuer and the underwriter.
In the model, each agent has a certain set of properties. By simulating real-world phenomena, the behavior of each agent can be studied.
The three-agent model that studies the behavior of decentralized agents is based on three main ideas:
- The objective orientation of information objects from the point of view of their controllability;
- The emergence and learning ability of agents;
- Classification of solvable problems according to their complexity by reducing them to a set of simpler problems with efficient algorithms for solving.

It is assumed that the regulator mediates the interaction between the issuer and the investor. The search for a mechanism for the regulator's influence on the issuer and the investor can be reduced to discovering cause-and-effect relationships in a complex context (Anderson and Scott, 2012) or by opening a “black box” (Bathaee, 2018). By simulating the actions of agents, the effectiveness of the interactions is tested. For this, a number of hypotheses are put forward.

A hypothesis can be defined as a logically implied relationship between two or more variables, expressed in the form of a testable statement. Communication is offered using rigorous logical reasoning. These logical relationships can be part of the theoretical framework for research. Let's consider some of the hypotheses: 1) the issuer of the network is interested in the investment (variable); 2) the level of interest in investments is related to the level of their solution to environmental problems; 3) the level of solving environmental problems is related to the level of the investment effect; 4) if the effect decreases, then the demand for investment falls; 5) if the effect grows, then the demand for investment increases. These are verifiable proposals. Moreover, the first hypothesis contains only one variable. And this hypothesis is rather abstract. The second and third hypotheses have two variables that are related to each other, but the nature of their relationships is not determined (there is no directional relationship). In the fourth and fifth hypotheses, in addition to the relationship between the two variables, directions are set (in the fourth - negative, and the fifth - positive). Regulators can test these hypotheses: market (exchanges) and government (special commissions, as well as by checking compliance with ESG criteria).

The evaluation of the participation of the parties in a triangle can be carried out from the graph theory. Directional graphs can be used to model information flows of financial intermediaries with clients. For this, the links between the nodes are given the necessary orientation. In graph theory, the Tutte-Berge formula (Berge, 1962) characterizes the size of the maximum match in a graph. It can be

used to determine the smallest distance between the vertices. Usually, the formula is used when organizing traffic - finding the best routes (Bondy and Merty, 2010). However, it is quite suitable for understanding the processes that determine (i) the issuer's interest in investments, with appropriate environmental regulation, and (ii) the investors' interest in financing projects with their corresponding efficiency. Thus, issuers strive to maximize the effect. This principle follows from the laws of entropy of information. Like gas molecules, agents interact with each other. Collective interactions can influence individual behavior.

The three-agent model makes it possible to establish certain rules for the behavior of agents located in time and space and located in networks. Moreover, the behavior of agents can be "tied" to a certain time and place. This approach allows you to focus not on the stable state of the system, but on how the system and agents adapt to internal and external pressure to maintain their functionality, which is extremely important in the face of changing requirements for protecting the environment and people from climatic and pandemic threats.

Conclusions

There is a strong likelihood that changes in the behavior of people, companies, governments, and investors as a result of the pandemic will have a significant impact on the state of green finance. The article substantiates the position that the way out of the economic crisis caused by the pandemic will be based on ESG criteria, the main link of which will be green financing.

There is a fairly wide range of assessments of financial mechanisms for overcoming the crisis caused by the pandemic and directions for financing economic recovery (Rathi, 2020). However, the prevailing opinion is that the way out of the economic crisis caused by the pandemic will be based on a further increase in the importance of sustainable financing with the transition to new norms that take into account the real threat to humanity, in particular, from natural disasters, primarily related to climate change (Krurowska, 2020), possible pandemics and other natural disasters.

Green finance is designed to address the challenges of economic recovery in ways that help not only reduce the risks and vulnerabilities of the economy and society to unwanted external influences, but also reduce emissions that cause climate change and increase uncertainties, and mitigate the negative impact of future pandemics.

The three-agent-based model proposed by the authors makes it possible to analyze the behavior of agents in the process of green financing. By simulating the various participants in the green finance system, a mechanism is considered for adapting both the system and the agents to internal and external pressures to maintain their functionality and increase the productivity and efficiency of green finance.

Developing the Design Assumptions of Robotic Process Automation Maturity Model

Andrzej SOBCZAK

Warsaw School of Economics, Warsaw, Poland
sobczak@sgh.waw.pl

Abstract

As weight of robotic process automation (RPA) increases, enterprises that implemented this approach should periodically perform a review and assessment of solutions applied – organizational and technological ones – and business benefits obtained. It should be conducted in systematized manner and include multiple factors. In particular, it should cover degree to which approach applied is aligned with organization's strategic goals, how efficiently activities related to robotic process automation are performed on operational level (during software robot development and maintenance), or finally – what the personnel's skill level and knowledge of robotic process automation is. If areas where improvements to the approach are necessary are identified, required improvement measures should be defined and implemented. Maturity models concept can be used to ensure systematized, complete approach to the review and assessment of approach to robotic process automation. Objectives of this article include: (G1) presenting key concepts of maturity models, (G2) analyzing existing approaches of robotic process automation maturity model for organizations, and (G3) defining the design assumptions of the proprietary robotic process automation maturity model, taking into account the imperfections and shortcomings of the existing approaches in this respect.

Keywords: Maturity Model, Robotic Process Automation, RPA, Robotic Process Automation Maturity Model

Introduction

For several years now, companies all over the world have been implementing digital transformation projects involving the "use of new digital technologies (…), in order to enable major business improvements like enhancing customer experience, streamlining operations or creating new business models" (Fitzgerald and others, 2013). The digital technologies are the foundations of the transformation projects implemented. In accordance with analytics companies' estimates robotic process automation (RPA) tools are currently the fastest growing group of digital transformation technologies on the IT market. According to Gartner the sales of solutions and services in this area rose 63.1% in 2019, as compared to 2018, coming in at USD 1.3 billion (Gartner, 2019). According to Forrester's analysts the value of RPA licenses and services sold is to reach USD 2.9 billion by 2021 (Clair and others, 2017). While according to Fortune Business Insight analytics company, the value of the RPA market is to reach USD 6.8 billion by the end of 2026.

Enterprises that use robotic process automation should periodically, in a systematic manner, conduct reviews of their approach in this area and business benefits obtained. The reviews should cover, among others, the degree to which the approach applied is aligned with the organization's strategic goals (both in the business, as well as the IT domain), how efficiently activities related to robotic process automation are carried out on the operational level (both during software robot development, as well as during their maintenance), or finally, what the enterprise personnel's level of skills with respect to robotic process automation is. This will allow for identifying areas in which it is necessary to improve the approach applied and it will be the starting point for defining improvement measures.

Cite this Article as: Andrzej SOBCZAK " Developing the Design Assumptions of Robotic Process Automation Maturity Model" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The topics discussed in the article fall within the thematic scope of the theoretical considerations and empirical research conducted as part of several sub-disciplines of the management science (Bełez et al., 2019), in particular:

- Change management (sub-discipline: Strategic management) - robotic process automation is considered in the article as a specific type of an organizational change that should be managed appropriately;
- Organization's maturity (sub-discipline: Process and project management) - the article presents the characteristics of issues related to the robotic process automation maturity of an enterprise, which is one of the aspects of an organization's maturity;
- Management in the robotic process automation environment (sub-discipline: Production, services and technology management) – the management context in the robotic process automation environment is the main theme of the discussion presented in the article.

The goals of this article include: (G1) presenting key concepts of maturity models, (G2) analyzing existing approaches of robotic process automation maturity model for organizations, and (G3) defining the design assumptions of the proprietary robotic process automation maturity model, taking into account the imperfections and shortcomings of the existing approaches in this respect.

A diverse set of research tools was applied to achieve each of the paper's objectives. They included, accordingly: literature review, partly structured expert interviews and creative thinking techniques.

Based on the above presented objectives of the article the following structure of the paper was adopted. Section two presents two interpretations of the "robotic process automation" concept. Section three includes the key concepts of maturity models. Section four presents the existing robotic process automation maturity model for enterprises. Section five presents the set of the design assumptions of the proprietary robotic process automation maturity model. Section six presents the summary of the thus-far considerations and potential directions of further research are outlined – in particular related to the set of the proprietary model's design assumptions.

Robotic process automation and software robot concept

Currently the "robotic process automation" concept is viewed in two different ways in the subject matter literature – narrow and broad.

According to the narrow view, RPA is a class of information technology tools, a part of a broader group of information technology solutions used to robotically automate business processes (this group also includes BPMS – Business Process Management Systems, Workflows platforms, API (Application Programming Interface) management tools and also LowCode/NoCode tools[i]).

RPA class tools enable developing software robots, most often using graphical wizards or by recording actions performed by a human operator, definitely less often by directly writing a robot code. Researchers dealing with robotic process automation have identified a number of distinguishing features of software robots developed using RPA tools (Aguirre and Rodriguez, 2017), (Anagoste, 2018), (Asatiani and Penttinen, 2016), (Lacity and Willcocks, 2017), (Moffitt and others, 2018), (Stople and others, 2017), (Suri and others, 2017), (van der Aalst and others, 2018), (Willcocks and Lacity, 2016):

- they are used to automate selected sub-processes that make up the given process or even groups of actions logically extracted out of such a process, definitely less often to automate end-to-end processes;
- they are, first and foremost, used with respect to operational processes and business support processes, they are implemented less often in the direct customer service area (Chatbots, Voicebots or Taskbots are typically used in the latter case);
- they automate sub-processes or large scale (mass) operations (performed multiple times within the assumed time unit – e.g. within a month or a year), most often by faithfully reproducing actions carried out by an operator thus far;

- their use does not entail the need to optimize or reengineer the processes that are being robotically automated (although it is recommended);
- they operate based on the preset algorithm, but more and more often are enriched with certain elements of artificial intelligence, and, as a result, they are able to make more complex decisions (in particular, they are able to learn based on the data provided – both structured, as well as unstructured) (Lacity and Willcocks, 2018, 26);
- they perform operations directly on a graphical user interface of IT systems – the same way as a human-operator does it (although some RPA tools allow for performing operations directly on the robotically automated applications' database layer);
- they do not require creating of dedicated APIs (Application Programming Interface) to exchange data between applications;
- they use business logic that constitutes an integral part of the applications that a software robot will be working with, which eliminates the problem of reproducing such logic within the robot itself;
- they do not require a change to the code of the applications that a robot is interworking with, and therefore no knowledge of the internal structure of the individual applications is required, which is very important in case of legacy systems.

In the broader view of the concept, "robotic process automation" can be regarded as a particular type of an organizational and technological change the inherent part of which is the deployment of specific software (including cognitive software), ultimately leading to the formation of a hybrid workforce (Fersht and others, 2019), (Lacity and Willcocks, 2018), (Willcocks and others, 2020). Such a workforce is understood as a coherent ecosystem of software robots, as well as human resources with specific skills and competences, performing specific business processes and processing specific data.

The latter, broader understanding of the robotic process automation concept has been assumed for the purpose of this article. The adoption of such an understanding of robotic process automation leads to the viewing of actions related thereto not only from the technology point of view but also from the organizational and cultural perspective.

Such an approach positions robotic process automation not in the domain of tools to be used for ad-hoc organizational efficiency improvements, but among approaches that would allow for implementing digital innovations in an enterprise (Willcocks and others, 2020, 28).

Key Concepts of the Maturity Model

In the paper (Kohlegger and others, 2009) maturity model is defined as a model that "represents phases of increasing quantitative or qualitative capability changes of a maturing element in order to assess its advances with respect to defined focus areas. The focus area determines which indicators for maturity can be used to assess a maturing element". On the other hand, in the article (Becker and others, 2009, 213) it is indicated that "a maturity model consists of a sequence of maturity levels for a class of objects. It represents an anticipated, desired, or typical evolution path of these objects shaped as discrete stages. Typically, these objects are organizations or processes. The bottom stage stands for an initial state that can be, for instance, characterized by an organization having little capabilities in the domain under consideration. In contrast, the highest stage represents a conception of total maturity".

It is noteworthy – at least based on the number of existing maturity models – that they have won broad recognition both among representatives of academic community, as well as practitioners. Their use is supported by simplicity and ease of applying the concept, use of coherent terminology, ease of understanding the results obtained and ability to undertake specific actions based thereupon (Lasrado and others, 2015).
