- the mechanism is considered as an integral part of the incentive system influencing the objects. In this incentive system, the assessment practice is introduced; specific techniques and tools are used to reward researchers in accordance with their performance and rating;

- the techniques in the incentive system are: document submission, moderation, incentive payments, control, amendments to regulatory documents;

- the criteria of the performance assessment and bonus accruals are clear. Research scientists are aware of the achievement rewards and the way incentive pay is calculated;

- the tools include: a list of achievements, verification of the authenticity of supporting documents, reward in accordance with the rating, control of activities, a list of supporting documents, regulations for the provision of information, criteria for evaluating information and achievement monitoring.

The incentive system can be introduced in any type of organization.

To implement an incentive system, it is crucial to draw up a local normative act "Regulations on incentives for research scientists of the organization". It should include the following sections:

1. General Provisions

2. The general procedure for a staff incentive program in the organization

3. The procedure for supporting documents submission

4. The procedure for moderating the achievements

5. The procedure for calculating incentive payments

6. The procedure for appealing

7. The procedure for bonus accruals

8. The procedure for introduction of changes

The incentive system should be introduced in accordance with the "Regulations on incentives for research scientists of the organization". The regulations should include such sections as: the procedure for bonus accruals; the procedure for supporting documents submission; the procedure for moderating the achievements and others.

Each employee receives an incentive pay in accordance with their performance and rating.

According to the "Regulations on incentives for research scientists of the organization", the size of an incentive pay depends on the scientific achievements of the employees (Table 1).

Table 1: Performance indicators in the incentive plan

APPLICATION DEVELOPMENT					
Indicator for which incentive payments are accrued	Sum of points for scientific result				
	Categories of researchers				
	Associate Researcher	Research Fellow	Senior Researcher	Lead Researcher	Chief Researcher
1. For permanent employees and teams

1.3. Article in the peer-reviewed journal	0,15	0,2	0,25	0,3	0,35
1.4. Publication of a monograph (peer-reviewed, with ISBM assignment)	0,3	0,35	0,4	0,45	0,5
2. Grant Application					
up to 100,000 rubles.	0,1	0,15	0,2	0,25	0,3
up to 1,000,000 rubles	0,15	0,2	0,25	0,3	0,35
up to 10,000,000 rubles	0,2	0,25	0,3	0,35	0,4
more than 10,000,000 rubles	0,7	0,75	0,8	0,85	0,9
3. Educational activities					

Speeches at international conferences (foreign)	0,1	0,1	0,1	0,1	0,1
Speeches at international conferences (in Russia)	0,05	0,05	0,05	0,05	0,05

There are two basic indicators: publication activity (all types of research articles, grant proposals, educational activity) and applied developments (scientific ideas and developments permanent and temporary employees work on).

The system of performance assessment is based on the specifics of the research activity and goals set by the organization.

The size of incentive payments directly depends on the requirements and values of the organization and working efficiency and it may vary in accordance with the goals.

Based on the process approach to the implementation of an incentive system, the authors developed an algorithm for the formation of merit awards given to the research staff of the organization. It regulates the activities of a researcher, moderator and heads of departments. The diagram is shown in Figure 2.

Fig.2: Algorithm for the formation of incentive payments

The algorithm for the formation of incentive payments falls into 6 stages. In some cases, a procedure for appealing has to be performed.
In accordance with its financial capabilities each organization determines the maximum possible score.
The authors analyzed the rating system of a specific organization.
Company data:
- the total number of employees - 2,200 people;
- 880 researchers;
- salary fund of the company - 2.996.000.000 rubles;
- incentive payments - 40% of the salary fund;
- the maximum possible score - 10[1] per year (an average level of work intensity).

Let's make calculations:
1) the total amount of incentive payments per year:
(percentage of the salary fund minus mandatory deductions - 38%) 40% of (2.996.000.000 - 1.138.480.000) = 743.008.000 rubles;
2) the incentive payments per year for research workers:
743.008.000 / 2200 x 880 = 297.203.200 rubles;
3) if the maximum possible score is achieved (10 per year), the cost of one point:
297.203.200 / 880/12/10 ≈ 3000 rubles per month.

There are some recommendations on how to make an incentive system more effective and to increase working efficiency:
- incentive payments should be substantial;
- the employee performance should be objectively assessed;
- all the assessment criteria should be transparent, clear and verifiable;
- all employees should be promptly informed of the changes made;
- performance assessment should be carried out in accordance with the job description of the employees;
- it is necessary to constantly monitor the process of bonus accruals;
- disputable situations should be dealt with in accordance with the Regulations on incentives.

Conclusions

An incentive system is a collection of related elements and measures motivating employees. These elements and measures are linked together to achieve a specific goal.

The authors of the article justified the need to introduce an incentive system for research scientists and examined the elements of the system (subject, goal, objectives, principles, mechanism, object, techniques, and tools) and their interconnection.

The system includes subject-object relations, where the head of the organization, heads of structural divisions and moderators are the subject. In the system of material incentives research scientists are the object. The goal of the incentive system is to stimulate research scientists to work more efficiently, which will improve the profitability of the organization. The objectives are: to increase motivation, to develop creative initiative, to determine the maximum potential, to introduce differential assessment practice, to improve working efficiency and to monitor results. The basic principles of the incentive system are: fairness, equal opportunities, objectivity, flexibility, perceptibility, consistency, transparency and awareness. The mechanism is considered as an integral part of the incentive system influencing the objects. In the incentive system, the assessment practice is introduced; specific techniques and tools are used to reward researchers in accordance with their performance and rating. The techniques in the incentive system are: document submission, moderation, incentive payments, control, and amendments to regulatory documents. The tools include: a list of achievements, verification of the authenticity of supporting documents, reward in

[1] The rating of a chief researcher.

accordance with the rating, control of activities, a list of supporting documents, regulations for the provision of information, criteria for evaluating information and achievement monitoring.
The authors of the article gave a number of recommendations on how to make an incentive system more effective and to increase working efficiency:
- incentive payments should be substantial;
- the employee performance should be objectively assessed;
- all the assessment criteria should be transparent, clear and verifiable;
- all employees should be promptly informed of the changes made;
- performance assessment should be carried out in accordance with the job description of the employees;
- it is necessary to constantly monitor the process of bonus accruals.

Sustaining Economic Development:

A Post Amnesty Therapy on Peace-Building in the Niger Delta

Godwin EGBE, Frederick AHMADU, David IMHONOPI and Ikechukwu ANUKWU

Department of Sociology, Covenant University Ota, Nigeria.
Correspondents should be addressed to egbegodwin01@gmail.com

Abstract

The Niger Delta is the focal point of attraction in Nigeria because of crude oil, which forms a bulk of the country's export earnings. In spite of this, the inhabitants are faced with terrible conditions such as; polluted air and water, destruction of aquatic life, land infertility, unemployment, low life expectancy and lack of basic social amenities. These forced the youths into arms struggle. The Federal government instituted amnesty program for militants in the area, in which they were trained, paid stipends and rehabilitated. Unfortunately this was not sustained, as some corrupt politicians hijacked the process for their selfish interest. This paper focused on the challenges of Niger Delta people after the ex-agitators embraced amnesty and the return of crisis in the area. The paper employed the use of primary and secondary data, quantitative research method were used with simple random sampling techniques, 381 copies of questionnaire were administered to respondents in selected Oil producing communities in Rivers State Nigeria. The data obtained from the field were coded and run on SPSS software such that they were presented with the aid of frequency tables and research questions were answered based on this. Findings show that the Niger Delta is not getting better even with the efforts and structures put in place. The recommendations made includes; the need for synergy between transnational companies and host communities, implementation of corporate social responsibilities, increased employment and vocational training for youths, these will reduce social unrest and enhance the standard of living.

Keywords*:* Pollution, Militants, Oil Companies, Niger Delta

Introduction

The economy of countries around the world always thrive when there is an atmosphere of complete peace, notwithstanding the Nigerian State has witnessed different forms of sectional uprising that has affected her growth and development. Some of which were political, religious and ethnic motivated. The Niger Delta regions in Nigeria have been researched on by other scholars and academics, especially on key issues such as resource control, host community marginalization and exploitation. However a lot of research has not ventured into the area of amnesty programme offered to youths from the oil producing region.

According to the Nigerian Bureau of statistics (2016), Crude oil constitutes about 97% of the foreign exchange earnings of Nigeria and it is gotten from the Niger Delta. In line with this Okafor (2017), explained that despite, the high presence of transnational companies and crude oil production in the Niger Delta there are still traces of high level poverty, unemployment, high rate of infant and maternal mortality, lack of basic social amenities, air, land and water pollution.

Egharevba (2016) Poverty is a multidimensional problem embedded in a complex and interconnected political, economic, cultural and ecological system. In consonance with this, Osabohien et al. (2019) opined that social security is being offered Programs boosted productivity by 3 per cent for households. The authors inferred that the West African Governments should effectively provide social incentives such as healthcare and individuals' grants, as theses will reduce poverty and inequality for residents in rural areas.

Iruonagbe (2011), Opines that the situation in the Niger Delta region is a paradox, that is; huge and abundance existing side by side with perpetual poverty, slack and underdevelopment.

The increasing unrest and crisis in the Niger Delta area is as a result of over 5 decades of continuous oppression and marginalization. Several persons have fought towards the liberation of the region from the time of Isaac Adaka Boro, who declared the republic of Niger Delta on the 23rd of February 1966 and was subdued by the federal forces after 12 days. Kenule Beeson "Ken" Saro Wiwa an environmentalist was hung alongside other Ogoni activist on the 10th of November 1995 (Osadolor, 2011).

According to Tambari (2012), there have been numerous agitation for resource control and better revenue sharing formula for oil producing states, emanating from leaders of different "Militant groups" such as Asari, who was the head of Niger Delta people's volunteer force (NDPVF), Ateke, who was leader of the Niger Delta Vigilante (NDV), others include: Tompolo, Soboma, Ebipodei, Ndigbara, Tubotamuno, Togo, Ebikabowei and Okah with a host of other groups that have violently expressed their grievances against the ill treatment experienced in the region.

According to Chibuike (2011), the Federal Government of Nigeria upon the review of the crisis in the Niger Delta region provided the "Amnesty Programme" as a medium towards ensuring lasting peace and collective progress within oil producing communities and Niger Delta at large. The militants were given sixty days (from August 4th to October 4th 2009) to turn in their armed weapons and embrace peace so as to be trained in different vocations and universities both in Nigeria and abroad, the leaders of these groups were awarded pipeline surveillance contract to help secure oil facilities in the Niger Delta from being vandalized.

The programme was to ensure peace and reconciliation among the warring youths, the government and transnational companies working in the area, in order to enhance oil production and the eventual revenue increase that will be reinvested towards undertaking the plague of backwardness in the Niger Delta region.

The granting of amnesty to ex-militants initially reduced the series of violence and invariably enhanced oil production in the region. It helped to reduce attacks on pipelines and increased oil production from Seven hundred thousand (700,000) barrels daily within the space of 2007 and middle of 2009, to about 2.4 million and 2.6 million towards the end 2009, (Dudu, 2016).

Furthermore the Amnesty programme was accompanied by peace in the Niger Delta, this transcended into reduced vandalism of oil pipelines, reduction in hostage taking of foreign expatriates, increased human capital development for the ex-agitators, provision of employment opportunities and the development of infrastructural facilities within the region, (Agbonifo, 2009).

In line with this Badmus (2014), opined that the Amnesty program included a transformational setting engrossed with the acquisition of vocational skills that helped to change the ex-militants. The youths that were enrolled into the programme were trained within and outside the country boarders while a handful of others have already been trained. According to Joseph (2010), peace building is systematic procedure of forming frameworks that eliminates the root of wars in a country and proffer change to states that may be faced with the challenges of war. Therefore the need to build an instrument that supports the resolution of conflict that is strengthen and has capacity to withstand any opposing force without soliciting for support or bowing to external pressure. In line with this Peace-building is an act that expedites the formation of a robust atmosphere of peace with the aim of preventing the reoccurrence of chaos thereby tackling the origin and impact of violence by building a structure that embraces the interest of all parties involved.

International Organizations such as the United Nations (UN), European Union (EU), African Union (AU), North Atlantic Treaty Organization (NATO) and Economic Community of West African States (ECOWAS) are interested in building world peace across global and regional ties, they are anti any event that will be a threat to world peace especially wars, violence and crisis, Peace-building strategy is used to cement the foundation for the beginning of peace in a state that has been ransacked by war, countries like Rwanda used this strategy after the genocide of 1994, the Nigerian Government employed Peace-building after the Nigerian civil war that lasted for over 30 months (1967-1970), the process tries to unite the warring factions with the aim of building the collapsed societal structure (Obong, 2010).

No doubt amnesty is one of the programmes that have seen the break of light in Nigeria, because of the successes it recorded towards dousing the tensions in the Niger Delta region. This was clearly indicated with over eight hundred and thirty four (834) youths enrolled in about a hundred (100) higher institutions within and outside the country. In consonance with this, during the 2013 academic session, about four hundred and fifty nine (459) ex-agitators were on fully funded scholarships in some universities in Nigeria, while two thousand four hundred (2,400), were sent to

different training centres to acquire different vocational skills. This was necessary for their reintegration (Folami, 2014).

Ofili (2014), opined that structure of the amnesty programme was supposed to be a win-win for the Nigerian Government, the ex-agitators and the transnational companies in the Niger Delta. The ceasefire was to bring complete peace into the area and birth development of human capital and infrastructures but the major player which is the government did not consolidate on the gains of the amnesty programme towards Peace-building and ensuring sustainable development in the region, rather it was interested in increasing oil production and government revenue, which affected the entire process and the sword of violence struck again in the region.

Statement of the Problem

According to Fynas (2013), there is no community, people or state that appreciates vehemence and restiveness. The relative peace experienced by the oil producing communities in the Niger Delta was truncated when their cry over the continuous environmental pollution and marginalization fell on deaf ears. This pushed the youths back into violent struggle due to lack of basic social amenities and infrastructure which showcases a developed society like; good drinkable water, power supply, proper health and medical care, standard and solidified roads and employment opportunities are nonexistence within the region.

Although the Amnesty programme in the Niger Delta recorded a significant level of peace and development, however this was not sustainable, as the youths whom were trained and later reintegrated into the society were not given starter packages after the programme, their monthly stipends were not paid and they were not absorbed by the transnational companies operating in the area, (Ogannah, 2009).

The walls of peace witnessed in the Niger Delta collapsed drastically by the uprising of another militant group called the Niger Delta Avenger (NDA) in 2015, this was due to the fact that there was no proper plan to manage the welfare and wellbeing of the ex-agitators after they have completed their training programme, this affected the security architecture within the region, as their sole aim was to completely destroy all the pipe lines and other oil facilities within the region.

The post-amnesty era has proven to be another nasty phase that is plugged into enriching the elite system without any iota of development for majority of the masses domicile in the oil endowed vicinity. Notwithstanding, life threatening situations centred around alienation of people, poverty, corrupt practices, exploitation, huge unemployment, non empowerment of women and youths are still glaring and visible in enslaving the progress of the Niger Delta. The continuous crisis in the Niger Delta between the ex-agitators from the oil producing communities and the government as well as the Transnational Companies has affected all the parties involved, this is because, there is a slowdown in the operations of the Transnational Companies, this has further affected their level of productivity as well as income. The government revenue has dropped due to the unrest in the area and the oil producing communities are faced with continuous molestation by Federal Government who has resorted into constantly sending military troops to the area to combat the youths in order to restore peace to the entire region (Ogege, 2011).

Objectives of the Study and Research Questions

The study seeks to examine the extent to which amnesty Programme has engendered peace in the Niger Delta. It also seeks to assess whether the amnesty programme has led to sustainable economic development in the Niger Delta. It would also analyse the measures taken to ensure Peace-building in the Niger Delta.

On the basics of these objectives the research questions eminent to this study will be answered accordingly:

A. Has the amnesty programme stimulated peace in the Niger Delta?
B. Did the amnesty programme produce sustainable economic development?
C. What actions can be adopted to guarantee Peace-building in the Niger Delta?

Theoretical Framework

The followings theories will be used to further demonstrate its scientific underpinnings and relationship to the main point of the study, they are the: Relative Deprivation theory and Social Exchange theory.

Relative deprivation in retrospect can be traced to the ancient Greece, when prominent personalities like Aristotle enunciated the fact that sudden change in the societal order originates from unfairness and disparity among the people.
Sam Stouffer and some of his colleagues were the first to associate themselves with the tenets of the theory, especially in their work on "The American Soldier" in 1949. Subsequently W.G Runciman gave a formal appraisal of the theory in 1966; the theory was further linked to Criminology in 1980 by Stack John.

Relative deprivation theory is essential in the explanation of the dictates of this study, situating the theory to the study underpins the agitation in the Niger Delta. Which was born out of the quest towards ensuring the people have a good life. Irrespective of the vast resources present in their area; they have been deprived, marginalized and exploited such that they don't have access to the dividends of being an oil producing community. This has surfaced into unemployment, high rate of poverty and environmental decadence in the region, which can be explained as hunger in the midst of plenty.

Moreover there have been scholarships, contracts opportunities to members of oil producing communities, but to an extent this has been made available to the house holds of the elite in the region, such as political office holders and traditional rulers while the entire masses are perpetually neglected.

Notwithstanding this theory explains social ills within the Niger Delta, predicaments of oil producing communities but its assertions are one sided, that is it focuses on the economy of the people alone, but generally it fits into the study by explaining the situation in the region. The shortcomings of this theory made it possible for the use of Social Exchange theory to further explain the study.

The Social Exchange theory was brought to limelight by the work of George Homan, a well-known Sociologist in 1958, he focused on "Social behaviour as Exchange". Homan gave a broad view of social exchange as give-and-take relationship that exists within the confinement of a society and it's determined by the interaction between actors. Notable scholars like Richard Emerson and Peter Blau gave a scientific attestation to the theory within the social science field of Sociology. Exchange can take place between two or more persons, sometimes it serves as an avenue for settling conflict among people, nation and sets, by this it paves way for a win-win situation.

Homans (1958) made a summary of the social exchange theory into three basic schemes: success, stimulus, and deprivation–satiation.

i. Success: This occurs when an individual is rewarded for his action, he tends to reiterate same gesture.
ii. Stimulus: When an act leads to a reward, people are more likely to be engaged in such actions again.
iii. Deprivation-satiation: This occurs when a person has received a particular reward several times; the more diminishing an individual's interest will be towards such rewards.

This theory captures the amnesty deal that was entered by the Nigerian Government and the ex-agitators from the Niger Delta, there was an exchange which culminated into the armed youths laying down their weapons and embracing peace. Where they were trained in different vocations and programme. This was to ensure the end of hostilities, destruction of oil installations and pipe line vandalism, the government made huge proceeds from oil production due to the relative peace that was recorded. This reiterates the theoretical narrative of cost, resources and rewards, therefore accepting to shift grounds and end hostilities were a huge cost. The government willingness to forgo all the criminal acts committed by the ex-agitators and putting up a programme to train them was another cost. It involved resources; the reward was peace, increased oil production and good life for the youths. The oil producing communities in return benefited from this act, because normalcy and stability reappeared.

Research Design and Methodology

This study employed the use of exploratory and survey design; exploratory design was adopted because the study tends to unknot key issues in the post-amnesty era, in which less concern has been given while survey design was used because of geographical area of the study and the need to gather data from the location. The data produced in this study were gathered from a mixture of primary and secondary sources.

The sample size was determined with use W.G Cochran sample size formula, third edition (1977).

S = Z2 x P x (1- P) / M2
S = Sample Size for Infinite Population
Z = Z score
P = Population Proportion which is Fifty percent (50%) = 0.5
M = Margin of error is Five percent (5%) which is = 0.05
S = (Z score) 2 x P x (1- P) / (Margin of error) 2
S = (1.96)2 x 0.5 (1 – 0.5) / (0.05)2
S = 3.8416 x 0.25 / 0.0025
S = 384.16 (Sample size for infinite population)

The population of Bodo was 1109, Nonwa was 987, Okochiri was 863 and Onne was 1305.

1109 + 987 + 863 + 1305 =4266
Therefore, the total population in the study area was 4266
Taking 384.16 as sample size for infinite population
Adjusted Sample = (S)/1 + [(S - 1)/ Population
= 384.16/1 + [(384.16 – 1)/4266
= 384.16/1.008981
= 380.74, Approximately 381
Therefore the sample size for the study was 381.
The distribution showed that; 98 copies of questionnaire were administered in Bodo Community, 85 in Nonwa, 79 in Okochiri and 119 copies in Onne.

A total of 381 copies of questionnaire were administered to respondents in the study area; however 375 were collected and found suitable for the study.

Response rate = Number of received questionnaire/ Number of Administered x 100
= 375/381 x 100
= 98.4 %
Therefore the response rate for the study was 98.4%

A pre-test was adopted to show the level of reliability of the research instruments before it was administered to respondents on the field, a total of 40 copies of questionnaire were issued at 4 selected oil-producing communities across four Local Government Areas in Rivers state. The confirmation of this was done with the aid of cronbach' alpha which indicated 89% level of reliability based on the yielded coefficient of 0.89. The questionnaire was designed in a likert scale and the variables were all divided into different segments that generated the required responses to the research questions of the study. Judicious and systematic processes were employed to scrutinize the validity of data collection instruments, the questionnaire was examined along-side the key informant interview questions and focus group discussion guide with the aim of ensuring that the qualitative data instruments corroborates with that of the quantitative.

The data were obtained, through issuing copies of questionnaire to respondents in which they provided demographic details of themselves and answered the various sections of questions that were draw from the research questions of this study.

Results

The data obtained were analyzed in frequencies and percentages, through the Statistical Package for Social Sciences (SPSS). 381 Copies of questionnaire were administered, 375 copies were accepted while 6 copies of the questionnaire were rejected.

Respondents' awareness of reduction in pipeline vandalism was the first inquiry of the questionnaire. Table 1 below shows the results obtained through the questionnaire.

Table 1: The socio-demographic characteristics of respondents:

	Frequency	Percentage
Sex of Respondents		
Male	263	70.1
Female	112	29.9
Total	375	100
Age of Respondents	**Frequency**	**Percentage**
16-25	211	56.3
26-35	77	20.5
36-45	48	12.8
46-55	39	10.4
Total	375	100
Marital Status of Respondents	**Frequency**	**Percentage**
Single	200	53.3
Married	88	23.5
Divorced	30	8.0
Widowed	24	6.4
Separated	33	8.8
Total	375	100
Respondents' Religion	**Frequency**	**Percentage**
Christianity	225	60

Distribution According to Sex

This table shows the distribution of respondents according to their sex. It is evident that 70.1% of the respondents were males while 29.9% of the respondents were females, this means that majority of the youths that are involved in several agitations in the oil-producing communities in the Niger Delta were majorly males, although there might be some females involved but their numbers were usually few compared to the male counterparts.

Distribution According to Age

This shows that 56.3% of the respondents were within the age range of 16-25, while 20.5% of the respondents were within the age range of 26-35, 12.8% of the respondents were within the age of 36-45 and 10.4% were within the age range of 46-55 years.

Distribution According to Marital Status

This indicates that 53.3% of the respondents were single, 23.5% were married, 8% of the respondents were divorced, 6.4% were widowed and 8.8% of the respondents were separated.

Distribution According to Number of Children

The number of children of the respondents represented in the table explains that 57.1% of the respondents have 0-3 children, 19.5% have 4-6 children, 16.5% of the respondents have 7-10 children and 6.9% of the respondents have 11 and above number of children.

Distribution According to Religion

The distribution of respondents' religion was illustrated in the table, it shows that 60% of the respondents were Christians, 19.2% of the respondents were Muslims, 13.9% respondents practiced African Traditional Religion while 6.9% of the respondents settled for other religion.

Distribution According to Education

The result reveals that 13.3% of the respondents had non-formal education, 23.7% of the respondents had primary education, 53.3% of the respondents had secondary education and 9.6% of the respondents had graduated from tertiary institutions. This shows that the level of education in the Niger Delta is relatively low, based on the data obtained from the field.

Distribution According to Occupation

This indicates that 9.6% of the respondents were into business, 10.9% of the respondents were civil servants, 16.8% of the respondents were factory workers, 42.9% were farmers, while 19.7% of the respondents were unemployed. This means that majority of the respondents in the study area were farmers and the rate of unemployment was high.

Distribution According to State of Origin

This shows that 35.7% of the respondents were from Rivers state, 9.9% of the respondents were indigenes of Bayelsa state, 20.3% of the respondents were from AkwaIbom, 9.6% were from Cross-Rivers, 7.2% were from Abia, 3.5% were from Imo, 3.5% of the respondents were from Delta, while 6.9% were from Edo and 3.5% were from Ondo state.

Table 2: Reduction in pipeline vandalism

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Strongly Agree	17	4.5	4.5	4.5
	Agree	23	6.1	6.1	10.7
	Disagree	232	61.9	61.9	72.5
	Strongly Disagree	103	27.5	27.5	100.0
	Total	375	100.0	100.0	

This shows that 4.5% of the respondents strongly agreed that pipeline vandalism has reduced in their community, 6.1% of the respondents agreed, 61.9% disagreed while 27.5% of the respondents strongly disagreed that the level of pipeline vandalism in their community has reduced.

Table 3: Decreased rate of kidnapping

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Strongly Agree	19	5.1	5.1	5.1
	Agree	52	13.9	13.9	18.9
	Disagree	196	52.3	52.3	71.2
	Strongly Disagree	108	28.8	28.8	100.0
	Total	375	100.0	100.0	

This reveals that 5.1% of the respondents strongly agreed that the rate of kidnapping in their community has reduced, 13.9% of the respondents agreed, 52.3% of the respondents disagreed while 28.8% of the respondents strongly disagreed. This means that kidnapping has not reduced in the oil producing communities; moreover it is on the increase.

Table 4: Reduced activities of cultists

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Strongly Agree	32	8.5	8.5	8.5
	Agree	53	14.1	14.1	22.7
	Disagree	228	60.8	60.8	83.5
	Strongly Disagree	62	16.5	16.5	100.0
	Total	375	100.0	100.0	

The result shows that 8.5% of the respondents strongly agreed that the activities of cultists has reduced in their community since the amnesty programme was conducted, 14.1% agreed while 60.8% of the respondents disagreed and 16.5% of the respondents strongly disagreed. This illustrates that the activities of cultists in oil producing communities in the Niger Delta has not decreased.

Table 5: Youth Empowerment

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Strongly Agree	18	4.8	4.8	4.8
	Agree	24	6.4	6.4	11.2
	Disagree	209	55.7	55.7	66.9
	Strongly Disagree	124	33.1	33.1	100.0
	Total	375	100.0	100.0	

This illustrates the distribution of respondents based on youth empowerment, 4.8% of the respondents strongly agreed that there have been youth empowerment programmes in their community, 6.4% of the respondents agreed, 55.7% of the respondents disagreed that the youths in their community have been empowered and 33.1% strongly disagreed that there have not been any form of youth empowerment in their community.

Table 6: Reduced Unemployment among youths

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Strongly Agree	25	6.7	6.7	6.7
	Agree	17	4.5	4.5	11.2
	Disagree	214	57.1	57.1	68.3
	Strongly Disagree	119	31.7	31.7	100.0
	Total	375	100.0	100.0	

This shows that 6.7% of the respondents strongly agreed that unemployment has reduced among youths in their community, 4.5% agreed, 57.1% disagreed and 31.7% of the respondents strongly disagreed. This means that youth unemployment in the area is on the increase, since the amnesty programme was conducted.

Table 7: Level of poverty

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Strongly Agree	13	3.5	3.5	3.5
	Agree	24	6.4	6.4	9.9
	Disagree	191	50.9	50.9	60.8
	Strongly Disagree	147	39.2	39.2	100.0
	Total	375	100.0	100.0	

This illustrates that 3.5% of the respondents strongly agreed that there is low level of poverty in their community, 6.4% agreed, 50.9% disagreed, while 39.2% strongly disagreed. This means that poverty is much pronounced in the oil producing communities in the Niger Delta.

Table 8: Youth training and education

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Strongly Agree	20	5.3	5.3	5.3
	Agree	34	9.1	9.1	14.4
	Disagree	225	60.0	60.0	74.4
	Strongly Disagree	96	25.6	25.6	100.0
	Total	375	100.0	100.0	

This reveals that 5.3% of the respondents strongly agreed that some youths have been trained in different vocations while others have been offered scholarships to study in reputable Nigerian Universities and abroad. While 9.1% agreed, 60% disagreed and 25.6% strongly disagreed. This indicates that although the amnesty programme led to the training of some youths but a bulk of the youths in the Niger Delta; who were ex-agitators were not trained.

Table 9: Social amenities in oil producing communities

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Strongly Agree	29	7.7	7.7	7.7
	Agree	21	5.6	5.6	13.3
	Disagree	264	70.4	70.4	83.7
	Strongly Disagree	61	16.3	16.3	100.0
	Total	375	100.0	100.0	

The distribution of respondents according to the presence of social amenities in oil producing communities reveals that while 7.7% strongly agreed, 5.6% agreed, 70.4% disagreed and 16.3% strongly disagreed. This means that there are less social amenities in the oil producing communities.

Table 10: Increased living condition of oil producing communities after the amnesty programme

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Strongly Agree	14	3.7	3.7	3.7
	Agree	31	8.3	8.3	12.0
	Disagree	209	55.7	55.7	67.7
	Strongly Disagree	121	32.3	32.3	100.0
	Total	375	100.0	100.0	

This shows that 3.7% of the respondents strongly agreed that there have been increase in the living condition of oil producing communities after the amnesty programme, 8.3% agreed, 55.7% disagreed, 32.3% strongly disagreed.

Table 11: The Development of Human Capital among youths

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Strongly Agree	31	8.3	8.3	8.3
	Agree	44	11.7	11.7	20.0
	Disagree	219	58.4	58.4	78.4
	Strongly Disagree	81	21.6	21.6	100.0
	Total	375	100.0	100.0	

This shows a visual representation of the respondents' view in relation to the development of human capital among youths, while 8.3% strongly agreed, 11.7% agreed, 58.4% disagreed and 21.6% strongly disagreed. This means that there was no development of human capital among youths from the oil producing communities after the amnesty programme was conducted.

Table 12: Actions taken to secure the future generation of oil producing communities

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Strongly Agree	33	8.8	8.8	8.8
	Agree	46	12.3	12.3	21.1
	Disagree	180	48.0	48.0	69.1
	Strongly Disagree	116	30.9	30.9	100.0
	Total	375	100.0	100.0	

This shows that 8.8% of the respondents strongly agreed that there have been actions taken to secure the future generation of oil producing communities, 12.3% agreed, 48% disagreed, while 30.9% of the respondents strongly

disagreed. This reveals that no actions were taken to secure the future of oil producing communities in the Niger Delta

Table 13: Clean up of oil spillage site in oil producing communities

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Strongly Agree	13	3.5	3.5	3.5
	Agree	13	3.5	3.5	6.9
	Disagree	249	66.4	66.4	73.3
	Strongly Disagree	100	26.7	26.7	100.0
	Total	375	100.0	100.0	

The chromatic representation of the respondents based on the clean up of oil spillage site in the oil producing communities, 3.5% of the respondents strongly agreed that there have been clean up of the oil spillage site, 3.5% agreed, 66.4% disagreed and 26.7% strongly disagreed.

Table 14: The collaboration of Government and Transnational Companies to resolve crisis in oil producing communities

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Strongly Agree	20	5.3	5.3	5.3
	Agree	17	4.5	4.5	9.9
	Disagree	234	62.4	62.4	72.3
	Strongly Disagree	104	27.7	27.7	100.0
	Total	375	100.0	100.0	

The result shows that 5.3% of the respondents strongly agreed that the government collaborates with transnational companies to resolve crisis in oil producing communities, 4.5% agreed, while 62.4% disagreed, 27.7% strongly disagreed. This reveals that the government does not collaborate with transnational companies on crisis resolution in the Niger Delta.

Discussion of Findings

This section gave a holistic explanation of the research questions of this study alongside important issues identified from literature.

RESEARCH QUESTION 1: Has the amnesty programme stimulated peace in the Niger Delta?

This research question was clearly explained by the survey carried out on the field, which indicated comparatively the positions of respondents in table 2, 3 and 4. It was discovered in the study that the amnesty programme to an extent brought about peace but this peace was truncated midway into the programme. Because activities of cultist, kidnapping and pipe line vandalism has been on the increase even after amnesty was given to ex-agitators from the Niger Delta. This indicated that the level of peace in the Niger Delta region has nose-dived due to the mismanagement of the amnesty programme. It was also discovered in the study that the political gladiators from the Niger Delta region hijacked the process, the pipeline surveillance contract that was given to the different militant leaders was cancelled by the President Muhammadu Buhari's administration which triggered another fierce form of unrest in the Niger Delta Region.

RESEARCH QUESTION 2: Did the amnesty programme produce sustainable economic development?

Responses to this question are shown in table 5, 6, 7 and 8 respectively, the respondents explained that the amnesty programme has not birthed sustainable economic development, as poverty is on the increase in the region in spite

of the rich natural endowment it possesses. The ex-agitators who were trained during the amnesty programme where abandoned in the process of the training, some were stranded overseas. The amnesty programme did not contribute to the empowerment of the youths in the oil producing communities, as the programme was ill funded and abandoned by the government. The stipends that the youths were paid was also suspended. It was also discovered from the study that unemployment has been on the increase in the Niger Delta region, some of the youths that were sponsored abroad for their education were not absorbed by the transnational companies operating in the region.

RESEARCH QUESTION 3: What actions can be adopted to guarantee Peace-Building in the Niger Delta?

Tables 9, 10, 11, 12, 13 and 14 gave a detailed explanation to this question in the study. It was discovered that for adequate peace to be restored in the oil producing Communities in the Niger Delta there is an urgent need for Social amenities as the area is faced with infrastructural decay, there is also a need to improve the living condition of the people. It was discovered that, areas which have been affected by oil spillage requires clean up, because the environmental pollution in the Niger Delta region is severe. The study also explained that the collaboration between the government and transnational companies towards changing the narrative in the oil producing communities in the Niger Delta is non-existence. Therefore, the study identified that if viable efforts are put in place by these actors positively there will be records of traceable peace in the Niger Delta region.

Conclusion

The Niger Delta people experience the highest form of exploitation and marginalization not because they are a minority ethnic nationality in Nigeria, but as a result of the selfish and self-centred nature of Nigerian political leaders who have turned the region into a poisonous zone filled with high level of environmental pollution and degradation, such as air pollution, water pollution (surface and underground), the lands are destroyed due to oil spillage, life expectancy is very low as a result of the inhalation of toxic gas emitted by the transnational companies operating in the area. Furthermore corporate social responsibilities such as the provision of basic social amenities are totally absent living the people to witness high rate of poverty, unemployment and high level of illiteracy, the youth felt the only language the government understands is violence and decided to take up arms and fight the government and the transnational oil companies which led to the government granting them amnesty that was seen as a breath of fresh air in the region that will lead to relative peace. However this acclaimed peace did not last long as it was truncated by selfish politicians and government officials who hijacked the amnesty programme and turned it to their own personal source of income, the youths where no longer paid stipends, those who were trained overseas returned frustrated without having any job, the pipeline surveillance contract given to ex agitators were withdrawn, this forced the youths to go back to their former ways of arm struggle but this time very fierce in nature, with the main aim of crippling the Nigerian economy and the destruction of oil installation facilities.

More so this paper sees economic development as an avenue through which sustainable peace can be built and normalcy restored to the Niger Delta people, because when the living condition of the people have been enhanced, there by leading to the reduction of poverty and unemployment with a proper reassurance of a secured future, the warring youths will desist from their acts.

Recommendations

These following recommendations have been identified as the strength that this paper projects for the sustenance of peace and development in the Niger Delta:

1. The people of Niger Delta should be given good life; that is they should be able to enjoy the dividends of being an oil producing area especially when the entire Nigerian economy is built on the resource from the region.
2. There should be proper consultation to foster peace between the militant youths, elders, traditional rulers of oil producing communities and the transnational companies.
3. The transnational companies operating in the area should have development plans that will touch the lives of the people directly through corporate social responsibilities such as the provision of basic social amenities, good roads, scholarships, employments and skill acquisition programme.
4. The government and transnational oil companies should not sponsor factional leadership in the oil producing communities; this will reduce the level of tension and social unrest in the area.

5. The government should avoid the use of combatants to attack the militants in the area, with the sole aim of subduing them, this will only result in more casualties rather a better pragmatic approach of mediation should be used.
6. The government should regulate the activities of the transnational companies such that issues like gas flaring, pollution should be taken care of and where there is possibly an oil spillage a clean should be done to avoid environmental degradation and health hazards on the residents and people of the Niger Delta.

Analysis of The Influence Factors of Mergers and Acquisitions

Irina CHIRIAC

"Alexandru Ioan Cuza" University, Institute of Interdisciplinary Research,
Social Sciences and Humanities Research Department, Iasi, Romania
irinaochiriac@yahoo.com

Abstract

Many successful businesses face a certain amount of time in their history with a decrease in performance. Increasing competition due to globalization or technological progress, high capital costs and other factors are leading more and more companies to go through difficult times. The analysis of the difficulties faced by companies as well as the means of preventing and overcoming the difficult situation is very important due to the economic consequences of the deterioration of the performance. This chain reaction can cause disruption to an industry or the economy. The aim of the paper is the analysis of the way in which economic factors influence the evolution of mergers at European union level. The analysis performed for the period of 2015-2019 has underlined that the distribution and the evolution of mergers is influenced by the following macroeconomic factors: economic growth, the stock market index, the opening degree of economy, the reference interest of the central bank and inflation. In order to test if the macroeconomic factors influence the number of mergers, the multiple regression, with the help of the statistical software SPSS 20, was used.

Keywords: M&A, economic growth, the stock market index, the opening degree of economy, the reference interest of the central bank, inflation.

Introduction

Mergers are a big and very important part of the corporate finance world. Every day there are M&A operations arranged which bring different companies together to form larger ones. consists of two groups – cross-border merger and acquisitions and domestic merger and acquisitions.

Three main reasons for firms to undergo an M&A process: synergies, diversification and the benefits from imperfect capital markets across countries. Historically, domestic mergers has always dominated the whole M&A activities due to language and culture barriers, government interventions, legal restrictions. However, as the global economy is becoming more connected and integrated, cross-border mergers are increasing in importance. Authors Martynova and Renneborg (2008) investigated the macroeconomic determinants of CM&A using a worldwide sample deals. Mentioning researchers claimed that most of the growth in foreign direct investment over the past two decades has been made via cross-border mergers. Current research on investigating M&A activities mainly focuses on developed countries at microeconomic level.

Other authors as Broaddus, Mueller and Burkhard (1998) mentioned in their research that scientific studies on macroeconomic determinants of mergers operations is relatively scarce, and with a focus on developing countries is even scarcer. The economic, political and social context can influence the evolution of the number of mergers. In the following we will analyze the impact of the macroeconomic factors on the mergers.

More specifically, we will study the link between distribution and the evolution of mergers and a number of macroeconomic factors, among which we note: economic growth, the stock market index, the degree of openness of the economy, the central bank's reference interest and inflation, and the ultimate goal is to identify through a statistical regression model which factor has the greatest influence on the number of companies that have merged. General hypothesis is: The evolution of the number of mergers is influenced by the macroeconomic factors.

Literature review and Hypothesis Development

Despite the large number of studies investigating the activities of M & A, most focus on microeconomic developed country markets. This study is also relevant in that it investigates the impact of macroeconomic factors on M&A volumes on a sample of European data from 2015-2019.

The need to analyze the connection between the evolution of mergers and acquisitions and macroeconomic factors.

Although numerous studies have had different results in relation to the influence of macroeconomic factors on the activity of mergers and acquisitions, the topic has remained attractive due to a peculiar feature of the merger activity, namely that mergers take place in waves (Shleife, Vishny, 2003).

One of the more noticeable limitations in these studies is that the data sets are outdated, especially lacking financial information from after the financial crisis of 2007 –2008. Based on this gap in existing studies, I plan, in my paper, to update the dataset with more recent figures while focusing on five specific macroeconomic factors, namely GDP, the stock market index, the opening degree of economy, the reference interest of the central bank and inflation.

Substantiation of Hypotheses

Starting from the aim of our research, we considered the following hypotheses:

Hypothesis 1 (H1).

There exists a considerable link between the number of M&As and GDP growth.

The authors Hyytinen and Pajarinen (2002) used to analyze the influence of the macroeconomic factors on the activity of mergers, the following variables: the economic growth and the reference rate of the central bank. An index of high economic growth shows that in a developed economy, there are more companies and more mergers. Companies are more willing to get involvedin Merger and Acquisition deals when the economy is booming, and less willing to get involved inthose deals when the economy is depressed, according to Xiaoxuan (2016). Most research focuses on how M&A business affects companies and consumers. There is more research on how GDP will trigger mergers and acquisitions. Kummer (2006) studied M&A transactions in the South American pharmaceutical industry and found that "the number of M&A transactions is correlated with the development and size of an economy measured in terms of GDP". Doytch, Cakan, Upadhyaya (2011) studied M&A sales in different sectors and how those transactions in different sectors affect the growth of the economy. Their study showed that cross-border M&A slows down the domestic economy (Doytch, Cakan, Upadhyaya, 2011). Moreover, Doytch (2012) studied the correlation of M&A supply and economic growth in OECD countries, found that the M&A services sector has a positive effect on service growth. As we can see from the literature review, even if there is some research on the relationship between M&A supply and economic growth, there is little research that uses the total real value of M&A transactions in Europe in relation to GDP.

Hypothesis 2 (H1).

There is a direct link between the stock index and mergers.

Merger waves appear in times of economic boom when, there is a rapid growth of the economy and thus the stock index increases (Mueller, Burkhard, 1998). These can affect mergers and acquisitions for at least two reasons: first, an increased stock index helps companies finance their acquisitions. In this case, the acquiring company does not have to invest the profit or increase the debts to finance the acquisition. Another reason is related to liquidity. So these factors increase the purchasing power of a company (Hyytinen, Pajarinen, 2002). The waves of mergers coincide with changes in the economic and technological environment. The most important force that led to the consolidation of banks in 1990 was the development of communications and data processing technology. The cost saved by using new technologies has increased with the growth of the company Broaddus, 1998). Nelson investigated the link between the stock index, field of activity and the number of mergers (Martynova, M., Renneborg, 2008). By using simple regression, they established that there is a positive and significant link between the analyzed variables. Nelson failed to establish a link between the field of activity of the companies involved and their merger activity. Authors Clarke and Ioannidis (1996) investigated the link between mergers and the stock market index. For this they considered both the number of mergers and their value. Clarke and Ioannidis used Granger's analysis mergers in the UK. The result of the study was that the stock market index influences both the

value and the number of mergers. The same results were obtained by researchers Sharma, Mathur and Cernat-Gruci (1989). Other studies have led to different results from those mentioned above. Thus, Geroski (1984) did not find a significant link between the merger activity and the macroeconomic factors. Author Guerard (1989) concludes that there is no connection between the field of activity and the activity of mergers in the United States.

Hypothesis 3 (H1).

The central bank's interest rate influences the mergers activity.

The relationship between interest rates and M & As is a widely researched topic. Researcher Marsh (1982) finds a significant and negative effect on interest rates and the evolution of mergers: firms borrow less when the interest rate is high and then prefer to merge. In addition, Taggart (1977) also finds a significant effect of the interest rate on mergers. The bottom line is that firms are more likely to issue equity when their share prices are high and to resort to borrowing (which makes a heavily financed investment) when interest rates are low. However, unlike Marsh (1982) and Taggart (1977), the authors Choe, Masulis and Nanda (1992) find no evidence that the interest rate effect is significant for M&A.

Hypothesis 4 (H1).

Between mergers and degree of openness of the economy it is a strong link.

The degree of openness of the economy is an indicator that reflects the degree of competitiveness of a country. The main weaknesses of the domestic economy that determine a low degree of competitiveness are: the precarious state of the public health system, government instability, crime, problems faced by the internal labor market (poor ethics, inadequate education, rigidity), inflation, corruption, fiscal instability, government bureaucracy and lack of infrastructure. The degree of openness is measured by the sum of exports and imports to the country's GDP. This variable is often used as a proxy to country's trade restrictions. he size of the economy, the degree of openness and the governance level are, in most cases, positively correlated with all series of inward and outward investment.

The research hypothesis predicts that countries with higher levels of openness tend to attract more foreign investment due to reduced trading costs. A high degree of openness encourages mergers and acquisitions, according to Culem (1988), Janicki and Wunnava (2004). Some studies, namely those conducted by Aminian and Campart (2005) and Kamaly (2007), also refer to the importance of this variable in explaining international M&A activity. Kyrkilis and Pantelis (2003) refer to the fact that the liberalization of international economic trade in a country is expected to positively influence the outflows of all kinds of investments. First, the absence of capital controls allows for unrestricted financing of investments abroad. Second, an export-oriented economy allows firms to acquire relevant information about foreign markets (knowledge, skills in organizing foreign operations and marketing their products internationally). Finally, companies can choose to combat competition from imports by involving them in the domestic markets of importing companies, and a certain form of retaliation is M&A.

Hypothesis 5 (H1).

The inflation rate influences the activity of mergers operations.

Inflation rate is considered one of the most important macroeconomic factors that affects investors decision when making an investment. A few existing research have done study in investigating the relationship between inflation and M&A operations.

Boateng, Hua, Uddin and Du (2014) found a negative relationship between inflation rate and the volume of M&A for UK firms during the period 1990 to 2008. The size of the coefficient shows that M&A will decrease by 1.47% if Inflation rate increases by one unit. However, the result is not statistically significant. Furthermore, the author Black (2000) investigated the M&A activities on American company in mergers and acquisitions deal between 1985 and 1999. The result suggests that inflation rate is negatively related with the growth of M&A transactions.

Materials and Methods

In order to reach the objectives formulated on the thematic approach, the study is based on a research approach and methodology, which is used to obtain information meant to elucidate the questions addressed in the research.

In the research activity, the constructivist paradigm will be used by formulating hypotheses or own opinions and validating them through interpretative demonstrations, using scientific validations.
In view of our scientific approach, I resorted to establishing the following hypotheses: General hypothesis: The evolution of the number of mergers is influenced by the macroeconomic factors.

The data source is the database of the Vienna Mergers and Acquisitions Institute and the European Commission database. Information collected are: number of mergers, economic growth index, stock market index, interest rate, degree of openness of the economy, inflation. Period analyzed is 2015 - 2019.

Analysis tools and procedures: data collection by observation method, statistical analysis using multiple regression procedure, SPSS 20.0 program and Pearson correlation indices.

The nature and characteristics of the variables used in the model are summarized in Table 1.

Table 1: The variables used in the econometric model

Variable	Abbreviation	Description
Dependent variables		
Mergers and acquisitions number rate	M&An	(M&An i,t – M&An i, t-1)/ M&An i, t-1
Independent variables		
Gross domestic product rate	GDP	(GDP i,t – GDPi, t-1)/ GDP i, t-1
Inflation consumer production index	I	(I i,t – I i, t-1)/ I i, t-1
Degree of openness of the economy	G	G = $\frac{Import+Export}{GDP}$ (G i,t – G i, t-1)/ G i, t-1
Interest rate	D	(D i,t – D i, t-1)/ D i, t-1
Stock market index	SMI	(SMI i,t – SMI i, t-1)/SM I i, t-1

The equation of the regression model is

$$\mathbf{N = \alpha + \beta^{1} * GDP + \beta^{2} * SMI + \beta^{3} * G + \beta^{4} * D + \beta^{5} * I + \xi}$$

Results

From table 2 it is observed that between the dependent variable - the number of mergers - and the independent variable - the reference interest - there is a strong direct link, the value of the correlation coefficient is equal to + 0.849, with a value Sig. less than 0.05.

Table 2: Correlations

N	GDP (0.0084)	SMI(0.0393)	G(0.0293)	D(0.008)	I(0.0460)	
1.000	0.104	0.584	0.127	0.849	-0.047	
0.104	1.000	0.444	0.023	0.537	0.435	
0.584	0.444	1.000	-0.500	0.621	-0.471	
0.127	0.023	-0.5000	1.000	0.227	0.825	
0.849	0.537	0.621	0.227	1.000	0.266	
-0.047	0.435	-0.471	0.825	0.266	1.000	

It is observed that 95% of the variation in the number of mergers can be explained by the influence of the independent variables in accordance to table 3. The difference is taken into account by other conjunctural factors.

Table 3: Model Summary

Equation	R	RSquare	Adjusted R square	Std. error
$N = \alpha + \beta^1 * GDP + \beta^2 * SMI + \beta^3 * G + \beta^4 * D + \beta^5 * I + \xi$	*0.958*	*0.918*	*0.505*	*2903*

From table 4 it stands out the equation of the regression model, according to the resulting data, is as follows:

N = 30222.896 + 418.584 * GDP - 1,640 * SMI– 0,000 * G + 5398.247 *D – 6611.128* I

Thus the regression coefficients are α = 30222.896; β_1 = + 418.584; β_2 = - 1,640; β_3 = - 0,000; β_4 = + 5398.247; β_5 = – 6611.128.

The model reflects the influence of economic growth (GDP), the stock market index, the degree of openness of the economy, the central bank's reference interest, inflation, on the number of mergers at European level.

Table 4: Regression coefficients

Variables	B	Std.error	Sig.	Tolerance	VIF
Constant	*30222.896*	*1924.68*	-	-	-
Gdp	*418.584*	*91.36*	*0.413*	*0.002*	*405.445*
Smi	*-1.640*	*14.639*	*0.084*	*0.001*	*772.599*
G	*0.000*	*0.001*	*0.393*	*0.008*	*130.630*
D	*5398.247*	*134.64*	*0.008*	*0.006*	*174.568*
I	*-6611.128*	*48329*	*0.460*	*0.001*	*11.96*

The results provided by the model can be interpreted as follows: If we keep constant: GDP, the stock market index, the degree of openness of the economy, inflation, a percentage increase of the reference interest rate leads to an increase in the number of mergers with 5,398 transactions.

Conclusions

The merger operation is directly influenced by the lack of liquidity and the credit constraint, which occur as a result of the economic crisis.

As the Gross Domestic Product is an indicator of measuring the well-being and quality of life, we can appreciate that a high value of the Gross Domestic Product per capita reveals a good result of the activity of the national economy, being reflected in a high standard of living of population.

A decrease in the reference interest determines a general decrease in the interest rate applied by commercial banks, increases the efficiency of the use of loans for companies and guides them towards developing their activity based on the commitment of additional capital. Increasing the interest rate makes it difficult to provide the capital needed to expand the business of a company.

It is known that the role of scholarships is that of financing. Thus, by listing on a stock exchange a company can finance from shareholders, this being an alternative to bank loans. The stock market is a barometer of the economy, anticipates economic developments. Used for comparisons over time, it turns out that the indicator also expresses the degree to which the general state of the economy allows to obtain high profits and thus, a better remuneration of the owners. The stock market index has been declining since 2016, a year characterized by an economic crisis.

The degree of openness of the economy, is an indicator that reflects the degree of competitiveness of a country. The main weaknesses of the internal economy that determine a low degree of competitiveness are: the precarious state of the public health system, the government instability, the crime, the problems faced by the internal labor market (poor ethics, inadequate education, rigidity), inflation, corruption, fiscal instability, government bureaucracy and lack of infrastructure.

Mergers have a cyclical character. As the economy grows, this market grows oversized, and when the economy is in decline, the merger market shrinks even more. Depending on the period in which the merger operation is analyzed, the results may differ due to the specific characteristics of each merger wave.

In times of economic crisis, the number of mergers increases, a fact due to rising inflation. A euro is worth less than it was before the crisis. Thus, the purchasing power of the population decreases, so the incomes of the companies decrease, and the companies are forced to resort to the merger operation in order to survive.

The period of economic crisis and the decline of interest at global and European level did not encourage companies to merge. A decrease in the reference interest increases the efficiency of the use of loans for companies and guides them towards developing their activity based on the commitment of additional capital. The merger operation is directly influenced by the lack of liquidity and the decrease in credit, which intervene as a result of the economic crisis.

The results of this research coincide with the opinions of the authors: Nelson, Mathur, Cernat-Gruci, Clarke and Ionnadis, Broaddus, namely: there is a significant connection between the economic factors analyzed and the evolution of the number of mergers. The study is useful for knowing the context in which the merging companies operate

Funding

Abstract

As a result of the growing competition within the consumer goods industry coupled with expectation of shareholders for profit maximization, the decision of optimal product mix and allocation of resources falls on the managers so that customers expectations can be met. As a result of this, this study examined how organizational resources can be strategically allocated for optimal business performance subject to labor machine and material constraints. These data were then analyzed through the linear programming solver software in order to allocate several the firms resources to competing variables (sachet water, bottle water and dispenser). The study therefore revealed that the Business Unit should focus on invest 23.4 minutes of labour hours, 23.4 minutes of machine and 480 minutes of material. And the analysis recommends x1=0, x2=60, x3=0 should be produced.

Keywords: Business Performance, Labor, Linear Programming, Machine, Materials, Resources

Introduction

Organisations resources vary, some of these resources include, technology, people, finance, raw materials, training, and many more. All these resources are important and crucial to the growth and success of every organisation. Adeyeye (2016) was of the opinion that for successful implementing of strategic plans, there is need for efficient allocation of resources. It is thus a challenging task to implement a strategy when the resources for such implementation of plans are unavailable. There is no disbelief that exists scare resources at the disposal of any organisation and because of this, managers and top level management are confronted with the judgment to select the best means of management of the scarce resources using linear programming in order maximise profit (Adeyeye, Ogunnaike, Amaihian, Olokundun, Inelo, 2016).

Human resource allocation may not sound like a resource, however, it is one of the major areas where resources can be best optimally utilized. Improper allocation of resources especially the human resource, can lead to wastage of energy and man-power. In addition, if the wrong individual is allocated to a task, this individual would end up dropping the productivity level of the organisation, prolong the output time and these would affect the quality of

"Allocation Organizational Resources for Production of Finished Goods Inventories Using Linear Programming Model" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

the output (Ibidunni, *et al.,* 2018*)*. It is therefore important to allocate the right individual to the specified job (Ibidunni, Ufua, Okorie, & Kehinde, 2019).

Physical resources limit the organisation's set of possibilities of production and affect the cost position. The key characteristics of these resources includes size, location, equipment, flexibility of plant, sophisticated technology, and many more (Nganga *et al.,* 2017)

The absence of conveniently engaging available resources coupled with the delayed in implementation of performance standards recommended has led to increase in operation cost and uncoordinated activities (Ogunnaike, Bishop, Akinsulire, Kehinde, & Oreagba 2018). This has resulted in the ability to effectively use its technology which comes in the form of machines, which when used properly can produce enough quantities of products in the organisation that leads to internally generated profit (Kehinde, Ogunnaike, Adegbuyi, & Ibidunni, 2020). This has also resulted in the inability in attracting and retaining skilled and experienced labour in the organisation, thus resulting in the low performance of the organization (Abiodun & Clement, 2017). Several studies have looked into the application of linear programming techniques to the analysis of manpower planning but little studies have looked into the labour hours and materials needed vis a vis the specified work to be done. The selected business unit for this study is experience high labour turnover. It is therefore expected that the managers of these business unit should be able to harness the available manpower for the required labour hour in order to optimise their profits. Linear programming belongs to the family of mathematical programming which deals with the efficient allocation of scarce and limited resources to diverse competitive activities in the organisation on the foundation of a given optimality criterion (Akpan and Iwok, 2016).

Objectives of the Study

The broad objective of this research is to identify the optimal quantities of products to be produced in order to maximise profit subject to the material/machine/labour constraints in Hebron Drinks.

Literature Review

According to Levinthal (2017), much of the allocation of financial and non-financial resources are facilitated by the firms. Therefore he studied resource allocation and firm boundaries where he considered the impact of perspectives, beliefs , diversity on allocation of resources to investment opportunities. He was of the opinion that mediation of allocation of resources by the organisation plays a major role with respect to resource allocation over time.

Okoye and Ezejiofor (2013) stated the extent to which human resource development can improve organisational productivity in which collected data was gotten from the primary and secondary sources. The data was then analyzed through the use of mean, variance and standard deviation using z-test statistical tool. Findings in their study showed that a business can not exist without the human resource, and allocating labour is behind the sales growth and profitability of any business.

Ismail, Rose, Uli and Abdullah (2012) examined the relationship that exists between resources, systems, capabilities and competitive advantage which was done empirically. Using multiple linear regression model which gave a variance of 56.2% , the findings showed that there exists significant and positive effects of the variables collectively on competitive advantage which provides crucial information to policy makers and practitioners in the research area.

According to Junaid and Muktar (2010), linear programming tools and MATLAB Algorithm was used in the development of optimal cutting plan due to the fact that various organisations and industries faced cutting stock challenges because of generic raw materials production. They made use of Archer (LP) tool and LINGO 8.0 to solve the mathematical and linear program for sheet metal cutting optimization plan in addition with ITEMIZER which is a graphical programming tool. It was then concluded that by keeping the trim loss at the least level, these methods developed can be applied successful to obtain optimal cutting plans and also can be used to solve stock problem

Methodology

The researcher made use of the primary as well as the secondary sources. The primary data was gotten from the survey field through the use of observation and semi-structured interview. Data was obtained directly from observing the activities of people, machines and materials and questions were asked with structured interview to

give light into the observed activities of the production process. Therefore, research was considered for this study is the observation. It involved obtaining information by observing the ongoing behaviour and activities in a phenomena. It relies on information gathered from the working hours of the employees, machines used in the production process and material used to make the product. This would also be done in conjunction with the employee to obtain information about the materials used for producing the different drinks in the organisation. The secondary data was obtained through organisational records such as production records, financial records and sales records. The collected data was analysed through various mathematical technique with the aid Linear Program Solver.

Model Specification

According to Fagoyinbo (2008), linear programming problem may be stated in the following form

Maximization Problem

The generalized variable for linear programming problem is stated below

Maximize $Z = H1X1 + H2X2 + H3X3 + \ldots + CnXn$
Subject to :
$a11x1 + a12x2 + a13x3 + \ldots + a1nxn \leq D1$
$a21x1 + a22x2 + a23x3 + \ldots + a2nxn \leq D2$
$a31x1 + a32x2 + a33x3 + \ldots + a3nxn \leq D3$
$am1x1 + am2x2 + am3x3 + \ldots + amnxn \leq Dn$
Non-negativity constraint
$Xj \geq 0$ (j = 1, 2, ….n)
Where:
Z =total profit contribution of products
H1… H3 = Profit contribution coefficients of products. i.e the numerical values that expresses the contribution of the profit equation per unit.
D1… D3 = This represents the resource values that the organisation needs to fully utilize
a= organisational resources coefficients expressed per unit of the usage of each of the resources (labour time, machine hours, materials resources).

Analysis of Business Decision Making using Linear Programming

Objective: To identify optimal quantities of to be produced to maximise profit subject to machine hours and labour and material constraints

Table 1 : Distribution of Production Cost, Selling Price and Profit for Sachet Water, Bottle Water and Dispensing Water

Name of Product	Production	Cost	Selling Price per loaf	Profit
	per loaf			
Sachet Water (X1)	3		5	2
Bottle Water (X2)	36		50	14
Dispensing Water (X3)	450		600	150

Source: Field Survey, (2020)

Table 2: Quantities of Sachet Water, Bottle Water and Dispensing Water used for Producing Water

Input	Type of Bread and their Raw Material Mix			Total amount of
Basis	X1	X2	X3	time (minutes)
				RHS
Materials	0.5	0.65	19	5000

Machine	0.13	0.39	1.22	480
Labour	3	8	2	480

Source: Field Survey, (2020)

Step 1: Formulate the problem

Max P = 2X1+ 14X2 + 14X3
Subject to
Materials: 0.5X1 + 0.65 X2 + 19 X3≤ 5000
Machine: 0.13X1 + 0.39 X2 + 1.22 X3≤ 480
Labour: 3X1 + 8 X2 + 2 X2 ≤ 480

Step 2: Put the problem in standard form
Max P = 2X1+ 14X2 + 14X3+ 0S1+ 0S2 + 0S3
Subject to
0.5X1 + 0.65 X2 + 19 X3+ S1 = 5000
0.13X1 + 0.39 X2 + 1.22 X3+ S2 = 480
3X1 + 8 X2 + 2 X2 +S3= 480
Non-negativity
X1, X2, S1, S2, S3 ≥0

Results and Discussion

Based on the study of the output from the optimal mix of 39 minutes of labour hours, 23.4 minutes of machine and 480 minutes of material. Based on this results, it is advisable for SBU to produce 0 units of sachet water (x1) , 60 units of bottle water (X2) and 0 unit of dispensing water (X3) should be produced in order to earn a profit of 480 at optimality.

The objective was to determine how machines, labour and materials can be allocated in order to maximise profit. Results showed that the organisation should invest in 39 minutes of labour hours, 23.4 minutes of machine and 480 minutes of material and 60 units of bottle water to maximise to maximise profit. The results matches with the efficiency argument for profit maximization says that corporations and their managers should maximize profits because this is the course of action that will lead to an 'economically efficient' or 'welfare maximizing' outcome (Agarana, Oguntunde, & Hammed, 2016).

The researcher also found out that in order to efficiently maximize profit in the study organisation, there must avoid wastage by recycling sub-standard products. Also, several factors accounts for the loyalty of customers to the study organisation. Such factors include taste of the product, size of the product, availability of such products to the customers, proximity, affective commitment to parent body, product quality and monopoly of organisations

Conclusion

The research examined the effects of linear programming in allocating resources within a production firm in order to attain profit maximization. The findings in this research revealed that linear programming is a viable technique to use in order to allocate different resources. Linear programming is thus one of the simplest ways to perform optimization (maximization or minimization). This is because it helps solve complex problems by making a few simplifying assumptions. Other studies have made used of other methods to allocate resources, but this study provides evidence of the applicability of linear programming on the strategic allocation of resources for optimal business performance.

Abstract

Society in general and the business world in particular start to behave sustainably. Therefore, we pay more and more attention to the principles of the Circular Economy (CE). The construction industry is no stranger to the problem and its companies are transitioning to this more sustainable production model. Society demands information about this transition, and it is not easy to establish when and with what degree of intensity a company implements the Circular Economy model. To provide a real and effective measurement system, we have designed a dashboard with the main KPIs of the construction industry, related to the CE. To do this, a review of the literature and analysis of the sustainability reports of the companies is first developed. Once the indicators are defined, they are classified into two levels, one based on the Life Cycle Analysis and the other based on the organization's level analysis. After that, a simulation is performed using the Monte Carlo technique. After multiple iterations, this method establishes the most likely KPI values as a result, which will be the limits used in the scorecard, establishing 23 critical indicators.

Keywords: Circular Economy, Construction Industry, Key Performance Indicators, Circular Economy Index, Dashboards.

Introduction

The Circular Economy (CE) consists of the simultaneous consideration of environmental and economic aspects with the objective that the value of products, materials and resources, remain in the economy for as long as possible and that the generation of waste is minimized [1] [2] [3]. It aims to move from the linear approach of the economy (extraction, manufacture, use and disposal) to a new circular one that modifies the traditional life cycle of products, materials and resources (water and energy, among others), by introducing them new in a closed cycle for economic purposes [2] [4]. This increases efficiency in the use of resources, especially in industry and urban areas, achieving a better balance and harmony between economy, environment and society [5] [6] [7].

Being this concept that applies to companies of all sectors [2] [6] [7] [8] [9], including the construction industry [4] [10], the efforts to measure it in this particular sector have been very scarce [11]. However, there is no doubt that the construction industry has a huge impact on the environment [12] and the use of materials [13] [14] and other resources [15] and, therefore, its importance for the Circular Economy is maximum [4] [12] [13] [14] [15].

Cite this Article as: Pedro NUNEZ-CACHO, Jaroslaw GORECKI and Juan M. MAQUEIRA-MARÍN "How Does A Building Company Perform In The CE? Analysis Taking Into Account Organizational Levels and LCA Stages" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The main causes of the construction industry's environmental impact are founded in the use of non-renewable resources and the generation of contaminant residues, both of which are increasing at accelerating pace [13] [14] [16]. The sector's primary effect is the significant destruction of the stock of natural capital [17] through entropic degradation, an issue that is particularly tangible when we observe its most visible or known effects, such as the fall of the native forest, the depletion of fossil fuels, the reduction of water reserves and the pollution of the atmosphere through the emission of greenhouse gases, acid rain and the destruction of the ozone layer [18]. Therefore, construction projects need to be designed from the beginning with criteria of environmental sustainability keeping into consideration their entire Life Cycle Analysis (LCA) (design phase, manufacture materials phase, construction process phase, maintenance phase and end-of-life phase) in a closed cycle [19] [20]. And it is that, in the construction industry, companies turn to general contractors who manage one or several phases of the life cycle of construction projects. Circular Economy must be present in each phase of the construction projects developed by these general contractors. Thus, it is needed the adoption of principles of Cradle to Cradle [21] [22] [23] [24], such as designing for deconstruction [16] [25], Building Information Modeling standard (BIM) [26] and Close loop instruction, in the design phase. Besides, also it is needed more initiatives for sustainable production and the use of sustainable sources, will minimize the waste generated and reduce the number of resources employed during the manufacturing materials, construction and maintenance phases [4] or the reuse and recycle in demolition end phase [16] [25]. All these are strategies of Circular Economy that the companies of the construction industry are already using in their projects' entire life cycle [4] [16] [21] [25] [27] [29]. Because of the importance of the CE today, the generation of a relevant set of Key Performance Indicators (KPIs) that allows us to identify and control if a construction company is applying circular economy practices in the different phases of construction projects, and with what intensity, is a subject of great interest [11]. The generation of these KPIs allows the development of software for control panels or control panels specific to this industry [28]. Precisely, this article puts the focus on these issues. In this way, the objective of this article is to identify a series of key performance indicators (KPIs) related to the CE, which are already being used by companies. On the other hand, it is also intended to illustrate the practical applicability of these indicators through the design and development of a dashboard or control panel software in Circular Economy for a relevant company in the sector.

Circular Economy´S Key Performance Indicators In The Construction Industry

Analysis of the life cycle

Among the tools that help to break down industrial processes are the Life Cycle Analysis (LCA). It is a method responsible for strictly measuring the average environmental impact of a building from five different stages, starting with its initial design and manufacturing, ending with its demolition and final conversion into byproduct [10]. In each of the phases, the sustainability indicators are analyzed. In this way, the LCA can establish the phases in which special care is necessary to avoid any environmental problem. This analysis is widely used by companies due to its optimization of resources and the consequent cost savings, but it can also be used as advertising and good practices of the company because it can be applied to environmental management standards, environmental labelling, etc. This analysis is performed for different sections of Cradle to Gate, which would be in the manufacturing process; Cradle to Grave takes into account from manufacturing to disposal; Cradle to Cradle, would be the new concept on the Circular Economy already explained, therefore there would be no waste [24].

However, this measurement is not simple. As Malabi et al [30] states, the multifunctionality of the CE represents an additional difficulty for the application of the life cycle analysis, which is based on the measurement of the impacts of individual products [31]. For this reason, it is necessary to evolve from a single life cycle approach to a multiple life cycle approach that supports continuous cycles of products and materials [32]. Also, a long-term scenario that presents the useful life of buildings adds another difficulty to its application.

To solve these problems, the segregation of the analysis of the transition to the circular economy in the construction sector could be done by breaking it down into the different phases of the life cycle analysis. This could reduce uncertainty regarding the effectiveness of the measurement of negative externalities of the company, within the CE scenario. As a starting point, a sustainable life cycle consists of five phases: sustainable design process; sustainable production of materials and equipment; sustainable construction process; Sustainable maintenance; demolition = conversion of products into inputs: reuse, remanufacturing or recycling [10].

Levels of organizational analysis

A second complementary classification of the previous one would be to establish levels of organizational analysis. According to Blakeney [33], the company can be considered as a system in which several subsystems interact to carry out a function. In this system, we find three possible levels, first of all, the organizational level, whose effectiveness was defined as the desired impact on the different levels of the organization [34]. The processes at the individual level, which are the basic unit of analysis and the workgroup in which different variables are taken into account, such as the individuals that compose it, the environmental variables and the tasks, certain behaviour is achieved.

To reduce the uncertainty of the LCA analysis, in addition to its life cycle phases, we will include three different levels of study: organizational level, which includes the variables related to planning and organization; Process level: where the variables related to the construction processes are framed; And workgroup level, where the decisions related to the worker are collected.

Fig. 1: Levels of analysis

Design of Circular Economy index for the construction industry, applying the Monte Carlo simulation

Index Design

To determine the main KPIs related to CE in the construction industry, we conducted a review of the literature that allowed the first identification of these indicators. A literature review is a technique generally used for this purpose [35] [36] [37].

For this task, two different sources were reviewed. First, the academic literature on the subject, articles previously measured by the CE, initially selected 21 articles. With this source, we intend to obtain a scale with updated and rigorous information. Secondly, for the scorecard to be operational in the field of business, the review was accompanied by an analysis of the sustainability reports of 10 of the main construction companies in the international arena. Indicators of the sustainability reports of the last 3 years were incorporated. With this, we intend to give maximum compliance from the beginning to the control panel that complies, incorporating indicators that companies are already measuring at present.

The next phase was to group the indicators to relate them to the CE and link them to the principles we have developed in the theoretical framework. Thus, with the sum of indicators collected from the two sources, an initial base was generated and then classified. The first classification was made according to its position within the company: based on the analysis of Blakeney [33]. Thus, KPIs related to the organization were obtained (1); KPIs related to the processes (2) and KPIs related to the workgroup (3). Secondly, the articles were reclassified according to the LCA phase [10] in which each one operated (design, material manufacturing, construction process, maintenance and deconstruction or end of life) [38] [36]. Thus, a final questionnaire was generated with 67 indicators classified according to the LCA and the total organizational level forming 15 subcategories (Tables 1, 2, 3, 4, 5).

Table 1: Circular economy Key Performance Indicators of the Design phase of LCA

DESIGN PHASE INDICATORS	SOURCE	ORG. LEVEL
Indicators for toxicity, scarcity and energy	[54]	ORGANIZ.
Existence of a secondary raw material market	[68]	ORGANIZ.
Is there a complete bill of materials and substances for the product?	[54]	ORGANIZ.

Total amount of industrial solid waste for final disposal	[53]	WORKGR.
CO2 concentration	[61]	PROCESS
Energy indirect greenhouse gas emissions	[55]	ORGANIZ.
Bouygues group greenhouse gas emissions	[50]	ORGANIZ.
Greenhouse gas emissions	[66]	PROCESS
Recycling rate of industrial solid waste	[53]	PROCESS
Energy consumption	[65]	PROCESS
Total amount of industrial solid waste for final disposal	[53]	PROCESS
Waste by quantity, type, and disposal method	[55]	WORKGR.
Initiatives to recover food waste in establishments open to the general public -	[66]	ORGANIZ.
Energy: Energy positive building – delivered	[63]	ORGANIZ.
Water use	[49]	PROCESS

Generation of probable values for the indicators through the Monte Carlo method

Simulation is an appropriate technique for the analysis and solution of complex problems, which mimics the functioning of a real-world system that evolves. The method applies to any type of problem, random or deterministic. Unlike other numerical methods, it has an absolute error in the estimate that decreases as 1 / N. This error decreases as the number of iterations increases, according to the principles set forth by the central limit theorem.

Monte Carlo simulations have been used to investigate many general aspects of companies and their projects [38], especially in the analysis of investment risks, and also in aspects related to sustainability [11] [39] [40]. Some approaches have been made to its application in the circular economy [41] [42] (Núñez-Cacho et al. 2018; Górecki et al. 2018) that demonstrate its usefulness in this purpose. We consider that Therefore, the use of these simulations as a reference to classify construction companies in terms of their propensity to carry out activities based on the CE concept is an innovative solution.

The procedure followed in the Monte Carlo simulation is as follows. First, a random variable based on probability distributions [38] [39] [40] is generated. Then, after defining a parametric model, we start saving the values. Then, the iterative process is repeated thousands of times (5,000 interactions in our case) until the moment when each range becomes a frequency distribution, which allows us to establish an estimated value and describe its statistics, such as the weighted average, variance, confidence intervals, etc. [40].

In the application of the Monte Carlo method, the following steps are included: first, the model is constructed; second, the stochastic input variables and their probability parameters are defined; third, random numbers are generated for each input variable according to its probability distribution; fourth, run the model; and fourth, system behaviour is visualized and captured [38] [39] [40].

The result of the simulation proposed in this document is a probability distribution for the 65 KPIs employed and their grouping around two levels, the LCA and the organizational analysis. In this way, a total of 24 indicators are generated, 1 general indicator of the Circular Economy that shows a degree of participation of the company in the CE (CE Scale); 5 related to the LCA; 3 related to organizational analysis; 15 indicators related to the subcategories used from the merger between LCA and organizational analysis (5 x 3). The output of the Monte Carlo method provides the most probable values (score) of each indicator, group of indicators and the final index so that these values can be used as cut-off values in the graphic representation in Dashboards (CE Scale).

Based on the frequencies of the indicators obtained in the literature review, the values are weighted according to their participation in the LCA and at the organizational level. The values desired by the organization for the indicator are also established. Companies can take as a reference to the value of the previous year increased in the percentage in which the company wishes to improve its position concerning the Circular Economy. This would show the degree of commitment of the organization to the circular economy. In our calculations, values from the analysis report have been incorporated, observing the evolution and annual improvement of the main construction companies in indicators related to sustainability. The objectives and weights are useful inputs to develop the Monte Carlo simulation technique. The weights performed and the desired values are shown in Annex 1. Thus, the parameters xi, xj and xk are input random variables that affect the probabilistic results of the construction enterprise project maturity in terms of the CE. The probability distributions of the variables and their statistical properties may be taken from a database or may be specified by experts too. The probability distributions, which are established for each random variable, enable simulation of the corresponding random numbers.

The output score is a Circular Economy Scale (CES), which includes two levels of simultaneous analysis, the first with the five phases of the LCA and the second studying each phase at the organizational level, of group work processes. There are a total of 15 categories. The general CES scale is generated in subsequent iterations by the values of the input variables. After each iteration, the output is different because each time a new draw is made, the CES values obtained in the simulation, after a defined number of iterations, create a random variable f. Multiple iterations allow us to calculate the most probable value of the maturity of the construction company in terms of CE and, therefore, the risk of the deterministic estimate of this indicator. The simulations were performed in the "@RISK" software for 5000 preset iterations.

The conceptual model, which is based on the formula for CE Index in the construction industry is described by the following equation:

$$CEI = \frac{SO + SP + SW}{3}, \tag{1}$$

Circular Economy Index (CEI)

Groups of Indicators generated

ORGANIZATIONAL LEVEL:

1. SO_Design – Score for the 'Design' level in the 'Organization' section
2. SO_Manufacture – Score for the 'Manufacture of materials' level in the 'Organization' section
3. SO_Production – Score for the 'Construction' level in the 'Organization' section
4. SO_Maintenance – Score for the 'Maintenance' level in the 'Organization' section
5. SO_End of life – Score for the 'End-of-life' level in the 'Organization' section

PROCESS LEVEL

6. SP_Design – Score for the 'Design' level in the 'Processes' section
7. SP_Manufacture – Score for the 'Manufacture of materials' level in the 'Processes' section
8. SP_Production – Score for the 'Construction' level in the 'Processes' section
9. SP_Maintenance – Score for the 'Maintenance' level in the 'Processes' section
10. SP_End of life – Score for the 'End-of-life' level in the 'Processes' section

WORKGROUP LEVEL

11. SW_Design – Score for the 'Design' level in the 'Workgroup' section
12. SW_Manufacture – Score for the 'Manufacture of materials' level in the 'Workgroup' section
13. SW_Production – Score for the 'Construction' level in the 'Workgroup' section
14. SW_Maintenance – Score for the 'Maintenance' level in the 'Workgroup' section
15. SW_End of life – Score for the 'End-of-life' level in the 'Workgroup' section

The scores are based on deterministic values passed by the experts. These values can vary so should be described by some probabilistic parameters that constitute foundations for the simulation model. The simulations run according to the following equation:

$$CES = \frac{\frac{\sum_{i=1}^{5} w_i \cdot x_i}{\sum_{i=1}^{5} \cdot w_i} + \frac{\sum_{j=1}^{5} w_j \cdot x_j}{\sum_{j=1}^{5} \cdot w_j} + \frac{\sum_{k=1}^{5} w_k \cdot x_k}{\sum_{k=1}^{5} \cdot w_k}}{n}, \quad (2)$$

Where:

wi – weights of particular indicators in the 'Organization' section
xi – set of probabilistic indicator values in the 'Organization' section
wj – weights of particular indicators in the 'Processes' section
xj – set of probabilistic indicator values in the 'Processes' section
wk – weights of particular indicators in the 'Workgroup' section
xk – set of probabilistic indicator values in the 'Workgroup' section
n – number of sections (n=Production)

The indicators related to each phase of the life cycle would be as follows:
Circular Economy LCA phase = Arithmetic mean (S_nO; S_nP; S_nW)

<u>Where:</u>

Weighted arithmetic mean (SO_Design; SP_Design; SW_Design)
Weighted arithmetic mean (SO_Manufacture; SP_Manufacture; SW_Manufacture)
Weighted arithmetic mean (SO_Production; SP_Production; SW_Production)
Weighted arithmetic mean (SO_Maintenance; SP_Maintenance; SW_Maintenance)
Weighted arithmetic mean (SO_End of life; SP_End of life; SW_End of life)
N= Phase of LCA (Design to End of life)

16. S_Design – Score for 'Design

17. S_Manufacture – Score for Manufacture of materials'
18. S_Production – Score for 'Construction' level
19. S_Maintenance – Score for 'Maintenance' level
20. S_End of life – Score for 'End-of-life'

Results

The results of the Montecarlo simulation method application allow us to obtain a probable value (score) for each key performance indicator and each of the three main groups of the organizational analysis and each of the phases of the LCA, starting from the desired target and the assigned weight and applying equations (1) - (2). The most probable value of the final score of the Circular Economy Index in construction companies can also be obtained, executing projects following the CE principles, of each of the phases of the LCA and each of the organizational levels. The result is shown in table 6.

If the indicator offered by the simulation is below the desired values for the specific index, the company in the construction industry is located in an area where it must be cautious (yellow) or in a danger zone (network), where the degree of CE application in the company would be below desirable. The desired value marks the beginning of the green zone and in our clock dashboard corresponds to the 135-degree position, above the desirable values an area of good behaviour starts where the degree of application of the CE would be above of the desirable.

These values can be used to graphically represent a partial CE measure for a company in the construction industry for each of the three main groups of indicators (Organization, Processes, Workgroup), for each of the LCA phases [43] and the general index of the Circular Economy. The general circular economy index is calculated from the arithmetic mean of these three groups (see equations 1 and 2). In this way, the most probable values of the indicators (score result in the Monte Carlo simulation technique or CE Scale) represent the limit that distinguishes when a company has a good performance in CE (its final result in each group and the general index is above the most probable value) or bad behaviour (its result in each group, and the general index, it is below the most probable value). Therefore, when determining the values presented by each KPI in the specific case of a particular company in the sector, and knowing these most probable values, it is possible to graphically represent a Circular Economy Panel for the analyzed company.

Building the Circular Economy dashboard

Introduction

With the results obtained, a dashboard for the measurement of the CE has been developed. As mentioned throughout this work, 15 main indicators will be presented based on the phases of the LCA and the organizational analysis (5x3). Each one is collected in the dashboard through a clock chart, with three categories: red, yellow and green. The beginning of the green category marks the value expected by the company for the indicator and therefore indicates compliance with the expectation. The complete dashboard is presented in Figure 2. In each row, the organizational levels appear and in each column the LCA phases. For example, in the first row, the general CE indicator appears, which establishes the degree of compliance with CE objectives. The arrow indicates the green with what we can see that the company has reached its objectives in general. Row 2 Column 2 shows the indicator of compliance with CE objectives at the organizational level within the design phase. In this case, it is shown in the yellow zone, indicating that it is below expected, without reaching the critical danger zone indicated by the red indicator.

Dashboard Design and Development

The KPIs included in Tables 1 to 5 were specified in possible measures, from the conceptual level of the business language to the technical level that allows its graphic representation in the form of a Board. A specific graphic representation was selected for each KPI, each KPI group and the CE Index. Therefore, the speedometer graphs were selected for the General CE Index and each of the three main groups of indicators. This type of representation, similar to those of the dashboard of a car, consists of three colours: (1) green indicative of good compliance; (2) yellow indicative of caution zone and (3) red, indicative of danger zone. The most probable values for each group and general index, according to the results obtained in the Monte Carlo simulation (exit score), represent the limit of the good performance zone (green). Below these values with a reduction of 10 units expressed in%, delimits the precautionary zone (yellow). Data with a greater reduction of this value make up the danger zone (red). Within each group, horizontal bar graphs of the semaphore type were selected for the representation of the individual KPI. The criteria for zone delimitation values (green/good compliance, yellow / caution and red / danger) are the same as before.

Once the graphics were selected, the different CE Board screens were designed. The data for represents and annual reports of Corporate Social Responsibility of the company or were expressly identified [36] [38]. In the development of

a Dashboard, it must prevail that, at a glance, managers can verify whether their objectives in the CE area are met or not [28]. This principle has been followed during the design and development phase [28] (see Figure 1).

When the simulation results are interpreted, it is observed that it obtains a good performance in the General Index of Circular Economy, above the most probable value obtained by the Monte Carlo simulation, as shown in Figure 2. Besides, according to the Indicator groups, both in In the Organization group and the Process group, it achieves good compliance, placing itself in the good zone (green).

Discussion and Conclusions

The measurement of the position of a company before the CE is a topic of great relevance within its corporate social responsibility. Many of the company's stakeholders are waiting for information in this regard, from the government to the surrounding community. The multidisciplinary nature of the CE entails an additional difficulty in carrying out this measurement, making it difficult to apply an approach such as the LCA [31]. To overcome this difficulty, measurement sub categories must be developed that allow us to provide more effective information for decision making. Our work, by jointly incorporating two classifications, such as the LCA and the analysis of different organizations) allows us to decompose information on CE into 15 subcategories. In this way, the company can know which aspects it is working properly in CE and in which not. The idea of transition and the commitment of the organization are also introduced into the model through the desired values of the indicators. On the other hand, the application of the Monte Carlo simulation facilitates the probable values of the 65 variables that make up the scale and with them the 15 commented indicators are formed. From these, eight additional indicators on LCA and organizational level and a general CE indicator that synthesizes the fulfilment of the objective are formed.

The previous contributions cited in this article allow us to design and develop a CE Board for a relevant company in the sector. Based on the specific data obtained from this company, the Board is designed and developed as a practical application. This article could be used as a guide for those companies in the construction industry (general contractors that participate in the complete life cycle of construction projects) who want to know what their performance in the CE is like. Also, the development of Dashboard software applications allows its managers, at a glance, to know the real situation of the company facing CE to make decisions related to this matter [44]. CE practices are needed in the construction industry due to the tremendous impact on the environment. These companies are aware of how their company's performance in CE is a necessity [44] [45] [46]. In this sense, this document contributes by creating an instrument available for managers to evaluate the implementation of the CE.

Abstract

As, the food safety behavior in the home-based business (HBB) is a concept that has not been given sufficient attention regarding training effectiveness, attitudes and commitment the evaluation of practices to achieve business success in the realization of the important food safety, and since there are fewer researches have been done in the area of HBB. Therefore, this research comes in to measure the effect of the training effectiveness, commitment, and attitude into food safety behavior that can be realized especially in the home-based businesses that serve the interest of the local communities in any given place. A quantitative deductive approach will be conducted to test the model, the research variable, and the outcomes for difference HBB within UAE. The research expects results will be a significant correlation between the food safety behavior variables, training effectiveness variables, commitment variables, and attitude variables, as well as thus developing a conclusion adoptable by the different governments, and other stakeholders may apply in the industry to create a higher value regarding food safety behavior.

Keywords*:* Food Safety Behavior, Training Effectiveness, Commitment, Attitude.

Introduction

There is a dramatic increase in the number of home-based businesses (HBB) especially in food that is showing the prevalence of the sector and its constituents, and for this influx some of the cities getting government regulations for this HBB, and it is still a field of interest in the current time. Food safety behavior concept that has not been given sufficient attention regarding standardization and the evaluation of practices to achieve business success in the realization of the food quality attributes. Hence, the researchers will come to address the effect between training and food safety behavior of home-based business and how it effects on human capital. This research also will focus on the development of the understanding food quality values that are applicable in the home-based business. Understanding the role of HBB in the counties economy is essential since most research do not show the same. Making safe of the operational environment conducive is always the purpose of the everyone and especially home-related business. The training of the personnel for efficacy in the handling of the business is also essential in reaching the said goal. However, the business operations also depend on the food and training of the personnel. The process of food storage and preparation both requires finance. It is therefore vital to moderate the amount of financial investment on the same. Accordingly, this is to be done so that to achieve the premium goal of maintaining HBB, food safety behaviour and training at considerably better finance. Human finance, on the other hand, the trainer and the trainee help in the integration of the said components above.

This study presents a comprehensive discussion of the three aspects and their separate integration in relation to the home-based business, specifically in training effectiveness, attitudes and commitment. In training effectiveness, it's important to identify and measure the impacts of the individual and observable changes in knowledge, skills, and attitude after training as well as organizational factors that affect training outcomes including training transfer. However, the scope of evaluating the effectiveness of training may help to identify the value of training programs and methods of techniques to improve training programs also will value training resources to the organization. As this study, the criteria to measure the training effectiveness by trainee reaction, learning, behavior and business results through, these criteria the organization can value the training program (MOLLAHOSEINI & FARJAD, 2012). SUN, LIU, WU, & ZHOU (2018) showed the measurement of training effectiveness by using the Kirkpatrick model which will give an indicator of the criteria that want to measure such as: how to evaluate the effectiveness of the trained (learning), how to quantify the improvement of the trainee's ability after training (behavior) and how to ensure the quality of training (knowledge). KIRCHER, & FOX (2019) argued that attitude is the second variable on this research which plays an important role in any organization, most of the studies have argued about this topic such as: that the attitudes composed of three components: cognition which means the beliefs held about the attitude object, affect the feeling elicited, and finally conation means the behavior directed. Additionally, all components are psychological characterized by stereotypes (beliefs), prejudices (feeling) and discrimination (behavior). When the food handlers have knowledge of food safety the attitude and behaviour towards handling food positive because the attitude can be positive or negative on the feeling which may influence the behavior (MOREAUX, ADONGO, MENSAH, & AMUQUANDOH,

2018). The last variable is the commitment defined as the employee's loyalty toward the organization, which reflected on the behaviour for the employees like contribute more effort to work. The benefits of commitment are the level of job satisfaction increase which leads to improved performance for the organization. Thus, when employees have a high commitment can contribute to actions that produce organizationally valued outcomes (MAHTO, VORA, MCDOWELL, &KHANIN, 2020). The employee's commitment grouped into three levels includes affective, normative and continuance. The affective commitment is concerned with employees feeling, continuance commitment which meaning costs associated with separation from the organization and last the normative commitment is concerned with moral commitment to continue with the organization (RAMESHKUMAR, 2019).

The following section views the literature reviews of the research. The third section conceptualizes a framework of the article and the methodology in the fourth section. The fifth section displays the expected results and implications. And the last section will be the conclusion and future works.

Literature Review and Hypothesis Development

Food Safety Behavior

To improve the food safety behaviors which many countries adopt is to implement mandatory food handler training and programs which may help them to correct readily fallen mistakes in their behavior (LIN & ROBERTS, 2020). However, many studies reported that training employees on food safety practices are a very important and essential factor to change the behavior. Therefore, most of the organizations consider developing food safety education for the employees. Building a good habit in behavior performed to lead to regularity behavior based on good practices, and that will order to control for the effects of past behavior which will contribute to reducing foodborne illness (MULLAN, ALLOM, FAYN, & JOHNSTON, 2014).

Additionally, MOREAUX, ADONGO, MENSAH, & AMUQUANDOH (2018)

Specify that the training is the most widely recommended for improving the food safety behaviors for the food handlers and leads to good attitudes which will turn to the practices for them in the future. Based on these when the food handlers have a significant knowledge of food safety they will relate to the attitude and behavior towards handling food.

In research, and based on an extensive literature review for the food safety behavior

(e.g. PARK, KWAK, & CHANG, 2010; ROWELL, BINKLEY, ALVARADO,

THOMPSON, & BURRIS, 2013; TURNBULL-FORTUNE, & BADRIE, 2014; LONDON SOUTH BANK, 2016; OVCA, JEV, KAV, & RASPOR, 2018; IDRISS, 2019; YOUNG, CHUNG, MCWHIRTER, & PAPADOPOULOS, 2020) the most common practices behavior among different researcher are Personal hygiene, Food hygiene, and Environmental hygiene, which will use it as a dimensions to measure the food safety behavior.

Training Effectiveness

The companies need to focus on measuring the effectiveness of the learning program to provide information as well as feedback about the adequacy of the implemented training program, and to have gap analysis to know the shortcomings of the training programs.

To enhance the training effectiveness must measure by some variables that could influence training like training climate, training evaluation, and degree (KODWANI, & PRASHAR, 2019). As a result, all variables can influence trainees, so the trainees need to know all about training. The criteria to measure the training effective depend on What the trainee learned from training course (Knowledge Criteria), how the acquires knowledge will change on job and performance (behavioral criteria) and last evaluate the course (results criteria), which considered as a primary decision to evaluate the effectiveness of training (ARTHUR, BENNETT, EDENS, & BELL, 2003). Although there are many evaluation and effectiveness methods for training must ensure to choose the correct method to measure, So, because this reason choosing the Kirkpatrick evaluation model, which defines the modules in four levels:- Reaction through examine what the trainer's learners and felt about the training, Learning the level of knowledge he gained, Behavior how it contributes on the job performance, and finally, Results examine the effects on organization or environment on the business (CHRYSAFIADI, & VIRVOU, 2012). From the above ideas, the first hypothesis (H1) is built up and presented in Fig.1. Hypotheisi1. There is an effect of training effectiveness on food safety behaviour.

Attitude

Attitudes are one of the characteristics of safety culture in an organization and it defined as a psychological tendency that is expressed by the assessment of a particular entity with some degree of satisfaction or unsatisfied and measured by three components (cognitive, behavioral and affective).

Additionally, the reasons to care about employees' attitudes could be due to the attitude that will affect outcomes of an organization by turnover or performance; also the satisfaction will impact productivity. Through the attitude of employees, the organization will have indicators of business performance and work environment and is there any development or not, because the internal and external factors will affect the attitude on all employees including cultural influences that will contribute to the employee's capabilities, and can evaluated by using the five job areas the promotion, co-workers, pay, supervision and work itself. This can best be described by the theory of planned behavior, which links one’s beliefs and behavior, such as negative employee attitudes to workplace diversity are multifaceted which lead to rejecting many initiatives used to promote workplace diversity. The behavior intention is influenced by the attitude regarding the possibility that the behavior will have the expected results and the subjective evaluation of the risks and benefits of that outcome. The attitude toward behavior, subjective norms, and perceived behavioral controls, together shape someone’s intention behaviors. The theory has successfully been used to predict health-behavioral intentions such as exercise and diet where the attitude and intentions to behave in a certain manner are mediated by objectives rather than need. The theory differentiates between three types of beliefs namely; behavioral, normative and control (ANGLIM, SOJO, ASHFORD, NEWMAN, & MARTY, 2019). The second hypothesis (H2) is there is an effect of attitude on food safety behavior in Fig.1.

Commitment

The employee's commitment can affect the level of organizational performance (JAROS, 2007). The organizational commitment as three components that are affective, continuance and normative. Most of the organizations follow the factors that support commitment like, continuance commitment which meaning employees desire to continue working, normative commitment facing pressure from there and last one affective commitment employee who agrees to work in this environment. The value and beliefs of food handlers can contribute to the commitment of the employees in the organization, and measure this commitment by dimensions such as reward valence (reward expect), reward instrumentality (performance), reward expectancy (personal effort will increase the performance), role overload (to reach to the role expectations must to work hard), role underload (perform excessive in work), job satisfaction (level of emotional), and employee empowerment (responsibility to take the decision).

Over the past years, organizational commitment has been the important subject for the research contributions, which defined as the individual's attitude towards an organization, especially in belief and acceptance of organizational goals and values, work harder for the organization. The definition the organizational commitment is a stage in which the employee recognizes a certain group with the goals (ELIYANA, MA’ARIF, & MUZAKKI, 2019). Also, through the organization's commitment the employees have a strong willingness to stay as a group member to work, also have a

willingness and aspiration to hard work to reach the organization's goals. The relationship between organizational commitment and work performance is very strong and positive and it can influence each other (ELIYANA, MA’ARIF, & MUZAKKI, 2019).

Organizational commitment very important to change employees through attitudes and conditions, and it refers to an employee's bond to the employing organization. The commitment depends on three major forms called continuance, normative and affective commitment, thereby the increase in these forms will contribute in further to the strengthening organizational commitment (LAMBERT, OTU, & ELECHI, 2019). Following this line of argumentation, the second hypothesis (H3) is there is an effect of commitment on food safety behavior in Fig.1.

Home-Based Business and Food Safety

The home-based businesses are a sector in the entrepreneurship whereby a person seeks to own a certain enterprise while working from home (JAYACHANDRAN, 2020). The United Arab Emirates has been experiencing steady increase in the G.D.P especially since the year 2004. There has been a significant and rampant increase in the number of HBB enterprises in many areas of the economy, including the food business sector. In the food industry, women have especially been at the forefront in establishing home-based businesses that prepare and sell all kinds of food products, but primarily cookies and cakes. The foreign policies pertaining to the open border have also contributed to the development of the country's economy. In the country, the number of players in the food industry is wide. In this case, it raises the need to create awareness on safe ways of preparing, transporting, and storing food to evade food health crises that may arise from contaminated foodstuffs. Sensitization of the benefits of handling food safety is an essential sector that should be endeavored by all players in the industry.

Conceptual Framework

This paper assumes in order to test the effect of four variables which are training effectiveness, attitude, and commitment on food safety behavior in HBB, through dimensions on these variables.

Fig. 1: Detailed Conceptual Research Model

Research Methodology

To test the paper's hypothesis, a home-based businesses sample of firms in UAE will be used. A quantitative deductive approach will be conducted. Hence, questioners will be sent to food handlers of this business. Elements that need to investigate are the effect of the (dependent variable for food safety behavior) and will measure it by dimensions of personal hygiene, food hygiene, and environmental hygiene, and (independent variable for training effectiveness: learning, behavioral, results), (independent variable for attitude: affective, cognitive, and behavioral) and (independent variable for commitment: effective, continuance and normative).

Expected Results and Implications

The anticipated results will be a significant correlation to the effect of training effectiveness, attitude, and commitment on food safety behavior of the home-based business and its effectiveness variables in success. And that support all the questions, hypotheses and the framework proposed for this research.

Conclusion and Future Work

As understand from (HBB) definition, the main goal is to reinforce know the effect of training effectiveness, attitude, and commitment on food safety behavior in a homebased business. The food handler is essential in the development of HBB and food safety behavior assurance. Therefore, it was essential to check the effect of training effectiveness,

attitude, and commitment variables on food safety behavior, as well as a substantial correlation link amongst the food safety behavior variable with other variables. And for future work that can come up from this research is to investigate other linkages, for instance, the food safety culture on (HBB).

Abstract

The new demand for modernization has made businesses perceive the globalization of their operations as a way of staying competitive. Globally, marketing strategy has been an effective resource for every company to survive in a competitive business environment and have become stronger. The major purpose of this research was to examine the effects of product differentiation strategy and pricing strategy on the performance of manufacturing firms in Nigeria. Product differentiation strategy and pricing strategy have been used as a tool for firm performance. The findings revealed that product differentiation strategy and pricing strategy has great influence on performance of manufacturing industry. This study therefore suggested that management must ensure that the contexts of their business environment are thoroughly examined, before any marketing strategy is adopted to determine whether the proposed step or decision is a suitable strategy for success in the sector.

Keywords: Marketing Strategies, Manufacturing Industry, Product Differentiation Strategy, Pricing strategy.

Introduction

The stiff competition in the market has rendered the success of any given firm to be largely dependent on its strategic awareness. In other words, managers must be cognizant of how these changes can affect their ability to compete remarkably in the marketplace (Onyago, 2017). Porter (2008) purports that business managers should continually look for ways in which they can exploit their strategic capabilities and this can be achieved through adapting and pursuing growths in all aspect of their businesses, building on brand awareness and understandings of present strategies and achievements (Onyago, 2017). Thus, Organizations must have the ability to respond quickly to threats and opportunities. For the purpose of market survival, Organizations need to compete successfully and beat their competitors in the ever-dynamic environment. This can be done by finding appropriate means to create and add value for their consumers in order to gain a competitive edge (Bukirwa and Kissing'u, 2017).

The ability to beat other players and to acquire beyond average returns hinge on pursuing and implementing a suitable business strategy as explained by Akingbade (2014). The pursuit of market competition is at the basis of strategic decision making and as such, having knowledge of the root of sustainable competitive advantage has turned out to be a significant field of study within the area of strategic management (Dirisu et al., 2013). In line with the above, organizations in any industry run their businesses with the awareness of developing their sales, dictating the space and ultimately becoming the dominant player in the market so as to acquire the biggest share of the market. These in mind as focused goals usually enable company to undertake any strategic measures that are ethical, legal and beneficial in an effort to attain those goals as elucidated by Abayomi and Akinmadelo (2014). Strategic decision is a vital decision that every top manager of an organization need to make, as this could ultimately have an effect on their company targets, either directly or indirectly (Monroe, 2003). Making an effective strategic decision for the product

Cite this Article as: Mary O. OGUNDIPE, Oladele J. KEHINDE, Samuel E. OIKEH and Dorothy OYO-ITA "Effects of Product Differentiation Strategy and Pricing Strategy on The Performance of Manufacturing Firms in Nigeria" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

or service of an organization is one of the most demanding and vital decisions a manager has to make, owing to the number of variables that ought to be considered. Some of the variables influencing strategic decision are customer satisfaction, company market share, sales growth and customer loyalty.

Differentiating one's products with an attempt to outperform competitors is one way of winning competition; differentiation means distinguishing products from those of competitors to make them more appealing to a specific target market. This can be done by observing customers, to discover and please users by offering unique products and creating a culture of innovation to be strategically positioned on the market and withstanding competitor attacks with the primary goal of meeting market demand. Consequently, it can serve as a basis for achieving a sustainable competitive advantage for businesses. It is therefore necessary for companies to offer new thoughts, ideas, differentiate and innovate their products (Kuncoro, 2017).

Marketing strategies has become a competitive strategy firms use to compete in the market as a solution for the difficulties they go through while trying to improve their performance (Onyejiaku, Ghasi, and Okwor, 2018). Even in the manufacturing industry of some western countries like Thailand, Singapore, China and America, marketing strategies is used as an instrument for corporate strategy (Moradian and Soufi 2015). This is why firms in these western countries, according to Moradian and Soufi (2015) have been growing in terms of market share and profit. Several studies [Adefulu (2015); Abu Aliqah, (2012); Gandhy and Harruidini (2018); Okeke and Onyemachi (2018)] have looked into the effect of marketing strategies as a whole in the manufacturing industry, but little research have been carried out on the effect of the composition of market strategies such as product differentiation strategy, pricing strategy, Promotion strategy and distribution strategy and how its affect their organization strategic decision.

Literature Review

Concept of market competition

For an organization to thrive successfully within a market, there must be true market competition. This can be defined as a business environment in which different companies, situated both within and outside a country, have to compete with each other simply on the merits of their goods and services. No company exists alone in the marketplace. There is always competition and knowing as much as possible about one's competitors, managers can make the business more successful, because they can formulate strategies that can help them compete successfully in a market (Adefulu and Adeniran, 2019).

Product Differentiation Strategy

Differentiation strategy aims at delivering products or services that provide results that differ from those of their rivals and are usually appreciated by customers (Virginia, 2017; Al-rfou, and Trawneh, 2010). When an organization can provide a product/service that is different, unique and beneficial to their consumers, it can differentiate itself from its competitors (Kago, Gichunge and Baimwera, 2018; Pereira, 2017). Product differentiation is prevalent throughout the financial world, especially in most production zones, and there is a wide range of differentiated products in the market. This is evident that when one walks into a store, one can encounters different products for instance soap, which comes in different varieties like liquid, detergent and bar soap and all being sold by different companies.

Differentiation is a sustainable strategy used by organization to generate beyond average incomes in a given organization due to the fact that the resulting customer loyalty lessens customers' price sensitivity (Okeke and Onyemachi, 2018; Stanley, Fred and Gregory, 2016). For an organisation to outperform its competitors, they must be able to build their own unique capability to differentiate its products in such a manner that allows them to compete effectively on the market (Anthony, 2018; Tanwar, 2013).

Product differentiation strategies used by business organization

(Stanley, Fred & Gregory, 2016; Thompson, 2014) stated that there are three aspects to successful differentiation: ordering a premium price for a product, growing sales due to the extra customers gained by differentiating attributes and increasing customer loyalty to its brand. They further assumed that a product is differentiated if it is perceived by customers as having features that make it discrete from competitor goods or services and preferably unique in a manner that makes it hard to compete with (Stanley, Fred and Gregory, 2016; Nolega, Oloko, William and Oteki, 2015; Al-rfou, and Trawneh, 2010). When looking at product differentiation, it is correct to say that it is not given by nature. Business firms themselves are the main agents behind the advent of product differentiation. There are times when companies are pressured to lessen the degree of product differentiation, which additionally affects the

profitability of the organizations. Organizations attempt to introduce the same features as their rivals when they discover that customers like some particular feature in the product, they sell with the aim of boosting their sales. The degree of product differentiation may fail when companies are handling products with similar features because differentiating the same product would be a greater challenge (Nolega, Oloko, William and Oteki, 2015).

Pricing Strategy

Pricing decision is a crucial decision that needs to be made at all levels by all organization and it has also posed a major challenge for top managers in these organizations. A company is set up to offer competitive prices whether complex or simple, public or private, large or small. According to Deonir, Gabriel, Evandro and Fabiano (2017), putting up a price for the products or services of an organization is one of the major decisions facing the manager and one of the most demanding because of the range of factors that need to be assessed. A number of the factors that influence pricing decision are competitors, legal, political, demand, environmental, image-related issues and cost. According to Rapaccini, (2015), the main approach to making a successful pricing strategy is to generate revenue in such a way that increase the profit margins of the firms, leading to the question; how well can we enhance the different factors influencing pricing decisions to attain our common goal, which is profit maximization (Deac, Dobrin, Girneata and Voicu, 2016).

Factors Affecting Pricing Decision

When making pricing decisions, some factors need to be evaluated, so that the choice of the decision will not have a negative impact on the firm's overall goal.

1. Cost of Production: for effective pricing decision, managers need to fully determine the total cost of production, leaving no stone unturned. They also need to determine their fixed costs as well as the variable costs and instil all other expenses that may be spent in the marketing process; transportation, sales promotion and advertising expenses.

2. Nature of market competition: knowing the nature of market competition when making pricing decisions is also essential. Competition may possibly not influence pricing decisions for an industry in a monopoly market, but it must be considered for an industry in the free market or oligopoly market where competition is tense.

3. Customers and market segment: when a manufacturer is familiar with its consumers, she can set her prices correctly. They also need to identify the market segment carefully and the price customers may be ready to pay for the identified products. For the manufacturers of phones, there are various models of phones for diverse set of persons, thereby manufacturing various types for different set of individuals.

4. Demand: for a new product, such a product needs to be strategically priced in a manner that penetrates the market, even when it is equivalent to the total cost, whereas in the case of highly demanded product, increase in prices might not have a negative impact on the demand for those products. So manager needs to analyse the demand for such products before making their pricing decisions.

5. Consumer behaviour and perception: when making pricing decisions, the behaviour and perception of consumers about the product must be taken into consideration. The company should also consider whether increase or decrease in price will result in higher or lower demand (Obigbemi, 2010).

6. Channel of distribution: the cost and channel of distribution must also be taken into account, when trying to set a product price. Manager should also consider whether the product will be delivered straight to the end user or it will have to be supplied through the multiple channels of distribution. For a product that have to be moved through the wholesaler, to the retailer and then to the end user, the incomes of these intermediaries as they are called must be taken into account, such that the retailer’s last price will not negatively affect demand (Obigbemi, 2010).

7. Company Objective: When making pricing decisions, manager need to ensure that the decision they are really making are in the line with general objective of the organization, as this will enlighten other members of the organization what the pricing objective is all about. So as to ensure that the pricing decisions made are in line with the general objective of the organization (Obigbemi, 2010; Luqman and Okewale, 2017).

Customer Satisfaction

The success of every organization depends on customer satisfaction. Customers always come "first" and then the profit when a business is about to start. Those companies that succeed in fully satisfying customers will remain in a

market's top position. Businesses today have demonstrated that customer satisfaction is a major element for achieving success in the industry and at the same time plays a major role in expanding their market share (Khadka and Maharjan, 2017). Customers are generally those who purchase products and services from a business or industry that satisfies their requirements and wishes. Customers also buy products to suit their needs in terms of cash. Organizations must therefore assess their price with product quality to attracts customer and maintain a long-term relationship with them (Khadka and Maharjan, 2017). One of the key element managers use to guarantee customer attention is delivering the best and the most satisfying products in this competitive market. If the satisfactions of customers are gained, then customer loyalty is sure to come along with it. Moreover, an organization will not be in existence without these customers. To raise the percentage of customers, it is very essential to develop customer satisfaction. These two terms are very important once it comes to achieving company objectives. Therefore, the most important is the relationship between customers and the business organization (Khadka and Maharjan, 2017).

Sales Growth

According to Kijewska (2016), deciding to grow the firm is the first and foremost strategic decision every organization must make. The political stability in Nigeria has resulted in economic liberalization, which in turn has had a great impact on operations of the company. It has also increased the competitive intensity and consumer demands in particular, especially in the manufacturing sector (Azigwe, Maryir, Asunka and Manamzor, 2016). As a result of this, many companies and organizations have made an effort to raise and develop customer trust and loyalty, which relies heavily on the behaviour of the sales representatives. (Paolo, 2002). As competition in the market becomes increasingly aggressive, the most essential thing for market players is not just to offer quality services or products, but to also retain loyal customers that will add value to their long-term success and profit margins (Kotler, 2012). As a result of this, organization need to constantly make decision on essential parameter for survival and financial growth of the company and this can be done, by creating measure in the firm in order to compete in the competitive market.

Conclusion and Recommendation

Analysis from the study revealed that marketing strategies are very essential for effective results in manufacturing companies as evidence in this research demonstrates how various marketing strategies of product differentiation and pricing strategy have a significant effect on organization strategic decision when measured by customer satisfaction and sales growth respectively. Likewise, based on the results of this research, managers of manufacturing companies should use a great deal of the product differentiation strategy as it has been proven to have the greatest impact on their competitiveness. Differentiating companies also need to look more deeply into how to make uniqueness less expensive, in an effort to make differentiation a major practice in the industry.

Furthermore, survival is a major concern for companies in the dense competitive business environment such as Nigeria. Due to high level of competition from larger businesses, this hasn't been an easy task for most manufacturing companies in Nigeria. For this reason, it is essential for managers to develop and implement appropriate strategies as this will serve as a guide to what the companies have in mind and also help define ways, they can attain their targets and objectives. They also need to consider the fact that they are within a highly competitive business environment and must implement competitive marketing strategies that are efficient and effective in order to have a strong advantage over their competitors and as well increase in all ramifications.

The recommendation to managers is that price is at least as important to consumers when purchasing products as customer service. Managers must spend equal amount of organizational resources on developing appropriate pricing strategies as is spent on customer acquisition and service efforts. Pricing must become a strategic capability within all manufacturing firms as well as other industries. Managers should recognize that differentiation strategies are ideal strategies to keep the organization competitive in the market. Therefore, coordination in terms of human and economic resources is needed to efficiently implement differentiation strategies in order to attain organizational objectives effectively.

Human Voice and Android Voice: A Comparative Study

Marek ZIMNAK

University of Lower Silesia, Wroclaw, Poland,

Email: marek.zimnak@gmail.com

Abstract

The idea of constructing androids using the human voice has become an element of the intensive development of artificial intelligence. Technological advances have made the android voice difficult to distinguish from the human voice. Such a situation may generate various dangers in the future. The author of the article prepared an experiment aimed at assessing how much people are able to judge the origin of the subject with whom they are in contact, based only on their voice. To this end, he presented samples of human voices and android voices for evaluation by participants in the experiment. Since both the ethical issues and the security issues of cooperation between the two species are not clearly articulated today, the results of this type of pilot study may have a practical dimension in the future in the context of social trust in artificial intelligence entities.

Keywords: Voice, Android, Artificial Intelligence (AI), Ethics.

Introduction

The beginning of Alan Turing's article, extremely important for the entire field of artificial intelligence, entitled Computing machines and intelligence, defines the essence of the challenge we face: Can machines think? The author specified it directly: is it possible to program an android in such a way that when talking to a person its statements are so convincing that it would not be possible to say whether this person is talking to a machine (Turing). And that was the task that the author of the presented article gave to the participants in the experiment. This is also the purpose of the article - to check to what extent we can be misled by a voice that is a very relistic copy of the human voice.

There is a strong research stream among the creators of artificial intelligence for whom the creation of a machine that the most resembles a human being has become the most important task. The ambivalence of this approach is obvious and dates back to the beginning of creating children's toys which exhibited similarity to a person. Artificial intelligence, having to implement its functionality as a competent and universal helper of the human kind, does not have to take human shapes and move, behave and speak like a human. And yet, since the end of the 1990s, that is since Cynthia Breazeal constructed the robotic head of Kismet in MIT, the attempts to bring the android closer in shape to a human being have continued. We would like to remind you that Kismet had a significant capacity for expression because it was designed to interact at a child's level, responding appropriately to people's statements and behaviours (Kaplan 186). This head did not try to "understand" what was said, but only brought out, from what and how it said, emotional overtones, or rather, it evoked emotional reactions in the form of its non-verbal behaviour. It could therefore express admiration, surprise, disappointment, shame, interest, excitement and fear, and other emotions through the movement of the head, eyes, lips, eyebrows and ears.

Over the past twenty years, more and more androids have been closer and closer with their physical shapes to a human being, while their ability to process information and communicate the results in a form adopted by people, and thus vocally or in writing, are now at a level that makes it difficult for a layperson to distinguish them from those communicated by human beings. While the results of work of android processors communicated to us in a form of text do not raise any doubts (they can be verified substantially), the situation changes when an android communicates to us something that depicts the state of its "feelings" and its use of voice is provided with human features, that is intonation, tone, phrasing, accent, etc. We stop handling the verifiable data, as in the case of text, but start dealing with the whole sphere of influence on emotions.

Cite this Article as: Marek ZIMNAK " Human Voice and Android Voice: A Comparative Study" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Du Sautoy (279) quoted a conversation between a client unaware of talking to a commercial client bot. His interlocutor is the early incarnation of Eliza the bot:

Visitor: Could I use the computer today?

Eliza: Why are you asking?

Visitor: Maybe I can conclude one more sale of telecommunications systems.

Eliza: Aren't you sure about that?

Visitor: My potential clients haven't seen the presentation of this system yet.

Eliza: Is that important?

Visitor: Of course.

Eliza: Now it seems you have no doubt.

Visitor: Please, don't make fun of me.

Eliza: What do you mean by saying "Don't make fun of me?"

Visitor: Is there a specific reason I can't use the computer right now?

Eliza: Tell more about these potential clients.

The Visitor lost patience because of evasive answers (…).

It did not take long to talk to Eliza to feel that something was wrong with its reactions. Their scope was limited, they were stiff and there was nothing to indicate that the bot remembered what was said before.

The fact that the currently constructed androids use the voice equipped with the features of the human voice in the sense of a carrier of emotion, not information, prompts a brief reflection on the position of this organ of communication in modern civilisation.

Michalik (278) asked about the ways in which voices function in culture. Development of technology makes us think about how the acoustic area in which we are present is changing, how the nature of voices that constitute it is varied. They come out of people present "here "and "now", but also telephones, radios, TV sets, answering machines, and various types of sound carriers. Artificial intelligence media, and so also androids, evoke these reactions to an even greater extent than only intuitive and thoughtless contact via a computer or a smartphone. And this changes the basically seemingly agreed interpretation of the functionality of technology, which supposedly gave us the possibilities of "how," but still did not give the content of "what." Listening to currently constructed androids, talking to them, we already know "what." However, a "what for" question remains unanswered because intelligent machines do not have this afterthought (a lack of it gives us a considerable margin of time to calm more fatalistic visionaries). Presented at Viva Technology fair in Paris in 2018, Google assistant who arranges a visit to the hairdresser conducting a conversation in such a way that it is difficult to believe that it is not a human, knows "what for", but it rather supports a trend among the creators of artificial intelligence which creates the idea of "a powered-up man" – a super unit that can do more, better and faster (Zaleśny 2018). It does not answer existential questions about the condition and vision of the future of the human species, but raises a number of questions from the border of new technologies and ethics. Can artificial intelligence impersonate a human being? Do we have the right to know that we talk to a robot and not another person? The Google assistant mentioned above, making a phone call does not inform that it is a bot, interrupts non-verbal expressions, deceiving the caller. The presentation evoked many critical opinions in the community, including Zeynep Tufekci, a well-known Turkish writer and lecturer, specialising in the field of new technologies and AI, who accused Silicon Valley on Twitter of ethical loss and inability to draw conclusions from technological development (Kania 2017) and the critical attitude to "animating" objects with the help of artificial intelligence is also manifested in her other texts (Tufekci 2015).

In this analysis, we deliberately omit a huge area of research, extremely useful – from the point of view of human health, therapy, addiction treatment, where the solutions based on artificial intelligence already used today provide the expected results. These include the research at the University of Alberta in Edmonton, where Mashrura Tasnim and her professor Eleni Stroulia developed a method of recognising depression based on the sound of our voice.

Both researchers used two sets of audio recordings of healthy and depressed people to train four different machine learning algorithms. The recordings were of various lengths – from 5 to 50 minutes. The algorithms have learned to correctly differentiate between healthy and sick people, and to correctly measure the severity of depression. In the future, researchers intend to use this method in a phone application that will record a user's voice and inform if there is something disturbing in the sound of the voice. Will we soon have a "depression meter" on our phone that will tell us how we feel, like today many of us have a pedometer on the phone that objectively shows us what distance we have covered in steps during a day? Are we so unaware of our emotions and we repress them so much that it can be universally accepted? Let's hope that is not the case. There are certainly groups for which such help would be very important, for example, people with autism spectrum (Redzisz 2019).

We have no way of controlling research directions in thousands of research centres around the world. If anyone sees development potential in the creation of an android which is an indistinguishable simulation of a person – with the voice, reactions, verbal and non-verbal behaviours, then it is to be hoped that no one will use it against mankind. Is such a construction possible? Assessing the progress so far, the answer is "yes", but these creators still face numerous problems to solve. Those grouped around non-verbal behaviour, as well as those associated with the cultural context seem to be the most difficult today. In conversation with an android, a person transmits a large part of the meaning with the elements of prosody (changes in volume and tone of expression). It is enough if we realise how many meanings we can get with one word "really?" during a dialogue with a bot. Will the android hear in it the desire to confirm previous statements, irony, curiosity or fatigue of an interlocutor? We do not know. "Who the speaker is, a field of discourse, previous context (if any at all), different voices, falling tone, the pace and the inflection complicate this task even more." (Kaplan 81). As we can see, this is about much more than grammar analysis alone can detect. That is the problem of an android which interprets our statement. But the other side of a dialogue is in an equally uncomfortable situation. The challenge posed to us by artificial intelligence is that we do not know how to describe, and thus how to understand and how to think about a phenomenon that human experience has never encountered before. A dialogue with a computational tool capable of perceiving, reasoning, building complex statements, and supporting itself with verbal behaviours modelled on a human being may turn out to be an experience with connotations far exceeding the expectations of normal civilisation – to the extent that even the concept of "singularity" understood as a belief that at some point machines will become intelligent enough to be able to redesign and improve, which will cause the so-called escape of intelligence (Kaplan 172). And it does not matter that the memory in the brain works completely differently than that inscribed in the disk that manages the activity of a bot. Construction is different, operation is different. To download the data from a hard disk, you must indicate where it is located, where it was saved. We bring memories in the brain to life by realising the reason they were recorded there.

Two researchers from the AGH University of Science and Technology in Cracow have identified the way of automatically recognising a person's needs through words, phrases, commonplaces, inflections and sentence structures that help a machine to understand and properly respond to them. Their research showed that satisfaction of a person from co-operation with the artificial intelligence system increases as the system properly relates to human needs. A person also assesses the system as more intelligent if it correctly recognises and responds to this person's needs (Tadeusiewicz, Horzyk 15). However, this is the result of the assumption of harmonious co-operation of both worlds. All that matters is the effects. "Imagine, for example, that one day we get an extremely personalised email, "phishing," trying to get us to disclose personal information. It was sent from a friend's account using AI, which, after hacking the account, impersonates our friend, imitating their writing style by analysing other emails they sent, and the message sent contains a lot of personal information about us downloaded from other sources. Could we be fooled by that? What will happen if a phishing email is allegedly sent by a credit card operator followed by a telephone conversation with a friendly voice generated by artificial intelligence that cannot be distinguished from human?" (Tegmark, 139). We can imagine much more such potential events in which, due to someone's bad will or maybe an operational error, a person, basing on the data obtained from a robot, will take action against themselves because they trusted the data processed from a huge amount of the output data that they would not be able to process in a reasonable amount of time.

Method

The attempt to answer the question to what extent a person is able to distinguish the voice of an android from the voice of a living person prompted the author to choose the survey method. A group of over a hundred students of the University of Lower Silesia, studying such specialisations as Image Management and ePR, Social Media and ePR, Media Design and Image Marketing and Creative Media were selected as respondents to complete the survey. The study was conducted at the beginning of 2020.

The choice of this group of respondents was not fortuitous. Students of these specialisations, due to both their predispositions (as indicated by their decision to choose the field of study) as well as the topics of lectures, exercises and workshops conducted with them, are significantly and above average sensitive to phenomena regarding artificial intelligence, IT applications and the impact of these areas on various spheres of social communication with particular emphasis on non-verbal communication. In the author's assumptions, completing the questionnaire by such a group was to bring the results that were expressive enough to be able to determine and describe the examined difference in the perception of two types of entities whose voices were evaluated by the respondents with a considerable dose of certainty. Random selection of the respondents from various social groups could not provide such clear answers. Also due to the homogeneity of the examined group, the respondent's particulars were omitted; all the respondents were in a similar age range of 20-30 years old, and their sex, place of residence or level of education were not of fundamental importance for the results of the survey. Therefore it was a group and anonymous survey.

The concept of an android understood as a product of artificial intelligence was not a problem in this study population, but the fact that the presented voice samples were not combined with the image contributed to abstraction of the questions asked and as such it was not an easy task (Mayntz, Holm, Hűbner 45).

The author's intention was also to separate the non-verbal features of the analysed voice samples of both people and androids from the linguistic content of the speech. Only the first ones were to be used for analysis, namely features such as speed of speech, tone, pitch, etc. In these statements they could be, and probably were, the direct content hints as to the entity pronouncing them. Therefore it was good that the voice samples available on the Internet used only English and Japanese, which significantly made text analysis more difficult for the respondents – the users of Polish. They were additionally sensitised not to pay attention to the content, but to some extent it was always inevitable – knowledge of English among the surveyed students could to some extent distort the result of such a structured study. However, it was suggested to the respondents that, for the purposes of the experiment, you could make the bots say "I am not an android" and people – reverse statements, so it was important that when making decisions about the type of the entity not to be guided by the content of the statement.

The traditional (paper) research questionnaire used was distributed to the respondents, and after completing it, collected for the results. Eight groups of students surveyed (of 7 to 20 people) as a homogeneous community filled in questionnaires in the presence of the interviewer who presented the subsequent voice samples, and the respondents gradually evaluated them.

From among five questions, the survey used twice (questions 1 and 3) single-choice closed questions, multiple choice closed questions (question 2), and closed matrix questions with one possible answer (questions 4 and 5). These were questions about the assessments, opinions and observations of the respondents, and thus referring to the way the respondents perceive certain facts, phenomena or processes (Krok, 60). All the questions were detailed and related to the assessment of the audio material heard, and the answers were intuitive. The interviewer played a sound file (each 15-35 seconds long), the respondents marked their chosen answer; in the case of questions 2 and 3 they received enough time to mark the selected option. The entire survey in a given group did not exceed 15-20 minutes, and this avoided the known effect of respondent's fatigue, which could bring the opposite effects to the expected (Rossi, Wright, Anderson, 163).

Question 1 contained a request to indicate whether the respondent heard the human voice or the voice of an android, after which the respondents were presented with six female voice samples. Three belonged to people and three to androids, and were arranged in a random order.

The available voice samples of androids came from the laboratories of various research institutes, both scientific and business, and have been presented in recent years (or months) on YouTube. They were listed below in the presented order, along with randomly selected voice files of people – women that appeared on the same website.

1. *Best Pick Up Line That Gets Women Talking*
2. https://www.youtube.com/watch?v=abWCMuFf1Fg&t=20s
   File length 4'04'' – an unknown woman's statement on the reasons for this sex to speak. File shortened to 37 sec.
3. *Erica emotional demo* https://www.youtube.com/watch?v=Qit2sxEmnxk&t=23s
   File length 1'41'' – the statement of Erica the Android in Japanese, shortened to 35 sec.

4. *Ada Lovelace: The Original Woman in Tech | Zoe Philpott | TEDxBucharest*
https://www.youtube.com/watch?v=1QQ3gWmd20s&t=92s
File length 14'01'' – Ada Lovelace's speech at a TED conference in Bucharest, shortened to 37 sec.

5. *Interview With The Lifelike Hot Robot Named Sophia*
https://www.youtube.com/watch?v=S5t6K9iwcdw&t=7s
File length 5'04'' – the presenter's interview with the android named Sophia. File shortened to 29 sec.

6. *Erica: 'I want to be more like a human'* https://www.youtube.com/watch?v=87heidlFqG4&t=186s
File length 5'26'' – Erica the Android answers (this time in English) questions from the Internet users from around the world. File shortened to 32 sec.

7. *MEETING THE ENEMY A feminist comes to terms with the Men's Rights movement | Cassie Jaye | TEDxMarin* https://www.youtube.com/watch?v=3WMuzhQXJoY&t=59s
File length 14'46'' – Cassie Jaye's statement about female-male relationships. File shortened to 30 sec.

Questions 2 and 3 concerned those features of the statements heard that determined the respondent's choice. On the other hand, in question 4, the respondents heard two female voices (two androids talk to each other), and they had one out of four options to choose from: whether it was a conversation between two people or two androids, whether the first voice was human and the second of an android, or the first voice was the voice of an android and the second – the voice of a human:

BINA48 Robot Talks to Evie the Avatar https://www.youtube.com/watch?v=HKOuJDP61NI&t=96s
File length 3'02'' – Android Bina48 talks to Evie the Avatar. File shortened to 31 sec.

And finally, question 5, the last one, in which the question sounded the same as in question 4, and we hear a man-android conversation:

8. Freaky AI robot https://www.youtube.com/watch?v=UIWWLg4wLEY&t=29s
File length 3'11'' – the presentation in the form of a short interview by Chad Cohen with Android Philip – file shortened to 16 sec.

All the files were shortened and edited with the help of *Audacity* software for the needs of the research.

Discussion of the results

The study was conducted in January and February 2020. A total of 121 students from eight different didactic groups, of varying numbers – from 7 to 21, filled in the questionnaire. These groups were undergraduate (7 groups) and master (1 group) as well as full-time (1 group) and extramural (7 groups) students.

Due to a certain result of the study (not assumed by the author of the questionnaire) separate signatures for groups studying specialisations related to Image Creation and Social Media (WS – from the words "image" (Polish wizerunek) and "social") and the other, for groups studying Creative Media (MK for Polish Media Kreatywne) specialisations have been introduced for the presentation of the results. A clear difference in the results of both these groups forced the author to reflect on its cause. To explain it, the professional profile and preferences of the respondents in both groups require characterisation. Students of Image Creation and Social Media (70 people in total), both full-time and extramural, motivate their choice of field of study in a variety of ways. Most of them are hoping to obtain formal qualifications for their interests, which range from motorisation, through sport, fashion, music, and photography to various forms of journalistic activities on the Internet (blogs, newsletters, website administration, etc.). Hardly anyone of those studying these specialisations already works in the chosen profession; in their opinion, the diploma obtained at the university is supposed to increase the chance for such work. The connection of this group with media and internet techniques is certainly above the social average, however we can imagine it, but it is rather due to age and general interests. The case is different with the Creative Media study group (51 people). These are studies closely related to the use of computer graphics for marketing purposes. Most of extramural students work in their specialisation on a daily basis and have considerable practical knowledge, and their everyday professional contact with various computer applications, programs with a much higher complexity than Microsoft Office, has caused, as the research showed, that the chances of correctly distinguishing the difference between the natural voice and the voice of artificial intelligence turned out to be much greater among them.

Complete Survey Results

The complete survey results have been presented in a table where items 2 to 7 indicate the number of correct indications for question 1 in individual groups. There is the number of the respondents in a given group in parentheses after the group reference (e.g. WS1). In items 8 to 14 the respondents were asked to indicate three features of the voice which prompted them with the correct answer – in their opinion, and in items 16 and 17 there is the number of answers to the question whether the presented voice controlled its rhythm itself or it was to some extent, according to a respondent, mechanised. In items 19-22 and 24-27 there is the number of answers to the questions drawn up in the same way, of which the first concerns two female voices and the second – two male voices. The correct variant is marked in yellow; the letter A means an android, the letter C means a human.

As we can see, the answers to question 1 showed a satisfactory average – over 50% of the correct indications. The lower average for the first voice is worth attention (position 2 in the table) – 64 percent, compared to the higher average when choosing the next voice. Listening to the first sound file, the respondents did not yet know what to expect, only the second voice in comparison with the first brought the determination of their own expectations, and with each subsequent voice these expectations were confirmed or corrected.

Table 2

Question	WS 1 (16)	WS 2 (7)	WS 3 (11)	WS 4 (15)	WS 5 (21)	MK1 (17)	MK2 (16	MK3 (18)	Aggregate 121	PERCENT
A (person)	8	4	7	12	12	9	12	14	78	64
B (android)	13	6	9	14	15	17	16	17	107	88
C (person)	16	7	9	13	19	16	16	17	113	93
D (android)	14	5	11	12	19	15	16	18	110	91
E (android)	11	6	9	12	18	16	15	18	105	87
F (person)	15	6	11	13	20	15	16	18	114	94

Percentage of correct answers in groups

And the second conclusion provided the solution to the issue of a generally high level of correct indications. The respondents had to be informed what the study was about, so from the beginning the answer to question 1 could only be zero-one (either android or human). We can imagine that any of the people asked, unprejudiced about the subject of the study, would answer the question “whose voice you hear” by “female” and the “android” variant would probably never occur to anyone.

The answers to question 2 (items 8 to 14) present the average values of recurrence of the voice characteristics heard in the audio files. The respondents, when asked to indicate three of the proposed set, most often mentioned *the sound* (61 percent), in the second place we see *the degree of tension in the voice* (44 percent), and in the third – *the phrasing* (42 percent). The voice features presented for the selection were defined and discussed before a survey participant completed it.

Table 3

Question	WS 1 (16)	WS 2 (7)	WS 3 (11)	WS 4 (15)	WS 5 (21)	MK1 (17)	MK2 (16	MK3 (18)	Aggregate 121	PERCENT
The speed of speech	7	4	2	7	7	7	4	6	44	36
The length of the pauses	9	3	3	1	8	7	8	7	46	38
Degree of tension	4	5	7	4	8	5	11	9	53	44
Diction	7	5	4	10	6	6	3	7	48	40
Phrasing	7	3	6	5	5	8	8	9	51	42
Voice color	8	1	8	12	15	11	8	11	74	61
Timbre	4	0	3	4	10	6	7	5	39	32

Percentage of voice characteristics heard in the presented statements

However, relatively small differences in the number of indications of the remaining proposed features of the heard statements (the lowest number of indications – tone of the voice, is 32 percent), and therefore the relatively large dispersion among the chosen features indicates rather that our everyday use of the voice, its reception and education around non-verbal features of statements leave much be desired. With the exception of specialised professions (actor, singer), we do not pay attention to the listed features of the voice and in their interpretation we use intuition rather than a conscious choice. Therefore, the answer to question 2 tells more about the respondents and their difficulties in correctly assessing the characteristics of the voice than about the samples presented. Such was the intention of the author of the survey; otherwise, the question about the features of the selected voice sample would have to be repeated for each sample.

On the other hand, the answers to question 3 could bring a suggestion whether the respondents, knowing that they would be dealing with artificial, crafted voices, would see in them too much of external interference, manifested in intuitively felt loss of integrity and sense of their own identity.

Table 4

Question	WS 1 (16)	WS 2 (7)	WS 3 (11)	WS 4 (15)	WS 5 (21)	MK1 (17)	MK2 (16	MK3 (18)	Aggregate 121	PERCENT
YES	10	6	11	12	15	10	13	6	83	68
NO	6	1	0	3	5	5	3	12	35	29

Percentage of responses indicating heard confidence in the presented voice samples

As we can see, almost 70 percent of the answers indicated that the presented voice (whether it was an android or a human), in the opinion of the respondents, controlled their speech, which is (probably unaware) praise of the designers of the presented androids, whose statements in the entire study were six in total compared to only four human voices. It may mean that, in the respondents' opinion, the voices heard, regardless of the species (human – android) did not differ in the control of their rhythm, which we can be indirectly read as the audible confidence of the speaking entity in the presented sample of voice.

And finally, closed matrix questions – 4 and 5, in which the respondents had to choose the right option after hearing a piece of a dialogue between two voices. It was a much more difficult task than that from question 1, as the respondents had two different voices combined in one situation, which gave them four options to choose from.

Table 5 & 6

Women voices	WS 1 (16)	WS 2 (7)	WS 3 (11)	WS 4 (15)	WS 5 (21)	MK1 (17)	MK2 (16	MK3 (18)	Aggregate 121	PERCENT
P+P	0	0	0	0	0	0	0	0	0	0

P+A	13	0	1	3	4	2	3	1	27	22
A+P	1	1	3	1	2	1	1	0	10	0,8

Men voices	WS 1 (16)	WS 2 (7)	WS 3 (11)	WS 4 (15)	WS 5 (21)	MK1 (17)	MK2 (16	MK3 (18)	Aggregate 121	PERCENT
P+P	0	0	0	1	2	1	0	0	4	0,3
A+A	12	0	1	4	4	9	4	6	40	33
P+A	1	6	5	10	11	7	10	11	61	50
A+P	3	1	5	0	3	0	2	1	15	12

Percentage of responses that accurately recognize entities in the android or interspecies dialogue

This increased level of difficulty was reflected in the results of the study. Just as two voices of female androids were recognised by 69 percent of the respondents, in the case of the human-android dialogue only half of the respondents correctly recognised the voices of participants. These indicators are significantly worse than those shown in the answers to question 1.

And finally it is necessary to refer to the result not assumed by the author of the study, differentiating the results of a group of students with a fairly general level of involvement in new media techniques (WS), compared with the results of students working with more advanced applications (MK) on a daily basis.

Table 7

Question	WS	MK
A (person)	61	69

A+P	11	0,4
Men		
P+P	0,4	0,2
A+A	30	37
P+A	47	55
A+P	17	0,6

Differences in the level of accurate answers for the groups of participants of the experiment advanced in working with more complex computer applications

A higher result has been marked in bold. As you can see, the MK group significantly better distinguished the voices of androids from human voices in question 1, achieving a result close to perfect in five out of six cases. In question 2, both groups chose slightly different sets of features, but the differences, as already mentioned, were not significant and rather indicated that the overall study population may have problems distinguishing between articulation, tone and pitch of the voice. The WS group achieved the only advantage in determining the level of control of the rhythm of speech, while in both matrix questions the clear advantage of the MK groups was again visible.

Discussion

What kind of conclusions can be drawn from the obtained results? They can be divided into two groups.

Direct conclusions

The respondents, knowing their task (distinguishing the human voice from the voice of artificial intelligence) coped with it satisfactorily, especially where it was necessary to make a zero-one decision. They did worse when they listened to the inter-species dialogue. The concern for the scale of errors could be significant if the respondents were not informed, before listening to the samples of voices, about the type of the task (I choose – whether it is the voice of a human being or an android), but this would probably contribute to the unrealistic results and undermine the sense of such a constructed study. These results are important in a situation when (maybe soon) we will commune with bots' voices on daily basis, and the question of the right decision (who I really talk to) will be important for the interlocutor. This, in turn, will depend on the legislators in different countries – whether they will be able to force artificial intelligence operators to always clearly warn a person entering a dialogue with a bot that they deal with artificial intelligence. This does not have to lead to the total elimination of cases of abuse, but then the situation would be clear from a legal point of view – the operator, without warning the interlocutor, would break a specific law and should bear the consequences.

Another aspect appearing in the background of the above results is another kind of self-defence of the human species against a bot-interlocutor, especially where the legislator does not sufficiently protect a person who, as a result of a conversation with a machine, can make decisions contrary to their own interests. It is likely that then – let's call them for the purposes of this article – "tests of truth", that is a set of behaviours, statements or questions that will allow a fairly simple and quick determination of the origin of the second interlocutor, will be introduced. Today, the creation of such tests seems quite simple, as the weaknesses of the conversation on the androids side are visible. One of them is, for example, taking on the role of the interviewer. A bot asks questions arranged in its algorithm in such a way, without losing the initiative itself, to force the interlocutor to say as much about themselves as possible, which in turn enriches the knowledge of the android with further elements that it will be able to ask about or refer to later in a dialogue.

Nowadays, in the field of computer security, the situation is beginning to resemble the 19th-century arms race between constructors of ever larger cannons and creators of ever thicker armour. Tegmark (139) claimed that unfortunately there is little indication that the defence would win.

Indirect conclusions

Attitude to the threat

Among the researchers, strongly generalising, two attitudes towards possible threats from artificial intelligence can be distinguished. There are those who underestimate the threat or they postpone its appearance until the indefinite but distant future. The reasons cited are different and depend on the adopted philosophy of civilisation development, practiced epistemological assumptions or giving adequate rank to certain technological development possibilities. John Searle proved that the computer really cannot think and understand language: because there is an ontological and philosophical guarantee that the machine does not threaten human uniqueness, so you can accept the machine and play with it (Żiżek 205). Many researchers correctly point out that computers alone cannot "think" in this sense at all because they do not really mean or do anything – they manipulate symbols at best. It is us who associate their calculations with the outside world. Searle went further, though. He indicated that even the statement that computers manipulate symbols is far-fetched. Electrons can flow through an electrical circuit, but this is us who interpret this activity as symbol manipulation (Kaplan 95).

Everett saw it similarly when analysing the essence of a statement: no matter how the grammar is presented in a given language, the whole person is involved in the language – intellect, emotions, hands, lips, tongue, brain. "Similarly, language requires access to cultural information and unutterable knowledge when we create sounds, gestures, key patterns, mimic means of expression, body movements and postures that together form different aspects of the language." – thus recalling such a number of cultural phenomena and behaviours, the number of which does not seem realistic to be simulated by any machine (Everett 311). Among the basic communication strategies, it is clearly noted that someone omits some information because they assume that they share it with the interlocutor. In a dialogue with a machine, the machine is unable to state what its interlocutor could omit. Communication failure can result from not remembering or from the very lack of a word, or more importantly, a sentence that would translate a concept that exists in one culture or mind of a person or some language into the native language of someone else. Human languages have gaps. They are not mathematical, perfectly logical codes, which brings the issue of full agreement of a

dialogue between objects to a level devoid of elemental accuracy (Ibid. 335). The unspoken is always crucial in interpersonal contacts, as there is no language without culture. Just think about how artificial the directions given by a car navigation system sound. Although IT professionals have long known that speech requires intonation, they have not yet produced a machine that can use or interpret it well – as a participant of a dialogue. The voice features, all layers of non-verbal communication supported by the content, create a structure built on stable grammar, being in this dimension unavailable today for artificial intelligence.

In fact, the simple truth according to Kaplan (175) is this: no evidence supports the view that today's technology signals the arrival of superintelligent supergiants of a technological origin. A more appropriate scope of reference, in which the promise and potential of artificial intelligence should be recognised, is perceiving it as a natural extension of long-standing efforts to automate various human activities. We can also include here intelligent machines that were designed to create painting, poetry or music. The Continuator, artificial intelligence programmed to compose and play jazz understood as improvised music, and thus being the expression of one's individuality, can create a few phrases of convincing music, but in the long run it becomes boring. It does not know where it is going. Du Sautoy maliciously wonders if "the algorithms have accidentally already been employed at Netflix and Amazon, where they mass-produce plots that hold our attention but ultimately lead nowhere." (312).

However, there is another group of researchers who do not underestimate the existence of bots in the current reality and indicate areas in which they began to play a significant role. Artificial intelligence has been employed as a serious force on social media. There, it may like people and matters, post comments, react to views contrary to those programmed. Bots can tweet insults in response to specific words, share Facebook pages, repeat slogans, sow distrust. Their influence is slowly growing. A director of a tech company said that, according to his estimates, half of Twitter users are bots created by companies that either sell them or use them to promote various issues. The conclusion is that bots distort communication, but no one knows why. The power of, for example, political arguments on social media eliminates each other; who can afford a larger troll factory, then gains a temporary advantage there. But in the meantime we have created a swamp of unreality, a world in which we do not know whether our emotions are manipulated by people or machines. A world in which, when all the news is online (which will happen) we will soon be unable to distinguish between what is real and what is imagined (Maikowski 2018). Certainly, we owe these growing problems to ever better technology. We are currently able to equip bots with large text resources, and such "bunches," as these text collections are called, have become larger and easier to obtain, as written language was increasingly available in computer-readable form (Kaplan 86). These bulk resources that the machine launches in a split second when necessary (also as needed when talking people) are overwhelming, but that is just one side of the coin. The other, completely different, is its ability to persuade, resulting from the efficiency of non-verbal communication – and here perhaps runs this impassable delineation between two entities: a human being and the machine constructed. And do we have to ask ourselves a question of whether machines feel? Maybe it does not matter; maybe it is important whether these very sophisticated, self-reproducing, adaptive devices, which we may be starting to manufacture, can inherit the Earth from us – regardless of what role we play in this process? Like many other species before, today we can simply be a stepping stone for something that we do not understand and what will come anyway (Kaplan 111). The important question, however, is not whether future generations will believe that machines are conscious, but whether people will recognise them as objects deserving moral judgment. Can we say with certainty that in the future, when this new "race" of intelligent machines will coexist with us, we will apply moral considerations that we extended to other people to certain non-biological entities, regardless of their internal psychological structure (Tegmark 190)? It is imagination and responsibility that command us, taking into consideration the social consequences, to impose "humanistic" restrictions on the "technological" impetus that we are currently experiencing. If we understood in the past what challenges were associated with social effects, technology would be so deeply rooted in our society that it would be very difficult to change its course. We see it today on the social media mentioned above. They ingrained in society before we realised how they could be manipulated in a way that undermines democracy (Wallach 2020).

Selected AI features

We can reach further conclusions as to the degree of possible communication threats by analysing the social characteristics of artificial intelligence, as determined by the researchers. The androids selected for our study certainly met Rogozińska's findings (192): "The difference between radio, television and telephone and the Internet is so large that it needs to be underlined by using the new term – "third orality," referring to communication via instant messengers and discussion forums. It is a type of text communication that has many characteristics of oral culture: it is community-based and community creating, based on participation,

involvement and emotions." According to the author, the orality of the internet statement (not paying attention to spelling and punctuation, informality, repeatability, redundancy) also has a connection with the expected speed of reaction, which in a dialogue with a human allows a bot to establish a common emotional and formal platform, thanks to which a human will feel comfortable in conversations (Ibid. 200). Let the question remain unresolved: Does a person have to feel comfortable during this action or can focus solely on the subject matter?

Harari (357) presented interesting evidence of unpredictability of the result in areas where the decision was left to artificial intelligence. Suppose we are constructing a robot whose processor is connected to a lump of radioactive uranium isotope. It will choose one of two options – pressing the right or left button – counting how many uranium atoms decay every minute. If this number is even – it will press the right button. If it is odd – the left. We can never be sure what the robot will do. But no one would call it "free," nor would it occur to us to allow it to vote in democratic elections or hold it legally responsible for its actions. Therefore paying attention to the area of freedom of artificial intelligence has a moderate sense.

And finally, let's try to place artificial intelligence in terms of that we have been using for decades: narrow and broad intelligence. The chess computer, which defeated grandmaster Garri Kasparov in 1997, could only perform a very narrow chess task and, regardless of the impressive hardware and software, and playing tic-tac-toe it could not even beat a four-year-old player. Google's DeepMind system achieves a slightly broader range of goals: it can play at a human level or better dozens of different computer games on the Atari console. In contrast, human intelligence is extremely broad, capable of mastering a huge range of skills. A healthy child, if trains long enough, can become quite good not only at every game, but also master any language, sport or profession. Comparing today's intelligence of people and machines, we must admit that humans win without a doubt in almost every field, while machines only surpass us in a small, though growing number of narrow areas (Tegmark 74).

Summary

The contradiction of views on the subject and the role of artificial intelligence in the future of the human species, as well as on the degree of danger resulting from the "escape of intelligence" is a fact, but it does not mean intellectual instability when facing the problem. Rather, it is a sign of a deficiency, a lack of a common intellectual framework that would be enough to resolve conflicting opinions, at least for now (Kaplan 91). It is important to understand what Searle did not claim. In his opinion, a player piano does not do the same as the piano virtuoso when it performs Rachmaninov's concert, even if it sounds the same. When it comes to computers – there is nobody there. Nor did he claim that a computer program can ever perform any specific task – whether it is creating beautiful images, discovering the laws of nature, or comforting someone after losing a loved one. However, he was convinced that the program simulates thinking, not duplicates the process that occurs in human minds when they engage in these activities. And this is something completely different.

It is likely that our fears about the future social role of AI are effectively shaped by job concerns. As shown by the well-known Oxford study from 2013, as much as 47% of today's jobs are at high risk of automation over the next few years and decades, and another 19% are at medium risk. The authors of the study say that only a third of today's employees can be confident about their jobs over the next decade or two (Frey, Osborne). According to this study, representatives of such professions performed by white-collar workers as engineers, multimedia artists and animators, executive directors, fashion designers, lawyers, writers, mathematicians, editors, or graphic designers may feel relatively safe. On the list of jobs at risk, in the area of manual and simpler white-collar workers, there are not included people who work mainly in the service sector, where direct contact with clients is an essential component of their duties, but in which observation or expression of human emotions is important, such as waiters and waitresses, police officers, administration employees, teachers, real estate agents, sales consultants, clergymen, controllers and nurses (Ibid.).

It is worth asking the question which "human" features these highly specialised computers with enormous computing power lack to be able to replace people in these professions based on such broadly understood emotional and non-verbal communication. From a technical point of view, when making decisions, a machine that works on the basis of tools uses "utility functions." These are formulas used by systems for data synthesis, variable balancing and maximising benefits. Ultimately, the decision path that gives the most rewards is the path that systems learn to choose to accomplish their tasks. However, these methods turn out to be insufficient for the future AI systems to enable them to operate autonomously, as human values, sometimes in a very short time and under the influence of a temporary stimulus, can clearly change. Ultimately, a Finnish artificial intelligence researcher Kaj Sotala explained that utility agents are too simple

and do not reach the root of human behaviour. "Tool functions describe behaviour rather than its causes ... they are rather a descriptive model, assuming we already know roughly what a person chooses." Although the descriptive model may recognise that people prefer to save money, it does not understand why, and therefore will not be able to predict or determine when other values, for example, the need for security, replaces "saving money." Suppose, for example, that an AI computer learns that people want to be happy, and trying to maximise human happiness, connects our brains with computers that provide electrical stimuli that give us a sense of constant joy. "In this case, the system understands that people value happiness, but there is no appropriate model for how happiness corresponds to other competing values such as freedom. In some ways, it makes us happy and eliminates all suffering, but at the same time people feel that "no, I didn't mean it when I said that AI should make us happy," noted Sotala (Creighton).

As artificial intelligence gets closer to the goal of full production of autonomous agents, the need to answer several questions increases, and the question of how to design and implement an artificial agent equipped with an ethical system is becoming more urgent. Machines with autonomy and the ability to do things useful for people will also have the ability to do things harmful to people and other sentient beings. This is not only a technological challenge, but also a philosophical one: What moral means should artificial intelligence be equipped with? The answer is not easy, because of the controversy among experts in ethics about the moral theory itself, computational limitations and the forms of implementation of these theories. Human actions involve immoral aspects that should not be implemented in machines, but moral perfection may not be computationally achievable, which can lead to threats harming people. "Development of machines with sufficient intelligence to evaluate the effects of their operation in such an aspect may ultimately be the most important task for designers of intelligent machines." (Allen et al. 260). The dispassionate assessment of all this disagreement between experts leads to the conclusion that the singularity, if anything ever happens, will most likely not occur in the near future and we will have many warning signals before it happens, and thus enough time to take appropriate corrective action if we deem it reasonable.

The race leading to the creation of AI has begun and we have no idea how it will develop. However, this should not stop us from wondering what consequences we want because what we want will affect the result. "What do you prefer and why," asked Tegmark:

- Do you want superintelligence to be created?
- Do you want people to still exist, something to replace them, to become cyborgs and/or emulated?
- Who is to take control: people or machines?
- Do you want artificial intelligence to be mindful or not?
- Do you want to maximise positive experiences, minimise suffering or leave these things up to chance?
- Do you want life to spread in space?
- Do you want civilisation that pursues a higher goal that you also share, or do you mind the future life forms suitable for us, even if you think their goals are senseless and trivial?
  (Tegmark 210)

Whatever the answers to the above questions may be, the scientific, technological and social community gathered around the emerging artificial intelligence is trying, on behalf of all of us, to formulate the principles of its development. The 2016 conference in Asilomar, California, during which perhaps the most comprehensive assessment of both the current state of development and development perspectives ended with the definition of a rather long thematic list, which in the form of paragraphs proposed for future legal codes tries to deal with the most important threats and issues of co-existence of the two systems. Let's list some of them that are important from the point of view of the subject of this article:

Security: Artificial intelligence systems should be secure and protected throughout their lifetime and verifiable whenever possible.

Error transparency: If an AI system is causing harm, it should be possible to determine why this is happening.

Human values: Artificial intelligence systems should be designed and applied in a manner consistent with the ideas of human dignity, rights, freedoms and cultural diversity.

Human privacy: People should have the right to access, manage and control the data they create, given the ability of artificial intelligence systems to analyse and use that data.

Freedom and privacy: Applying artificial intelligence to the personal data cannot unreasonably limit people's real freedom or what they perceive as freedom.

Human control: People should have the right to decide if and how artificial intelligence systems can be able to make decisions aimed at achieving goals chosen by people.

Prohibition of subversive activities: The power that gives control of advanced artificial intelligence systems should respect and improve social and civic processes on which healthy society depends, not violate them. (A Principled AI Discussion in Asilomar).

Today, all creativity in generated computer systems is initiated and driven by a code that is a manifestation of humanity. Machines are not forced to express themselves. They seem to have nothing to say, except for what we suggest. They are a ventriloquist doll, a tool for our desire to express ourselves. And this creative momentum is an expression of our faith in free will (Du Sautoy 327). The results of the study, which has been the inspiration for the above content, are also compatible with these desires.

Abstract

In recent years, the financial crisis has led to a global impact, affecting the performance of banking system. For the countries which implemented dual banking system, the extent of the impacts in both systems might not be similar because of the characteristics of the banking system structure. Thus, this paper aims to assess the impact of financial crisis and bank risks on deposit variation in Malaysia Islamic banks. The impact of the crisis will be evaluated by a dichotomous variable, which aims to assess level of deposits during the crisis period. Using 15 Islamic banks in Malaysia spanning from 2008 to 2016, with 135 observations, panel data estimation technique is applied. Finding shows that the financial crisis has deteriorated the level of deposits in Islamic banks. It implies that Islamic banks might face a panic attack when crisis happened. This has led banks for not been able to survive during financial crisis as there are huge amount withdrawals of the deposit. While, two major bank risks which are credit and bank risk are used to test whether they can significantly variate the deposit in Islamic banks have reveal a clear indication to Islamic banks that undertaking risks will let to the losses in their deposits. Thus, further actions should be taken to by Islamic banks to overcome the impact of financial crises and bank risks problem.

Keywords: Financial Crisis, Deposits, Bank Risks, Panel Data.

Introduction

Financial crises are considered as one of the most important financial events in recent decades. The financial crisis has impacted the financial institution in particular banking institutions worldwide. In fact, a wide array of impacts to the operating and financial performance of the banks has occurred globally (Smolo & Mirakhor, 2010; Kassim & Majid, 2010). Thus, number of fundamental questions on banking institutions has been raised. It creates challenges to the developed and developing countries in managing the risk management of the crisis. However, there are number of studies, such as Smolo and Mirakhor (2010), Kassim and Majid (2010), Ahmed (2010) and Zuriyati and Nurul Huda (2017) show the impact of financial crisis on banks and number of experts in Islamic banks have even claimed that Islamic banks are either less or not affected by the financial crisis.

Financial crises could affect the financial stability and promote the deterioration of the banking indicators. This is due that the banks hold a small amount of cash deposits and in case of unexpected deposits withdrawals will affect their liquidity. Prompting the emergence of a financial crisis, bank panic can affect the entire banking system. Bank risks also may arise during financial crisis (Zuriyati et al., 2018) and exacerbated the bank conditions. Among the major risks in the banking system are credit risk and liquidity risk. These risks are directly linked to what banks do and why bank fails (Ameni, Hasna & Mohamed Ali, 2017)

The decrease in deposit during the financial crisis might bring a negative impact to the bank. Firstly, it will create an intense deposit competition among banks and leading to higher cost of deposits as well as causing the bank to have thinner margins. Secondly, when deposit is weaker the source of the bank funding might also affect and the operation of the bank activities as well. This is because when source of funding and bank liquidity drop, the confident level of customer toward the bank will also decrease. The conflict between customer and banks will arise and slightly affect the bank profitability. Wiranatakusama and Duasa (2017) stated that the level of resilience of Islamic banking can be determined by bank deposit and financing. As bank deposit is one of the major sources of bank liquidity and it can

Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

be affected by any changes from the global economic event and led to the problem of Islamic bank resilience. Thus, this paper aims to assess the impact of financial crisis and bank risk on deposit variation in Malaysia's Islamic bank.

The remaining of the paper is organized as follows. Section 2 discusses the literature review. The methodology under consideration will be highlighted in section 3. Section 4 discusses result and discussion. Lastly, section 5 offer conclusions.

Literature Review

There is substantial literature in the area of financial crisis. Earlier works such as Hasan and Dridi (2010), Abdulle and Kassim (2012) Shafique et. al (2012), Hidayat and Abduh (2012), Zuriyati and Roziani (2014) and Zuriyati and Nurul Huda (2017) have explored several dimensions of Islamic banks behavior during financial crisis. Hasan and Dridi (2010) reveal that the recent financial crisis affected Islamic banking institutions differently than conventional banks. Studies by Abdulle and Kassim (2012), Shafique et. al (2012) and Hidayat and Abduh (2012) show the Islamic banks are more stable during global financial crisis. While, Hidayat and Abduh (2012) conduct the study in the case in Bahrain found there is no significant impact to influence the Islamic bank performance during the crisis period. Zuriyati and Roziani (2014) and Zuriyati and Nurul Huda (2017) found financing in Islamic banks are not affected by the crises. Nonetheless, Uppal and Mangla (2010) reveal a contrary result. They examined the experience of Islamic banks of two countries, Pakistan and Malaysia) and found that the Islamic banks in the country "were not immune from the ravages of the global financial crisis" to the financial crisis.

Concentrating on the impact of financial crisis and bank deposit, Abduh, Omar and Duasa (2011) investigates in the case of Malaysian Islamic banks. Using Johansen cointegration test, it shows that financial crisis has a positive impact on fluctuation of Islamic bank deposit level in Malaysia. This study claims that the previous financial crises during 1998 and 2008 had given an opportunity to Islamic Banking to become more resilience on gaining customer trust in managing their deposit. The high expectation from customers has led Islamic banking to have less impact on financial crisis compare to conventional bank. Therefore, whenever the crisis emerges, depositors will not withdraw their money subsequently instead will deposit more in Islamic banking. While, Turhani and Hoda (2016) found macroeconomic crisis has a positive relationship on the level of deposit. The research indicates that financial institution performance showed a positive relationship during the financial crisis due to compliance policy between a commercial bank and central bank. Thus, deposit insurance also becomes one of the reasons why performance level of total deposit in banking system in Albania had improved even during financial. Finding by Ferrouhi (2017) also has been supported by Turhani and Hoda (2016) where financial crisis is not found to be a major impact on deposit behavior in Morrocco.

Concerning the impact of bank risks and deposit behavior, many studies (Andriyanti & Wasiah, 2010; Harfiah, Purwati & Ulfah, 2016; Yulianto & Solikhah, 2016 and Pimada, Mawardi & Herianingrum, 2017) have done in the case of Indonesia. Andriyanti and Wasiah (2010) for example study on deposit level (Mudharabah deposit for the period of one month) at Bank Muamalat Indonesia. Bank liquidity risk is found to be an indication of the impact of liquidity risk on the bank deposit. If the liquidity risk increases the deposit bank of one-month Mudarabbah in BMI will also decrease. Andriyanti and Wasilah (2010) stated that high FDR of banks can be interpreted that the bank's liquidity is low. This is because the higher the bank's FDR, the bank's risk to problem financing will also rise. Therefore, it led to withdrawal of deposits by depositors simultaneously and in large quantities. While, Harfiah et al. (2016) reveals that liquidity risk has a positive and significant effect on bank deposit influence the level of bank deposit of Islamic banks in Indonesia when they tested using seven Islamic banks in Indonesia It indicates that when liquidity risk is high, mudharabah deposit will increase in a similar magnitude.

Yulianto and Solikhah (2016) attempt to determine the internal factors of sharia banking to predict the Mudharabah deposit in Indonesia. This study proposes hypotheses whereby both liquidity and credit risk have negative influence on the amount of deposits mudharabah. 34 banks are selected and cover the period of January 2010 until December 2013. The credit risk shows a negative and significant impact in influencing mudharabah deposit. Meanwhile liquidity risk has a contradict result to credit risk as it is positive but insignificant in affecting the mudharabah deposit in Indonesia. The higher ratio of risk led to high unemployment that recorded by the country in recent years which cause more financing defaults faced by bank. Another study in Indonesia, Pimada et al. (2017) examine the impact of liquidity risk on Mudharabah deposit reveal a similar finding with Yulianto and Solikhah (2016). It is found the higher liquidity risk will influence mudharabah deposit in Indonesia. The positive result is obtained due to the number of Indonesian's financial literacy and financial inclusion keep increasing and people start to gain awareness on how important the function of liquidity risk nowadays.

A comparison in fluctuation of deposit in Islamic bank in Malaysia and Indonesia has been highlighted by Noraziah and Dety (2017). Using generalized method of moment (GMM), this study found that credit risk has negative effect with both deposit of Islamic bank in Malaysia and Indonesia. The study claims that when Islamic banks experienced a higher risk, the performance of Islamic bank deposit will decline. Noraziah and Dety (2017) stated that when relationship of credit risk is negative it showed that the problem that faced by Islamic banks is bigger and can led to unhealthy performance for the Islamic bank. On the other hand, Turhani and Hoda (2016) found that the level of liquidity risk gives impact on the level of deposits in banking system in Albania. The higher level of liquidity risk, the reliability of depositors in the banking system will be shaken. This is due to the role of liquidity is seen as guarantee to depositor to preserve their deposit in when the banking system faced a negative trend.

Methodology

Deposit of Islamic banks is the primary concern of the study to be affected by the financial crisis. While this study also focusing the impact of credit and liquidity risk on deposit, therefore the impacts of these variables need to be controlled. The effect of aforementioned risk factors therefore could be isolated. This is to show the more realistic model the controlling variables are also included. Thus, the estimating model is respectively written as follows:

$$DEP_{it} = \alpha - \beta_1 CR_{it} + \beta_2 LR_{it} + \beta_3 BSit + \beta_4 PR_{it} - \beta_5 UR_{it} - \beta_6 FC_{it} + \varepsilon \qquad \text{Equation 1}$$

Based on Equation 1 DEP represents total deposit from customers in Islamic banks, α is a constant, β represents the coefficient of the variables. CR indicates the credit risk which is represented by non- performing loans. LR is liquidity risk. It is calculated based on the total liquid asset per total deposit acts as a proxy for liquidity risk. BS indicates the bank size representing the total bank asset and PR is the profit rate. UR represents the unemployment rate of the country at the same time showing the economic condition of the country. FC shows the financial crisis is a dichotomous variable. 1 will be indicates if the financial crisis happened and 0 will indicates year without financial crisis. Lastly, Ɛ shows the idiosyncratic error.

This paper uses 15 Islamic banks spanning of nine years from 2008 to 2016, with 135 observations. Due to the characteristic of data under observation itself, panel data estimation technique is more appropriate to be applied. The panel data model has the advantage of handling data limitation and control heterogeneity among variables. Moreover, this estimation technique is appropriate to test more complex behavioral models.

The model specified in equation (1) serves to test the impact of financial crisis and bank risks on deposit behavior of Malaysia's Islamic banks. The models are estimated in three different approaches. Firstly, the model is estimated using panel least square method and test for the pooled ordinary least square regression (POLS) model. POLS is considered to denying heterogeneity or individuality among banks. Thus, the model is assumed to be a constant intercept without explicitly contain an unobserved effect. However, not controlling for this unobserved individual specific effect leads to bias in resulting estimates. Since individual effects are treated included in the model the study should have treated them to Random effect model (REM) and Fixed Effect Model.

For modelling the relationship among bank Islamic bank deposit and bank risks, financial crisis and controlling variables following bank specific data are collected from Eikon and financial statement of annual reports from Malaysian Islamic banks. Meanwhile the macroeconomics data is collected from Bank Negara Malaysia report.

Findings

In order to ensure the robustness of the result, series of diagnostic tests such as multicollinearity and heterocedasticity are conducted. Variance inflation factor (VIF) for example is carried out to confirm the existence of multicollinearity problem Multicollinearity statistics reliable measure to calculate the validity of regression analysis. The Variance Inflation Factor (VIF) and tolerance level are calculated in Table 1. As suggested by Gujarati (2007) the VIF value should be under 5 and the 1/VIF value should be nearer to zero. In order to ensure the analysis to be valid, these conditions need to be met. As shown in Table 1 VIFs of variables are under 5 and 1/VIF values are nearer to zero. The results indicate the absence of multicollinearity in regression analysis. VIF is found to be 1.18 less than 5 threshold. There is absence of multicollinearity problems in the model.

Table 1: The Vector Inflation (VIF)

Variables	VIF	1/VIF
CR	1.07	0.938952
LR	1.12	0.891951
BS	1.15	0.870831
PR	1.09	0.914101
UR	1.23	0.810324
FC	1.41	0.711302
MEAN VIF	1.18	

The problem of heteroscedasticity exists when size of error term distinct across the values of the independent variable. The Breusch Pagan or Cook-Weisberg test is applied to ensure the problem does not exist. The rule of thumb in testing for heteroscedasticity problem is when the probability value is less than significant level of 0.0.5. The result obtained shows that probability value is 0.000. Therefore, there is heteroscedasticity problem exists in this study. Chi^2 (1) = 21.30 Prob > chi^2 = 0.0000. However, following Stock and Warson (2008), the heterocedasticity problem can be dealt using heterocedasticity robust standard error method.

After the series of the test, the results from the models are compared in Table 2. In order to choose, which model is estimated the best, Breusch Pagan test is used to test whether POLS and REM is more appropriate. It is found that the validity of the result is more to Pooled OLS, thus the results will be analyzed based on this model.

Judging from the result obtained in Table 2, the R squared of regression model is 0.6767 which indicates that 67.67% of the variation in total deposit can be explained by financial crisis, bank risks and controlling variables used. The finding shows credit risk and liquidity risk are in the expected magnitude. These bank risks have negative effect towards Islamic bank deposit. Moreover, it is revealed that credit risk has a negative and significant relationship with total deposit where p-value for the credit risk is 0.00. A change in credit risk, will led to reduction of the total deposit of Islamic banks as found in Yulianto and Solikhah (2016) and Noraziah and Dety (2017). It implies that if the problem of credit risk is bigger it can lead to unhealthy performance for the Islamic bank.

Table 2: Result of the Models

Variable	POLS		REM	
	Coefficient	t stat (p value)	Coefficient	z stat (p value)
C	16.5267	17.81 (0.000)	16.6178	36.80 (0.000)

While, liquidity risk also shows that there is negative and significant relationship with total deposit is significant at 1% significance level. The result obtained reveals that an increase in the liquidity risk will reduce the total deposit. The result is in parallel with Andriyanti and Wasilah (2010) and Yulianto and Solikhah (2016). This situation happens due to when ratio of liquidity risk is higher, it will reduce the capability of liquidity of bank whereas depositor might withdrawal their money thus it leads to decrease in amount of deposit in bank.

The result for bank size is significantly positive with the total deposit at 1% of significant level. Similar magnitude is found in parallel with Ferrouhi (2017) and Andriyanti and Wasilah (2010). The larger the amount of bank assets, the greater the amount of bank deposit. In other word, larger bank can able to encourages and attract more customer than smaller bank to put their deposit. The positive relationship can be explained as large bank size has stronger financial base as well as the bank performance and the exposures of bank risk is more than bank that have smaller bank size. Besides, depositor feels more secure when bank can manage to paying depositor funding.

This study also reveals that profit rate is insignificant to the total deposit. It shows that profit rate has negative relationship with the amount of deposit where 1 percent increase in profit rate will reduce the total deposit. The assumption from negative relationship between profit rate and total deposit can be assumed where depositor from Islamic banks are not motivated by profit and profit rate are not bring greatness affect towards customer when invest their money (Akhtar, Akhter & Shahbaz, 2015). Depositors might withdraw their money or not putting their money even though the profit rate that bank offer is high which lead to decrease in bank deposit. In addition, the result found that the p-value of unemployment rate is 0.0433 where it shows an insignificant and positive relationship between unemployment rate and total deposit.

The major highlight of this study is the impact of financial crisis on the total deposit. In comparing with previous finding on the bank performance (Hasan & Dridi, 2010; Abdulle & Kassim, 2012; Shafique et. al 2012; Hidayat & Abduh, 2012; Zuriyati & Roziani, 2014; and Zuriyati & Nurul Huda, 2017) the result of financial crisis reveals a really significant impact on total deposit at 1% level of significance. A negative relationship is found when financial crisis happened and it will reduce 0.348% of total deposit. The result obtained in this study is in contrary with previous literature (Abduh, Omar & Duasa, 2011, Turhani & Hoda, 2016 and Ferrouhi, 2017) as it is found financial crisis is significant with total deposit. The highly significant impact is assumed bank faced a panic attack when crisis happened and this has led for customer not able to survive during financial crisis. The withdrawal or not investing in deposit in banks will lead to decline in amount of money. Besides, for the smaller banks, they will experience lower risk exposures and unable to manage efficiently the performance of banks during that time.

Conclusion

This paper attempts to assess the impact of financial crisis and bank risks on the deposit variation in Islamic banks in Malaysia. Two major bank risks which are credit and bank risk with financial crisis are used to test whether they can significantly variate and distort the deposit behavior in Islamic banks. It is found that both risks have significant impact on the depletion of deposit in Islamic banks. The finding shows credit risk and liquidity risk are in the expected magnitude. This result reveals a clear indication to Islamic banks that undertaking risks will let to the losses in of total deposit from Islamic banks. While, as claimed by many researchers that Islamic banks are immune to financial shocks, this paper reveals a different finding which Islamic banks deposit will be distorted by the financial crisis. The highly significant impact of financial crisis will lead to higher withdrawal of money and lower total bank deposit. Islamic banks need to be caution on the global event that can create problems to their total bank deposits.

Work Life Balance and Remote Working during the Pandemic: Assessment of Parents' Working Conditions in Polish Reality

Malgorzata MARZEC

Jagiellonian University, Krakow, Poland
malgorzata.marzec@uj.edu.pl

Abstract

The study analyzes the issue of reconciliation of private and professional life during the COVID-19 pandemic. For some time now, problems in reconciling work and private life have been noted. The global lockdown has forced workers and employers to change the conditions and the manner in which they work. At the same time, many parents were confronted with the need to reconcile professional work with parental responsibilities in a situation where educational institutions could not provide direct childcare. Parents had to perform their family duties during standard working hours with additional tasks resulting from home education, the required social isolation and childcare. During the pandemic, a strong blurring of boundaries between professional and private life and problems of symbiosis of professional and family duties has taken place. The aim of the study is to indicate the importance of the idea of Work Life Balance in the perspective of changes in the labor market caused by the Covid-19

Keywords: Work Life Balance, COVID-19 pandemic, labor market, remote working

Introduction

The global problem that modern organizations face is the extension and intensification of employees' working time. The problem at hand is subject to numerous analyses, including through the development of the Work Life Balance (WLB) concept; (Directive EU2019/1158). The WLB concept refers to the management of working and leisure time in order to maintain a balance between two aspects of human life – work and personal life. The imbalance between the various aspects of employees' lives has a negative impact on work efficiency and lack of life satisfaction, which in turn may have a negative impact on both the quality of professional duties performed and the way families function, which may lead to a conflict in combining professional and family roles. The pandemic challenged the working conditions and the way work is organized in all areas of the economy. Around the world, employers and employees have been adapting to the need for social distancing measures. The word flexibility (balancing, reconciliation) between work and family life has been redefined. The introduced WLB Directive was a major step towards a healthier way of life for workers at a time when technology was increasingly bringing work into the home. However, no one thought that the proposed idea would be implemented so quickly. The arrangements concerning work during the pandemic have shown how to balance work and private life by using technology that is already at our disposal. The question is, however, whether employees who combine work and parental roles have the right conditions for combining work and private life created for them? Here, the role of the state's instruments (tools) will be important in order to protect those who are most burdened with parental duties / tasks. At present, it is no longer just a matter of ensuring a balance between private and professional life, but also of promoting new rules for functioning of the labor market. In the literature, you can know studies on remote work (telework)(Karczewska,2019; Lescevica & Kreituze , 2018) and a description of idea of Work Life Balance (Crompton & Loynette, 2006; Dolot, 2020; Piecuch&Szczygieł, 2019). However, there are no studies linking the importance of remote work with the performance of parental responsibilities. Additionally, in the new pandemic situation, the problem requires a new analysis and description. Observing the changes in the labor market and the pandemic, a research problem was identified, the aim of which was to determine how working parents combine childcare during a pandemic.

It is important to track the changes in the labor market from the point of view of the idea of Work Life Balance in the perspective of different countries, so that different experiences, instruments / tools used in the labor market can be shared.

Various research methods were used in the study, including mainly descriptive methods, comparative methods and the CAWI (computer assorted Web interview). The results of a nationwide survey, which was piloted and conducted

among parents working remotely during the pandemic, are presented in Poland.[1] The main aim of the study is to indicate the importance of the idea of WLB in the perspective of changes in the labor market caused by the Covid-19 pandemic The article is a contribution to the global discussion on the problem of work-life balance, especially for employees who are parents. The query of literature, legal acts, analysis of publicly available statistical data and the results of own research made it possible to achieve the aim of the article and to draw conclusions.

Work Life Balance and Remote Working

The contemporary problem of various organizations and the whole economy is the extension and intensification of employees' working time. There are changes in the labor market which are blurring the boundaries between professional and private life and the lack of free time related to family life, social life and leisure. People spend more and more time working, which affects the way people function in the private sphere. (Sadowska-Snarska, 2007). Work provides a person with a certain social and economic position so that they can meet different needs and experience recognition and acceptance in society. Many key decisions in a person's life, related to the choice of education or place of residence, are centered around work. It is often thanks to work that a person has the opportunity to establish social contacts and build interpersonal relations, which often go beyond professional relationships and are formed on a private level. But work should not be the only source of meaning in human life. Work life should be reconciled with the personal sphere, including family duties, but also free time used to regain strength and improve health, and for personal development.

Active professionals face many difficulties in combining family and professional roles. Employed women are in a special situation here, as they are still burdened by the stereotypical duty of caring for children. Traditionally and culturally, there is a conviction that the professional fulfilment of women should not take place at the expense of the family. Many women consciously choose to combine work and family life. There is a structural and cultural conflict that puts women at two polar opposites – from demobilization of women on the labor market to limiting procreation decisions. The structural conflict is related to the mismatch between institutional solutions and women's professional work. In turn, the cultural conflict results from a different understanding of the social roles of women and men, including the relationship between women's professional work and the family. (Urbańska, 2015, p.88)

For several years now, discussions have been taking place on the development of policies to promote reconciliation of professional and private life. The concept of human resources management has become popular, the main aim of which is to find a balance between work and private life. The background to this reflection is ensuring equality between women and men and economic and demographic change in the labor market. (Borkowska, 2011, pp.22-23) The work-life balance is a multidimensional phenomenon. This trend emerged in the late 1970s and early 1980s in the USA and the UK, when regulations limiting weekly working hours came into force. It was then that attention began to be paid to the role of leisure time in the development of individuals, businesses and societies as a whole. The reasons for the idea are sought in social and cultural changes related mainly to the entry of women into the labor market and the need to apply a new division of household duties. The main idea behind this concept was to support employees in combining work and private life. It has been pointed out that a harmonious coexistence of both areas of human life allows to achieve better results than limiting one of them. A satisfied employee is more effective, enjoys work and private life, is resistant to stress, is less ill, but also has convenient conditions to perform family duties and improve the quality of their life.

In 2019, the European Union developed a directive on work-life balance for parents and carers, known as the Work Life Balance Directive. (Directive (EU) 2019/1158) The regulation introduced aims at finding solutions useful for working parents and carers so that women and men have equal opportunities in the labor market and have the possibility to reconcile work and family life. The legal act regulates the issues of employees' access to flexible working conditions, and introduces and expands the existing legal regulations on the use of parental, paternity and partner leave and leave due to force majeure in urgent family matters caused by illness or accident. (Siemienkiewicz, 2020). The introduced regulations were designed to draw attention to the role of men in participating in part of their caring duties. Measures have been taken to change the perception of the role of a woman as a carer and a parent taking on a significant part of the parental responsibilities, with shaping a new model of a woman and new rules of functioning of modern families in mind. The aim of the work was also to prevent women from withdrawing from the labor market and to counteract the professional inactivity of women, in response to the demographic changes of ageing European societies.

[1] Author of the study: A. Szczudlińska-Kanoś, M. Marzec, Institute of Public Affairs, Jagiellonian University. The research was conducted on a random group of 80 people between May 15 and June 15, 2020.

One of the planes that helps to maintain a balance between the private and professional lives of parents and carers is flexible organization of work. Parents of children under 8 years of age have been given the possibility to benefit from flexible working time arrangements under conditions of protection against dismissal and discrimination. (Directive 2019/1158, Article 9) Flexible working time provides opportunities for remote working, as well as the introduction of variable working time schedules or reductions in working time (Labor Code Article 3 sec. 1 item f). So far, Polish legal regulations do not provide for special rights for working parents to introduce remote working, only the regulations concerning teleworking, which are part of the idea of flexible organization of work performance, are in force (Labor Code, Article 67; Siemienkiewicz).

During the pandemic, both companies and employees quickly adapted to the new working conditions. The imposed requirements for social distance have led to the use of remote forms of communication using different tools in all possible areas of the economy and the society. In many areas, remote working on a permanent basis became necessary and required the development of new rules for fulfilling professional duties. Parents were faced with the difficult task of reconciling work in the new conditions with childcare. The idea of WLB requires a redefinition and a new look at the possibilities of reconciling professional and private life. It is interesting to point out how working in new conditions – during a pandemic, can affect the symbiosis of work and private life.

Working Conditions During a pandemic.

The development of modern forms of communication has led to changes in the scope of work performance. Today's workforce, equipped with modern technologies, is ready to work anywhere. For some time now, literature has described the concept of remote working or telework. In 1997, the European Commission recognized that teleworking will become a part of professional life and initiated the European Telework Development to raise awareness of teleworking issues and support development in Europe (Nojszewski, 2004; Belzunegui-Eraso, Erro-Garces, 2020). There is a wide range of new, flexible ways of working, including the possibility of partial relocation outside the traditional office. There is no commonly accepted single definition of teleworking, it can be defined as a type of work and/or service provided remotely, at a distance and online using a computer and telematics technologies (Belzunegui-Eraso & Erro-Garces & Pastor-Gosálbez, 2013). According to the International Labor Organization, teleworking is work that utilizes information and communications technologies (ICTs), such as smartphones, tablets, laptops and/or desktops to perform work outside the employer's premises. (Telework in the European Union, 2010) In practice, teleworking enables employees to work from home or other premises using appropriate information technology. (Hraskova & Rolkowa, 2012, pp. 39 -42). According to the European Commission, remote work is “the form of organization and / or performance of a work, whereby an employee can carry out work that could also be carried out at the employer's premises regularly out of these premises through the use of information technology” (Lescevica & Kreituze, 2018, p. 174).

Today, many workers, but also employers, appreciate the possibility of flexible working hours and remote working, paying more and more attention to the possibility of reconciling work and family responsibilities. (Olson, 1983) In the current conditions of the pandemic, no one is able to accurately estimate the changes that will occur as a result of the popularization of work using various tools of modern communication and information transmission.

In Poland, WLB is slowly being popularized and tools for reconciling professional and private life are being introduced. Poles work a lot and feel overburdened in quantitative and qualitative terms. In addition, they often work overtime and admit having problems related to reconciliation of work and private life. (Pieluch, Szczygieł, 2019, p. 16; Bartkowiak, 2009, p. 47; GUS 2020, Liszka, Walawender, 2019). During the pandemic, Polish parents had the opportunity to use different tools applying the WLB idea.

The COVID-19 epidemic began in November 2019 in China. Initially, it seemed that the problem only affected one part of China. However, in March 2020, the World Health Organization (WHO) announced a state of pandemic, seeing that the virus was spreading worldwide and the number of people affected was increasing. In Poland, in mid-March, all educational institutions were closed down and restrictions on the functioning of many areas of the economy were introduced (shops, cultural institutions, state and local government offices, etc.), and regulations on maintaining social distance were introduced. An attempt has been made to adapt working conditions to the new conditions. According to Polish analyses from June 2020, the COVID-19 epidemic brought negative effects in the sphere of employment. One fifth (20%) of those employed are working reduced hours and three in a hundred (3%) have lost their jobs during the pandemic. Moreover, one fifth of Poles (21%) worked remotely (from home) (CSO Report from June 10, 2020). Only one twentieth (5%) of the employees used the care allowance to take care of children. Due to the epidemic, 7% of people lost or closed their own businesses and a quarter (25%) experienced unfavorable changes in their earning opportunities due to reduced working hours or reduced activity of their company. (CBOS NEWS Newsletter 19/2020)

Remote working during the pandemic made it possible to reconcile work and family responsibilities, but at the same time the boundaries between private and professional life were blurred. It is important to follow developments in the labor market and to continuously monitor the tools for reconciliation of work and private life in line with the WLB concept.

Evaluation of working conditions during the pandemic. Analysis of own research.

On the basis of the literature query and in the new situation of the labor market during the pandemic, it was decided to conduct pilot research. The main aim of the research was to assess and analyze selected aspects of the WLB concept in families with children during a pandemic. The research conducted was of quantitative nature. The selection of the test sample was deliberate. The research was addressed to people working remotely, who looked after children and performed their professional work during the pandemic. The research was anonymous and participation was voluntary. It should be noted that the research was carried out in the form of an internet survey (CAWI) between May 15 and June 15. In total, 80 people participated in the study, including mainly women (92%), people between 31 and 50 years of age (31-40 years of age – 34% and 41-50 years of age – 58%), residents of large cities (100,000 and more – 70%), taking care mainly of two children between 2 and 15 years of age and working professionally for 10 to 20 years (work experience from 11 to 20 years – 69%, work experience from 21 to 30 years – 22%). The characteristics of the research sample do not give grounds for conclusions for the whole population of Poland, as it is not representative. However, the selection of the pilot sample provides the basis for demonstrating general trends and describing the problems of combining remote working and family life in the WLB perspective during the pandemic. In recent years, remote working has been gaining in popularity and has been a privilege for many employees, but it turns out that for most of the respondents such a system of work was a new experience. Only 10% of the respondents were working in a remote system, while 56% of them had no experience with working at a distance using various forms of communication. Such an arrangement of answers characterizes the Polish conditions of remote working well.

WLB promotes work in such conditions that employees can freely reconcile work and private life. The survey asked the respondents to assess the difficulties in combining work with parental duties during the pandemic. A scale from 1 to 5 was used to allow working parents to freely assess the situation. The majority of the respondents assessed reconciliation of professional work and childcare as difficult, with 48% indicating it as very difficult and 24% as difficult. A negligible part of the respondents, because only about 4% of them, assessed the combined professional and private life as easy and very easy. In order to check the symbiosis of work and private life, a question was prepared concerning the possibility of separating working time from private time. The majority of respondents assess the possibility of separating work from private life during the pandemic as definitely impossible (39%) and as rather impossible (36%). Only every 5th employee is able to clearly draw a line between time spent at work and private life. Professional work requires continuous improvement, training and adaptation to the environment. Employees in a highly competitive market and in fast-changing conditions have to take constant care of their professional development. Therefore, the study asked whether the current situation creates opportunities for professional development. A scale was used to determine the issue, so that the respondents could freely assess the situation. A significant proportion of working parents assessed the conditions for professional development during the pandemic as very unfavorable. Three quarters (75%) of the respondents do not have time for professional development, only 7% have enough time to improve their qualifications.

Fig. 1. Combining remote work and parental duties vs. possibility of professional development during a pandemic (data in % at different scale levels)

Source: own study based on research results.

The EU Directive aimed to change the roles played by women and men in modern Europe. In the study, an attempt was made to determine whether there was a change in the performance of family members' duties during the pandemic and the remote work. The pandemic triggered minor changes in the distribution of responsibilities within families. Almost half of the respondents (48%) indicated that there was no change in the division of roles and tasks in the family. Every third working parent (31%) reported that part of the duties were taken over by their spouse or partner. An interesting observation is also the fact that about 8% of the respondents each indicated that children or other people, e.g. grandparents, took over some duties or tasks at home.

The flexible working methods introduced during the pandemic were to ensure, on the one hand, that work would be carried out in new circumstances and, on the other hand, to create conditions for childcare in situations of closure of educational institutions and forced social isolation. The research was summarized by asking a question, the aim of which was to determine the relationship between the reconciliation of work and the performance of parental duties. Respondents had the opportunity to assess their situation through the prism of indicating how their professional and parental responsibilities are adapted to each other. Half of the respondents indicated that "remote work is adapted to childcare". One fourth (24%) of the respondents indicated that "childcare is adapted to the conditions of professional work". 18% of the respondents each indicated that the working time is adjusted to the conditions of functioning of schools and other educational institutions and to the working time of other people who take care of the children. Here we can see that the pandemic work system has made it possible to reconcile private life with professional duties. The manner of working was mainly adapted to childcare, not the other way around.

Fig. 2: Reconciliation of professional and family duties vs. remote working hours (data in % at different scale levels)

Source: own study based on research results.

The study also asked to identify improvements / facilitations that could help in the performance of work and parental duties. On a scale from 1 to 5 (where 1- indicated low importance, 5 meant help to a significant extent), the highest grades were given to such determinants as: working time, use of various IT tools, working methods and scope of professional duties. Working parents also pointed to other important elements related to WLB, such as: openness of supervisors to taking days off and holidays, flexible work schedules, support in taking advantage of government benefits, as well as psychological support for those who have difficulties in combining professional and private roles, and the employer's organization of additional online activities for employees' children. Legal regulations were also indicated, which may enable greater flexibility of working time for persons performing parental and caring duties, without the need to take into account the current system of work in individual workplaces, i.e. changes in the Labor Code. Working parents also described social policy instruments such as care allowances, which can supplement family budgets in the absence of a permanent work benefit for the care of family members.

The proposed tools for assessing the use of Work Life Balance showed how difficult it is to reconcile working time and professional development with parental duties. Moreover, the adaptation of the professional duties of remote-working parents to childcare shows what is really a priority in the lives of parents, mainly women. The modern labor market should adapt to the prevailing conditions and not oppose it. The conducted research identified the problems of combining professional and private life during the pandemic and showed the conditions for the dissemination of the Work Life Balance idea in Poland. The conclusions of the research should be used for further analysis, especially for international comparisons and to further develop tools to facilitate symbiosis between professional and private life. Studies show that the pandemic has only made the implementation of WLB more difficult.

Conclusions

Reconciling work and private life requires a comprehensive approach. The pandemic has triggered a process of changes in the functioning of the labor markets, which creates new conditions both for the employees, the employers and the institutions regulating the labor market. It seems extremely important to study and analyze the changes occurring on the labor market, to harmonize different spheres of human life and to set standards of implementable tools facilitating reconciliation of work and private life on different levels. Despite the many solutions available to the employees and the employers, it turns out that most working parents still encounter problems in maintaining their work-life balance. It should be pointed out that employees who enjoy a balanced professional and private life will be more satisfied with their work, will be productive, but also satisfied with their private life.

Fig. 1: WORK LIFE BALANCE and remote working during the pandemic.
Source: own study based on research results.

The WLB Directive gives Member States freedom to choose the tools and forms of implementation of ideas. European Union regulations have initiated deeper changes in the labor market and indicated possible trends. However, the Directive itself will not create favorable conditions for promoting WLB. The symbiosis between private and professional life can be reinforced by the actions of various institutions, which include the state, local authorities and individual entities (Borkowska, 2011, pp.22-23).

The global Covid-19 pandemic enabled remote work on a massive scale. Both employees and employers have been forced to adapt to the new conditions of the labor market and different areas of life. At the same time, the pandemic caused factors that hindered the daily performance of professional tasks performed before the pandemic. Working parents were confronted with the fact of reconciling professional work with parental duties under completely new conditions, restrictions of the operation of educational institutions, closing shops and the required social distance. Many parents declare difficulties in combining childcare and work duties. The improvements introduced, for example in relation to childcare benefit, have been used to a small extent by employees, mainly because of fears about the future of employment and the fall in wages. Only the flexible working model, implemented in the remote working system, has been successfully introduced on a mass scale. There is a lack of specific regulations for remote working, especially in the new conditions, but this system of work can reduce the feeling of variability, uncertainty, complexity and ambiguity of the environment in which working parents will have to live after the pandemic. One might ask another question — how long will this be possible? Will employers not want to terminate employment in relation to employees – parents who put childcare before work during the crisis caused by the pandemic. Further research will be needed to find answers to these questions. On the basis of the literature review and the research, it can be concluded that it is extremely important to follow the trends (models) of work performance especially in view of the WLB idea. The presented research results are a contribution to the analysis of changes taking place on the contemporary labor market.

Social Economy Entities Viewed Through the Prism of Reported Information. Dilemmas of Evaluation of Social Economy Entities Based on The Example of Polish Conditions

Malgorzata MARZEC

Jagiellonian University, Krakow, Poland, malgorzata.marzec@uj.edu.pl

Abstract

Societies are reporting an increasing demand for information on the activities of entities. The social economy sector requires separate recognition and setting of its standards for the presentation and evaluation of entities' activities. The study subsequently describes the operating conditions, evaluation methods and the scope of information provided by social economy entities. The summary indicates the gaps in the possibility of evaluation of social economy entities on the basis of the information collected and presented. The aim of the study is to identify significant problems in the assessment of social economy entities through the prism of provided financial statements and to indicate the gap between the reporting system and the needs of social economy stakeholders.

Keywords: social economy entities, effectiveness, reporting, information gap.

Introduction

Modern societies have a strong demand for information on the activities of individual entities. Information presented in different content and time profiles is required, therefore the actions taken to develop appropriate information systems for different organizations acquire new significance. Social economy entities (SEE) are governed by their own rules of operation, but this does not exempt them from appropriate, legally compliant presentation of their activities through the prism of the objectives and results achieved. In this respect, the SEEs require that their standards for recipients of information be separately presented and established.

The literature on the subject contains theoretical and methodological analyses related to the third sector, applying numerous evaluation criteria. The concepts of effectiveness, efficiency of operation and social impact were introduced. (Głowacki & Jelonek,2013; Głowacki & et al.,2012; Chomluk & Gabrysiewicz,2107; Goleński, 2017; Andrałojć,2012; Clifford, 2015; Holstein-Beck,1987, Price 1968; Steers 1977; Bielski 1986; Kafel & Ziębicki 2009). However, there is a mismatch between the methods and tools for evaluating social economy entities and the information made available to different stakeholder groups. On the basis of a literature review and formal requirements, three levels of analysis of mismatch between presented and needed information can be distinguished. One concerns the conditions of functioning of non-government organizations, their characteristics determining the scope of their activities. The aim of SEE's operation is not to generate a financial surplus (profit) but to achieve social objectives. The second level concerns methods and tools for evaluating social economy entities. The last one is related to formal requirements and the possibility of obtaining data on the basis of reports or obligatory compilations and publicly available information (satellite accounts of social economy enterprises).

The aim of the study is to identify significant problems in the assessment of social economy entities through the prism of provided financial statements and to indicate the information gap limiting the evaluation of social economy entities. There are no studies in the literature that would combine the problem of assessing the efficiency of social economy entities with reports presenting the activities of such entities. Therefore, the study attempts to identify the gap between the information needed and provided by third sector organizations.

Various methods of analysis were used in the study, including descriptive and deductive methods supported by literature studies and analysis of legal acts. The article is a contribution to the discussion on the problem of evaluation of the social economy sector. The query of literature, legal acts, analysis of publicly available statistical data and reporting systems made it possible to achieve the aim of the article and to draw conclusions.

Features of Social Economy Entities Vs. Operating Conditions.

The manner in which contemporary societies function requires the existence of a separate sector called social economy. Economic and social phenomena are accompanied by positive and negative social effects, which affect the social policy of the state and socio-economic concepts in the background with emerging problems of market or non-market allocation. In the social area, market allocation requires organizational and financial effort and often involves economic risk. Emerging organizations related to the social sector create conditions for the elimination of areas at risk of marginalization and may contribute to the creation of new social value. In addition, social sector organizations can limit the development of social pathologies, accelerate and harmonize the social and economic development of the society as a whole, as well as bring benefits in the long term (Płonka, 2009, p. 207–2016; Hausner, 2008, pp. 12–13).

There is no consensus in the literature on the scope of activity of the social economy sector. Terminological ambiguity makes it difficult to understand the essence of social economy as a sphere of society-oriented economic activity. The principles of operation of social economy entities evolved over time and their operating conditions depend on changes in external conditions. In the CEP-CMAF Charter signed in Brussels on 10 April 2002, the social economy sector is defined as "s*ocial and economic actors active in all sectors, distinguished by their objectives and specific form of entrepreneurship (...) such as cooperatives, mutual societies, associations and foundations*" (CEP-CMAF, Charter 2005, p. 9). The most important thing is that social economy entities are organizations oriented on social utility, and what is important, the surplus accumulated in the course of activity can be used to achieve the social objective set by the entity. An important premise for the development of social economy entities should be the solidarity of members, a well-recognized local market and adaptation to the needs of a given local environment. Social economy entities cannot operate effectively without public support and acceptance of their activities in the local community.(Kwaśnicki,2005,p.16)

The specificity of a given country or region influences the scope of the subject, determining the institutional framework and the possibilities of operation of social economy entities. In Poland, the basic legal act defining the formal, legal and organizational scope of the third sector organizations' activities is the act on Public Benefit Activity and Volunteering (Journal of Laws from 2019, item 688, 1570, 2020, consolidated text from 2020, item 284). Article 3 of the above mentioned Act specifies that <u>non-governmental organizations are entities which are not entities of the public finance sector (separation from the public sector) and entities which do not operate for the purpose of making a profit (non-profit nature), but have legal capacity granted on the basis of relevant provisions (formal nature)</u> (Kwaśnicki, 2005, p.20).

Social economy entities operate in a number of areas of the economy, offering different products or services on different terms. The sense of existence of this type of entities is determined mainly by the implementation of social objectives, which dominate over economic objectives. However, the activities of the social economy entities should be evaluated in terms of the achievement of social objectives in conjunction with economic efficiency. This raises some questions: How to evaluate activities of social economy entities? Is it possible to use tools (methods) used by other actors in the assessment of social economy entities? Or should other ways of assessing their activities be sought? According to Głowacki, Płonka and Rosiek, measuring the effects of operation of SEEs poses some difficulties due to the fact that "*traditional indicators used to assess the effectiveness of companies fail in this respect, as they focus on measuring their value generated within the entity and expressed in money (revenue, income, profit)*" (Głowacki, et al., 2012, p. 327; Łącka, 2015,p. 244). When assessing the activity of social economy entities, tools should be used to determine both the financial value of entities and products and services provided, as well as categories to evaluate the social effects of activity (the concept of social added value can be indicated). A wide range of organizational forms operating in the social economy sector makes it difficult to carry out comparative research, but this does not mean that analyses of individual entities operating in the social economy sector should be abandoned, quite contrary. It is necessary to assess the performance of the entities by examining whether the objectives were achieved, whether the problems for which the entity was established were resolved and whether the needs of the beneficiaries were met. It is also necessary to determine whether an entity has an impact on solving social problems in the short and long term, and to what extent it has done so and what results from the entity's action for the wider community (Juraszek-Kopacz & Tyrowicz 2008; Stiglitz et al., 2009; Zahra et al., 2009; Łącka, 2015,p.244). The catalogue of questions concerning the evaluation of SEEs' performance is very broad and should be combined with some criteria: tools and evaluation methods.

Evaluation of the activities of social economy entities.

There has been a discussion in the literature for some time on the criteria for evaluating social economy entities' activities.(Kafel&Ziębicki 2009; Goleński 2017; Głowacki&Jelonek, 2013; Głowacki&et al., 2012;

Chomluk&Gabrysiewicz, 2107; Andrałojć, 2012; Borzaga&Toria, 2007) There is a terminological ambiguity in the area of evaluation, measurement and influence of the social sector. Against the background of activity of entities operating in the economy, social economy entities are distinguished by the priority of social objectives over economic ones. The social economy sector provides products or services that fill a gap in the market in areas where traditional operators do not operate due to insufficient profitability. The entities operating in the social economy sector, like other entities, need resources to carry out their statutory activities and incur costs in the course of performing their tasks. Two main directions of development of social economy institutions can be distinguished from the point of view of economy analysis — rationalization of management of the resources held, i.e. socialization of economic objectives or economization of social objectives (Płonka, 2017, p. 41). The given criterion for distinguishing social economy institutions is quite important because of social and economic objectives implemented by social economy entities. Social enterprises are those that carry out business activities or paid statutory activities and transfer their surplus to social purposes. The CEP-CMAF's Charter of Principles of the Social Economy states that the success achieved by social economy actors cannot be measured solely in terms of their economic performance, although it must not be overlooked, it should also be assessed in terms of their contribution to solidarity, cohesion and territorial ties (www.cepcmaf.org).

The quantification of effectiveness usually comes down to measurement based on numerical values. However, the effectiveness of certain activities, especially those concerning social economy entities, is difficult to measure using classical economic methods, therefore other ways should be sought to define the effectiveness of their impact or effects. In the literature you can find effectiveness analyses compared with efficiency in economic terms, but also with performance and degree of preference (Pyszka, 2015, p. 17; Stoner & et al.,, 2001, p.24; Guo Bielefeld, 2014, p. 3)

Traditional tools for evaluating the effectiveness of entities do not pass the exam, because they focus on measuring the value generated inside the entity, expressed in money (costs, revenues, income, profit). Therefore, in order to evaluate the effectiveness of social economy entities, tools are necessary that will evaluate not only the financial aspects of the entity's operations, but also measure the social impact of the sector, expressed in terms of external benefits generated by the entities on societies. Table no. 1 presents two levels of effectiveness testing and the tools used to evaluate the performance of social economy entities.

Table 1: Evaluation of effectiveness of social economy entities

Financial / economic effectiveness	Social effectiveness
Based on entity reporting / financial documentation – narrow scope of analysis	Based on reporting and various documents, as well as analysis of the economic and social policy of the country and the region – wide scope of analysis

Examples of indicators: profitability, financial liquidity, efficiency (rotation), debt, rate of return, leverage, analysis of revenue sources, analysis of cost structure, etc.	Examples of indicators: social impact assessment (including: Social Return on Investment (SROI), Local Multipli□r 3, so□ial audit; so□ial □□t□rpris□s□or□□ard, social added value, etc.), determination of social effects of entities' influence (e.g. by determining the impact on environmental protection and ecology, changes in the labor market, revitalization of regions, etc.)

Source: own compilation based on: Emerson & et al.; Płonka 2008; Sacks, 2002; Juraszek-Kopacz & Turowicz, 2008; Clifford, 2015; Goliński, 2017.

Evaluation of the effectiveness of social economy entities should be multidimensional and also cover their non-financial (social) objectives. This requires a different approach as well as the development of different methods and criteria for assessing effectiveness, taking into account the specific conditions of social sector organizations. Several key problems related to the assessment of the effectiveness of social economy entities can be distinguished:

- Diversified distribution of social and economic objectives in the sector, which implies a different approach to social activity in the hierarchy of objectives;
- The achievement of social objectives is less quantifiable and the period of return on social investments is longer than for commercial investments;

- The complementary nature of conducting business activity and generating revenues on this account implies a different distribution of risk of activity conducted by the social economy sector and forces the implementation of separate procedures for its assessment;
- Different sources of financing for the social economy sector, combining features specific to the business sector, the public sector and specific to this sector, imply a specific way of accounting and scope of published financial information;
- The dominance of revenue characterized by low stability (e.g. membership fees, donations and subsidies from public and private institutions and individuals) hinders long-term planning and reduces the credibility of an entity in the commercial environment;
- Low capacity to capitalize the potential of social economy entities related to the fact that a possible financial surplus is used for the implementation of statutory objectives, and not for the increase of assets, or investments, which weakens the sector's potential for market competitiveness;
- The different and internally diverse structure of the sector's resources and capital makes it difficult to assess the credibility and compare the social economy entity to business entities with regard to typical procedures and standards. (based on Płonka, 2008, pp. 26-34).

Diversified scope of activity and degree of economization of social economy entities makes it difficult to determine a uniform system of effectiveness assessment. The main problem in assessing the effectiveness of the social economy sector is the inability to estimate, on the basis of existing financial and management reporting, the key components of social potential and impact, which often influences the underestimations of the values created by social economy entities and distorts the effectiveness of social projects. The presented methods and criteria for assessing the performance of social economy entities aim at estimating the social economy entities activity based on various criteria adjusted to the specificity of the social economy system. In conclusion, it should be stressed that the evaluation of actions taken by social economy entities should take into account not only the relations between objectives, inputs and outputs, but also the social impact of the sector on the economy and society.

Scope of information provided by social economy entities in Polish conditions

The problem of assessing the activity of social economy entities should be linked to the way in which the activity is presented in terms of the information provided. This is where national conditions are important in terms of the information systems developed for individual entities, concerning accounting rules, reports and tax obligations. 1 An assessment of the activities of third sector operators can be made on the basis of information provided by individual operators, such as financial statements or other reports required by law. The Polish legal regulations governing the preparation of financial statements are vague and require great commitment and expertise. The formal requirements for the reports or statements provided depend on the legal and organizational form of the entity and the scope of its activities. The table below compares the types of social economy organizations with the formal requirements for providing information on their activities. The basic criterion here is whether an entity conducts business activity or not and the inclusion of said entity in the group of public benefit organizations and so-called “small” non-governmental organizations. Most organizations are required to prepare and provide basic financial statements, consisting of the balance sheet, the profit and loss account and supplementary information as defined by specific accounting rules (Accounting Act of 29.09.1994 as amended, Journal of Laws from 2020, item 568). The formal requirements for making reports available depend on the organizational form of the entity and sources of funds obtained. Moreover, the foundations are obliged to prepare a report on their activity according to the template defined by the Minister of Justice and deliver it to a competent supervisory body indicated in the statutes of the organization. In addition, public benefit organizations publish their factual reports in the report database maintained by the National Freedom Institute. All registered organizations are obliged, regardless of their scope of activity and budget, to draw up and publish their approved financial statements on their websites. Table no. 2 presents information provided by social economy entities required by law in the system of individual institutions operating in Poland.

Table 2: Information provided by social economy entities and formal requirements taking into account the form of activity

Type of entity	Type of report/publication obligation
Associations Foundations Not conducting businesses / not registered in the National Court Register (without entities conducting tax accounting in the form of a simplified revenue and expense register)	Financial statements (balance sheet, profit and loss account, supplementary information; template in the Accounting Act dedicated to non-governmental organizations) signed by all members of management board. Obligation to publish on websites and the Public Information Bulletin
Associations Foundations Businesses / registered in the National Court Register (without entities conducting tax accounting in the form of a simplified revenue and expense register)	Financial statements (balance sheet, profit and loss account, supplementary information; template in the Accounting Act dedicated to non-governmental organizations) — facilities providing the possibility of filing financial statements through an application provided prepared by the state
Associations, foundations with the status of Public Benefit Organizations	Financial statements (balance sheet, profit and loss account, supplementary information; template in the Accounting Act dedicated to non-governmental organizations) Substantive reports published on a dedicated website of the Public Information Bulletin and the National Freedom Institute
Foundations	Reports and statements drawn up in accordance with the template set by the Minister of Justice shall be submitted to the relevant supervisory authority.
Organizations keeping simplified records of revenues and costs (applies to so-called small non-governmental organizations)	The simplification concerns records of, i.a. the revenue in a division into revenue from unpaid, paid and other activities; costs must be recorded with an indication whether they are tax deductible or not; additional records of individual employees and fixed assets; Detailed list of organizations and imposed formal requirements to meet the conditions to be included in the group of so-called small organizations It does not exempt them from the obligation to submit reports to the tax office (below); Detailed description in the Act on public benefit activity and volunteer work and in the detailed disposition of the Minister of Finance (item. 2050)
All entities	Tax return (CIT-8 form); statement of income and expenses, tax-free income and corporate income tax

Source: own study based on provisions of the law.

In addition to the prepared financial statements, social economy sector entities are required to provide factual or organization activity reports. The non-financial accounts shall include in particular:

- data concerning the scope of the entity's activity (name, form and scope of the statutory activity, specifying the achievement of statutory objectives and information on the business activity, if any),
- information about the amount of revenue gained, with a division into sources and forms of payment for paid benefits provided by the entity under statutory objectives, taking into account the costs of these benefits; if a business activity is conducted, the financial result of this activity should also be presented, as well as the percentage ratio of revenue obtained from business activity to revenue obtained from other sources,
- information about the costs incurred for the implementation of statutory objectives, administration, business activity and other costs with a separate form of payment,
- data on the number and form of persons employed with information on their basic and additional remuneration,

- data on the financing of activities, loans taken and investments made,
- data on the activity commissioned to the foundation by state and local government entities,
- information on the foundations' settlements on account of their tax obligations, as well as data on submitting tax declarations (based on www.poradnik.ngo.pl).

The prepared reports (financial statements and factual reports) provide knowledge on the activities of individual social economy entities. They allow to determine the extent of the assets at the disposal, the amount and structure of the sources of financing, as well as the structure of the revenue generated in combination with the costs necessary to achieve the intended objectives. Factual reports make it possible to assess revenues, costs, employment structure, investments made, as well as cooperation with governmental and local government entities. This provides a basis for evaluating the activities of individual entities. However, the information provided in the reports is not uniform for all actors and, more importantly, may be difficult to understand by some social economy stakeholders. Moreover, the report required by law does not provide an opportunity to assess social effectiveness in terms of the social impact of social economy entities on the local community or society as a whole.

Conclusions. The information gap between social economy entities and recipients of information.

The Polish system of reporting social economy entities is characterized by asymmetry causing gaps between the available and the needed information. A gap can be understood as a mismatch which, due to difficulties in diagnosing and assessing a given phenomenon, may negatively affect the relations of a given entity with its environment. On the one hand, difficulties in the choice of SEEs' assessment methods can be noted, while on the other hand, the information available limits the tools used. The information gap concerns the scope of information provided from the social economy sector as well as the reported needs for information that is not collected. There occurs a dissonance between recipients (stakeholders) and senders (PES) in terms of communication. This situation may result in stakeholders not taking into account the information provided by the SEEs. This may concern, for example, the range of services offered, knowledge about the functioning of individual institutions, cooperation of individual entities with different public or social institutions, the possibility of transferring funds, as well as the feeling of improvement of the quality of life.

In Poland, there is a high discrepancy between the information needs and the formal requirements imposed by financial and factual reports. Based on the analysis, the following information gaps limiting the assessment of SEEs can be identified, i.e.

- Communication gap – it is related to the difference between the information received by users and the level of satisfaction of information needs (e.g. in Poland many tax or accounting reports are required, but these reports do not provide the information needed by all SEE stakeholders, e.g. concerning the scope of services offered),
- Reporting gap – a discrepancy between the assessment of individual categories and the level of activity in reporting (e.g. there is no detailed information on costs and revenues in the perspective of various products and services),
- Perception gap — a difference between the importance of the information provided in the reports and the possibility of using this data by different recipients (e.g. there is no information on the extent of social impact of social economy entities on the local community)
- Gap in understanding — a difference between the information included in the reports and the importance assigned to it by users (e.g. information on the financial result of SEEs)

The article links the three layers, i.e. the characteristics of the activity of social economy entities, conditions of their functioning, methods of activity evaluation, and it indicates a mismatch in the scope of the possibility to evaluate SEEs' activity on the basis of information presented by social economy entities. There is a big discrepancy between the presented information and the needs of information recipients. A gap can be identified that is characterized by hope and disagreement. The hope of providing the relevant information refers to the situation when the recipient receives incomplete information that does not give the opportunity to take the required / expected action. Information does not correspond to the reported needs when the recipient does not agree with some or all of the information provided and is not able to use it for action (decision making, reporting).

Fig. 1: Information gaps in the evaluation of social economy entities.

Source: own study.

The issue of evaluation of social economy organizations is subject to numerous analyses, at many levels. At the same time, it has not yet been possible to develop a universal model, a concept linking information (reporting) systems with the levels of evaluation of the social economy sector. The paper analyses the complexity of the problem and presents theoretical and cognitive deficiencies in this area. The article presents the conditions of the emerging information gap between social economy actors and its stakeholders. The analysis was made on the basis of Polish conditions, as the scope of activity and the manner of organization of the social economy sector is determined by formal, legal and social conditions in a given country. The presented study may be used for further analysis in individual countries. The problems identified are a contribution to creating theories and standards of evaluation of the social economy sector.

Abstract

Due to the significant internal regional diversity of territories, spatial settlement and heterogeneity of the population, Russia is faced with the peculiarities of geographical, natural, demographic, historical characters in the development of modern infrastructure. This explains the timeliness and relevance of the study of modern infrastructure, which is aimed at developing and improving the socio-economic triad towards building its equilibrium model in the field of production, social sphere and housing, as a reflection of the universal infrastructure of the region - an integral part of the country. The study is also aimed at a deep study of theory, facts and a description of various points of view of different authors on this topic. This, in turn, requires the organization of a theoretical attempt to synthesize existing approaches in order to overcome the existing diversity and develop a common view on the essence of the concept of infrastructure. In the process of this study, the experience of summarizing various copyright approaches was considered. At the same time, the authors' points of view and their theoretical justifications became the object of analysis.

Keywords: Regional Infrastructure, Municipalities, Crisis.

Introduction

The demand for this study is due to the objective difficulties of both economic and social evolution currently observed, as well as the features of geographical, natural, demographic, historical characters in the development of modern infrastructure, which such a large country as Russia faces due to its significant internal regional diversity of territories, spatial settlement and heterogeneity of the population.

The need for such a study is also caused by the fact that a rather long time was not given due, in-depth attention to such theoretical issues, and their study was limited to the statement of facts and the description of various points of view of different authors on the topic, which led to a colorful and wide variety of opinions, definitions and opinions. This, in turn, requires the organization of a theoretical attempt to synthesize existing approaches in order to overcome the existing diversity and develop a common view on the essence of the concept of infrastructure. In the process of this study, the experience of summarizing various copyright approaches was considered. At the same time, the authors' points of view and their theoretical justifications became the object of analysis.

All this, on the one hand, made it possible to identify the established approaches, on the other, to form a generalization reflecting and summarizing various theoretical views on the concept of infrastructure.

Cite this Article as: Dmitry N. LEONTIEV, Maxim V. IVANOV and Angelina V. NEVZOROVA“ Infrastructure of Municipal Units” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

It should be noted that public planning and regulation of infrastructure development and functioning in different regions and in the country are always the focus of attention of the Governments of almost all States with highly developed market economies. Several well-known scientific studies (for example, D. Ashauer (USA), K. Khubiev (Russia)) have established and justified the strong and direct relationship of government infrastructure costs with economic growth rates in the national economy and regions.

An analysis of the current state of this area shows that research on infrastructure development is taking place mainly in two global directions - from the point of view of management theory and from the point of view of economics. In the first case, it refers to a set of interconnected service structures, and in the second, a set of industries that provides general conditions for the functioning of the economy. Traditional political economic science divides infrastructure into production and non-production. Modern economists practically adhere to traditional political economic definitions, making some adjustments in the spirit of new trends, replacing such concepts as non-productive infrastructure with a more modern-sounding social one. Moreover, in any economy, as a rule, production is the dominant role, which is the basis for the development of society. And, therefore, this provision leads to the fact that the initial consideration of the production infrastructure is determined, sidelining the non-production (social) infrastructure.

Of course, production infrastructure is a direct source of livelihood for each individual and society, providing society with jobs without which it is difficult to satisfy material and spiritual needs, if not impossible. At the same time, this means that production infrastructure is social in nature and that the division of infrastructure into production and social is to some extent conditional. Therefore, the division of infrastructure into production and non-production (social) in its pure form in our time seems somewhat outdated. This is evidenced by the changes in concepts that occur before our eyes - the figurative name "tourism industry" has gained an industrial meaning, the same thing happened with show business and the "entertainment industry." The main determining factor is gradually the monetary valuation of the final product, its ability to be sold as a product.

In view of the above, the aim of our study was to examine existing approaches to the definition of infrastructure in relation to the municipality (region), with the following objectives:

1) determining the place and role of infrastructure in human life and modern society at present;
2) analysis of existing approaches and points of view;
3) their generalization and justification of the division of infrastructure into production and social;
4) formulation of the socio-economic triad.

Theory

In the context of the growth and progressive movement of the modern economy, the development of various territories takes on importance. And such as large economic regions and such as subjects of the Russian Federation and such as municipalities. Currently, the Russian Federation consists of 85 entities and each of them unites and includes a different number of municipalities united by the borders of this particular entity. Almost on the territory of each municipality or region there are some economic facilities - companies, organizations, enterprises, etc., which are parts of industries or sub-sectors and social facilities - kindergartens, polyclinics, schools, etc. In this regard, the issue of subdivision of infrastructure industries in relation to a municipality or region at the level of a subject, at present, can be considered as a certain subject of discussion. You can notice that it (the concept) is applied in many areas of our life. It is enough to recall the collocations that appear in this word - "infrastructure of engineering structures," "transport infrastructure," "information infrastructure," "production infrastructure," "infrastructure of the district," "infrastructure of municipalities," "social infrastructure," etc. The list can be continued. Basically, such phrases when pronouncing and perceiving them are perceived by people quite calmly and do not cut their hearing. Reading any article, listening to a report or the most ordinary news where such words are found, an ordinary person rarely thinks about the essence of the infrastructure itself and takes it as something clear and for granted, without delving completely or very superficially into the content of this concept.

Several specialists, researchers very widely interpret the concept of infrastructure. So, for example, in the Big Economic Dictionary of Borisov A.B. you can find the following definition: Infrastructure - a set of industries, enterprises and organizations that are part of these industries, directed activities designed to create conditions for the normal functioning of the production and circulation of goods, as well as the vital activities of people. The interpretative dictionary of foreign-language words of Krysin L.P. interprets infrastructure as components of the general structure of economic or political life, which are subordinate, auxiliary in nature and ensure the normal activity of the economic (political) system. Rumyantseva E.E. refers to infrastructure as a set of material and organizational and legal conditions that ensure sustainable economic development. Bulyko A.N. believes that infrastructure is a set

of enterprises, institutions, management systems, communications, etc., ensuring the activities of the society or any of its spheres. In general, one cannot disagree with the possibility of a broad and narrow interpretation of this concept, believing that infrastructure is directly related to all spheres of life and activity of a person and society.

Method

The methodological basis of this study is the well-known general scientific methods of cognition - dialectical, deduction, induction, comparison method, observation, hypothesis; special methods - logical, modeling.

The modern development of infrastructure, its consideration in relation to the new, today's conditions challenging the realities of the present, requires a rethinking of the existing traditional approaches in the issues of studying this sphere. Infrastructure development is closely linked to the evolution of both social relations in society and changes in the economic and social spheres. The infrastructure of the municipality, the region is represented in a dialectical relationship with the level of development of social and economic relations and a comparative analysis with existing practice is made to determine the prospects for its development in Russia.

Taking as a basis the basic level of the economic division of the infrastructure for production and social and to avoid various possible conflicts, it makes sense to limit the production infrastructure to industrial material production, which will lead to the fact that only industrial enterprises of all forms of ownership located in the territory of this region or municipality and engaged in material production will fall into it (i.e. in the production infrastructure) of the region.

It is also necessary to allocate the housing sector as a separate component of the infrastructure, without classifying housing as either productive or social infrastructure. Attempts to solve the housing problem over the past 5-6 decades have generated many government programs, none of which have been fully implemented. Russia, which inherited the whole set of social problems from the USSR, aggravated as a result of full-scale social experiments conducted in the country for a couple of decades, is at the level of the third world in terms of the quantitative parameters of housing supply, and in some cases it is significantly lower in terms of housing quality.

Everything that remains applies to social infrastructure. Then, we can conclude that the social infrastructure of the municipality, the region is what ensures life and its comfort for everyone in the territory and the population as a whole, except for housing, and not related to production infrastructure.

The chosen method of conducting the study is based on the study and consideration of the existing approaches to the essence of the concept of infrastructure, their interpretation and assessment of the current state, the identification of options and implementation models in order to summarize the available data for the development of a universal concept and a unified approach to the development and improvement of the existing infrastructure of a particular region, municipality in modern Russia.

Results and Discussion

Currently, it is usually customary to include a combination of industries, organizations and enterprises that are part of these industries, whose activities are of a directional nature. All of them are designed to create conditions for the effective functioning of production or trade, as well as the normal life of people.

At the same time, it should be understood that the specifics of infrastructure industries are that these industries do not create any kind of product (i.e., material products), but create the necessary conditions for its production or provide services without which successful activities and functioning of material production industries, and therefore the entire economy as a whole, are impossible. It is impossible to reserve the products of infrastructure industries, it is impossible to add, save or store in a certain place, since it manifests itself in the form of the process of moving, storing, transferring information.

The study made it possible to identify existing approaches in science and practice to determining the essence and features of the concept of infrastructure, as well as to determine its state, level of development and compliance with today's conditions that have developed at the present stage of socio-economic development. In all definitions and concepts almost all aspects of our lives are affected - and the production aspects and economic, social, political and information. No important area of activity remained unaffected. It seems that they are an attempt to cover, list all possible directions, features and views of our being in modern conditions. On the one hand, such views very broadly and deeply describe infrastructure from different points of view and positions, on the other hand, they can lead far away from the issue being studied.

What's really going on in reality? The study of infrastructure is very important not only in the field of production, but also for the social and cultural life of society. In ordinary life, a person encounters real problems and issues, daily contacting three components in the person of production, social sphere and housing. In our study, based on the literary review, we propose to get acquainted with the below-presented hypothesis, formulating a socio-economic generalization that infrastructure is what ensures the life of each individual person and the human community.

Summary

The study provides some conclusions and suggestions.

1. In modern conditions, the division of infrastructure into production and social seems more consonant than the division into production and non-production.
2. The development of the socio-economic triad in the municipality (region), which includes the sphere of production, social sphere and housing, reflects the development and improvement of the universal infrastructure.

Corporate Social Responsibility – How to Change the Attitude of the Top Management from Image to Real – A Case Study of a Listed Company

Tomasz URBANCZYK

Nicolaus Copernicus University, Toruń, Poland,
tomasz.urbanczyk@umk.pl

Abstract

The purpose of this article is to take up the discussion about how to change the unethical behaviors of top management in relation to corporate social responsibility (CSR). The research is based on a case study of a company listed on the Polish Stock Exchange (SE) on the Respect Index (RI) of socially responsible companies. The analysis was carried out on the basis of an in-depth interview with selected still working as well as former employees of a listed company. The case study reveals that CSR may only be of an image-related nature. It shows the lack of consistency of the declared values in CSR reports with the unethical behavior of the company's management towards its employees. The author proposes a concept in which SE authorities would extend the scope of their activities to preventive and intervention measures. Preventive actions would concern (1) top management education in relation to the impact of ethical behavior and positive relationships on the company's results; (2) implementation of 360 degree feedback. Intervention, in turn, would relate to (3) whistleblowing.

Keywords: CSR, Ethics, Positive Relations, 360 Degree Feedback, Whistleblowing.

Introduction

In the last few decades, there has been a trend to develop the concept of corporate social responsibility. According to Caroll (1991), it is constituted by four kinds of social responsibilities: economic, legal, ethical, and philanthropic. The author refers to an ethical one. Such standards as ISO 26000 (guidance on social responsibility) or global reporting initiative (GRI) also show different dimensions of CSR, but the presented case study touches the principle of ethical behavior or, respectively, social standards. The analyzed case study shows a contradiction between the unethical behavior of the top management of the listed company and their declared CSR policy in relation to the company's employees. At this point, it is necessary to point to the central role of a human being - the employee. The essence and foundation of human acts - economic ventures, all activities and relationships built - cannot be profit maximization without prior respect and recognition of the good of another person, be it as an employee, as employee teams in a supply chain, or as a customer to whom the subject of work is to serve. "The truth about good is based on the understanding of the nature of man and his goals, because good is what corresponds to nature due to the purpose of being itself" (Wojtyła, 1999, p. 27). An employee is the most important stakeholder and a key asset of any company (Anam et al., 2012). This is mainly reflected in the definition presented below. "CSR is a long-term, voluntary strategy of well-thought-out and ethical relations with all stakeholders, based on the principles of social dialogue, and a management concept in which the company makes decisions and actions that, on the one hand, contribute to the self-interest of the company, and on the other hand, lead to protection and multiplication of social welfare" (Madrak-Grochowska, 2010, p. 46). Although there are many definitions of CSR with differently distributed accents, the key element is the ethical shaping of relations with stakeholders, through dialogue for the good of the company and society. So ultimately, shaping the CSR policy will always relate to the good of the person, and foremostly the employee.

Cite this Article as: Tomasz URBANCZYK " Corporate Social Responsibility – How to Change the Attitude of the Top Management from Image to Real – a Case Study of a Listed Company" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The analyzed listed company had the status of a socially responsible company (RI) on the Polish Warsaw SE. On the one hand, participation in the index of socially responsible companies can raise the company's rank (GPW, 2018; Lee, 2019; Matuszak and Różańska, 2017) and show it to shareholders as caring for social welfare, as well as ethical in the context of business activity. On the other hand, the companies themselves, and especially their management boards, are interested in increasing the value of companies, which is one of the parameters of the performance assessment by supervisory boards. Consequently, there is a risk that CSR may be perceived as a tool to increase the value of shares, and not as an integral element of the philosophy of doing business (Smit and Bierman, 2017). CSR report, of course, presents the actions taken. However, it may be superficial and may not reveal the true intentions and behavior of the company's management. Dyduch and Krasodomska (2017) confirm existing practice to use CSR disclosures just to create positive impression and build corporate legitimacy despite negative activities.

With regard to the analyzed case study of unethical treatment of employees by top management, the author is looking for a way to eliminate, or at least reduce, such behavior. Hence, the author proposes, as part of the CSR policy, on the one hand, preventive measures consisting in educating the top management in the context of positive economic effects of building positive relations with employees, as well as 360 degrees feedback, in order to reveal pathological behavior among the company's management. On the other hand, intervention measures through whistleblowing, which in relation to SE authorities would be independent and effective in the context of SE supervision.

Research Methodology

This research is based on a case study. As it is advised by Yin (2015), direct observations of the studied phenomena and interviews with their participants should be used. The analysis was carried out on the basis of an in-depth interview with chosen still working as well as former employees of the listed company. They played the role of "key informants". Because of the risk of revealing specific persons, their positions in the organization and other research details are not disclosed. At the same time, the "principle in collection of data in case research" was followed using methods such as "direct observations, content analysis of documents, and archival research" (Voss et al., 2002, p. 206).

Case study

Unethical treatment of employees by top management under the cover of CSR

It would seem that a listed company, especially one listed on the index of socially responsible companies, will pay particular attention to ethical treatment of employees, the more that human capital is the main asset of company (Tejedo-Romero and Araujo, 2018). Moreover, it should promote ethical behavior and eliminate all pathologies. In a special way, such an attitude should be expected from the supervisory board and top management. However, the analyzed case shows that this is not always the case, and CSR can be used primarily to achieve image goals. Loud scandals of multinational companies such as Cendant (1998), Xerox (2000), Enron (2001), Adelphia (2002), WorldCom (2002), AIG (2004), Lehman Brothers (2010) (Mironiuc et al., 2013) or Volkswagen (2015) indicate that the dual morality of management boards is not unique. Hence, in order to properly assess the real motivation of the management boards of CSR companies, it would be necessary to conduct in-depth research that goes far beyond the CSR report.

Based on the interviews conducted with several current and former employees with long seniority level, a picture of sophisticated, consequent and at the same time unethical behavior of the company's top management is drawn. It shows the process of coming to power and exercising it by eliminating unwanted employees, i.e. those with a different opinion, those who did not agree to participate in manipulation, or those who could compete for promotion, as well as those who had to fulfill the role of a scapegoat.

The depicted case shows a career path, from the position of sales manager, through sales director, to the president of the company. It is known that the head of sales is expected to systematically increase

sales through the penetration of new markets and implementation of new products for sale. It is also known that maintaining a managerial position in the sales department in turbulent economic conditions is not easy. The case shows the career tactic of finding the culprit. It was realized by undermining the authority of various organizational units or blaming chosen employees, also from the sales department, for the consequences of lower than expected sales results. It was a ruthless policy of trying to get rid of allegedly underperforming employees that was successfully demonstrated to management board. In this way, the reputation of an uncompromising man in the fight for the company's results could be easily gained. In fact, undermining the authority of other people was usually behind the scenes, systematic and long-lasting, so that the persecuted person was unable to defend themselves. After several months or even years, when a negative opinion about a given person was already well-established, the employee was dismissed. In this way, at least a dozen people were removed from their positions. People who stayed in the organization, but in a different position, were salt in the eye, because in other roles they gained recognition and became valued employees.

When, at one of the internal meetings a former sales employee was insulted in his absence, his new manager publicly defended him, drawing the sales director's attention to his unfair evaluation and unethical behavior. After the meeting, the head of sales made an attempt to intimidate this manager, pointing out that he had no right to reprimand him in public and that he should not speak up, because he would lead to his dismissal, as he had done with other employees before, and in which he was very effective. After some hours the sales director asked the manager not to reveal this incident. However, the same day he contacted the director of this manager, pointing to his offensive behavior. When the manager was informed about this, he decided to report the matter to the then president of the company. He expected support from the president and punishment of the sales director. However, the president said that sales are very important for the company and he did not take any disciplinary steps. After some time, the management board was changed and the sales director was appointed the new president. Taking into account the fact that his practice of firing unwanted people was already known, he announced at a meeting of middle-level managers that he was not planning any layoffs. Moreover, he told the manager in private that he did not have to worry about being dismissed. However, after a few months, the practice of dismissals came back. The manager was dismissed under the pretext of eliminating a position for reasons not related to the employee. After some time, a new manager was hired to replace him.

One may ask why this manager did not receive the support of his director. There are two reasons. First of all, the director, for fear of losing his position, made every effort to flexibly adjust to the decisions of the management board, even if it was to have negative consequences for the company or individual employees. According to the classification of susceptible followers (Padilla et al., 2007), he could be categorized as a conformer who complies with destructive leader out of fear. Secondly, this manager was a very troublesome employee as he questioned some of director's decisions. From the most trivial ones, such as honest payment for employees' overtime, to those that could lead the company to multi-million financial losses. In a situation where the manager refused to purchase a component that would cause mass product complaints, the director not only threatened him with disciplinary action, but when the manager's position was found valid, he never appreciated his effort. Instead of recognizing him as a person protecting the company from negative consequences, there was a desire to weaken the professional position of the manager and then remove him from his post. The director, even before dismissing the manager, during the term of the previous management board, had tried to lower his annual assessment and to issue a written warning. Thus, the unethical behavior of the president was not unique in the company's top management. This is confirmed by Thoroughgood et al. (2012), who observed that "no matter how clever or devious, leaders alone cannot achieve toxic results. Destructive leaders are capable of carrying out their toxic agendas with the assistance of susceptible followers and conducive environments." (p. 901). In this case, conducive environment was created by supervisory board, which supported any human resources (HR) policy, hoping to increase the profitability.

Subsequent reports by respondents indicate attempts of formally unjustified punishments or dismissals of unwanted employees. It concerned people with many years of work experience and committed to the company. Systematic redundancies covered a dozen or so people in managerial or specialist positions. The reasons for the layoffs were to reduce costs, improve efficiency, professionalize staff,

however, they were often perceived by the workers as a form of getting rid of unwanted people. The president's practice has not changed. In response to the company's weaker than planned results, the alleged culprits had to be dismissed or punished so that the supervisory board was convinced that the president was taking corrective actions, as the fight for the company's results was a priority. The conducted HR strategy led to getting rid of people with extensive experience, which had to have a negative impact on the company's results and its development. At the same time, the remaining intimidated employees were made to carry out their over-standard, unpaid work, which was to fill the gaps left by the dismissed employees. Wu et al. (2018) prove that employees significantly resort to silence in the workplace due to their feelings of role overload when they face destructive leadership. Despotic supervisor gains the silence among employees and feels audacious and unpunished.

Einarsen et al. (2007) defined destructive leadership as "the systematic and repeated behavior by a leader, supervisor, or manager that violates the legitimate interest of the organization by undermining and/or sabotaging the organization's goals, tasks, resources, and effectiveness and/or the motivation, well-being or job satisfaction of subordinates" (p. 208). According to the aforementioned definition, negative consequences may concern the employee and the organization. With regard to CSR objectives, the beneficiary of the policy is to be a person, especially an employee who is involved in the development of the organization, especially that abusive supervision can negatively influence human health (Liang et al., 2018). In turn Milliken et al. (2003) point to the counterproductive nature of such behavior. Employees with the fear of retaliation or punishment (loosing job or not getting promoted) do not speak up about potential problems or issues of significance to the organization. Respondents indicated that during managerial meetings or other company meetings, for fear of losing their jobs, employees did not speak out if they were to express a different opinion from the president or even defend themselves against harmful assessment or offensive behavior. Meanwhile, the learning organization should create such an atmosphere that employees feel completely safe when reporting any problems. In turn Schyns and Schilling (2013) show that the highest correlation arises between destructive leadership and attitudes towards the leader, while the second highest correlation is between destructive leadership and counterproductive work behavior. Their "meta-analysis shows the expected negative effects of destructive leadership and thereby confirms the urgency for organizations to deal with prevalent destructive leadership and avoid the occurrence of destructive leadership in the first place" (p. 152).

On the basis of the case study it can be seen that CSR disclosure or the status of social responsible company (RI) obtained on the SE does not have to coincide with the actual behavior of the management board. The purpose of this article is not only to stigmatize the unethical behavior of top management or to point out that destructive leadership leads to the weakening of the organization and its results. It is all about asking a question and discussing how to reveal and change this kind of negative behaviors. The author presents his proposal and encourages a broad discussion in this regard.

Concept

When assessing the company's activities in relation to CSR, it is quite easy to evaluate its activities for the benefit of society, financing education, sport and people in need. Such activity is based on documented financial flows, often publicized, especially in social media. Companies prepare CSR reports which very precisely indicate the positive social impact. However, it is much more difficult to gain insight into internal organizational behavior. In the case of the listed company, none of these incidents went to court. In Polish realities, the use of the court route is not very common. Employees usually only do this in extreme situations. Going to courts is costly, unpleasant, time-consuming and puts the victim in a bad light in the context of finding a new job. Moreover, highly qualified dismissed employees are able to find a new job, leaving behind unhealthy working environment that they would not like to return to, even if it were through a court order. Thus, the absence of litigation does not determine the true behavior of an organization. The company's report, endorsed by its president, shows on the one hand that it undertakes obligations with regard to respect for human rights, emphasizing in the first place that "all employees are treated with respect". On the other hand, the report emphasizes the achievements which resulted in the development of "clear, precise rules of conduct in accordance with the Code of Ethics". As to the achievements concerning human rights, the implementation and

application of a number of internal regulations regarding norms and values applicable in relations between employees, as well as non-acceptance of behaviors such as discrimination, intimidation, mobbing were indicated. The described situation clearly indicates that from the formal point of view, the organization made effort to pay attention to ethical issues, made a number of efforts, also financially, to promote prosocial behavior. However, the declared policies were not consistent with the attitude towards an employee. In the face of such a contradiction, the key question should therefore be asked about the source of unethical behavior. Why does the top management remove valuable employees from the organization. It can be an issue of the whole sphere of the human psyche related to fear, complexes, a sense of internal competition, aggression, the desire to dominate or demonstrate power. But all this may also be accompanied by the conviction that it is the way to achieve maximum organizational results, which is what the company's top management is called for and what shareholders and its representatives on the supervisory board expect. If such goal orientation has the strongest effect, the unethical behavior may be misconstrued as justified.

The analyzed case study shows that such a process may take years. It means that during this time the top management hurts selected employees, losing valuable company capital and lowering the morale of the staff, at the same time not letting the organization develop to the best of its abilities. Diers-Lawson et al. (2020) point to the fact that unfair treatment of employees leads to the CSR declaration being perceived as inauthentic not only by the employees themselves, but also by customers and investors. Thus, even legitimate efforts and undertakings implemented under the CSR program may thus be undermined and not bring the expected effect of building social trust.

In view of the above, is it possible to build a mechanism for changing the attitude of the top management within CSR? It seems so. There can be at least two ways to do this, preventive and interventional. The first way is related to the education of the top management organized by SE authorities for companies listed on the index of socially responsible companies. Education would not be about ethical rules, as these are well known to all, but it would show the impact of ethical behavior and positive relationships on the company's results. Glińska-Neweś (2017) points out that positive interpersonal relations are one of the key dimensions of the innovative climate in an organization. Thus, the long-term development of the enterprise will be strongly dependent on interpersonal relations. Skrzypczyńska (2013), in turn, presents the results of research indicating that among many CSR manifestations, the greatest correlation exists between friendly HR management policy (employee satisfaction, development of careers, work conditions, leaves, safety and remuneration) and organization development as well as company performance. Newman et al. (2020) provide evidence of employees' reciprocity and a positive relationship between adoption of CSR initiatives and firm efficiency. The presented results of scientific research, as well as specific examples from economic life, could be an impulse to free the desire to shape ethical attitudes of the top management. Of course, the source of ethical attitudes should be primarily a person's moral backbone, and not only a vision of greater benefits. But, if such a route could lead to a gradual improvement in behavior, it would also be worth taking. However, it may be difficult to convince managers that business conducted honestly can thrive and prosper. Especially since there are many negative examples from the economic life that taking shortcuts simply pays off, at least in the short term.

An additional preventive measure would be 360 degrees feedback in relation to the disclosure of unethical management behavior towards employees as well as other areas of CSR. In order to be credible, evaluation would have to be organized by SE authorities to achieve the effect of independence from the company's governing bodies. Employee confidence that the survey is completely anonymous and that an employee cannot be identified would also play a key role. Hence, each employee should be able to evaluate not only his supervisor but also other managers in the organization. Especially since employees take part in meetings with different functional managers, work in miscellaneous project teams or organizations with a matrix structure. One of the solutions could be a system where employees would draw envelopes with unique links (or codes) when they leave work, so that they could complete the survey from anywhere using the Internet. In the case of large organizations, perhaps it would be worth arranging a separate draw of blue and white collar workers. The survey results would allow the identification of managers acting in an unethical manner, especially those with the greatest negative impact in the organization. Communicating the results to employees, management and the supervisory

board would have a strong forward-looking and positive impact on management behavior. This behavior has been explained by Kahneman (2012), a Nobel laureate, who describes an experiment with payment for coffee and tea. When a poster with human eyes was hung over the tea and coffee making machine, payments were almost three times higher. It can therefore be expected that awareness of 360 degrees feedback, and especially of making the results public, would stimulate improvement in management behavior. Karkoulian et al. (2016), on the basis of empirical research, indicate that "the implementation of 360-degree feedback in an organization not only gives rise to organizational justice, but also aids in sustaining this justice and making justice an integral part of the organizational culture" (p. 1862). Cheng and Wu (2020), in turn, prove that "implementation of 360 degree evaluation benefits principals in improving leadership effectiveness" (p. 65). However, Bracken and Rose (2011) point out that relevant content, credible data, accountability, and census participation are required to successfully create organization change.

The second way - intervention, would allow employees to report negative incidents directly to SE authorities responsible for the index related to CSR companies on a whistleblowing basis, with the possibility to place complaints past the hierarchy (Christian 2018). At the same time, all employees would need to know that such a possibility exists and is trustworthy. Then it can be expected that in fear of losing reputation by publicizing the matter through stock market announcements or social media, financial consequences and even removal from the CSR index, top management would be much more restrained in their unethical behavior. However, the condition for effectiveness would be the complete financial independence of the supervisory body, which surely would be guaranteed by SE authorities.

Conclusions

The described case study clearly shows that the declaration of compliance with CSR, published CSR reports, or participation in the SE index of CSR companies do not reveal the true intentions and unethical behavior of the top management. Conducted and demonstrated prosocial activities can only be image-related in order to positively influence the public perception and interest of SE investors.

Therefore, the question arises how to react to such situations and what remedial measures should be taken. The author proposes two parallel paths of preventive and intervention measures. Preventive actions would concern two directions. The first direction would be educating the top management and making them aware that ethical behavior can serve the development of the company, while bringing abundant social benefits, at the same time recognizing that only a change in the mindset of the top management is the best guarantor of the implementation of the CSR policy. The second direction would be 360 degrees feedback, which would encourage the reduction of unethical behavior and expose the managers with the greatest negative impact in the area of CSR. The third direction would relate to the following intervention measures. Employees should be able to individually report management behavior inconsistent with the declared CSR policy to SE authorities responsible for the index of CSR companies on the basis of whistleblowing. Certainly, this concept does not fill the entire range of possibilities, but it is an invitation for scholars and specialists in the field of CSR to seek solutions that could motivate entrepreneurs to act not only for show, but to a greater extent for the benefit of all stakeholders.

Abstract

The purpose of the paper is to indicate if two-speed Europe is an existing and real concept in the context of the EU strategy - Europe 2020. Based on the selected indicators of: Employment, Research and Development (R&D), Climate Change and Energy, Education, Poverty and Social Exclusion, it was examined whether the division of countries corresponds to the assumptions of the two-speed Europe concept and if it is equivalent to the countries of the euro area, which is the novelty factor in the paper. Cluster analysis and Mann–Whitney U test were used in the study. It turns out that in the context of conducted research, in the EU we are dealing with a model of a Europe of two speeds, but the separation line is not equal to membership of the Eurozone, i.e. with the concept of two speeds formulated based upon political criteria.

Keywords: Two-speed Europe, Multi-speed Europe, differentiated integration, Europe 2020 Strategy, cluster analysis

Introduction

The economic and financial crisis of 2008 has fostered considerable changes in social and economic policy of the European Union (EU) member states. There is a noticeable tendency to improving integration of countries sharing a single currency, with a simultaneous choice faced by derogating countries – a rapid fulfillment of conditions for fully-fledged membership in the Economic and Monetary Union (EMU) and accepting supplementary requirements imposed as part of the European Semester regarding the economic and budgetary policies, or keeping away from the area with a perspective of greater autonomy in action and internal policies, but at the same time with possibly less decision-making powers regarding the future of integration. In effect, the expression "two-speed Europe" has been used more frequently, dividing EU member states into euro-area countries and the countries beyond of it. Such approach to two-speed Europe is first and foremost political in nature, rather than economic. Two-speed Europe might be interpreted as a theoretical concept considered in terms of science, and moreover as a proposal of the future acts of an international organization that the European Union has become after entry into force of the Lisbon Treaty and finally, as a natural progression of functioning in the Union structure of several dozen countries with a varying level of social and economic development.

The aim of the article is to indicate if the Union of two speeds is an existing and real concept in the context of the EU strategy - Europe 2020. Based on the selected indicators of: Employment, Research and Development (R&D), Climate Change and Energy, Education, Poverty and Social Exclusion, it was examined whether there is indeed a clear division into groups of member states in terms of diversity of the level of economic wealth within individual societies, and finally if the division of countries corresponds to the assumptions of the two-speed Europe concept and whether it is equivalent to the countries of the euro area.

Two-Speed Europe as a Concept of Differentiated Integration

Two-speed Europe is a concept that has been present in European politics for nearly forty years, i.e. the time when the European Community was joined by Greece, and later Spain and Portugal. The accession of Great Britain, Ireland and Denmark in the 1970s was not yet the origin of the debate on differentiated integration, but the different vision of cooperation that the United Kingdom began to present was a prelude to changes in the activities of six member states. A discussion about the possibility of faster integration of those countries that are more advanced in the adoption of the European Communities' law on its territory was started in the report of Belgian Prime Minister L. Tindemans in the mid-70s of the twentieth century (Stubb, 1996; Tindemans, 1976). Over time, European integration became less uniform, leading to the phenomena of differentiated integration. Certain activities and concepts (for example the Schengen area and the common currency as well as other opt-outs[1]) began to affect some member states or not only member states. (Schimmelfennig, 2016, pp. 5-7).

The question about a two-speed or multi-speed Europe began to emerge mainly in political considerations, followed by scientific deliberations with a progressing process of admitting new members to the European Union, shaping the single European market and, at the same time, geopolitical shifts in Europe in the late 1980s and early 1990s, and then after 2008, along with adopting new solutions in response to the economic and financial crisis and in the face of Brexit (Adler-Nissen, 2016; Campiglio, 2017; Kundera, 2019; Piris, 2012; Troitiño et al. 2018). The first half of the 1990s saw the intensification of the debate on the future of the European Union and its development trends (Alesina & Grilli, 1993; Martin, 1995). It was proposed to integrate the founding members as core countries with the possible German-French leadership at the time. However, this concept involves a statement that other countries can also join this process (Koenig, 2015). This model met with little agreement on the EU forum, where, for example, Great Britain preferred a model with the possibility of freely combining member states for a common aim, which was close to the essence of the concept of variable geometry (Salmon & Nicole, 1997).

Currently, in the literature attention is drawn to the benefit and threats of differentiated integration (Holzinger & Schimmelfennig, 2012; Jensen & Slapin, 2012; Koenig, 2015; Novotný, 2012; Rosefielde, 2019; Yanniris, 2017). Recalled are ideas of multiple or two speeds, where not all countries participate in the same joint actions, but move in the same direction (Piekutowska & Kużelewska 2015), and while the former does not have strictly defined groups of countries, the latter clearly indicates the division: the countries inside and outside the euro area. A considerable threat of these ideas is to move to such functioning of the member states as Europe à la carte, i.e. selecting only those elements that suit a given state. However, in this latter case, there is strong opposition from the majority of member states, defined as "no cherry-picking" expressed in negotiations with the UK on a withdrawal agreement (Laffan, 2019).

Therefore, one can assume that expanding and deepening integration quite naturally causes diversified membership, if members jointly decide under applicable law that only some of them will work together on specific issues (Jokela, 2014). Crucially, however, the group of states that do not join further processes does not object to the new activities of the more strongly integrating countries. According to Art. 20 of the Treaty on European Union: Member States which wish to establish enhanced cooperation between themselves within the framework of the Union's non-exclusive competences may make use of its institutions and exercise those competences by applying the relevant provisions of the Treaties, subject to the limits and in accordance with the detailed arrangements (…). Enhanced cooperation shall aim to further the objectives of the Union, protect its interests and reinforce its integration process. Such cooperation shall be open at any time to all Member States (Treaty on European Union, 2012).

An example of a constructive breaking of the deadlock in decision-making by an increasing number of EU members is the possibility of enhanced cooperation of at least nine member states in matters falling within the scope of Community policy, but covered by the EU's non-exclusive competences enshrined in the Treaty on the Functioning of the European Union (Articles 326-334 of the Treaty on the Functioning of the European Union, 2012). In this formula, of considerable importance are the reservations that, firstly, any country outside the cooperating group may declare its willingness to join and, secondly, activities within the framework of enhanced cooperation may not have harmful effects for countries outside this group (in terms of the rights, competences and obligations of those countries).

According to Schimmelfennig (2017), differential integration is allowing member states to cooperate at different levels of integration that fit their preferences and capacities based on (…) the legal exemption of a member state from an article. In effect, differentiated integration mustn't necessarily be perceived as a threat, but as a solution breaking down the paralysis as part of seamless integration (a facilitator of integration). Therefore, the aim of multi-

speed integration does not need to be the desire to exclude anybody, but undertaking new activities that other members can join at any time (sometimes after meeting certain conditions, which is why discussions about differentiated integration involve talk of capacities and willingness). The quest for solutions for a more robust functioning of the euro area should not violate the cohesion of the entire European Union, and should even lead to its strengthening (Barcz, 2015a). It is possible to maintain the systemic consistency of the European Union and, at the same time, to use its internal differentiation to develop the integration process (Barcz 2015b).

The debate on two-speed Europe was re-opened in 2012 at the occasion of discussion on the future and development of the Economic and Monetary Union, with particular emphasis on the euro area countries (President of the European Council, 2012a, 2012b). There also began a search in the literature of constructive solutions for a smoother functioning of the euro area (Mazier & Valdecantos, 2015). In 2012, the activities and changes in legal acts allowing for the creation of a "genuine Economic and Monetary Union" were also clarified (European Commission 2012, Van Rompuy, 2012). The areas of chief interest include: closer coordination and monitoring of fiscal policy, supervision of banking system, economic policy (including improving competitiveness of economies and employment growth) and decision-making at EU level. It was emphasized that the aim of the measures in the short to medium term until 2025 is to strengthen the stability of the euro area and the European Union as a whole, while scenarios of possible faster and deeper integration of the euro area with its own institutional and legal solutions were presented.

Another document dated 2015 was developed which mainly referred to the euro area countries through, inter alia, creating a future fiscal stabilization mechanism for the euro area to counter the crisis (Juncker et al., 2015). As a consequence of the abovementioned report, a White Paper was published in 2017. It contained scenario analyses of different lines of action in which the formation could evolve in the near future (European Commission, 2017a). Among the options mentioned, a scenario emerged: Some do more: the EU-27 allow groups of Member States to do more in specific areas such as taxation, social issues, defense, internal security and justice. However, it was emphasized that the unity of the European Union remains unchallenged and that other EU countries may join collective undertaking upon their consent. Another important document which included the statement about working in the same direction but at different speeds was the Rome Declaration (European Commission 2017b). As part of EMU, the necessity to complete the banking union and capital markets integration were emphasized, and financial instruments and procedural solutions were proposed to allow for greater convergence in the actions of the euro area countries at the economic and public finance level (European Commission, 2017c). It was stressed at the same time, that the single currency was to be an element uniting the EU member states by proposing the creation of a means of support in the form of technical and financial assistance for countries willing to adopt the single currency (Juncker, 2017; Gostyńska-Jakubowska, 2017; Gordon, 2018, Haas et al. 2018).

Work on deepening the functioning of the Economic and Monetary Union was reflected in a document prepared by the European Commission (2019). It contained a summary of the achievements to date and a call for further actions in the field of completing the construction of the banking union with the European Deposit Insurance Scheme, coordination of details for the Budgetary Instrument for Convergence and Competitiveness, changes in the European Stability Mechanism combined with a backstop to the Single Resolution Fund, progress on the Capital Markets Union and consolidation of the euro as an international currency.

Some EU member states, mainly the Visegrad Group countries, fear that the implementation of a multi-speed Europe will strengthen divisions between the members of the European Union, weaken solidarity not only with regard to the internal policy of the European Union, but also in relations with third countries, and lead to disintegration. At the same time, uneven integration is what some perceive a necessity with such a large number of members, emphasizing that it viably already exists. An interesting concept was proposed by Godino and Verdier (2014), who demonstrated the theoretical possibility of creating a federation within the European Union based on parliamentary democracy with a group of six or seven countries. The proposal became a kind of peculiar novelty in that, firstly, it does not cover all euro area countries, although the authors underline the importance of the single currency for the entire project, and, secondly, Poland could also be included among the federation states, i.e. a country located outside the euro area for the time being.

Methodology

The study covered indicators adopted in the Europe 2020 Strategy for the period of 2010-2018 and additionally GDP per capita. In the Europe 2020 Strategy, the European Commission set out three priorities, which were subsequently divided into headline targets and specific goals: 1) Smart growth: developing an economy based on knowledge and innovation, 2) Sustainable growth: promoting a more resource efficient, greener and more

competitive economy, 3) Inclusive growth: fostering a high-employment economy delivering social and territorial cohesion (European Commission 2010). The indicators for individual areas, their average values in 2008 and the targets for 2020 are presented in Table 1.

Table 1: Prospects for achieving the goals of the Europe 2020 Strategy

Area	Indicator	Past situation - 2008	Target 2020
Employment	Employment rate (% of the population aged 20-64)	70.3	75
Research & Development	Gross domestic expenditure on R&D (% of GDP)	1.85	3
Education	Early leavers from education & training (% of population aged 18-24)	14.6	<10
	Tertiary educational attainment (% of population aged 30-34)	31.2	>+40
Poverty and social exclusion	People at risk of poverty or social exclusion (cumulative difference from 2008 in thousands)[2]	-	-20,000
Climate change and energy	Greenhouse gas emissions (base year 1990=100)	90.64%	80%
	Final energy consumption (million tonnes of oil equivalent (TOE))	1179.5	1086
	Share of renewable energy in gross final energy consumption (%)	11	20
	Primary energy consumption (million tonnes of oil equivalent (TOE))	1693	1483
	Greenhouse gas emissions in ESD sectors (ESD-Effort Sharing Decision base year=100 / million tonnes CO2 equivalent)	2787.7	2618.17

Source: Eurostat (2019)

Variables used in the research are selected indicators from the Europe 2020 Strategy: Employment rate, Gross domestic expenditure on R&D (% of GDP), Greenhouse gas emissions, Early leavers from education and training, Tertiary educational attainment, Poverty and social exclusion. Moreover, GDP per capita was used in the research as an indicator of countries' wealth. Based on the selected data, it was examined whether the division of countries corresponds to the assumptions of the two-speed Europe concept and if it is equivalent to the countries of the euro area. Nonparametric tests of significance for differences were done using a test for independent samples by Mann-Whitney U test (MacFarland & Yates, 2016). This test enables the verification of the research hypothesis that individual samples were taken from the same population, or in more detail – from populations with equal medians (at $\alpha<0.05$ of significance level). The Mann–Whitney U test consists in ranking the value of the dependent variable (from the smallest to the largest) in the studied groups, and comparing them (Aczel & Sounderpandian 2018). The condition for applying this test is measurement of the analyzed variables on at least ordinal scale. Furthermore, multidimensional exploration in the form of data clustering was used to group the EU member states due to similarity as regards the level of indicators of the Europe 2020 Strategy and assessment of the selected groups against the background of countries inside and outside the euro area.

Results of Research and Discussion

Tables 2 and 3 present descriptive statistics for chosen indicators of the Europe 2020 Strategy in 2008 and 2018 for 28 EU countries. Given the average values of the analyzed variables, it should be noted that for all indicators there was an improvement and thus their levels were brought closer to the set goals. The largest improvement was recorded for Share of renewable energy in gross final energy consumption (53%). A dramatic improvement was also noted in the field of education – an increase in the Tertiary educational attainment index by 36% and a decrease in Early leavers from education & training by 32%. It is worth noting that in the analyzed years there was a very slight increase in GDP per capita (by less than 2%). Interestingly, when comparing 2008 and 2018, it can be seen that the minimum value of GDP per capita increased by as much as 18%, and at the same time the maximum value decreased by 1%. These changes could be attributed to the financial crisis that emerged in the EU countries at the end of 2007.

Table 2: Descriptive statistics of the selected indicators from Europe 2020 Strategy in 2008

Specification	N	Mean	Min	Max	SD	CV
Employment rate (% of the population aged 20-64)	28	70.95	59.20	80.40	5.46	7.70
Early leavers from education & training (% of population aged 18-24)	28	13.45	4.40	34.90	7.44	55.30
Gross domestic expenditure on R&D (% of GDP)	28	1.43	0.39	3.54	0.90	62.41

Tables 4 and 5 present a comparison of values between indicators in the Eurozone countries in 2008 in 2018. In Table 4, 15 countries were included in the Eurozone (according to the actual status for 2008), and in Table 5, the group of Eurozone member states increased to 19 countries due to the adoption of the common currency by other countries (Slovakia, Estonia, Latvia, Lithuania). In 2008, GDP per capita was the only variable which notably differentiated the countries of the Eurozone and those outside of it. Hence, the average level of the analyzed indicator of the Europe 2020 Strategy did not differ substantially in both groups of countries. On the other hand, in 2018 the average level of both GDP per capita and the analyzed Strategy indicators did not differ significantly in the analyzed groups of countries. Interestingly, conducting the Mann–Whitney U test for the 2018 data while maintaining the country breakdown for 2008 indicates that GDP per capita in the Eurozone countries was considerably higher than in other EU countries. On the other hand, adopting a division into euro-area and non-euro-area countries from 2018 (i.e. the inclusion of Slovakia, Estonia, Latvia and Lithuania in the Eurozone) means that GDP per capita from 2008 did not differ significantly in both analyzed groups of countries. This implies that the key to studying the concept of a two-speed Europe is the division of countries, and not the choice of indicators.

The further phase of research involved cluster analysis to distinguish two groups of countries that could be described as a two-speed Europe. The same group of variables was used for the division. Ward's method and Euclidean distance were used. The results of cluster analysis for 2008 and 2018 are presented in Figure 1.

Fig. 1: Cluster analysis for 2008 (left) and 2018 (right)
Source: prepared by the authors

Both in 2008 and 2018, there is a clear division into two groups of countries. In 2008, the first group contained 12 countries, i.e. Austria, Germany, Denmark, Finland, Sweden, Ireland, Netherlands, Belgium, United Kingdom, Cyprus, France and Luxemburg; only 3 of those did not belong to the Eurozone (Denmark, Sweden. United Kingdom). Meanwhile, it is important to mention that it was not due to the non-compliance by these countries with the necessary conditions for joining the zone, but resulted from their voluntary resignation from membership in the zone. With the exception of Cyprus, these countries constituted an essential part of the "first fifteen" (EU15), as they formed precursory elements for the present European Union, first by creating the European Coal and Steel Community, then the European Economic Community and the European Atomic Energy Community. After all, the idea of integration was to promote harmonious and sustainable growth of the European Community and accelerated raising of living standards (Balassa, 1962; Tinbergen, 1964; Baldwin & Wyplosz, 2015).

In 2018, the first group contained nine countries. The first group remained virtually unchanged from 2008 (except for Cyprus, France over United Kingdom, which were placed in the second group). Thus, in 2018 the second group increased by the above-mentioned countries. As part of those countries, we may indicate on the one hand such which were a part of the former Eastern bloc and acceded to the European Union during the last sixteen years, and

on the other, the countries of southern Europe, which were particularly hard-hit by the financial crisis of 2007. Firstly, these states underwent a political and economic transformation and the period of building a market economy in their case is much shorter, and therefore they are continuously treated as developing countries. On the other hand, the Southern European countries, referred to as PIGS (Portugal, Italy, Greece, Spain), have a particularly difficult budgetary situation with a high level of public debt, which is the effect of the existing policy consisting in indebtedness with relatively low economic growth and high unemployment. This problem is more fully explained by Albonico et al. (2016), Christiansen (2014), Siemiatkowski & Jankowska (2013).

The conducted analysis of clusters enabled to select two groups of countries in a substantive manner on the basis of statistical data (key indicators from the perspective of development of the European Union). Such an approach is fundamentally different from the one used in the first part of the analysis, where the criterion of belonging to the Eurozone was adopted, which is the product of economic and political criteria. Afterwards, using the obtained results of the cluster analysis, we compared the levels of indicators of the Europe 2020 Strategy in the selected groups.

The comparison of the average levels of indicators in the Europe 2020 Strategy in two groups distinguished in the cluster analysis reveals the existence of statistically significant differences. In 2008, there were differences in the level of variables: Employment rate, Gross domestic expenditure on R&D, People at risk of poverty or social

exclusion, Tertiary educational attainment. In 2018, differences appeared in the same indicators, except for the Employment rate. The first group, both in 2008 and 2018, had higher levels of the Employment, R&D and education indicators and a lower poverty-related indicator. Thereby, countries from this group are much closer to achieving the goals of the Europe 2020 Strategy in those areas. A second factor significantly differentiating the selected groups is the level of GDP per capita. In 2008, in the first group, the average level of this indicator was almost twice as high as in the second one (134.42 in the first group and 72.31 in the second). Such a relationship also occurred in 2018. In the case of the Share of renewable energy in the gross final energy consumption indicator, there are no considerable differences between the study groups, which stems from the big differences in the level of this indicator in individual countries. In some countries in the second cluster (e.g. Latvia, Estonia, Portugal), this indicator is over 30%, while in others included in the first cluster (Belgium, Netherlands and Luxembourg) it does not exceed 10%. Also in the case of the Early leavers from education & training index, there is a large internal differentiation of its level in groups 1 and 2. Although the observed differences are not statistically significant, the average level of Share of renewable energy in gross final energy consumption in the first group is higher, and the average level of Early leavers from education & training is lower.

In summary, the conducted research suggests the existence of two groups of countries within the European Union, differing in the level of socio-economic development. At the same time, it should be emphasized that although some of those groups correspond to the division into countries of the Eurozone and those beyond it, the group of "faster speed" identified in the cluster analysis covers only part of the euro area countries. Thus, the direct adoption of the political concept of two-speed Europe is not fully consistent with to the actual socio-economic status.

Conclusion

The concept of a two-speed Europe is based on the division of EU countries into two categories of members. i.e. countries seeking closer integration among the founding countries of the European Communities and a group of countries that are outside the euro area. This approach to the two-speed Europe, however, has more political than economic background. The political division based on membership in the Eurozone in 2008 indicated economic differentiation (measured by GDP per capita), but did not entail differentiation in social development in the areas of: education, poverty, R&D, employment, and environmental protection. After the decision to accept subsequent countries to the Eurozone, the economic divergence between the countries inside and outside the euro area also declined in importance. The conducted research indicates that there are two groups of countries within the EU, differing in the level of socio-economic development measured by the indicators of the Europe 2020 Strategy and GDP per capita. The cluster analysis demonstrates that the two separate groups coincide, if only partly, with the division into the euro area and the other member states. On the one hand, this is due to the fact that some wealthy countries with a high level of social development (Denmark, Sweden) have voluntarily resigned from membership in the Eurozone, while on the other hand, especially in the last 10 years, the Eurozone has been joined by, among others, countries of the former Eastern Bloc, whose level of economic development, although it has increased significantly in recent decades, is still lower than in the so-called "European core" (EU15). It turns out that in the context of conducted research, in the EU we are dealing with a model of a Europe of two speeds, but the separation line is not equal to membership of the Eurozone, i.e. with the currently much debated concept of two speeds formulated based upon political criteria (Koenig, 2015; Yanniris, 2017).

There is quite broad consensus that differentiated integration is not a negative phenomenon as long as there is no one strict group of core states and the so-called marginalized countries and that the status quo axis of the Union as a whole, such as: the single European market, including the customs union, competition policy, environmental protection, will remain undisturbed. Those in favor of the multi-speed approach (two or more) mention the benefits of such a solution, when in the absence of comprehensive agreement among all EU members, more immediate actions can be taken in a narrow group of countries. Such a view can be considered correct under the assumption of no more activity in the subgroups at the expense of the development of the entire organization. Moreover, opponents of such a model argue that it can lead to rejection of the idea of solidarity, i.e. decreasing disparities through integration.

In conclusion, it is worth to note that the conducted research may give rise to further, thorough analyses related to the raised topics. Subjects of particular interest are the impact of Brexit on the further functioning of the European Union and the change in the composition of power, as well as continuous EU integration involving the admission of new members. Moreover, interesting findings could be provided by the study of the impact of the economic crisis resulting from the COVID19 pandemic on the shape and scope of revision in the economic policy of the European Union.

Market Structure and Market Power in Selected Sectors of The Polish Economy Based on COICOP Classification

Pawel Uminski

Gdańsk University of Technology, Faculty of Management and Economics, Gdańsk, Poland
pawel.uminski@zie.pg.gda.pl

Abstract

This paper present new and simple measures of market structure and market power. Based on the classical models of market structures, where a given structure is determined by the number of enterprises, indexes of degree of monopoly have been estimated, representing an average number of entities per branch. Additionally, market power indexes have been determined as an average revenue per an enterprise in a given branch. This approach has been employed to the analysis of market structure and market power in the Polish economy in the period from 2001 to 2013, according to COICOP classification. The obtained results indicate that both market structures and market power of companies are quite diversified. Classes with large number of entities, e.g. Medical Services and low number of entities (Gas) could be indicated. Market power is also diversified – relatively low rates occurred in Medical Services class, while the highest rates were determined for Fuels class. The conclusions from the analysis imply that in many sectors with considerable market power, State Treasury is highly significant. Established measure of market power was compared with the well-known measures – Lerner's index and HHI. Correlation coefficients indicate that the relation is statistically significant but moderate or weak.

Keywords: Degree of Monopoly, Market Power, COICOP, Polish Economy.

JEL Classification: D42, D43, L13

Introduction

Market structure and market power analysis is crucial both for micro and macroeconomics. The way enterprises operate in the market structure in the microeconomic aspect may be essential, through price-setting processes, for the entire economic system. This study focuses on the markets structure and market power of enterprises in the Polish economy in the period from 2001 to 2013. Considering the fact that this study is a part of a wider research project[1], the analysis of the market structure and degree of monopoly will be conducted on the basis of the "Classification of Individual Consumption according to Purpose" adapted to the needs of Harmonized Indices of Consumer Prices (COICOP/HICP) (GUS 2014a).[2]

The purpose of the study is to present new measure of market structure and market power and to determine the degree of monopoly and market power in selected[3] branches of the Polish economy, based on COICOP and determination of the statistical relation between both. The analysis has been conducted using aggregated annual data (from 2001 to 2013), concerning the number of enterprises and net revenue from sales of products under a given PKD code (Polish Classification of Activities). The data refer only to enterprises with 10 or more employees.

The analysis used new and simple measures of degree of monopoly and market power, corresponding to the classical models of market structures. Degree of monopoly has been defined as the index of average number of enterprises present in a given branch based on COICOP. The measure of market power is the index representing the average net revenue from sales of products recorded per enterprise in a given branch based on COICOP. The use of these measures has been determined by the purpose of the research project, analysis of the literature and the availability of statistical data.

In the first place, this paper presents the measures of degree of monopoly and market power most commonly used in empirical studies, as well as theoretical assumptions that must be made when using certain methods of measuring these market categories. Next, it describes the statistical data used in this paper along with their sources, as well as the new approach to the measurement of the degree of monopoly and market power. Necessary assumptions for the approach are discussed. The following part contains the outcomes of the study and results analysis. The paper ends with the summary.

Degree of Monopoly and Market Power – Theoretical Background

A.P. Lerner defined market power as the inverse of elasticity of the demand for the company product. Assuming profit maximisation, the larger is the difference between the price and marginal cost, the larger is the market power. (Lerner 1934; Elzinga, K., & Mills, D. 2011). Microeconomic data concerning the price and marginal cost are needed to calculate the Lerner's index, which makes it difficult to obtain the result4. J.S. Bain suggested that the rate of profit could be used as the measure of market power. It concerns the profit that exceeds the normal profit, which also occurs in companies functioning based on the perfect competition model (Bain 1941).

This paper presents the numbers of enterprises in individual branches based on COICOP, which allows to compare the results between branches and gives an overview of the market structures in specific sectors of economy. Due to availability of data and the purpose of the study, new measures of degree of monopoly and market power have been used.

As it has already been mentioned, the study of market structure is limited to the analysis of the number of enterprises in a given sector. It is rooted in the classical models of market structures, from the model of perfect competition, through the model of monopolistic competition and oligopoly model to monopoly model (Moss 1984). These assume that market power of enterprises is determined by the market structure. Perfect competition and monopoly models, being the most extreme approaches to the market structure, derived market power (or lack of it) from the number of enterprises that form a given branch. In the perfect competition model, the number of companies was unlimited, which deprived individual entities of any possibility to affect its market environment, including the price of their products (Robinson 1934). In the monopoly model, there was a single company representing a branch, that considering the fact of having no competitors at all, possessed significant market power to be used to set prices allowing to maximise their profit (Fisher 1898; Morrison 2003).

A proper method to measure market power for the purposes of the analysis based on the classical models of market structures, is the Lerner index (Lerner 1934).5 However, it should be noted that this approach to market power analysis requires a number of restrictive assumptions, typical for classical and neoclassical economics, such as products homogeneity and profit maximisation as the goal of business activity. But if we reject the assumption of goods homogeneity, it turns out that individual enterprises can shape their situation, and also their prices (see: Carlton 1986; Gordon 1998).

Another assumption needed to describe the market structure and market power in a given sector using the number of enterprises representing that particular branch, is a reference to literature concerning the growth of the markets and the number of enterprises that form the given market. It indicates that a specific market structure is the effect of the competition, which may lead to bankruptcy of companies that cannot withstand the market conditions. The competition may also lead to acquisitions and mergers between businesses. There are many well acknowledged reasons accounting for motives of M&A, such as opportunity to increase prices of products (Farrell and Shapiro 1990, Deneckere and Davidson 1995) or reduction of the degree of competition (Perry and Porter 1985) (for comprehensive discussion of motives for M&A see Motis 2007) All these activities most often result in a decreasing number of companies representing the given sector, economies of scale and determining a specific market structure (Klepper, Graddy 1990).6 This assumption is necessary to perceive presented in this paper indexes as measures of market structure and market power. Otherwise market structure with one huge firm and great deal of small enterprises is possible, and our market power measure will not point it out.
The usefulness of the Lerner index as a measure of degree of monopoly is also closely related with the assumption of profit maximisation. On the other hand, the theoretical background of economics includes a large number of publications7 which assume alternative goals pursued by enterprises than profit maximisation (Coase 1937; Galbraith 1978, Galbraith 1984, Dunn 2011), which in turn results in a different price policy. Additionally, the assumptions of rationality and complete information available for business entities may be neglected (Simon 1979; Simon 1987). It would be followed by the elimination of the assumption to maximise any values by the enterprise. An enterprise pursues most certain goals, but due to limited rationality and incomplete information, maximising those goals is out of question. Thus the assumption that market power, used e.g. in the pricing decisions, is determined solely by the market structure, may be an oversimplification. In that view, the size of the sector with a given market structure may affect market power of relevant enterprises. Much larger market power is held by companies that operate among a relatively small group of competitors within a branch, and additionally the size of the sector is relatively large (e.g. in terms of net revenue from sales of products), compared to an enterprise that might be a monopolist, but operating in a market niche. The strength of impact on the market environment is completely different in this case (Galbraith 1973). Based on this assumption, average revenue indexes for individual sectors have been estimated according to COICOP. It is assumed that the larger is the revenue of a company representing a given industry, the larger is the market power of enterprises in that sector. It implies that market power is determined by the number of enterprises in particular industry (less players means lower competition) and by the size of the sector (larger revenue generated within the branch increases the chance that enterprises hold significant market power).

In general, assuming the own measures of degree of monopoly and market power in this study is determined by several reasons: 1) broader scope of study – the goal is to verify the dependence between the degree of monopoly, market power and price flexibility in the branch; since time series of price indexes for branches based on COICOP were available, market structure and market power indexes had to be estimated for branches grouped according to the same classification; 2) rejecting the assumption of profit maximisation, and thus rejecting the Lerner's index – as the goal of the company is, for instance, increasing the sales or market participation, most probably it will not maximise the profit; 3) data have been obtained at the level of aggregation of the 4-digit PKD code, which makes it impossible to determine the Concentration Ratio and HHI; 4) it is assumed that in the relevant period, market structures are determined by the market competition in a given institutional environment and the weakest business entities are eliminated.

Statistical data and methods of analysis

The obtained statistical data concerning the number of enterprises and net revenue from sales of products are grouped according to the PKD classification of activities. Considering the fact that the study of market structure and market power in the Polish economy is a part of a wider research8, the PKD and COICOP/HICP classifications must be matched. The method of finding corresponding codes in both classifications is presented in detail in the Appendix.

As it has already been mentioned, in this study, market structure is measured as an average number of enterprises representing a given sector. The lower is the number, the less competitive is the analysed structure. To estimate the degree of monopoly (competitiveness) of a given sector, the Average Numbers of Companies Index (ANoCI)9 has been used. The value of the index has been determined using annual data of the period from 2001 to 2013, concerning the number of active businesses employing more than 9 persons. The data have been acquired from the Polish National Official Business Register REGON, where numbers of registered entities according to the PKD classification are available. The data obtained concerned approximately 40,000 companies (lowest number recorded in 2004 – over 35,000 thousand, highest number in 2013 – almost 42,00010). ANoCI has been determined according to the following formula:

$$ANoCI_i = \frac{\sum_{j=1}^{n} n_{jt}}{\sum_{j=1}^{n} N_{jt}} \Big/ \overline{\frac{\sum_{j=1}^{n} n_{jt}}{\sum_{j=1}^{n} N_{jt}}} \qquad (1)$$

where:

$ANoCI_i$ – average numbers of companies index in sector *i*, based on COICOP

n_{jt} – number of companies having PKD code *j* in the year *t*;

N_{jt} – number of PKD codes representing sector *i*, based on COICOP in the year *t*;
i – COICOP code;
j – PKD code;
t – year (t=2001,…,2013)

This index has been transformed into a single-base index by determining the ratio of the average number of companies in a given COICOP sector (code) in the whole analysed period and the average number of companies in all COICOP sectors (code) in the whole analysed period.[11]

Market Power Index (MPI) has been determined using additional data concerning net revenue from sales of products achieved by companies grouped according to the PKD classification. The input data were annual records of the period from 2001 to 2013, derived from the SP or F-02 analyses (F-01 in 2013) concerning entities with at least 10 employees, conducted by the Central Statistical Office.[12] The obtained average net revenues from sales of products have been transformed into a single-base index base chain by dividing individual values by the average revenue in all COICOP sectors (codes) and in all years encompassed by the analysis. The mean value[13] was PLN 93.733 million, which was the average yearly net revenue from sales of products in all COICOP codes (period from 2001 to 2013). In other words, the average net revenue from sales of products among the companies encompassed by the analysis, in the period from 2001 to 2013, for all COICOP codes, was PLN 93.733 million. Consequently, the values of the MPI index represent the ratio of the average revenue in particular sector and the mean value. MPIs for individual COICOP sectors have been estimated with the use of the following formula:

$$MPI_i = \frac{\sum_{j=1}^{n} \frac{r_{jt}}{n_{jt}}}{\sum_{j=1}^{n} N_{it}} \Big/ \frac{\overline{\sum_{j=1}^{n} \frac{r_{jt}}{n_{jt}}}}{\sum_{j=1}^{n} N_{it}} \qquad (2)$$

where:

n_{jt} – number of companies having PKD code j in the year t;
N_{it} – number of PKD codes representing sector i, based on COICOP in the year t;
r_{jt} – net revenue from sales of products of PKD code j in the year t;
i – COICOP code;
j – PKD code;
t – year (t=2001,…,2013)

Unfortunately, part of the data concerning net revenue from sales had not been disclosed, due to the possibility of identifying the entity concerned. According to the statistical confidentiality principle, individual data or data in which aggregation comprises less than three entities, or in which the proportion of an individual entity exceeds 3/4 in a particular aggregation, cannot be made available (Journal of Laws of 1995 No. 88, item 439). In view of that, Statistical Confidentiality Indexes (SCI) have been determined, being the ratio of companies in which net revenue from sales had been made confidential and the number of all companies included in a given branch. If there were years available in which for a given COICOP branch the value of statistical confidentiality index was 0 (data concerning net revenue from sales have not been made confidential for any of the PKD codes in a given year), then MPI has been calculated based only on those years. If there were no data that have been made statistically confidential in any of the analysed 13 years, the selection has been limited to the years with the lowest SCI level. Considering 58 branches specified based on COICOP, in 20 cases there were no years (in the period from 2001 to 2013) in which the data concerning net revenue from sales were fully open. The data used in determining the MPI have been limited only to those years in which SCI was relatively lowest.14 Considering the high statistical confidentiality in group 08.1 Postal Services (lowest SCI or 23.8%), that group has been excluded from the market power analysis.

Outcomes

Figure 1: ANoCI and MPI based on COICOP
Source: author's calculations.

Statistical analysis of the dependence between the degree of monopoly index (ANoCI) and the market power index (MPI) indicates that such dependence is statistically significant[15]. The results of the correlation analysis are presented in detail in Table 1, while the simple regression models are shown in Table 2. Correlation coefficient indicate that the larger is the number of companies in the branch, the lower is the average profit achieved by the companies in that branch. The strength of the correlation is moderate (from -0.44 to -0.65; the value of -1 of the correlation at the subclasses level is achieved in very few observations). The correlation analysis is confirmed by the analysis conducted with the use of simple regression models. The market power index (MPI) was the dependent variable, while the predictor was the average numbers of companies index (ANoCI). In all cases, ANoCI was a statistically significant variable, the relation was negative, while the coefficient of determination was from 37% to 57%.

Table 1: Results of calculation of the Spearman's rank correlation and Kendall's Tau coefficients between the MPI (market power indexes) and the ANoCI (degree of monopoly)

			MPI	
			coefficient value	p-value
ANoCI	divisions 12	Spearman	-0,53	0,10
		Kendal	-0,45	0,04
	groups - 20	Spearman	-0,65	0,00
		Kendal	-0,45	0,00
	classes - 19	Spearman	-0,55	0,02
		Kendal	-0,44	0,01
	sub-classes - 6	Spearman	-1,00	0,03
		Kendal	-1,00	0,00

Table 2: Results of regression analysis between the MPI (market power indexes) and the ANoCI (degree of monopoly)[16]

		MPI		
	Sample size	**Model**	**P-value**	**R^2**
ANoCI	divisions - 12	MPI_Divisions = 2,47 - 4,81 ANoCI_Divisions + 2,61 ANoCI_Divisions ^{2}	0,01 0,02	0,56
	divisions - 11[17]	MPI_Divisions = 0,18 - 0,84 ln_ANoCI_Divisions	0,01	0,57
	groups - 20	ln_MPI_Groups = - 1,24 - 1,01 l_ANoCI_Groups	0,00	0,37
	classes - 19	ln_MPI_Classes = - 0,64 - 1,49 ln_ANoCI_Classes	0,00	0,47
	sub-classes - 6	insufficient observations	----------	----------

The correlation analysis has also been used to compare the obtained results with the results presented in the cited analysis of monopolistic margins (Gradzewicz, Hagemejer)[18]. That analysis is a comparison of the results given by the commonly used indexes and the MPI index, used in this study. It is a comparison of the results obtained using the MPI measure and the results obtained based on the commonly used measures. For the purposes of that comparison, MPI indexes had to be calculated based on the PKD classification. Table 3 presents the results of the correlation between the MPI and the Lerner's index, and also the Herfindahl index. The said comparison indicates that there is a statistically significant positive relation

between MPI and the Herfindahl index (all 3 indexes with 10% significance level). The strength of that relation is moderate or low. The dependence of MPI and Lerner's index is moderate but it's statistically independent in two out of three cases.

Table 3: Results of calculation of the Pearson correlation coefficient, Spearman's rank correlation and Kendall's Tau coefficients between the MPI (market power indexes) and the Lerner index and Herfindahl index for PKD classification

		MPI	
		coefficient value	p-value
Lerner index	Pearson	0,43	0,0194
	Spearman	0,11	0,5651
	Kendal	0,08	0,5851
Herfindahl index (3-digit)	Pearson	0,58	0,0011
	Spearman	0,34	0,0687
	Kendal	0,24	0,0828

Conclusion

This analysis gives an overview of the structure of branches and the market power of companies in the Polish economy. New and simple measures of the market structure and market power and been employed. Measure of the market structure was based on the number of enterprises in an industry and the measure of market power takes revenue in the industry into account. A great differentiation of individual branches should be emphasised. MPI values indicate a great diversity of market power in COICOP branches of the Polish economy. The analysis has been conducted on the basis of aggregated data. However, no information concerning the form of ownership of companies in individual branches was available. An in-depth analysis based on individual data would provide an answer to the question of the origin of market force in particular branches, i.e. to what extent it is the effect of the presence of the public sector. However, just a rough analysis of the list of the largest companies in Poland shows that in such classes19 as 07.2.2 Fuels, 04.5.2 Gas and 04.5.3+04.5.4 Liquid and Solid Fuels, 04.5.1 Electricity, 07.3.1 Transport: Service: Train, as well as in subclass 01.1.8 Sugar, companies with a significant State Treasury contribution can be found. They affect the MPI values in the entire branch, also with lower degree of aggregation (groups and divisions). On the other hand, there are branches dominated by few relatively large companies of the private sector, as 02.2 Tobacco, or to a lesser extent class 08.3 Telecommunication Services. Finally, to get a clear overview of the structure of ownership in sectors with high market power, ownership data or individual data are required.

However, it is difficult to compare these results with the outcomes of the other researchers.20 It is possible only when MPI indexes for PKD classification are estimated. The study of Gradziewicz and Hagemejer21 indicates relatively high values of Lerner's index and HHI index in the following branches: 1) Tobacco (16 PKD) and 2) Coke, oil, nuclear fuel (23 PKD), which was also confirmed by high MPI values in these branches. The correlation analysis indicates that higher values of HHI are followed by higher values of the MPI index, but the correlation is weak, and the correlation between Lerner index and MPI is weak, and mostly statistically independent. It may point out differences in theoretical background of those measures – MPI assumes that the size of the industry in the economy matters in market power while the Lerner index and Herfindahl index does not.

Acknowledgment

[1] The analysis of degree of monopoly and market power is only a part of the project. The results of this study will be used to verify the assumption pointing out the correlation of degree of monopoly, market power and flexibility of prices. Price indexes used for the estimation of the price flexibility measure are quoted based on COICOP. It is therefore essential to obtain the measures of monopoly, market power and flexibility of prices based on the same classification.

[2] *Classification of Individual Consumption by Purpose worked out for the needs of Harmonized indices of consumer prices*; Considering the fact that there are only minor differences between COICOP/HICP and COICOP classifications, both will be referred to as COICOP in the following part of the paper.

[3] Degree of monopoly and market power have been analysed only for COICOP codes for which price indexes are published by the Central Statistical Office (GUS).

[4] The category of marginal costs is usually replaced with average costs.

[5] Lerner index has been estimated by the authors of the paper: (Gradzewicz and Hagemejer 2007).

[6] See the analysis of changes in the number of American manufacturers representing the following sectors: automotive, tyres, TV sets and penicillin. See (Klepper, Simons 2005)

[7] It is rooted in the study of Veblen and the revolutionary work of Berle and Means. (Veblen 1904; Berle and Means, 1932).

[8] See footnote 3.

[9] In particular it refers to an average number of companies under the same PKD code. One COICOP code usually covers several PKD codes. It is the effect of matching of both classifications.

[10] The variability in the number of companies with at least 9 employees in the analysed period may result from the changes in the number of employees in the enterprise sector.

[11] The average number of companies per PKD code in all COICOP codes, in the whole analysed period, was 102. If ANoCI in group 02.2 Tobacco is 0.26, in means that in PKD codes included in this COICOP group there were 26% of the average number of companies for all analysed branches in the entire period. The average number of companies is 102, so the number of companies having a given PKD code in a given branch can be easily calculated – in this case it would be 26 companies.

[12] These data have been prepared by the Central Statistical Office (GUS) upon the author's request and funded from the grant of the Polish National Science Centre, mentioned above.

[13] Excluding group 08.1 - Postal Services, due to high statistical confidentiality index (further information in the Appendix hereto).

[14] The highest SCI value for which data have been taken into account in MPI estimations was 3.3% (in 3.3% of the number of companies under a given PKD code, the data concerning net revenue from sales of products were not available due to statistical confidentiality).

[15] Of course, it is partially determined by the fact that the market power index calculation formula is related with the average number of companies in a given branch.

[16] The specification of the obtained models meets the requirements of the classical linear regression.

[17] The regression analysis has been performed for all 12 divisions and for the same group without division 04 - Housing, Water, Electricity, Gas and Other Fuels. For this division, relatively high values of MPI (1.04) and ANoCI (1.41) have been obtained. Shifting to a lower level of aggregation indicates that this division includes branches varied in terms of degree of monopoly and market power (in particular 04.1 - Actual Rentals for Housing – fragmented branch with low market power of companies and 04.5 - Electricity, Gas and Other Fuels Equipment – with a relatively low number of companies and high market power.

[18] The research period is not fully covered – the cited paper encompassed the period from 1994 to 2004, so based on the data used in the study, MPI has been estimated according to the PKD classification valid for the period from 2001 to 2004, and these particular measures have been compared.
[19] Which is certainly reflected by higher MPI values in higher COICOP aggregation levels, i.e. in groups and divisions.
[20] In the article cited before, *Marże monopolistyczne i przychody skali w gospodarce polskiej*, authors also claim that their outcomes could not be compared with other results, due to lack of such results. pp. 536-537. As it has also been mentioned, the analysis conducted by Gradzewicz and Hagemejer refers to a different classification than the one used for the purposes of this study.
[21] Data concerning the period from 1996 to 2004 were used.

Incidence of "Premature Sign-off" on Audit Procedure: Preliminary Analysis

Halil Paino[1] and Siti Aisyah Mohd Amran[2]

[1]Faculty of Accountancy, Universiti Teknologi MARA Malaysia
[2]Lieutienant for National Hydrography Department, Royal Malaysian Navy, Malaysia

Abstract

Audit role is significant in determining the fraudulent that occurred in corporate sectors by providing a quality audit report to assist the management in making effective and efficient decision to strengthen the business operation. Throughout the audit career path, completion of audit assignment within the time set by the audit manager is difficult to attain and gives greater pressure to audit staff. Hence, this problem may lead to Premature Sign-Off (PMSO) practices among the audit staff. PMSO occurs when an auditor signs off the required audit procedures without being covered by another procedure. This may lead to mitigating the effectiveness of audit process and compromising the audit quality. This paper examined the current level of incidence of PMSO among Malaysian external auditors, as well as to analyze the audit steps which appearing unnecessary, time budget constraint, inadequate supervision and readily accept the client explanation that affect the PMSO. Questionnaires were distributed to 125 audit firms in the Peninsular Malaysia and 99 responses were received. The result showed that, issues of PMSO definitely exist in Malaysia, and all the variables were significantly influenced the PMSO. Therefore, we should aware that the problem of PMSO exists in the audit environment, and preventive steps are needed to overcome this problem.

Keywords: Premature Sign-Off, Audit Steps Unnecessary, Time Budget Constraint, Inadequate Supervision, Readily Accept Client Explanation.

Introduction

In the recent year, audit profession had been questioned by shareholders in terms of credibility, integrity and objectivity due to the audit failure cases such as collapse of Enron, Worldcom and Parmalat. Auditors are regularly blamed for failing to discover material misstatement and various parties were questioned on the quality of the audit report. Generally, auditors are perceived to complete the audit works on time. However, in real practice this is difficult to attain because time budget allocated to audit staff sometime is not relevant and too short. According to Paino, Ismail, & Smith (2010), performance evaluation and career advancement in audit firm depend on the ability of the auditor to complete audit task on time and within time budget. Eventually, auditors may tend to practice Dysfunctional Audit Behaviors (DAB) in order to achieve good performance appraisal.

According to Paino et al. (2010), DAB comprises of variety of unethical behavior such as premature sign-off (PMSO) of audit procedure. According to Otley & Pierce (1996), PMSO occurs when auditor signed off a required audit step, not covered by another audit step, without actually completing the work or completely omitted the audit procedures which could affect the quality of final audit opinion and report. This would lead the client to make a misleading decision.

The purpose of this study was to investigate the level of incidence of PMSO by Malaysian auditors and examine the significant relationship of four major factors which had been highlighted by previous researcher (Alderman & Deitrick, 1982; Otley & Pierce, 1996; Paino et al., 2010; Reckers, Wheeler, & Wong-On-Wing, 1997) towards PMSO among Malaysian auditors. Besides that, this study also figured out which audit procedures in these behaviors were the most prevalent.

The Incidence of PMSO

First documentation of exploring PMSO of audit procedure among auditors were made by Rhode (1978) which discovered almost 58 percent of the respondents at least engaged one time of PMSO. Followed by Alderman & Deitrick (1982), the study was actually the replication and extension of the Rhode's study by adding several issues relating to PMSO such as causes for PMSO occurred in the audit field and which audit areas these behaviours are most prevalent. This study pointed out that 31 percent of the respondents acknowledged PMSO occurred in real practice.

Next, the study done by Kelley & Margheim (1987) revealed consistent result with Alderman & Deitrick (1982) with 30 percent of the auditors admitted to commit PMSO at least once in their entire career. Then, Raghunathan (1991) conducted a research of audit personnel in offices of Big Eight accounting firm and discovered 55 percent of respondents responded ranging from very rarely to very frequently in engaging PMSO. After that, research conducted by Otley & Pierce (1996) which collected the data from all of the audit seniors in three Big 6 firms in Ireland found that 60 percent of respondents did at least once in signing off on audit steps without doing the work.

Then, Reckers et al. (1997) examined the incidence of PMSO among auditor using different methodology, namely by comparing the Direct Method (DM) and the Randomized Response Technique (RRT). As a result, the study reported significant higher frequencies of PMSO among auditors by using RRT. Over 78 percent of the auditors admitted that they had engaged at least once in PMSO. This indicated that there was a high degree of biasness when using the DM as compared to RRT as DM tends to influence respondents to respond inaccurately or to refuse to respond at all. In contrast, RRT is the technique that reduces or eliminates respondent's bias by guaranteeing the confidentiality of their responses through a randomization procedure.

The most recent study related to investigation engagement of PMSO among auditors were done by Paino et al. (2010). This study was an exploratory study of the incidence of dysfunctional audit behaviors', particularly in premature sign-off (PMSO), audit quality reduction behaviour (AQRB) and the effect of time budget pressure. This study concluded that PMSO problem exists among Malaysian auditor, with 57 percent of respondents admitting to signing-off prematurely.

Most of the previous studies done were based on the sample which included all range of positions in the audit firm including the top position. However, this study differs by only focusing on junior and senior auditors as the respondents as these groups were regularly face high pressure position to complete the audit works within the time budget planned.

Factors Contributing to PMSO

Audit Steps Appearing Unnecessary or Immaterial

Theoretically, auditors are required to test all audit procedures and give reasonable assurance toward client's financial statement. However in real practice, there are some auditors had prematurely signing off the audit procedures because they consider that audit procedures are unnecessary or immaterial. According to CAR Report explored by Rhode (1978), perceiving audit step as is one of the major causes of dysfunctional audit behavior. This is consistent with the study reported by Alderman & Deitrick (1982); Otley & Pierce (1996); Paino et al. (2010) which found out audit step that appearing unnecessarily is a top perceived cause of PMSO.

Otley & Pierce (1996) and Paino et al. (2010) showed that the incidence of PMSO often occurred during the review of internal control system (ICS) and vouching of expense as the auditor just concerned only with the existence and completeness of the transaction on audit assertions and objectives besides using the previous year's recorded understanding as an evidence of the existence of ICS. Thus, auditors tend to sign-off those audit procedures because they consider it unnecessary or immaterial as these areas involve relatively small amount of working paper documentation (Alderman & Deitrick, 1982).

Time Budget Constraint

Time budget constraint always become a problem to the auditors to finish the audit work on time (Braun, 2000). Supposedly, auditors are allocated with reasonable time budget by the audit manager to complete the audit task. However, time budget allocated to audit staff sometime is not relevant and too short compared to audit task assigned. Based on the survey conducted by Cook & Kelley (1988), 36 percent of the respondents admitted time budgets were ''very tight and practical unattainable''. Similarly, survey conducted by Kelley & Margheim (1990) to audit staff in

US found that 18 percent of the respondents believed time budgets are either ''very tight, practically unattainable'' or ''impossible to achieve''. Willet & Page (1996) reported that 15 percent of the respondents believed time budget was ''not nearly enough'', 53 percent believed it was ''not quite enough''.

Meanwhile, Otley & Pierce (1996) showed that nearly 17 percent of time budget were ''impossible to achieve'', 29 percent were ''very tight and practically unattainable''. Coram, Ng, & Woodliff (2003), indicated that 51 percent of the respondents who were the Australian auditors considered that time budgets ''sometimes'' adequate and 2 percent believed that were ''never'' adequate. Moreover, Pierce & Sweeney (2004) conducted a survey to Ireland senior auditors which finally found 36 percent of the respondents indicated that time budgets were either ''very tight, practically unattainable'' or ''impossible to achieve''. Therefore, from the result of plenty past research indicated that time budget allocated to audit staff was considered inadequate and difficult to attain and to complete the audit task within time budget assigned to them. For that reason, Hyatt & Lovig, (2001) concluded that one of the most common reasons why auditors engaging PMSO was because of the time budget pressure and Coram et al. (2003) recommended that the level of time budget pressure may tend to mitigate the audit quality.

Inadequate Supervision

Audit supervisor or manager's role is quite important to detect the poor work done such as PMSO of audit procedures by audit staff. Generally, audit manager is responsible for organizing and overseeing the audit process in accordance with audit planning and expected to supervise and coach the audit staffs to ensure that audit process are completed in line with all the relevant requirements. According to Alderman & Deitrick (1982), Otley & Pierce (1996) and Paino et al. (2010) inadequate supervision was among the top causes of PMSO.

Sometimes, audit senior or supervisor has discovered PMSO of audit steps done by audit staff, but they refused to report that dysfunctional behavior. In fact, Alderman & Deitrick (1982) found that 78 percent of the respondents agreed that their firm's review procedures were adequate to detect PMSO among the audit staff. According to Hyatt & Taylor (2013) who investigated the reporting intention of auditor's managers discovered that audit staff under their supervision has prematurely signed-off the audit step and they were less likely to report the incidence when the audit staff worked under tight time budget or when unintentionally committed. Due to that reason, audit staff believes that they can easily commit PMSO because audit supervisors are not stringent in formally reported that behavior. Thus, audit staffs feel that they are not adequately supervised by their supervisor or manager and can simply prematurely signed-off the audit steps especially those perceived unnecessary or immaterial. Previous research suggested to solving inadequate supervision by providing adequate training to audit supervisors. The effective training can allow them to prevent and more likely to detect PMSO committed by an auditor under their supervision. In addition, Hyatt & Prawitt (2010) discovered that when the firm policies regarding PMSO were clearly stated, the supervisors were more likely to report the incidence detected.

Readily Accept Client Explanation

Sometimes, when the time budget planned reach the limit or auditors lack an effort to carry out the audit work, they tend to accept the client explanation as a sufficient evidence matter without further investigation. Acceptance of weak client explanations and superficial review documents may give a direct threat to the quality of the audit (Coram et al., 2003; Otley & Pierce, 1996; Paino et al., 2010). Commonly, this factor occurs when auditors do not have enough time to do a proper test or conduct audit procedure to the client's accounts due to time budget constraint. When the auditors need to finish the audit task in a short period, they may tend to omit or sign-off some audit procedures that they feel as immaterial and not significant. Then, they just accept the client explanation without extensively check and review the client's documents. Studies conducted by several past researchers obviously proved inclination to readily accept client explanation was among the major perceived cause towards PMSO.

Based on study conducted by Alderman & Deitrick (1982), unquestioning acceptance of client representation was the top perceived cause contributed to PMSO among auditors. Otley & Pierce (1996) found that the inclination to readily accept client explanation was the fourth place that cause PMSO of audit steps or procedures and this result was consistent with exploratory study by Paino et al. (2010).

Hypothesis Development

The development of hypothesis was to determine the top four perceived causes that have been discovered by previous researchers (Alderman & Deitrick, 1982; Otley & Pierce, 1996; Paino et al., 2010) on engagement of PMSO among Malaysian external auditors. This study examined the relationship between audit steps appearing unnecessary (ASU), time budget constraint (TBC), inadequate supervision (IS) and readily accept client explanation (RACE) on the incidence of PMSO among Malaysian external auditors (IPMSO). Thus, the hypothesis developments are as follows:

H1. High perceived cause of an audit step appearing unnecessary will be associated with high level engagement of PMSO among Malaysian external auditors.

H2. High perceived cause of time budget constraint associated with high level engagement of PMSO among Malaysian external auditors.

H3. High perceived cause of inadequate supervision associated with high level engagement of PMSO among Malaysian external auditors.

H4. High perceived cause of readily accept client explanation associated with high level engagement of PMSO among Malaysian external auditors.

Research Methodology

This study distributed 125 survey questionnaires to the various audit firms in Peninsular Malaysia which randomly selected from the Malaysian Institute of Accountants (MIA) website. 99 responses were received with 79 percent response rate. Sekaran (2007) mentioned that a sample size which was larger than 30 and less than 500 would be appropriate for most research. Thus the sample size was considered acceptable for this study. The focus for this study was the audit seniors and audit juniors from various sizes of firms, Malaysian-wide ranging from small firms to the big '4' firms. In Malaysia, audit senior is usually involves in deciding the audit procedures and the audit programmes. They are also the person around the mid-point in the firm's hierarchy and occupies the most high pressure position in the firm (Otley & Pierce, 1996) and responsible to coordinate and supervise the execution of the audit work programme and are responsible to liaise with client. Meanwhile, audit junior is a person around the lower-point in the firm's hierarchy and also faces high pressure position in order to complete the audit works within the time budget planned. Due to high pressure, audit senior and audit junior may tend to commit PMSO on audit steps.

This study used multiple linear regression analysis to test the relationships. Multiple linear regression analysis was suitable for this study because both independent and dependent variables were numerical (Hair, Anderson, Tatham, & Black, 1998) and was well-recognized for bridging the gap between analysis of variance and correlation in addressing research hypothesis (McNeil, Kelly, & McNeil, 1975).

Analysis and Result Discussion

The incidence of Premature Sign-off (PMSO)

This study found that PMSO problem exists with 34.3 percent of the respondents admitting to commit PMSO during their audit work. This result closes to the 31 percent and 30 percent reported by Alderman & Deitrick (1982) and Kelley & Margheim (1987) respectively, but much lower than the 57 percent reported by Paino et al. (2010). Table 1 shows the level of engagement PMSO among auditors in Malaysia.

Table 1: Level of Engagement PMSO

PMSO among Malaysian external auditors	External Auditor's Rank	
	Yes	No
Number of respondents admitting to signing-off prematurely	34.3 %	65.7 %

Audit Areas or Procedures in Which PMSO Most Prevalent

Next, this study presented with a list of the major audit areas on which auditors felt PMSO prevalently occurred. Two areas of audit stand out as having a significant greater likelihood of PMSO were vouching expenses and

followed by physical inventory count. The finding from this study was slightly different with previous study by (Alderman & Deitrick, 1982; Otley & Pierce, 1996; Paino et al., 2010) which highlighted review/testing of the ICS was the most prevalent audit areas has been prematurely signed-off and followed by vouching expenses. Vouching expenses was expected to be the most common auditors likely to sign-off as it involved relatively small amount of working paper documentation (Otley & Pierce, 1996).

Area	Mean score	SD	Percentage of respondents who reported that PMSO occur at least sometimes
Vouching of expenses	3.20	0.94	77.8
Physical inventory count	3.05	0.98	73.7
Account receivable	2.92	0.94	74.8
Cash	2.92	1.03	73.8
Account payable	2.91	0.97	73.8
Other inventory	2.88	0.90	70.7
Review/testing of internal control system (ICS)	2.84	0.90	68.7
Fixed assets	2.71	0.96	64.6

Note: Frequency was scored on a scale of 1 to 5, where 1=never, 2=rarely, 3=sometimes, 4=often, 5=nearly always.

Statistical test of hypotheses

Results of the regression analysis shows *H1* has positive and significant relationship between audit steps unnecessary with the engagement of PMSO with t-value of 2.435, ($p < 0.01$, one-tailed). Next, *H2* also has been supported whereby time budget constraint were significantly associated with the engagement of PMSO with t-value of 2.075, ($p < 0.05$, one tailed). Based on the result in Table 2 below, the regression result also supported *H3*, inadequate supervision and engagement of PMSO with t-value of 2.833, ($p < 0.01$, one tailed) and *H4* also has positive and significant relationship between readily accept client explanation and engagement of PMSO with t-value of 1.945, ($p < 0.05$, one tailed).

Table 2: Regression Result between variables

	Std Error	Beta	t-value	p-value
Audit Steps Unnecessary (ASU)	.091	.234	2.435**	.017
Time Budget Constraint (TBC)	.100	.198	2.075*	.041
Inadequate Supervision (IS)	.103	.263	2.833**	.006
Readily Accept Client Explanation (RACE)	.090	.190	1.945*	.055

**p<.05; ** p<.01 (One-tailed test for hypothesized analysis)*

Conclusion

This study intended to close the gap by testing the relationship between perceived causes that have been discovered by previous researchers towards the incidence of PMSO among Malaysian external auditors and investigating the current level of PMSO in Malaysia. Subsequently, this study has developed four hypotheses whereby high perceived causes of audit steps unnecessary (ASU), time budget constraint (TBC), inadequate supervision (IS) and readily accept client explanation (RACE) will be associated with high level engagement of PMSO among Malaysian external auditors.

The result showed significant positive relationships between four independent variables with the level incidence of PMSO in Malaysia. The linear regression was used to test the relationship of four independent variables. The t-value of all independent variables reported significant result by using one-tailed measurement, whereby audit steps unnecessary (ASU) having t-value of 2.435, time budget constraint (TBC) with t-value of 2.075, inadequate supervision (IS) with t-value of 2.833 and readily accept client explanation (RACE) with t-value of 1.945. Therefore, all of these independent variables have significant impact to the incidence of PMSO among Malaysian external auditors.

Limitation

The limitation of this study would be the possibility that the respondents may not respond to the survey in the same way that they practice in their audit task. The questionnaire may have not been given to personnel who might have made the most negative behavior during their audit works, namely in relation to PMSO. Respondents may not accurately answer the survey. Thus, a few of respondents may significantly understate the incidence of PMSO.

One of the limitations includes the sampling bias whereby this study only focused on the senior and junior auditors as the target respondents and this do not cover the whole level of personnel in the audit assignment, namely the audit manager and partner.

Abstract

This study aims to examine the factors influencing employees' whistle blowing practices. Specifically, this study examines the effect of job satisfaction, fair treatment and cooperativeness among the employees in the public listed companies. This study utilizes the Miceli-Near-Dworkin model that discusses on the characteristics of an individual, the situation as well as the organisation that commit events of misconduct and the relative power of the parties over one another as well as the consequences for the individual who blows the whistle. Using questionnaire survey on 137 employees in a public listed company in Malaysia, this study shows that there is a significant relationship between fair treatment and whistle-blowing practices. However, the remaining two factors which are job satisfaction and cooperativeness do not have significant relationship with the whistle blowing practices among the employees in the public listed companies. The findings of this study provides understanding to the management of the public listed companies in relation to whistle blowing practices. The findings of this study offer information to the management of the public listed company regarding the whistle-blowing practices. The findings of this study would be able to raise awareness amongst the officers in terms of being willing to report the occurrence of any wrongdoings in the organisation. This study also provides awareness among the employees and subsequently, create a better and healthier environment in the organisation.

Keywords: Job satisfaction, fair treatment, cooperativeness, corruption, whistle blowing.

Introduction

Corruption has continued to become a serious problem throughout the world. In Malaysia, the Malaysian Anti-Corruption Committee (MACC) in its 2016 annual report reported 6,551 corruption cases. Out of the 6,551 cases, 3,417 cases were related to corruption issues such as accepting bribe, giving bribe, abusing power and false claim. These wrongdoings provide negative impacts to the organisation and affect the nation's economy. The Malaysian government have taken various control mechanisms to curb such practices. One of the control mechanisms to avoid corruption cases is by implementing whistle-blowing practices in the organisation (PWC, 2014). According to Near and Miceli (1985), whistle-blowing can be defined as the disclosure by organisation members on illegal or illegitimate practice to a person (Brennan,

2012). Good whistle-blowing practices in an organisation may lead to good governance practices as well as ensuring good working environment (Zakaria, 2000)
.
The 2009 Global Corruption Report noted that whistle-blowing is one of the control mechanisms that can enhance accountability and honesty in an organisation by detecting wrongdoings which include unethical acts, fraudulent activities, mismanagement and corruption. However, only 23% of the corruption cases were informed by the whistle-blowers (Global Corruption Report, 2009). The low number of whistle blowers indicates that many employees are still afraid to report any wrongdoings in their organisation. In Malaysia, the Act for the protection of whistle-blowers has been established in 2010. The objective of implementing this whistle-blowing protection act is to give protection to those who blow the whistle which is by ensuring confidentiality of the information given and protecting them from criminal actions as well as detrimental actions being done to them. This Act is one of efforts done by the Malaysian Government's to reduce corruption cases as well as promote good governance under the name of Government Transformation Program (GTP).

According to the PWC report in 2014, most of the companies in Malaysia have effective whistle-blowing systems but they are not practiced in the real life. Even in Malaysia, most of the companies are still lacking in whistle-blowing practices due to the gaps in the law (IDEAS, 2017). In addition, the MACC chief commissioner noted that there is still a lack of public awareness on the protection of the informants. The agency has to convince the public that all the information given will be fully protected under the 2010 whistle-blower Act. It was reported that only 214 out of 1.6 million government servants have the courage to practice whistle-blowing since 2011 (Bernama, 2018). For example: A corruption case involves one public listed company, where the MACC has raided the company over alleged power abuse over training contracts worth RM4 million since 2014 (Bernama, 2018). The conflict of interests in the organisation may lead to intentional or unintentional corruption activities. The second issue is regarding the chairman of the company who was accused of feasting with the company's money. This case was reported by an external informant who was willing to report the wrongdoing in the organisation. Based on the cases, it is proven that whistle-blowing might not be practiced in the organisation. Understandably, whistle-blowing is not an easy task. This action needs one's courage to be able to put the public interest ahead of his or her own interest. In order to encourage whistle-blowing practices, the organisation needs to provide the right channel to whistle-blow and implement whistle-blowing policies that can protect the whistle-blowers (Said, Alam, Mohamed & Rafidi, 2017).

This study aims to examine the factors influencing whistle-blowing practices among employees in the public listed company. Specifically, this study examines the effect of job satisfaction, fair treatment and cooperativeness on whistle-blowing practices among employees in a public listed company. These factors are chosen based on the Miceli-Near-Dworkin model that discusses on the characteristics of an individual, the situation as well as the organisation that commit events of misconduct and the relative power of the parties over one another as well as the consequences for the individual who blows the whistle (Near, Dworkin & Miceli, 1993; Miceli, Near & Dworkin, 2008). The findings of this study can provide insights into corruption cases for the management of the public listed companies in general. The findings of this research will assist the management to execute policies to encourage employees to blow the whistle and consequently, promote effective internal control mechanism. The next section, Section 2 presents the relevant literature review. Section 3 explains on the research design. This is followed by Section 4 that presents the results and discussion. The last section, Section 5 concludes this study.

Literature Review

Whistle Blowing

The whistle-blowing term which originated from England, arises from a case of English Policemen who blew the whistle to alert the public and the authority to the crime cases that were occurring among them (Hersh, 2002). It is defined as the disclosure by employees of any organisation of any illegal, unethical or unlawful practices controlled by employers to the person or organisations that may affect the action (Mesmer & Viswesvaran, 2005). Other studies defined whistleblowing as the deliberate disclosure of information on non-trivial activities that are considered hazardous, illegal, unethical or discriminatory as well as any wrongdoings done by any employees in the organisation (Hersh, 2002)

In terms of whistle-blower, the 2010 Whistle-blower Protection Act (WPA, 2010) referred whistle blower as anyone who discloses wrongful behaviour to the enforcement agency. The Securities Commissions Malaysia on the other hand,

defined a whistle-blower as a person who informs someone in the authority on the basis of information reasonably believed to disclose an unlawful, illegal or dishonest activity. Certainly, these definitions involve all activities in which the employees use their power to report a wrongdoing in their organisation to the right channel, which is not for their own benefits, but for the company's sustainability in the industryEssentially, the definitions contain the idea that the employees willingly report any wrongdoings such as corruption, misappropriation of assets, fraudulent activities, and the abuse of power to the right channel. The whistle blower can practice to blow the whistle to the correct channel, either internal or external. Internal channel, such as the department of internal audit is responsible for taking action on all wrongdoings reports done by the employees. They have to investigate the level of seriousness of the case. If the case can affect the whole organisation proper actions will be taken by following the standard procedures (Said et al., 2017). The whistle-blower can report wrongdoings to the external channel as well. In Malaysia, there are a few enforcement agencies who act as an agent to enhance the whistle-blowing practice. Whistle blower may report the wrongdoing to the seven Malaysian law enforcement agencies, such as the Royal Malaysian Police, MACC, Department of Immigration, Department of Road Transportation, Securities Commission and Companies Commission of Malaysia. According to WPA, general powers have been given to enforcement agencies to receive any report of inappropriate conduct, to enforce protection of whistle blower, to deal with the inappropriate conduct disclosure, to receive and deal with complaints of inappropriate actions, and to enhance the provisions of the Act.

There are a few steps in the process of whistle-blowing. First, whistle-blower must do an observation with regard to the wrongdoing. Secondly, the whistle-blower must assess whether the event requires someone to be reported to the right channel or not. Thirdly, the whistle-blower evaluates if that is her/his responsibility to blow the whistle. After that, the whistle-blower will perform a cost-benefit analysis of blowing the whistle. This is required to determine whether the decision is sound or not. Lastly, the whistle-blower may take an action as to whether he or she should leave the organisation or make a report to the right channel or refrain from making any action and remain silent (Keil, Lockhart & Schlegel, 2010). It is hard for the employees to practice whistle-blowing in the organisation due to many factors that may affect the action. In addition, The Miceli-Near-Dworkin model explains about whistle-blowing specifically in terms of its predictors and consequences. This pro-social behaviour model also discusses about the characteristics of an individual, the situation as well as the organisation that is involved with the event of misconduct, the relative power of the parties over one another and also the consequences for the individual who blows the whistle (Miceli, Near & Dworkin, 2008). However, most of the studies that examined whistleblowing focused on individual personal intention and qualities that shape the whistle blowing practice in an organisation. This study extends the literature to include not only individual but also on situation and organisation. Specifically, this study focuses on three factors that may influence whistle-blowing practice of an individual (job satisfaction), the situation (cooperativeness) and the organisation (fairness treatment).

Job Satisfaction

Job satisfaction indicates the degree of the employees' positive emotion toward their job. The definition of job satisfaction is a composition of both the environmental and physiological circumstances that will make the person contented with his or her task (Aziri, 2011). There are three components in job satisfaction which are the affective, cognitive and behavioral components (Jex, 2002). The intuitive component referring to the sentiment towards the job. The cognitive factor represents the belief regarding the job. The cognitive and affective components are two closely related aspects. For instance, an employee may feel motivated towards their job and believe that they can perform well. The behavioral component represents the behavioral aspects of the job such as never being late to work and giving full attention towards their job in order to maintain the quality of work. Job satisfaction is difficult to measure. An individual may be satisfied with one aspect of job, while others may be dissatisfied with the same aspect of the job. Job satisfaction can be measured in many aspects, such as the pay and promotion, level of supervision, colleagues' attitudes, working environment and many more (Cranny, Smith & Stone,1992; Guo, Li & Wu, 2015).

In the context of job satisfaction on whistle-blowing practice, a study found individual factor such as job satisfaction may increase the probability of whistle-blowing practices in an organisation (Said et al., 2017). According to Alleyne (2010), individual factors such as attitudes towards whistle-blowing, perceived behavioural control, independence and commitment can also be factors influencing whistle-blowing. Employees who are highly satisfied with their current job scope, the work environment as well as the payment received, are very likely to protect the job and the organisation from any improper conduct (Cecilia, 2013). This implicates that attitudes of individuals are important in enhancing whistle blower practices. For example: A survey conducted by Cecilia (2013) on 24 federal departments in the US found a negative correlation between job satisfaction and the whistle blowing practice in the federal government. Employees are

highly satisfied with their job, thus reducing the whistle-blowing practice which may affect the image of the organisation. The employee who blows the whistle on any improper conduct can be seen to express revolution (Cecilia, 2013), which mirror to disloyalty to the organisation (Johnson, 2003) and indicates superior's disobedience (Glazer & Glazer., 1987).

To ensure that employees are all able to practice whistle blow, they need to be willing to report the misconduct to the right channel. Other studies found that satisfied workers are less likely to practice whistle blow. For example: Cecilia (2013) found that a good working environment as well as internal control may shape the employees to follow the organisation's policies and procedures, thus reducing number of fraudulent activities in the organisation while Shawner and Clement (2008) found that with a high job satisfaction employees are more likely to blow the whistle internally. There is no evidence on the correlation between job satisfaction and external whistle-blowing. However, if employees do not practice whistle-blowing, it can affect the organisation as a whole. A study in an organisational context by Miceli and Near (1992) stated that people who are satisfied with working life aspects are more likely to participate in whistle-blowing. Hence, the first hypothesis is proposed as follows:

H1: There is a significant positive relationship between practice of whistle-blowing and job satisfaction among employees in a public listed company.

Fair Treatment

Fair treatment can be defined as the state of being equal in many aspects such as in status, right and opportunities among employees in the organisation (Keil et al., 2010). The concept of fair treatment is to ensure that the employees are not be treated differently or less favourably regardless of the different position, characteristic, gender, religious or belief and age. Fair treatment and equality are important to the public value outcome as they can prevent from any negative impacts to the society and economy. In the context of an organisation, fair treatment usually refers to the organisational justice. Generally, the concept of organisational fairness is referring to the employees' fairness perception in the organisation (Colquitt, Greenberg & Zapata-Phelan, 2005). It is a multidimensional structure comprising three components which are distributive justice, procedural justice and interactional justice. Distributive justice refers to the equality of the allocation of company's resources and rewards among the employees (Adams 1965). The work rewards such as the bonus and salary are expected to be fairly allocated among the employees. The second component is the procedural justice. Procedural justice is referring to the equality of treatment and equality in formal policies and procedures which are used for decision-making (Lind & Tyler, 1988). Furthermore, the decision-making process must be fair, accurate, consistent, unbiased, representative as well as ethical. The third component which is interactional justice referring to the quality of interpersonal treatment in the organisation (Bies, 2000).

Fair treatment or equal treatment is one of effective mechanisms for lowering the degree of the employees' intention to leave their current organisation. Some previous studies have found a negative relationship between the perceptions on procedural and distributive justice and federal employees' turnover intention (Rubin 2009). A study has found that equal treatment and equality within the organisation may increase the number of wrongdoings reports (Said et al., 2017). The working environment is one of the factors influencing the employees' behaviour as well as the way they react towards the organisation. The perception of having organisational justice in the organisation will make the employees feel comfortable with the management with regard to improper conducts that may affect the organisation's objective. (Trevino & Weaver, 2011) Found that fair treatment and equality are significant predictors to the number of wrongdoing reports being lodged. It shows that fair treatment makes the employees to be willing to help the organisation to deal with improper conducts. In addition, Murray (2006) also found that the tendency to report improper conducts is positively correlated to the organisational justice. Hence, it can be concluded that fair treatment and equality in the context of whistle-blowing procedures will increase the willingness of employees' to practice whistle-blowing. However, the opposite finding was found by Cecilia (2013) in which there is a negative correlation between fair treatment and whistle-blowing practice. Refusal is one of the reasons why there is none of employees do whistle-blowing.

Previous studies have also found that equality and fair treatment could increase the probability of misconducts within the organisation being reported (Trevino & Weaver, 2001). In contrast with the Miceli-Near-Dworkin Model, their study suggested that higher employee's satisfaction towards the organisation's fairness system leads to more favourable and less retaliatory responses for the whistle blower. A scholar has found that when organisations are perceived to be fair, observers are more likely to blow the whistle internally and less likely to blow the whistle externally. Therefore, this study develops the following hypothesis:

H2: There is a significant positive relationship between whistle-blowing practice and fair treatment among employees in a public listed company.

Cooperation

Cooperation in the organisation is a process whereby employees are involved in the management processes including consultation, discussion, and decision-making and resolving an issue. Cooperation starts with a good communication among the employees which is to understand each other's interests and difficulties. Cooperation is an important aspect in organisational behaviour. An employee who cooperates with the other employee at work is seen to increase his or her loyalty and commitment to the organisation (Hage, 1980). A scholar defines cooperation as a part of the contextual performance or organisational citizen behavior (LePine & Van Dyne, 2001). The competitiveness of any organisation can be enhanced when the top management is able to form a highly motivated, dedicated and efficient team of employees. A dominant factor of workplace cooperation is the support by the employees' and management involvement. Top management's commitment is crucial to ensure that all employees are efficient and effective. Effective workplace cooperation will minimize any misunderstanding or miscommunication. To create a highly motivated workplace, the organisation has to absorb all the costs of training and accept the fact that the process is time-consuming. It will be a worthwhile investment as the outcome may boost the organisation's image in the future. The advantages of having cooperative workers in the organisation include the organisational and the employees' performance as well as the decision-making process will be improved, building trust among one another in the organisation as well as increase the job satisfaction. Other than that, cooperative employees in an organisation may lead to a positive working environment.

In terms of employees' cooperativeness to blow the whistle, a previous study found that whistle blows are more common in the public sector than in the private sector (Rothschild & Miethe, 1999). Whistle-blowing is very likely in an organisation with high performing work groups (Brewer & Selden, 1998). Another scholar has found that an organisation with a strong culture of teamwork or friendship and ethical values or that a democratic organisation is probably more practicing whistle-blow when the employees observe a misconduct. A study conducted by Rothwell and Baldwin (2007) on 184 private employees and 198 public employees in Georgia revealed that team cooperativeness among public employees caused to be more willing to blow the whistle. The result are in lined with prior studies (Vadera, Aguilera, & Caza, 2009) also found similar results, where a cooperative and friendly team is probably more to engage in practicing a whistle blow. In contrast, other scholars found a different results from the above findings. According to (Said, Alam, Mohamed, & Rafidi, 2017), the better cooperative team and flexibility of working environment may diminish the tendency of practicing whistle-blowing. A cooperative team would create a good environment and better communication mechanisms, thus reducing misconducts or whistle-blowing practice (Cecilia, 2013). Cecilia (2013) found that cooperativeness in the working environment may reduce events of wrongdoings. Moreover, cooperative team and flexible working environment with good dissemination and level of dedication would encourage the employees to internally handle the misconduct due to the excellent teamwork. Therefore, the following hypothesis is developed:

H3: There is a significant positive relationship between whistle-blowing practice and cooperativeness among employees in a public listed company.

Research Design

Sample Selection

The target population involved in this study is the employees in one of the public listed companies in Malaysia. This company is chosen due to its corruption case, where the MACC has raided the company over alleged power abuse over training contracts worth RM4 million since 2014 (Bernama, 2018). The conflict of interests in the organisation may lead to intentional or unintentional corruption activities. The second issue is regarding the chairman of the company who was accused of feasting with the company's money. This case was reported by an external informant who was willing to report the wrongdoing in the organisation. Therefore, this company deems suitable to be used to examine the factors on why the employees do not want to do whistle blow.

This study focuses on all departments in the public listed company. The participants for this study range from the lower to the upper ranks which are as follows: Assistant Executive, Senior Assistant Executive, Executive, Senior Executive, Manager, Senior Manager, General Manager, Senior Group General Manager and Top Management. The total number of employees in the company was about 200 employees.

Research Instrument

This study used a questionnaire survey as the research instrument. The questionnaire was developed based on the Miceli et al. (2008) with some modifications. The questionnaire contains five parts, which are Parts A, B, C, D and E. The first Part A contains five questions that dealing with the whistle blowing practice in the company, for example "*Management in this company disciplines unethical behaviour when it occurs", "Penalties for unethical behaviour are strictly enforced in this organisation.", "Top managers regularly show that they care about ethics in this organisation" and "My organisation enforces the code of ethics"*.

Next, Part B contains (5) questions that address the Job Satisfaction that determine the intrapersonal characteristics in the company such as "*I am satisfied with the task given to me", "All jobs done by me are appreciated by the upper level management"* and *"I feel motivated working in this organisation"*. Whilst, Part C contains (5) questions that address the Fair treatment by the organisation towards all employees in the company. For instance, "*There is equal opportunity for advancement at the Company", "Job promotions are awarded fairly and without bias" and "Performance Appraisals are fair and unbiased"*.

Part D contains (5) questions that address the Cooperativeness of the officers in the company such as "*My work unit is able to recruit people with the right skills", "Information is shared freely in my work unit"* and *"A spirit of cooperation and teamwork exist between my work unit and other work units"*. Lastly, Part E consists five questions that address the respondents' demographic. The participant are required to share their basic information such as gender, education level, job position, age, department, years of service in the company and their working experiences.

Data Collection

The data were collected via the Google form to distribute the questionnaires and personally meeting up the respondents, one by one. The total number of respondents in the company's Headquarter was identified to be about 400 employees in total. Thus, a duration of about a month was taken in order to attain the task of collecting all data from the distributed questionnaires. At first, this study tried to gather the information from all employees of the company as well as its subsidiaries. Out of the 200 questionnaires distributed, a total number of 137 respondents was acquired, resulting in a 68.5% response rate.

Results and Discussion

Descriptive Analysis

In this study, descriptive analysis was used to summarize data for each variable namely, job satisfaction, fair treatment, cooperativeness and whistle-blowing practice among employees of the public listed company. Table 1 depicts the overall means and standard deviations for the variables used. The whistle-blowing practice as the dependent variable score a mean value of 3.275 with standard deviation of 0.9208 and it was measured based on a five Likert scale point ranging from 1 as strongly disagree to 5 as strongly agree. The mean for job satisfaction is 3.425 with a standard deviation 0.8428 indicating that the respondents agree that job satisfaction is one of the factors that influence whistle-blowing practice in the public listed company. Meanwhile, the mean values for fair treatment and cooperativeness are 3.003 and 3.546 with standard deviations of 0.9033 and 0.7501 respectively.

Table 1: Descriptive Statistics

	N	Mean	Std. Deviation
Whistleblowing Practices	137	3.275	0.9208
Job Satisfaction	137	3.425	0.8428
Fair Treatment	137	3.003	0.9033
Cooperativeness	137	3.546	0.7501
Valid N (listwise)	137		

Validity Analysis

A factor analysis was carried out to test the validity of the instruments used in this study because the factor analysis is used to reduce a high number of variables to a smaller set of underlying factors containing all the essential information (Pallant, 2005). This method was used in this study to identify the underlying dimensions of job satisfaction, fair treatment and cooperativeness. Two statistical measures of the SPSS are used to assess data factorability, namely the Bartlett Test of Sphericity as well as Kaiser Meyer Olkin (KMO). The KMO measures the sampling adequacy and the sphericility test of Bartlett is used to measure the factorability of the matrix. If the KMO value exceeds 0.60 and the sphericity test of Bartlett is significant (less than 0.05), the data set is therefore suitable for factor analysis, as recommended by Pallant (2005). To interpret the results for each factor, the load factor for each measured item must be at least 0.30 in order to meet the minimum level. According to Field (2009), loading factor that values more than 0.50 is considered important and therefore any item that values a factor load of less than 0.50 has been eliminated in this study to achieve the most significant value.

Table 2 depicts that the result for factor loading for each question on whistle blowing-practices ranges from 0.882 (A01) to 0.807 (A03). The KMO test shows a value of greater than 0.60 which is 0.655 (Chi-square = 184.828, p-value = 0.000). However, there are two items removed which are B04 and A05 because the factor loading values were lower than 0.50. Therefore, the sample is sufficient to be used in this factor analysis and the knowledge variable supported in this study.

Table 2: Factor Analysis – Whistle blowing practice

Whistle blowing Practice	Factor	
A01	0.882	
A02	0.88	
A03	0.807	
A04	0.201	
A05	-0.145	
Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		0.655
Bartlett's Test of Sphericity	Approx. Chi-Square	184.828
	df	10
	Sig.	0.000

Table 3 depicts that the result for the factor loading for each question on job satisfaction ranges from 0.899 (B03) to 0.729 (B01). The Kaiser-Mayer Olkin test shows a value of greater than 0.60 that is 0.824 (Chi-square = 381.092, p-value = 0.000). Therefore, the sample is sufficient to be used in this factor analysis and the knowledge variable supported in this study.

Table 3: Factor Analysis – Job Satisfaction

Job Satisfaction	Factor	
B01	0.729	
B02	0.839	
B03	0.899	
B04	0.879	
B05	0.735	
Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		0.824
Bartlett's Test of Sphericity	Approx. Chi-Square	381.092
	df	10
	Sig.	0.000

Table 4 shows that the result for the loading factor for each question on fair treatment ranges from 0.905 (C02) to 0.598 (C03). The KMO test shows a value of greater than 0.60 that is 0.837 (Chi-square = 342.369, p-value = 0.000). Therefore, the sample is sufficient to be used in this factor analysis and the knowledge variable supported in this study.

Table 4: Factor Analysis – Fair treatment

Fair Treatment	Factor	
C01	0.858	
C02	0.905	
C03	0.598	
C04	0.865	
C05	0.762	
Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		0.837
Bartlett's Test of Sphericity	Approx. Chi-Square	342.369
	df	10
	Sig.	0.000

Table 5 shows that the factor loading result for each cooperative question ranges from 0.820 (D02) to 0.674 (D01). The Kaiser-Mayer Olkin test shows a value of 0.60 that is 0.775 (Chi-square= 252.285, p-value= 0.000). The sample is therefore adequate for this factor analysis and the test supported the variability of knowledge in this study.

Table 5: Factor Analysis- Cooperativeness

Cooperativeness	Factor	
D01	0.674	
D02	0.820	
D03	0.819	
D04	0.781	
D05	0.749	
Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		0.775
Bartlett's Test of Sphericity	Approx. Chi-Square	252.285
	df	10
	Sig.	0.000

Reliability Test

The ideal alpha coefficient of Cronbach should be higher than 0.700, according to Pallant (2005). Likewise, a modest reliability of 0.500 to 0.600 would be sufficient, as supported by Nunally (1978). Before testing the hypotheses in this study, an alpha test was used to ensure the reliability of the questionnaire instruments developed in this study. All variables used in this study were measured on the basis of a 5-point liker scale from 1 to 5. Table 6 shows the statistical test of reliability for all variables. The reliability coefficient Cronbach's alpha for whistle blowing practice had a scale of 0.824. This shows that the practice of whistling is good for the reliability of all three scaled items. Besides that, the job satisfaction had a reliability coefficient of 0.876. This result indicates that job satisfaction are consistent for the 5 items in the questionnaire where it is good and reliable. This results in a good and reliable job satisfaction for the five items in the questionnaire. In addition, Cronbach's alpha reliability coefficients were 0.858 and 0.823 respectively for fair treatment and cooperation. This indicates that both variables are good and reliable with 5 scaled items.

Table 6: Reliability test

Reliability coefficients	Cronbach's Alpha	Cronbach's Alpha Based on Standardized Items	N of Items
Dependent Variable			
Whistle Blowing Practice	0.824	0.824	3
Independent Variables			
Job Satisfaction	0.876	0.875	5
Fair Treatment	0.858	0.858	5
Cooperativeness	0.823	0.827	5

Normality Statistic

A normality test was conducted to determine whether the data used in this study are properly modelled according to the rules of normality. Table 7 shows that all data sets are normally distributed across all variables where the skewness values for the variables are in the positive or negative range of 2, while the kurtosis values for all variables are below 7.

Table 7: Normality test

	N	Skewness		Kurtosis	
	Statistic	Statistic	Std. Error	Statistic	Std. Error
Dependent Variable					
Whistle blowing Practice	137	-0.414	0.207	0.006	0.411
Independent Variables					
Job Satisfaction	137	-0.078	0.207	-0.501	0.411
Fair Treatment	137	0.060	0.207	-0.341	0.411
Cooperativeness	137	-0.154	0.207	0.002	0.411
Valid N (listwise)	137				

Pearson Correlation Analysis

This study carried out a correlation coefficient test of Pearson to measure the strength of the variables. Based on Table 8, the correlation between whistle blowing practice and fair treatment is moderately positive with a coefficient of r= .537 with a p- value of less than.01. This indicates that there is a positive relationship between both variables with an increase in fair treatment, the whistle blowing practice is likely to increase and vice versa. In addition, there is a low positive correlation with a coefficient of r = .482 and r = .405 with a p-value of less than .01 between the whistle blowing practice and job satisfaction and cooperativeness. This indicates that there is a positive relationship between these three variables, where an increase job satisfaction and cooperativeness will likely result in an increase in whistle blowing practice.

Table 8: Correlation Test

Pearson Correlations Coefficient Test				
	Whistle Blowing Practices	Job Satisfaction	Fair Treatment	Cooperat iveness
Whistle blowing Practice	1			
Job Satisfaction	.482**	1		
Fair Treatment	.537**	.782**	1	
Cooperativeness	.405**	.676**	.602**	1
***. Correlation is significant at the 0.01 level (2-tailed).*				

The Pearson correlation coefficient was used in the previous section to determine whether there is an important relationship between the independent variables and the dependent variable. The result shows that all independent variables have positive related to the dependent variable in a significant way. However, the correlation is interpreted as moderate and low based on the r coefficient, as all values are below 0.70 and 0.50. Fair treatment has the strongest correlation between the three independent variables with whistle blowing in comparison with job satisfaction and cooperativeness. However, correlation analysis could only explain the relationship between two variables in terms of their magnitude and direction, in which they are a direct relationship. It can therefore be said that cooperativeness, fair treatment and job satisfaction are the causes of whistling among the employees.

Multiple Regression Analysis

Multiple linear regressions can be used to investigate the linear relationship between one variable dependent and two or more independent variables. It can therefore be used in this study to determine the relationship between the independent variables and the dependent variable. There are three independent variables, job satisfaction, fair treatment and cooperativeness. The results of the multiple linear regression test are shown below in Table 9. The results indicate that R is 0.303. This indicates that 30% of the variation in whistle blowing practice is due to the variation in job satisfaction, fair treatment and cooperativeness.

Table 9: Regression Analysis

Variables	B	Std. Error	t-stat	P-value	VIF
(Constant)	1.250	0.332	3.767	0.000	
Job Satisfaction	0.121	0.139	0.865	0.389	3.104
Fair Treatment	0.403	0.120	3.356	0.001	2.644
Cooperativeness	0.114	0.122	0.930	0.354	1.889
R				0.55	
R Square (Adjusted R Square)				0.303 (0.287)	
F-statistic				19.261	
Durbin-Watson statistic				1.848	
a. Dependent Variable: Whistleblowing Practice					

Based on Table 9, the result for job satisfaction is no significant positive relationship between job satisfaction and whistle blowing practice ($\beta = 0.121$, $t = 0.865$, $p = 0.865$) and hence the H1 hypothesis is not supported. Although the result shows a positive relationship, however, the result is insignificant. This finding could be attributed to the attitude or character of the employees. Often when the employees are not happy with their job, it is not because of corruption but more because they are not happy with their job. Therefore, they would leave instead of detecting corruption activities and reporting to higher authorities. In contrast, the result for fair treatment indicates that there is a significant positive relationship between fair treatment and whistle blowing practice ($\beta = 0.403$, $t = 3.356$, $p = 0.001$) and hence, H2 hypothesis is supported. The beta coefficient for fair treatment is 0.403 indicating that for every 1 variation change in fair treatment could contribute to a change in whistle blowing practice by 0.403. Arguably, employees who feel that they are not being treated fairly by their superiors would likely report their superiors' wrongdoing. For example: the salary of an existing employee obtained lower salary compared to a new employee who has been accepted into the company. As for cooperativeness, the result shows no significant positive relationship with whistle blowing practice ($\beta = 0.114$, $t = 0.930$, $p = 0.354$), hence, the H3 hypothesis is not supported. This finding suggests that cooperative which is more related to task

and teamwork and may not be able to influence whistle blower practice. For example, an employee who is willing to do whistle blower whilst his team mate is against it may somehow deter the one who is willing to do whistle blow due to no cooperativeness from his team mate.

Conclusion

This study examines the factors influencing whistle blowing practices among the employees in a public listed company in Malaysia. Specifically, this study examines the effect of job satisfaction, fair treatment and cooperativeness among the employees in the public listed companies. The results of this study provide information on the practice of whistling among the employees. The first hypothesis, H1 predicts that there is a relationship between job satisfaction and whistle blowing practice in the public listed company. Based on analysis, it was found that there is no significant relationship between these two variables. This result is similar with a study done by Said et al (2017). The finding is also similar to an earlier study conducted by Shawver and Clement (2008) which revealed a positive but insignificant relationship between employees' job satisfaction and whistle blowing practice.

Secondly, the results for fair treatment in this study showed that the employees have a significant and positive relationship between fair treatments and whistle blowing practice. The result of this study show the consistency result with a research done by Said et al. (2017) which described that fair treatment dimensions such as performance appraisal, job assignment, career advancement, award and pay have positive significant relationships with whistle blowing practice. The result of this study also shows consistency with a study done by Trevinor and Weaver (2001) which noted that equality treatment in the workplace may increase the number of misconduct reports.

Thirdly, the results of this study for cooperativeness variable showed that there is no significant relationship between cooperativeness and whistleblowing practice among the employees. This indicates that employees' cooperativeness does not influence whistle blowing practice. The finding is consistent with the results previously observed by Said et al. (2017). A previous study conducted by Cecilia (2013) also found similar results where cooperativeness and flexible environment did give any impact to whistle blowing practice.

The findings of this study have several implications. First, this study revealed that fair treatment has a significant influence as well as positive impact on the perception on whistle-blowing practice among the employees of the public listed company, where the existence of fair treatment would trigger wrongdoings to be reported. A prior study discovered that fair treatment in the workplace would increase the number of wrongdoing reports (Said et. al, 2017). Additionally, according to other studies such as the research by Trevino and Weaver (2001), it is indicated that the environment of fairness in the workplace will be a factor for employees to be more open-minded with regard to reporting wrongdoings. Hence, the management should treat all employees' fairly to prevent any wrongdoings from happening. However, this study found that cooperativeness is not significantly and positively linked to the practice of whistle blowing among the employees. Hence, cooperativeness among employees would not influence or drive employees to report any wrongdoings.

This study is not without limitations. First, the number of respondents is significantly small and a large number of respondents would lead to a more concrete analysis and results. Another limitation of this study is that the first and third objectives have not been achieved as discussed previously, where the results show that job satisfaction and cooperation have not influenced the practice of whistling among employees of the public listed company. It is therefore suggested that more respondents should be involved in the future to enable the researcher to generalize the entire population of the selected group of respondents. It is also suggested that, in order to avoid biased responses in the survey, as whistling normally requires respondents to answer sensitive questions, the researchers may also use indirect ways to ask questions. However, the limitations of this study do not affect the findings of this study, but have been recognized to highlight possible future research opportunities.

The findings of this study offer information to the management of the public listed company regarding the whistle-blowing practice. The outcomes of this study would be able to raise awareness amongst the officers in terms of being willing to report the occurrence of any wrongdoings in the organisation. Most officers know of fraudulent activities in the organisation, but they may be too afraid to act. The aim of this study is to improve the practice of whistleblowing among employees and to create a better and healthier environment in the organisation. This study also helps to view the concept of whistle from a new perspective. Most of the research carried out on whistleblowing focused only on individual personal intention and qualities that shape whistleblowing in an organisation. However, this study attempted to shift the focus on

job satisfaction, fair treatment and cooperativeness in an organisation and how these factors lead to the practice of whistle-blowing in an organisation.

Abstract

The Industry 4.0 solutions have capabilities of enriching the labor of the 4.0 operator, so they are perceived as the ergonomic interventions. According to the analysis of technological processes (TP) in a world-class organization of manufacturing, the complexity of human-machine-environment (HME) systems contributes to the occurrence of ergonomic factors adversely affecting the efficiency of the pursued tasks. In this context, it is important to develop the proper methodology for comprehensive determination of the ergonomic intervention scope within the 4.0 Industry, as well as the artificial intelligence systems taking into account the impact of ergonomic interventions within the 4.0 Industry. The purpose of this papers is the holistic approach into the TP ergonomics intervention management, within the 4.0 Industry. The result of such considerations is the holistic model determining the scope of ergonomic interventions within the I 4.0, as well as the example of the Hybrid Expert System (HES), in order to determine the scope of ergonomic interventions on the operational level of organization (microeconomy), with its subsequent integration with superior levels of the ergonomic intervention management. When reaching the settled goal, the following was detailed in the papers: ergonomic intervention types and examples, the levels and stages of their implementation, the areas and states of their impact, i.e. resulting from the route of technological lines, the selection criteria and their implementation approaches. The selected results of the relationship between the preferential variables of users under research with resource deficits (lacking capabilities) and the properties of manual control devices, are also presented. The obtained results demonstrate differentiation of the preferred device properties in relation to the preferences (age, anthropometric features and health ailments) of the group of people under research. The test results were implemented into the HES inference model and validated, and nearly 80% factor of the system was obtained.

Keywords: Management, Ergonomic Interventions, 4.0 Industry, Artificial Intelligence.

Introduction

The 4.0 Industry (I 4.0) has capabilities of qualitative improvements on operational level, as it is based on proven solutions arising from the Industry 3.0 and implements many new (innovative or inventive) solutions. In this context, the I 4.0 solutions have the capabilities of ergonomic interventions (EI) (as long as their selection increases the quality of human-machine-environment interaction, also referred to as the HME), with consideration to the fact that focus in the I 4.0 is made on a human being, who is referred to as the 4.0 Operator (O 4.0). The O 4.0 in smart factories constitutes the element of operation, with respect to which the remaining elements of the organization make self-improvements towards diversified skills, capabilities and preferences of the O 4.0 (Kaasinen at in., 2020; Fletcher et al., 2020), and technological processes (TP) are simultaneously implemented on a previously unprecedented perfection level, with a dynamic reaction to the changes in the organization and its environment.

Cite this Article as: Kamil WRÓBEL, Tomasz HOFFMANN, and Krzysztof CZARNECKI "Management of Ergonomic Interventions When Modeling the Technological Processes in The Industry 4.0" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

This concept is achieved with means of the solutions based on artificial intelligence (AI). On the one hand, such solutions adapt the TP to the changes at higher levels of organization's operation, with a simultaneous consideration to interaction between the HME and the TP. On the other hand, such solutions improve the manufacturing organization management (Longo, Nicoletti, Padovano, 2017). In terms of ensuring the proper quality of HME interaction, there are measures for the replacement or strengthening the O 4.0. Whereas, the empowerment of O 4.0 is based on the holistic implementation of the EI, by designing or reengineering the products, TP (means of production, i.e. technological lines, technological devices (TD), etc.), as well as the management systems and organization of labor. Thus, the purpose is application of the approaches and methods of ergonomics design and reengineering in the complex and smart (with application of) EI management within the I 4.0.

The ergonomic interventions within the I 4.0 are nothing more than the response to the posed paradigms i. e. Panetto et al., (2019), Pacholski and Kałkowska (2019) and Tan et al. (2019) indicating the integration on the i.e. management, production, logistics and analysis level of organization, whereas their implementation enables i.e. unlocking creativity of the employees (Taylor et al., 2020), the ergonomics improvement for the HME interaction through the selection of the TP elements and their properties, establishing the competitive advantages (Wróbel, 2020b), as well as professional stimulation of people with resource deficits (Butlewski, 2018).

The results of the analysis for EI processes and technological lines of a world-class manufacturing organization demonstrate lacking holistic approach to the management (modeling, implementation and diagnosis) of ergonomic interventions (fig. 1).

a). b). c).

Fig. 1: The examples of lacking EI holistic implementation and diagnosis - a) BMW S1000RR technological line - a standard static computer stand is seen, whereas the display monitor distance to the stand under research is considerable, what requires remote communication; b) BMW S1000RR technological line - the system status indicator insufficiently informs about the progress in operation when completing the motorcycle; c) BMW S1000RR technological line - despite the ergonomic electric handheld devices, the workspace of the assembly stand induces the forced body posture

Source: based on (Vyas 2017)

In the context of difficulties that arise when modeling the I 4.0 solutions, there are detailed directions of researches for development of a methodology, towards the EI implementation within the I 4.0.

On the other hand, the purpose of this papers constitutes determination of the nature of variables that are substantial for the EI implementation, as well as presentation of the Hybrid Expert System used for determination of the EI scope, in terms of adjusting the manual devices and control elements to the O 4.0 with specific resource deficits.

The EI in modeling the HME interaction of technological processes within the I 4.0

Types of Ergonomic Interventions

When modeling the I 4.0 technological processes, the ergonomic interventions constitute the activities and solutions aimed at increasing the quality of HME interactions. They are based on:

1. improving a specific product, organizational operation, IT system or service within the defined ranges of changes, e.g. technological device parameters, duration of operational tasks, or brightness of computer monitors - which allows a slight increase in the overall quality of the solution, service, interactions, etc.,

2. innovation, i.e. a new product, service, or application, that results from the innovative combination of the existing elements; innovation does not exclusively pertain to the technical cases, devices and systems; it can also be searched in development, implementation and improvement of organizational processes on a macro- and micro-scale, as well as organization of people and multidimensional feedback to people (Grabowski, Muraszkiewicz, 2017); as well as ergonomic innovations are also an interdisciplinary approach to the radical and continuous search for new ideas and concepts, based on the knowledge from the applied/development researches from the anthropocentric, social, biotic and technical point of view (Dewicka, 2016); they synergistically increase the overall quality of the solution, or
3. inventions - substantially defining a new quality level for a given solution.

Among the types of interventions referred to above, the ergonomic innovations, constituting the innovations in general, are one of the main factors enabling the comparative and/or competitive advantage. Nevertheless, such innovations may become a decisive factor for the survival on the market (Grabowski, Muraszkiewicz, 2017). The EI are of great importance at times of progressive globalization, development of communication, the increasing competitiveness, the overwhelming importance of financial markets, as well as the enormous advancement in science and technology (Grabowski, Muraszkiewicz, 2017) . In this context, the EI can be discerned as the product, process, technological, marketing, organizational and development innovations, according to the direction of activities (Dewicka, 2016).

The levels and areas of EI implementation during modelling the HME interaction in the technological processes

The ergonomic interventions within the organization are implemented at the strategic, tactical, operational and activity levels (fig. 2). Whereas, the interventions are implemented in relation to the resources and with means of the resources, that are typical to them (soft and hard elements of organization (Marilungo et al., 2017), as well as resource relationships (Wróbel, 2020a).

At the strategic level, it is important to define the goal, form and method of operation in the organization, in a specific environment. The tactical level includes the selection and development of system management solutions. The operational level requires stipulation of technological processes (their number, types, properties of the features). Based on the higher-order levels, the activity levels should be determined, e.g. the implemented movements and their ranges, with division into the activities of the O 4.0, Technical equipment and robots. Panetto and Molina (2008) also distinguish the areas of the I 4.0, such as business, knowledge, applications and communications, in which the EI is implemented (Panetto, Molina, 2008; Panetto at al., 2019). Whereas, the I 4.0 technological frameworks are distinguished (fig. 2) (Frank, Dalenogare, Ayala, 2019).

Fig. 2: The levels and measures for the EI implementation within the TP environment of the 4.0 Industry

Source: Own study based on (Panetto, Molina, 2008; Sławińska, 2011; Panetto et al., 2019; Pacholski and Kałkowska, 2019; Sparrow, 2020)

The social function, such as meeting the customer needs, is implemented with means of functional levels of manufacturing organizations. Thus, the qualitative satisfaction of consumer needs depends on the quality of the designed and manufactured product. According to the I 4.0 paradigms, this function is implemented at the TP level. The quality of TP, as well as its outputs, depends on the quality (the range of parameters) of inputs, i.e. resources (TP elements), according to the systems theory. Technological processes are implemented in the environment with three layers (fig. 2) (Sparrow, 2020).

In the presented TP environment within the I 4.0, interactions in the area of cyber-physical systems are also typical, diagram of which is presented and discussed by Molina and Jacob (2018).

Based on the literature analysis and the adopted division of the I 4.0 solutions, the range of examples for EI types has been presented, according to their areas of application (table 1), which shows the method of their aggregation.

Tab. 1: The examples of ergonomic solutions/interventions within the I 4.0

		The examples of ergonomic solutions/interventions within the I 4.0			

Source: own study based on (Sławińska, 2011; Dewicka, 2016; Frank, Dalenogare, Ayala, 2019; Li, Fast-Berglund, Paulin, 2019; Villalba-Díez et al., 2020)

The list of I 4.0 ergonomic solutions/interventions, that is presented in table 1, is certainly not exhaustive. With regard to the fact, that the issue of the I 4.0 concept is under research, new directions for its concept, implementation and validation may take place. For example, Rauch, Linder and Dallasega (2020) present directions for new researches in the field of CPS systems, whereas Hofmann et al. (2019) discusses directions for further researches in the field of supply chain management. In the field of CPS systems, the convergence of the 3.0 ergonomics and the 4.0 ergonomics is interesting, that was presented by Rauch, Linder and Dallasega (2020).

Implementation stages for the ergonomic interventions within the I 4.0

Panetto and Molina (2008), based on the paradigms and requirements of the I 4.0, proposed 4 implementation challenges/stages for ergonomic solutions (Panetto, Molina, 2008; Panetto et al., 2019):

1. grand-challenge 1 – cpps-based manufacturing plant control,
2. grand challenge 2 – resilient digital manufacturing networks, collaborative control for industry 4.0 and cyberphysical supply chains,
3. grand challenge 3 – cyber-physical system of-systems interoperability
4. grand challenge 4 – interdependent networked systems and data analytics for decision suport.

Above presented challenges constitute the possible stages and directions of EI implementation, and their sequence and degree of implementation depends on the decision criteria. For example, the research results of Frank, Dalenogare and Ayala (2019) demonstrate that the order can be different, depending on the organization size and its industry.

Implementation criteria and limits for ergonomic interventions within the Industry 4.0

When modeling the complex anthropotechnical systems, decision criteria are also important. It can be proved by the fact, that many criteria for the EI scope can be found in the literature. These include the economic and organizational criteria (e.g. with consideration to the organizational structure and division of labor), methods of organizing and performing the work (Pacholski and Kałkowska, 2019), operational (Sparrow, 2020), as well as ergonomic criteria (e.g. Jasiak, Misztal, 2004) (cognitive, sociological, physiological, physical, anthropometric, motor, cultural, etc. requirements). While these criteria constitute decisive factors for certain levels of organization's operation, you should remember that they may appear at other activity levels.

When reaching the specific implementation criteria for the I 4.0 ergonomic interventions, the problems within the manufacturing organizations are related to the specific barriers. According to the research of Türkeș et al., the EI implementation barriers, with application of the solutions determining the I 4.0, involve lacking knowledge of the Industry 4.0, lacking standards, greater emphasis on activities at the expense of the company's development, lacking knowledge of the strategic importance of the Industry 4.0, shortages in human resources, as well as requirements towards continuous employee trainings (Türkeș at in., 2019). Ślusarczyk and Ul Haque came to similar conclusions with means of the research results, in which they demonstrated that "a limited knowledge", "implementation barriers", "identification of potential changes", "periods of new advantages", "preparation of the personnel to challenges" and "priorities other than implementation of the Industry 4.0", in relation to the Industry 4.0, are statistically significant and are intermediate in the relationships between the I 4.0 solutions and the efficiency of logistics companies in Canada and Poland (Ślusarczyk, UL HAQUE, 2019).

Whereas, the stimuli for implementation of the I 4.0 solution are as follows: customer requirements, implementation of the I 4.0 concept in competitive companies, cost-reduction related requirements, time-reduction related requirements for placing the product on the market, as well as legal or industry requirements (Türkeș at in., 2019).

Types of processes and technological lines in the aspect of EI modeling

In the aspect of the IE modeling for the processes and technological lines, one should find the properties existing between the respective elements of operation, and consequently the properties affecting the respective O 4.0. The properties existing between the elements of operation i.e. depend on the order and location of them along the technological line (fig. 3) and the location of the O 4.0 workstations in relation to them, which is i.e. determined by technological process during the production of a specific product.

The functionally grouped elements in a given three-dimensional space (it should be noted in this respect, that the technological line can be i.e. single or multi-storey) create specific workstations, e.g. assembly station, packing station, quality-control station, or the area of raw material processing into semi-finished products or products (e.g. the operational area of the injection molding machine, also consisting of the operator's or the service worker's workstation).

Fig. 3. Types of technological lines according to the orientation of technological equipment (TE) - a). straight; b). broken; c). in an arc; d). reverse; e). zigzag; f). circular; g). with one input direction and multiple output directions; h). with many input directions and one output direction; i) with one input and multiple outputs in the same direction; j). with multiple inputs from the same direction and one output

Source: own study based on (Marilungo et al., 2017)

In the context of the I 4.0, the applied and deployed passive, active and post-accident safety system elements, as well as the ICT systems, are also important (Marilungo at al., 2017).

Implementation of Ergonomic Interventions in The Technological Processes

Designing and Reengineering During Implementation of The Ergonomic Interventions Within The TP

In order to implement the ergonomic interventions within the TP, it is important to consider the relationships in the activity management process in the area of organization's ergonomics (Słowikowski, 2003), as well as process design and reengineering.

During the design and reengineering works, both, it is important to consider the state of other systems in the conceptually or correctively established, new HME systems, which requires a macro-ergonomic approach (Jasiak, Misztal, 2004). Differences between the HME systems are multidimensional, what i.e. results from the changes in general techniques, as well as the changing user features of such systems, as well as the manufacturing systems, by which they are produced (Butlewski, 2019). The result of these changes is the increasing technicalization of human life and TP. Consequently, a human being must be considered, altogether with its role, limitations, etc., when modeling the objects and TP. Despite the fact that designing is often an unstructured process, several stages are discerned, i.e. identification of the problem, formulation of the problem, selection of the solution evaluation criteria, generating the alternatives, evaluating the alternatives, selection of solutions, implementation of decisions, as well as evaluation of a decision effectiveness. It should be noted that these stages are based on a selected decision-making and design strategy (Butlewski, 2019).

On the other hand, the TP reengineering is defined, i.e. as a research procedure including the analysis and diagnostics of the HME system, with purpose of establishing the information processing mechanisms for the designed operational system, thanks to which the optimal load is ensured for a human being who operate the Automated Technical Equipment (Sławińska, 2011).

Determining the scope of EI with means of reengineering i.e. includes consideration to and acquisition of data for O 4.0 labor load factors, a matrix of ergonomic reengineering elements for operational processes, the ergonomic sub-system model, the ergonomic reengineering model for operational processes, data resources on the ergonomics of anthropotechnical systems when modeling the operational chain, criteria for ergonomic reengineering variants, the ergonomics reengineering variants - ergonomic interventions, a model of labor situation for the operational control function with respect to ergonomics, the human activity stages as an operator, human reaction times, methods and techniques of data acquisition and analysis for ergonomic factors when designing the technical systems, the stages of ergonomic data acquisition during the ergonomic reengineering, cyclical reconfiguration model for operational chain supporting the ergonomic reengineering, as well as the stages of research documentation for modification of operational conditions of the O 4.0 (Sławińska, 2011).

Despite the distinction between the design and reengineering processes, it can be clearly seen that these processes are interrelated and require a comprehensive approach to the diagnosis and modeling the HME systems (Wróbel, 2020a).

Identification of The EI Scope for The Technological Processes

With consideration to the issues presented in the article (types and examples of EI, the levels and stages of their implementation, areas and states of their impact, the selection criteria and implementation approaches), a general model of EI implementation with means of the expert system was defined. (fig. 4).

Fig. 4: The inference model for identification of the scope ergonomic interventions in the I 4.0
Source: own study

The model includes data analysis stage for current characteristics of environment and organization, validity diagnostics for EI implementation at an early management stage (AI inference), identification of possible EI determined on the basis of the organization strengths, the identified ergonomic problems (at all levels and areas of the organization) and knowledge in the field of ergonomics, determination of the scope of planned EI implementation when diagnosing the intervention impact on the organization and its environment, as well as resource analyzes of the organization (economic, etc.), evaluation and determination of the sequence for implemented innovations, implementation of innovations, diagnosis and determination of characteristics of the organization and its surrounding (fig. 4).

Application of AI inference based on the presented identification model for EI scope can be carried out in accordance with the Demming's improvement model, in a closed inference cycle (fig. 4 - directions of activities are highlighted in green; while directions of complementary activities are highlighted in black, red and blue, or are periodical.

Determining the EI on the example of shaping the ergonomics of handheld control devices and elements for the O 4.0 having resource deficits

Operation of the O 4.0 is largely based on the human-computer interaction. In this aspect, a hybrid expert system (HES) was developed with consideration to the required feedback for determination of ergonomic interventions and the diagnostics of interaction between the O 4.0 and manual control devices (MCD) for people characterized by resource deficits (the elderly – E). The HES consists of four classification blocks of inference and a fuzzy cognitive map (FCM) (Wróbel, 2020b) for which the methods of supervised learning (node determination module; node strengthening or weakening module; FCM activator module) and unsupervised learning (data control approach with non-linear Hebbian learning; particle swarm optimization approach) have been selected (Stach, Kurgan, Pedrycz, 2008). This system constitutes a proposal for a holistic modeling, implementation and diagnosis of a functional level within the I 4.0. The inference stages and scope, based on the analysis of the operational context, include the selection of the MCD type and the test type in order to validate the system recommendations, the selection of MCD features based on the user's preference options, as well as validation of the system recommendations.

The system was built with consideration to the conclusions from the literature analysis (incl. Hertzum, Hornbæk, 2013; Lin, Young, Dennerlein, 2015) and the empirical research results. The research included the preferences of 14 people aged 52-77 and the properties of 18 MCD features, i.e. vertical and horizontal computer mice, trackballs, joysticks and touch screens. In order to carry out the research, the E had to perform 5 interaction attempts with each device. The tests produced 1225 observations of interactions with partial indices, on the basis of which the aggregated evaluations of interaction ergonomics (AEI) were calculated.

Surprisingly, there was a very large differentiation in the significance of relationship between individual variables, thus the strength of interaction between them (fig. 5).

Fig. 5: Significance of the selected relationships between the E preferences and the MCD properties

Source: (Wróbel, 2020b)

The research also produced directions and strength of relationships between the selected variables, with consideration to characteristics of tested people and devices. Whereas, device features were divided into two extreme properties, e.g. small/large or light/heavy, etc. in order to demonstrate direction and strength of relationships between the variables, as well as the ergonomic interaction was evaluated in a cumulative manner, on the basis of which the relative deviation was calculated, as well as the absolute values for such deviation for 2 variable (tab. 2). The results of the relative deviation demonstrated that there are differences in the influence of MCD properties on the obtained ergonomic interaction level, with respect to the specific preferences of elderly people. However, there were few such observations and they pertained to three groups of preferences - age, anthropometric features and upper limb ailments (tab. 2) (Wróbel, 2020b).

Tab. 2: Differentiation of the MCD properties, with regard to the specific preferences of the E - selected results of the relationship between variables under research

Variables			Research results			Assessment	
Variable 2 (feature MCD)	Variable 1 (option elderly preferences)		Variable 2 Characteristics of the feature 1	Variable 2 Characteristics of the feature 2	Aver-age	Relative deviation [%]	Absolute value of the deviation from variable 2 result [%]
Mass of the device	Age	50-54	1.85	1.93	1.89	4.3	3.1
		55-59	1.75	1.97	1.87	11.9	4.5
		60-64	2.09	2.30	2.21	9.8	2.3
		65-69	2.04	2.21	2.13	7.8	0.3
		70-74	1.82	1.94	1.89	6.0	1.4
		75-79	2.24	2.15	2.19	-4.0	11.5
The length of the device under the fingers	The length of hand (130-170 mm)	Yes	2.00	2.09	2.04	4.3	9.2
		No	2.08	1.96	2.03	-5.6	0.7
The length of the device under the fingers	Finger cramps 3-5	Yes	2.00	2.09	2.04	4.3	9.2
		No	2.08	1.96	2.03	-5.6	0.7

Source: (Wróbel, 2020b)

Conclusions and data from the research were implemented into the HES inference model and validated for the selected input and output data. For example nearly 80% of the system efficiency was achieved for the selected device type in relation to the preferences of the group of people under research (Wróbel, 2020b).

Conclusions

The issues discussed in the article along with the studies cited above provide a holistic view of the undertaken research goal. The development of the methodology and integrated EI management system in I 4.0 is also justified by Fantini, Pinzone and Taisch (2020). On the other hand, supporting the determination of ergonomic interventions and the diagnosis of O 4.0-MCD interactions for people characterized by resource deficits (the elderly) due to demographic changes and aging societies becomes crucial. In these contexts, the novelty of the article are the methodology and the developed HES, which, however, require detailed refinement. Therefore, it is postulated to develop and use HES to support E in the work of O 4.0, which requires, inter alia, creating and selecting AI methods and approaches dedicated to the purpose of supporting decisions, teaching expert systems with different input and output data, or integrating expert systems at various levels of the organization.

Evidence Driven Model for the Rationality of HR Decisions in the Organization

Kamila LUDWIKOWSKA

Wroclaw University of Science and Technology, Poland
kamila.ludwikowska@pwr.edu.pl

Abstract

The article indicates that human resource decisions (HRD) are one of the most critical tasks of the modern manager. HRD refer to the human resources in the organization and aims at shaping the desired job-related behavior of employees to carry out organizational tasks efficiently. Due to that fact, in human resources (HR) literature, there is a growing interest in how to make more efficient decisions, and rationality is one of its indicators. The first part of the article explains models of decision making, elements, and connections between them, pointing at those who are essential from the rationality point of view. Next, the notion of rationality in the context of HRD is explained. On this basis, the rationality model of HRD is proposed with factors which should be analyzed before making any of HR decision.

Keywords: Human Resource Decision, Rationality, Evidence-Based, Decision Making, HRM, Decision Theory.

Introduction

Making human resources decisions (HRD) in the human resources management (HRM) area is the key domain of modern managers. HRD refer to all decisions that involve organizational human resources (HR), aimed at shaping the desired job-related behaviors of employees to carry out organizational tasks efficiently. Some HRD may be guided by organizational rules, hence staying beyond the manager influence. However, many decisions are dependent on the decision-maker and the way he analyzes the best choice.

In recent years, in the HRM literature, the issue of making mature HRD and the right choices has been analyzed. Scholars try to answer the question of how to make the right choices and decisions to improve decision quality and avoid errors. One of the factors is rational decision making.

Rationality in management sciences has been mostly shaped by economics. However, in the last decades, an increased influence from psychology has been observed (Basel and Brühl, 2013). The notion of rationality is not operationalized in HRM, and there is little study on how to make the right HR decisions.

A consistent conclusion resulting from the currently available research is that the concept of rationality is a complex, ambiguous, and differently perceived problem (Power, Cyphert, and Roth, 2019). HRM researchers are consent that decisions in the HRM field do not consider reflection, critical thinking. Decisions are intuitive and based on wrong beliefs and subjective opinions (Bezzina *et al.*, 2017). Moreover, while making decisions, managers do not consider the variety of available information (Martelli and Hayirli, 2018). HRD decide about people's existence in an organization (e.g., decisions regarding promotion, dismissal, awarding, training), hence cannot be guided solely by intuition (Dhami and Thomson, 2012) or past experiences.

Although the nexus of rationality and decision making has been explored, there is very little academic work that links rationality with human resources decisions. Each decision making concept has its limitations. Rationality and intuition are significant components of most of the models. Both are likely to be effective cognitive mode. Hence, they cannot be neglected (Dhami and Thomson, 2012). However, their interdependence is not evident. Hence, further analysis should reflect how intuition and rationality interact and under which circumstances managers make decisions (Basel and Brühl, 2013). This article refers to the human resources management field. It provides an overview of rationality and decision making models pointing at those which are essential from the rationality point of view. Therefore, the article seeks to contribute to the HRM literature developing the evidence-driven model of rational HRD in the organization.

Decision-Making Models and Approaches

Decision-making describes certain patterns of behavior in specific decision-making situations, aimed at maximizing the effect of the decision made. The literature provides different decision approaches: rational, behavioral (bounded rationality, heuristic), dual process models (intuitive and integrative approach oriented to rational analysis with an approach oriented to intuition). In management sciences, there are two more approaches to decision making: normative and descriptive. The first approach aims at following universal rules and patterns in specific activities. The second considers recreating processes and activities that are carried out in reality. Decision-making models may also be categorized into rational and intuitive. All remaining are a combination of both approaches, hence called dual-process models. It is worth to notice that the rational model complies with the normative approach and the intuitive model with a descriptive approach (Gigerenzer and Gaissmaier, 2015).

Rational Models of Decision Making

Rational models emerged from the decision theory that describes a rational human having more than one option. In such circumstances, a decision-maker will be guided by utility rule, taking into consideration options that will bring benefit (or the smallest possible loss), and probability rule option less probable (Dhami and Thomson, 2012). Expected utility theory has been developed in the frame of the normative model of rational choice and is applied as a descriptive model of economic behavior.

Rational models describe the most appropriate procedure where performing a certain number of intentional, structured actions will lead to an optimal solution (McGuire *et al.*, 2006). Those steps are describing the problem situation, defining the problem and goal, establishing the selection criteria, creating and examining variants, choosing the optimal variant, implementation of the selected variant. It assumes that the manager has complete information, is logical, and makes an optimal choice with maximum utility. Rational decision making requires substantive, analytical, forecasting competences.

However, there are various definitions and approaches to rational decision making. Hence, there is no one universal model of rational decision making (Gigerenzer and Gaissmaier, 2015). Cabantous et al. (2010) revised rational decision theory into practice and developed a three-step process model of decision making, including contextualization, quantification, and calculation. Contextualization aims to create a fit between the organizational context and decision analysis principles, turning potential problem situations into decision analyzed problem. The contextualization step relies on social interactions. It requires gaining information from other sources and organizational members to develop possible solutions for identified problems. The quantification step aims to make the decision context calculable. It includes data collection. In the last step, calculation, organizational members are already prepared for finding a solution to the problem through decision analysis. They use statistic techniques to calculate solutions (Cabantous, Gond, and Johnson-Cramer, 2010). These three stages describe how rational decision is constructed and finalized. Using the model requires the support of analysts-engineers. Hence, it cannot be fully utilized by managers for HRD making in the HRM area. However, the social context and practice approach is relevant to HRM decisions. In such a context, rationality becomes something that can be acquired by managers. The model brings new insight into normative theory by enabling an understanding of the process from inside.

Critics of rational theories noted some limitations. In reality, decision problems and situations do not work according to the laws of logic. Hence, they are not compatible with the assumptions of the models described. Moreover, factors that hinder the implementation of a rational decision-making process are not taken into account, assumptions of making the right choice by the decision-maker, also knowledge, skills, and experience of the decision-maker are not analyzed.

Behavioral Models – Bounded Rationality

Alternative decision-making models manifest real decision processes performed in organizations. In the literature, those models are named behavioral, and two models have been distinguished within: bounded rationality models and heuristic models.

In the bounded rationality approach manager has limited access to information and hence is bounded in own rationality. The manager makes a satisfying choice, with a minimum level of sufficiency. Decision-makers follow rationality rules; however, their rationality is prevented due to cognitive and motivational limitations.

Bounded rationality, introduced by Simon (Simon, 1979), is focused on how we deal with the limitations of decision-makers (Basel and Brühl, 2013). The model reveals a vital role of unconscious factors, stereotypical thinking, and job avoiding. These factors result in cognitive limitations when a decision-maker is not able to gain required information and generate potential solutions, and motivational limitations, when decision makes aims to achieve satisfaction through finding the solution that meets the minimum level of sufficiency (Aharoni, Tihanyi and Connelly, 2011), however, cannot reach perfect outcomes (Basel and Brühl, 2013). The theory assumes that human is not guided by the maximum utility of a variant but make value-maximizing calculations (Dhami and Thomson, 2012) to find an option that meets a minimum of "satisfaction". Both limitations may lead to deterioration of the quality of the decision.

Behavioral Models – Heuristics

Heuristics in decision-making is the ability to make decisions based on unjustified or routine thinking. Heuristic models, also considered as behavioral, are concerned with psychological realism related to the capacities and limitations of humans (Gigerenzer and Gaissmaier, 2015). A heuristic is a strategy that ignores part of the information to make the decision making process accurate and quick (Gigerenzer and Gaissmaier, 2015). Heuristic models present real decision processes, rationality assumptions are rejected. These decision-makers do not even consider bounded rationality. They are creative without any specified algorithm of decision making.

In relation to heuristics and contrary to the theory of expected utility, Kahneman and Tversky developed an alternative model, called prospect theory (Kahneman and Tversky, 1979). They showed that human decisions depart from ideals of logic, unbounded rationality and behavior (Basel and Brühl, 2013). The theory demonstrates that humans reduce cognitive effort through the use of heuristics (Aharoni, Tihanyi, and Connelly, 2011). It assumes that people consider some benchmark when making decisions and judge the results as profit or loss. According to this theory, people are more likely to take a risk when they judge the outcome as a loss against a set benchmark. If, on the other hand, the result is perceived as profit, they will be risk-averse and will choose a small but specific reward, rather than profit, which is uncertain (Bromiley, 2010; Aharoni, Tihanyi and Connelly, 2011). Their study revealed that choices among risky prospects reveal effects which are not consistent with assumptions of utility theory. In particular, people underweight outcomes that are merely probable in comparison with outcomes that are obtained with certainty. It is crucial to formulate the problem because it largely determines what option the decision-makers choose. They may be risk-averse and may remain risk indifferent. The theory is explained mostly by the literature on strategy and influence the development of the economy (Bromiley, 2010).

An example of a heuristic model is a garbage can model developed by Cohen (1972). This model can be broadly defined as a form of organized anarchy, where problems, solutions, and participants exist as a separate organizational stream, goals, plans, selection rules, and priorities are mixed. The organization initiates opportunities, however, decision-makers do not know what they want. They do not find the resources to solve the problem; they solve problems by chance without a structured decision-making process (Cohen, March, and Olsen, 1972).

A critical assessment of heuristics stresses that heuristics lead people to errors in decision making. Hence, they are not considered as efficient solutions compared to logical analysis (Basel and Brühl, 2013). However, it should be noted that heuristics revealed significant insight into human decision making showing that cognitive restrictions cause errors in the decision-making process.

This debate illustrates that heuristics do not clearly define how humans decide. Such contribution is made by the dual processes framework (Basel and Brühl, 2013).

Dual-Process Models

In the literature, dual-process models describe intuition-oriented decision-making models and an approach to integrating rational and intuitive decision making. These models respond to complex conditions of modern organizations, related to excess or lack of information, high levels of uncertainty, and strong competition.

In recent years, the dual-process received lots of scholars' interest. While the notion of cognitive processing has been sufficiently discussed, there is an ongoing discussion about the components of mind and how they both interact (Basel and Brühl, 2013). The dual-process theory stresses the role of intuition. However, it is assumed that managers should make decisions based on rational reasoning, intuition, or a combination of both approaches. Intuition is linked with experience, which leads to intuition as an expertise perspective (Salas, Rosen, and DiazGranados, 2010). Expertise is built during learning.

Among dual process models, Evans (2008) distinguished models with a clear distinction between rationality and intuition based on defined features; models suggesting using both rationality and intuition; and models which assumes that the decision-making process first activates intuition, analysis is used when corrections or support for intuition is needed (Evans, 2008).

Stanovich and West (2000) distinguished two categories of decision making. The first, intuitive, is characterized by automatic, rapid, and effortless processing, second, reflective, is controlled, effortful, self-aware, and deductive (Stanovich and West, 2003). Both systems are working concurrently. The theory has been criticized for its limited explanation of how the two systems may interact (Dhami and Thomson, 2012).

Considering the interaction of both systems leads to a holistic approach where heuristics are initiated by intuition but adopted by reflective thinking. Both systems highlight a dynamic relationship. Such development has been made in Hammond's Cognitive Continuum Theory. The theory differentiates intuition from rationality but also allows to integrate both (Dhami and Thomson, 2012). The theory distinguished cognitive processes based on rational analysis, intuition, and those who integrate both. Rationality and intuition are assumed as a continuum where different experiences happen between those two notions. The combination of rationality and intuition is the most common choice while making decisions in organizations. It depends on the type of problem and task performed by managers, as well as the decision situation. The theory allows measuring the properties of managerial rationality (Dhami and Thomson, 2012).

Burciu and Hapenciuc (2010) distinguished nonrational thinking, called also double bounded rationality, as an extension of rational thinking, which requires abilities and skills of conscious and unconscious thinking for decision making (Burciu and Hapenciuc, 2010). They state that nonrational thinking and acting does not assume a lack of logical thinking (Gigerenzer and Gaissmaier, 2015), it considers different than rational rules of thinking. Nonrational thinking consists of diverse human skills, including experience, intuition, imagination, and emotions (Burciu and Hapenciuc, 2010). Intuition is a vital element of the decision process and is defined as the ability to identify a solution resulting from the unique experience and combination of explicit and implicit knowledge of an individual. Experience indicates a set of abilities a person accumulates during life through formal and informal practice, learning, observation (Burciu and Hapenciuc, 2010). Each decision-maker has intuitive potential, which may be developed by gaining knowledge and experience. Imagination refers to the human capacity to create new ideas based on knowledge gained in the past. The last component, management of emotions, is comparable to intuition and imagination. All components are activated during the decision making process. The authors argue that both rational and nonrational thinking is influenced by the manager's personality type and the context of the situation.

Also, Gigerenzer et al. (2000) proposed several heuristics as adaptative strategies of environmental structures. They depart from rationality and go beyond the satisfying heuristics of Simon, describing the problem-solving process in a fast fashion (Gigerenzer, Todd, and Group, 2000; Basel and Brühl, 2013). The ecological rationality view of decision making describes heuristics as cognitive shortcuts that exploit the social environment to seek for information to make a quick decision (Gigerenzer, Todd, and Group, 2000; Fodor, Curşeu and Fleştea, 2016). Managers engage in the social learning process and use the experience of others to validate their views.

Nonrational thinking assumes that there is no specific scheme of conducting for decision making. The decision-maker is looking for a solution to problems that may appear in the future. Hence collect information to be ready to confront initial intuition with facts gathered. The intuitive model requires conceptual competences and the ability to synthesize.

Intuition is a necessary cognitive mode, however, it is not sufficient and cannot constitute the sole base of the decision-making process (Dhami and Thomson, 2012). Each solution generated as a result of using intuition should go through steps of rational assessment. Moreover, relying only on intuition may result in adopting the same standards of conduct that have worked well in a similar decision-making situation in the past.

Nonrational thinking is a result of managers' thinking mechanisms, while bounded rationality results from organizational rules, not sufficient resources, time, and information.

The debate on two types of rationality reveals that they are not mutually exclusive and do not impose unrealistic standards of decision making (Basel and Brühl, 2013). Unbounded rationality shows how humans achieve goals, and bounded rationality explores the true beliefs of the world (Gigerenzer, Todd, and Group, 2000; Stanovich, 2010). In order to be successful, managers need to apply both types of rationality.

In the classical model of decision making, some stages may require the application of nonrational thinking, such as identifying a decision problem and selecting a decision among various alternative solutions. Correct implementation

of these stages requires the use of all available sources of information, even such as intuition, imagination, emotions (Burciu and Hapenciuc, 2010), values (McGuire *et al.*, 2006; Dhami and Thomson, 2012).

From the above discussion, it may be concluded that managers who strive to achieve high efficiency of the decision process should enrich rational thinking with nonrational. They should also use all available data calling to their consciousness and subconsciousness, use both explicit and implicit knowledge. They should also continuously gain new knowledge and experience to be able to develop new strategies of acting and make good choices.

Nowadays, managers make decisions in complex, uncertain, and unpredictable contexts. The efficiency of their actions requires the ability to use analytic techniques and to react quickly.

Rationality as the condition of effective HRD

HRD refer to all decisions that involve organizational human resources (HR). The notion of decision is defined as a conscious choice made by the decision-maker and as a human activity aimed to find goal-oriented solutions. In HRM, that process is initiated by an HR problem that needs to be solved. It happens when the real state is inconsistent with the desired one, i.e., with the defined goal of HRM. Decisions are finalized with a manifestation of choice. Formalization of HR processes relates to organizational policies, procedures set by the employer. Those decisions are repetitive and routine, named programmed (Larsson, 2000) (for example, taking leaves). Hence, they are not recognized as a decision problem.

On the other hand, some decisions require creative effort at different stages of the decision-making process, named non-programmed (Larsson, 2000). Those are decision problems (Dhami and Thomson, 2012), where intuition, decision-makers' and experts' experience play a significant role (for example, effective task execution, giving feedback to employees). Since they have not occurred before, they require extensive analysis. Managers use skills and subjective judgments of the situation to solve problems through analysis and logical reasoning.

Both types of decisions lie on the continuum between totally programmed and non-programmed. In HRM, both types of decisions are present, however, more decisions are non-programmable.

The outcomes of decisions made in the HRM have been clearly defined by the Harvard model of HRM, which shows that these are both direct effects: job performance, commitment, employee competencies, compliance; as well as future (long-term) effects: employee satisfaction, organizational efficiency and social welfare (Brunetto, Farr-Wharton and Shacklock, 2011). The most crucial component and effect of implementing HR decisions are gaining approval by employees. Acceptance is the main element of the readiness and ability of the personnel to perform organizational tasks. Expressing consent or acceptance by the employee results in making their own decision concerning a specific HR decision. The implementation of an agreed decision results in changes in job-related behaviors. Acceptance of HRD by employees influence the efficiency of HRD.

The concept of rationality is deeply rooted in economics, however, rationality as a concept has many facets and is one of the broadest concepts used in social science (Basel and Brühl, 2013). One of the main reasons is that the concept of rationality is complex, ambiguous, and incoherent (Basel and Brühl, 2013; Power, Cyphert and Roth, 2019). Rationality is a product of social interaction, collaboration in a broad context, not merely organizational. Hence, rational decision making is considered as social practice (Reckwitz, 2004).

The rationality of the decision-making process is a central topic in the organization theory (Hodgkinson and Starbuck, 2008). Researchers have clarified the rationalistic model in terms of its positive consequences on organizational performance. Nevertheless, it has received criticism as well. There is a gap between what the ideal normative model is and what decision-makers do (Cabantous, Gond, and Johnson-Cramer, 2010). Also, the normative model does not refer to the analysis of socio-technical conditions that may enable to construct the rational decision (Cabantous, Gond and Johnson-Cramer, 2010).

This study provides an overview of rationality and decision making models. It can be noticed that all the distinguished typologies include rational and intuitive components as well as others, often constituting a specific combination of the models mentioned.

In the context of existing decision-making models, it seems to be significant to identify key conclusions that should be considered for HR decisions:

in the view of rational decision-making models:

- decision-maker resources (skills, knowledge) are not analyzed
- gaining information from other sources and organizational members indicates the social context
- statistic techniques are used to calculate solutions

in the view of bounded rationality theories:

- in reality, decision problems and situations do not work according to the laws of logic
- human has limited access to information
- rationality rules are followed
- the maximum utility of a variant does not guide human, human looks for a minimum of satisfaction
- nowadays, the world is full of uncertainty

in the view of heuristics:

- the decision-making process is accurate and quick
- creativity has great importance
- the environment is uncertain and competitive
- intuition plays a significant role; however, it is assumed that managers should make decisions based on rational reasoning also
- nonrational thinking and acting does not assume a lack of logical thinking
- an intuitive potential which may be developed by gaining knowledge and experience.
- the social environment is a source for information to make a quick decision

The above conclusions indicate that each component does not exist exclusively. They are influenced by the classical theory of decision, and the assumption of humans are both rational and social beings. In HR practice, there are many situations where both modes will be necessary to make a decision. However, it may be difficult to apply some of the practices into HRM, for instance, applying statistic techniques to calculate solutions of everyday HR decisions.

HRD Rationality Model

In response to the conclusions of the analysis of decision-making models and limitations identified, the author proposed a theoretical evidence-driven model of HRD rationality stressing real decision-making context. The rationality of HRD is a measurable feature of decisions (Dhami and Thomson, 2012), which measures its maturity and accuracy in specific HRM context. Evidence-driven indicates the significance of information through an analysis of available data to support variants of possible solutions (Barends and Rousseau, 2018). Evidence includes a broad spectrum of internal and external data that may support a decision, including scientific data, expert opinion, big data, analytics, organizational information, case studies, opinions of individual colleagues, as well as intuition. Evidence-based approach is central in the proposed model to understand how the decision should be made. It requires asking good questions to the organizational problem, collecting, assessing, and aggregating data, making a decision, and its implementation (Barends and Rousseau, 2018). Evidence-based approach is a novel perspective of acting and looking at the everyday life of the organization, and decision making is one of such activities.

The author points out that efficient use of the rational model of HRD needs to consider four major criteria: analysis of the situation and resources, analysis of solutions, data analysis, potential problem analysis.

The process is initiated by the HR problem and followed by a willingness to act. The first criterion, analysis of the situation and resources, refers to environmental variables that may influence the decision (McGuire *et al.*, 2006), including organizational strategy, HRM philosophy, technology, others, and analysis of decision-maker resources, including knowledge, skills, experience, as well as emotions (Burciu and Hapenciuc, 2010) and values (McGuire *et al.*, 2006). It aims to recognize the current situation based on the facts, the environment of the situation, and decision-maker resources. Analysis of solutions indicates an alternative solution to the HR problem. The third criterion, data analysis, highlights the importance of information for enabling better HRM decision-making (Cassar and Bezzina, 2017). It refers to a broad scope of possible evidence, not only analytic-approach but also experience, intuition. As an outcome, the best variant is selected. The last criterion, potential problem analysis, aims to forecast potential future problems emerging from the decision selected.

HRD outcomes have been framed based on the Harvard model of HRM (Brunetto, Farr-Wharton, and Shacklock, 2011), including direct and future (long-term) outcomes.

The proposed model considers HR decisions as a social construction that involves seeking information and a set of analyses.

The model is presented in Figure 1 and will be used for empirical verification of the hypothesis on the rationality of HRD in contemporary organizations. However, its empirical verification is necessary before using it.

Summary

A dynamic and uncertain environment requires managers to work under time pressure and make fast decisions. The literature review revealed that both rational and intuitive thinking has a significant meaning. In the real world, managers make decisions based on logic, experience, rationality, intuition, emotions. Human thinking is not always precise, structured, predictable. However, while considering the organizational context and objectives of managers' performance, it is evident that their decisions in the HRM impact humans and their organizational existence. Hence, the decision should be supported by the best available evidence.

Each decision-making concept has its limitations, and there is no unified conceptualization of rationality and intuition. Hence, researchers call for more studies in managerial decision making (Basel and Brühl, 2013). Further analysis should reflect how intuition and rationality interact (Dhami and Thomson, 2012) and under which circumstances managers make decisions. This article fills that gap through exploiting those notions in the human resources management field and attempt to build a novel evidence-based model of HR rationality in organizational practice.

Abstract

Recent events and data provided by Eurostat on pesticide sales lead us to highlight once again the concerns about pesticides consumption in agriculture. That is why this paper aims to provide an analysis of risks and vices with consequences in the sustainable agricultural economy, influenced by traditional agricultural practices. Last but not least, we consider it important to analyze the subsidies granted to support farmers who practice sustainable agriculture, thus eliminating fertilizers, in the context of the demands imposed by climate change. From this perspective, we have highlighted in part why it is important to pay attention to the risks of pesticides in the agricultural sector, and how good faith influences the use of good practices, agricultural production. That is why during the research we tried to highlight aspects that, in our opinion, are important for the food security of the agricultural sector, to the current challenges caused by the need to supply agricultural products of the highest quality, using pesticide control. Proper land management plays an important role. We hoped that our guidelines would capitalize on those alternative methods of reducing pesticide use by switching to organic fertilizers.

Keywords: Traditional Agricultural Practices, Pesticides, Fertilizers

The article addresses a possible interdependence between pesticide consumption of the European Union (EU) agro-ecological indicator as a concern of recent growth data during the Pandemic in 2020, the increase being statistical. We ask ourselves serious questions if this increase in the sale of pesticides is not aimed at price increases or decreases on world stock exchanges and interested groups cartels or consortia would have a purpose in themselves, these being only presumptions, which will be certified with subsequent data.

Without moving away from the subject of research in our opinion, the consumption of pesticides provides an image of agro-ecological indicators in the EU, which would show the percentage allocated for organic products to which traditional practices can be applied in Romania zonal products, for example mountain products. But how do we understand to promote sustainability for farmers, or associated producer companies if we do not analyze the concrete possibilities of correct application of fertilizers in the production process? How do we guide the purpose of pesticide application and what processes should be applied by farmers to avoid and even exclude the risk of climate pollution, but also the role of fertilizers in increasing the performance of soil properties? To increase plant resistance, properly applied fertilizers can increase the resilience of our global food system by providing nutritious products. The word sustainability is often spoken, but we do not know the scope of this definition. That is why we will say sustainable for farmers means sustainable for the environment, plants, soil, climate and biodiversity all contribute as a whole to the sustainability of the agricultural system.

The Relation Between A Three-Sector Economic Model with Social Inequality in Poland, Differentiated by Region

LUDWICZAK Anna

University: CALISIA UNIVERSITY - KALISZ, POLAND, Faculty of Social Sciences
City: Kalisz, Country: Poland
E-mail: a.ludwiczak@pwsz.kalisz.pl

Abstract

One of the most vital goals of any national policy is economic development. This however poses the interesting question of whether this should be treated as a means to an end or as an end in itself. Everyone surely expects that economic development inexorably delivers both an improved quality of life and social wellbeing. For this reason we have differentiated between the concept of economic growth and development/efficiency with socio-economic-related wellbeing; thus clearly demonstrating the multi-dimensional nature between these two areas. This study aims to investigate the relationship between the economical structure in a three-sector system with social inequalities according to the diversity of regions found in Poland. Straightforward statistics were used to seek for correlations between the factors under study. A strong correlation was found between employment structure in those regions with existing social inequalities; especially in poverty and social exclusion.

Keywords: Sustainable Development, Economic Structure, Quality of Life, Regional Diversity.

Introduction

Economic growth appears to be a key term or lock by means of which a given country's economic status is defined. Quite clearly, achieving the best growth rates is a situation best desired. Such growth most commonly refers to a tangible part of the economy such as the manufacturing base, raw materials/natural resources, population changes and the manufacture of products and consumer goods. When perceived in this way, economic growth is however a narrower concept than economic development, which is much more broadly defined.

The actual structure of any given economy is mainly determined by markers/indicators/indicies of economic development and the degree to which a given economy is market-based. Numerous theoretical studies have been devoted to economic structures and economic growth in attempts to formulate models/theories of structural change; this including empirical studies for investigating the structural regularities of economic development. The first historical writings on this subject can be traced back to the works of classical economists. Adam Smith (1776) refers to the perception of such structures in 'Studies on the nature and causes of the wealth of nations'. Other international literature of significance on these issues inter alia include: AG Fisher (1935; 1945), C Clark (1957), J Schumpeter (1934; 1942) and later S Kuznets(1955; 1966).

One of the earliest models of economic development was proposed by Fisher-Clark, often termed as the three-sector concept of economic structures. This theory propounds that economies develop in three stages: the first most predominantly consists of agricultural production (sector I), the second realises the advantages of the industrial sector (sector II), whilst the third is dominated by the services industry (including education). Economies thus pass through successive stages in achieving higher levels of development due to cross-sectoral differentiation in labour productivity. Countries where agricultural production dominates, however have low GDP growth rates because this sector is limited by inefficient labour productivity. Market forces trigger change which primarily arise from demand-related variation in the income elasticity for a variety of consumer product categories. As the GDP per capita increases, the demand for foodstuffs and low-value goods decreases, whilst there is variable demand for quality industrial products and in providing different types of commercial services. An increasing proportion of the GDP and national added value is thus provided by industry and services. Such changes typically lead to higher/more efficient labour productivity, resulting in higher economic growth. Economic progress enhances the demand for services, thereby

constraining a labour-force to abandon those sectors with the lowest productivity (ie. sector I) to ones where productivities are higher; sector III, (Nordhaus, 2001; McMillan, Rodrik, 2011).

Changes considered desirable in a given economic structure bring about increases in the indicators of economic performance such as gross domestic product or gross value added. Although these are not ideal, they are undoubtedly some of the best measures that reflect economic growth. However, does this refer to growth or development? The concept of development is considered both broad and qualitative in nature, however if economic changes are meant to improve people's quality of life, then the aforementioned indicators cannot alone suffice. A leading question could be posed about whether conditions harmonious and conducive to economic growth can achieve a fair form of social equity. Studies by Piketty (2014) have importantly concluded that the dynamics of how wealth is distributed triggers powerful mechanisms that alternate between convergence or divergence and that there are no spontaneous nor natural processes which can avoid permanent trends that destabilise or promote inequality. This book has been so widely read that it has lived to see a collective and polemical work published, entitled 'Piketty and what next? A plan for economics and inequality' (2017). Among the authors were three Nobel Prize laureates, Robert *Merton Solov, Paul Krugman* and *Michael Spence* as well as *Thomas Piketty* himself.

Economic analysts are ever more frequently drawing attention to how a nation's increased wealth can be fairly/equitably distributed. To quote, *Joseph Stiglitz* writes 'For many years, the dominant economic paradigm [...] has ignored the problem of inequality- both its role in triggering crises and the impact of economic fluctuations on inequality, and whenever such crises occur. The recent financial crisis has however proved that this thinking is flawed and these views are at last now finally being questioned' (Stiglitz, 2012, 2013). Social inequity has been much studied, but is often presented in a global context; for example by C. Lakner and B. Milanovic (2016), who found that inequality decreased during 1988-2008, as measured by the global Gini coefficient. They also showed that the majority of the world's population live in countries where inequality is intensifying. Nonetheless, small-scale/ local/ micro-data studies are still lacking.

It should be remembered how important inequalities are (or should be important), to the quality of an individual's life in their given country. These determine the dislikes of a person's life, which off course are inherently relative and usually based on ones immediate surroundings.

This study has aimed to investigate the relationships between economic structure in a three-sector system with that of social inequalities divided according to Polish regions, by means of using simple statistics. Objectives were to establish whether employment structure and socio-economic development are correlated; namely, does having high proportions of farm workers within a given region adversely affect its economic development, and also does having a higher proportion of workers in the services sector benefit the economy and reduce any adverse effects thereof.

Materials and Methods

The relevant study data for 2015 was taken from the Chief Statistical Office for all provincial regions of Poland (these are the latest official data on the regional level). Levels of employment were compared in 3 economic sectors throughout Poland; ie. the rural/agricultural, industrial and services sectors. Outcomes were then also compared to those indicators chosen that reflect levels of economic development and people's financial status; based on the so-called 'social cohesion studies' (2017). These indicators consisted of: gross domestic product (GDP) per capita, median income groups, high income groups and a poverty income index.

Gross domestic product- GDP is a monetary measure traditionally adopted for assessing economic development, but however this should not be confused with being a measure of the quality of life; although this could also be used for its improvement.

Middle income- median income is the amount that splits a given population equally in half, where one half earns above this amount, whilst the other half less. When used formally, this divides income into so-called equivalence units and is thus not per person. The Central Statistical Office uses the so-called modified OECD equivalence scale for its calculations, adopting equivalence unit values per person, per household as follows: for the first adult - 1, for each subsequent household member (aged>14 years) - 0.5 and for each child below 14 years old – 0.3.

High income index- the proportion (%) of households with the highest income ie. those whose monthly equivalent income was higher than 5/3 (approx. 167%) of the median equivalent income, ie. approximately 2.8 times higher than the accepted relative poverty line/threshold.

Income poverty index- the proportion (%) of households in which the disposable monthly equivalent income, (in the 12 months prior to the survey), was lower than the poverty threshold amount. This poverty threshold was set at 60% of the median equivalent income, ie. comparable between households with diverse demographies.

Descriptive statistics were used for our study and the employment structure in the country was analysed according to region/province (voivodship). The correlation was then determined between employment rates per individual sector of the economy with indicators of socio-economic circumstances.

Results

Economic structure broken down according to sector employment

Poland's economic structure is disadvantageous. The employment rate for sector I (agriculture) in 2015 was 11.5%, whereas the European Union (EU) average was 4.2%. In addition, Poland's employment rate in sector II (services) is lower than the EU average; respectively 60% vs 71.6%.

Employment rates throughout individual sectors of the economy show a large regional variation. Compared to the country's overall 11.5% employment rate for agriculture, the Silesian and Lower-Silesian regions are significantly lower at respectively 2.6% and 4.8%, whilst conversely they are the highest in Podlasia, the Holy-Cross province and the Lublin province; all being at over 22%. Employment rates in the industrial sector are however less diversified, with the average rate being 30.5% and ranging from 40% (the highest) in Silesia and the lowest in Mazovia (22.3%). The latter province however, has the highest employment rate in the third sector (services) at 66%, compared to the country's average of 57%; with the lowest service sector rate being in the Holy-Cross province at less than 50%.

Table 1: Economic structure in Poland (2015); employment rates according to economic sectors; agriculture, industry and services broken down by region.

Region/province	Agriculture	Industry	Services
Lower Silesia	4.8	35.3	60.0
Kujawy-Pomerania	14.0	30.9	55.1

Source: prepared in-house, based on Central Statistical Office data.

It appears that there are very large regional variations in the country's three-sector economy. It should however be stressed that this is nothing new in Poland, which has witnessed significant changes over the last 20 years; although ultimately not to a sufficiently strong extent. As a comparison, in 1995 the average employment rate in the agricultural sector was 22.6%, whilst the then employment rates in the aforementioned provinces (Podlasia, Holy-Cross province and Lublin province) were significantly the highest, just like today, and were respectively at 42.2%; 41.6% and 44.5. Nevertheless, sectorial variations between regions has declined overall within the last 20 years.

The economic theory of sectorial division states that higher employment in agriculture coupled with low rates in the services sector result in a reduced regional productivity, thus a lower GDP per capita.

Economic structure and socio-economic indicators

Table 2 shows the breakdown of employment rates according to economic sectors in terms of socio-economic factors by region in 2015.

Table 2: Economic structure in Poland (2015) and socio-economic factors broken down by region.

	Employed in the sector (as %)			Indicators of the socio-economic circumstances			
	Agriculture	Industry	Services	GDP per capita	Middle income (median)	High income indicator	Income poverty rate
Lower Silesia	4,8	35,3	60,0	52203,0	1883,8	21,2	11,3
Kujawy-Pomerania	14,0	30,9	55,1	38190,0	1666,7	13,6	17,3
Lublin province	22,0	23,1	54,9	32074,0	1381,5	8,9	26,5
Lubusk province	6,3	35,0	58,6	39052,0	1785,7	13,8	10,8

Source: prepared in-house, based on Central Statistical Office data.

Gross domestic product (GDP) per capita

This indicator is first discussed. The Mazovia region had the highest rates, quite naturally, because this is where Poland's capital city is located; for this reason statistics often treat the capital subregion and the remaining region separately. The Upper Silesian, Greater Poland and Silesian regions had above average rates.

Fig. 2: Gross domestic product per capita according to regions in Poland (2015).

The distribution of GDP per capita according to regions shows that their economic structure is correlated with economic efficiency. This is particularly evident in those regions with high employment rates in the agricultural sector coupled with relatively lower efficiency per capita indicators. However, employment rates in the services sector have a more powerful impact on the productivity of the economy; especially in Mazovia.

Middle income groupings

The median income (middle income) indicator more clearly reflects the potential quality of life than for example the average income (like ordinary wages in relation to the average wage).

Fig. 3: Median income within Polish regions in 2015.

The highest scores were found in the Mazovian, Silesian, Pomeranian and Lower Silesian regions. However, the distribution trends of middle-income scores by region proved to be inconclusive. For instance the Podlasian region has the highest employment rates in the agricultural sector but relatively low rates in services (51.5%) ie. the one before last in the rankings. Nevertheless, any unfavourable indicators are absent.

High income indicator

This represents the proportion of households whose income exceeds 5/3rds of the average income. Likewise with the median incomes scores, higher than average high income scores were observed in the same regions ie. Mazovia, Silesia, Pomerania and Lower Silesia.

Fig. 4: Breakdown of high-income indicator outcomes in Polish regions (2015)

The greater diversity between regions merits attention. The largest differences to average levels of this indicator were noted in the Sub-Carpathian, Holy-Cross province and Lublin province regions, which are precisely those regions with a disadvantageous employment structure; although this is somewhat less marked in the Sub-Carpathian region.

Income poverty index

This represents the proportion of households with a monthly income lower than the accepted value considered as the poverty threshold, ie. 60% of the country's median income. Overall, 14.4% of households in Poland are in this situation. Nine regions had higher than average indicators, whilst they were lower in seven. The Lublin province was worst-off in this respect, with more than a quarter of the population affected. Other regions showing high rates were the Holy-Cross province, Sub-Carpathia and Podlasia. It should also be noted that these regions have the highest rates of employment in the agricultural sector; although not in this order.

Fig. 5: Breakdown of the income poverty index in Polish regions (2015).

Polish regions with the lowest rates for these poverty indices were Silesia, the Opole province, Mazovia and the Lubusk province.

Correlation between economic employment structure with selected indicators/indices

For each region, correlations were calculated between employment structure and socio-economic circumstances; shown in Table 3.

Correlation coefficients were calculated by the formula below, with values ranging from -1 to +1.

$$Correl(X,Y) = \frac{\sum (x-\bar{x})(y-\bar{y})}{\sqrt{\sum (x-\bar{x})^2 \sum (y-\bar{y})^2}}$$

To ensure clarity of interpreting the magnitude of the correlation coefficient (r), the following ranges and degrees of significance were adopted: 0.3-0.5 (+/-) was considered moderately significant, whilst 0.5-0.7 (+/-) was highly significant (ie. highly correlated and marked in a light font in Table 3). Any values of (r) above 0.7 (+/-) were taken as very highly significant/correlated (marked in a bold font).

Table 3: Correlation between employment rates within the defined sectors of the economy and selected indices/indicators of socio-economic circumstances according to the regions of Poland (2015)

	Employed In the sector (as%)		
	Agriculture	**Industry**	**Services**
GDP per capita	**-0,46**	**-0,02**	**0,68**
Middle income	**-0,76**	**0,39**	**0,68**
High income indicator	**-0,65**	**0,14**	**0,80**
Income poverty rate	**0,80**	**-0,59**	**-0,52**

The most significant correlations within the agricultural sector were found as follows:

1) A highly significant and positive relationship between employment rates in the agricultural sector with the income poverty index.
2) A significant correlation of employment rates with median income.
3) A highly significant negative correlation with the high income index.
4) A highly significant negative correlation with the GDP per capita.

Equally important correlations can be observed between employment rates with socio-economic indicators that are negative. A highly significant correlation was demonstrated between services employment rates with high income indices/indicators as well as with all the other socio-economic indicators; as had been expected. Lowest (r) values were found within the industrial sector, nevertheless employment rates were significantly correlated with the poverty income index.

Conclusions

This study has demonstrated a significant relationship between economic structure with the socio-economic development according to the regions of Poland. Whenever employment rates are higher in the agricultural sector, then the poorer become the economic outcomes. Both GDP per capita and the average income of residents are reduced, coupled with an elevated income poverty index, where there are strong correlations pointing to higher employment rates in the services sector delivering a higher value to the economy. This confirms one the study's initial suppositions as well as validating the well-recognised development of the three-sector economic division adopted in other studies.

This study aimed to investigate and highlight the relationships between economic structure, with productivity and social inequalities. The issue of whether the economic structure of Poland's economy has the ability to generate sufficient income has been an ongoing concern for many years. Evidence suggests that the three-sector economic model is still valid, based on studies carried out in the 1940s and 1950s (for example: Hirschman (1958), Rosenstein-Rodan (1943), Singer (1950)) and thence has continued on in seeking for effective development pathways/strategies (Hausmann et al, 2014; Cristelli, 2015; Hartmann, 2014). This is frequently found to depend on studying the evolution of economic structures according to changes in productivity of selected individual economic sectors (Go et al., 2019; Quintana-Romero et al., 2019).

There have been many studies done on a theory proposed more than half a century ago by *Simon Kuznetz,* which states that economic structural transformation leads to an increase in the level of inequality, whose effect should be treated as a by-product of economic growth. This had been extensively researched by for example '*C. Baumul and K. Sen*', who demonstrated that the influx of employees from the agricultural sector to the production sector did not increase social inequality. On the contrary, this reduced income inequalities regardless of the stage of transformation, whilst the influx of the labour-force to the service sector increased social inequality during the early stages of transformation, but which then later became decreased (Baymul, Sen, 2019; Baymul, Sen, 2020). Indeed, this can be considered to confirm our study's hypothesis.

The relationship between economic growth with poverty levels (Bourguignon, 2004; Ravallion, 2004) and social inequalities (Forbes, 2000; Madsen et al, 2018) has also been extensively investigated. Such studies have been ongoing for years, where outcomes of the latest studies have proved inconclusive. A frequently encountered problem is to decide which phenomenon is the cause and which is the effect: does economic growth increase or decrease social inequality in a given country? Or perhaps the converse is true, that a certain level of inequality determines growth opportunities? Studies often divide countries into high-, middle- and low-income, or to developed and developing ones or they are grouped according to their consumption proclivities; and there are many other proposed division (Sakaki, 2019; Vo et al., 2019; Arestis, 2020; Xx Alvaredo, 2018). It seems that despite so much knowledge, successful outcomes have still not been achieved and remained elusive; income inequalities are rising in many countries and reaching alarming levels.

The literature often also abounds with critical and polemic articles regarding existing scientific studies. These rather do not rely on refuting any analyses of the aforementioned relationships, but are mainly concerned with their simplification. Such criticism may certainly be levelled at this paper: dividing Poland's economy into three sectors is, after all, greatly simplifing the currently complex economic realities of this country. In the end, internal differentiation of each sector is important. This issue has indeed been addressed by studies on productivity, particularly within the agricultural sector. These studies do not agree with making any simplified comparisons such as labour productivity between agricultural and non-agricultural sectors, but note the heterogeneity of such divisions, as well as synergies existing between such sectors (Imai et al, 2019; Dorosh, Thurlow, 2018). For example, large increases of people

employed within services in 'naturally agricultural' or 'historically agricultural' areas (especially in developing countries) appear to be due to the creation of small, trade or transport companies (often sole ownership ones), whose economic activities are small scale and may not only be inefficient, but also lead to income disparities becoming wider, or at the very least being ineffectual in reducing poverty levels.

For this reason studies should not only focus on the economic effects of growth, but also duly address the way it is distributed (Hartman et al, 2017). At all times it should be emphasised that a high level of inequality can lead to serious social, political and economic problems (Choi, 2019), which in turn cause unrelenting demands for sustainable development and by what appropriate means this can be achieved (Bilan et al, 2020; Ergashey, 2019; Georgescu, Herman, 2019).

Hence, there is a constant need for in-depth research between the developed products of an economy, its productivity, income levels and degrees of social inequality. This issue is not only of interest to economic scientists/experts (Lyubimov, 2017), its subject matter appears in popular science publications/magazines, as well as being readily available to everyone. After all, such issues raised affect everyone. However, knowledge is very widespread now about social inequalities and the risk of poverty, the scale of these phenomena, as well as their adverse consequences, and even social and political threats. The problem is that the world is still unable to deal with them.

It appears that the scale on which economic research is performed is also vital, especially when it concerns all the measures of a population's quality of life. Differences in the quality of life within a given area, a given country, region, subregion, etc. may turn out to be more socially acute than if comparisons are made on an international or global scale. Therefore, despite the undoubtedly very important studies conducted on a global scale, one must never forget about the unique character of conducting research at the local level.

Abstract

Inland waterway transport and its development is way of creating a more sustainable transport system in any country or region in the world. At declaration level, the EU shows some action in this regard. However, at the level of real actions the situation is far less satisfactionary. The main objective of the article is to identify opportunities to enhance the role of inland waterway transport (IWT) in the EU transport system and thus create a more sustainable transport system. On the basis of a critical analysis of the professional literature, the participation of IWT in freight transport in the EU, examination of EU programmes for the IWT development and the adoption of a logical reasoning approach, it might be concluded that, in the best-case scenario, the current role of IWT in the EU transport system will be maintained.

Keywords: Inland waterway transport, sustainable development, transport system.

Introduction

Modern economies, as a result of progressing liberalization and globalization, are characterized by accelerated growth and development and a growing dynamics of contacts established on a national and international scale. This contributes to, among other things, the increase in the quantity of goods to be transported and stresses the importance of rationalizing the transport service of the increasing load weight. In rationalizing this service, the basic conditions are created by the transport system, including in particular its spatial arrangement, the mode structure and participation of individual modes in the system.

In the context of increasing overloading of certain modes of the transport system (TS) as well as the occurrence of bottlenecks in certain areas of the transport systems, the issue of seeking methods to use the resources of individual modes of the transport system in a more sustainable manner has been raised. This requires a greater focus on inland waterway transport (IWT) and, more specifically, on the search for opportunities to make better use of IWT resources and the validity of taking such actions.

The purpose of the analysis is to present: the characteristics of sustainable development, EU TS policy and the grounds for EU's support for IWT in order to increase the sustainability of the European TS.

The manner in which the EU has influenced IWT raises the following research questions: how to assess the EU's activities in the area of IWT so far and what are the chances of increasing the role of IWT in the European TS in practice?

With reference to the adopted objective of the analysis and the research questions raised, the article focuses on the characteristics of sustainable development of TS and EU transport policy with particular emphasis on the impact on IWT, the conditions for increasing the role of IWT in the EU TS and the capability of providing these conditions.

Cite this Article as: Maciej CZAPLEWSKI and Rafał KLÓSKA "Developing Inland Waterway Transport as A Potential Method of Balancing the Transport System in Europe - Opportunities and Limitations" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

For the purpose of this article, the following methods were adopted: scientific methods for critical analysis of literature on economic policy, land management and transport economics and organization with a particular focus on IWT, analysis of the contribution of IWT to freight transport in the EU and EU programmes and regulations concerning TS and IWT, a method of observing the socio-economic policies applied in this area and a method of logical reasoning.

The Characteristics of a Sustainable Transport System

The concept of sustainable development was first defined by the World Commission on Environment and Development (Kotowska, 2014, p. 43). In a report published in 1987, sustainable development was defined as "development which meets the needs of present generations without compromising the ability of future generations to meet their own needs" (UN, 1987). Moreover, sustainability was addressed, for example, at the so-called Earth Summits in Rio de Janeiro in 1992 and 2012, and the first summit resulted in a document entitled Agenda 21, which sets, inter alia, objectives of sustainable transport like: reducing transport demand, development of public transport and integration of transport processes between various countries (EC, 2001, p. 6).

In the European Union, the foundations for the sustainable development of transport systems were laid in the early 1990s, issuing Community legislation and developing scientific and research programmes in the field of environmental protection (Załoga, 2013, p. 85). Today's definition of the concept of sustainable transport often uses the approach of the European Federation for Transport and Environment which considers sustainable transport as "a movement which meets the mobility needs of today's generations while taking care of the state of the environment, living conditions and economic development opportunities of future generations, emphasizing the contribution of transport to sustainable development" (T&E, 2004, p. 7).

European Union transport policy with a particular focus on inland waterway transport

The development of transport systems comprising different modes entails the need to improve individual modes, a process which should encourage their integration through the introduction of inter-modal technologies. The EU attaches great importance to the development of integration processes for transport infrastructure, as exemplified by the implementation of the so-called common transport policy.

The principles of the transport policy introduced in the EU reveal the need to create multi-modal transport systems which allow the use of different functions and properties of individual modes. The changes in EU TS observed in economic practice, especially at the turn of the 20th and 21st century, indicate that the actions taken within these systems are primarily focused on the role of car transport and thus contribute to a relative decline in the roles of rail transport and IWT. Data on the role of road, rail and inland waterway transport in freight transport in the European Union in the years 1995, 2000, 2005, 2010, 2015 and 2018 are presented in Table 1.

Table 1: Data on the role of road, rail and inland waterway transport in European Union freight transport in the years 1995, 2000, 2005, 2010, 2015 and 2018 (in billion tkm)

Year	Road transport	Rail transport	Inland waterway transport
1995	1289	388	122
2000	1509	405	134
2005	1755	416	139
2010	1710	394	156
2015	1722	418	148
2018	1908	421*	135
2018/1995	+48%	+9%	+10%

** data for 2017*

Source: Own work based on (Eurostat, 2012, p. 36; Eurostat, 2017, p. 36; Eurostat, 2019, p. 34).

The forecasts prepared for the inland waterway transport in the EU between 2017 and 2030 do not predict a major increase in the role of IWT. At the same time, the scientific literature emphasizes the need for a greater inclusion of high-performing, energy-efficient and environmentally friendly modes of transport in transport systems (Gorlewski, 2007, p. 315), which include, inter alia, IWT. In order to strengthen the market position of IWT, EU began to:

- take measures to liberalize the market of EU IWT services, particularly through Regulation 1356/96/EC of 8 July 1996 aiming at full freedom to provide inland waterway services and ensuring full market access within the EU for inland waterway operators after 1 January 2000;

- implement transport investment programmes, e.g. TEN-T presenting the main transport route systems and underpinning the EU common transport policy;

- implement combined transport development programmes, such as Marco Polo;

- implement inland waterway development programmes, such as NAIADES.

The approved EU programmes and documents indicate that the EU transport policy strongly emphasizes the positive features of inland waterway transport, in particular its relatively low level of adverse environmental impact (Neider, 2012, p. 106-107; Wojewódzka-Król, Rolbiecki, 2007, p. 247) and the need to strengthen the role of this mode in the European transport system mainly through:

- development of navigable inland waterways (Łepek, 2008, p. 275);

- development of container shipping which additionally requires improvement of the infrastructure of inland waterway transport (Rydzkowski, Rolbiecki, 2008, p. 318);

- introduction of an obligation for carriers of particular transport modes to bear external costs generated by them, e.g. the costs of adverse environmental impact (Montwiłł, 2008, p. 301).

However, the positive attitude to strengthening the role of inland waterway transport in the transport system as presented in EU documents rarely translates into concrete investment measures in the area of inland waterway transport and consequently is not reflected in the improvement of statistical data demonstrating the role of inland waterway transport in the European transport system. This is proven by Eurostat data, according to which in the last 30 years the weight of goods transported through inland waterways in Europe has only increased by 17% (Künast, Trittin, 2012), while the participation of inland waterways in the total load weight transported in the EU in 2010 was 6.1% and was clearly higher mainly in the Rhine corridor (14.3%) and the Danube corridor (7.2%) (Theologitis, 2012).

In June 2006, the European Commission reviewed the achievement statues of the White Paper's objectives (COM, 2006). It decided that achievements were not satisfactory and initiated the introduction of new instruments, including, inter alia, the integrated European inland waterway programme – NAIADES (Navigation and inland waterway action and development in Europe) (EP, 2006). The NAIADES programme was formally terminated in 2013, however it is to be continued through “NAIADES II: European inland waterway policy for the next decade”.

The European Commission indicates that the NAIADES II programme may be financed by the funds from the Marco Polo Programme and the Trans-European Transport Network (TEN-T) programme. In line with the priorities of the TEN-T programme (EC, 2013), it may be assumed that this will involve the modernization of two inland waterway corridors included on the list of priorities of the TEN-T programme (EU, 2013) – the Rhine Main-Danube corridor (EBU, 2005, pp. 46-47) and the Seine-Scheldt corridor (Hacksteiner, 2010, p. 12). Recent EU actions taken under the TEN-T programme, relating to IWT. focus on the financing of River Information Services (RIS), a system to provide and obtain information on inland waterway traffic, shipping and port charges, hydrological conditions, investment plans as well as other statistics and administrative regulations (Schilk, Seemann, 2012, pp. 622-631). This means, however, that no funds are earmarked for the implementation of NAIADES II programme (COM, 2013).

The conducted study indicates that, at a declaratory level, the EU emphasizes the need to strengthen the role of inland waterway transport in the European transport system. On the other hand, EU actions to strengthen the role of IWT in economic practice are very limited. They solely include analyzing forecasts for the development of inland waterway transport and designs of future inland waterway networks as well as very limited financial involvement in the development of the inland waterway network, and the investment support is mainly planned for the expansion of the inland waterway network in regions already having a well-developed inland waterway network, which raises concerns about reinforcing inequalities within the EU.

Conditions and opportunities for strengthening the role of inland waterway transport in the European transport system

The development of inland waterway transport in markets which already have a high demand for its services requires substantial and comprehensive infrastructure investment to improve navigation conditions, including in particular the capacity of inland waterways, and to enhance the performance of watercraft and transport technologies used. In more analytical terms, in order to ensure the strengthening of the inland waterway transport role in markets in which this mode of transport is already present, it may be particularly desirable to integrate more closely inland waterway transport with the inter-modal logistic chains, achieved through:

- actions to reduce the adverse effects on inland waterway transport resulting from so called low water levels, which should in particular involve: construction of storage yards and warehouses used by loaders during periods of low water levels and construction of multi-modal ports allowing other modes of transport to take over the tasks of inland waterway transport during periods of low water levels;

- the development of containerization, which will ensure a better connection between inland waterway transport and seaports;

- increasing the participation of inland waterway transport in waste and bulk transport.

In order to open up new markets for inland waterway transport, infrastructure investments in the improvement of the waterway system and the development of inland waterway connections should play the major role. Taking into account the fact that economic results and the supply of transport infrastructure determine each other (Ahlfeldt et.al., 2015), improvement and expansion of this infrastructure should take place especially in respect of water connections between the countries of the so-called old Union and the new EU members, representing Central and Eastern Europe, characterized by high quality navigation conditions.

Amongst the projects prepared by the EU to develop inland waterways and their connections, particular attention should be paid to:

- the project to connect the Oder with the Elbe and then with the Danube (Janak, 2003);

- the TEN-V waterway project (COM, 2017);

- the project for trans-European inland waterways, including, inter alia, the planned connection between the Oder and the Elbe and Danube (EFIN, 2004, p. 95).

These projects are not new and the International Union for Inland Navigation (IBU) and the European Skippers Organization (ESO) in particular are making efforts to implement them. To this end, they appeal to individual Member States to increase expenditure on removing barriers on national inland waterways, and to EU authorities to take greater interest in the trans-European inland waterway network.

Significant investment is needed to pursue both main courses of action which may support the development of inland waterway transport, i.e. developing existing markets and opening up new ones. In 2003 (Ion), the costs of building a trans-European waterway system was already estimated at 220 billion euros. It will be difficult to meet the investment needs of inland waterway transport to increase its role in EU transport systems. This is mainly due to two important reasons:

- the limited budgetary resources of individual countries due to “tying up” budgetary expenditure and revenue and the necessity to abide by the maximum level of the budget deficit imposed by the Union;

- relatively small investment resources of inland waterway carriers, the large number of which are small enterprises.

This situation creates the need to look for other sources of financing the development of inland waterway transport, including e.g. EU funds, bank loans, the creation of national and sector-specific funds. It may be predicted that raising funds for the development of inland waterway transport in Europe will not be easy, especially considering the limited interest of the EU itself in engaging in investment projects to expand the inland waterway network and

thus improve the European inland waterway system. The lack of interest in financing the European Inland Waterway Network stems additionally from the fact that different economic sectors, such as tourism, sport and leisure, housing, the natural environment and water management, report their needs and requirements, which are clearly contradictory, in respect of the said waterways (TINA, 2007). This means, in the broadest sense, that it is necessary to consider the waterways used by IWT both in economic and ecological terms. With regard to the economic aspect, the opportunities for the development of IWT are primarily contingent upon access to infrastructure enabling the provision of transport services at competitive prices and upon shipping significant masses of cargo through IWT.

As regards IWT infrastructure, with certain exceptions (e.g. the Rhine), investments in this area are at best stagnant (EFIN, 2004, p. 21), which entails high costs and expenses and the need to comply with environmental requirements, the fulfilment of which increases expenditure further. Moreover, unwillingness to invest in IWT infrastructure results from the limited interest of shippers in using IWT. To certain extent, this is due to the fact that the economies are dominated by small and medium enterprises, for which the parameters offered by IWT are less useful and which are neither willing nor financially capable to adapt to the service provided by IWT. Such caution also stems from the fact that the environmental aspect is playing an increasingly important role in this area. There is a tendency to depart from recommendations of cautious fulfilment of IWT and environmental protection requirements and to emphasize the need to prioritize ecology, tourism and flood protection requirements. The conflict between flood protection and IWT is primarily due to the fact that to protect against flooding it is necessary to maintain empty retention tanks, whereas IWT needs full tanks, emptied to create a wave on which barges can sail (Gawlik, Smolnicki, 2000, pp. 1-2). Furthermore, the declining position of IWT results from the growing impact of climate change on the deterioration of the water level of inland waterways, which in turn deteriorates navigational conditions. The conducted analyses indicate that IWT is adversely affected by climate change and, in connection with the regulatory changes introduced as a result of the liberalization of its market, it may be considered as a so-called double loser.

These factors are not conducive to the development of IWT, and this trend may be observed not only in moderately developed countries, such as Poland, but also in rich countries, where IWT has traditionally played a greater role in the transport system, such as Germany.

Conclusions

On a declaratory level, EU transport policy emphasizes the strengths of inland waterway transport and the need to strengthen its role in the European transport system. In practice, however, the EU approach towards inland waterway transport is not very consistent. It often boils down to formulating recommendations which are not connected with specific funds allocated for the implementation of these recommendations. The EU stronger financial commitment to promote the role of inland waterway transport in the European transport system is mainly hampered by the limited and often declining interest of customers in inland waterway services. This results in a small share of cargo transported through inland waterways in the total transported cargo, which according to Eurostat estimates (2020) averaged 6.5% in the EU at the end of 2017, while for Poland it was 0.1%, and it is also one of the lowest results among the EU countries. Furthermore, the unwillingness to financially contribute to the development of inland waterways results from the growing need to abide by ecological requirements, which significantly increases capital expenditure related to the improvement of the waterways. In the current situation, the EU is unlikely to invest significant resources in inland waterway transport. Therefore, it may be expected that, in the best case scenario, the EU will take measures to maintain the status quo of this mode of transport.

Acknowledgment

The project is financed within the framework of the program of the Minister of Science and Higher Education under the name "Regional Excellence Initiative" in the years 2019 - 2022; project number 001/RID/2018/19; the amount of financing PLN 10,684,000.00

Abstract

The end of the XXth– beginning of the XXIst century is characterized by the significant increase of competition basically at all world markets. For Russia, full-fledged entry into the global system of the world economy acts, on the one hand, as a vital resource for development, on the other hand, as a threat of displacement to the periphery of the world economy. From this point of view, it is relevant to analyze general trends in ensuring national competitiveness worldwide and for the Russian economy in particular. The current stage of economic development brings to the fore the issue of increasing the competitiveness of the Russian economy. The main weaknesses of Russia's competitiveness are related to administrative procedures and rules. Corruption in Russian society today is one of the main internal risk factors. Nowadays, it has turned from a trivial criminal problem into a key threat to Russia's competitiveness.

Keywords*:* Competition, Hypercompetition, National Competitiveness, Competitiveness Rating, Problems of Competitiveness, Corruption, Corruption Perception Index, Globalization, World Economy.

Relevance and Problem Statement

A distinctive feature of recent decades is the increased competition basically at all global markets. More recently, it has been absent in a number of countries and industries. The competition was not so fierce there where it took place. Global transformations that have taken place in the world development since the last quarter of the XXth century have led to significant changes in the world economic environment. The main positive effect of globalization is related to the effect of competition. The globality of markets means nothing more than the globality of competition. Under the condition of the globalization in the economic space, competition has been filled with a new, more complex content, and therefore a new form of competition has emerged such as hypercompetition (Strokov, Rudakova and Kusnetzova, 2016).

The problem to determine the level of national competitiveness and develop measures of its improvement has become particularly urgent when the global financial and economic crisis made fundamental changes, both in the economic development of most countries and in the dynamics of the development of the entire world economy. These changes have had a significant impact on the level of competitiveness between many national firms, as a result there have been significant changes in the ratings of the national competitiveness level (Strokov, Rudakova, 2016).

As for Russia, on the one hand, full integration into the global system of the world economy is a vital resource for development, on the other hand, it poses a threat of displacement to the periphery of the world economy. It is obvious that there is a possibility to solve the problem of strengthening Russian authority in the international arena, improving the standard of living of the country's population, and gradually approaching the standard of living of the most

Cite this Article as: Olga RUDAKOVA, Elena KOLESNICHENKO , Lyudmila KUZNETSOVA and Natalia PYANOVA“ Corruption as The Main Problem of Russia's Competitiveness” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

developed countries in the world only if there is a strong, dynamically developing economy. From this point of view, it is relevant to analyze global trends in ensuring national competitiveness and the conceptual theoretical and methodological foundations to form competitive strategies of international firms.

Until the 90s of the last century, there was no practical need to study the problems of competition and competitiveness in Russia. It was assumed that there was no competition in an administrative-command economy based on public ownership, on the means of production and systematic organization of production. The economic crisis of 1998 became the starting point for studying the problems of competitiveness in Russia, since the growth of the competitiveness of national enterprises was one of the positive consequences after this crisis. It should also be noted that since 2003 the growth of national competitiveness has become an integral part of the country's development priorities.

Research Result

World economic forum (WEF) has been ranking countries in terms of competitiveness since 1979. Global competitiveness monitoring is based on a combination of publicly available statistical information and the results of a survey of CEOs conducted annually by the WEF in conjunction with a network of partner organizations in the countries analyzed in the report. The global Competitiveness Index 4.0 is based on 113 variables grouped into 12 sub-indices divided into 4 groups. The 2019 global competitiveness index was calculated for 141 States. Beginning from 2018, each global economy is assigned a GCI on a scale from 0 to 100, where 100 represents the ideal state when considered factors are no longer obstacles to productivity growth.

According to the Global Competitiveness Report 2019, Singapore, the United States, Hong Kong SAR, the Netherlands and Switzerland led the national competitiveness ranking (figure 1). The last place in the ranking was taken by Chad, scoring only 35.1 points out of possible 100. Among the countries of the BRICS group, China has the best position in the ranking (28th place), and Brazil has the worst (71st place), while China's positions in 2019 did not change in comparison with 2018, and Brazil fell one line down. India dropped to 68th place in the GCI 2019 ranking compared to 2018. South Africa, on the other hand, significantly improved its position in the 2019 ranking, rising by 7 lines and taking 60th place. The Russian Federation ranked 43rd in the 2019 ranking, the same as the year before, with 66.7 points this time. It should be noted that the neighbors of our country in the rating were Slovak Republic (42nd place) and Cyprus (44th place).

Figure 1: Position of some countries in the rating by The Global Competitiveness Index 4.0 2019 (The Global Competitiveness Report 2019)

Russia is ranked 43rd for the second year in a row, gaining an additional 1.1 points in 2019 compared to 2018. The Russian Federation's positions in the global Competitiveness Index 4.0 2018-2019 ranking are shown in table 1. Our country's best position in Pillar 10: Market size is 6th in both 2018 and 2019; the worst in Pillar 5: Health is 100th in 2018 and 97th in 2019. It should be noted that in 2019, compared to 2018, Russia significantly improved its position on Pillar 4: macroeconomic stability, rising from 55th place to 43rd (+12 positions in the rating) due to low inflation and stable finances. In addition, progress has been made in Pillar 12: Innovation capability, moving from 36th to 32nd (+4 positions in the ranking) due to improved quality of research institutions, increased R&D spending, and widespread Internet coverage. There was a significant deterioration in the position of Pillar 9: Financial system, the country moved from 86th place in 2018 to 95th place in 2019 (-9 positions in the rating), which was due to an increase

in the share of problem loans from banks, problems with obtaining loans for small and medium-sized enterprises, and a relatively low development level of the stock market.

Table 1: Components of Global Competitiveness Index 4.0 for the Russian Federation in 2018-2019 (The Global Competitiveness Report 2018, 2019)

Index Component	2018		2019	
	Score	Rank/140	Score	Rank/141

Pillar 12: Innovation capability	50,7	36	52,9	32
Global Competitiveness Index	65,6	43	66,7	43

Based on the Global Competitiveness Report 2019, it can be confirmed that the main competitive advantages of the Russian economy were the inflation rate (1st place), electricity access (2nd place), gross domestic product by purchasing power parity (6th place), the number of mobile-cellular telephone subscriptions (9th place), the news of research institutes prominence (9th place), budget transparency (15th place), shareholder governance (17th place).

Figure 2 shows the weaknesses of Russian competitiveness. The labour tax rate in Russia is one of the highest among the economies considered in the Global Competitiveness Report, which puts our country on the 134th place out of 141 according to this indicator. Banks' regulatory capital ratio allowed Russia to take only the 132nd place in the Global Competitiveness Index 4.0 rating. Significant difficulties exist in the Russian economy: financing of SME-only 118th place. A distinctive feature of the Russian economy is the incident of corruption – 116th place. It should be noted that in the Global Competitiveness Index 4.0 rating in 2018 Russia ranked 113th out of 140 possible countries.

International ratings indicate that Russia has a very low corruption perception index. The Corruption Perception Index (CPI) is a composite indicator calculated on the basis of statistical and expert information. The value of this indicator can vary from "0" (the highest level of corruption) to "100" (the lowest level of corruption). The ranking of countries on the corruption perception index is compiled by the international non-governmental organization Transparency International.

Figure 2: Weak points of national competitiveness in Russia in 2019
The Global Competitiveness Report 2019

In 2019 Transparency International presented the next corruption perception rating for countries all around the world. The 2019 ranking compiled 180 countries, including Russia. The leaders of the Corruption Perception Index 2019 rating were New Zealand and Denmark (87 points each), Finland (86 points), Singapore, Sweden and Switzerland (85 points each), outsiders – Somalia (9 points), South Sudan (12 points) and Syria (13 points). Russia ranked 137th out of 180 possible countries in the 2019 CPI ranking, scoring 28 points. Lebanon, Kenya, Mauritania, Uganda, Liberia, Paraguay, the Dominican Republic and Papua New Guinea scored the same number of points and were in the same positions. In recent years, Russia's position in the rating under review has been relatively stable (Fig. 3). Minor changes are due to changes in the ranking of other countries, the inclusion (or exclusion) of other countries from the rating, and the lack of a systematic fight against corruption. It is obvious that the world community perceives Russia to be a country with a high level of corruption and low efficiency of public administration. It should be noted that the Convention on civil liability for corruption has not been ratified by Russia yet (Civil Law Convention on Corruption, 2020).

Figure 3: Corruption perception index in Russia in 2000-2019
(CPI 2019 Global Highlights, 2020)

According to Russian law, corruption is "abuse of official position, giving a bribe, receiving a bribe, abuse of authority, commercial bribery or other illegal use of an official position by an individual contrary to the legitimate interests of society and the state in order to obtain benefits...". Statistical reporting on corruption-related crimes can become one of the most effective administrative and legal means to improve the anti-corruption mechanism.

According to the General Prosecutor's office of the Russian Federation, in 2019, the country's law enforcement agencies registered 30,991 corruption-related crimes, which accounted for 1.5% of the total number of all crimes. According to the data provided in table 2, the number of registered corruption-related crimes in 2014-2019 is relatively stable, as well as the number of people involved in this type of illegal activity.

Table 2: Dynamics of the number of registered corruption crimes in the Russian Federation in 2014-2019 (Crime situation in Russia, 2020)

	2014	2015	2016	2017	2018	2019
Number of registered corruption-related crimes	32,060	32,455	32,924	29,634	30,495	30,991
Identified people committing crimes	15,831	16,926	16,680	15,940	15,908	15,773

The percentage of corruption-related crimes in the Federal districts of the Russian Federation is of interest (Fig. 4). The largest share of corruption-related crimes in 2019 was in the Volga (24.9%) and Central (21.0%) Federal districts, the smallest was in the Far Eastern Federal district (5.2%). It should be noted that this situation persists throughout the analyzed period. In 2014 the Volga and Central Federal districts accounted for 23.9% and 20.5% of corruption-related crimes registered throughout the country, while the Far Eastern Federal district accounted for only 4.2%.

Figure 4: The share of corruption-related crimes registered in Federal districts, as compared to their total number in Federal districts of the Russian Federation (Crime situation in Russia, 2020)

Bribery (articles 290, 291, 291.1, 291.2 from the criminal code) is the main type of corruption-related crimes (Criminal code of the Russian Federation, 2020). If the share of all corruption-related crimes in 2019 was 1.5% of the total number of registered crimes, then fraud accounted for 0.7% of their number. We should note a steady increase in the number and proportion of crimes related to bribery in the period 2016-2019.

In general, the number of crimes under article 290 from the criminal code of the Russian Federation (receiving a bribe) has increased in the Russian Federation: from 3,499 in 2018 to 3,988 in 2019. The number of crimes under article 291 from the criminal code (bribery) increased by 21.5%: from 2,612 in 2018 to 3,174 in 2019. The increase

in the number of crimes under article 291.1 from the criminal code (mediation in bribery) was 32.5%: from 979 in 2918 to 1,297 in 2019, there was a slight (0.5%) decrease in the number of crimes under article 291.2 from the criminal code (petty bribery) - from 5,437 in 2018 to 5,408 in 2019 (General Prosecutor's office of the Russian Federation, 2019).

Figure 5 : Dynamics of the number of crimes under articles 290, 291, 291.1, 291.2 from the criminal code (bribery) in 2014-2019 (General Prosecutor's office of the Russian Federation, 2019)

The overall increase in the number of corruption-related crimes is associated with an increase in the number of crimes under article 285 from the criminal code in the Russian Federation (abuse of official authority). Abuse of official authority undermines the effectiveness of state power and undermines the belief of citizens that their interests can be protected. An important measure of anti-corruption policy is the inevitability of punishing those who abuse their official authority. According to the data in figure 6, the number of registered crimes under article 285 from the criminal code of the Russian Federation in 2014-2019 is relatively stable. A significant reduction was recorded only in 2017.

Figure 6: Dynamics of the number of crimes under articles 285 from the criminal code in the Russian Federation (abuse of official authority) in 2014-2019 (Crime situation in Russia, 2020)

Conclusions and Suggestions

It should be noted that the weakness of Russia's position in the Global Competitiveness Index 4.0 rating is largely due to the low effectiveness of public policy. Russian corruption has been systematic for a long time. Corruption has permeated all strata of Russian society. It particularly affected the state authorities and administration. Illegal actions of officials covered a wide range of public relations.

We should agree with Transparency International experts that in order to establish an economy where corruption is not a threat to national security and personal safety of citizens, as well as to the country's competitiveness on the world stage, Russia needs to (Russia in CPI – 2019: 28 points and 137th place (2019):

- regulate lobbying activities by ensuring the openness of decision-making in government bodies;
- exclude the influence of personal interests and connections on any decisions made by public authorities, especially those related to the allocation of budget funds;
- improve the legislation concerning settlement between conflicts of interest;
- ensure the protection of journalists, activists and other applicants for corruption crimes;
- follow the norms of international law and comply with the obligations assumed in the framework of interaction with other states and supranational organizations.

Abstract

The organizational attractiveness is crucial in attracting talent amidst the talent crunch in Indonesia. A frequently cited recommendation of organizational attractiveness is to use perceived person-organization fit to attract talent to work within the organization. Given its importance, the impact of perceived person-organization fit on organizational attractiveness is essential to explore. Several studies have shown that perceived person-organization fit has a positive influence on employer branding and use of social media. Also, employer branding and use of social media were found to have a positive influence on organizational attractiveness. However, empirical evidence demonstrating the usefulness of addressing employer branding and use of social media as a mediation between perceived person-organization fit to organizational attractiveness is limited. Therefore, this study examined the role of employer branding and use of social media in transferring perceived person-organization fit to organizational attractiveness. This study uses a quantitative approach with cross-sectional design and purposive sampling method to collect primary data. The sample was obtained from 311 Undergraduate and Graduate Students in Indonesia while data is analyzed using Structural Equation Modelling (SEM). The findings indicate that perceived person-organization fit has a negative effect on organizational attractiveness. However, perceived person-organization fit's influence becomes positive on organizational attractiveness when adding the role of employer branding and social media as mediation.

Keywords: Organizational Attractiveness, Employer Branding, Use of Social Media, Perceived Person-Organization Fit.

Introduction

Talent is seen as an essential asset in the organization (Ahmad, 2018). They are unique and take a vital position to achieve a sustainable competitive advantage (Dries, 2013). Talent cannot be bought (Greene, 2020); however, companies can obtain, utilize, and protect these resources through talent management (Sparrow & Makram, 2017). In recent practices, talent management has been recognized as an innovative instrument of human resource management practices and has become the main focus of organizations in the twenty-first century (Mensah, 2019). However, organizations worldwide view talent management as the most critical challenge in this century (Jooss, Burbach, & Ruël, 2019). This challenge arises because of talent issues that have become the primary concern of many CEOs (Bhalla, Caye, Lovich, & Tollman, 2018). A survey conducted by PWC in 2019 showed that four out of five CEOs complained about a lack of skills in their employees and identified this factor as a threat to company growth. Moreover, the lack of skills in employees can also obstruct innovation and increase labor costs.

Cite this Article as: Yessi INES and Elok Savitri PUSPARINI "The Effect of Perceived Person-Organization Fit on Organizational Attractiveness: Mediating Role of Employer Branding and Use of Social Media" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Companies in Indonesia also experience a lack of skills in the availability of labor. Based on the research by Korn Ferry in 2018 revealed that Indonesia will experience the gap between supply and demand for the availability of skilled labor called talent crunch in 2020 and will continue to increase until 2030. Talent crunch in a category of individuals who have completed tertiary education reaches 1.3 million in 2020 and will continue to grow until 3.8 million in 2030 (Korn Ferry, 2018). This indicates that 29.9% of people who have completed tertiary education lack the skills and abilities that the organization needs in 2030.

This condition is exacerbated by the low level of people who took tertiary education in Indonesia. A survey conducted by Kemenristekdikti (2018) showed that the total number of people aged 19 - 23 years who should be currently studying in tertiary education are 80 - 107 million. However, only 7.5 million of them were pursuing tertiary education. The main problem in Indonesia's workforce is the low number of people who have been completed tertiary education and have the skills they should possess. Based on the survey conducted by Badan Pusat Statistik (BPS) Indonesia in 2020 regarding the workforce percentage according to education level, the total workforce in Indonesia is 137.910.000 people, 13.16% or equivalent to 18.148.956 of them who had taken tertiary education. The survey results support the gap between the demand and supply of skilled labor in Indonesia. Besides, a survey conducted by BPS Indonesia in 2020 shows that 5.95% of people who took tertiary education have no job or can be categorized as unemployed.

Given the low availability of skilled labor supply, there are several ways that organizations can protect themselves from the effects of this condition. To attract, retain, and motivate talent, organizations must be seen as the employer of choice (Greene, 2020). Organizations must be able to attract the right talent by using organizational attractiveness (Greene, 2020). Organizational attractiveness is applicants' willingness to pursue the jobs and to accept job offers in an organization (Story, Castanheira, & Hartig, 2016). The survey conducted by Korn Ferry Indonesia and collaborated with SWA since 2013 regarding The Top Companies Organization to Work For in Indonesia in 2019 was aimed to provide consistent feedback to the companies to increase employee engagement. There are top 5 companies that become Top Companies Organizations to Work For, namely Pertamina, Bank Central Asia, Bank Mandiri, Bank Rakyat Indonesia, and Unilever Indonesia.

Related to organizational attractiveness, De Cooman and Sels (2020) found that perceived person-organization fit has a strong antecedent to organizational attractiveness. This indicates that people try to find an environment that can meet their needs and strengthen themselves. Cable and Judge (1996) suggest that job seekers develop their perceived person-organization fit, which came from the congruence between their perceived values and their values. Perceived person-organization fit is a person's perception of the conformity between the values he has and the values that the organization has (Hoffman & Woehr 2006).

The perceived fit between applicants and companies can be achieved with the use of social media. Research conducted by Tanwar and Kumar (2019) found that use of social media helps strengthen the existing relationship between potential employee's perceived person-organization fit on organizational attractiveness. In addition to using social media, companies can also use employer branding to increase perceived person-organization fit on organizational attractiveness. Chawla (2019) found that person-organization fit has a positive relationship with employer branding. Chhabra and Sharma (2014) found that employer branding has a positive influence on organizational attractiveness. Therefore, perceived person-organization fit can affect organizational attractiveness through use of social media and employer branding.

Literature Review

Relationship Between Perceived Person-Organization Fit and Organizational Attractiveness

Perceived person-organization fit is defined as a condition in which there is a match between the individual's values and the organization (Kristof-Brown, Zimmerman, & Johnson, 2005). Hoffman and Woehr (2006) define perceived person-organization fit as a person's perception of the conformity between the values he has and the values that the organization has. A research study by Ghielen, De Cooman, and Sels (2020) found that person-organization fit has a robust positive relationship with organizational attractiveness. Organizational attractiveness is defined as the extent to which potential employees view the company as an excellent place to work (Ehrhart & Ziegert, 2005). This study confirms the idea that individuals seek an environment that can fulfill their needs and strengthen themselves. This study is also in line with previous research that states a positive relationship between the value of person-organization fit and organizational attractiveness (Uggerslev, Fassina, & Kraichy, 2012). Also, a research study by Dineen, Ash, and Noe (2002) found that a higher level of person-organization fit leads to a higher level of organizational attractiveness. Therefore, the researcher proposes the following hypothesis:

H1: perceived person-organization fit has a direct, positive, and significant influence on organizational attractiveness.

Relationship Between Perceived Person-Organization Fit and Employer Branding

Person-organization fit has generally been defined as an organization's compatibility with an organization (Sekiguchi, 2004). Within employment selection research, specifically, the person-organization fit has been defined as a match between a prospective employee and the organization aside from knowledge, skills, and other physical and cognitive abilities (KSAs) (Westerman & Cyr, 2004). In a research study by Chawla (2019) found that person-organization fit has a positive relationship with employer branding. Employer branding is defined as the total of a company's efforts to communicate to existing and prospective employees about the company as a desirable place to work at, with advertising being key to creating an employer brand that is differentiated and compelling (Berthon, Ewing & Hah, 2005). Employer branding can also be defined as the employer attractiveness, that is, envisioned benefits that potential and current employees see in working for a specific organization (Berthon, Ewing & Hah, 2005). Also, as a total package of functional, economic, and psychological benefits provided by an employment experience (Ambler & Barrow, 1996). Therefore, the researcher proposes the following hypothesis:

H2: perceived person-organization fit has a direct, positive, and significant influence on employer branding.

Relationship Between Perceived Person-Organization Fit and Use of Social Media

Person-organization fit is defined as the congruence between organizations' norms and values and persons' values (Chatman, 1989). Job seekers prefer organizations whose characteristics align with organizational attributes (Cable & Judge, 1994). Theories about the person-organization fit state that person-organization fit is formed when the company's characteristics match a person's characteristics. The level of conformity will affect individual attitudes and characteristics (Pervin, 1989). According to Kristof (1996), the person-organization fit will occur when a company meets individual needs, wants, and preferences. A research study by Tanwar and Kumar (2019) found that person-organization fit has a positive and significant relationship to use of social media. Social media is defined as digital applications that facilitate interactive information, user-created content, and collaboration (Elefant, 2011). Tanwar and Kumar (2019) mentioned that the contribution of person-organization fit depends on the contribution of social media in building the company as an attractive employer. Therefore, the researcher proposes the following hypothesis:

H3: perceived person-organization fit has a direct, positive, and significant influence on use of social media.

Relationship Between Employer Branding and Organizational Attractiveness

Employer brand is the perception the world has about a company as an excellent workplace (TTI, 2010). The perception indicates a company as a great place to work in current and potential employees (Berthon, Ewing & Hah, 2005). Backhaus and Tikoo (2004) define employer branding as an effort by the organization to market their employment value proposition to improve recruitment and retention and also increase the value of human capital. A research study by Jiang and Iles (2011) found that employer branding could be a robust antecedent of organizational attractiveness. In a research study by Chhabra and Sharma (2014) found a significant and positive relationship between a strong employer brand and organizational attractiveness. Organizational attractiveness is defined as applicants' willingness to pursue the jobs and to accept job offers in an organization (Story, Castanheira, & Hartig, 2016). Berthon, Ewing and Hah (2005) defined organizational attractiveness as the intangible and invisible benefits of an organization for future employees. By implementing a substantial employer, branding will encourage companies to become attractive companies. Therefore, the researcher proposes the following hypothesis:

H4: employer branding has a direct, positive, and significant influence on organizational attractiveness.

Relationship Between Use of Social Media and Organizational Attractiveness

Social media is defined as digital applications that facilitate interactive information, user-created content, and collaboration (Elefant, 2011). In human resource management, especially in the recruitment process, social media can be used to win the competition in getting potential employees who have the required skills. In a research study by Carpentier, Van Hoye, Stockman, Schollaert, Van Theemsche, and Jacobs (2017) found that social media significantly affects organizational attractiveness, which means that the more information available to the potential employees on a company's social media, the higher their interest to the company. Organizational attractiveness refers

to the extent to which potential employees view the company as a positive place to work (Ehrhart & Ziegert, 2005). Besides, a research study by Kaur, Sharma, Kaur and Sharma (2015) mentioned that companies should consider using social media and organizational attractiveness as two critical things. Applicant perceptions of a company changed after viewing the company's web site, and those site design impressions were positively related to application intentions (Dineen, Ash & Noe, 2002)). Therefore, the researcher proposes the following hypothesis:

H5: use of social media has a direct, positive, and significant influence on organizational attractiveness.

Relationship Between Employer Branding and Use of Social Media

Employer branding is defined as a process that is concerned with building a positive image of a company in the minds of current and potential employees. Above all others, it is a great place to work and is an employer of choice (Ewing, Pitt, De Bussy and Berthon, 2002). Wallace, Lings, Cameron, and Sheldon (2014) defined employer branding as a combination of marketing and recruitment practices that allows employees and other stakeholders to recognize the desired corporate image. In other words, employer brand can be represented as the organization's image is perceived by actual and prospective employees (Gehrels, Wienen & Mendes, 2016). A research study by Kaur, Sharma, Kaur and Sharma (2015) found that social media and employer branding have a significant relationship and revealed that the most effective tool for communicating a brand is using social media. Bondarouk, Ruël, Axinia, and Arama (2013) mentioned using social media can encourage a company that wants to build a strong employer brand reputation. Therefore, the researcher proposes the following hypothesis:

H6: employer branding has a positive and significant direct effect on use of social media.

Relationship Between Perceived Person-Organization Fit, Employer Branding, and Organizational Attractiveness

Employer branding refers to how branding concepts and marketing, communications, and Human Resources techniques are applied to create an employer brand (Martin, Gollan, and Grigg, 2011). Employer brands aim to create an identity through differentiation in key stakeholders (Carrington, 2007). In a previous research study by Ghielen, De Cooman, and Sels (2020) has tested the role of employer branding as a moderation between the relationship of person-organization fit and organizational attractiveness. These findings found that person-organization fit has a robust positive relationship with organizational attractiveness. However, the relationship between person-organization fit and organizational attractiveness becomes low because of employer branding. A research study by Chawla (2019) found that person-organization fit has a positive relationship with employer branding. A research study by Chhabra and Sharma (2014) found that positive employer branding will increase organizational attractiveness. In this study, the researcher wanted to expand the research by examining the role of employer branding as a mediator in the influence of perceived person-organization fit on organizational attractiveness. Therefore, the researcher proposes the following hypothesis.

H7: employer branding mediates the relationship between perceived person-organization fit and organizational attractiveness.

Relationship Between Perceived Person-Organization Fit, Use of Social Media and Organizational Attractiveness

Social media is digital applications that facilitate interactive information, user-created content, and collaboration (Elefant, 2011). In human resource management, especially in the recruitment process, social media can be used to win the competition in getting potential employees who have the required skills. Dineen, Ash, and Noe (2002) mentioned an individual interest in a company is based on the fit between the individual and the organization (person-organization fit), which indicates a higher PO-fit will result in a higher level of interest to the organization. A previous research study by Tanwar and Kumar (2019) found that person-organization fit has a positive relationship with use of social media. A research study by Carpentier, Van Hoye, Stockman, Schollaert, Van Theemsche and Jacobs (2017) found that social media significantly affects organizational attractiveness. In this study, the researcher wanted to expand the research by examining the role of social media in mediating the influence of perceived person-organization fit on organizational attractiveness. Therefore, the researcher proposes the following hypothesis:

H8: use of social media mediates the relationship between perceived person-organization fit and organizational attractiveness.

Research Methodology

This study obtains primary data using survey techniques, conducted with structured questionnaires and a single cross-sectional design. Questionnaires are self-administered and distributed online using social media. This study uses a non-probability sampling with a purposive method to obtain samples within the required information criteria. Other than primary data, this study also collects secondary data from the literature review, books, institutional research reports, and other related literature to identify, define, develop an approach, formulate the design, answer research questions and test hypotheses, and interpret primary data more meaningfully (Malhotra and Dash, 2016).

Five different sources are used as indicators of each variable. *Perceived person-organization fit,* the scale developed by Kristof (1996) and Cable and Judge (1996) with four items, "My skills and abilities match the skills and abilities that this organization looks for in employees." *Employer branding,* the scale developed by Tanwar and Kumar (2019) with eighteen items, "This organization offers good internal training opportunities. *The use of social media* was measured using six items developed by Collins and Stevens (2002) "I have seen advertising for jobs at this organization in social media." *Organizational attractiveness,* the scale developed by Highhouse, Lievens, and Sinar (2003) with fifteen items "This organization is the most attractive employer for me."

This study uses a Likert scale ranging from 1 (Highly Disagree) to 7 (Highly Agree) for each indicator used. The questionnaires were addressed to Undergraduate and Graduate Students in Indonesia. Before the main test questionnaire distribution, the researchers first conducted a wording test of 10 people whose characteristics matched the targeted population to ensure the questionnaire's understandability and minimize bias. The pre-test stage involves 30 respondents, and the data were processed using SPSS to ensure the validity and reliability of questionnaire items used.
The research model presented below:

Fig. 1: Research Model

Results

Demographics

A total of 226 (72.67%) women and 85 (27.33%) men have participated in this study. Respondents in the range of 21 - 25 years dominated by 81.67%. Based on the level of education, undergraduate students dominated as much as 96.78%. The majority of respondents came from the faculty of economics and business, 52.73%. This could happen because the questionnaires' distribution was carried out around students from the economics and business faculty and includes influencers from the economics to distribute the questionnaire. Hence the data collected was dominated by the students who studied at the faculty of economics and business. Furthermore, 151 respondents (48.55%) chose Unilever Indonesia as the organization to work for, 100 respondents (32.15%) chose Pertamina, 25 respondents (8.04%) chose Bank Central Asia, 21 respondents (6.75%) chose Bank Mandiri, and 14 respondents (4.50%) chose Bank BRI.

Analysis – Structural Equation Modelling (SEM)

The primary test analysis consists of first-order and second-order measurement models analysis involving tests of validity, reliability, and goodness of fit and analysis of structural models consisting of analysis of causal relationships, the goodness of fit, and hypothesis testing. The data was processed using Lisrel 8.80.

The Measurement Model

Based on the results of validity and reliability testing data on the first order of measurement model in this study showed that all indicators of organizational attractiveness, employer branding, use of social media, and perceived person-organization fit had valid SLF ≥ 0.05 and reliable CR ≥ 0.7 and VE ≥ 0.5 (Hair, Black, Babin & Anderson, 2014). Furthermore, the goodness of fit on first-order measurement model showed a good fit result such as ECVI = 5.43, NNFI = 0.98, NFI = 0.96, RFI = 0.96, IFI = 0.99, CFI = 0.99, and critical N = 206.08. Meanwhile, the rest of the GFI, RMR, and AGFI showed a marginal fit. After conducting the first order, the second-order measurement model was carried out. The validity and reliability testing data on all indicators of the second order measurement model showed valid and reliable. In addition, the goodness of fit on first-order measurement model showed a good fit result such as RMR = 0.051, ECVI = 5.31, NNFI = 0.98, NFI = 0.96, RFI = 0.96, IFI = 0.98, CFI = 0.98. On the other hand, RMSEA, AGFI, and critical N showed a poor fit.

The Structural Model

The structural model fit was evaluated and the result of GOF showed good fit for RMR = 0.059, ECVI = 6.02, NNFI = 0.98, NFI = 0.96, RFI = 0.96, IFI = 0.98, CFI = 0.98. Meanwhile, RMSEA, AGFI, and critical N showed a poor fit. Table 1 showed the hypothesis test results in the path analysis that illustrated the causality relationship between variables in the structural model. According to the result of the structural model, perceived person-organization fit had a negative and significant direct effect on organizational attractiveness (SLF: -64.11, t-value ≥ -1.645), but perceived person-organization fit had a positive and significant direct effect on employer branding (SLF: 1.00, t-value ≥ 1.645) and also had a positive and significant direct effect on the use of social media (SLF: 8.33, t-value ≥ 1.645). Employer branding had a positive and significant direct effect on organizational attractiveness (SLF: 56.96, t-value ≥ 1.645). Social media also had a positive and significant direct effect on organizational attractiveness (SLF: 8.77, t-value ≥ 1.645). Employer branding had a negative and significant direct effect on social media (SLF: -7.43, t-value ≥ -1.645). Hence, this study also found the indirect effect of perceived person-organization fit on organizational attractiveness through employer branding and use of social media. Therefore, H2, H3, H4, H5, H7, and H8 were supported, but H1 and H6 were not supported.

Table 1: Hypothesis Testing

Hypothesis	Path	SLF	T-value	Result
1	Perceived Person-Organization Fit → Organizational Attractiveness	-64.11	-1.92	Significant
2	Perceived Person-Organization Fit → Employer Branding	1.00	11.08	Significant
3	Perceived Person-Organization Fit → Use of Social Media	8.33	4.37	Significant
4	Employer Branding → Organizational Attractiveness	56.96	1.85	Significant
5	Use of Social Media → Organizational Attractiveness	8.77	3.51	Significant
6	Employer Branding → Use of Social Media	-7.43	-4.30	Significant
7	Perceived Person-Organization Fit → Employer Branding → Organizational Attractiveness	56.96	20.498	Significant
8	Perceived Person-Organization Fit → Use of Social Media → Organizational Attractiveness	73.054	15.3387	Significant

Discussion

The first hypothesis (H1) regarding the positive influence of perceived person-organization fit on organizational attractiveness is rejected. The finding contradicts the studies belonging to Ghielen, De Cooman, and Sels (2020), which showed that perceived person-organization fit positively influences organizational attractiveness. However, the negative influence may be explained through the studies belonging to Rentcsh and McEwen (2002), which showed that perceived person-organization fit (value and goals) sometimes has different effects on the individual to organizational attractiveness. This indicates the possibility that several undergraduate and graduate students in Indonesia also have the same behavior to the compatibility of their values and goals with the company's values and goals. Thus they were not interested to the company. Although perceived person-organization fit was found to harm organizational attractiveness in the first hypothesis, perceived person-organization fit was found to positively affect organizational attractiveness when mediated by employer branding and use of social media.

The indirect effect of perceived person-organization fit on organizational attractiveness is measured by looking at the effect of perceived person-organization fit on employer branding in the second hypothesis (H2) and employer branding on organizational attractiveness in the fourth hypothesis (H4). The second hypothesis (H2) regarding the effect of perceived person-organization fit on employer branding was found to have a positive effect, which aligned with Chawla (2019) findings. This study shows that undergraduate and graduate students in Indonesia believe they will find colleagues who have the same thoughts like them on the company. This indicates a high perceived person-organization fit on undergraduate and graduate students in Indonesia will affect their complementary view of the company's employer branding. Furthermore, the fourth hypothesis (H4) regarding the effect of employer branding were found to have a positive effect on organizational attractiveness, which aligned to the previous research by Chhabra and Sharma (2014). The positive and significant effect can be explained through the high average value of employer branding and organizational attractiveness. Refers to the dimensions of salary and incentives with the highest average value show undergraduate and graduate students in Indonesia will be more interested in companies that offer salary and incentives above their competitors' average. Moreover, the companies should build a strong employer brand because potential employees are willing to work to companies with a positive and strong reputation and prestige. Therefore, to attract potential employees, the company should increase potential employees' perceived person-organization fit by utilizing employer branding dimensions.

Furthermore, the indirect effect of perceived person-organization fit on organizational attractiveness can also be measured through the effect of perceived person-organization fit on the use of social media in the third hypothesis (H3) and the effect of the use of social media on organizational attractiveness in the fifth hypothesis (H5). The third hypothesis (H3) regarding the effect of perceived person-organization fit on use of social media were found to have a positive and significant effect that aligned with the findings of Tanwar and Kumar (2019). Refers to the result of the highest average value on use of social media, shows students attracted to the job advertisement with the company they aspire to. High perceived person-organization fit in students would be easier to attract them through the use of social media by the company. Furthermore, the fifth hypothesis (H5) regarding the effect of use of social media by the company positively affect organizational attractiveness are aligned to the previous research from Carpentier et al. (2017). The positive influence of social media on organizational attractiveness can be explained through the word-of-mouth endorsement dimension. The finding indicates students who receive a positive view from their lecturers about a company as a place to work probably think of the company as a prestigious place to work. Moreover, using word-of-mouth endorsement can accelerate the spread of information about the company and deliver the information directly to the intended object. This study's object is undergraduate and graduate students in Indonesia, which implies the lecturers are the right subject to deliver the information and can be trusted by the students.

Further attention is given to the rejection of the sixth hypothesis (H6) regarding the positive influence of employer branding on use of social media. This study suspects that employer branding's negative influence on use of social media can occur because three out of five companies used as triggers are in the banking industry. This assumption is supported by the average value of work culture dimensions. The statement "the company provide flexible working hours" has the lowest average value among other employer branding indicators.

Based on the previous hypothesis testing, there is a positive and significant influence from perceived person-organization fit on employer branding, employer branding on organizational attractiveness, perceived person-organization fit and use of social media, and use of social media on organizational attractiveness. This finding supports the acceptance of the hypothesis that tests the mediating role of employer branding and use of social media. The seventh hypothesis (H7) found a positive influence on perceived person-organization fit on employer branding and influence on employer branding on organizational attractiveness. Perceived person-organization fit of undergraduate and graduate students in Indonesia can affect organizational attractiveness through employer branding. Therefore, to improve organizational attractiveness, the company has to pay attention to employer branding to increase perceived

person-organization fit. The findings of the eighth hypothesis (H8) found a positive influence on perceived person-organization fit on use of social media and influence on the use of social media on organizational attractiveness. Perceived person-organization fit of undergraduate and graduate students in Indonesia can affect organizational attractiveness through use of social media. Therefore, to improve organizational attractiveness, the company has to increase their intensity and quality of company's social media to increase student's perceived person-organization fit.

Conclusion

Conclusion

This research indicates that undergraduate and graduate students in Indonesia have different actions towards the conformity between the values and goals they have and the organizations have, thus indicating a negative and significant influence of student's perceived person-organization fit on organizational attractiveness. However, perceived person-organization fit positively and significantly impacts employer branding and use of social media by the company. Employer branding and the use of social media have a direct and positive influence on organizational attractiveness. These findings indicate that students will be more attracted to companies with a strong employer branding by offering salaries and incentives above their competitors. Companies can also attract students through use of social media by using word-of-mouth endorsement, which involves the roles of the closest parties to the students they trust the most, namely the lecturer in college. In terms of mediation relationship, employer branding and use of social media positively mediate the effect of perceived person-organization fit on employer branding. This finding indicates to attract students in Indonesia, the company should consider the role of employer branding and the use of social media in increasing student's perceived person-organization fit.

Limitation

The distribution of respondents in the study was dominated by students who come from the faculty of economics and business, which have an impact on the high number of enthusiasts towards the company were not evenly distributed to other trigger companies, which can potentially cause a little or much bias to the results. Moreover, the study was conducted when coronavirus (COVID19) occurred in Indonesia and obliged universities to implement a distance learning policy that affected the low response rate of research objects in filling out questionnaires and made it difficult to collect data distribution evenly.

Going Serverless with AWS Athena, Data as a service

George Paul OPRESCU

PHD Student at The Bucharest University of Economic Studies, Bucharest, Romania
oprescugp@gmail.com

Abstract

An e-commerce platform is not just a web page with buttons and text that can be easily controlled. In addition to the economic factors and the field in which it operates, the technologies behind the platform are critical in its development. Maintenance involves costs, and they vary depending on the complexity of the data storage services. The layout of the page is also essential, but in order to develop it, a favorable environment for storing data and information is needed. It is essential to know how data is being transformed for analysis and statistics that facilitate business decisions. Most applications use a relational database, the most common being SQL Server from Microsoft. This database is physically stored on virtual machines alongside the application. There is the possibility of having a virtual machine for each application, but in the presence of several applications, users can experience an increase in costs. Kubernetes allows an application to start a virtual machine only when it is being used, resulting in low maintenance costs. However, the future does not consist of virtual machines and servers, cloud services from Amazon being much more efficient. Data and information are stored in the cloud, being exposed to the customer whenever he needs them. Data is then intelligently transformed into statistics and business information through various, almost autonomous data streaming and business intelligence tools.

Introduction

Information is one of the most important resources we have, both digitally and physically. Before the appearance of the Internet, information in society was perpetuated with the help of one of the most enigmatic entities that does not yet know its own limits, namely, man itself. Man was the "hardware and software" through which information circulated in the world, later managing to store all his knowledge in the form of papers, parchments, books and if we use the time machine beyond, stone inscriptions. The power of this resource is the reason why society has reached the pinnacle of technology and manages to surprise even more. With the appearance of technology and the Internet, information has been redefined, evolved into a form easily accessible through television, computers, tablets and mobile devices. By definition, information is the meaning of certain variables, the links between them and is most often associated today with data manipulation and transformation. The data is taken by various methods and subsequently converted into information, to be used further by any individual. In a technology-dominated society however, those who reap the benefits are the big data companies, with Amazon being one of them. The company initially operated as an e-commerce platform, being a simple website for purchasing books online. Subsequently, the business developed in several fields, from electronics, mobile, toys, food, video games and of course their main source of income that currently expands: software services. Amazon is one of the top 4 technology companies in the world to provide a multitude of cloud, e-commerce and artificial intelligence services, all integrated into AWS or Amazon Web Services. [**Figure 1**] A subsidiary of the giant provides companies, state entities or individuals the ability to access on-demand cloud computing platforms and APIs, or application programming interfaces. These services charge the user based on how much they use them. In the case of cloud services, a user is charged according to the storage space used. Microsoft Athena is a cloud data query service, through which a client can extract only the data he needs through his own scripts. After the execution of the scripts, a fee is charged and the results displayed. Thus, the client only gets the information he needs and pays for it accordingly.As mentioned on the official Amazon website, in extracting and preparing data for analysis, customers can use AWS Glue, **Error! Reference source not found.** an ETL service more commonly known as Extract Transform and Load. AWS Glue "pastes" data stored in the AWS

cloud, along with their metadata into a data catalog. This data catalog is then easily accessible by any other AWS service, such as Athena. In terms of structured query language, PostgreSQL is preferred in this case due to the scalability and speed with which it executes queries, much more efficient than the traditional SQL Server from Microsoft or the database management system from Oracle.

Figure 1 : Going serverless with AWS

Amazon Web Services

PostgreSQL is an open source relational database management system that supports several types of queries (relational - SQL or non-relational - JSON). Most PostgreSQL users focus on the area of mobile and web applications, analytics, statistics and geospatial data. Compared to SQL Server, PostreSQL can integrate other programming languages into its code to run at the same time without the need for an external application. The net framework through which the application interface is created or the front end used with PostgreSQL, currently has the fastest response time, thus offering users the comfort of an application that does not crash and responds in real time to business requirements. The programming languages that integrate well with PostgreSQL are among the top 10 most used and efficient: Python, Java, .NET, C / C ++, Ruby, ODBC and Pearl. Amazon manages to integrate this relational database management system directly from the cloud into its services. Through a PostgreSQL extension, geospatial databases and graphical objects can be created to store both traditional and geospatial data with geographic data, under the name of GIS (Graphic Information System). A recent practical application involving geospatial data can be found at Johns Hopkins University in the United States, which has managed to monitor in real time all coronavirus cases displayed in each country, along with their location on the map.

Amazon Athena is a serverless service that allows users to run queries on a cloud stored database. Each query depending on its complexity and the number of data, generates costs for users. Therefore, they can carry out their economic activity in real time knowing exactly how much data they have extracted and what their costs are. By serverless it refers to the ability to interact with Athena without the need for external applications or tools and a server to monitor. The database is strictly created in the cloud by data-as-a-service providers, and then through Athena data is prepared in an intelligent and efficient way for statistical analysis and forecasts. They will afterwards integrate the data into their informational system and use different query languages and reporting tools to get the desired business results.

As depicted in 'Streaming Data Solutions on AWS with Amazon Kinesis', The entire Amazon suite offers a wide range of tools through which a developer can create his application. Source data that comes from files, FTP (File Transfer Protocol), other APIs, but also a tool called Amazon Kinesis. Through it, a user can obtain real-time data from other applications, logs and recorded events obtained from user-client interaction, audio and video recordings. The recorded data reaches the user in real time without the need for him to wait a certain period of time for the data to be collected. Kinesis does not require the user to perform any maintenance or monitoring of the process, the data extraction being completely autonomous for millions of rows in real time. Through artificial intelligence algorithms, the data is taken in an intelligent way, and in time, after its model has been sufficiently trained, it can even learn new

rules of data extraction, as well as adapt to new data that is being streamed in the process. With batch processing data is not being processed in real time, requiring a certain amount of delay for it to be uploaded to the database. The advantage of stream processing is that it does not store data in a database, which will then be processed and forwarded. Instead, it processes data even before being stored in the database, all without user intervention. Building such a system, with the participation of artificial intelligence is a complex process and very difficult to build. The system must be prepared to collect, manipulate and transmit data efficiently from several external or internal sources. Initially, it is necessary to monitor the system during its implementation, due to errors that may occur along the way. Once it is revealed that the data is being processed the wrong way, the intervention is necessary to modify the algorithm so that in the future it knows what kind of model to apply. Once sufficient maintenance has been performed and the system has filled all its gaps, it becomes autonomous. The data sources may have different data upload speeds, all of which are updated based on data priority. If the user receives data that he does not need very quickly, because it depends on other processes that are slower, the accuracy of the whole streaming process is bottlenecked. Thus, the speed at which the data reaches and how each transfer from different sources complement each other is very important. Another step to take when making the system is for the user to monitor duplicated data. Duplicated data is not wrong, but a large amount of the same data can ruin statistical indicators in the data formatting and analysis processes. An aggregation function such as minimum and maximum would not be influenced by data duplication, but other data aggregation functions and statistical indicators like average, median, aggregation by weeks, month, year, have a major impact. Although it doesn't seem like an advantage at first glance, the presence of real-time data can save many businesses or multi-million euro contracts, and the opportunity can be seized faster, compared to a company operating on the same market that relies on traditional predictions. In order to make subscription costs more efficient, critical processes within a company should be monitored through Kinesis, while other processes, although equally important, do not always require real-time data. Many companies prefer to use automated data collection processes from the services their customers use, as they are being notified how much they have to pay by the end of the month. With real-time data, customers can analyze how much they should use the services and whether they are still able to pay without having a surprise bill. As depicted on the official Amazon website, Amazon Kinesis uses Amazon Firehose to collect and upload real-time data in an S3 Bucket, alongside Amazon Redshift, and Amazon's fast search engine Elastricsearch. Kinesis Firehose is a stand-alone, autonomous service that does not require maintenance and training, data being sent or even processed directly to the chosen destination. The only parameters that need to be changed are the destination of the data and the amount, specifying the categories to which they belong. Data is being transmitted regardless of their type, each having a storage capacity of 1000kb in the form of data BLOB. In a database management system, a blob is a collection of data stored binary on a drive. Most BLOBs are multimedia: images, video and audio. Amazon Firehose's rotation of uploading and sending data is automatically monitored by a service called Amazon Kinesis Agent. It always checks the integrity of the data and whether it has been sent successfully or not. In case of a transfer with incorrect data, Amazon Kinesis applies new methods to analyze why the process in question was not executed successfully and records all the information in a log so that it can be subsequently accessed by the user. After accessing the logs, the user can make the decision to change the destination parameters or the type of data transferred, in case of incompatibility. The user can monitor the behavior of these Amazon services, through another service in the same suite called Amazon CloudWatch. A very important resource for storing data of any type, both traditional and multidimensional (images, videos) is Amazon S3 Bucket and the objects that it stores. The name of a bucket is unique and cannot be duplicated in Amazon's service infrastructure. Regardless of the region in which it is created, the bucket is globally unique. The data is encrypted and integrated into an object, which is then stored in an S3 Bucket. There are some limitations depending on the subscription that each user has, from 100 to 1000 objects. Items can be stored in a single bucket or in separate buckets by preference.

Artificial Intelligence in AWS

Artificial Intelligence makes its appearance in AWS with Sage Maker, a service through which a developer or a data scientist can train and automate learning models or machine learning. [**Figure 2**] By machine learning training, the behavior of an individual or robot that adapts over time, changes and learns from its previous iterations to perfect the process. With each iteration, he comes close to simulating the behavior of an intelligent decision-maker. Without entering the realm of fiction, most processes of artificial intelligence are used for economic purposes, such as the evolution of prices over time and forecasts or the detection of diseases in patients depending on how accurate and trained the algorithm is. Within e-commerce platforms, understanding the consumer's needs, studying them in order to provide exactly the products and services they require, is crucial for the proper functioning of any online trading company.

Figure 2: Machine Learning steps

When working with machine learning, there are a few steps a programmer needs to keep in mind according to Matthew Mayo:

- **Data collection**

- the data come both from external sources and from the training of the artificial intelligence model
- as mentioned in 'A Survey on Data Collection for Machine Learning', the model is much more accurate depending on the amount and quality of the data; a more complicated forecasting operation would need much more data to understand the behavior of the factor in question; As an example, a study to identify flu symptoms and the optimal use of appropriate treatment can cause problems in artificial intelligence; despite the fact that the model is trained and receives large amount of data, the virus undergoes unique mutations in each person affected by it, and therefore the model is not able to understand the new behavior; in this case it is necessary to adapt the model to apply methods similar to the previous scenarios, discovering methods that would not be obvious with a simple visit to the doctor;
- can be achieved through efficient data mining methods and complex analysis processes that train the model in future decision making; these data collection techniques fall into the Big Data area;
- there are 3 data collection methods that can be used separately, in any order or even at the same time: identification of data sets and new data collection methods; once these data sets are valid, the behavior is identified and trained for each set; behavior recognition can be replaced with the training of existing data;

- **Data preparation**

- the data is prepared for "training"
- data is cleaned, normalized, duplicates and errors are removed as well as missing values being replaced with relevant or similar data in order not to confused the algorithm, assigned data types and necessary conversions being made along the way;
- the data may also be mixed in order to preserve their initial meaning, without the intervention of the user;
- data can be previewed in order to observe the relationships that reside behind; subsequently they are included in categories according to the most dominant features; this type of inclusion is similar to the cluster group, where the

variables have common features; based on these features, statistics can be made and sent to the model; another method is filtering until the cleaning is complete

- **Model selection**

- the stage at which the model is chosen based on to the characteristics of the data; not every model is a good match for all types of data;
- According to Vladimir Fedak, there are several models in artificial intelligence, the most popular being: linear regression, decision trees, nearest neighbors, logistic regression, neural networks, and linear discriminant analysis
-linear regression is an algorithm and is most often used in mathematics and statistics, in order to train the accuracy of the model and to discover the values of the coefficients that have the greatest impact; by adjusting these coefficients more training results can be discovered by data analysts or data scientists;
- logistic regression is used when we want to understand the connections between two events or two variables and their behavior; the logistic regression is binary and discovers in itself how well two variables can reach a common goal; like linear regression, it is a prediction algorithm, but often the result is difficult to interpret as several such analyzes are needed before the final decision is made;
- linear discriminant analysis is the simplest algorithm of them all and is used to integrate different values into their specific classes; then the class that can bring the highest value to the model is determined and the predictive model is further constructed;
- decision trees appear not only in the statistical and mathematical field, but also in computer science; decision trees are the reason why many programming languages exist today; for example in SQL or Structured Query Language, when creating an index that physically or logically creates a sorted list; this list helps the user in quickly retrieving data; in this case the b-tree or binary tree is used to easily traverse the list and reach the sorting order specified by the index as soon as possible; the index can be physically stored, clustered and is declared only once, being the image of a table in the database; an image cannot exist multiple times and the rows can only be placed in one order; a similar example would be three chairs sitting in a room, a chair can't be to the right, middle or left at the same time, having a fixed position; in addition to the clustered index that is created based on the unique key of a table, the non-clustered index declared by the user intervenes to facilitate subsequent data searches in a certain order; being a binary tree, it helps to search for data, but encounters extensive problems when the user is changing the contents of a table; if the user constantly adds, updates and deletes data, the list is sorted with each data manipulation operation and thus we encounter performance issues; because sorting is the main function of a binary tree, if a search returns more than 70% of the rows in a table, the index loses its functionality and advantage due to the number of rows very close to the total number of rows in the table ; the binary search tree is also a recursive algorithm;
- the Naive Bayes model is one of the most powerful algorithms, easy to use; this is a "naive" model because it always assumes that all data entered by the user is not correlated; this scenario in practice does not present cases that can happen in reality, but due to the possibility to imagine that several participants are not correlated, it determines a very high accuracy for the artificial intelligence model.

- **Model training**

-the purpose of artificial intelligence training is to get a correct prediction or to answer certain questions as often as possible
-every time the model gets a result it will be much more accurate in its next iteration; the more interactions a model performs, the more effective it will be in the future; for example, a test was conducted online in a game in which there were two characters: red people looking for blue people in order to catch them; the blue people had walls and objects to make it impossible for the red people to reach them; after being found a few times at first, they learned how to isolate themselves better; In the following iterations, the people in red discovered a way to use the objects of the blue people to their own advantage and thus adapted to the adaptation of the blue ones; As a result, the blue people have increasingly isolated themselves by learning new effective methods of isolation along the way;

- **Model evaluation**

-a scale of results is used to verify that the model has met all the conditions, reached the results and answered all the questions;
-the model can be tested by adding new parameters to observe the change in behavior or if it can adapt to a similar scenario in another context or even a completely different scenario; in reality things may differ from the virtual scene; some analyzes and predictions cannot be made in reality and the intervention of artificial intelligence is needed to go further than the human mind can;

- **Improvement of the model**

- after evaluating the model, the initialization parameters can be changed to better answer questions depending on how close or far the model was to the result; a major change can confuse the algorithm, if it has not been trained enough to adapt;

-a few questions can be asked in at this stage: how fast the algorithm can learn and whether the learning rate evolves over time, the number of training steps required for the model to reach a state of accuracy of more than 80%; a model can use few resources to reach this threshold; after exceeding the threshold, the chances of the accuracy to increase by even 1% become more difficult than its previous stages and the real question would be whether it is ultimately worth to exponentially increase your costs and usage time for greater accuracy and whether accuracy itself makes sense for the decision, as the existing vision (with an accuracy of 80%) of the result may be sufficient for the user's purposes, even without the remaining 20%, the prediction was made and the user understood which direction he could take in order to satisfy the business requirements;

- **Predictions**

- the model itself can predict a result according to the parameters provided by the user and adapts over time; in order to be as efficient as possible, he needs to get data that it has never trained before, a test to see how he would react in real life and not just in the virtual environment;
-there are models that are specially trained to procure parameters for other artificial intelligence models; training and learning can go both ways, each model learning from the other in order to limit human interaction; one model can expect results from another model, which will then provide back results; this is much more efficient, with greater accuracy than a user's ability to parameterize new data for the algorithm; thus forming a chain of models that adjust exponentially is crucial for machine learning;
-the problem with predictions can be incorrect data or out-of-date data, most often found in the field of statistics under the name of outliers; the places where the algorithms get their data can be from multiple sources such as video cameras, images, sensors and therefore, a point of interest would be the places that are very often accessed by people; they can provide data online from e-commerce platforms, shops, gas stations, tv shows, traffic interactions and cafes; a lot of people go to gas stations and supermarkets every day because of the need for mobility and in general just to get food; in the event of an economic crisis or pandemic, these facilities are restricted and therefore the rate at which they are accessed by people drops drastically; the question is whether artificial intelligence algorithms and their trained model can understand when the profits that came daily in considerable quantities will be reduced to 0 the very next day; here the level of training of the algorithm is determined, whether it has been prepared for such a situation, or if not, whether it has an ability to adapt to the new situation; depending on the amount of data provided in time and learning rate, the algorithm is more likely to understand the new behavior; later, after the event that caused the instability has been removed from the equation and prices return to their initial value, it would be able to understand both scenarios in the future: the day by day average activity and further fluctuations;

Amazon SageMaker and new tools for artificial intelligence

Traditional artificial intelligence methods are part of a complex process that requires a lot of effort and time to follow the steps mentioned above and combine the necessary tools for machine learning. In **Amazon SageMaker**, as mentioned on the official Amazon website, all these tools are integrated and can be easily accessed by the user. [

Figure ***3***] Because these tools are available to the user in an instant and facilitate the development of AI processes, the effort distribution is oriented more to the logical side and algorithm implementation. All steps are highlighted in a web platform in the Amazon suite, where the user can control and access them, enter data ready to be processed, train and supervise the performance of artificial intelligence models, observe the results and create Python notebooks. These one-click Jupyter Notebooks are available at any time for any user in the respective Amazon account, the resources being accessible in real time regardless of when the code change was made. This is a favorable working environment where collaboration between developers is encouraged. The SageMaker autopilot chooses for itself the best artificial intelligence models, the right algorithm, the number of processors to use together with the analysis of the raw data received from the user. Manual intervention of the user is possible, where he can choose from 50 models of artificial intelligence. If he does not consider any of them suitable to answer business requirements, there is the possibility to combine them or even create a new model. In general, people with experience in the field of artificial intelligence and data scientists are the ones who create the model and all its specifications, after which application developers intervene to use the model in order to create intelligent predictions. In artificial intelligence, it is not all about algorithms and models, but also the quality of the data entered. Amazon SageMaker Debugger, as mentioned on the official Amazon website, is a compiler that gives the user transparency when he runs the model, by providing easy access to change the parameters for a different set of results. This transparency is described by the compiler's ability to provide the user with real-time metrics for a good understanding of the behavior, learned by the model. The processing capacity of the platform is due to the Amazon TensorFlow tool, an open-source library that offers the possibility to go through all the necessary stages of popular data and create complicated models in a short period of time, with the help of hundreds of processing units.

Figure 3 : Amazon SageMaker Tool for ML

Automatic Model Tunning, as depicted on the official Amazon website, most commonly referred to as hyperparametrization, involves, as the name suggests, changing model execution parameters and performing training multiple times on the same data set. Subsequently, the parameters that obtain the best result according to the test indicators chosen by the user become the basic hyperparameters. In order to best understand how hyperparametrization works, a user must know very well the type of algorithm used and its specifications, the origin and quality of the data set and an efficient method of checking and testing the results, while comparing them with the expected values. There are two types of parameter search:

- **Random search**

- the user specifies a range of values, from where values are randomly selected by hyperparametrization, that will be sent further to start the training iteration; the values of these hyperparameters do not depend on the values of past data and can be run multiple times without affecting performance and quality

- **Bayesian search**

- in the Bayesian search the hyperparametrization process tries to reach the best result assuming which values would be optimal; hyperparametrization in this case uses statistical regression to solve the problem, looking for previous values that were very close to the desired result, to see if they can further increase the accuracy; in some cases hyperparameterisation looks for outliers that would normally provide a incorrect result in order to observe the behavior and the result of their hyperparametrization;

SageMaker Neo, as depicted on the official Amazon website, allows users to store their artificial intelligence models in the cloud and run them anytime, anywhere and twice as fast. This tool is most often used in cases where the user's resources are limited and a real-time performance and fast prediction is desired. SageMaker Neo targets a user-chosen destination to solve performance issues using neural networks, Apache TVM, and kernel libraries. Apache TVM is a compiler that optimizes the execution time of applications by increasing the performance of processors or graphical processing units.

Conclusions

With the appearance of new cloud services, compared to traditional machine learning and data mining models, Amazon Web Services provides users with a set of smart, standalone tools that facilitate the creation of an automated process for extracting and transforming data into information to be later used for business decisions. All of these cloud services do not require a database or server for the user to monitor, everything being controlled directly from AWS. Data is obtained from different sources and using BIG Data they are stored in clusters, later to be retrieved by

ML algorithms or data collection processes. Algorithms and machine learning models have evolved so that the user's intervention is at a minimum and even aids him in their optimization and monitorization of the processes in a transparent and suggestive approach.

Abstract

Leadership in organizations is one of the most important subjects analysed in contemporary management literature. This paper focuses on the roles of leaders that they can play in different types of organisations. The purpose of the article is to answer the following research question: Are there any differences between nonprofit, for-profit and public organizations regarding the performance of the leader's roles? To that end, a cross-sectoral survey was conducted in 2019 among 105 leaders and 210 non-leaders (the sampling was non-random). The statistical analysis showed that there are no fundamental differences in leaders' roles in nonprofits, for-profits and public organizations. In all three, the most important roles were those of a: working leader, trusted leader, strategic leader, and supportive leader.

Keywords: Leader's Roles, Nonprofit Organizations, For-profit Organizations, Public Organizations

Introduction

Leadership in organizations is one of the most important problems analysed by scholars in various disciplines, including management science. Inadequate leadership or lack thereof may, in certain circumstances, provoke a crisis in prosperous organizations that may prove difficult to overcome, even in the long-term perspective. Therefore, understanding the essence of leadership is crucial not only for the theorists but also for the practitioners of management science. Despite the numerous publications on leadership, there are still many research gaps in this area.

The leadership literature examines topics such as: attributes of an effective leader (e.g. Bass and Bass, 2008; Hughes, 2005; Zaccaro et al., 2018), leadership styles (e.g. Blake and Mouton, 1985; Bryman, 1986; Hersey and Blanchard, 1977; Nanjundeswaraswamy and Swamy, 2014), leadership models (e.g. Avolio et al., 2003; Morrison, 2000; Sarros and Santora, 2001), etc. The leader's roles have also been analysed (cf. Quinn, 1988; Simerson and Venn, 2006; Wegner, 2016). It should be noted that the display of these roles may depend on the organizational context. We know from current research that organizational behaviour in public, for-profit and nonprofit entities varies (Almond and Kendall, 2000; Benz, 2005; Borzaga and Depedri, 2005; Borzaga and Tortia, 2006; Laczo and Hanisch, 1999; Melnik et al., 2013; Mirvis, 2006). Cross-sectoral differences have also been found in the performance of the leadership function (Neck et al., 1998; Egri and Herman, 2000; Rierson and Miller, 2006; Suarez, 2009; Rowold et al., 2014).

The literature review showed a lack of comparative research concerning the leader's roles in various types of organizations. The purpose of the article is to answer the following research question: Are there any differences between nonprofit, for-profit and public organizations regarding the performance of the leader's roles?

The article is divided into sections, which are as follows: introduction, literature review, methods, results, and conclusions.

Leader, leadership and the leader's roles

Leaders and leadership have been the focus of research investigations spanning across different scientific disciplines, including sociology, psychology, education, political science, etc. These topics have also for years been relevant for management theorists and practitioners. A search ran in the Google Scholar database for articles employing the term

'leadership' in the title, performed in July 2020, returned more than 287,000 items. The growing scale and complexity of global problems and challenges make the need for effective leaders and better leadership more pivotal than ever.

Drucker (1996, p. 54) states briefly that 'the only definition of a leader is someone who has followers'. A more detailed definition of the leader is presented, e.g. by Winston and Patterson (2006, p. 7), according to whom 'a leader is one or more people who selects, equips, trains, and influences one or more follower(s) who have diverse gifts, abilities, and skills and focuses the follower(s) to the organization's mission and objectives causing the follower(s) to willingly and enthusiastically expend spiritual, emotional, and physical energy in a concerted coordinated effort to achieve the organizational mission and objectives'. Leaders normally deal with issues such as future directions, goal-setting and strategies necessary to meet goals (Kaplan and Kaiser, 2003). Although leadership is the ability 'to get men do what they don't want to do and like it' (Cohen et al., 1984) or 'to inspire, direct, motivate and encourage others positively to targeted end' (Olusoji, 2002), it is perceived as a process, too. According to Northouse (2013, p. 5; cf. Hogan et al., 1994; Hogan and Kaiser 2005; Schermerhorn et al., 2000), while in that process 'an individual influences a group of individuals to achieve a common goal'. Cohen et al. (1984) add to it that leadership is 'the process of social influence in which one person can enlist the aid and support of others in the accomplishment of a common task. It is ultimately about creating a way for people to contribute to making something extraordinary happen'. Leaders influence their followers 'through motivating, inspiring a shared vision, and supporting higher level of need of the followers; and defining a competent rewarding system, so as achieve the challenging organizational goals, effectively and efficiently, through collective efforts' (Aalateeg, 2017, p. 37). Bass (1990a; cf. Antonakis et al., 2004, p. 5) argues that leadership consists of two elements, which are: 1) the focus of group processes and a form of persuasion in inducing compliance and influence, 2) a particular behaviour, a personality, a power relation, an instrument to achieve goals, an effect of interaction, a differentiated role and an initiation of structure.

There are several explanations, classifications and theories of leadership to be found in the contemporary literature. A study of some of these scientific works reveals that their theories have been refined and modified over time (Ahmed et al., 2016; cf. Aalateeg, 2017; Avolio et al., 2009; Asrar-ul-Haq and Anwar, 2018; Bass and Bass, 2008; Day, 2012) and none of them is entirely irrelevant. The main directions of empirical research on leadership include, e.g. leadership vs. management, traits and skills, power and influence, situational determinants of leader behaviour, and the importance of leadership for organizational effectiveness (Yukl, 1989).

Early research used to analyse leadership based on hereditary attributes (e.g. Galton, 1969); the trait approach emphasizes leaders' attributes such as personality, assets, motives, cognitive abilities, values and skills. By identifying the specific characteristics of leaders, a leader could be distinguished from a follower (Hughes, 2005, p. 25). These characteristics include: drive, desire to lead, honesty and integrity, self-confidence, cognitive ability, and knowledge of business (Bass and Bass, 2008). As the time went on, attention was focused on the behavioural styles of leadership (e.g. Blake and Mouton, 1985; Bryman, 1986). This is essentially when researchers attempted to identify the critical situational factors that affect leadership effectiveness, including the degree of structure in the task being performed, the quality of leader-follower relations, the leader's position power, subordinates' role clarity, group norms, information availability, subordinate acceptance of leaders decisions or subordinate maturity (e.g. Hersey and Blanchard, 1979; Howell et al., 1986; Robbins, 1997). Furthermore, Burns (1978) indicated the concept of transactional leadership while e.g. Bass (1990b) defined the transactional leader as a person who pursues a cost-benefit, economic exchange to meet subordinates' current material and psychic needs in return for contracted services rendered by the subordinate. Burns and Bass also examined the concept of transformational leadership. According to Burns (1978), transformational leadership is a process where leaders and their followers help each other in order to advance to a higher level of morale and motivation. For Bass (1990b, p. 21; cf. Chemers, 1997) meanwhile, transformational leadership occurs when 'leaders broaden and elevate the interests of their employees, when they generate awareness and acceptance of the purpose and mission of the group, and when they stir employees to look beyond their own self-interest for the good of the group'. Avolio et al. (2009) reviewed the more recent theoretical and practical developments made within the leadership literature. This led them to outlining concepts such as: authentic leadership, cognitive leadership, complexity leadership, cross-cultural leadership, new-genre leadership, shared leadership. Hiller et al. (2011) summarized leadership outcomes in four domains, based on the nature of leadership and on the measurement criteria, namely: effectiveness, attitude, behaviour and cognition. According to

Boal and Hooijberg (2000; cf. Osborn et al., 2002), many leadership theories appear to be context-free and they fail to consider how environmental or organizational context influences that process.

Research indicates that leaders can perform different roles as a way to impact employees. The review of leadership literature and the analysis of leadership behaviour, performed by Simerson and Venn (2006; cf. Quinn, 1988; Wegner, 2016), suggest that successful leaders perform the following nine roles: custodial leader, trusted leader, trusting leader, nurturing leader, strategic leader, supportive leader, developmental leader, inspiring leader, working leader (Table 1). However, no cross-sectoral research findings were identified that would report on the roles performed by leaders in organizations.

Table 1: Leader's roles in organizations

Leader's roles	Characteristics
Custodial leader	He/she strives to secure the continuity of the organization in the long term, ensures a steady flow of leadership talents, sometimes being side-lined in order not to stop others.
Trusted leader	He/she is fair, honest, keeps his promises, sets an example, admits mistakes, is consistent, collaborative.
Trusting leader	He/she trusts others, relies on their work and support, praises their achievements and allows failures, appreciates ideas, shares power
Nurturing leader	He/she shapes family relations in the organization, takes care of the needs of co-workers, including the development of their knowledge and skills
Strategic leader	He/she observes the environment, develops a vision and a strategy of the organization, motivates.
Supportive leader	He/she shares important information, provides conditions conducive to the achievement of objectives, encourages cooperation, ensures an even distribution of work, delegates competitions, reorganizes teams in order to increase effectiveness.
Development leader	He/she creates conditions for learning, gaining experience, enhancing talent, shaping the path of development, challenges, stimulates creative thinking.
Inspiring leader	He/she motivates to act, encourages to achieve goals, reminds about successes, creates a feeling in members of the organization that they are not alone, that obstacles can be overcome together.
Working leader	He/she helps to focus on the goal, is creative, works with others on solving problems, provides tools, is open to suggestions from others, monitors progress.

Source: own elaboration based on Simerson and Venn (2006)

Leadership roles are performed in a specific organizational context, so let us now look at the differences between three types of organizations: nonprofit, for-profit and public.

Differences between nonprofit, for-profit and public organizations

The three main types of organization: public, for-profit and non-profit, differ in their goals, methods of obtaining financial resources, organizational structure, staff structure, cultural values and norms, and organizational behavior. According to Moore (2000; cf. Drucker, 1990), public organizations implement politically mandated mission, satisfy the needs of citizens and their aspirations, and they derive their income from taxes. For-profits provide financial returns to shareholders and value in use to buyers, and their source of income are proceeds from sales. Nonprofits, meanwhile, pursue social purposes and guarantee satisfaction to donors, raising funds through charitable contributions. However, the differences between these three types of organizations are also axiological. The principle value for nonprofits is solidarity (Jager and Schroer, 2014), but they also profess values such as: equality, compassion, community, responsibility, trust (Whitman, 2009). Ultimately, they are driven by the beliefs and passions of their employees (Rothschild and Milofsky, 2006) and what stands out in their behavior is, among others, self-transcendence, universalism and kindness (Stukas et al. 2016). Managerial positions in nonprofits are usually held by women, which may suggest a more feminine dimension of the organizational culture of the third sector (Claus et al., 2013; cf. Lee and Wilkins, 2011). In commercial organizations, the most important thing is the ability to break profit (Van der

Wal et al., 2008), but also competition on the market, growth, quality, adaptation, rigour in management, professional integrity, will to be number one (Calori and Samin, 1991; cf. Marcoulides and Heck, 1993). In what concerns public organizations, a still separate set of values can be distinguished (Van der Wal et al., 2008).

The three types of organization under review are also structurally different (Anheier, 2005; cf. Froelich, 1999). While public and for-profit entities tend to be larger, more complex, hierarchical and bureaucratic, also their staff structure is what sets them apart, in the sense that they employ paid workers whereas nonprofits rely on free work. In nonprofits, participation is voluntary, rather than compulsory, and the activity itself has no explicit ownership or accountability (Frumkin, 2002). Nonprofits also lack the element of top-down superiority exerted over volunteers, whose work instead is based on values (Neck et al., 1998). The literature also identifies the differences regarding aspects such as personality, motivation, values and attitudes between paid and non-paid employees. Altruism (Rose-Ackerman, 1997; cf. Hustinx and Lammertyn, 2003; Rehberg, 2005) and the pro-social orientation of non-profit workers (Briggs et al., 2010; Studer and Von Schnurbein, 2012; Stukas et al., 2016) are indicated. Additionally, volunteers have been shown to be more agreeable and extraverted than paid workers (Elshaug and Metzer, 2001), while Ackermann (2019; cf. Vantilborgh et al., 2013) found that extraversion is the most consistent driver of volunteering. There are also differences in job attitudes between these two categories of employees. Pearce (1993) identified reliability as the central distinguishing feature between volunteers and paid workers. Volunteer workers exhibited lower levels of both job withdrawal and work withdrawal than paid employees, and higher levels of organizational commitment than paid employees (Laczo and Hanisch, 1999). Volunteers also were more likely to participate in organizational citizenship behaviors. Non-profit workers are more willing to 'donate work' and more loyal to the organization than paid workers (Almond and Kendall, 2000). Non-profit work is also associated with greater overall job satisfaction, where staff in nonprofits is more satisfied with work than employees in for-profits (Benz, 2005; Borzaga and Depedri, 2005; Melnik et al., 2013).

The results of studies cutting across these three sectors show that people employed in nonprofits experience greater job satisfaction compared to employees of public and business organizations, plus they also have greater trust in their superiors (Mirvis, 2006). Borzaga and Tortia (2006) found that nonprofit workers tend to be more satisfied with their professional tasks compared to those employed in the other two types of organizations, despite the fact their salary is generally lower. Public-sector employees have been found to be the least satisfied of all three. Goulet and Frank (2002) argue that organizational commitment is the highest among employees in commercial enterprises, followed by employees of nonprofits, and then those hired in public organizations. Lyons et al. (2006) pinpointed differences in the value of labor between employees operating in the private, public and para-public sectors, and they confirmed that commercial employees tend to be more committed to work than employees in the other two sectors.

Study findings touching on institutional, cultural and personal differences in individual sectors prompt an assumption that can applied to the differences between the leaders representing each of these sectors (Suarez, 2009). Liao-Troth (2003) found that organizational context influences the behavior of non-profit and for-profit employees, which is why it can be expected that their leadership model will also differ. Voluntary-work entities 'have people who work with them and not for them' (Rierson and Miller, 2006), which is one of the conditions that favors the development of self-leadership in nonprofits (Neck et al., 1998). In working with volunteers, leaders have limited opportunities to impose their plans and decisions on a top-down basis. Jager et al. (2009) identified five major practices relating to volunteers, which are: focusing on people first, cautiously balancing ‘free wills’, awakening a volunteer’s strength, leading by recognition and selective non-recognition, leading by immediacy.

Rowold et al. (2014) found that the greatest impact on job satisfaction in nonprofits is the use of the leader-member exchange (LMX) model, whereas the transformational leadership model stimulates employee commitment. In for-profits, job satisfaction is mostly influenced by the LMX model while commitment draws from the initiating structure model. Among environmental organizations, nonprofits were highly receptive contexts for transformational leadership, whereas for-profits were moderately receptive in this regard (Egri and Herman, 2000; cf. Riggio et al., 2004; Jaskyte, 2004).

Suarez (2009) draws attention to the importance of the ethical dimension of leadership in nonprofits. Among the CEOs of voluntary and for-profit organizations, the tendency to use power in a morally responsible way was differentially related to charismatic leadership (De Hoogh et al., 2005). Leaders high on both power motivation and responsibility were rated more charismatic in voluntary organizations than in for-profits.

The analysis of the literature did not allow for the identification of publications concerning the comparison of the leader's roles in the discussed types of organizations. The identified research gap was the inspiration for our research.

Methods

The cross-sectoral study was conducted in 2019, in Poland's Lubuskie Voivodship. It concerned differences in the management of three types of organisations: nonprofit, for-profit, and public[i]. One of the research areas was related to the leader's roles.

The research process consisted of the following stages: literature analysis, research gap identification, formulation of research questions and hypotheses, sample selection and development of adequate research tools, data collection and analysis, formulation of conclusions, indication of research limitations and future directions.

The following general hypothesis was formulated: There are differences between nonprofit, for-profit and public organizations regarding the implementation of the leader's roles. To test this hypothesis, a survey was conducted.

The research tools comprised six questionnaires designed for six samples (leaders and non-leaders of nonprofit, for-profit and public organizations). They were used to identify whether there are differences between certain aspects of management and the type of organization. One of the questions concerned the roles of the leader. The questionnaires were sent out to different respondents (representatives of one of the three types of organizations - public, for-profit and nonprofit) whose participation in the study was voluntary.

Nonparametric tests were performed - the Kruskal-Wallis test and the U Mann Whitney test. These were preceded by examining the normality of the distribution of individual research groups - using to this end the Kolmogorov-Smirnov test along with the Lilliefors correction.
A total of 315 questionnaires were completed correctly by 105 leaders and 210 non-leaders (3*35 and 3*70). There were more women (65.23%) than men. The average age of participants in the research was 36.6.

Public employees most often worked in medium-sized (50-249 employees; 35.14%) or large entities (over 250 employees; 35.24%), while other members mostly worked in small or micro entities (up to 50 employees; 27.62% in total). Those were mostly: offices (42.86%), army and police and prison (18.09%), educational institutions (15.24%), hospitals (13.33%). Every fifth (19.05%) for-profit respondent worked in a company with fewer than 10 employees, while every fourth (25.71%) - in a small, every third (30.48%) - in a medium-sized and every fourth (24.76%) - in a large enterprise. The predominant industries were wholesale and retail trade (23.81%) and manufacturing (22.86%). Nonprofit employees more often represented associations (74.3%) than foundations (25.7%). Every third (30.48%) worked for an entity with fewer than 10 permanent employees (paid, non-paid, members). Almost half (47.62%) were involved with organizations employing 11-50 people, while the rest (11.90%) worked for larger organizations. They represented entities operating in various areas but mostly: social & humanitarian aid (37.14%), education & research (35.24%), culture & recreation (24.76 %) or development & housing (22.86%).

The Roles of The Leader – The Perspective of Leaders and Non-Leaders

The six groups of participants were presented with a short description of nine leader's roles according to Simerson and Venn (2006). They were then offered the opportunity to identify the three roles most frequently performed in the organisation by themselves (in the case of leaders) or by their superiors (in the case of non-leaders). During the research, these opinions were compared with each other. The Kruskal-Wallis test was performed to determine whether the roles played by leaders differentiate the type of organization. The feedback obtained from leaders and non-leaders was analysed separately (Table 2).

Table 2: Results of the Kruskal-Wallis test regarding the leader's roles assessment by the surveyed employees representing nonprofits, for-profits and public organizations

Leader's roles	Independent (grouping) variable: **organization type** α=0,05 Kruskal-Wallis Test					
	Leaders			**Non-leaders**		
	H(2,N=105)	**Chi²**	**Results of partial hypotheses testing[ii]**	**H(2,N=210)**	**Chi²**	**Results of partial hypotheses testing**
Custodial leader	3,792941	3,829412		4,992347	5,016234	
Trusted leader	0,075472	0,076197		7,159483	7,193739	
Trusting leader	0,000000	0,000000		0,483796	0,486111

Reasons for rejection found
No reasons for rejection found

It was found that only in 2 out of 18 cases there were reasons for rejecting the null hypotheses about the uniform distribution of the assessment of the leader's roles by leaders and non-leaders working in nonprofit, for-profit and public organizations. In the case of leaders, this concerned the role 'working leader', while in the case of non-leaders – 'trusting leader'. Subsequently, the U Mann Whitney test was conducted to determine whether leaders' roles in the analysed three types of organizations are differentiated by the function of the employee in the workplace (Table 3).

Table 3: Results of the U Mann Whitney test regarding the leader's roles assessment by the surveyed employees representing nonprofits, for-profits and public organizations

Leader's roles	Independent (grouping) variable: **function within the organization** α=0,05 U Mann Whitney Test					
	Nonprofit		**For-profit**		**Public**	
	p-value	**Results of partial hypotheses testing[iii]**	**p-value**	**Results of partial hypotheses testing**	**p-value**	**Results of partial hypotheses testing**
Custodial leader	0,55426		0,636619		0,074919

Reasons for rejection found
No reasons for rejection found

In nonprofits, there were no reasons for rejecting the null hypotheses about the uniform distribution of the assessment of the leader's roles by employees performing different functions within the organization. In for-profits and public organizations, reasons were found for rejecting the null hypotheses in 4 cases, which concerned the roles 'trusted leader' and 'working leader'. Hence the decision to undertake further analyses (Table 4).

Table 4: Leader's roles in nonprofits, for-profits and public organizations –the perspective of leaders and non-leaders

Leader's roles	Total		Nonprofit		For-profit		Public	
	Leaders	Non-leaders	Leaders	Non-leaders	Leaders	Non-leaders	Leaders	Non-leaders
	[%]							
1. **Custodial leader**	19,05	26,67	25,71	32,86	22,86	17,14	8,57	30,00
2. **Trusted leader**	**49,52**	27,62	48,57	38,57	48,57	18,57	51,43	25,71
3. **Trusting leader**	11,43	22,86	11,43	21,43	11,43	21,43	11,43	25,71
4. **Nurturing leader**	17,14	8,57	17,14	8,57	20,00	4,29	14,29	12,86
5. **Strategic leader**	24,76	**35,24**	37,14	34,29	22,86	41,43	14,29	30,00
6. **Supportive leader**	**41,90**	**32,38**	34,29	31,43	34,29	30,00	57,14	35,71
7. **Developmen-tal leader**	15,24	18,57	17,14	18,57	14,29	18,57	14,29	18,57
8. **Inspiring leader**	24,76	16,19	28,57	20,00	17,14	14,29	28,57	14,29
9. **Working leader**	**63,81**	**42,86**	57,14	42,86	71,43	47,14	62,86	38,57

Source: own study

According to the leaders' self-assessed feedback, they most often performed the role of a 'working leader' (63.81%), 'trusted leader' (49.52%) and/or 'supportive leader' (41.90%) in their organizations. Less frequently they displayed behaviors characteristic of a 'trusting leader' (11.43%), 'developmental leader' (15.24%) or 'nurturing leader' (17.14%). Employees who did not hold managerial posts also indicated the following roles as those most often performed by their leaders: 'working leader' (42.86%) and 'supportive leader' (32.38%). This, however, was a smaller percentage share compared to superiors. Let us also note that this group of respondents identified another role of their leaders, which was 'strategic leader' (35.24%). In their view, superiors relatively less frequently displayed behaviors typical of the following leadership roles: 'nurturing' (8.57%), 'inspiring' (16.19%) or 'developmental' (18.57%).

Leaders of all three types of organizations indicated the 'working leader' as the most frequently performed role, followed by the 'trusted leader' (2nd in for-profits and nonprofits, and 3rd in public), and then the 'supportive leader' (2nd in public, 3rd in for-profits, 4th in nonprofits). Similar feedback was observed among non-leaders, who indicated the working leader as the most common role performed by their superiors. The rest of the ranking, meanwhile, was

slightly more diverse than in the case of leaders, but among the three most frequently cited roles, in addition to the 'working leader', there were: 'trusted leader', 'strategic leader' and 'supportive leader'.

Conclusions

The visible structural, cultural and personal differences between public, for-profit and non-profit organizations prompt the question about the differences regarding leadership in these entities (Rowe, 2014). In fact, similar explorations can already be found in the literature (Egri and Herman, 2000; Suarez, 2009; Rowold et al., 2014), with the results of these studies suggesting that said differences do not relate largely the implementation of leadership roles. The statistical analysis showed there are no fundamental differences in this respect. Leaders of organizations of various types tend to prioritize very much the same roles, and in a similar fashion, too. The most frequently performed roles included: 'working leader', 'trusted leader', 'strategic leader', and 'supportive leader'. In public, for-profit and non-profit entities alike, leaders decided that the 'working leader' role is the most common, with the 'trusted leader' role also ranking high. Noteworthy here is the significant similarity of the roles in for-profits and non-profit. The hierarchy in public organizations is only slightly different, where the 'supportive leader' role ranked second while that of the 'inspiring leader' was indicated as important.

Feedback obtained from leaders coincided with that shared by non-leaders representing the three analyzed sectors. Also, according to their indications, in all types of organizations the role of the 'working leader' was the most common, although it was cited as important somewhat less frequently. In the case of nonprofits, the arrangement of the four most important roles, as per responses of their leaders and non-leaders, was identical. In for-profits, non-leaders pointed to the priority of the 'working leader' role, but in their view, the 'strategic leader' role was performed more often while the 'trusted leader' role – less often. In this context, non-leaders suggested that leaders overestimate their ability to build trust. In what concerns public organizations, non-leaders affirmed the 'working leader' and 'supportive leader' roles, but similarly to for-profits, they hinted at a greater importance of 'strategic' over 'trusted leader'. Let us also note that these minor differences in the perception of leadership by leaders and non-leaders in public and for-profit organizations provide a valuable springboard for further research. Why do these differences exist, and why are the disparities between leaders and non-leaders smaller for nonprofits? This certainly warrants further investigation.

Finally, let us stress once again that the results of our research indicate that the performance of leadership roles in for-profit, public and nonprofit organizations is essentially the same (cf. Rowe, 2014). This conclusion is an important one to draw, as it can be applied, among others, to the context of nonprofits and to the debate on optimal management in these entities. Having said that, these findings require further testing against a larger research sample, as well as additional qualitative methods, such as in-depth interview or observation, that will allow to overcome the limitations of the survey method.

---

[i] The sampling was non-random. No list of leaders' and non-leaders working in organizations of Lubuskie Voivodship was available.
[ii] The null hypothesis (about uniform distribution) is rejected when H value is larger than the Chi^2 distribution (Ostertagová et al., 2014).
[iii] If the p-value is below the materiality threshold, there are reasons to reject the null hypothesis (Moczko, 2014).

Abstract

The present paper identifies new ways of adaptability for human resources in waste management and highlighting the challenges on how organizations influence and deeply can affect the sustainable development of areas and communities regarding the responsibilities related to waste collection and recycling. The research team used the concept of the "4 R", respectively reduction, reuse, recycling, recovery. This concept is attributed because it can optimize and increase product life, generating advantages for achieving a circular economy. Capabilities of human resources in waste management at the local level play a key role in communities' ability to use resources efficiently and make progress towards achieving a more circular economy. The research problem arises from how we stimulate managers to generate proactive ideas to upgrade human resources in waste management and spread ecological education to communities. The primary objective of the paper is to motivate managers to invest in special training of current employees according to the economic realities. Waste management will develop innovatively over the years. For an efficient and sustainable system, some useful strategies are needed to achieve the objectives, such as recycling, reuse, rethinking the current rules. Using appropriate creative tools, human resources management pays more attention to training processes, improvement, promotion, reward, all this leading to more substantiation of specific smart decisions.

Keywords: Waste Management, Sustainable, Human Resources, Selective Collection, Recycling, Reuse, Reduction, Rethinking.

Introduction

Economic progress at the level of the European Union countries has contributed to the increase of the living standard, implicitly supporting the consumerism of the people, who have generated an increased volume of waste from both production goods and consumption. (Guerrero, et al., 2013). Due to the increase in waste volume, it was essential to find the best experts in the field to find proactive solutions for waste management both for the

introduction of innovative technological mechanisms and for the ecological education of operators and communities. Fortunately, businesses, decision-makers, researchers are taking steps to manage waste in the community, being achieved a collaboration between companies, non-profit organizations, foundations and government leaders that have come together to analyse the problems caused by waste and to develop practical solutions (Xu, et al., 2018). Thus, visionary initiatives to support ecological activities among the population have led to an emphasis on methods and techniques for integrating social responsibility among communities on the waste selection and cultivating environmentally-focused behaviour. (Troschinetz, and Mihelcic, 2009). Such an initiative can be achieved by rethinking the directions in human resources management, putting more emphasis on the collaboration of the parties directly involved in the issue of waste management. Human resource management provides a supporting role in sustainable development, as well as basic guidelines for actors who are internal or external to the waste organization (Iacovidou, et al., 2017). Human resource management allows the use and maximization of labor resources at an optimized cost and time by ensuring a key commitment to people and people-related activities. In a very simple sense, coordinating the relationship between human resource management, sustainable development, and waste management leads to effective results for the community if they are done correctly. (Dhokhikah, 2015).

In this sense, although there are situations when the collaboration actions between the municipality and the sanitation companies are often hindered by bureaucratic procedures, there is a need to find a common efficient direction through which must allocate the necessary resources for waste control in the community. Thus, on the one hand, the municipality, the local authorities must present to the community the problems caused by the faulty selection of waste, so that they are aware of the damage caused to the environment in which they live. (Al-Khatib, 2015). At the same time, it is essential to promote the best practices of waste management in the community through all means of communication. On the other hand, actions of education, training and finding the responsible workforce for waste management are needed. Training and finding a workforce is a complex topic that needs debate because the tasks and duties of workers are not properly rewarded.

Treating this subject is based on the improper waste selection, respectively waste evidence provided by the community following the emergency situation instauration due to the COVID-19 pandemic. The emergency situation instauration caused an exaltation/hysteria in the buying behavior of the citizens. Was noticed excessive buying products that exceed the normal consumption limit. Also was noted the incorrect storage of waste by some citizens, although the collection operator made public the information on ten rules to follow regarding waste management during the coronavirus pandemic.
The paper started from the premise that by ecologically educating the human resource and the local community, sanitation companies are motivated to carry out optimal collection activities even in risky conditions (COVID-19) and also can cultivate behaviors that can generate changes in community. Ecological education is a process meant to attract categories of people who are aware and concerned about environmental and complementary issues, people who have the knowledge, attitude, ability, motivation and ability to work individually and collectively, to find solutions to current problems but also to prevent the appearance of others.

In this research, the emphasis is on educating the community in a sustainable way in risk conditions. More precisely, the education of the community leads to a better collaboration between the municipality and the sanitation companies, for the redesign of the new positions in the hazardous waste management. (Ahmed and Ali, 2004).

In the realization of the proposed research direction, the authors of the paper reconfigured a conceptual framework, starting from the research initiated by Muller and Hoffman (2001). This framework provides a sustainable direction for the proper conduct of waste management under special conditions. Muller and Hoffman (2001) carried out a pilot project aimed at expanding waste collection services in several lower- and middle-class neighborhoods. Their recycling program has had a positive impact, motivating neighborhood associations, community members to participate and initiate neighborhood cleanup activities. Thus, the research team considered this model opportune, using the concept of the 4Rs (Reduce, Reuse, Recycle, Recover). Although in the case of applying the model of Muller and Hoffman (2001) the organizers ignored the political realities and did not build an institutional development strategy, in the current situation, in the Western region the authorities are dormant to create a sustainable environment for the inhabitants.

Fig. 1: Conceptual model for sustainable management

The research team used the concept of the "4 R", respectively reduction, reuse, recycling, recovery. This concept is attributed because it can optimize and increase the life of a product, generating advantages for achieving a circular economy:

- Reduction means minimizing product consumption that cannot be reused and raising in communities public waste awareness, or means by which portions of the consumed products can be reused. Through reduction, people are informed not to buy products that they do not use, not to waste, and to buy products that can be reused.
- Reuse refers to the reuse of the product (by reselling / donating it to another customer) or the partial reuse of the product. The population is informed to manage their products by classifying them into products they use and products they no longer need. Waste products can be resold and donated so that the amount of waste is reduced.
- Recycling allows the reintroduction of waste into the consumption cycle in general and secondary applications. Optimal recycling is achieved only if the amount of energy consumed in the recycling process is less than the energy required to produce new objects. Plastic objects can be recycled using two different approaches: mechanical recycling and raw material recycling. In the first situation, plastic objects are recycled as polymers, while in the second situation, plastic waste is transformed into chemicals or fuels.
- Recovery involves the partial or total use of the product in the manufacturing process of a new product. Materials recovery encourages people to turn waste materials into new products, thus saving natural resources (Sadi, et al., 2012).

Fig. 2: The 4R for Waste Management

To achieve the 4R it's absolutely necessary to educate the population to find effective ways to sustain a cleaner environment. People need to understand that the harmfulness of the waste produced spreads to their health and well-being. Information projects are timely to raise public awareness. The media, the internet, school programs are optimal tools that can present the real impact of waste on the environment.

Changing Community Responsibilities in Urban Waste Management

The local authority, from a traditional and ideal point of view, is the only legal entity that allows the provision of services for waste collection. It provides all the elements of the waste management system: physical and intellectual infrastructure; institutional framework and day-to-day operation of collection services. Although it can be considered an ideal module of operation, there is also a deviation from this ideal in certain areas where waste collection is done improperly.

For a real scenario the local authority has teams for collection services only for a relatively small section of the central business and residential area, while the middle- and lower-class neighbourhood's and areas outside the city center, in crisis scenarios (economic, sanitary) do not have the same validity for the same services. In these areas, structural adjustment and fiscal discipline impose strict limits on government spending, which restricts the expansion of conventional services. Expectations for quality services demanded by the urban population are increasing but in most cases the authorities cannot give up traditional services this leading to the inability to provide satisfactory services to the community. The local administration is able to take responsible measures while being aware of the effects caused by inadequate waste management. At the same time, they are looking for new ways to share traditional collection responsibilities with the neighborhood by seeking partnerships with micro, small and medium-sized enterprises (SMEs), large entrepreneurs and private industries, hospitals, schools and other stakeholders. (Taboada-González, et al., 2011).

Increasingly, the local authority is trying to mobilize the human and financial resources of these actors to develop an appropriate system for expanding collection services. By understanding waste management issues, the population can participate in certain effective actions to reduce waste in the community. For example, there are certain volunteer programs in which people are engaged in actions to collect waste spread irresponsibly in nature. Another situation is the selective collection, proper recycling of waste, are two good ways to reduce the amount of waste.

Thus, there are actions through which the responsibilities of the community related to waste collection and recycling can be implemented:

- Application of 4Rs principles;
- Increased responsibility of producers;
- Citizen participation;
- Cooperation partnerships between economic units in the field.

Reducing the impact on the environment and implicitly the amount of waste starts by educating mankind, every human being should be informed, aware, and act so as to produce less waste, recycle and contribute to the cleaning of contaminated sites. Responsibility for a clean environment is not only attributed to the authorities but also to every human being in particular.

Approaching an ecological education in the community also implies a visibility on the civic responsibilities. By being aware of the harmful effects produced on the environment we can reduce our consumption, waste production and our impact on the environment, practicing responsible consumption. All that is needed is a limitation on our purchasing power. Buying something means guaranteeing the waste and greenhouse gases that have been caused in future production, transport, packaging and disposal.

A correct approach would be to try to reuse the products. Reuse helps to reduce not only the contents of the rubbish bins but also the contents of the recycling bin. The process itself is simple, economical, and available to everyone. Extending the life of a product by using it several times requires only a drop of creativity. Like reuse, recycling means recovering an object and giving it a new life. Recycling brings back an object in the raw material: the paper returns to cellulose, the plastics are melted and poured into new products. Those products that were considered waste are reintroduced in the process of extraction-production-consumption-destruction, becoming an important resource for the realization of other products. Addressing this mentality, the community restores an ecological cycle and sustainable development, which over time reduces consumption and the negative impact on natural resources. A recycling center is indispensable in the community because all recovered materials (paper, cardboard, plastics, glass and metals) after sorting can sustain a community economically. More, each material after being compressed into a cubic shape that weighs a ton can be sold to the companies that actually recycle these resources.

Applying 4Rs means smart consumption, thus making substantial savings (in terms of money, time, pollution, waste and energy).

Waste collection by training the community and using the 4Rs

In this paper, several solutions are developed to improve the waste management system in Timiș County. Creative solutions have been proposed to encourage citizens to pay more attention to selective collection, recycling, responsible consumption so as to reduce the amount of waste produced. In order to fulfill the mentioned objective, the concept of the 4Rs was used and the main benefits brought by the creative ideas through the prism of the concept were shown.

Case study on solid waste management for the western region of Romania

Taking into account the collection systems designed (feasibility study) 7-8 years ago, the situation was reconsidered taking into account new challenges (objectives set and tools to be implemented), as well as market developments (standards life and waste generation, behavioral trends). According to the plans made for the improvement of waste collection services, a new collection system is foreseen which is being implemented in Timișoara, Romania as part of the EU funded projects. Integrated waste management systems at county level, creation of infrastructure (transfer stations, integrated waste management sites: sorting, mechano-biological treatment, storage) and provision of new collection systems in order to achieve environmental objectives for the recycling and reduction of landfilled waste.

The analysis is reduced to the current systems designed and / or used in Romania, focusing on the correct match with the category of users (urban or rural population, individual or collective building, business), as well as with the desired results. The collection system should be analyzed in particular for each waste fraction (a type of waste collected separately): residual waste, biodegradable waste (still collected mostly together with residues), recyclable waste.
In general, waste is a waste of natural resources, such as recyclables, which, if not recycled, harm both the environment and the economy. (loss of the ability to become a source of energy). The amount of waste will continue to increase, with the economic development and the increase of the living standard of the population. The lack of specific structures for waste storage and mismanagement leads to a high risk to the environment and society. The main effects of waste pollution are: contaminated water, air and soil, changes in soil fertility, visual and olfactory discomfort. In Timiș County, the way in which the waste management system works is the classic one, it is based on the waste collection by the sanitation companies.

Waste collection in Timiş County is divided into three categories:

• "wet fraction" (residual and biodegradable waste)
• "dry fraction" (recyclable waste, such as paper, plastic, cans of aluminum, metal and wood, cardboard)
• glass.

In recent years, Timiș County has prepared and financed a new integrated system for waste management. Thus, various aspects were analyzed in Timiș County, such as environmental, economic, sociocultural and technical issues. The zones division of Timiș County according to the specificity, distribution of the population and according to the amount of municipal solid waste generated led to its division into five collection areas comprising four transfer stations and a central waste disposal site. Timiș County is divided according to the waste collection and waste transfer areas at the Ghizela central landfill.

Methodology

The methodology used involved finding creative ideas within the 4R concept and analyzing the benefits they bring. In order to analyze the performance of the ideas, we calculated the proposed practices in relation to a small number of citizens (275), and these calculations will be subsequently reported to the entire population of Timisoara.

Fig. 3: The 4R concept and the percentages that capitalize on the degree of 275 citizens involvement

With the help of the percentages present in Figure 2, we calculated the percentages coming from the population of Timișoara, which according to the data from the 2011 census, the municipality of Timisoara had approximately a value of 310,000 inhabitants. The percentage was 62.89%, which means that the level of citizen involvement in reducing the amount of waste has increased favorably, and the waste management system has improved considerably. Through 4R solutions, 62.89% of citizens will be involved in responsible waste management. Less waste will be produced, more will be recycled, and awareness will be growing. With the involvement of the population and by creating an underground collection system, the use of individual application and transport, recycling and recovery of materials, reducing product consumption, reusing products, the amount of waste in the city of Timisoara would decrease consecutively. Below, a table is made with the analysis of a residential complex house (southern area of Timisoara) with 275 citizens respecting the mentioned solutions.

Table 1: Waste statistics in Timisoara after the application of creative solutions through the "4R"

The number of citizens of the residential area	The volume of purchased products tons/4 weeks	The volume of reused products tons/4 weeks	The volume of waste collected tons/4 weeks	The volume of recycled waste tons/4 weeks
275	40,00	25,00	5,00	2,00

From the total number of inhabitants of Timișoara, 310,000, we calculated the waste collected from 275 inhabitants per month. Referring to the entire population of the city, we divide no. of inhabitants at the reference number in the table and the result (310,000: 275 = 1,127) we multiply by the volume of waste collected per month (5 tons / 4 weeks) and by the number of months in a year, to result the quantity of waste collected in -one year. The result is lower, which means that the volume of waste has decreased, following the path of the 4R applied in Timisoara.

By implementing these solutions, the city of Timisoara would benefit from a volume of 8,229.09 tons of waste collected / year, given that in 2019, 134,446 tons of waste were collected. Involvement and awareness of the population is the most important way to reduce consumption and efficient waste management. Using real solutions, waste is controlled and can become significant resources. For example, with the help of building a proper system, waste can be turned into fuel and produce energy used for the whole city. The reuse, recycling and reduction of products consumed by citizens must be done in a smart way so that waste generation decreases.

Also, a participatory approach of stakeholders interested in local waste management could lead to the sustainable development of the area, supporting the local economy. Some alliances with community stakeholders have numerous advantages, and some examples are presented below:

• A mixture of waste categories services is responding very often (to variation) for residents' demands.
• Household and community resources are mobilized by taking responsibility for environmental cleanliness and payment of waste collection fees.
• The economy of waste collection and recycling is offering a lot of jobs and income opportunities.
• Residents are pleased of the local authority and respond appropriately to their requests for waste services

• Residents gain a better understanding of the problems and the ability to organize waste services for themselves.
Partnering is a process that gradually attracts more residents and more organizations to promote various aspects of waste management and urban sanitation at the local level. The partnership process makes the municipal waste system more efficient - meeting the needs of residents more directly - and more sustainable.

Conclusions

Urbanization has an overwhelming impact on the way communities expand and produce more and more waste annually. Due to this, urgent measures are needed to implement proactive actions for household waste and transform it into other resources. At present, consumerism is one of the great problems of our society, a consumption that generates tons of waste daily. One of the first steps we need to take is to understand through environmental education the benefits of separate waste collection, how we can recycle products and how we help the community to improve living conditions.

Waste management in Timisoara will develop innovatively over the years. For an efficient and sustainable system, some useful strategies are needed to achieve the objectives, such as recycling, reuse, rethinking the current rules.

Reducing per capita consumption is one of the priorities that the city of Timisoara must take into account.

We need to be aware of reducing waste consumption as an important first step in waste management, because if we continue to abuse natural resources and maximize the amount of waste consumed, we will reach a level of atrocious pollution that can no longer be controlled by the authorities.

Polish Experience from 25 Years of the Operation of Special Economic Zones as a Form of Support for the Development of Selected Regions

Malgorzata OFIARSKA

University of Szczecin, Szczecin, Poland
malgorzata.ofiarska@usz.edu.pl

Abstract

The study involves an examination and assessment of the period of 25 years of the operation of special economic zones in Poland, using the legal-dogmatic, legal-historical, and empirical methods. Special preferences are applied in these zones, the primary aim of which should be to promote investment and increase employment in economically neglected areas. The intended purpose of the research was successfully achieved, showing that despite several significant changes in the legal regulations regarding the forms of state aid (subsidies, support from a separate special-purpose Zone Fund, tax reliefs and exemptions), special economic zones do not fulfil their basic function, i.e. they are not a mechanism to promote investments involving advanced technologies and associating economic activity with scientific research. Furthermore, the possibilities of extensive development of the zones by expanding their areas have been exhausted, and even some of these areas have not been developed. It was found that these were the main reasons for the radical change in the concept of promoting new investments implemented from 2018 throughout the country and the possibility of granting state aid in this regard in the form of income tax exemptions for a period of 10 to 15 years. The "Polish Investment Zone" thus created did not, however, result in the liquidation of the existing special economic zones, which will exist until the end of 2026. Under the conditions specified by the legislator, an entrepreneur may simultaneously benefit from state aid for investing in both types of zones.

Keywords: Economic Zones, Economic Development, New Investments, State Aid, Tax Privileges.

Introduction

The issues related to the functioning of special economic zones (hereinafter referred to as SEZs), as one of the categories of economically privileged areas, has been the subject of research in various aspects in the doctrine for many years. However, areas in which economic activity can be conducted and developed on preferential terms do not constitute a uniform category (Artman, 2019, pp. 93-99). They vary in terms of their genesis, organisational and legal features, and development directions. They constitute a permanent element of the modern world economy and exist in countries with different levels of regional development, while being most common in developing countries.

The aim of this study is to demonstrate that despite the relatively frequent changes in the legal regulations concerning SEZs and the large scale of state aid granted to investors, the effectiveness of SEZs is too low in promoting regional economic development. In particular, there has been no intense development in the high-technology sector and no increase in research spending. The complicated and lengthy procedures for expanding SEZ areas also represent a serious problem.

The functioning of SEZs is associated with legal and economic problems. This determined the use of appropriate research methods. Using the dogmatic and legal method, the basic elements of the legal structure of SEZ (Special Economic Zone), as well as the interpretation of legal provisions and their exegesis were established. This made it possible to examine the legal essence of the SEZ institution. In order to present the evolution and its main trends in the development of SEZ in Poland, the historical and legal method was used, examining the scope and context of changes in the applicable legislation. Using the empirical method, numerical data showing the most important effects of SEZ functioning in Poland, including the development of their area, dynamics of investment outlays,

increase in the number of jobs and the amount of public aid in the form of tax exemptions for investors, were presented.

Literature Overview

The problem of special economic zones has been studied in many countries. The world literature analyses various aspects of the organisation, functioning and impact of economically privileged zones, most often in: China (Zeng, 2010; Crane et al., 2018, pp. 98-107), India (Tantri, 2016; Mukherjee et al., 2016), Mexico (Zaldivar, Molina, 2018, pp. 11-32), the Dominican Republic (Reyes, et al., 2017), Russia (Maslikhina, 2016, pp. 275-279; Boyko, Usmanova, 2018, pp. 48-57) and Ukraine (Pidorycheva, 2020, pp. 5-30). The research conducted so far focused on the importance of special economic zones and their impact on: economic development and acceleration of transformation processes, local economy, inflow of investments and employment growth, promotion of industrialisation in developing countries. Comprehensive analyses of the functioning of special economic zones worldwide and the prospects for their development are also prepared by the World Bank (World Bank Group, 2017; Farole, 2011; Farole, Akinci, 2011).

In Polish literature on the subject, special economic zones are the subject of in-depth interest in legal sciences (Ofiarska, 2000; Białas, 2015) as well as economics and finance (Ambroziak, 2009; Kryńska 2000; Pastusiak, 2011; Nazarczuk, Umiński, 2019), and less frequently in management sciences (Glinkowska, 2016, pp. 283-293) and urban planning (Błachut, 2011, pp. 209-213). In the last decade of the 21st century, the leading issues of research on SEZs in Poland included: conditions and instruments of state aid (Nazarczuk, Kisiel, 2013, pp. 7-16; Borkowski, 2014, pp. 30-47; Piontek, 2020) and the effectiveness of state aid in SEZs (Kisiel, Lizińska 2012); assessment of the effects of SEZ functioning on the basis of various indicators (Pastusiak et al., 2016; Ajchel, 2016, pp. 517-527; Lichota, 2016, pp. 99-130; Ciżkowicz et al., 2015); the impact of SEZs on the development of the commune (Józefowski, Młodak, 2017, pp. 33-47; Pastusiak, Jasiniak, 2015, pp. 261-274), poviat (district) (Ciżkowicz et al., 2014, pp. 17-29; Typa, 2013, pp. 16-25) or voivodeship (province) (Narojek, 2015, pp. 119-134) in which they are located (these are the units of the three-tier territorial state division in Poland) and on regional (Ambroziak, Hartwell, 2018, pp. 1322-1331; Szymańska, Wajer, 2012, pp. 219-232) or country development (Przetacznik, 2016, pp. 27-43); the effectiveness of SEZs as an instrument of economic policy (Kołodziejczyk, 2018, pp. 84-89; Pastusiak, Keller, 2014, pp. 29-39); the impact of SEZs on local labour markets (Cicha-Nazarczuk, Nazarczuk, 2017, pp. 183; Wysocka, 2018, pp. 373-388; Struzik, 2014, pp. 212-219); factors influencing the level of investment attractiveness of SEZs in Poland (Sobol, 2016, pp. 155-170; Franczak, 2015, pp. 26-35). Research also covered the impact of the global economic and financial crisis on the functioning of SEZs in Poland (Golik, Kątnik-Prokop, 2014, pp. 180-193; Hajduga, 2013, pp. 190-198; Nazarczuk, 2013, pp. 241-250). The SEZs existing in the European Union Member States were also analysed and assessments of the prospects for their further operation and development were formulated (Stawicka, 2012, pp. 434-443).

A review of the Polish literature relating to SEZ issues leads to the conclusion that the most studies were prepared in the field of economics and finance. Less frequently analysed are the adopted legal solutions concerning the principles of establishing, organising and operating special economic zones. Meanwhile, the quality of legal regulations largely determines the results of the operation of SEZs (Zeng, 2016, p. 22).

Genesis and motives for establishing SEZ in Poland

Recognizing the diversity of definitions, typologies and examples of SEZs (Mokrzyc, 1998, p. 20; The World Bank, 2008, pp. 7-22; Typa, 2016, pp. 25-26) used in world and Polish literature, the considerations focused mainly on their legal structure regulated in the Act on special economic zones of 20 October 1994. The SEZ Act - setting out the principles and procedure for establishing and managing SEZs on the territory of the Republic of Poland, as well as specific rules and conditions for conducting business activity in SEZ areas - has been amended over 30 times since its adoption. Over 300 executive acts were issued for it, which were also amended many times. The amendments varied in scope and nature, but they primarily determined the variety of forms of state aid granted to entrepreneurs operating in SEZs. These, in turn, were: budget subsidies, tax reliefs and exemptions, support from a separate special-purpose fund.

Since 1994, 17 SEZs have been established in Poland, and after the liquidation of two zones and the merger of two zones into one in 2001, 14 such zones are currently in operation. Decisions regarding their operation period were made three times. When creating individual zones by way of a regulation of the Council of Ministers, it was assumed that they would only function for 20 years. Nevertheless, as a result of subsequent amendments to the legislation, the period of their operation was extended (in 2008 - until 2020, and then in 2013 - until 31 December

2026), so that entrepreneurs had more time to benefit from the maximum permissible state aid for the activities conducted in the SEZs. This did not, however, increase the confidence of entrepreneurs, especially foreign ones, in the idea of SEZs in Poland and, as a result, did not increase the inflow of investments to these zones.

They cover areas located in 186 towns and 311 communes, with a total area of 22,949.5 ha (0.08% of the country's area). In Poland, SEZs are not territorially compact. Some of them are in the form of dispersed zones (groups of separate "subzones", located at a considerable distance from each other), located in the most attractive regions in central and south-western Poland, where infrastructure and human capital are at a higher level. They are located in all voivodeships, but due to their dispersed nature, in some voivodeships there are more than one SEZ.

The motive for establishing SEZs in Poland is to create separate areas with more favourable conditions for running business activities than those available outside the zones, in order to accelerate the development of underdeveloped regions by locating new investments, increasing innovation and competitiveness of entrepreneurs, as well as reducing structural unemployment and promoting the creation of new jobs. The function of stimulating (motivating) entrepreneurs to conduct business activity in SEZ areas is performed primarily by tax exemptions and reliefs. Moreover, non-returnable support from the Zone Fund is used for new investments in SEZs. The types, forms and scope of aid have evolved over the 25-year period of SEZ operation. So far, however, the largest role has been played by tax preferences, the scope of which has been changed several times. The most significant changes can be divided into six stages. The first three stages fall on the period of Poland's preparations for accession to the European Union. The next three stages of profound changes to Polish legislation were determined by the necessity to adjust national solutions to EU standards. The directions of these changes resulted from the obligations of the Polish state which already had the status of a member state.

The Period of The Initial Concept of Tax Preferences

By adopting the SEZ Act in 1994, special legal solutions were introduced in the field of personal and corporate income taxes, as well as real estate tax and in the procedure of issuing permits for the purchase of real estate by foreigners. Special legal solutions in regards to taxes took the form of tax exemptions and other preferences in this area. The first group included: income tax exemption for all or part of the income obtained from business activity specified in the permit to conduct business in a SEZ and exemption from property tax. The other group consisted of: accelerated (degressive) depreciation of fixed assets used to conduct business activity specified in the permit or the possibility of including expenses incurred for the purchase of intangible or legal assets related directly to the economic activity in the zone specified in the permit as tax deductible expenses. Income tax exemptions and preferences were granted on equal terms to both domestic entrepreneurs (residents) and foreign entrepreneurs (non-residents). Income tax exemptions could only be used by natural persons and legal persons in connection with conducting business activity in a SEZ on the basis of a permit and meeting the requirements set out in the regulation of the Council of Ministers on the establishment of a given zone (e.g. as regards the scale of permanent production investments implemented within the zone and achieving the designated level of employment and maintaining it for a specified period of time).

The period of including SEZ in the public aid program

As of 1 January 2001 - as a result of adjusting Polish law to the Community state aid regulation - the conditions for conducting business activity in SEZs were changed for entrepreneurs who obtained a permit to conduct business in a SEZ after 1 January 2001 (Act amending the Act on special economic zones and amending certain acts of 16 November 2000). SEZs were included in the state aid program as part of the state's regional policy. The accumulation of tax exemptions for entrepreneurs conducting business activity in SEZs was limited to the level of the aid value established for the region in which the zone is located. The amount of state aid for entrepreneurs taking up economic activity in SEZs was covered by the limit set by the Council of Ministers and could not exceed the maximum value set for a given area (the maximum level of SEZ state aid was 50%, but it was possible to increase it to 65% for small and medium-sized enterprises). At the same time, the possibility of using tax preferences by new entrepreneurs was abolished. Additionally, in the same period, the obligatory real estate tax exemption for land, structures and buildings located in SEZs was abolished (Act amending the Act on the income of local government units in 1999 and 2000 and certain other acts of 13 October 2000). Entrepreneurs who obtained permits to conduct business in SEZs by the end of 2000 were guaranteed to retain the right to tax exemptions and tax preferences under the previous rules throughout the entire validity period of the permit.

The period of modification of the rules of public aid for investors from SEZ

In the course of negotiations for membership in the European Union, the rules of Poland's participation in the Community policies in the first years of membership were established, and in November 2002, a transitional period, i.e. the maintenance of the existing rights, was agreed for medium and small entrepreneurs in SEZs (until the end of 2010 and 2011, respectively), as well as the ceilings of state aid for large entrepreneurs (The Council of Ministers, 2002, p. 15). These arrangements were included in the Act amending the Act on special economic zones and certain acts of 2 October 2003, which introduced new rules for granting state aid in SEZs as of the day of Poland's accession to the EU. For all entrepreneurs operating in SEZs, on the basis of the permits issued before 1 January 2001, new, less favourable rules were introduced regarding income tax exemptions on income earned from running business activities in SEZs. The principle of guaranteeing that tax exemptions and tax preferences for entrepreneurs set by the Council of Ministers when establishing a SEZ would be maintained throughout the period of its operation, in force since 1994, was repealed. The established rules for granting state aid in SEZs were made dependent on, inter alia, the entrepreneur category and the date of obtaining the permit to operate in a SEZ (e.g. large enterprises operating in a SEZ on the basis of a permit issued by the end of 1999 received the maximum allowable aid in the amount of 75% of the investment costs incurred by 31 December 2006, while large enterprises authorised after 31 December 1999 received the maximum allowable aid of 50% of the investment costs incurred by 31 December 2006). In order to encourage entrepreneurs to accept the new conditions regarding tax exemptions, solutions were introduced to partially compensate for lost profits. Their essence consisted in:

– the possibility of changing the terms of a permit to conduct business activity in a given zone, entitling to benefit from state aid, to more favourable conditions (e.g. in terms of the level of employment and the size of investment outlays);
– creating, for the period 2005-2023, an account of special funds intended for non-returnable support for new investments (the Zone Fund) from part of the amounts of taxes paid by entrepreneurs operating on the basis of permits issued before 1 January 2001. The aid may be one-off or successive (i.e. in annual tranches), whereas the total amount of support may not exceed the amount of funds accumulated on the separate fund account for a given taxpayer and the maximum allowable amount of state aid;
– restoration of the statutory exemption from real estate tax on land, structures and buildings located within SEZs, but at the rates applicable in 2000 in relation to land, structures and buildings put into operation in 1999 (communes receive compensation from the state budget for lost revenues from this tax).

The period of differentiating the amount of public aid according to the status of an entrepreneur operating in SEZ

The fourth stage of changes in tax preferences applied in SEZs was carried out in 2007-2009 in connection with the new EU planning period covering the years 2007-2013.

Taking into account the new EU rules for national regional aid, the aid map for Poland (Regulation of the Council of Ministers on the establishment of the regional aid map of 13 October 2006; Journal of Laws No. 190, item 1402) has been changed (the maximum amount of state aid varies by region and concerns mainly the poorest regions, the so-called eastern wall). The SEZ Development Concept developed in January 2009 by the government defines the categories of investments most desirable for the Polish economy (i.e. innovative investments or investments in priority sectors, which include the automotive, aviation, and electronic sectors). The general area of SEZs was increased from 12,000 to 20,000 hectares (by almost 70%) (Act amending the act on special economic zones of 30 May 2008), which made it possible to include new investment areas, attractive from the point of view of entrepreneurs, into the zones (the harmonisation of state aid regulations with EU law prevents the creation of new zones). However, the maximum intensity of state aid for 6 out of 16 voivodeships in Poland was reduced. They became less attractive to investors, despite the increase in the maximum allowable state aid ceilings for small- and medium-sized enterprises compared to the pre-2007 level. Large investments (i.e. investments with a value exceeding the equivalent of EUR 50 million) were redefined and subjected to state aid restrictions. However, the existing tax preferences in the form of income tax exemptions and real estate tax exemptions were retained. In conclusion, the changes introduced in this period were less favourable for entrepreneurs planning to start operations in SEZs as compared to the conditions applicable to entrepreneurs continuing such activities. The level of state aid was reduced mainly for large entrepreneurs, while small entrepreneurs were given preferential treatment. At the same time, the required level of consistency of national regulations with EU standards was achieved.

The period of increased support for new investments in SEZ

The fifth stage of changes in the functioning of SEZs covers the years 2014-2017. As in the previous period, the possibility of differentiating the intensity of state aid in individual SEZs was maintained. With regard to the maximum value of regional aid, it has been significantly reduced (Regulation of the Council of Ministers on the establishment of the regional aid map for 2014-2020 of 30 June 2014), e.g. by 15% in the areas of the Łódź, Lesser Poland, and Opole voivodeships. The level of state aid intensity was left unchanged only in a few regions (i.e. at the level of up to 50% in the areas belonging to the Lublin, Podkarpackie, Podlaskie and Warmian-Masurian voivodeships). The same rules were maintained for determining the maximum value of regional aid granted for the implementation of large investment projects as in the 2007-2013 perspective. In order to encourage entrepreneurs to take up business activities in SEZs, the concept of initial investment was extended to include the acquisition of an enterprise that is in liquidation or would have been liquidated had it not been acquired. Significant changes were made to the so-called relocation of investment projects. It was prohibited to grant regional investment aid to an entrepreneur who discontinued the same or similar activity in the European Economic Area within 2 years preceding their application for regional investment aid.

The period of departing from the concept of territorial dispersion of SEZ

The last (sixth) stage of significant changes to the legal basis for the operation of SEZs in Poland occurred in 2018. Due to the entry into force of the Act on supporting new investments of 10 May 2018, the entire country in fact became a special zone and thus the lengthy procedure related to the expansion of the boundaries of SEZs was eliminated. Support for a new investment is now possible regardless of its location. Therefore, the doctrine and some official documents use the term "Polish Investment Zone". However, this does not equal full freedom of action in this area. The scope of support only covers new investments located in the poviats included in the list prepared by the Council of Ministers. In addition, new investments must meet certain quantitative criteria (regarding the eligible costs of investment implementation, which vary for individual poviats depending on the unemployment rate; the requirements for the amount of investment outlays decrease with the increase in the unemployment rate) and, what is a novelty, also certain qualitative criteria (conditions of compliance with medium-term national development strategy, in particular relating to investing in specific sectors of the economy with the aim of strengthening Poland's competitiveness and economic growth of a given region). The minimum investment costs are PLN 10 million (i.e. approx. EUR 2.4 million) in the poviats with the highest unemployment rate, while in the poviats with the lowest unemployment rate, the minimum investment costs are PLN 100 million (i.e. approx. EUR 24 million). Moreover, the fulfilment of both types of criteria depends on the size and nature of the planned investment, as well as the size of the enterprise (small, medium or large), with the size of the enterprise being determined on the basis of EU law, not Polish law. The support consists in tax exemption of income obtained from the new investment. It is granted on the basis of an administrative decision for a period of 10 to 15 years (up to 15 years for entrepreneurs in areas belonging to the existing SEZs). Continuing the previous solutions applied in SEZs, the Polish Investment Zone adopted the definition of a new investment which was already used for the needs of SEZs since 1 July 2014.

Conclusions

Poland was a precursor among the countries of Central and Eastern Europe in terms of establishing special economic zones. The solutions applied in Western European countries were modelled on, but legislative errors were not avoided, especially in the pre-accession period. Nevertheless, Poland's experiences, including the negative ones, may be used in other countries in order to apply the correct mechanisms for the functioning of similar-type zones.

After about 25 years of the operation of SEZs in Poland, it was not decided to liquidate them on entry into force of the act on supporting new investments, i.e. making the territory of the country one Polish Investment Zone. Instead, it was decided to operate SEZs and the Polish Investment Zone in parallel until 2026. The introduction of radical changes in the form of the Polish Investment Zone was caused by negative experiences related to the functioning of SEZs, which included, in particular: long-term and complicated procedures for incorporating new areas into SEZs, the functioning period of SEZs in Poland only until 2026 as defined by the act, relatively low effects in relation to the value of state aid granted to entrepreneurs (annually approx. 2.5 billion PLN, i.e. approx. EUR 0.6 billion), failure to achieve territorial and economic cohesion, and creating only narrow enclaves of accelerated economic development. The analysis of the successive changes to the law regulating the functioning of SEZs shows that they were too frequent and even chaotic. A certain justification, especially referring to the application of various principles of granting state aid to various groups of entrepreneurs, may be the need to adjust the national legal regulations to EU standards in the first period after the country's accession to the European Union.

Table 1: Dynamics of tax preferences in SEZ for taxpayers of personal income tax in 2010-2018

Year	Personal Income tax				
	Number of taxpayers	Tax-exempt income (in PLN thousand)	Dynamics of the value of tax-exempt income (in%)	Tax exemption (in PLN thousand)	Dynamics of the value of tax exemptions (in%)
2010	115	223 861	100,00	70 195	100,00
2011	105	150 181	67,09	46 942	66,87
2012	107	119 548	79,60	36 915	78,64
2013	164	212 504	177,76	38 846	105,23
2014	182	134 551	63,32	39 678	102,14
2015	173	151 574	112,65	46 357	116,83
2016	136	160 521	105,90	49 416	106,60
2017	147	185 515	115,57	57 701	116,77
2018	145	184 730	99,58	57 397	99,47

Source: Own study based on the Information of the Ministry of Economic Development on the implementation of the Act on SEZ, Warsaw, May 2020.

The data contained in Table 1 shows that the greatest effects in the form of the amount of tax-exempt income were achieved in 2013, i.e. directly after the previously amended legislation governing tax preferences for investors in SEZ. This result was mainly due to an increase in the total number of investors and an increase in investment expenditure. In the following years, however, the interest in running a business in SEZ clearly decreased (a decrease in the number of investors and the related decrease in investment outlays). It can be concluded that the positive motivation of investors was related to the so-called effect of new legal regulations.

Table 2: Dynamics of tax preferences in SEZ for taxpayers of corporate income tax in 2010-2018

Year	Corporate Income tax				
	Number of taxpayers	Tax-exempt income (in PLN thousand)	Dynamics of the value of tax-exempt income (in%)	Tax exemption (in PLN thousand)	Dynamics of the value of tax exemptions (in%)
2010	511	7 619 874	100,00	1 447 776	100,00
2011	535	9 383 215	123,14	1 782 811	123,14
2012	538	8 402 465	89,55	1 596 468	89,55
2013	603	11 843 653	140,95	2 250 294	140,95
2014	687	13 220 306	111,62	2 511 858	111,62
2015	763	13 237 183	100,13	2 515 065	100,13

The data contained in Table 2 on the effects of the legislator's influence on taxpayers of corporate income tax allow for the identification of similar trends as in the case of personal income tax payers. The best results were also achieved in 2013, thus discounting the changes to the legislation introduced in the previous year. Their stimulus impact on investors, however, was short-lived, because in the following years, despite the growing number of taxpayers, their investment outlays decreased, so it had a direct impact on the decrease in the value of tax-exempt income. The passage of time had a decisive impact on the decline in interest in locating new investments in SEZ.

Table 3: Growth rate in the number of taxpayers of personal and corporate income tax and the value of tax exemptions used by them in 2010-2018

Year	Number of taxpayers	Dynamics (in%)	Total value of tax exemptions (in PLN thousand)	Dynamics (in%)
2010	626	100,00	1 517 971	100,00
2011	640	102,24	1 829 753	120,54

Source: Own study based on the Information of the Ministry of Economic Development on the implementation of the Act on SEZ, Warsaw, May 2020.

The data contained in Table 3, covering taxpayers of personal and corporate income tax, shows that the increase in the total number of taxpayers operating in the SEZ brought the greatest effects also in 2013. They reacted positively by increasing investment outlays in response to changes in legislation and in this way, they used the tax exemptions they were entitled to. In the following years, investment outlays grew, but the dynamics of this growth was lower and lower. The interest in creating new investments with the passage of time was exhausted. The effect of the novelty of changes to the legislation turned out to be short-lived. The legislator used the experience gained in this area to carry out a revolutionary change of law in 2018, establishing the entire country as an investment zone. Too short period of time since the changes were made does not yet allow for reliable assessments of their impact on investors.

However, the functioning of SEZs in Poland cannot be assessed solely negatively. From the beginning of their existence until 2019 inclusive, entrepreneurs made investment outlays in the amount of PLN 132 billion (i.e. Approx. EUR 31.4 billion) and employed approx. 388,000 people. Nevertheless, SEZs have not become an effective instrument encouraging foreign entrepreneurs to invest. Moreover, in recent years, zones and subzones have not been located in the most economically neglected areas, but in locations agreed with investors, i.e. those that are already well-equipped with infrastructure (e.g. roads, airports, on the outskirts of large cities). This means that SEZs are systematically losing their original function, which should be the activation of the most economically and developmentally backward areas. From the macroeconomic perspective, it can be concluded that the long-term operation of SEZs did not significantly reduce the disproportions in the regional development of Poland.

Also, government strategic objectives related to servicing large investors and complex investment processes have not been achieved. The waning interest of investors in locating their activities in SEZs is also evidenced by the incomplete use of the available area of the zones. This is partly due to the inclusion of areas of low attractiveness for investors within the SEZs. Another noticeable phenomenon is the little interest in starting a business in SEZs by investors from the priority sectors of the economy, in particular those using advanced technologies and creating jobs for people with the highest qualifications. There are relatively few production plants located in SEZs, whereas logistic parks, storage facilities and assembly plants for devices and components are most prevalent.

High hopes are associated with the new act on supporting investments. The resignation from the territorial restrictions regarding the possibility of obtaining support in the form of income tax exemption should intensify the investment process. More favourable conditions for the implementation of the sustainable development principle have thus been created. This is in line with the objectives adopted in the Strategy for Responsible Development - a government document constituting the framework for Poland's socio-economic development until 2030.

Fostering the Engagement on The Companies' Facebook Pages in The Fuel's Retail Sector

Martin CEPEL

Pan-European University, Faculty of Economics and Business, Bratislava, Slovakia
martin.cepel@paneurouni.com

Abstract

Social networks change the way how companies realize their marketing activities. Potential customers become part of companies' marketing activities instead of just being passive participants. The ability to actively involve customers thus becomes a critical factor in the success of marketing activities. The study aims to determine how the posts' different content on the companies' Facebook pages affects the engagement of the message recipients. A retrospective, longitudinal study approach was used. Five hundred fifty-three posts from the four Slovak largest fuel retail sellers' Facebook pages were analyzed. The results revealed the significant difference in the medians of the passive engagement ($\chi2$ (3, N = 533) = 85.685, p-value = < 0.0001) and active engagement ($\chi2$ (3, N = 533) = 85.685, p-value = < 0.0001) according to different content types. The paired rank differences suggest that while entertainment messages (EM) significantly encourage both types of engagement (passive and active), informational messages (IM) and social messages (SM) encourage mainly passive engagement. The study extends the research on active and passive customer engagement, and thus, it contributes directly to understanding engagement and customer experience with social media and expands the knowledge about the Facebook content strategy. Finally, it offers recommendations for future research in the examined area.

Keywords: Content, Engagement, Fuel, Retail, Facebook.

JEL classification: M31, M370, M15.

Introduction

Social networks such as Facebook, Instagram, and Twitter affect how today companies deliver their services (Zilber et al., 2019) and realize their marketing activities. In particular, marketing activities are increasingly being transferred to social networks because they easily allow reaching right customers, include them to participate in marketing activities (Rehman et al., 2020), and make them more aware about the benefits of companies' products (Dincă et al., 2019). The ability to actively involve customers in marketing activities becomes a critical factor of companies' success (Rozsa et al., 2020; Mura et al., 2019), mainly because their resources for traditional forms of marketing are limited (Kotaskova et al., 2020). Social media have a positive impact on the entrepreneurship intention of a student to start doing business (Ojewumi, Fagbenro, 2019) and also for raising of the entrepreneurship in many lines of business (e.g. in services (Ferencakova et al., 2020), tourism (Srovnalíková et al., 2020) or transportation (Bertan, 2020).

Facebook, as the most popular social network in the Slovak Republic (Hootsuite, 2019), allows customers to engage with organizational messages through different tools (Like (in various forms), Share, and Comment) (Cho et al., 2014). However, not all tools indicate the same customer engagement. For instance, sharing and commenting requires more appreciable support from customers, and thus it can be considered as a more engaging behavior (Bitiktas et al., 2020; Cooper et al., 2019; Kent et al., 2020; Ngai et al., 2020; Rakoczy et al., 2019; Rajnoha et al., 2016), than liking. Consequently, companies should achieve higher levels of the customers' engagement because it positively impacts outcomes such us sales, competitive advantage, profit, and brand evaluation (Gruss et al., 2020; Harrigan et al., 2017; Kim et al., 2020; Rather, 2020; So et al., 2016; Zheng et al., 2016, Zámečník et al., 2015). Nevertheless, the link between the content and customer engagement in the form of likes, comments, and shares is still under-researched (Ngai et al., 2020).

Because of the above reasons, the study aims to determine how the different content of the posts on the companies' Facebook pages affects customer engagement to address the mentioned research gap. However, unlike already published studies, which in most cases deals with the influence of post type (f. e. link, status, picture, video, (Siyam et al., 2020; Thongmak, 2015; Villamediana-Pedrosa et al., 2019; Wijonarko et al., 2019)), media richness (Banerjee

Cite this Article as: Martin CEPEL“ Fostering the Engagement on The Companies' Facebook Pages in The Fuel's Retail Sector” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

et al., 2019; Moran et al., 2019) or posts' frequency or timing (Fähnrich et al., 2020; Mariani et al., 2018) on customer engagement, this study focuses on posts' text analysis, specifically in terms of used message type (informational, entertainment, remuneration, social).

The paper contains four sections, besides this introduction. Firstly, it presents a brief theoretical background on customer engagement and social media message categorization. Secondly, the methodology section explains the research context, methods of data collection, and analysis. After that, the results are discussed. Afterward, suggestions for further research and the study's limitation are presented in the conclusion.

Literature Review

Customer engagement marketing is defined as a company's "deliberate effort to motivate, empower, and measure customer contributions to marketing functions"(Harmeling et al., 2016), beyond purchasing (Kim et al., 2020). Customer engagement (CE) in the online environment refers to the motivational state that occurs through the interactive experience with brand content on social networks and is expressed in the form of relevant cognitive, emotional, and behavioral practices such us sharing company's messages, writing reviews, recommending company's products and other similar activities (Abuljadail et al., 2019; Avnet et al., 2018; Brodie, 2011; Dolan et al., 2019; Eigenraam et al., 2018; Hollebeek et al., 2014). Therefore, this study operationalizes CE as customers' liking, commenting, and sharing behaviors on a company's activities on the Facebook Page (Gruss et al., 2020).

Several authors divide individual customer responses on Facebook (or social media in general) into those that require less or more customer involvement (Cooper et al., 2019; Dolan et al., 2019; Malthouse et al., 2013; van Asperen et al., 2018). Van Asperen et al. (2018) recognize two forms of social media engagement. Passive (engagement) which is based primarily on consuming social media content, and active (engagement) which occurs when customers contribute to social media. Similarly, Cooper et al. (2019) consider liking as a static measure that is not good for engagement measurements because of customers' limited interaction. On the other hand, they indicate that commenting is the highest form of engagement, requiring the customers to write and post their thoughts or tag friends and thus provides them with the opportunity to engage in dialogue with brands and their own social networks simultaneously (Cooper et al., 2019). A highly engaged customer might even choose to distribute an independent review of the company's product or reveal promotional offers that the company might prefer not to expose to a wide audience (Malthouse et al., 2013). In accordance with the above-mentioned research works, the study operationalizes passive engagement customer behaviors which manifests itself as liking (i.e. Like, Love, Haha, Wow, Sorry, Anger) of the company content and active engagement as the commenting of the company content. Sharing company content is also considered an active form of engagement, despite the fact that this contradicts with the above findings, mainly due to the fact that by sharing company content, the customers actively identify with the company among their friends. Customer reviews are not classified because they are not the subject of this study.

Based on the Uses and gratifications theory (UGT), which explain how media consumers' social and psychological needs are satisfied by actively choosing media channels and information (Li et al., 2019), social media content can be categorized into four main groups as follows (Dolan et al., 2016): Informational, Entertaining, Remunerative, Relational (social interaction) content. Informational messages contain resourceful and helpful information about the company brand or its products and services. Entertainment messages are a type of messages which contain fun and entertaining information and do not directly encourage the customer to consume the company's products or services such as questions, quiz memes, funny videos. Remuneration company messages include specific monetary and rewards information such as special promotions, trials or other offers. Social messages contain information that usually occurs in personal interaction and may include information such as shared personal experience, sociable events (e.g. Birthdays) or small talk (Dolan et al., 2019; Kujur et al., 2020; Vaičiukynaitė et al., 2018; Seilerová, 2019). In line with the UGT, these four specific types of content result in different expressions of active and passive engagement (Dolan et al., 2019).

Methodology

The study aims to determine how the different content of the posts on the companies' Facebook pages affects the engagement of the message recipients. The hypotheses were formulated as follows:

- H1: Diverse post content does not lead to different degrees of passive engagement on the companies' Facebook pages.
- H2: Diverse post content does not lead to different degrees of active engagement on the companies' Facebook pages.

A retrospective, longitudinal study approach was used. The four largest companies engaged in the retail sale of fuels in the Slovak republic were selected as participants in the study. Data (posts) from participants' company Facebook

pages were extracted using the Fanpage Karma web application (https://www.fanpagekarma.com/) for 12 months period (from 1st August 2019 to 31st July 2020). A total of 556 posts were collected. Thirty-six of them were excluded because they did not contain text; therefore, 553 posts were used for further analysis (see Table 1).

Table 1: The study participants

Participant	Facebook page ID	Number of Posts	% of Total
Benzinol	1089162457824646	109	20.45%
OMV Filling Stations (SK)	342218085894136	148	27.77%
Shell	304290527049134	128	24.02%
Slovnaft	52904571954	148	27.77%
All		**533**	**100.00%**

Source: Author calculations

Deductive coding was used to analyze posts' content (independent variable). Firstly, the flat coding frame was set with codes as follows: informational message (IM), entertainment message (EM), remuneration message (RM), social message (SM). Secondly, three doctoral students were hired to assign codes to posts manually. To eliminate cognitive biases, coders checked one another's coding, and the founded differences were resolved by mutual agreement. Table 2 presents the posts coding final results.

Source: Author calculations

The dependent variables were calculated as follows. The passive engagement was calculated as the sum of all forms post's Likes (i.e., Love, Haha, Wow, Sorry, Anger). The active engagement was calculated as the sum of the post's comments and shares. The above procedure corresponds with studies of Cooper et al., 2019; Dolan et al., 2019; Malthouse et al., 2013; van Asperen et al., 2018.

Before data analysis, ANOVA assumptions were checked. The normal quantile plot and the Anderson–Darling test showed that both Passive (p-value < 0.0001) and Active (p-value < 0.0001) engagement data are from a non-normal distribution. Bartlett test of homogeneity of variances showed that data were not from populations with equal variances (Passive engagement data p-value < 0.0001, Active engagement data p-value < 0.0001). Because the ANOVA's assumptions were severely violated Kruskal-Wallis Test instead of an ANOVA was used. SAS JMP 15 was used for all calculations.

Results and Discussion

The results of the passive engagement data analysis indicate that there is a significant difference in the medians, $\chi 2$ (3, N = 533) = 46.1106, p-value = < 0.0001 (see Tab. 3), and thus H1 can be rejected. Because the overall test is significant, pairwise comparisons among the four groups should be completed.

Table 3: Kruskal-Wallis Tests (Rank Sums) for passive engagement

Level	Count	Score Sum	Expected Score	Score Mean	(Mean-Mean0)/Std0
EM	84	30014.5	22428	357.315	5.856
IM	186	50263.5	49662	270.234	0.355
RM	107	22137.5	28569	206.893	-4.516
SM	156	39895.5	41652	255.74	-1.086
Total	533				

Source: Author calculations

The p-values indicates that we should reject the null hypothesis that the paired rank differences in passive engagement are symmetric around zero between SM and RM (p-value = 0.0222), RM and IM (p-value = 0.0002), SM and EM (p-value < 0.0001), IM and EM (p-value < 0.0001), and RM and EM (p-value < 0.0001).

Table 4: Comparisons for each pair using Wilcoxon Method (Passive engagement)

Level	- Level	Score Mean Difference	StdErr Dif	Z	p-Value
SM	RM	21.83	9.54597	2.28683	0.0222
SM	IM	-10.1542	10.7329	-0.94608	0.3441
RM	IM	-37.9831	10.27869	-3.69533	0.0002
SM	EM	-41.7582	9.39493	-4.44477	<0.0001
IM	EM	-49,0870	10,26449	-4,78221	<0,0001
RM	EM	-52,3720	8,05785	-6,49950	<0,0001

Source: Author calculations

Table 4 also presents the pairwise differences in passive engagement, which can be interpreted as follows: Difference scores above zero mean that the engagement of the message type in the first-row exceeds engagement of the message type in the second-row. Analogically, difference scores below zero mean that the engagement of the message type in the second-row exceeds engagement of the message type in the first-row. Practically speaking, we conclude with 95% certainty that performance (passive engagement) of the social messages (SM) exceeds the performance of the remuneration messages (RM, the median of the difference in performance fall between 1 and 18); that performance

of the informational messages (IM) exceeds the performance of the remuneration messages (RM, the median of the difference in performance fall between -22 and -5). Also, we can conclude that the entertainment messages (EM) exceed the performance of the social messages (SM, the median of the difference in performance fall between -77 and -28), informational messages (IM, the median of the difference in performance fall between -76 and -30), and remuneration messages (RM, the median of the difference in performance fall between -99 and -52).

The results of the active engagement data analysis indicate that there is a significant difference in the medians, $\chi 2$ (3, N = 533) = 85.685, p-value = < 0.0001 (see Tab. 5), and thus H2 can be rejected. Because the overall test is significant, pairwise comparisons among the four groups should be completed.

Table 5: Kruskal-Wallis Tests (Rank Sums) for Active engagement

Level	Count	Score Sum	Expected Score	Score Mean	(Mean-Mean0)/Std0
EM	84	34147.5	22428	406.518	9.051
IM	186	47911	49662	257.586	-1.033
RM	107	24300	28569	227.103	-2.999
SM	156	35952.5	41652	230.465	-3.525
Total	533				

Source: Author calculations

The p-values indicate that we should reject the null hypothesis that the paired rank differences in active engagement are symmetric around zero between RM and EM (p-value < 0.0001), SM and EM (p-value < 0.0001), and IM and EM (p-value < 0.0001).

Table 6: Comparisons for each pair using Wilcoxon Method (Active engagement)

Level	- Level	Score Mean Difference	StdErr Dif	Z	p-Value
SM	RM	-0.1103	9.53748	-0.01156	0.9908
SM	IM	-18.5580	10.72753	-1.72994	0.0836
RM	IM	-19.6688	10.27209	-1.91478	0.0555
RM	EM	-62.4660	8.05336	-7.75652	<0.0001
SM	EM	-75.3938	9.39155	-8.02783	<0.0001
IM	EM	-80.5645	10.26211	-7.85068	<0.0001

Source: Author calculations

Table 6 also presents the pairwise differences in active engagement, which can be interpreted as follows: Difference scores below zero mean that the engagement of the message type in the second-row exceeds engagement of the message type in the first-row. Practically speaking, we conclude with 95% certainty that performance (active engagement) of entertainment messages (EM) exceeds the performance of the informational messages (IM, the median of the difference in performance fall between -165 and -69), social messages (SM, the median of the difference in performance fall between -164 and -63), and remuneration messages (RM, the median of the difference in performance fall between -174 and -65).

The previous results also suggest that while entertainment messages (EM) significantly encourage both types of engagement (passive and active), informational messages (IM) and social messages (SM) encourage mainly passive engagement.

The results of this research in line with Dolan et al. (2019) demonstrate that the effectiveness of different types of social media content have varying effects on social media engagement behavior. Contrary to Vaičiukynaitė & Gatautis (2018) and Mura et al. (2018) they show that in the fuel's retail sector social messages do not support active engagement.

Conclusions

As part of their social media marketing efforts, many company brands seek to communicate with the customers online. They create Facebook Fan Pages, submitting posts, and try to involve customers in their marketing activities through liking, sharing, and commenting published content. The importance of content is frequently highlighted (Eggers et al., 2017). Especially in the service sector, where the use of social media platforms is the most significant (Bejtkovsky et al., 2018). However, few studies consider the effort and resources the content creation process takes, or what alternative tactics can be employed (Kraus et al., 2019; Mészáros et al., 2019) to create compelling content.

The study aimed to determine how the different content of the posts on the companies' Facebook pages affects the engagement of the customers. The results revealed that different content types (Informational, Entertaining, Remunerative, Social) affect differently passive and active engagement. Specifically, entertainment messages (EM) significantly encourage both types of engagement (passive and active), informational messages (IM), and social messages (SM) encourage mainly passive engagement.

These findings show that social media marketers should better select content based on their marketing goals, as well as provide a potential explanation for the success of campaigns, gingerly. For instance, they should be careful with using entertainment messages even if they cause a high degree of engagement, because their significance for achieving other marketing outputs may be questionable.

Although the study extends the research on passive and active customer engagement in relation to the content type, the results should be generalized with consideration of the following limitations. Firstly, the study focused exclusively on one social network channel (Facebook). Secondly, posts on the Facebook pages in the fuel's retail sector were analyzed.

In future research, it would be useful to address the limitations of this research and other content strategy elements, such as another network channel, and passive and active customer engagement, according to the types of appeals.

Abstract

The article proposes an algorithm for the formation of a nomenclature of quality indicators and qualification assessment of household appliances. The range of quality indicators is formed on the basis of the applicability of products to a group, taking into account the definition of complex quality indicators and single quality indicators of different levels. Qualification assessment was carried out by an expert method based on the calculation of a comprehensive quality indicator taking into account the weighting coefficients of individual indicators of quality and safety of individual consumer properties of technical products.

Keywords: Household Appliances, Quality of Household Devices and Machines, Nomenclature of Quality Indicators, Qualification Assessment.

Introduction

According to several authors (Borgia et al, 2013), increasing competition in global markets requires companies to focus on two main aspects of the production system: cost reduction and product quality.

On the one hand, cost reductions are directly related to improving the energy efficiency of products. Here too, experience in researching purchasing intentions for energy-efficient appliances (Zhaohua Wang et al, 2019) and assessing the noise level of household appliances (Jackson & Leventhall, 1975) is of particular interest.

Reducing the environmental impact of household appliances is also an important aspect. For example, a number of authors proposed a mitigation scenario (Hischier et al. 2020) or an analysis of particulate emissions from household electrical appliances (Schripp et al., 2011).

On the other hand, cost reductions are due to the introduction of innovative developments that improve certain consumer properties of products.

Thus, a number of authors (Bansal et al., 2011) reviewed achievements aimed at potential energy savings through the use of advanced technologies in household appliances. In our view, the development of intelligent online machine quality control using discrete wavelet analysis (Goumas et al., 2001) and a prototype of an ice machine with periodic solar energy adsorption using water as a cooling agent and silica gel as an adsorbent (Souissi, Guidara and Maalej, 2019) may have some interest.

In the case of household appliance products, we cannot help but notice the trend towards fault diagnosis and longer product life. A number of studies are being carried out in this area by teams of authors (Arcos et al., 2020), the

Cite this Article as: Olga KOTOMENKOVA and Anna VINOGRADOVA" Formation of A Nomenclature of Indicators of Household Appliances Qual-ity and Its Qualification Assessment" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

analysis of which can be widely used in the practice of repair or disposal of equipment (Tecchio, Ardente and Mathieux, 2019), and the development of an interactive diagnostic system for monitoring the quality of household appliances (Paone et al.,1999).

At the same time, the competitiveness of any product on the market, including household appliances, is conditioned by consumer preferences in market segmentation. According to a number of authors (Huang et al., 2018), ergonomic factors, reliability factors (Krumm, 1986) and, of course, environmental ones (Holsteijn & Kemna, 2018) must be taken into account.

At present, authors (Stamminger, 2020) are paying increasing attention to testing the condition of products, including household appliances, in order to determine their competitiveness in the market.

In order to create competitive products that meet all customer requirements and maintain a targeted assortment policy, it is proposed to use qualification evaluation.

Previously, we proposed an algorithm for forming a nomenclature of quality indicators and qualified assessment of perfumes and cosmetics products using the example of hair care products (Kotomenkova & Vinogradova, 2019). However, the nomenclature of quality and safety of technically complex products has its own characteristics.

Methods

To assess the quality of technical products, all indicators of their properties are organized into 5 groups. The applicability of quality indicators to product groups is shown in Table 1.

On the basis of Table 1 materials, a list of quality indicators is formed taking into account the technical characteristics of products offered by manufacturers for information to potential consumers of household appliances and the requirements set forth in regulatory and technical documentation for a particular type of technical product (Figure 1).
In order to implement the expert method for determining the weighting coefficients of product quality indicators, a preferred method is used in which an expert group of 5 people numbers the weighting coefficients of product quality indicators in the order of their importance (weighting): the least important property is assigned to property 1, the most important property to property −2 and further increasing.

The expert method for determining weightiness is based on the averaging of weight ratings given by the expert group. The weight of the object propertiesq_i is determined through an expert survey.

The reference (complex) property weighting factor is one (1):

$$\sum_{i=1}^{n} q_i = 1 \quad , \tag{1}$$

where q_i is the weighting factor of the i-th quality and safety indicator;
n is the number of assessed quality and safety indicators.

Table 1: Groups of product quality indicators

Name of the group of indicators	Product groups				
	group 1: natural raw materials and fuel	group 2: materials and products	group 3: consumables	group 4: non-repairable items	group 5: repairable items
1. Destination indicators	+	+	+	+	+
2. Reliability indicators:					
– reliability	–	–	–	+	+
– durability	–	(+)	–	+	+
– repairability	–	(+)*	(+)*	–	+
– maintainability	+	+	+	+	+
3. Indicators of economic use of raw materials, fuel and energy	–	–	–	+	+
4. Indicators of manufacturability	+	+	+	+	+
5. Indicators of transportability	+	+	+	+	+
6. Indicators of ergonomics	–	(+)	+	+	+
7. Indicators of environmental	(+)	(+)	(+)	(+)	+
8. Indicators of safety	(+)	(+)	(+)	(+)	(+)
9. Indicators of aesthetics	–	(+)	+	+	+
10. Indicators of standardization and unification	–	(+)	(+)	+	+
11. Patent and legal indicators	–	(+)	(+)	(+)	+
12. Economic quality indicators	+	+	+	+	+

*Note: – non-applicability; + applicability; (+) limited applicability; * instead of repairability - recoverability.*
The weights of all properties of the same level have a certain relationship: "the sum of the weights always remains constant, a predetermined number" - the weights are determined by the requirements of the related property (i-1)-level (2):

$$\sum_{j=1}^{n} q_{ij} = const \quad , \tag{2}$$

where $\sum_{j=1}^{n} q_{ij}$ in the sum of the weighting factors of the i-th quality and safety indicator of the j-th expert;
n is the number of assessed quality and safety indicators.

On the basis of the developed nomenclature of product quality indicators, the weighting coefficients of all selected product quality indicators are calculated using the rank method, where the expert group directly assesses the importance of each property on a scale of relative significance with a range of values from 1 to 10. It is permissible to assign both whole and fractional values to the properties. The same values are permitted for indicators of equal importance.
The value of the weighting factors for quality indicators is calculated using the formula (3):

$$q_i = \frac{p_i}{\sum_{i=1}^{n} p_i} \quad , \tag{3}$$

where q_i in the weighting factor of the i-th quality and safety indicator;

p_i in the rank (assessment) of the significance of the quality and safety indicator by an expert;
n is the number of assessed quality and safety indicators.

The accuracy of expert assessments is determined by the consistency of expert opinions. The degree of coincidence of the experts on the commission is calculated using a reconciliation factor (4):

$$W = \frac{12 \cdot S}{m^2(n^3 - n)} \quad , \tag{4}$$

where W – reconciliation factor;
S is the squared deviation of the ranks or scores of the quality and safety indicator from the arithmetic mean;
n is the number of assessed quality and safety indicators;
m is the number of experts.

The sum of squares of deviations of rank (S) from the arithmetic mean for all quality indicators and the auditors is calculated using the formula (5):

$$S = \sum_{i=1}^{n} (\sum_{j=1}^{m} p_{ij} - \frac{\sum_{i=1}^{n} \sum_{j=1}^{m} p_{ij}}{n})^2 \quad , \qquad (5)$$

where S is the squared deviation of the ranks or scores of the quality and safety indicator from the arithmetic mean;
p_{ij} is the score in ranks given to the i-th quality and safety indicator by the j-th expert;
n is the number of assessed quality and safety indicators;
m is the number of experts.

In order to carry out the qualification evaluation of products, the values of quality and safety indicators are systematized according to their hierarchical structure.

The product quality assessment methodology consists of the following grades: "excellent" (3), "good" (2), "satisfactory" (1), "bad" (0).

An arithmetic weighted average can be selected for a comprehensive product quality assessment.

Determination of the arithmetic mean weighted index taking into account the weighting factor of the i-th index calculated by the expert method using the formula (6):

$$Q_i = q_i \times a_i, \qquad (6)$$

where Q_i is the a single quality indicator of the i-th property, taking into account the weighting factor a_i;
q_i is the single absolute indicator of quality;
a_i is the the weighting factor of the i-th quality and safety indicator.

Figure 1. Algorithm for assessing the quality and safety of product

Results and Discussion

According to Table 1, household appliances can be classified as Group 5 products - repairable products, therefore, its range of quality and safety indicators will include single indicators of all 12 complex properties. For example, 24 quality and safety indicators were defined for domestic robots; 26 for domestic air conditioners and 36 for domestic refrigerators (Figure 2).

Figure 2. Quality and safety indicators of household appliances

The analysis of the data in Figure 2 shows that in the process of formation the consumer properties of the products under study were taken into account to the maximum extent possible. It should be noted that indicators can be defined both quantitatively and qualitatively (those that do not have specific values in quantitative terms, but can be represented, for example, in the meaning of "presence" or "absence").

Also, not all indicators can be used for preliminary (initial) qualification assessment, but a part of them, which have the highest weighting coefficients based on the results of expert assessment.

The results of the qualification assessment of individual models of household appliances sold on the Russian market are presented in Figures 3-5.

It should be noted that the consolidation ratios of this study were in the range of 0.82-0.84, which indicates a high degree of consistency of opinion among the members of the expert group.

The data in Figures 3-5 show that, overall, the quality of the products studied was assessed by the expert group as good, often closer to excellent.

At the same time, this method allows for end-to-end analysis of the indicators of the products under study to identify their "strengths" and "weaknesses" in relation to competitive products in the household appliances market. For example, the most preferable household refrigerators in their segment were Liebherr, Daewoo and Samsung; Hoover and Bosch household vacuums and Ballu and Samsung household air conditioners.

In conclusion, the qualification assessment includes a set of methods for measuring and quantifying the quality of products and processes used to make informed decisions during product quality management. The application of this assessment method will not only create a high level of quality, but also minimize adjustments to products after they enter the market and establish a high level of safety for consumers.

Figure 3: Qualimetric assessment of household vacuum

Figure 4: Qualimetric assessment of household air conditioner

Figure 5: Qualimetric assessment of household refrigerator

Conclusions

1. The empirical study presented is dedicated to assessing the quality of household appliances. The study presents the methodology of the study and its testing in assessing the real quality of products on the Russian market of

household appliances. An evaluation algorithm is presented.
2. The range of quality indicators is formed on the basis of the applicability of products to a group, taking into account the definition of complex quality indicators and single quality indicators of different levels. In the case of household appliances, all performance indicators, including those for consumer properties, must be taken into account to assess quality and safety: …
3. The qualification assessment of household appliances sold on the Russian market was carried out by an expert method based on the calculation of a comprehensive quality indicator taking into account the weighting coefficients of individual indicators of quality and safety of individual consumer properties of technical products. The results of the assessment identified the most consumer-friendly household appliances in their segment.
4. In conclusion, it's noted that the qualification assessment includes a set of methods for measuring and quantifying the quality of products and processes used to make informed decisions during product quality management.

Abstract

Depopulated villages have contributed to the increasing number of empty and abandoned houses in rural areas, which have subsequently causing wasteful use of rural land resources. Having this phenomenon, many countries have undertaken measures to repopulate the rural areas in a way to make it more livable as well as to secure its resources so that the environment, social and economic benefits could be sustained. In this paper, the policy undertaken by the Malaysian Government to address and overcome the issue of depopulated villages, particularly the empty and abandoned houses in the country is presented. This is done by analyzing secondary data on rural population, rural population issues as presented in past studies besides looking into the respective policy implemented by the responsible rural agencies in the country. Lastly, this paper concludes with recommendations for further policy improvements.

Keywords: Depopulation, Empty and Abandoned House, Hollow Village, Rural, Policy

Introduction

Rural areas, with its natural beauty and tranquil surroundings, should be an attractive option of lifestyle for most people. However, rapid industrialization and urbanization have contributing to massive migration of the rural communities to the urban areas. As a result, rural depopulation has turned out severe, increasing the number of empty and abandoned houses and farmlands over the years. Sun et al (2011) mentioned, China called this as 'Hollow Village' phenomenon; whereby, likely phenomenon has long hit other countries too including North America, Japan (see Caraveli, 2000; Rudel et al., 2005; Sluiter & De Jong, 2007; Yunjie, 2017), Western & Eastern Europe (see Garcia & Ayuga, 2007; Reichert-Schick, 2010; Aleksander, K. & Tomasz, M., 2013), Iran (see Dewey et al., 2014) and United States (see Adam, et al., 2016).

This paper focuses particularly on the empty and abandoned houses in the rural areas, as a result of the massive rural communities' migration to the urban areas over the years. The houses that were kept unoccupied and abandoned for a long period as described by Jianping & Yasushi (2016) are in a state of grave disrepair, that could be strewn with trash, and scrawled with graffiti. Liu et al. (2010) initially illustrated that damaged houses have different degrees of destruction, ranging from slight to severe, as some vacant houses fall into disrepair; some may even collapse and weeds growing in half-meter height; some get damaged to such a degree that they are deemed unsafe for inhabitation. In worst situation, Liu et al. (2010) who studied the Hollow Village in China found that the phenomenon has changed the whole socio-economic function of a village, whereby the tendency of a village to completely vanish is high. As they described, it shows that empty and abandoned houses would bring negative image to a rural settlement, affecting the sustainability of the rural area.

In a study carried out in Malaysia (see Abdullah et al. 2019), it was found that the 49 out of 172 houses that were left empty and abandoned by their owners were mainly due to the death of the first generation of family members, who were the first to settle down when the village was opened around the 1990s. When this first generation dies, the

tendency for the next generations to move out of the village to continue living elsewhere were high then. With nearly 30 percent of the houses have been left abandoned, it was worst enough to have caused the increasing unsafe and discomfort feeling among the remaining villagers. The abandoned houses were left without maintenance, mostly filled with bushes and dirty courtyards.

Therefore, rural repopulation is vital, being the foundation for rural settlement development that could support local shops, schools and other facilities, to sustain the local economy (Owen, 1996). The movement of population outflow to the city limits rural workforce, thus worsening agricultural activities and less developed land has subsequently increased. In pursuant to this phenomenon and the awareness on the needs to sustain the rural areas, rural development strategies have been established and implemented in the affected countries, most importantly are aimed to repopulate the rural areas. In this paper, the policy undertaken by the Malaysian Government to address and overcome the issue on empty and abandoned houses in the rural areas in the country is presented. This is done by first analyzing secondary data on rural population, rural population issues as presented in past studies besides looking into the respective policies implemented by the responsible rural agencies in the country. Lastly, this paper concludes with recommendations for further studies.

Rural Population Issues

The problems that are often faced by rural communities have narrowed their thinking, especially young people in continuing a better life in the urban areas that seem to have more attractions. In Europe, Owen (1996) found that the common problems of its local rural communities were their difficulties in gaining employment, the young and elderly were socially and physically isolated due to the reduction in services and accessibility by public transport to facilities and services in urban areas as well as the reduced investment in rural infrastructure. These have long been the pushing factors that making rural communities to move to urban areas, whilst the urban attractions have been the pulling factor that keep worsening the rural-urban migration issues. Mabogunje (1970) elaborates that when the attraction factor in one area is greater, it has prompted people to move to that area on a more privileged basis than the other area. Therefore, it shows that rural depopulation has been contributed by the failure of the attractiveness factors in rural areas to keep their people in. He further suggests for the rural communities to sustain, the economic development, provision of facilities, and protection of nature should first be strengthened.

Repopulating the Rural Areas

Sustaining rural areas involves multidisciplinary efforts. From the perspective of rural depopulation issue itself, we could not ignore for instance the role of the agricultural sector since the areas are largely and naturally landscaped with land resources that vital for agricultural related economic sectors. Besides providing food for people, the land resources create socio-economic mobility opportunities that thereafter would at least support local services. Having all these in one place, thus outmigration could be prevented. This is the ecosystem that needs to be taken care of by rural institution for the rural areas to be independent.

Rural depopulation that have kept houses in villages empty and abandoned is an alarming indicator of rural decay. Without sufficient source of labour in the rural areas, agricultural investments would be affected. When the investments slowing down further, rural decay becomes severe. Repopulation of rural areas is thus important and effective policy is needed. In China, in addressing the rural hollowing issue, the country acts by launching a new 'increasing vs. decreasing balance' land use policy in 2005 that was aimed to reconciling demands of urban development and protecting farmlands. The strategies involve agricultural modernization and improvements to rural infrastructure as an effort for rural settlement rationalization (Long et al. 2012). Germany have seen protecting agricultural industry in rural area as a good step towards overcoming the problem of rural decay too. They have introduced their Land Consolidation Policy, a comprehensive reallocation procedure of a rural area consisting of fragmented agricultural (Long et al., 2009). With the policy, the production and working conditions in agriculture have been improved through the re-arrangement of agricultural land. Nevertheless, besides strengthening the agricultural industry in rural areas, Owen (1996) also suggests that sustaining rural communities should involve strategies to protecting water quality and natural heritage, and strengthening the established village and smaller settlements structure to accommodate people in a way that supports the viability of public transport and services.

Policy for Empty and Abandoned Houses in Malaysia's Rural Areas

Our analysis is based on a set of policies established and implemented in Malaysia by its responsible agencies for rural development. Policies involving rural development in Malaysia have evolved since the First Rural Development Transformation Policy was issued in 1957 until the National Rural Physical Planning Policy 2030 (NRPPP2030) was launched, to be guiding the physical planning in the rural areas for the period from 2014 to 2030. In the NRPPP2030, the issue of rural depopulation has been highlighted. It is reported that by 2020, the total rural population is expected

to decrease from 7.7 million people in 2016 to 7.39 million people (NRPPP2030). The same concern is also mentioned in Rural Development Policy 2019 (RDP2019), in which, the policy is targeting to create economic opportunities with conducive environment and social atmosphere to attract rural communities especially the youth for continue to live in the rural areas. More than that, the Government also intends to attract some urban dwellers and investors to migrate to rural areas to increase the volume of productive population and economic capacity in rural areas. In contrast to other rural development policies in Malaysia which are led and monitored by the Ministry of Rural Development, NRPPP2030 is on the other hand formulated by PLANMalaysia under the responsibility of the Ministry of Urban Wellbeing, Housing and Local Government.

NRPPP2030 is needed to clearly address and overcome rural development issues especially on the lack of rural data, rural-urban development and economic gap, rural to urban migration, increasingly affected rural image and characters, unsustainable rural resources and biodiversity as well as the failure of rural institution. Therefore, through the implementation of NRPPP2030, all related rural policies in the country are interpreted into physical plans, integrated into databases established by PLANMalaysia. The databases are established to gather and classify spatial data to ease the formulation of better and specific strategy according to the villages' characters and also to monitor the implementation of the NRPPP2030. Rural Grid System and Characteristics of Rural Malaysia System (CHARMs) are two examples of databases developed to fully support the recent rural planning and development in Malaysia.

The issue of rural depopulation and empty and abandoned houses are specifically mentioned under Thrust 3 (Reinforcing Rural Liveability) of NRPPP2030. This thrust is aimed to turn the rural area as an option for living because of its nature, supported by employment opportunities and good public facilities. This effort is to be achieved through the implementation of five Policy Statements and 19 Strategies as follows:

Table 1: Policy Statements and Strategies for Reinforcing Rural Liveability

Policy Statement	Strategy
Preservation of Village Spatial Characters	1. Determining village boundary 2. Asset Mapping 3. Controlling land use conservation 4. Preserving the 'green belt' areas 5. Increasing rural population especially the young people and retirees from the cities 6. Managing abandoned houses for better image
Preservation and Conservation of Village Heritage	1. Conserve traditional Malay house 2. Foster Malay traditional house industry 3. Raise public awareness on cultural heritage 4. Recognize the living person heritage
Increasing Efficient Infrastructure	1. Ensuring a continuous and adequate source of clean water supply 2. Supports comprehensive 24-hour distribution of electricity supply 3. Driving Information and Communication Technology in supporting the rural economy 4. Strengthen solid waste management system 5. Strengthen sewerage system
Provision of Public Amenities	1. Providing of adequate and quality public amenities 2. Foster community ownership element and social enterprise concept
Strengthening and Increasing Public Participation	1. Strengthen feelings of love and a sense of belonging 2. Strengthen the concept of neighborhood and community in daily life

Source: NRPPP2030

Clearly, issue on empty and abandoned houses in rural areas is mentioned by Policy Statement No.1 Strategy No. 5 and 6. It is reported in the NRPPP2030 that 7.5 percent of villages in the country (especially within the areas that

PLANMalaysia categorized as Rural and Major Rural Grid) were found to have low occupancy rate. From the Rural Grid System that monitored by PLANMalaysia, there are a total of 43 grids that with empty and abandoned houses exceeding 30 percent. This situation is due to population size that becoming smaller over the years thus has not entitled them to be equipped with basic amenities, high reliance on a single economic sector i.e. agriculture and lack of diversity and aspects of employment, business and technological facilities. Without immediate actions, it is feared that the image of the village will be affected, disrupting the smooth running of development programs. Therefore, Strategy No. 6 is planned to manage the empty and abandoned houses by first, building up the 'old and abandoned house inventory' to gather the details of the house physical conditions as well as the ownership information. The physical conditions are to be classified into three stages:

Fig .1: Stages of Old Houses

Source: NRPPP2030

The whole process to manage the empty and abandoned houses in the villages starts with identifying the old houses, categorizing their stages and finally to be managed according to their conditions. If the houses are still occupied, thus minor repair works will be carried out by the community itself. And, if the houses are abandoned and not claimed by the heirs, the houses will be demolished or may be repaired if they are still potentially developed as rental houses.

PLANMalaysia have set for this process to be executed within three phases of timeline. The first phase has begun in 2017 and to be ended in 2020. The second phase will be implemented from 2021 until 2025 and the final phase is beginning 2026 until 2030. All these phases are to be monitored by PLANMalaysia; whereby, they have identified several agents to directly involve in executing the process namely the Village Development and Security Committees, Land and District Offices as well as the local authorities. Eventually, this process is targeting to renovate the empty and abandoned houses in rural areas and to develop them as homestays or rental houses.

Conclusion

A policy that formed to solve the communities' problems must have clear goal, target and indicators so that it can easily be evaluated for further and better decision making and management. Same goes to NRPPP2030, when tackling rural depopulation issue, it goes into detail about the ecosystem that manifesting the whole issue, including the empty and abandoned houses. The houses form the rural settlement, being an important support system to sustain the rural areas. The setting up of Thrust 3 to reinforce rural livability in NRPPP2030 shows that the Malaysian Government has been taking proactive measures to strengthen the rural settlement structure by looking into the abandonment of houses in its rural areas. This effort is important as the basis for supporting the social and economic development planning in the rural areas. Without the people to reside in the rural areas, the country would be losing source of labour for rural economic industry, which without them, the productivity thus investment in such industry would be detrimental. The implementation of the Thrust 3 is targeted to be completed by year 2030. Along the way, reports on its progress should be regularly monitored to assure its success. The monitoring should involve the assessment on the agents that have been assigned to that tasks too. It is to ensure proper implementation of the policy so that the targeted goal would be attainable. Therefore, it is suggested for studies to be further conducted from the perspective of the appointed agents, as an effort to closely evaluate the effectiveness of the set policy.

Abstract

The level of wages and their ability to cover the cost of living is a key issue for both employees and economic policy makers. In some cases, wages paid to a worker are not sufficient to cover the average cost of living, which is especially relevant in Croatia, Bosnia and Herzegovina, Serbia and Montenegro, so the topic of this paper is the level of wages in Croatia, Bosnia and Herzegovina, Serbia and Montenegro in the period from 2011to 2019 and comparing them with the EU. The survey is based on Eurostat data and authors calculations. The average monthly net salary is not sufficient to cover the average cost of living in Croatia, Bosnia and Herzegovina, Serbia and Montenegro. The observed countries record significantly lower levels of purchasing power and living standards compared to other European countries, and achieving stronger economic growth has been hampered by inefficient economic policies. The corona crisis will have a profound effect on the economy of these countries.

Keywords: Croatia, wage levels, cost of living, countries of the region.

Introduction

Numerous authors have dealt with the topic of wage values and living standards in general in the Republic of Croatia. In 2011, Radman Peša, Stanković and Štajduhar published a paper entitled "Survey of the level of salaries in Croatia in relation to countries of the region and EU countries" in which the level of salaries in Croatia in relation to Bosnia and Herzegovina, Serbia and Montenegro and the EU countries for the period 2001-2010 was analyzed. This paper is intended as a continuation of this work, and the purpose is to investigate the level of wages in Croatia in relation to Bosnia and Herzegovina, Serbia and Montenegro and EU countries for the period 2011-2019**.** According to the newest data by Central Bureau of Statistics, average net wages in Croatia. Similar trends were recorded in Bosnia and Herzegovina, Serbia and Montenegro, but regardless of wage growth, available data indicates significant differences in purchasing power and living standards in Croatia, Bosnia and Herzegovina, Serbia and Montenegro compared to other countries. Available sources indicate a problematic feature in the observed group: the average monthly net wage is not sufficient to cover the cost of living (coverage rate generally ranges from 40-80). At the same time, Croatia is one of the European countries with an above-average share of wages in GDP (Eurostat, 2020a). In this paper,

Cite this Article as: Stela PRVONOŽEC, Anita PEŠA and Berislav BOLFEK" Wage Level Survey In Croatia In Comparison to Countries of The Region and The EU from 2011-2019" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

therefore, the value of wages in Croatia and selected countries in the region is analyzed, as well as the present differences in purchasing power and living standards in these countries towards the EU. Considering the current global pandemic of coronavirus, the paper also deals with the current socio - economic effects of the corona crisis on the economies of Croatia, Bosnia and Herzegovina, Serbia and Montenegro. This paper is divided into three parts: the introductory part that briefly introduces the reader to the issues addressed in this paper, elaboration of the topic analyzing the value of wages in Croatia compared to countries in the region and the EU and the conclusion that summarizes the most important facts presented in this paper.

Literature Review

Šućur (2014) notes in his paper that the crisis in 2008 resulted in the emergence of new subgroups in the category of poor citizens. As members of these subgroups, Šućur lists the employed, young people, children, the homeless and the unemployed. As sources of poverty in Croatia, Šućur cites financial uncertainty, indebtedness, rising unemployment, an increase in the number of people living in absolute and deep poverty and child poverty. In 2018, 24.8% of people in Croatia lived at risk of poverty or social exclusion, and there is a significant dependence of the population on social transfers (Croatian Bureau of statistics, 2019d). According to Eurostat (2019) data, in 2017 Croatia was one of nine EU member states with one fifth of the population or more at risk of poverty. Nestić and Vecchi (2007) note that the level of wages and living standards in Croatia vary according to the counties, and the leader is Zagreb. Bejaković (2018) also mentions the issue of the employed population that receives a salary insufficient to cover the average cost of living. According to Eurostat data (2020b), in Croatia in 2018, after social transfers, 19.2% of the total population lived at risk of poverty, of which 5.2% were employed and 30.3% were not employed. Similar trends can be observed in Serbia and Montenegro, while data for Bosnia and Herzegovina is not available. Ivanda (2017) mentions that it is extremely important that economic growth "spills over" to the living standards of the citizens. Rančić and Durbić (2016) also emphasize the importance of high employability and adequate salaries of employees in the process of increasing the standard of living in Croatia. It is clear from the mentioned sources that the problem of wages in Croatia cannot be examined individually. Savić and Zubović (2015) point out that the countries of the Western Balkans have a common characteristic that prevents the improvement of labor markets: inflexibility. Muja and Gunar (2019) state that in the countries of the Western Balkans the standard of living is largely conditioned by the quality of government in the country. Economic situation in Serbia is described by Pavlović et. al (2016). The authors state that the macroeconomic environment in Serbia is extremely unsatisfactory, and is characterized by a high level of illiquidity, high inflation rates, rising unemployment and declining capacity utilization. Fetahi-Vehapi et. al. (2015) note that there are significant differences between the countries of the Western Balkan in terms of economic development.

Economic Review of Croatia from 2011-2019

In 2008, the effects of the global financial crisis that started in the United States spilled onto Europe. The macroeconomic implications of the crisis were most pronounced in the countries of Central and Eastern Europe (Mihaljek, 2009). In six years, Croatia's GDP has fallen by 12.6% in real terms. During 2014 and 2015, the fall in oil prices and changes in the income tax system enabled the gradual recovery of the Croatian economy (Croatian Chamber of Economy, 2017a). In the following period (2016-2018) positive trends from 2015 continued, although the dynamics of growth itself slowed down. In 2018, the most profitable economic activities in Croatia were trade, tourism and transport, and the most unprofitable were industry and mining and quarrying (Croatian Chamber of Economy, 2019b; Croatian National Bank, 2017b, 2018c). Eurostat (2019c) states that in the third quarter of 2019, Croatia was one of the European countries with the highest growth rates compared to the previous quarter (along with Poland, Hungary, Estonia, Bulgaria and Slovenia). The global corona virus pandemic will determine economic trends in 2020 and later, and it remains to be seen whether economic policy measures adopted in Croatia, Bosnia and Herzegovina, Serbia and Montenegro will result in faster stabilization of the national economies.

The share of wages in GDP in Croatia

According to Eurostat data (2020a), in 2019, above-average shares of wages in GDP were recorded in eleven EU Member States, including Croatia (40.5%). At the same time, Eurostat (2020d) notes that the share of wages in Croatia's GDP in 2019 is lower by 3.2 percentage points than in 1999. Similar developments have been reported in Ireland, Portugal and Malta. In 2010 nominal and real wages began to decline (Kunovac and Pufnik, 2015). 2014 marked a turning point in terms of wages; Croatian Chamber of Economy (2019a) states that real wages in Croatia have been growing continuously since 2014. However, the same source states that wages in Croatia are growing more slowly than in similar countries. The link between wage growth and productivity is described by Orsini and Ostojić (2015). They state that wage growth that is faster than productivity growth will adversely affect countries 'competitiveness. According to the European Commission (2018a), wage growth that occurred in 2017 was higher than productivity growth in most Central and Eastern European countries, with the following exceptions: Croatia, Poland and Slovenia.

Wages and consumer baskets in Croatia and the region

In this segment of the paper, data on wages and consumer baskets in Croatia, Bosnia and Herzegovina, Serbia and Montenegro is processed. All mentioned countries have one thing in common: the average wage is insufficient to cover the consumer basket (Nacional, 2019). For example, in Bosnia and Herzegovina, more than two average wages are needed to cover the necessary costs, while in Serbia in November 2018, 1.39 average wages were needed to cover the average consumer basket (Obrenović, 2019). In Montenegro, at least two average wages are required to cover minimum costs (Nacional, 2019). Below are the average net wages in the countries of the region for the period 2011-2019 years. For easier comparison, all values are expressed in Croatian kuna. Average net wages in Bosnia and Herzegovina, Serbia and Montenegro are all expressed in Croatian kuna and were obtained as follows: values expressed in the domestic currency of the observed country were converted into euro and then converted into Croatian kuna (according to the middle excange rate of Croatian National Bank on July 29, 2020).

The average net wage in Croatia grew during the observed period, and is at the same time the highest in the observed group of countries.

Table 1: Average net wages in Croatia from 2011-2019

2011	2012	2013	2014	2015	2016	2017	2018	2019
5.441,00 kn	5.478,00 kn	5.515,00 kn	5.533,00 kn	5.711,00 kn	5.685,00 kn	5.985,00 kn	6.242,00 kn	6.457,00 kn

Source: National Bureau of Statistics, Croatia (2015c, 2020d)

Data on the consumer basket in Croatia is as follows: prices are very high compared to the incomes of Croatian citizens, in most European countries the consumer basket is cheaper than in Croatia, the purchasing power of Croatian citizens is among the worst in the EU and finally, the indebtedness of Croatian citizens is high. Also, the growth of purchasing power in Croatia is relatively slow compared to other European countries (Turčin and Milovan, 2019).

Bosnia and Herzegovina also recorded an increase in average net wages in the period 2011-2019. However, the coverage of the average consumer basket by wages in Bosnia and Herzegovina remains very low; the latest data from March 2020 indicate that the coverage of the consumer basket with the average wage is only 47.43% (Vrisak.info, 2020).

Table 2: Average net wages in Bosnia and Herzegovina from 2011-2019 (in Croatian kuna)

2011	2012	2013	2014	2015	2016	2017	2018	2019
3.132,67 kn	3.171,12 kn	3.174,94 kn	3.186,43 kn	3.186,43 kn	3.217,14 kn	3.267,08 kn	3.412,97 kn	3.562,69 kn

Source: Author developed (2020)

In November 2018, the average wage in Serbia was approx. 428 EUR, and the consumption of a family of four in the same period amounted to 597 EUR. In the structure of the consumer basket in Serbia, 41% of monthly expenditures are spent on food. In Croatia, this figure is 32%, in Montenegro 37%, and in Bosnia and Herzegovina 36% (Nacional, 2019).

Table 3: Average net wages in Serbia from 2011-2019 (in Croatian kuna)

2011	2012	2013	2014	2015	2016	2017	2018	2019
2.434,52 kn	2.652,57 kn	2.186,33 kn	2.854,70 kn	2.848,39 kn	2.955,17 kn	3.070,27 kn	3.182,90 kn	3.520,72 kn

Source: Author developed (2020)

In Montenegro, the average net wage in December 2019 was EUR 484, and the average consumer basket in the same period was EUR 484. Data on the net wage in 2011 is not available on the official website of the Montenegrin Statistical Office. As in other countries, the average wage is not enough to cover the cost of living - additional sources of income in this case are obtained by borrowing (Nacional, 2019).

Table 4: Average net wages in Montenegro from 2011-2019 (in Croatian kuna)

2011	2012	2013	2014	2015	2016	2017	2018	2019
	3.656,70 kn	3.596,63 kn	3.581,61 kn	3.604,14 kn	3.746,80 kn	3.829,40 kn	3.836,90 kn	3.866,94 kn

Source: Author developed (2020)

The graph below shows that the highest wages in the observed group of countries were recorded in Croatia, followed by Montenegro, Bosnia and Herzegovina, while the lowest wage levels were recorded in Serbia.

Figure 1: Wage level comparison in Croatia, Bosnia and Herzegovina, Serbia and Montenegro from 2011-2019, Author developed (2020), source: Croatian Bureau of Statistics (2015; 2020), Agencija za statistiku BiH; Avaz.ba; Monstat; Republički zavod za statistiku (2020)

Below is a graphical representation of the value of wages in Croatia, Bosnia and Herzegovina, Serbia and Montenegro and the average cost of living in 2018.

Figure 2: Average net wages and living costs comparison for the year 2018 for Croatia, Bosnia and Herzegovina, Serbia and Montenegro, Author developed (2020), source: Lemajić, Nacional, I.Dž (2019)

Net wage in Croatia 2018 covered 83% of living costs in 2018, in Bosnia and Herzegovina only 44%, in Serbia 71% and in Montenegro 80%.

Wages in Croatia and the EU

Šućur and Babić (2019) in their analysis of IWP (in-work-poverty) in Croatia, state the following: first, Croatia records a high share of low-paid employees, secondly, after 2008 the share of temporary employment contracts increased significantly, third, taxes are high, which reduces net wages and finally, the availability of tax breaks or social benefits is limited and affects only employees earning more than the minimum wage (European Commission, 2019b). All of the above contributes to the increase in the number of residents at risk of poverty. According to Urban (2016), Croatia, along with Estonia, Slovakia, the Czech Republic, Poland and Hungary, is the EU member state with the lowest wage level. In 2019, the estimated hourly wage in Croatia was 11.1, Euro for the EU = 27 the average was EUR 37.7, and for the euro area member states 31.4 Euro. In particular, the highest hourly rates were recorded in Norway (50.2 Euro) and Denmark (44.7 Euro). The countries that, along with Croatia, recorded the lowest hourly rates are Poland (10.7 Euro), Latvia (9.9 Euro), Hungary (9.9 Euro), Lithuania (9.4 Euro), Romania (7.7 Euro). and Bulgaria (6.0 Euro) (Eurostat, 2020). According to the data on the minimum wage from January 2020, Croatia is classified in group 2 - countries with a minimum wage of at least 500 EUR, but not more than 1000 Euro per month (specifically, in Croatia the minimum wage for January 2020 was 546 Euro). The countries with the highest minimum wage in January 2020 are Spain, France, Germany, Belgium, the Netherlands, Ireland and Luxembourg (Eurostat, 2020e). When it comes to the minimum wage expressed in PPPs, two groups of countries are distinguished within the EU; the first group, with a minimum wage of less than 1000 PPPs (Latvia, Bulgaria, Estonia, Slovakia, the Czech Republic, Croatia, Hungary, Portugal, Greece, Romania, Lithuania and Malta) and the second group, countries with a minimum wage of at least 1000 PPPs (Poland, Slovenia, Spain, Ireland, France, Belgium, the Netherlands, Germany and Luxembourg).

In 2019, Eurostat (2020f) recorded data on annual net earnings according to the following categories (all values are expressed in EUR): a married couple with two children in which both partners are employed (both 100% of the average worker), a married couple in which both partners are employed,

without children (both 100% average worker), a married couple in which one partner works with two children (100% average worker) and singles without children (100% average worker). In 2019, the values by categories for Croatia are as follows: for the first and second category, the annual net earnings amounted to approx. 20,000 EUR, and for the third and fourth category approx. 10,000 EUR. In addition to Croatia, countries with similar trends are Slovakia, Hungary, Latvia, Lithuania, Romania and Bulgaria. The average for EU = 27 is 50,000 EUR (1st category), approx. 48,000 EUR (2nd category), approx. 29,000 EUR (3rd category) and finally, approx. 23,000 EUR (4th category). The highest values were recorded in Luxembourg, the Netherlands and Denmark (Eurostat, 2020).

Expected future trends in the region

Economic trends in the region in the coming period will be conditioned by the consequences of the corona crisis. On the official website of the Croatian Chamber of Commerce, it is stated that the corona crisis has an increasingly strong impact on the Croatian economy, with micro-entrepreneurs being the most endangered (Croatian Chamber of Economy, 2020c). Other unfavorable trends include the decline in retail turnover (data for May 2020) (Croatian Chamber of Economy, 2020e), the decline in tourist activity of the population (noting that the corona crisis has affected the change in the structure of guests, so entrepreneurs in tourism are increasingly oriented to domestic tourists (Croatian Chamber of Economy, 2020d).

The Croatian National Bank Council (2020a) projected a 9.7% drop in real GDP in 2020 and a 6.2% growth in economic activity in 2021, but also noted that the projections of the trends themselves are very uncertain due to their conditionality by the epidemiological situation. Projections of economic trends are also affected by the potential deterioration of the epidemiological situation announced for the end of the year.

Adverse developments are expected in the labor market, although somewhat mitigated by economic policy measures (Croatian National Bank, 2020a). Bosnia and Herzegovina also witnessed a serious decline in the number of people employed (approx. 28,000 workers in the Federation of BiH and approx. 2,000 workers in the Republic of Serbia since mid-March), and the effects of the crisis have hit services, trade and manufacturing the hardest. It is estimated that three billion euros will be needed to address the coronavirus crisis in Bosnia and Herzegovina (Husenović, 2020). In addition, the crisis caused by the coronavirus will result in worsening of the already unfavorable demographic trends in Bosnia and Herzegovina. Job losses will also affect the health and pension system of Bosnia and Herzegovina (Domazet, 2020).

Companies in Serbia expect a 25% drop in profits and a 30% drop in investments as result of the corona crisis. At the same time, 63% of companies plan to keep their business at the current level. The sectors most affected by the crisis are tourism, catering, transport and real estate, the auto industry, the consumer durables industry and the consumer goods industry. Losses of up to 80% were recorded in these industries (Poslovni dnevnik, 2020b). Also, a state measure was adopted according to which the citizens will be able to apply for financial assistance in the amount of 100 Euro until June 5 (Poslovni dnevnik, 2020c).

Tourist trends in Montenegro are very unfavorable; more than 50% of hotels along the coast have been closed due to undercapacity, the situation is similar in private accommodation, with domestic guests as the dominant group (Maksimović, 2020). The IMF predicts a 9% drop in GDP in Montenegro, and a high share of citizens who have applied for one-time social assistance. The corona crisis will also affect public finances in Montenegro, as well as the living standards of its citizens (Poslovni dnevnik, 2020a).

Tisdell (2020) states that most pandemics resulted in declining economic activity and rising unemployment. In the case of the corona virus pandemic, governments have enacted a series of measures aimed at halting the spread of the virus, which have resulted in reduced employment and economic activity globally. The author also notes that the recovery of economic activity after COVID-19 is highly dependent on medical discoveries regarding the treatment and prevention of disease.

Nicola et. al. (2020) note that the consequences of a pandemic are felt in all sectors, but that some sectors recorded sharp increase in revenue (for example, the video game industry, the pharmaceutical

industry) due to the nature of the disease and the method of prevention. Also, in some industries, the increase in demand for products required a change in the business model (food industry).

The European Union adopted a number of economic policy measures aimed at remedying the consequences caused by the corona virus pandemic. Each Member State has been granted a financial assistance package to remedy the crisis. According to the forecasts, the European economy will record a decline of 8.3% in 2020 and a growth of 5.8% in 2021, assuming the gradual abolition of restrictive measures and the absence of a "second wave". The European Commission Summer Forecast for 2020 notes that the differences in the extent of the consequences of pandemics and the speed of recovery of member states' economies will be even greater than those predicted in the spring forecast (European Semester, 2020a).

In the context of a global pandemic, making forecasts for economic recovery is extremely difficult due to the unpredictable epidemiological situation, and in countries such as Croatia, Bosnia and Herzegovina, Serbia and Montenegro it is even more demanding.

Purchasing Power Parity

Purchasing power parity (PPPs) is an indicator of the level of prices present in countries. The official website of the European Commission states that data on purchasing power parity is used for international comparisons of GDP and for analysis of relative price levels in countries. It is also an important tool for comparing and analyzing the purchasing power of the population (Eurostat, 2018g). PPPs is also used by the IMF to determine quotas for its members (Croatian Bureau of Statistcs, 2019d).

GDP per capita in PPS

According to Eurostat (2020h) data from for EU = 27_2020 = 100, in 2019 the highest levels of GDP per capita according to purchasing power parity were recorded in Luxembourg (261) and Ireland (191). The lowest values were recorded in Romania (69), Greece (68), Croatia (65) and Bulgaria (53). Although at the bottom of the EU, Croatia's GDP per capita in purchasing power parity is the highest among the observed countries in the region.

Consumer price levels in Croatia

According to Eurostat (2020i), in 2019 consumer price levels varied significantly within the EU; the highest levels of consumer goods prices were recorded in Denmark (41% above the European average) and the lowest in Bulgaria (47% below the European average). The EU has also defined the HFCE (household final consumption expenditure) parameter, which consists of an overall overview of individual goods and services purchased in resident households, including those sold at below-market prices. HFCE also includes an estimate of non-monetary costs or transactions that cannot be measured directly (Eurostat, 2017j).

Consumer goods are divided into the following categories: food, beverages, tobacco products, clothing and footwear, energy, furniture, white goods, consumer electronics, personal transport equipment, transport services, communications and restaurants and hotels. Price levels in Croatia for all described categories of goods in 2019 are below the European average, and the leading category is "household costs" (53.3% below the European average) (source: Eurostat, 2020; 2019), "recreation and culture" (24.7% below the European average) and “furniture and carpets” (23.3% below the European average).

Wage growth comparison in Croatia and EU

Croatian Chamber of Economy (2019b) points out that real wages in Croatia have been growing continuously since 2014, which has a positive effect on household consumption and GDP in general. The sources of wage growth are the stabilization of the economy, positive developments in the labor market and tax changes (which result in reduced labor taxation and a general increase in net wages).

The same source states that there are significant differences in the amount of wages by counties; above - average wages were recorded in the City of Zagreb, Dubrovnik - Neretva County and occasionally in Primorje - Gorski Kotar County. In 2016, the counties in Adriatic Croatia recorded an acceleration in

wage growth (all except Lika-Senj County). In the years preceding the global financial crisis, wages in Croatia not only grew at a similar rate as in the EU = 10, but also adjusted more slowly to contractions in economic activity (Orsini, Ostojić, 2015). Kunovac and Pufnik (2015) also mention this. The Joint Employment Report (2019) points to another important feature of the economies of Central and Eastern Europe - wage growth is present, but not accompanied by adequate productivity growth.

Since the mid-1990s, nominal wage growth in the EU has been closely linked to inflation and productivity growth. The EU also points to the importance of economic policies that result in increased labor productivity in order to achieve wage convergence. In the post - crisis period, wage growth was moderate due to low inflation, high unemployment rates and declining productivity. At EU level, only a few countries (including Croatia) recorded nominal wage growth below the expected level based on inflation, productivity growth and unemployment rates after the global financial crisis (Labor market and Wage Developments in Europe, Annual Review 2018).

Wage growth in Croatia is largely “artificial” - it is the result of temporarily positive economic trends (the effects of the corona crisis are yet to be seen) and changes in labor taxation. The European approach to wage growth is based on effective economic policies that result in increased labor productivity and, consequently, lead to a change in living standards.

Purchasing power of the citizens of the Republic of Croatia

According to Croatian Bureau of Statistics data (2019a), in 2018 the Republic of Croatia recorded one of the lowest levels of actual individual consumption (AIC) per capita in the EU. In Montenegro and Serbia, the value of CEC ranged between 30-60% below the European average, while in Bosnia and Herzegovina the value of CEC was 59% below the European average.

In 2017, in the structure of consumption expenditures in Croatia, the dominant item was "food and non-alcoholic beverages" with 28.2% (on average, 23,253 HRK per household was spent on food and non-alcoholic beverages, and within this category food expenditures dominated - 91.8%). In addition, in 2017, Croatian citizens spent the most on "housing and energy consumption" (on average HRK 12,967 per household - the dominant item is the cost of electricity, gas and other fuels with 62.8%) and for "transport" (on average HRK 12,766 per household - the dominant item is vehicle maintenance expenditures with 63.3%). During 2010 and 2011, there was a decrease in total consumption expenditure in Croatia compared to 2009. In 2014, the total value of household expenditure amounted to HRK 81,315. In 2017, consumption expenditures amounted to HRK 82,530 per household, but due to changes in the methodology of data collection, it is not possible to compare them with previous years (Croatian Bureau of Statistics, 2019b).

In 2018, the dominant consumer item in the EU was "household expenses" with 24.0% in total expenditures and "food" with 11.0% in total expenditures. Similar trends were recorded in Croatia (the most represented consumer categories were also “household expenditure” (16.8% in total expenditure) and “food” (16% in total expenditure)) (Eurostat, 2019k).

Results of the research

As part of this research, wage values in Croatia, Bosnia and Herzegovina, Serbia and Montenegro for the period 2011-2019 were analyzed. The crisis in 2008 resulted in a number of changes in the labor market, including the emergence of new subgroups in the category of poor citizens (Šućur, 2014). In 2018, a quarter of the population in Croatia lived at risk of poverty (Croatian Bureau of Statistics, 2019). The research established that the highest levels of wages were recorded in the Republic of Croatia, while the lowest were in Serbia. The paper also analyzes the adequacy of wages to cover average monthly expenses in 2018. In all observed countries, average net wages were not sufficient to cover all living expenses, but covered approx. 70-80% of living costs (with the worst situation being recorded in Bosnia and Herzegovina, where the average net salary covered only 44% of costs). In general, the standard of living and purchasing power in all observed countries are below the European average (Croatian Bureau of Statistics, 2019). For foreign citizens who buy in Croatia, Bosnia and Herzegovina, Serbia and Montenegro, consumer goods are very affordable, but the situation is completely different when it comes to the domestic population. Eurostat data (2019k) indicate Croatia's

convergence with the EU when it comes to consumer goods - both in Croatia and in the EU the highest share in the structure of food waste expenditure and household costs (although prices vary significantly). Wages in Croatia are growing as a result of temporary positive trends in the economy, but also changes in legislation in labor taxation (Croatian Chamber of Economy, 2019b). According to Eurostat (2020h) data on GDP according to PPS for the period 2011-2019, it is evident that a more serious change in Croatia occurred only in 2019. In 2020, and later, economic trends will be determined by the global corona virus pandemic. Tisdell (2020) notes that most of the pandemics the world has faced in the past have resulted in rising unemployment and declining economic activity, and that the recovery of national economies will depend heavily on medical discoveries in COVID-19 prevention and treatment. The European Commission (2020l) notes that the recovery of the European economy will be asymmetric and that the differences in the consequences of the epidemic and the strength of the recovery in each Member State will be even more pronounced than projected in the spring forecast. Labor market and Wage Developments in Europe, Annual Review 2018) notes that Croatia is one of the European countries with nominal wage growth is below the level expected given inflation, productivity growth and unemployment rates after the global financial crisis. In future research, the topic of wage values could be extended to other countries from the group of southeastern countries - Albania, Kosovo and Macedonia and their comparison with the EU. Given the current situation of the global corona virus pandemic, future research could analyze the speed and background of the recovery of Southeast European countries in relation to the EU.

Conclusion

The dynamic of wage growth in Croatia is slower compared to countries with similar economic characteristics. In all observed countries, an increase in average net wages was recorded in the period from 2011 to 2019, however, wages are not sufficient to cover the average monthly cost of living. Croatia's GDP in terms PPPs is one of the lowest in the EU but it is the highest among the countries in the region (followed by Montenegro, Serbia and Bosnia and Herzegovina). Wages in Croatia, grew at the same rate as the EU = 10 in the pre-crisis period, they also adjusted more slowly to the contractions of economic activity. Central and Eastern European countries record wage growth that is slower than productivity growth. The levels of actual individual consumption (AIC) in Croatia, Bosnia and Herzegovina, Serbia and Montenegro generally range from 30-60% below the European average. Future economic policies will be determined by the corona virus pandemic, so it remains to be seen whether the measures taken by the states will accelerate the remediation of the consequences of the crisis in Croatia, Bosnia and Herzegovina, Serbia and Montenegro.

Abstract

The main aim of this paper is to analyses the impact of consumer behavior on online shopping in order to increase the sales and respective profit and also the confidence of consumers on this process. For this purpose, an online and direct questionnaire was used in Karachi City (Pakistan) in order to analyses consumers' attitudes via unrestricted non-probabilistic sampling technique. The methods used includes univariate and econometric models, including the main dimensions of online shopping. The main results highlines confirm the importance of the dimensions attributed by the consumers while they choose to shop online, namely, delivery risk, financial risk, trust and security and web design. Therefore, marketers should ensure that all these elements are included in their source of online shopping forum. It will certainly provide them increasing sales and loyalty from consumers. Also, marketers should consider that there is minimal risk involved for the online shoppers and should develop all the software support tools to avoid fraud in order to increases the confidence of consumers on online purchase system.

Keywords: Consumer Behavior, Web Design, Convenience, Financial Risk, Non-Delivery Risk.

Introduction

The innovation of Web has changed the world and the way how organizations run the business (Greenfeld, Becker, Bornman, Dos Santos, & Angel, 2020). Nowadays, there are so many ways that customer can connect with the organization. One of the main options that are available is via *online*. Online shopping behavior can be defined as "The course of online purchasing of goods or services through e-commerce platforms" (Wai, Dastane, Johari, & Ismail, 2019). Online shopping is attracting more customers because of the time saving, comfort, and convenience available. Quick delivery is one of the main factors that differentiate online shopping with the tradition shopping (Adnan, 2014). Besides that, other authors, namely Nowadays the web has turned into a critical medium of communication and web-based shopping. The customer can now search different types of products or information about any specific product any time by using the internet. Due to the advancement in technology, the customer can now obtain a product without actually visiting the market physically. Online shopping not only acts as a platform where the consumer

Cite this Article as: Maria José Palma Lampreia DOS-SANTOS, Nawaz AHMAD and Aisha Yusuf MESIYA "Factors Affecting Customer's Online Purchase Behavior: The case study of Karachi, PK" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

can buy products but also gain information about the product. Web-based shopping relates to the consumer's psychological state in regard to the achievement of online purchasing. Before buying an item, buyer keeps all the risks involved in the purchasing product online. It can be financial, product or non-delivery risk and web design are also psychological factors that can impact consumer's buying decision (Moshref Javadi, Dolatabadi, Nourbakhsh, Poursaeedi, & Asadollahi, 2012). The manner in which consumers perceive these risks shape their purchasing behavior, as their target is to minimize the risks to the utmost level (Donni, Dastane, Haba, & Selvaraj, 2018). If these consumers engage actively in online shopping behavior, it depicts success on the marketers' side (Satar, Safie, Dastane, & Maarif, 2019).

Consumers can easily receive the products they buy in less than 24 hours due to the fast delivery services offered now. Consumers have less trust over online sellers and for this reason they resist to shop online. These factors influence the buying intentions of the online buyers (Yu & Wu, 2007).

Although online deals have peaked as of late, there improve that customer only buys a product after proper research and on recommendations of others. Costumers sometimes search online just to get the information about the product, which does not necessarily lead to actual buy (Kim, Lee, & Hae, 2004). In Pakistan, increasing numbers of customers have started to buy a product online. Organizations need to decide the key factors that impact consumer motivation. Once the factors are determined organizations then can formulate the strategy according to it.

Product association is a critical factor that has an extensive effect on buyers' buy choices and has along these lines pulled in significant consideration from consumer behavior research. Customers tend to effectively accumulate and scatter data on items or services that they are keen on, while low-contribution shoppers don't. Item inclusion has been found to have an extensive impact on different sorts of customer reactions. (Richins & Bloch, 1983).

The relation of buyer and seller through online shopping forums is an interesting topic to discuss and evaluate. It gives a picture of potential buyers and what they choose and what sellers they reject. This insight helps how the seller can expand their business, it implies through what ways they can facilitate the buyers that can attract and retain them. The consumer first decides what he wants to purchase and then chooses from the variety of available online shopping forums where he can purchase the product of his choice. The choice of selecting the source of buying something is based on certain factors including trustworthiness of the seller, its image in the market and what is the brand-named etc. (Hong & Cho, 2011). The case study will be comprised of the youth of the city of the Karachi. We will be analyzing the shopping patterns of the people living here and particularly the youth will be focused. As the internet is most used by young people and online shopping is an increasing trend among people because they want to save time and travel hassle. Therefore, people who are leading busy lives are more prone to order stuff online rather than going for shopping themselves.

The main aim of the study is to find the importance of the factors that can impact consumer online buying behavior. It is also important to know how much these factors impact the consumer's online shopping behavior.

Online shopping, where it is convenient and comforting for the people, it also has some issues associated that we will focus on this research study. For instance, late delivery of goods, wrong goods delivery, the threat of use of information of the consumer, overcharging and getting something else instead what was ordered all are the concerns that we will address in this study.
The research questions are the following:

1) How does the convenience of online shopping impact consumer buying behavior?
2) How do financial risks impact online buying behavior?
3) How do non-delivery risks influence online shopping behavior?

4) How do trust and security issues impact online buying behavior?
5) How does website design can affect the online buying behavior?

Literature Review

The literature has identified convenience as a discrete intention to visit physically malls, general stores, and street shops. Consumers always prefer to those stores that based on time or effort saving (Nobre and Dos-Santos, 2020). Previous research suggests that convenience is a most important factor it is necessary location relate to irrelevant in the online shopping scenario online shopper may be motivated by the convenience to place the order through websites at the general public place where they can easily punch the order for home delivery any suitable time. Convenience consistency with past research regarding time and effort saving (Bellenger, Danny, & Korgaonkar, 1980). Overall convenience is defined as time and effort saving for the purchaser. Convenience is a key intention that encourages the consumer to do shopping online (Swaminathan, Lepkowska-White, & Rao, 1999). However, according to other authors to (Dos Santos, 2018 and Nobre & Simões, 2019), convenience is a not relevant item for the consumer. Based on these previous literature, convinience is not relevant for consumers of short supply chains (ex: agricultural products) or luxury goods according to Nobre & Simões, (2019).

Time and effort cut down and sellers could be found easily through E-commerce (Schaupp & Bélanger, 2005). According to another research, if we match conventional shopping to online shopping, online shopping is more comfortable due to its easy usage and convenience and it is getting more prominence in Pakistan (Nazir, Tayyab, Sajid, Rashid, & Javed, 2012). Convenience is beginning to product information and penetration it could facilitate and help shoppers to motivate an online purchase decision.

According to Katawetawaraks & Wang (2011), customers tries to find out products on online stores not only for getting products but also to catch related special discounts and offers. Bhatnagar & Ghose (2004) confirm that convenience is one of the key factors for online purchasing. But for Robinson, Riley, Ruth & Gill (2007), convenience is most of the stimulus for online buyers as it provides benefits and people can buy anytime and can deliver anywhere to their preferred places. According to these authors, accessibility provides consumers to save their time and effort and it possibly poises buyers Brand conscious and store-oriented customers it based upon their present shopping motivation. On the other hand, Rohm & Swaminathan (2004), suggested that online shoppers may convenience shoppers to save time and effort or it may be balanced buyers Brand conscious and store-oriented customers it based upon their present shopping motivation.

The topmost benefit of online shopping is convenience is referred for (Clemes, Gan, & Zhang, 2014): "People who do online shopping can identify the prices and offers old-style purchases and therefore price is considered to another important aspect of convenience for online shopping. Convenience is a key motive for shopping online and save energy to buy from nearby stores".

Usually, customers get a return of a product, repair, substitute, or refund of money. It must be free of cost, if the customers have to pay for acquiring these services then definitely, they get dissatisfied which affect the online shopping market unconstructively. It is normally observed that most of the online retailers do not let the customers examine the product before the buying process and then after the delivery of products, charge on the return or delay the process of services and make the customers dissatisfied (Kunz, 1997).

Another side online customers have apprehension about monetary loss if item they shopped online neglect to execute as they are predicting besides Shoppers might be apathetic to buy online because of another cost, for example, shipping general monetary threat has been contrarily connected with web-based shopping (Forsythe, Liu, Shannon, & Gardner, (2006) and Bhattacharjee, Salman, & Rao (1999).

As customers cannot try products before buying so they are given options like money-back guarantee which must include shipping expenditure to decrease risk. Also, they should avoid delays by working together with logistics proficiency to improve delivery channel according to Comegys, Hannula, & Váisánen (2009). The capacity by which protection is given for personal information of the customer on the website is termed as security. The data of the customer must be kept secure from unauthorized use of information or disclosure of the private items during an online transaction. Security is always taken as an important factor by any online customer. It assumes an essential part of creating trust in internet shopping condition. Security alludes similarly to two sections the information and exchange security and in addition validation of the client or user (Guo, Ling, & Liu, 2012).

Trust towards web-based shopping could be measured by the security level for credit cards, private subtle elements of the client, and wellbeing and the dependability of the site. If these elements are overlooked, then it can influence the maintenance of potential clients according to Merrilees & Fry (2003).

Security refers to safe, protected and defensive acts during an online transaction in terms of financial assets and the privacy of the personal data and information. Apparently, customers have taken online transactions as a greater risk than traditional buying trend. Risks include the immoral usage of credit card information that must be safeguard by the sellers and they must assure the minimum risk to build strong relationships with the customers to retain them and provide trust over this new trend (Bhianmani, 1996).

Hong (2015) suggested that if a product is purchased from a famous online shopping store the delivery risk could have a positive result. If the online sellers are reliable, they minimize the delivery risk amongst the consumers. Because of the good reputation of big stores, consumers feel secure from unwanted transfer matters. According to Adnan (2014), the product delivery negatively affected the customer's purchasing conduct. This author also proposed that an online seller needs to give insurance coverage to online purchasers if a thing isn't conveyed to the customer in time. One of the biggest fears in consumer’s mind is not to receive the product in time and at right address (Yeniçeri & Akin, 2013).

Due to delivery risk, many consumers don’t purchase the product online. This then motivates consumers to purchase a product by hand rather than online. Those peoples who make very few purchases online do not have the effect of delivery risk. Similarly, the one who makes a lot of purchases online does have a constructive effect on product delivery (Koyuncu & Bhattacharya, 2004).

Moshref Javadi, Dolatabadi, Nourbakhsh, Poursaeedi, & Asadollahi (2012), analyses the attitudes of Iranian consumers who shop online and to see the impact of varying perceived delivery or transferring of goods risk that is involved in online shopping. They concluded that delivery risk and financial risk has not that much of an impact on consumers. While others factors positively affected the buying behavior of online customers of Iran (Moshref Javadi, Dolatabadi, Nourbakhsh, Poursaeedi, & Asadollahi, 2012).

Psychological features that include belief recognized with the graduation of the assurance a site and safeguard the consumer’s material and data secure are referred by Ariff, Yan, Zakuan, Bahari, & Jusoh (2013). They further stated that security and trust had an essential and constructive impact on consumer’s demeanor in web-based spending. The security factor demonstrates shopper’s conviction viewing web-constructed shopping and in addition the safety of money of clients’ information that must not be compensated to a stranger in web-constructed shopping according to Roman (2007).

Monsuwe & Dellaert, (2004) defined that if the consumer trust is broken; it has a negative effect on the online shopping. Again, when there is strict vigilance of the security of the client it built a positive approach towards internet-based shopping by the consumers. In this way, trust plays an important role which serves as a psychological factor that impacts the expectation of the buyer over the internet.

Online shopping has gained spark in the past years. It disguised itself as the safest thing for the customers but most people don't feel safe while shopping online. They think that it is not a safe platform for revealing their personal information because of the virtual dealing. People find online market risky and there is uncertainty among people but however, people are getting similar to online shopping (Forsythe, Liu, Shannon, & Gardner, 2006).

According to Turkey and Rome (2019); Véreb, Nobre, & Farhangmehr (2020) and Dos Santos (2018) the purpose of shopping is more towards socializing, they like to go to different markets for shopping, interact with the people over there and want to touch the product before buying it but online shopping is opposite of it. It gives ease to the shopper but beside this, there are some trust and security issues too. People don't rely on online businesses as there is no physical appearance of it (Yörük, Dündar, Mihaela Moga, & Mihaela, 2011).

The level or intensity of trust towards shopping through online sources could be gauged through several factors including credit card information protection, personal information provided by the buyer and the dependability and protection of the online shopping source (Dos Santos, & Ahmad, 2020; Nobre, Dos-Santos, & Silva, 2020). If such elements are not clearly watched and addressed, it can lose the loyal and the probable buyers (Merrilees & Fry, 2003). The key to success for the online seller is to build the trust among consumers. Surveys show that the consumer buys a product from the online websites, which they trust the most (Jiang, Jones, & Javie, 2008).

The literature confirm that websites design may attract or prevent the customers from online shopping. A customer friendly website may attract new and existing customers. Excellency of websites also increases the customer's satisfaction.

For online shopping, Secure Web design possesses fundamental importance (Shergill & Chen, 2005). A decent web design would look after all the aspects of privacy and customer services. Buyers become a victim of fraud commonly in online shopping. Therefore, having good quality websites play a vital role in attracting the customers as they can rely on the security of the website. The first impact is created by the design of the website on consumers. Prime quality and secure website captivate more customers. Most customer's gratification and disappointment depend upon the web design features.

There is a strong relationship between companies' website and consumers satisfaction. Researchers show that the positive relationship between the authentic website and customer's relationship. The more customers are satisfied with the website the more persistently they will buy from it. The appearance of the website also counts as it shows two acute elements; entertainment and information. A strong relationship was found between online shopping and website design (Prashar, Vijay, & Parsad, 2017).

The research not just focused on the impact of post-purchase on uncertainty but also on the part of pre-purchase. For retention and satisfaction of the consumer, the company should focus on pre and post-purchase level in the decision process made by the customers, for that manager should take the design of website seriously as it is the only channel which communicates the customer with the company. Website designs do not directly play a vital role in the satisfaction of the customer but may help the customer to visualize the product more conveniently (Luo, Ba, & Zhang, 2012).

To appear on the market, it is necessary for the online businesses to have their own website. The superior quality of website differentiates the company from others. It is the first interaction of the customer to the company, so, it has to be faultless. User-friendly websites play a vital role in attracting and retaining the customers (Kalia, Kaur, & Singh, 2014). For the online business, the website is the only way through which they sell their product to the end user. Indeed, depth information should be provided in the websites to clear

any type of confusion in the mind of the users. By providing good services through websites companies can attract more people and can be successful in changing the perception of doubtful quality of the product.

Consumer Behavior

Consumers use many different channels that are uncontrollable by the manufacturers and retailers (Nobre & Simões, 2019). However, there is a must needed redesign of the traditional marketing strategies to be made. All modern technologies have become modified and the internet has changed our way of shopping (Edelman & Singer, 2015).The issue that consumer has with online shopping is they hesitate due to the inability of touching the product (Choudhury & Dey, 2014).

Shopping has moved from offline to online and it is evident that stores are closing down (Cuong, 2020). Quality, trust, customer's income, security and delivery risks are such factors that emphases consumer towards online purchasing. People find online shopping more easily than traditional shopping. Online shopping does not only save time but gives a platform from where the consumer can compare product easily. However, the perceived risks associated with online transactions hold more significant and detrimental influence on consumers' shopping behaviors as compared to offline or traditional means (Li et al., 2020). There is a factor in product customization that is not much appreciated by the respondents. In a nutshell, high security during transaction should be given to the customer in order to create loyalty in them towards the company. According to the research, there are 3 big causes "fear regarding security"," poor navigation" and "inconvenience" that are creating hurdles in changing the minds of people from traditional shopping to online shopping (Vaghela, 2014).

Based on the literature the present paper presents the following hypotheses:

H1: Convenience in online shopping has no impact on the online buying behavior of the consumer.
H2: Financial risks have no impact on consumer's online buying behavior.
H3: Non-delivery risks have no impact on consumer's online buying behavior.
H4: Trust and security issues have no impact on consumer's online buying behavior.
H5: Website design has no impact on consumer's online buying behavior.

Methodology

To find the relationship between convenience, financial risks, non-delivery risks, and website design and trust and security issues on online consumer's online buying behavior of Karachi, following theoretical framework is used.

Figure 1: Theoretical Framework

Source: Results of authors (2020).

The paper determines the impact of different factors (convenience, financial risks, non-delivery, trust and security and website design) on the online buying behavior of the consumer.

Quantitative research was conducted to analyses the impact of factors on the online buying behavior of the consumer. To meet the objective of the study, primary data was collected through a direct and online questionnaire in Karachi. The Likert scale questionnaire was used to find the relationship between dependent and independent variable. It consisted of 28 questions and the response rate was about 90 %.

The sample of population consisted of those people who are frequent online shoppers and are of the middle-middle class, middle-upper class, lower-upper class and middle-upper class. Moreover, the geographical location used for this study duly comprises of Karachi, Pakistan. A total of 390 sample size was taken and convenient sampling technique was used. These also included students (from different universities of Karachi), housewives, teachers, businessman, and employees.

The model used the multiple regression model (*1*) to identify the impact of different variables on online consumer buying behavior.

$$Yij = \alpha + \beta_1 X_{1ij} + \beta_2 X_{2ij} + \beta_3 X_3 ij + \beta_4 X_{4ij} + \beta_5 X_{5ij} + \theta \qquad (1)$$

Where,

Yij= Online buying behavior of the consumer.

X_{1ij}= *Convenience.*

X_{2ij}= *Financial Risk.*

X_{3ij}= *Delivery Risk.*

X_{4ij}= *Trust and Security.*

X_{5ij}= *Website Design.*

α and β= Coefficients for i consumer *and j* period of time and error *θ.*

The econometric analysis was done in SPSS version 23 and EViews version 11..

Results and Discussion

The main age of consumers was between 21 to 30, which is almost 63.1% of the sample size. More female respondents participated in this study compared to male. Moreover, the respondents include a slightly higher percentage of unemployed and unmarried people.

Table 1: Socio-demographic characteristics of respondents

Socio-Economic Characteristics		Frequency (number)	Percent (%)
Age (years)	Under-20	123	31.5
	21-30	246	63.1
	31-40	17	4.4
	41-50	1	.3
	51+	3	.8
Gender	Female	221	56.7
	Male	169	43.3
	Other	0	0
Marital status	Single	337	86.4
	Married	48	12.3
	Divorced	5	1.3
	Other	0	0
Employment	Unemployed	285	73.1
	Employed	105	26.9
	Total	390	100.0

Source: Results of authors (2020).

The Cronbach's Alpha value of convenience is 0.727 which is greater than 0.6, which shows the reliability of the variable.

Table 2: Cronbach's Alpha value

	Cronbach's Alpha	Number of Items
Convenience	.727	5
Financial Risk	.805	4
Non-delivery Risk	.689	3
Trust & Security	.738	4
Website design	.819	4
Consumer Behavior	.727	4

Source: Results of authors (2020).

There is a statistically significant relationship between consumer behavior and convenience, financial risk, delivery risk, trust and security risk and web design in online shopping. Because sig value is less than 0.05.

Table 3: Correlation Analysis

		Convenience	Financial Risk	Delivery Risk	Trust Security	Web-Design	Cons_Behav

**. Correlation is significant at the 0.01 level (2-tailed).							

Source: Results of authors (2020).

There is a statistically significant relationship between consumer behavior and convenience, financial risk, delivery risk, trust and security risk and web design in online shopping. Because sig value is less than 0.05.

Table 4 presents the results of regression analysis. The simple correlation is .574, which shows a moderate degree of correlation. About 32.1% variation in dependent variable (Consumer behavior) can be explained by Independent variables (web design, delivery risk, trust and security, convenience and financial risks).

Table 4: Results of Regression Analysis

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.574[a]	.329	.321	.677

a. Predictors: (Constant), Web-Design, Delivery_Risk, Trust_Security, Convenience, Financial_Risk
Source: Results of authors (2020).

Table 5 presents the ANOVA analysis and indicates the significance of the model. Since the sig value is less than 0.05, the model is statistically significant.

Table 5: ANOVA Results

Model		Sum of Squares	Df	Mean Square	F	Sig.
1	**Regression**	86.356	5	17.271	37.712	.000[b]

Table 6: Results of Regression Analysis

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	.431	.218		1.975	.049
	Convenience	.233	.041	.250	5.709	.000
	Financial_Risk	.135	.040	.155	3.356	.001
	Delivery_Risk	.115	.037	.135	3.109	.002
	Trust_Security	.180	.037	.225	4.926	.000
	Web-Design	.199	.041	.218	4.866	.000

a. Dependent Variable: Consumer Behavior

Source: Results of authors (2020).

The equation of the regression will be:

Consumer Behavior = .049 + .233(Convenience) + .135(financial risk) + .115(delivery risk) + .180(trust and security) + .199(Web design).

Table 7 refers the results of hypothesis evaluation. The results highlines confirm that all the hypothesis from H1 to H5 was rejected. All the five hypotheses have been rejected that implies that all the factors studied have an impact on consumer buying behavior.

Table 7: Hypothesis Assessment Summary

Hypothesis	Sig value	Retain or Rejected
Convenience in online shopping has no impact on online buying behavior of the consumer.	.000	Rejected
Financial risks have no impact on consumer's online buying behavior.	.001	Rejected
Non-delivery risks have no impact on consumer's online buying behavior.	.002	Rejected
Trust and security issues have no impact on consumer's online buying behavior	.000	Rejected
Website design has no impact on consumer's online buying behavior.	.000	Rejected

Source: Results of authors (2020).

H1: Since p-value = .000, which is less than .05. Therefore, convenience in online shopping has an impact on consumer's online buying behavior. That means one unit change in convenience in online shopping will brings .233 unit changes in consumer's online buying behavior.
H2: Since p-value = .001, so, financial risks in online shopping have an impact on consumer's online buying behavior.
H3: Since p-value = .002, delivery risk in online shopping has an impact on consumer's online buying behavior and the hypothesis was rejected.
H4: Since p-value = .000, which is less than .05. So, trust and security issues in online shopping have an impact on consumer's online buying behavior. One unit change in trust and security issues in online shopping will bring .180 unit changes in consumer's online buying behavior.
H5: Since p-value = .000, which is less than .05. Therefore, web design has an impact on consumer's online buying behavior. One unit change in web design will bring .199 unit changes in consumer's online buying behavior.

Discussion

Convenience in online shopping has a direct impact on consumer's online buying behavior. This study also relates to the (Iqbal, Rehman, & Hunjra, 2012) that convenience in online shopping is one of the main variables. Different variety of products available online, availability of product 24/7 helps consumers to save time and traveling cost. The risks involved in online shopping like trust and security, financial risk, non-delivery risk can impact consumer's behavior online. In studies conducted by (Iqbal, Rehman, & Hunjra, 2012), (Nazir, Tayyab, Sajid, Rashid, & Javed, 2012) stated that consumer show reluctance in buying products online because of these risks. Web design of the online website shows an impact on consumer's attitude towards online shopping. A study conducted by (Lee & Lin, 2005) also showed the impact of web design on consumer buying intentions. Marketers can change the consumer attitude towards online shopping by increasing the convenience in online shopping and by improving the web design of the page but also keeping in mind all the perceived risks (financial risk, delivery risk, trust and security risk) involved in the online shopping.

Conclusion

The main results confirm that for online consumers' convenience, delivery risk, financial risk, trust and security and web design all are of importance while they choose to shop online. Therefore, marketers should ensure that all these elements are included in their source of online shopping forum. It will certainly provide them with higher sales and more loyal consumers. Also, marketers should consider that there is minimal risk involved for the online shoppers. Furthermore, there must be enough variety of products offered by one's online shopping site so that consumers can select out of the many different options. However, there must be easy exchange or return policy procedures defined by the online sellers as this facilitates the shopping patterns of the consumers. In this fast-moving world and in the era of tough competition marketers should also design their shopping platform in a way that is attractive and easy to use for the consumers so that they retain as their regular customers.

Therefore, it should be of integral importance for the marketers when they are launching an online business. It portrays that consumers focus how easily and without hassle, they can receive any product, their money is safe during transactions and they won't be overcharged or being tracked by the scammers during this process. Their personal information should be taken care of by the seller source in order not to be exploited by any scammer. Consumers are also concerned about the product safe reach to their doorstep; therefore, this should be taken care of by the online sellers. Also, the designing of the website or any other source of online shopping should be designed in a way that is lucrative for the shoppers and is user-friendly.

Acknowledgment

The authors express their gratitude to the ISCTE-IUL – DINÂMIA´CET for their financial support and also to all the respondents of the present inquiry.

The Breakthrough Technologies of a New Generation Are the Basis of An Innovative Method of Social Reproduction in Russia

Victor N. Potekhin

Candidate of economic sciences, The Urals State Agrarian University,
Ekaterinburg, Russia, e-mail: vnp1@ya.ru

Abstract

The article considers the requirements and characteristics of new-generation breakthrough technologies as the basis of a new – innovative method of social reproduction. They will provide a multiple increase in labor productivity, quality improvement of working conditions, life and well-being of the entire population of the country. On their basis, humanity will create technological, economic and basic environmental conditions for the preservation and sustainable development of civilization on Earth.

Keywords: Innovative Reproduction, Breakthrough Technologies of a New Generation, Innovative Method of Social Reproduction, Sustainable Development of Civilization on Earth.

Introduction

The history of the evolution of civilization and the constantly increasing systemic crises of the world community over the past 50 years confirm the inevitability of the transition of leading countries, and with them other countries, to a new cycle of renewal of social production. This new cycle is called an innovative production method [1]. An innovative method of reproduction is a qualitatively new set of interacting productive forces, production, superstructure and environmental relations, based on a radically new scientific, socio-economic, scientific and technical, educational, information, management base, and environmentally friendly technologies that ensure the implementation of the idea of sustainable development of society and civilization without crises and losses.

The essence of the innovative method of social reproduction

The innovative method of social reproduction involves:

- a qualitatively new scientific base for research and use of all breakthrough domestic and foreign developments in science and practice, including cinetronic supertechnologies, for the entire previous period of the history of human development. It provides a concentrated, comprehensive in a short time, the accelerated implementation of the Second industrialization in Russia, and then on the basis of cinetronic supertechnologies the creation of material-technical, socio-economic, natural, environmental, scientific-technical, educational, moral and spiritual and other prerequisites for sustainable development of the entire population on Earth [2; 3];
- transition to a qualitatively new humane model of human and social life - "Each person is the master of his life", to the advanced development of fundamentally educated and professionally trained personnel of all categories on a new scientific basis, who possess a system-integrated methodology for understanding the phenomena of nature and society, and have a harmonious high level of spiritual, moral, physical, cultural and professional development;
- breakthrough and cinetronic supertechnologies (CST), environmentally friendly and humane production of household and personal consumption;
- new generation information technologies using artificial intelligence;
- effective management systems based on a new generation of information systems at the levels of management, providing universal synergy with the plus sign;
- multiple growth of social labor productivity;
- growth of welfare and cardinal improvement of living conditions of the entire population of the country to the level of comfortable, humane, harmonious;
- environmentally friendly technologies and 100% reclamation of man-made waste and the natural environment;

Cite this Article as: Victor N. Potekhin " The Breakthrough Technologies of a New Generation Are the Basis of An Innovative Method of Social Reproduction in Russia" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

- a General civilizational approach, and with it taking into account the totality of common goals, interests, needs, and opportunities for further growth of each person, society, and the world community of the planet Earth;
- significant increase in the budget structure of social time in the proportion of useful cost-benefit and a corresponding decrease in the proportion of useless, harmful, loss cost results in the structure of social time budget [1].

The innovative method of social reproduction completely excludes: aggressive approaches and concepts of the "new world order", "golden billion", "order from chaos-controlled chaos", "liberal-democratic reforms and restructuring of the social system"; absolutization of the role of the market in regulating social production; degradation of the development of the population of Russia and the countries of the world community using various explicit and hidden methods of socio-economic, organizational-political, religious, environmental, military, etc. order and with all the resulting negative consequences.

To fully understand the essence of breakthrough technologies that make up the scientific and technological base of an innovative production method, it is necessary to recall the types (groupings) of technologies known to mankind:

- first group. Traditional technologies and groups of traditional technologies are distinguished by the degree of mechanization, automation and complexity. Moreover, the efficiency is about 0.16-0.3 of the unit;
- second group. There are breakthrough technologies based on individual physical effects of materials (for example, the so-called nanotechnologies) and their combination, on the properties of living organisms, etc., aimed at solving the problem of multiple increases in labor productivity, product quality, environmental cleanliness of production and the environment with high efficiency and EC (efficiency coefficient), close to one, but used only in individual industries and very rarely encountered in practice;
- third group. Qualitatively new cinetronic supertechnologies based on the constant use of the effect of basic physical particles in the conditions of Brownian motion of Chaos, aimed at creating hybrid cinetronic and optimizing all types of technologies into complex multifunctional modules, based on the holistic knowledge and systematic use of universal fundamental laws in practice, are distinguished – energy conservation, power conservation, cinetron pulse, golden ratio, energy information potential conservation, and others that reflect all types of movement of inanimate and living matter, the possibility of conducting public production with very high efficiency, quality, reliability, environmental cleanliness, do not violate or impoverish the natural environment in general, and provide comfortable living conditions for civilization on Earth [3; 4; 5].

Moreover, if traditional technologies are based on electromagnetism, on individual physical effects, then cinetronic supertechnologies are based on the widespread and constant use of the movement of the smallest particles, physical and socio-economic effects of the flow of Brownian Chaos, which excludes harmful effects on humans and the environment in the production and management of production. An example is the work of N. Tesla on energy.

The integration of cinetronic supertechnologies and other alternative technologies based on individual physical effects, etc. into unified complexes and systems is designed to form the scientific and technological core of using new-generation breakthrough technologies in public production in modern conditions – the basis for innovative development of Russia and the entire world community.

The most important objective characteristics of new-generation breakthrough technologies are the coefficients:

- the efficiency coefficient (EC) of the society in nature, including the tools used by it (the society), objects of labor, means of labor – means of production, production and superstructure relations, expenses for restoring the environment, from diseases, etc.;
- efficiency of machinery, equipment, machinery, technology, and other technical systems;
- the coefficient of reproducibility of natural resources (CRNR) used in public production.

They (the specified coefficients) reflect the effect of general and socio-economic laws in social production and give an objective picture of the state of affairs.

Until now, the scientific and practical literature has not developed requirements and criteria for such breakthrough technologies of a new generation, and they have not received legislative consolidation in regulatory legal acts and state standards. Accordingly, such breakthrough technologies, in our opinion, should meet the following set of criteria:

- maintaining the heat balance in nature, increasing the share of renewable and reducing the share of non-renewable energy and natural resources at the first stage to 62% and 38%, at the second-to 100% and 0%, respectively;

- high degree of technical, socio-economic and environmental efficiency of breakthrough technologies (efficiency, EC and CRNR (coefficient of reproduction of natural resources), close or more units, 100% ecological purity);
- high degree of organization of society and production through a multiple increase in the share of utility costs-results, positive implementation of the provisions in the budget structure of social time and its links simultaneously, an adequate decrease in the proportion of useless, harmful, loss cost results;
- multiple increase (in 2 – 8 times) of useful expenses-results in the budget of social time of society and its links;
- multiple (corresponding) reduction of losses, useless and harmful costs-results in the social time budget of the society and its links;
- multiple growth of social labor productivity;
- multiple reduction of production costs and saving of all types of resources;
- environmental cleanliness of production, use of man

The widespread introduction and use of advanced technologies of new generation, providing an innovative path of development and implementation of scientific and technological breakthrough, involves going on a qualitatively new level of scientific productivity, socio-economic, cultural, environmental activities economic complex of Russia, which makes it inaccessible to other states and their enterprises, developing on the basis of theories of the "golden billion", "order out of chaos", "competitive advantage", "liberal-democratic" state-monopoly system, crisis management and other similar concepts.

There are opportunities to implement such a scientific and technical breakthrough-the Second industrialization (as a form of transition to an innovative model of development – an innovative method of production) in Russia. It has the necessary scientific, technical, resource and human resources that can implement complex implementation of breakthrough technologies in all other areas of public production in a historically short time and in a concentrated manner, most of which will not become obsolete for another 50-75 years.

This will determine the strategy of socio-economic, scientific and technological development of Russia and the geopolitical development of the world civilization of the XXI century on a qualitatively new system of goals, principles, criteria and management mechanism.

The most important problem of the implementation of this technological breakthrough – the Second industrialization in Russia-is the dead-end ideas that have developed among would-be leaders about the forms and ways of technical re-equipment of industry, agriculture and other areas in the country. The prevailing traditional opinions and experience of "modern managers" to purchase foreign equipment and technology 10 or more times more expensive than a similar domestic one – with personal benefit for themselves-lead to the fact that the ratio known for extensive production remains: ensuring a 2-fold increase in labor productivity requires an 8-fold increase in investment costs. Purchased imported equipment and technologies increase labor productivity, as a rule, by 10-30%. Hence, the investment costs will be 8 times more, plus an increase of another 10 times, taking into account the prices of foreign equipment and spare parts, a total of 80 times. Is such equipment and technology worth the cost? Moreover, this technique and technology are quite old. They are usually produced for more than 40 years. This automatically determines the lag in quality and cost, and implies high costs for the products of Russian enterprises in the domestic and foreign markets.

The accelerated introduction of new-generation breakthrough technologies will allow changing the above-mentioned ratio between labor productivity growth and investment almost completely to the opposite: labor productivity will increase by 6-8 or more times, while investment will only increase by 1.5 – 2 times. As a result, government and domestic business spending on technical re-equipment of industry and other spheres of life will be significantly reduced.

Abstract

Economic activity is the main concern of society and it takes place in enterprises that use resources and become sources of wealth for the same society. The main goal of any business/enterprise, regardless of its form, has been to make a profit and gradually improve it. This is only possible through cost control and revenue growth, which is directly linked to the constant adaptation to market demands. Managing the company's activity and analyzing the level of performance are essential to have financial stability and a competitive advantage. Performance analysis techniques have a special role in following the evolution of the company and determining the problems in the processes. Thus, the company manager can set standards of excellence and ensure that they are met. The use of these methods ensures that appropriate decisions are taken to reduce costs and maximize profits. This paper aims to identify the main methods and techniques of enterprise performance analysis and proper data management, and the case study is focused on Carrefour, with the aim of studying the main key performance indicators and identifying problems. The own approach of this research consists in identifying the most important key performance indicators from the financial perspective for the elaboration of a dashboard at the level of the Carrefour organization. It could contribute to a change in the way of analyzing and investigating performance, by intervening in time on the analyzed indicators when they no longer perform.

Keywords: KPI, Dashboard, logistic regresion, performance analysis techniques;

Introduction

Currently, the enterprise has a special role in the economy, the ability of the entrepreneur being a very important neo-factor of production. Western entrepreneurship and technological progress have sprung up for centuries, with a positive influence on the world.

The basic context for the emergence of the enterprise is considered to be composed of constants such as money, accounting for the calculation of earnings, credit and basic contractual formalities.

The company's origins date back to the 16th century in India, when there were certain groups of merchants and artisans who played an important role in trade. The importance of traders grew in medieval Europe. Trade began as a profitable exchange between individuals and households, gradually growing in an organized form. Since the 1980s, organizations have replaced typewriters with computers to perform certain tasks, such as processing fees. During this

period there was a rapid increase in the outsourcing of goods and services, while firms sought new ways to reduce costs and increase efficiency.

The end of the twentieth century was marked by a rapid transition from mechanical to digital, with new technologies being used more and more, and at the same time the Internet would become a platform with a major impact on world trade. It significantly changed the way businesses operated and began to be used as an important aspect of a stable business model, through which reservations could be made for means of transport or banking.

The 21st century has meant the development of new technologies with a role in the outsourcing of administrative services, thus creating a new branch of service companies, now a competitive industry. The company has evolved in direct proportion to technology, leading to the facilitation of operations through digitization, the result being an increase in the complexity of how the company operates.

The article is structured in three main chapters that combine the theoretical elements with the practical ones, considering the efficient management of the activity and the monitoring of the performance using certain instruments later transposed in a dashboard.

The first section looks at the evolution of the company and how it was born, as well as the role of knowledge in achieving performance. Theoretical aspects of managing large volumes of data and in-depth understanding of the activity are also described. Also, in this chapter is analyzed the composition of the supply chain of a company and its importance in terms of consumer satisfaction.

The second chapter presents at a theoretical level the analysis of performance in terms of efficiency, effectiveness and adaptability. This chapter highlights the most important methods for obtaining a clear picture of the entire business and increasing customer satisfaction. At the same time, the key performance indicators that underlie the diagnosis of the company's economic activity are described, as they have an essential role in measuring progress. Also, the methods through which forecasts can be made are detailed, some of them based on mathematical elements.

The last section contains the case study on the Carrefour company, having as objective the analysis of the performance and the identification of the problems using the key performance indicators. The analysis was performed over a period of eight years (2012-2019), using as a forecasting method the logistic regression starting from financial indicators. In addition, in order to have an overview of the entire activity, a performance dashboard will be created.

The key performance indicators (KPIs) considered were used to track the evolution of the company from several points of view such as the ability to use capital efficiently and make profitable investments. On the other hand, the degree of indebtedness and the ability to fulfill one's obligations are monitored. The results of the scoreboard analysis were used to identify the level of financial stability and the degree of risk in the last eight years.

Enterprise, big data and the role of knowledge in the enterprise

At present, the enterprise has a special role in the economy, the ability of the entrepreneur being a very important neo-factor of production. Western entrepreneurship and technological progress have sprung up for centuries, with a positive influence on the world.

The basic context for the emergence of the enterprise is considered to be composed of constants such as money, accounting for the calculation of earnings, credit and basic contractual formalities.

The notion of knowledge-based organization was born in 1984-1988, being “a community of workers with design work, interconnected through a computerized infrastructure” (Holsapple C.W., 1987). A knowledge-based enterprise is focused on using and integrating knowledge to achieve performance, and resources are mainly focused on learning. Within such a company there are many opportunities for employees to learn, which are non-existent in a traditional company.

The main aspects of the knowledge-based organization are the knowledge fund, which is considered a main resource of the organization, with an important role for its performance and intellectual-intensive processes, essential for the functioning of the enterprise and achieving its objectives.

A knowledge-based enterprise has four essential dimensions:

1. Process - consists of activities carried out within the company, some of which are related to the production or sale of a product. A knowledge-based organization is focused on two interconnected processes, which support the core activities: the efficient use of existing knowledge, and the creation of new knowledge.
2. Place - refers to the boundaries of an enterprise that, for the purpose of sharing or creating knowledge, can cross traditional legal boundaries.
3. Purpose - includes the mission and strategy of the company, starting from the premise that the main strategic resource is knowledge.
4. Perspective - a knowledge-based enterprise is oriented more towards the exploitation of knowledge than towards the sale of products, knowledge being applied in any aspect of the activity.

Knowledge and organizational culture are strongly linked, and improving the way a company creates and implements knowledge could not be achieved without a simultaneous change in culture.

In its basic form, knowledge is a combination of information and the human context that enhances the capacity for action. The first dimension of knowledge can be seen at the individual, group or organizational level. The second dimension includes explicit and implicit knowledge, or structured and unstructured. Explicit or structured knowledge can be found in documents, databases and processes, and implicit or unstructured knowledge is dependent on context and personal experience.

Figure 1: The hierarchy of knowledge

Knowledge management helps the company find, select and organize important information for problem solving and decision making. It addresses issues of organizational adaptation and survival in the context of discontinuous environmental change.

Organizational culture is an important aspect in promoting knowledge sharing and creation. It can be described by values, norms and practices. Values highlight the beliefs of members of an organization about what should be done, indicating preferences for a specific outcome or behavior. The rules are common views on how members should behave or how to perform their tasks. Practices include the formal or informal routines of the organization to achieve its goals, such as implementation processes or group meetings.

Culture has a mediating role in the relationship between knowledge at the individual level and at the organizational level, creating the context for social interaction. It also has a significant role in the efficient management of knowledge. Knowledge shared and maintained within the enterprise has a key role to play in productivity and process improvement. Knowledge management aims at the simultaneous development of each component within a company, such as staff, equipment, space.

Big Data refers to the large volume of data that is difficult to manage, which requires the use of various technologies in order to obtain information. The term "Big Data" was coined to differentiate the abundance of unstructured data, machine-generated data from ordinary data that has been generated by transactional systems for many years. Unstructured data is represented by documents, photos, videos, social media, while structured data comes from relational databases, company resource planning, customer relationship management.

The McKinsey Global Institute predicts that the volume of data will increase by 40% per year (James Manyika, 2011). Although the volume of data is often the most visible parameter, there are other issues that matter. The four characteristics that define Big Data are:

- Volume: Represents the amount of data generated, the volume of data can reach unprecedented levels. It is estimated that 2.5 quintillion bytes of data are generated every day, with large companies having terabytes or petabytes of data stored on devices or servers. This data is used to shape the future of an enterprise and its activities, while monitoring progress.
- Speed: Social media data produces a large flow of valuable opinions for the customer relationship. Facebook users upload more than 900 million photos in a single day. Speed is directly related to the entire data infrastructure in managing and delivering data to recipients as quickly as possible.
- Variety: Variety in Big Data refers to structured and unstructured data that can be generated by either humans or machines. The most frequently added data are txt structures, tweets, videos and images. Variety involves the ability to divide the data received into various categories.
- Truthfulness: refers to an uncertainty of available data, preventing companies from reacting quickly and finding appropriate solutions. The main problem in such a large data environment is accuracy. For a better data use strategy, the data must be organized according to groups, value and significance; data needs to be clean, consistent and consolidated.

Big Data analysis can be used to discover certain opportunities that are not obvious at first glance; many companies extract large amounts of data in order to find out hidden information that was not previously available to them.

In order to capitalize on everything related to a large volume of data, it is necessary to structure all non-structured data, and this can be done by using approaches to decipher the meaning of unstructured data and group them according to important areas, such as customer, product, market, company, etc. The next step is to perform a predictive analysis by extracting templates from the data and using them to predict possible future trends. Because they cannot be determined exactly, probability intervals can be useful in regulating resource implementation decisions and setting expectations.

Following the predictive analysis, the future requirements of the market can be identified, thus managing to attract a larger number of consumers. Big Data also allows you to profile customers and engage in a real-time conversation with them. For example, when a customer enters the bank, the official can check his profile, finding out his preferences, using this information to recommend the relevant products and services for that customer.
The tools in this field allow the mapping of all data within the company and the analysis of all internal threats. Thus, sensitive information can be kept secure in accordance with regulatory requirements. Security and data protection are indispensable in financial organizations.

Methods for measuring the performance of an enterprise

Regarding the analysis of a company's performance, as well as its competitiveness in the market, three dimensions can be identified: efficiency, effectiveness and adaptability.

Efficiency assesses the proportion of limited resources used in the production process to achieve a certain result. This concept is based on the terms inputs and outputs, an efficient enterprise being the one that results in as much volume as possible using a limited amount of inputs. Efficiency is not a measure of market success, pursuing productivity and minimizing costs.

Effectiveness is determined by the degree to which the result obtained is in line with the proposed objective. It is also closely linked to the means adopted by each company to generate sustainable growth in the business environment.

Adaptability involves analyzing changes in efficiency and effectiveness that have occurred as a result of a change in the company's environment.

An important aspect is also the focus on efficiency and neglect of effectiveness result in temporary profitability. On the other hand, considering only efficiency has the effect of lack of profitability given that the opportunity cost of capital is higher compared to the profit obtained.

Efficiency involves financial discipline as well as control over working capital, while efficiency requires the ability to adopt the appropriate means for sustainable growth, being directly proportional to the firm's access to and differentiation from other companies' private resources.

Businesses apply various methods to increase both the level of efficiency and effectiveness. More and more companies have taken over the organization of staff in teams as a technique to increase performance, being considered a key element for increased efficiency. It was also tried to identify the bases of effectiveness starting from the nature of teamwork. Cloud computing has proven to be a tool with many advantages in terms of efficiency through easy document sharing and active collaboration, while reducing certain costs.

In order to be considered competitive, a company must use its resources to produce the appropriate, quality goods, setting an appropriate price. In the long run, competitiveness is measured by the company's ability to continue its business and protect its investment, generating its profitability. Productivity is considered a determining factor for a company's competitiveness, along with profitability and participation in the internal and external market.

Productivity is the result of the interaction between organizational management and external factors, constituting the ability to transform the inputs used into products. In economics, this is the rationale of what is produced and what resources are needed for that production, which is measured by comparing inputs and outputs. Productivity measurement is reflected in changes in production efficiency. Also, in order to increase the company's productivity, it is recommended to identify and analyze inefficient resources, so as to reduce unnecessary expenses. In highly productive organizations a direct link can be seen between productivity and competitive advantage.

Customer Relationship Management

Customer Relationship Management is a business strategy that involves understanding, anticipating and managing customer needs, in order to maintain long-term mutually beneficial relationships. This is a shift from traditional marketing that focuses on retaining current customers and attracting others. A CRM tool creates a simple interface for a data collection, so that the company can communicate with consumers in an accessible way.

The objective of this strategy is to create value for both buyers and the company in the long run, offering the opportunity to have a competitive advantage over companies in the market that offer similar products and also an increase in profit.

Customer relationship management helps companies find out useful information about them, such as the category they belong to and why they buy products, forecasting purchasing trends. Thus, the needs that need to be met later can be anticipated. By organizing customer data, the appropriate selection of recipients for promotions and new products is ensured.

Another advantage of this concept is the increase of efficiency by automating certain aspects such as sales processes and marketing campaigns, allowing the structuring of processes into simpler data.

The main types of customer relationship management are: operational, analytical and collaborative.

Operational CRM focuses on automating and improving processes based on customer relationships, being suitable for companies with a shorter sales cycle and e-commerce.

Analytical CRM specializes in analyzing information about buyers, determining their behavior and market trends. It uses data mining techniques, being suitable for companies in a market with high prices and many competitors.

Collaborative CRM involves sharing information with external companies, by combining data, being possible to increase customer satisfaction. It is suitable for markets where innovation and the development of new products are essential for success.

Technology has an important role in customer relationship management, involving the use of databases and data mining techniques. The benefits are reduced costs by increasing effectiveness and efficiency, making a long-term profit and maximizing opportunities.

Dashboard

A dashboard is an information management tool that analyzes, selects and displays key performance indicators (KPIs) to identify the situation of the company and the synthesis of the activity carried out. It offers the possibility to monitor in real time and increase the performance, thus reducing the analysis time.

Dashboards can make it easier to view data and share key information both internally and outside the company. They also contain predictive analyzes, determining trends and patterns. Thus, it can be useful for strategy, planning and analysis.

The main features of a dashboard are:

- Synergy- A visually efficient and ergonomic design is needed to be able to synthesize certain information from a single view.
- Accuracy - The information captured must be accurate in its entirety, the rendering of economic processes must be accurate, and their transmission in real time.
- Flexibility- The structure can be adjusted according to the changes.
- Accessibility- The information must be configured so that it can be used quickly and meet predefined thresholds.
- News- Data display must be done in real time for effective decisions.

The elaboration of a dashboard can be done in four stages:

1. Identifying problems and determining objectives- Choosing key data and performance indicators to be highlighted in the dashboard.
2. Determining end-users and establishing a plan- Identifying information that is relevant to the end-user and that directly influences the objective.
3. Selection of appropriate indicators - Selection of the most relevant indicators in terms of assessing the outcome of actions.
4. Drawing up the dashboard - Using ways that allow a good view of the indicators, so that the message is communicated effectively.

Dashboards can be of three types: operational (allow supervisors to monitor operational processes), tactical (allow analysis of processes in each department) and strategic (monitor progress towards the proposed objective).

The advantages of dashboards include: real-time monitoring of changes, centralization of all data in one place so that they can be accessed by all users, forecasting based on current trends and identifying negative trends.

Dashboards can be made for each department of the company, such as: legal, IT, financial, human resources, accounting, marketing.

Balanced Scorecard

Balanced Scorecard is a method of aligning the company's activities with the vision, while evaluating performance. It is also a mechanism that can be used to implement the strategy, defining important success factors.

This technique can be used to improve organizational performance, focus on strategy and results, and communicate vision and strategy appropriately. Scorecards consist of quantitative components, both visual (tables, graphs) and symbolic (key performance indicators).

The Balanced Scorecard model includes viewing the business from four perspectives:

- Financial- Satisfying the requirements of shareholders and creating value. Examples of measures: economic added value, cash flow.
- Internal business processes - The quality of internal processes, establishing the desired level of productivity. Includes measurements in terms of innovation, activities (quality, time, cost) and after-sales services.

- Development and innovation- Engaging all intangible resources in order to improve critical processes. Includes measurements in terms of staff (training, skills) and system.
- Customer- Satisfying customer needs. Examples of measures: customer satisfaction, profitability, market share.

Figure 2: Integrating the four perspectives of the Balanced Scorecard

Source: Processing according to Building Performance Dashboards and Balanced Scorecards, Christopher Price et al., 2014, pp 7;

The main advantages of Balanced Scorecards are: providing a clear image of the company, understanding strategies at all levels and continuous improvement of economic activity.

The difference between scorecards and dashboards is their functions: although they are related techniques, the former can be used to manage performance, while the latter helps to monitor performance. Also, the application context is different: scorecards are strategic and dashboards operational. A scorecard provides information that is not found in a dashboard, with in-depth analysis capabilities and performance predictions. On the other hand, the second is more open to interpretation.

Benchmarking

Benchmarking is a continuous systematic process of measuring outputs and processes, identifying the main sources of competitive advantage. Through this method an enterprise can protect itself against competition.

The main types of benchmarking are:

- Internal - Comparison of processes carried out within the company. It is easy to implement and provides quick access to data, but is time consuming.
- Functional - Comparison of functions and work tactics activated in different sectors. It is not suitable for any type of business.
- General- Identifying innovative technologies that can be used in several types of economic activities.
- Competitive - Comparison with similar companies based on performance measures.

The benefits of benchmarking include identifying the strengths and weaknesses of an enterprise and improving its competitive advantage. It is also cost-effective and time-efficient. These can be done for goods and services, work processes, human resources department, organizational performance and strategies.
Using this method, standards of excellence can be established and met by constantly searching for the best processes and applying them, while improving organizational performance. On the other hand, one can identify how the processes of the best listed companies on the market work.

Key Performance Indicators

Key performance indicators are financial and non-financial indicators used to estimate a company's success, pursuing long-term goals previously set. High-level KPIs focus on the overall performance of the company, and on the other hand low-level KPIs consider processes in departments such as marketing, sales, human resources.

These indicators are focused on future results, underlying decision-making by providing accurate information on trends. They are also used in various industries for specialized purposes, such as: maintenance, sales, construction, marketing, supply chain management and information technology (IT). KPIs used in IT contain: code (number of lines of code), complexity (loops), understanding inputs and outputs, antivirus.

The purpose of a KPI is to track performance measures that track changes towards a target, indicating the level of progress made in achieving the project objectives. At the same time, key performance indicators identify the relevant elements for performance and for providing information on the appropriate controllable factors for making decisions that will lead to a positive outcome. On the other hand, they do not indicate the measures to be taken to correct deviations from the target.

The three high-level goals of the indicators are: team motivation, compliance with the use of organizational process assets and alignment with company objectives, improving performance and taking over best practices.

The SMART rule is used in the literature to identify the characteristics of a KPI:

- Specific (S) - is focused on performance goals;
- Measurable (M) - can be expressed quantitatively;
- Achievable (A-attainable) - targets are reasonable, achievable;
- Realistic (R) - is relevant to the work done in the project;
- Time-based (T) - is measurable over a period of time.

The components of a key performance indicator are: measurement, target (a set of values against which measurements will be made), data source and reporting frequency (at least monthly). The main types of targets are: simple quantitative, time-based objectives (measurements performed at a certain time interval), completion objectives (measurements performed at the end of the project).

The most used financial KPIs are: net profit margin, operating cash flow, inventory turnover (sales / inventory), return on equity (return on equity) and EBITDA (profit before interest, taxes, depreciation and depreciation). The latter is calculated by the sum of net profit, interest expense, tax expense, depreciation and amortization expense. Depreciation refers to property, plant and equipment and depreciation to intangible assets.

The net profit margin (net profit / income) indicates the level of efficiency of a company that generates profit compared to its income. Usually calculated as a percentage, it shows how many monetary units earned are translated into profit.

Return on equity measures a company's ability to use shareholder investments efficiently, generating high profits. It is calculated by dividing net income by equity.

Non-financial KPIs can be an advantage in identifying strengths and weaknesses, as well as providing better feedback to employees on how to meet strategic objectives. Thus, the staff is able to understand exactly what they have to do, there is a link between daily tasks and strategic direction.

Examples of non-financial indicators are: customer retention rate (number of consumers remaining customers over a given reporting period, calculated as the ratio of customers lost in a given period to the number of customers at the beginning of the period), employee productivity rate (force efficiency of labor, calculated as the ratio between the total income of the company and the total number of employees), the percentage of project delays (number of delayed projects / total number of projects).

Key performance indicators are of particular importance in monitoring the state of the enterprise and in measuring progress. They can also be used to make adjustments and predict future results, but also to solve certain problems and address opportunities.

The techniques of analyzing the performance of an enterprise are of particular importance for its stability, determining the current financial position. They identify the company's situation, assessing whether it is in line with the vision and objectives, thus highlighting the main problems.

The main advantages of these techniques are the centralization of all data in one place so that it can be accessed by all users, the identification of trends and the significant reduction of time. Also, through these techniques predictive analyzes can be performed based on current trends, highlighting certain patterns useful for strategy and planning.

Proper management of information using these techniques ensures that the right decisions are made to remedy problems and focus on results. On the other hand, standards of excellence are set and the best processes are determined to achieve them.

In conclusion, the techniques of analyzing the performance of an enterprise are essential for an enterprise, providing a clear picture and understanding of strategies at all levels. With their help, a continuous improvement of the economic activity can be ensured, at the same time reducing the costs.

Case Study: Carrefour performance monitoring

Carrefour is a French multinational corporation specializing in retail, being among the first positions in the top supermarket chains globally. It was founded in 1959, with Marcel Fouriner and Louis Defforey as founders. In 1960, the first store was opened in the Annecy district of Haute-Savoie.

The Carrefour Group was the first to introduce the concept of a hypermarket in Europe, opening one in 1963 in a town near Paris, Sainte-Geneviève-des-bois. The success was based on low prices, stock turnover and reduced equipment costs. The innovative nature of weighing, packaging and collection has also attracted a large number of consumers, with a negative impact on small businesses.

In 1970, the company's shares were listed on the Paris Stock Exchange. At that time, high inflation resulted in increased competition for food prices. In 1973, the Royer law was passed in France, imposing restrictions on large stores. Thus, Carrefour focused on expanding to other countries (Spain in 1973, Brazil in 1976 and Argentina in 1982).

In April 1976, a line of fifty foodstuffs was launched with a private label called “Produits libres” and substantially lower prices.

Carrefour merged in 1999 with its main competitor, Promodès SA, with the effect of increased competition and weaker sales in France, and thus its market share decreased. On the other hand, during this period the first hypermarkets were opened in Asia.

In 2017 Carrefour gave birth to a French start-up, Expliceat, building a mill designed to crush the remaining bread, later using the crumbs for various pastries. A strategic plan ("Carrefour 2022") was also announced a year later, which includes improved food sustainability, waste reduction and the development of organic products.

Figure 3: Swot Analysis

In terms of listing, the market capitalization is $ 12.04 billion and the value of the enterprise is $ 29.76 billion. Also, the profit margin is 1.53%, which means that the company earns $ 0.0153 for every dollar traded.

Database Description

In this research we chose as an analysis study the financial indicators of Carrefour from the period between 2012 and 2019, the data source being the site http://www.carrefour.com/content/results, accessed on 15.09.2020. Thus, the indicators contained in the database are total revenues, gross profit, net sales and net income, expressed in millions of euros. Also, the evolution of performance can be analyzed using EBITDA (profit before interest, taxes, depreciation and amortization), cash flow, but also marginal indicators such as gross margin (calculated as the ratio between the difference between income and costs of goods sold and income) , net profit margin, return on equity (ROE), return on investment (ROI) and return on assets (ROA).

Return on investment measures the return on investment relative to its cost, calculated as net profit divided by cost and expressed as a percentage.

The return on assets indicates the efficiency of the firm's use of assets, calculated as the ratio between net profit and total assets.

In terms of net sales, they are recorded between 2012 and 2019, expressed in detail for each continent (Europe, Latin America and Asia). On the other hand, the database contains information on the main categories of products sold in Carrefour stores, as well as the number of products of each type.

Another category of financial indicators included in the database is liquidity, efficiency and exchange ratios. Thus, data on the current ratio, the fast ratio and the debt / equity ratio of the last eight years were introduced in order to analyze the company's ability to meet its financial obligations. The database also contains stock turnover rates, which are then used to measure the short-term performance of the company.

In addition, essential data of the company are included such as share capital (contributions of all partners), depreciation, amortization and investment expenses, net debts and the total number of employees.

Behavioral influence of consumers using logistic regression

Key performance indicators are of particular importance in measuring overall performance and determining the factors that directly influence consumers. In the case of Carrefour, there is a strong link between these indicators, significantly impacting financial results and market positioning.

Figure 4: Correlation matrix of key performance indicators

At first glance, we can say that in the matrix of correlation coefficients there are both positive and negative correlations. Also, some variables are strongly correlated with others, with a correlation coefficient higher than 70%. Thus, they have a similar behavior and evolve in the same direction. In the figure above you can see very high correlation coefficients. Thus, the net sales strongly impact the revenues (correlation coefficient 93%) and implicitly the gross profit (correlation coefficient 94%), these variables having a special relevance in the analysis of Carrefour's performance. On the other hand, gross profit is 75% influenced by investment expenditure, suggesting that the increase in investment would result in higher gross profit.

Another direct relationship is between the net result and ROE, the correlation coefficient being 73%.

It can be stated that EBITDA has a behavior similar to that of the ROA variable, the first indicator directly influencing the return on total invested capital, but also the efficiency of shareholders' capital use with ROE, coefficient of 73%). Also, the ROA variable is 74% dependent on net debt, an increase in debt means a low rate of return on assets. On the other hand, in terms of net profit margin, it is strongly correlated with ROI, the coefficient being 72%, both indicators being significant for determining the level of efficiency of Carrefour.

Observing the two figures, one can see a low relevance of the variables net cash flow and operating expenses, which can be eliminated from the analysis.

Figure 5: Analysis of the evolution of the ROA indicator according to the EBITDA indicator

Although it is a difficult approach to understand and can be criticized if we think only inside the box and not outside the box, the following regression was performed to observe the links between ROE and EBITDA influence in measuring the performance of the analyzed enterprise. From the figure above, we can see a direct and positive link between the financial indicators EBITDA and ROA in the case of Carrefour, evolving in the same direction. On the other hand, the values are not evenly distributed on the regression line, there are certain values as outliers.

```

Figure 6: Relationship between EBITDA and ROA indicators

Regarding the analysis of the link between EBITDA and ROA indicators, we can say that the linear regression model is a valid one, p-value having the value of 0.002096, less than 0.05.

The relationship between the two financial indicators is strong, the variation of the ROA variable being determined in proportion of 81.61% by the evolution of the EBITDA variable, the rest being explained by other factors. Thus, a higher value of profit before interest, taxes, depreciation and amortization would mean an increase in the efficiency of the use of assets.

The linear regression equation is $y = -2.39097 + 0.00143 * x$, where the dependent variable (y) is ROA and the independent one (x) is EBITDA, which assumes that when changing the value of the EBITDA indicator by a monetary unit, the rate of return on assets for the firm Carrefour will be modified by 0.00143 units.

The Carrefour store network is predominant in France and other European countries, as well as in Latin America. Also, approximately 250 supermarkets are opened in Asia, in 2016 the company also approached the African market. Consumer satisfaction varies from region to region, being influenced by certain factors.

We will establish the link between consumer satisfaction and the number of stores open in each region, net sales and operating income. The dependent variable is the degree of satisfaction, having 3 values: dissatisfied, satisfied and very satisfied, taking as a reference the number of very satisfied consumers.

The equations of the regression model can be described as:

$$\ln\left(p\left(\frac{Dissatisfied\ customers}{Very\ satisfied\ customers}\right)\right) = 0.0032 + 0.00022 * net_{sales} + 0.22 * operating_{income} - 0.033 * number_{stores} = y_1;$$

$$\ln\left(p\left(\frac{Dissatisfied\ customers}{Very\ satisfied\ customers}\right)\right) = -0.0017 + 0.0026 * net_{sales} - 0.16 * operating_{income} + 0.005 * number_{stores} = y_2;$$

$$\frac{p(Dissatisfied\ customers)+p(Satisfied\ customers)}{p(Very\ satisfied\ customers)} = e^{y_1} + e^{y_2};$$

$$p(Dissatisfied\ customers) = \frac{e^{y_1}}{e^{y_1}+e^{y_2}};$$

$$p(Satisfied\ customers) = \frac{e^{y_2}}{e^{y_1}+e^{y_2}};$$

Thus, we can see that an increase by one unit in the number of stores is associated with a decrease in the chances of being dissatisfied consumers compared to those who are very satisfied by 0.033 and also an increase in the chances of being satisfied consumers by 0.005.

>exp(coef(model)

Table 1: Coefficients of the logistic regression model

	Intercept	Net sales	Operating income	Number of stories
Dissatisfied	1.0031857	1.000224	1.2444328	0.9674362
Satisfied	0.9983065	1.002599	0.8539176	1.0046503

We can say that the chances that the degree of satisfaction will be reduced are 3% lower, and those that the degree will be high are 0.5% higher than the chances that the degree of satisfaction will be very high in case of increasing the variable number of stores by one unit.

Table 2: Matrix of confusion

	Very satisfied	Dissatisfied	Satisfied
Very satisfied	1	0	0
Dissatisfied	0	2	0
Satisfied	0	0	1

Of the 4 regions (Latin America, Asia, France, Other European countries), all were correctly labeled (being positioned on the main diagonal). Thus, consumers attracted by Carrefour in Latin America and Asia are dissatisfied, those in France are satisfied, and customers in other European countries are very satisfied. Following the analysis, we can see that the opening of new supermarkets would result in a higher degree of satisfaction.

Figure 7: Analysis of the evolution of net sales according to the number of stores

Also, the link between the number of stores and net sales in the four regions is a direct one, and the increase in the number of supermarkets would lead to an increase in sales.

Key performance indicators (KPIs) are of particular importance in analyzing the evolution of the enterprise from a financial point of view. As for Carrefour, there is a strong link between certain kpi, the indicators can be divided into several classes. These indicators represent the effects of the realized production and the services offered to the consumers, highlighting the company's efficiency.

Based on the analysis of the correlations between the indicators, we proposed the grouping of revenues, net sales and gross profit in a first cluster, debt and EBITDA in a second cluster, and ROI, ROE and net income in a third cluster, evolving in the same sense.

The first cluster contains the most important results, highlighting the company's ability to obtain revenue and at the same time satisfy customer demand. It is directly related to the company's objectives, indicating its financial stabilization and position.

The second cluster contains indices through which it is possible to analyze how efficiently the assets are used and the ability to pay their debts. It has a direct relationship with the third cluster, highlighting how efficiently equity is used, but also investments to increase the value of the net result, this being one of the main objectives of Carrefour.

As for the financial indicators belonging to the first class, they have an oscillating trend. Between 2012 and 2014, the trend was a decrease in net sales and revenues, following a slight increase that reached its peak in 2017. Starting with 2017, revenues and implicitly profit were continuously decreasing.

The decrease in revenues is caused, according to critics, by the follow-up of a business model developed in 1960, which does not comply with the current market situation, requiring an improvement in the mode of operation. Also, the negative trend of margins in France was caused by high costs related to the acquisition and transformation of a network of 400 Dia supermarkets, this acquisition being made in the fourth quarter of 2016. Thus, in 2017 the company Carrefour suffered significant losses, taking at least a year to form a customer base. These results were also felt in the company's net result.

Although the net result has been steadily declining since 2014, it was positive until 2017. In 2017 and 2018 Carrefour had very high losses in France, which represents half of the group's revenues, sales falling for six quarters row. The negative net results were a consequence of the large loans made to purchase the Dia chain of stores in France. The investment did not generate the expected revenue, and the costs of keeping stores in France open resulted in significant losses.

After two years in which negative results were registered, in 2019 the net result was 1311 million euros, Carrefour investing in remodeling the initial format and modernizing the stores to increase sales. The company's transformation plan includes reducing sales promotions in France, focusing on lower prices and reducing the number of non-food items. In addition, they initiated the merging of supply chains of supermarkets with those of hypermarkets and the restructuring of IT systems to generate savings.

Carrefour recorded the highest level of debt in 2014, reaching the threshold of 9 billion euros. The increase in net debt was caused by the group's desire to accelerate expansion in emerging markets in Brazil and China by taking over a network of competing stores, which is only possible through large loans. After 2014, the debt level had an increasing trend, in 2019 reaching the lowest threshold in the last 10 years.

Regarding the EBITDA indicator (the company's earnings before interest, taxes, depreciation and amortization), it had an upward trend until 2016, after which it started to decrease gradually. Thus, the company generated a higher income before the acquisition of the Dia supermarket network.

Return on equity decreased significantly between 2014 and 2017, reaching a negative threshold, suggesting an inefficient use of shareholder investments by acquiring non-profit chain stores in France and Latin America during that period. Starting with 2018, the results have increased as a result of the implementation of the project to transform the initial format.

Regarding the ROI indicator, it fluctuates from year to year, registering decreases between 2013-2014 and 2015-2017, in 2017 having a negative value. Thus, Carrefour did not always invest efficiently, with the total costs exceeding the return on the investment. Starting with 2018, the return on investment has been constantly growing, with the competing networks purchased generating higher and higher revenues.

The decreasing trend of net profit was also felt in the net profit margin, which had a negative value in 2017, indicating that Carrefour no longer had the ability to make a profit effectively relative to its revenues. As a result, the market share decreased, leading to an increase in the market share of the main competitors.

Since 2018, the net profit margin has had an increasing trend, the evolution being similar to the other key performance indicators, this being the year in which Carrefour began to recover financially.

Another category of financial accounting indicator used as enterprise performance measures includes liquidity, efficiency and exchange ratios. Liquidity ratios highlight the company's ability to meet its short-term financial obligations without the use of external capital. The main liquidity ratios are the current ratio and the fast ratio.

The current ratio measures the ability to pay current debts with current assets (cash, accounts receivable and inventories). It is calculated by dividing current assets by current liabilities.

The rapid report analyzes the ability to meet short-term obligations with the most liquid assets.

Efficiency reports (or activity reports) are used to measure the company's short-term performance, highlighting the ability to use assets appropriately to generate revenue. An example of such a report is the stock turnover rate, which shows how many times the inventory has been sold and replaced in a given period.

In terms of stock turnover, its value is quite high, meaning that Carrefour can meet consumer demand without depleting its stock, and at the same time does not have a lot of money stuck in stocks. Also, the costs of storing the products are low, because they are sold in a short time. The lowest value of the stock turnover rate in the case of Carrefour was met in 2016 as a result of the slowdown in sales.

In 2018, Carrefour started implementing the Carrefour 2022 strategic plan, with the main objectives of streamlining the organizational structure, obtaining higher productivity gains, investing in e-commerce and focusing on product quality. Thus, the aim is to reduce management costs in order to offer competitive prices, increased control over

expenditure and improve operational efficiency. The initial proposal is to reduce spending by 2.8 billion euros gross by 2020.

Significant cost reductions and a more effective investment policy are needed to increase growth and improve competitiveness. The cost reduction plan focuses on the operational efficiency of the supply chain and the simplification of headquarters organizations. Therefore, the group's intention is to reduce the number of stores that belonged to the Dia chain by 273, as they are not adapted to their catchment area.

In terms of investments, a large part of them will be allocated to the supply chain for the automation of order preparation platforms. It also aims to open 2,000 stores between 2018 and 2022 and invest 2.8 billion euros in the digital platform.

Following the implementation of the strategic plan, in 2019 there were solid increases in sales, with 25% more in terms of organic products (sales worth 2.3 billion euros) and 30% more in the case of e-commerce (up to € 1.3 billion). At the same time, recurring operating income increased by 145 million euros compared to the previous year, suggesting a solid and profitable growth.

Carrefour has managed to achieve a satisfactory level of competitiveness in key regions such as Latin America and Spain, and in France it has refocused, improving its price positioning. While the profit margin decreased by 0.7% in France due to increased competition, it stabilized at 3.2% in the rest of Europe, and in Latin America Carrefour consolidated its operating profit margin from 4.5% to 5.7%. The company also managed to save 1.05 billion euros following the closure of the 273 Dia stores.

Observing the results obtained by applying the Carrefour 2022 plan, we can say an increase in the level of efficiency due to financial discipline, complemented by an increase in efficiency, the results being in line with the proposed objectives. Thus, Carrefour has adopted the appropriate means for sustainable growth and high competitiveness.

The productivity of the company can be measured by comparing the inputs used and outputs, also reflected in changes in efficiency.

Figure 8: Value flow analysis

Dashboard Carrefour

There are many factors that directly influence the performance of Carrefour and should be taken into account to improve the business. Given that about 50% of the company's revenue comes from sales in France, it is necessary to bring innovative elements to retain or even increase the number of customers. Latin America is also an investment-friendly region, with the opening of new stores leading to increased profits. As for the Asia region, it has a lot of potential for the development of a hypermarket chain, with high purchasing power.

Figure 9: Dashboard Carrefour

Debts are an important aspect in the company's analysis, as they have been growing since the last quarter of 2016. Thus, the debt / equity ratio has had a significantly higher value in recent years, indicating that much of Carrefour's financing comes from bank loans. Observing these indicators, we can say that the company is subject to a rather high risk, and it has a low capacity to pay its outstanding debts.

In the case of returns, in recent years the company has used its capital inefficiently, and on the other hand has had losses caused by certain investments, meaning that in the future the following investments should be analyzed in detail for a low degree of risk.

The current report recently suggests that the Carrefour group does not have enough assets to pay its current debts, unable to meet its obligations without selling inventory. One cause of the low current ratio would be too many loans made to buy a competing chain of stores.

Gross margin has a declining trend since 2017, although it does not deviate much from the average of recent years. The average value of the gross margin is 23, meaning that for every euro generated from sales, Carrefour generated 23 eurocents in gross profit before other expenses, which is not a high value. Also, the company's problems between 2016 and 2018 were felt in the net profit margin, suggesting a reduced ability to generate profit from sales.

Regarding the overall performance of Carrefour, it reached the lower threshold between 2017 and 2018, the uninspired decisions of the company being felt in the case of all financial indicators. The gradual increase in debt has led to financial instability, and the inefficient use of all available resources has severely reduced profitability. In addition, there was a major impact on the net result, which was negative for two consecutive years.

Although in 2019 the indicators suggest an improvement in the financial situation, a careful analysis of all investments and avoidance of loans is necessary. In order to increase profits, it would be advisable to exploit potential regions by gradually opening new stores. The region that could negatively influence the results is France, and for this reason a strategy for financial stabilization is indicated by closing stores that have low sales and offering competitive prices.

After the large losses in 2017 and 2018, Carrefour is on an upward slope due to the Carrefour 2022 project aimed at improving the business by reducing costs and investing in technology. However, the level of performance cannot be maintained on this upward trend if equity and equity are not used effectively, which is something to keep in mind. On the other hand, the increase in sales and the increase in net income are directly linked to meeting market requirements and openness to online commerce, which are among the main objectives of Carrefour's new strategic plan. Thus, the chances of paying off debts and generating profit are high.

Conclusions

Performance analysis is one of the main concerns of a company's management, because only by analyzing the activity and identifying problems in the processes can maximize profit. Thus, it is necessary to select the most appropriate methods according to the company's objectives.

Another important concept for the company is customer relationship management (CRM), facilitating communication between the company and consumers and helping to increase efficiency by automating certain sales processes.

The main tools for information management and analysis of the indicators detailed in this paper are: Balanced Scorecard, which aligns the company's activities with its vision, Benchmarking, through which you can identify strengths and weaknesses, the performance pyramid, which is focuses on external effectiveness and internal efficiency and the dashboard, which presents an overview of the company's results. At the same time, it is necessary to determine trends and predict future market requirements, in this regard being addressed certain methods such as logistic regression and extrapolation.

An effective analysis of an enterprise starts from key performance indicators (KPIs), which are the basis for decision-making. They aim to align with the objectives and take over the best strategies and practices.
The present research has as practical object of study the analysis of the KPIs of Carrefour and the follow-up of the evolution from the financial point of view between 2012 and 2019. Thus, we noticed a strong relationship between certain indicators which were later grouped as follows: revenues, net sales and gross profit in a first cluster, debt and EBITDA in a second cluster, and ROI, ROE and net income in a third cluster, evolving in the same direction.

Analyzing with the help of Excel the indicators of Carrefour company, we identified certain problems starting with the last quarter of 2016 until the end of 2018, being registered a net negative result two consecutive years. In 2017, the losses caused by the investment made at the end of 2016 were most felt through the purchase of a competing chain of stores in France, the profitability and the net profit margin decreasing sharply.

Although Carrefour encountered some difficulties and a high degree of risk generated by inefficient investments and excessive bank lending, the strategic plan "Carrefour 2022" launched in 2018 generated positive results and a visible upward slope due to reduced spending and investment in technology. In 2019, the company managed to reach a satisfactory level of competitiveness in key regions and to save more and more. Thus, we can say that through the implementation of this project the levels of efficiency and effectiveness and implicitly the performance has increased.

The evolution of the main key performance indicators of Carrefour company was captured in a Dashboard, through which they can be monitored by year.

In future research we want to apply the viable system model developed by the father of managerial cybernetics, Stafford Beer, to make a diagnosis of Carrefour which would have the role of investigating the functioning of the organization and its management. This qualitative method helps to identify the basic deficiencies that can lead to poor performance.

Elimination of Correction Mechanisms in The EU Budget – Financial Consequences for Member States

Katarzyna STABRYLA-CHUDZIO

Cracow University of Economics, Cracow, Poland
E-mail: stabrylk@uek.krakow.pl

Abstract

The withdrawal of the United Kingdom from the European Union and the negotiations on the Multiannual Financial Framework 2021-2027 prompted a discussion on the possible liquidation of correction mechanisms in the EU budget and thus simplification of the EU's own revenue system. The article attempts to estimate the changes in the contribution to the EU budget after the UK withdrawal and resignation from any correction mechanisms. Two research problems were posed - what would the payments of member states to the EU budget look like after elimination of the British rebate or other correction mechanisms, and which country would gain and lose with each of the solutions, taking into account the net budgetary balances concerning EU budget. In the considerations, Eurostat data from 2014-2019 were used, including the currently functioning correction mechanisms and scenario analysis. The balances of the member states were calculated based on the modified formula of the European Commission. The research was limited only to determining possible changes in amounts of payments to the EU budget. This research may contribute to the ongoing negotiations and scientific debate on the European Union's financial plans for the next seven years.

Keywords: Correction Mechanisms, EU Budget, British Rebate.

Introduction

In the face of new Multiannual Financial Framework negotiations and the resignation of Great Britain from membership in the European Union, a question arises about the further contributions to the EU budget. The elimination of the British rebate and other correction mechanisms could be a fundamental change in the way the EU budget works. The fact that Great Britain leaves the European Union makes it possible to eliminate at least two correction mechanisms, i.e. the British rebate and its addition, i.e. rebate on the rebate. So Brexit simplifies EU finances in this regard, which has not been possible for at least thirty years. This paper addresses two questions:

- what would the payments of the Member States to the EU budget look like after the British rebate or other correction mechanisms were eliminated,
- which country would gain and which would lose from such a solution.

In the paper the author attempts to estimate changes in the contribution to the EU budget as a consequence of resignation of all correction mechanisms.

The considerations are divided into three main parts. The first section describes the application of correction mechanisms in the EU budget so far and highlights the critical opinions expressed in the literature on the subject in terms of the structure of the EU budget own revenues. The second part presents the adopted research methodology, while part 3 shows the research results and alternative solutions for the contribution to the EU budget of individual member states after resigning from the correction mechanisms or eliminating only the British rebate and thus adopting the assumptions resulting from the European Council's proposal of July 2020 on the Multiannual Financial Framework for 2021-2027.

The research used Eurostat data and a scenario analysis based on data from the current Multiannual Financial Framework. The research was limited only to determining possible changes in amounts of payments to the EU budget. This research may contribute to the ongoing negotiations and scientific debate on the European Union's financial plans for the next seven years.

Correction mechanisms as a bargaining force in budgetary negotiations

The system of EU budget revenues requires profound changes due to the lack of transparency, complexity and little connection with the essence of the functioning of the European Union as an international organization. It consists of the so-called own resources, which include: traditional own resources, value added tax and contributions based on gross national income (Council of the European Union, 2014). The remaining revenue of the European Union is of marginal importance and includes, among others, budgetary surpluses from previous years, fines, interest on late payment, taxes on EU staff salaries and pensions, proceeds from bank interest and contributions from third countries participating in common programs etc. A critical approach to the structure of the EU budget revenues, the lack of real European taxes and the maintenance of correction mechanisms was the subject of multiple analyzes, which emphasized the need for changes and proposed new sources of own revenues of the EU budget (Le Cacheux, 2007; D'Alfonso, 2014; 2016; 2017; Cieślukowski, 2013; Núñez Ferrer et al., 2016; De Feo and Laffan, 2016). Additionally the High-Level Group on Own Resources established in 2014 and chaired by M. Monti prepared analysis of the current EU financial system and gave specific highlights for the reform inside EU budget including the proposal of new own resources and abolition of correction mechanisms (Monti et al., 2016).

So far, the rebate in favor of Great Britain has been the most controversial. Corrective mechanisms appeared in the Community budget as one of the consequences of Great Britain's accession to the European Communities. The turn of the 1970s and 1980s is an attempt to find a constructive solution to UK claims concerning the reduction of contributions to the Community budget. During the meeting of the European Council in Fontainebleau on June 25-26, 1984, the model on the basis of which the value of the British rebate was to be calculated was approved. This mechanism was modified several times to take into account the changes introduced in the EU budget financing system and the accession of new member states (Begg, 2016, p. 7-8; Keedus et al., 2018, p. 141-143; Keep, 2019, p. 11).

According to European Commission (2019, p. 36) and Núñez Ferrer et al. (2016, p. 24-25) the computation mechanism is quite opaque, and consists of several stages due to the numerous adjustments introduced over time. First, the difference between the UK VAT base in total VAT base for all member states is determined as if the 1980s own resources system (VAT based) was still in place and the UK share in total EU expenditure allocated to member states. Then, a downward adjustment is made for the allocation of the costs of the EU enlargement with new members, which joined the EU after 30 April 2004 (because this financing was classified as an external action, and therefore is not part of the calculation of the rebate excluding agricultural payments) and the neutralization of the effects of the introduction GNI-based contribution and change in the cost of collection of traditional own resources. As a result, 66% of the difference between what the UK contributes and what it receives from the EU budget is returned to the UK, and in fact reduces its contribution. The cost of the UK correction is borne by the other Member States in proportion to their GNI, but the share of Germany, the Netherlands, Austria and Sweden is reduced by three-quarters of their normal share. The reduction is covered by the remaining 23 member states (table 1).

Cipriani (2014, p. 45-47) points out that the rebate algorithm does not take into account the full changes in the wealth of Great Britain, which has become one of the richest EU member states over the last few decades. Since the creation of the formula for calculating the correction mechanism for the United Kingdom in the mid-1980s, this solution has been widely criticized among member states. As a consequence, other net payers to the EU budget have begun demanding corrections and discounts, which led to further complicating EU finances. In addition, since the beginning of the 1990s, the European Commission has unsuccessfully proposed to member states other solutions to reduce a financial burden of other major net contributors.

In addition to a special mechanism for Great Britain, there are also less complicated discounts for other countries that are net contributors to the EU budget. In the EU value added tax, the rate is 0.3% of member state's harmonized VAT base, with Germany, the Netherlands and Sweden benefit from the reduced call rate of 0.15%. In the previous programming period, i.e. in 2007-2013, the rate of collection of VAT-based resources for Austria was 0.225%, for Germany 0.15%, and for the Netherlands and Sweden 0.10% (table 1).

In order to improve the balance of payments and withdrawals from the EU budget to the largest net payers, the Council of the European Union, by virtue of a decision of 2007 (Council of the European Union, 2007), introduced another change in the calculation of the contribution based on gross national income. For two countries that are net payers to the EU budget, i.e. the Netherlands and Sweden, lump sum reductions were introduced. As a result, after calculating the nominal GNI contributions of both countries, the amounts assumed in advance are deducted from them. In 2007, it was agreed that the reductions would amount to EUR 605 million for the Netherlands and EUR 150 million for Sweden. Values are indexed annually based on the price deflator. Then, under the decision of 2014 (Council of the European Union, 2014) Denmark, the Netherlands and Sweden benefit from reductions of their GNI payments of

EUR 130m, EUR 695m and EUR 185m, respectively. The Austrian annual GNI contribution was reduced in the period 2014-2016 by EUR 30m, EUR 20m and EUR 10m, respectively (table 1).

Table 1: Evolution of the EU correction mechanisms

Member state	1985	2002	2007	2014
Austria		Rebate on the UK rebate (three quarters)	Rebate on the UK rebate (three quarters); Reduced VAT call rate	Rebate on the UK rebate (three quarters); GNI contribution reduction (lump-sum correction)
Denmark				GNI contribution reduction (lump-sum correction)
Germany	Rebate on the UK rebate (one third)	Rebate on the UK rebate (three quarters)	Rebate on the UK rebate (three quarters); Reduced VAT call rate	Rebate on the UK rebate (three quarters)' Reduced VAT call rate
Great Britain	UK rebate	UK rebate	UK rebate	UK rebate
Sweden		Rebate on the UK rebate (three quarters)	Rebate on the UK rebate (three quarters); Reduced VAT call rate; GNI contribution reduction (lump-sum correction)	Rebate on the UK rebate (three quarters); Reduced VAT call rate; GNI contribution reduction (lump-sum correction)
The Netherlands		Rebate on the UK rebate (three quarters)	Rebate on the UK rebate (three quarters); Reduced VAT call rate; GNI contribution reduction (lump-sum correction)	Rebate on the UK rebate (three quarters); Reduced VAT call rate; GNI contribution reduction (lump-sum correction)

The proposals of the European Commission of 2018 and 2020 (European Commission, 2018; 2020) present the gradual elimination of all corrections. It can be assumed that the European Commission (1998; 2004a; 2004b; 2011) and the European Parliament (1999; 2007; 2011; 2018; 2020), after unsuccessful attempts from the 1990s and the beginning of the 2000s, decided to introduce greater transparency in financing EU expenditure. take advantage of the opportunity that arose due to the withdrawal of Great Britain from the EU and thus the automatic abandonment of the so far inviolable rebate and carry out a major reform of the EU budget. Nevertheless, there are many important issues to be resolved with vital implications for the EU budget as well (Chomicz, 2016, p. 8). Zuleeg (2014), Bachtler and Begg (2016), Bachtler and Mendez (2016), Núñez Ferrer and Rinaldi (2016), Begg (2017), Haas and Rubio (2017) and Gordon (2018) were among the first to write about possible changes in the size and structure of the EU budget after Brexit. These works often postulate the abandonment of correction mechanisms. For example Pasimeni and Riso (2016, p. 19) have shown that various correction mechanisms applied to the EU budget significantly limit its redistribution capacity. In turn, possible alternative scenarios after Brexit from the point of view of British public finances and the continuation of activities previously financed from the EU budget are presented, among others, by Darvas et al. (2017) and Wishlade (2019).

However, the conclusions of the European Council (2020) summit in July show that the member states assumed the continuity of the existing mechanisms, excluding the British rebate. As a consequence, political decisions and particular interests of EU members continue to be put before the pursuit of a more efficient functioning of the European Union as a whole. As Haas and Rubio (2017) emphasizes, Brexit may therefore have a negative impact on the structure of the EU budget, giving room for the implementation of the particular interests of some member states.

Methodology

The study used averaged data from 2014-2019, i.e. the period preceding the transition phase before the United Kingdom finally left the European Union. Averaging is necessary due to year-to-year fluctuations in individual values and retroactive adjustments made by the European Commission. The following correction mechanisms were taken into account: the British rebate and the so-called rebate on the rebate, i.e. lower payments from Germany, Austria, the Netherlands and Sweden, lower by half the payment on account of VAT for Germany, the Netherlands and Sweden, reduction of the contribution for the Netherlands, Sweden, Denmark and Austria and the so-called opt-out for Denmark, Ireland and Great Britain which are exempted from contributing to some parts of security and citizenship policies.

The data on Great Britain was left in the research due to the fact that the elimination of UK's share, both on the revenue and expenditure side, would force the necessity to make additional assumptions regarding the size of the EU budget, which would significantly change the amount of contributions from other member states. Meanwhile, the simulation carried out was to compare the actual data for 2014-2019 with two possible changes related only to the correction mechanisms that may occur after 2020. The contribution of this research is to show possible financial effects in member states payments to the EU budget after eliminating correction mechanisms which could be useful for the future reform of the EU financial system.

After these adjustments were made, two alternative results were presented, ie the amount of burdening the member states with the contribution to the EU budget, leaving the other correction mechanisms without the British rebate and after eliminating these mechanisms. For both solutions, it was also examined whether the current status of net payers and beneficiaries will change using the modified European Commission method (operating budgetary balances method).

The approach based on the net balance is treated only as an accounting exercise (calculating only the values of budget revenues and expenditures) and consequently does not take into account real integration effects and the consequences of the investments made. Real investment flows are very significant for the creation of European added value (Núñez Ferrer et al., 2016, p. 30, 35; Monti et al., 2016, p. 57; Heinemann, 2011). Critical analysis of operating budgetary balances (OBB) in a wider context of European integration is performed by Asatryan et al. (2020a; 2020b), Pilati and Zuleeg (2020) and Le Cacheux (2005). However, in this study, the aim is to show the effects of abandoning the correction mechanisms in terms of strictly financial terms.

The OBB method consists of calculating the difference between the amount that MS receives from and pays into the EU budget. Total national contributions (own-revenues payments, excluding traditional own resources considered as a result of common policies, not national contributions) are adjusted to total EU allocated operating expenditure (excluding external and administration expenditure) as weighted national contributions, so that operating budgetary balances sum to zero (European Commission, 2019, p. 72). In the simulation presented in the article, a weighting procedure was abandoned, as it was intended to show the actual flow of funds. Modified equation presents as follows:

$$OBB_i = (TAE_i - AE_i) - (TR_i - TOR_i)$$

where:

OBB_i - operating budgetary balance of member state *i*, where i = 28;
TAE_i - total allocated expenditure of member state *i*, where i = 28;
AE_i - administrative expenditures allocated to member state *i*, where i = 28;
TR_i - total revenue of member state *i* , with i = 28.
TOR_i – traditional own resources of member state *i* , with i = 28.

Research Results

Presented simulation show that the removal of all discounts leads to a reduction in the membership contribution for 21 countries in the range of 6.5-7.5% on average in the period 2014-2019 (figure 1). Belgium, Austria and Denmark generate a slightly lower benefit, while Germany, the Netherlands, Sweden and the United Kingdom record an increase in payments to the EU budget, which is due to the fact that these members are among the largest beneficiaries of correction mechanisms in the analyzed period. In the case of resignation from the British rebate only and the rebate on the rebate, the only losing country is, of course, the United Kingdom (contribution increases by one third), while Austria, Germany, the Netherlands and Sweden record a reduction in payments, but relatively small compared to other countries (between 1.1 and 1.4%) due to the previously mentioned limited share in covering the British rebate.

Figure 1: Simulation of changes in the amount of contributions to the EU budget, average change from 2014-2019, in % of MS total own revenues

Source: Author's own calculations based on Eurostat database (2020).

The results shown in Figure 2 confirm the previous observations. After calculating the modified operational budgetary balances, attention is drawn to the MS division into net payers (with a negative balance), which include the "first fifteen" (EU15), except for Ireland, Greece, Spain, Portugal and Luxembourg. These five countries, along with the so-called "new members" form a group of net beneficiaries. Figure 2 also presents the change in budgetary balances in the two variants previously shown. Resignation from all correction mechanisms means that the negative budget balance improves in the case of all net contributors, except for Germany, the Netherlands, Sweden and Great Britain. The negative change for net beneficiaries shows that their balances are also improving. In the second option, i.e. removing the British rebate and rebates on the rebate, the situation of Germany, the Netherlands and Sweden (to a lesser extent of Denmark) changes significantly compared to the first option, which improve their negative balances while still remaining net payers. In the case of other countries (except Great Britain), the improvement in the balance is obviously lower than in the first option.

Conclusions

The results presented above indicate that resignation from all discounts will be difficult to implement for political reasons. Most likely, Germany, the Netherlands and Sweden will opt for keeping the current correction mechanisms with the exception of the British rebate. As significant net contributors, they have an important voice in the discussion on the future structure of the budget, especially since changes to the revenue side of the budget (including rebates) require unanimity.

In order to find constructive solutions in spring 2020, the president of the European Commission has already announced a new proposal for the Multiannual Financial Framework for 2021-2027 and a recovery plan "Next Generation EU", the idea of which was largely based on obtaining funds from the financial markets in the form of loans, but also on the need to reform the revenues of the EU budget. The fundamental problem arises in terms of repayment of loans taken, which is to be done gradually after 2027. The loans will be guaranteed by the EU budget, and not directly by the member states. It proposes either an increase in the contribution to the EU budget based on Gross National Income or new taxes: revenues from the EU's Emissions Trading System (ETS), digital tax, a carbon border adjustment mechanism and fees on non-recycled plastic packaging waste. While these proposals allow for a significant change in the structure of EU budget revenues, the issue of correction mechanisms is not so obvious. In July 2020, the European Council proposed that the corrections reducing the contributions to the EU budget of five member states (Austria, Denmark, Germany, the Netherlands and Sweden) should not be gradually withdrawn (as requested by the European Commission), but, on the contrary, maintained and increased overall (European Council, 2020).

As Cipriani (2014, p. 49) rightly points out, the proposed possible limitation of the lump sums in time, linking to the duration of the Multiannual Financial Framework provides only apparent progress. This is because the time limitation does not in itself constitute a guarantee against the consolidation of such corrections, especially as the rebate beneficiaries may treat it as given once and for all. Thus, there is a risk that the concept of improving the transparency of EU revenues in this area will have to wait until the next budget negotiations without any guarantee of success.

Abstract

The website is the foundation of electronic administration. A website that has been search-engine optimised has a better potential to reach users. The purpose of the paper is to assess the degree of search engine optimisation of local government websites in Lesser Poland. The research covered 182 websites. The website quality was measured with selected automatic testing tools. Each test gave a final synthetic score. The scores were aggregated with zero unitarisation. The investigated websites scored 1,007.5 technical SEO points in total, which is about 55% of the available points. The websites demonstrated a significant potential for search engine optimisation (in the employed research design). A significant variance in technical SEO attribute scores urges in-depth analysis of results offered by each tool. The synthetic technical SEO score identifies websites in need of in-depth quality analysis or an SEO audit. Such an analysis will pinpoint trouble attributes requiring optimisation. A large number of relatively easy to fix errors and technical flaws suggests that municipalities do not audit their websites. Insufficient knowledge regarding weak points of municipal websites can hinder the development of e-administration. The research approached the websites from two browsing perspectives, desktop and mobile. Such a design facilitated a comprehensive investigation of technical attributes of the websites. The results were presented as statistics and in spatial terms.

Keywords: website quality, e-administration, quality audit, optimisation.

Introduction

The website is the e-administration hub for all levels of e-service provision. Its sites offer components that facilitate information flow between the citizen and administration, such as interactive forms or scripts. Public administration websites are developed in various ways and provide diversified e-services (Manoharan and Carrizales 2011, Cegarra-Navarro et al. 2012, Fietkiewicz et al. 2017).

As e-administration developed, its models of e-services grew more numerous. Most of them consist of four levels of maturity, presence, interaction, transaction, and integration (Layne and Lee 2001, Andersen and Henriksen 2006, Coursey and Norris 2008, Shareef et al. 2011). Moreover, in most cases, the framework for the models are the citizen – service and operations – technology relationships (Lee 2010). At the basic level, e-administration merely informs and presents. Information about the office and its services is displayed on a website. The customer is just a passive recipient of content that was prepared for them. In the one-way communication model, information comes with electronic forms that can be downloaded, printed, and filled in, or filled in and printed if they are interactive. In the transaction model, customers can search for information as well as download and send completed forms online (two-way communication). Ultimately, e-administration should follow the integration model and the personalisation model. The integration model

Cite this Article as: Karol KROL and Dariusz ZDONEK "The Quality of Local Government Websites from The Technical SEO Perspective" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

provides for completion of all activities necessary to handle official business online. It further offers an electronic way of certification of the arrangements made, for example, with a digital document, such as a permit or certificate. In the personalisation model, the customer is offered services tailored to their needs and situation. Thanks to data processing algorithms, services are automatic and provided proactively.

To exploit the potential of digital technologies in e-administration, one needs hardware infrastructure, software, organisational and legal changes, and a way of making sure e-services meet the demand. Moreover, activities are necessary to improve the public interest in e-services and present their advantages. The primary benefits of e-administration are the speed of business handling and no queues (Wolniak and Skotnicka-Zasadzień 2012). The technical quality of websites used to provide the services and their general accessibility for people with disabilities, mobile devices, and search engines are just as important (Galvez and Youngblood 2016).

Search engine website optimisation (SEO) is usually a personalised commercial service. Its quality depends mostly on the experience of the SEO auditor or interactive agency. A website that has been search-engine optimised has a better potential to reach users with its message. It applies to public administration websites as well. The purpose of the paper is to assess the degree of search engine optimisation of local government websites in Lesser Poland.

This paper is organised as follows. The second section describes the essence of SEO with a particular focus on technical SEO and its impact on the quality of a website. Section three describes the methodological framework for the research. Next, we presented the results in tables and in spatial terms. The paper ends with a discussion and summary.

Search Engine Optimisation

Search engines are an important way of obtaining information on the Internet. Many people use search engines as a starting point for navigating the Web, making search engines a crucial link in connecting content providers and users (Baye et al. 2016, p. 6). Search engines have two primary functions: they build a content index and provide an ordered list of websites (resources, search results). Search engines answer questions. The search engine searches a corpus of documents (indexed resources) and returns results that answer the question.

Website quality verification and determination of popularity and accuracy of results are not done manually. They are decided by algorithms that analyse up to several hundred variables, so-called ranking factors. Many of them are technical. When optimised, they can improve website usability (user experience) and their rank in search results (machine experience).

Search engine optimsation (SEO) is a process of increasing the number of visitors to a website by achieving a high rank in search results returned by a search engine (Moreno and Martinez 2013, p. 564). The higher a website ranks in the search engine results pages (SERPs), the greater the likelihood of users visiting the site. Search engine optimisation is a process of improving a website's position so that the webpage comes up higher in the search results of major search engines (Curran 2004, p. 202). SEO is a process that manipulates website characteristics and incoming links to improve a site's ranking in the search engines for particular search terms. Because of the importance of high search engine rankings and the profits involved, search engine optimisers look for tools, methods, and techniques that will help them achieve their goals (Malaga 2010, p. 3). The practice of search engine optimisation can significantly increase a website's search rankings, driving more traffic to the website, and thereby increasing revenue. The three primary SEO strategies are Content, Link Building, and Social Sharing (Zhang and Cabage 2017). Moreover, search engine optimisation has been considered one of the most important techniques in Internet marketing (Tsuei et al. 2020).

In general, the process of SEO can be broken into four main steps: (1) keyword research, (2) indexing, (3) on-site optimisation, and (4) off-site optimisation. One can distinguish between technical SEO and search experience optimisation (SXO) (Figure 1).

Fig. 1: The scope of website search engine optimisation

On-site optimisation is a process of developing or making changes to a website to improve its search engine rankings. Search engines return the most relevant documents determined by complex algorithms that adopt a plethora of criteria or ranking factors continually changing over the last decade (Mavridis and Symeonidis 2015).

There are a lot of on-site factors that are considered in determining a site's ranking for a particular term (Malaga 2010, p. 11). Some of them are technical and hence belong to technical SEO. Search experience optimisation (SXO) is a process aimed at improving the experience related to the presentation of a specific website in search results. Moreover, search experience optimisation recognizes that it is the user experience, not search engines (machine experience) that ultimately determines SERP position and rank.

Some of the main on-site factors used by search engines to determine rank include the title tag, meta description tag, bold text, keyword density, and the constant addition of relevant, unique content (Malaga 2010).

Technical SEO

Technical SEO focuses on the improvement of technical attributes of websites. The perfected technical side of a website enhances both machine experience and user experience. Technical SEO is part of on-site SEO and supplements activities belonging to off-site SEO to amend site visibility. A technical SEO audit includes such operations as the verification of the robots.txt file and sitemap, verification of the structure of URLs (Uniform Resource Locators), including breadcrumbs, and measurement of website performance and usability on mobile devices. A sitemap presents information on sites and other pieces of content (files, resources) that comprise the website and their relations, which facilitates indexation of individual sites. The robot.txt file contains information for search engine crawlers regarding indexable resources (Gudivada et al. 2015). Technical SEO is also about security (for example, Secure Socket Layer certificates, SSL) and website indexing in search results.

A technically well-developed website has a carefully built link profile, Especially internal links and outbound links. A large number of bad links hinders user experience and machine experience and may contribute to worse ranks in search results (Król and Zdonek 2019). Technical SEO concerns optimisation of metadata as well (title tag, meta description, meta keywords, favicon). Furthermore, it identifies and eliminates duplicate content, optimises internal links and URLs, optimises anchor texts and descriptions of images (alt tags), and optimises headers (header tags) (Tsuei et al. 2020). Technical SEO attaches great weight to website conformity to the standards of the World Wide Web Consortium (W3C), including code syntax, and Web Content Accessibility Guidelines (WCAG) for accessibility to people with disabilities (Król and Zdonek 2020a). Technical SEO effort focuses particularly on improving website performance, including the load time. Performance optimisation includes file compression or code minification (Giannakoulopoulos et al. 2019). Things technical SEO strives to avoid is embedded objects, such as iframes or Flash. It rather tends to

optimise websites for mobile use instead. Optimisation of all these factors affects website quality and may improve its search results rank (Berman and Katona 2013, Zhang and Cabage 2017).

Materials and Methods

The research involved 182 websites of local government units of Małopolskie Voivodeship, Poland (Figure 2). The study included all municipalities of the province. Their technical SEO quality measurement was conducted with eight web applications and the Lighthouse plugin (Table 1).

Fig. 2: Małopolskie Voivodeship, Poland

The research was informal, quantitative, and carried out under normal use conditions. The total number of unique tests amounted to 1,820. We have selected free tools available under a thin client framework. It means that the entire infrastructure the test application requires is on the service provider's end and tests are performed on a client device in a web browser window. Each test was concluded with a final score aggregated from individual technical SEO tests. The final scores were positioned in various ranges and resulted from the aggregation of multiple tests (Table 1).

Table 1: Test applications and scope of tests

Item	Test application (Application type)	Scope	Score range
1.	SEO audit (online)	SEO analysis, analysis of the most frequent keywords, backlink analysis, number of sites indexed by Google	0–5
2.	ZadroWeb SEO Auditor (online)	Page Authority; Domain Authority; Google Page Speed; SEO stats: meta title, description, keywords, heading tags, img alt tags, site map, inline code; URL stats	0–100
3.	Website Grader (online)	Website tests: performance (including page size, page speed, minified JavaScript and CSS, image size), mobile, SEO, security	0–100
4	Blink SEO Audit (online)	HTML structure and metatag analysis, website load time analysis, security analysis, and semantic analysis	0–100

5.	Seobility SEO Checker (online)	Meta information, page quality, page structure, link structure, server parameters, external factors	0–100
6.	Sitechecker (online)	SEO stats: description tag, headings, title tag, alt tag, etc.	0–100
7.	Ionos SEO Checker (online)	Search engine visibility, content (link, page title, headlines, page descriptions), backlinks audit, mobile tests	0–100
8.	Foxy SEO Checker (online)	SEO stats: title tag, description tag, keywords tag, headings, alt attribute, text/HTML ratio, XML sitemap, robots.txt, embedded objects, iframe, etc.	0–100
9.	Lighthouse (Chrome plugin)	Mobile mode measurements. Google Developers. Content best practices, meta tags, alt tags, other.	0–100
10.	Lighthouse (Chrome plugin)	Desktop mode measurements. Google Developers. Content best practices, meta tags, alt tags, other.	0–100

1) https://www.pozycjonowanie.pl/audyt-seo; 2) https://zadroweb.com/seo-auditor; 3) https://website.grader.com; 4) https://audyt.blink.pl/; 5) https://freetools.seobility.net/en/seocheck; 6) https://sitechecker.pro/pl/; 7) https://www.ionos.com/tools/seo-check; 8) https://www.seofoxy.com/seo-checker/

The research approached the websites from two browsing perspectives, desktop and mobile. Such a design facilitated a comprehensive investigation of the technical attributes of the websites (Figure 3). The tests followed the cross-validation model with the test tools chosen to complement each other (Król and Zdonek 2020b).

Fig. 3: Diagram of the research process

Each website was described with ten different quality indices. The scores were normalised and aggregated with zero unitarisation so that the websites could be juxtaposed. Zero unitarisation is recommended for multidimensional comparative assessment (Jarocka 2015).

Normalisation was performed with Equation 1. Normalised variables lie in the (0,1) interval. We then added up all the normalised variables to obtain the aggregate index. It means that each website we tested could earn up to 10 points.

$$zij = (xij - mini\{xij\}) / rj \quad (1)$$

where $zij \in (0,1)$. and:
zij – a normalised characteristic;
$zij = 0 \Leftrightarrow xij = mini\{xij\}$;
$zij = 1 \Leftrightarrow xij = maxi\{xij\}$;
xij – the value of the characteristic before normalisation;
mini{xij} – the minimum value of the characteristic before normalisation;
maxi{xij} – the maximum value of the characteristic before normalisation;
rj – the range for the j-th variable.

The normalisation of diagnostic characteristics is an important stage of comparative analysis of multivariate objects. The idea behind a multidimensional comparative analysis is to build a synthetic index that facilitates the total ordering of objects. Here, the term normalisation means unification, standardisation of values of characteristics regarding a specific criterion. The main objective of the transformation is to conform to the addition postulate by rendering characteristics of different measures comparable (Jarocka 2015).

We then used QGIS to visualise the results in spatial terms. Finally, we classified the municipalities to respective types (using the technical SEO aggregate index). We used the equal interval classification method to this end (objects are divided into types delineated by equal intervals). The typology was based on the technical quality of the websites.

Results

A website in need of complete optimisation reached 2.77 points out of 10, which was the smallest technical SEO score in the study. A website that has been search-engine optimised scored a little over 8 points out of 10 (Table 2).

In total, the websites had 1,007.47 technical SEO points out of 1820, which is about 55% of the maximum number of points. The websites demonstrated a significant potential for search engine optimisation of a little over 44.5%.

Table 2: Selected technical SEO statistics

Quality index	Numeric value	Percentage (%)
Minimum	2.77	27.69
Maximum	8.06	80.64
Range	5.29	52.90
Maximum score	1,820	100.00
Measured score	1,007.47	55.36
SEO potential	812.53	44.64

About 45% of the websites needed a comprehensive search engine optimisation (Table 3). The websites usually scored about 5 points for technical SEO attributes and were classified to types III and IV (in the employed research design). Websites classified to type II scored slightly better, from 5.4 to 6.8 points. Only 11.5% of the websites scored high.

Table 3: Quantitative summary of websites classified with the technical SEO index

Website type	Type IV	Type III	Type II	Type I
Technical SEO quality index	2.5–4.099	4.1–5.417	5.417–6.741	6.741–8.064
No. of municipalities	11	71	79	21
Percentage (%)	6.04	39.01	43.41	11.54
SEO summary	Websites requiring search engine optimisation		Websites (relatively) search-engine optimised	
Number of websites	82.00		100.00	
Percentage (%)	45.05		54.95	

The websites could score up to one point in each test. Therefore, each test tool could award up to 182 points (for the set of investigated websites). Each test application performed a different set of tests both as regards the number of tests and the scope of tested attributes. The websites scored the best in technical SEO measurement by Lighthouse (both desktop and mobile mode). The worst scores were awarded by Ionos SEO Checker (Table 4). A significant variance in technical SEO attribute scores urges an in-depth analysis of the results.

Table 4: Technical SEO potential according to each test application

Item	Measuring tool	Total for measurement (normalised); max. 182	Percentage (%)	SEO potential (%)
1.	SEO audit	122.60	67.36	32.64
2.	ZadroWeb SEO Auditor	87.33	47.98	52.02
3.	Website Grader	83.65	45.96	54.04
4.	Blink SEO Audit	94.73	52.05	47.95
5.	Seobility SEO Checker	105.80	58.13	41.87
6.	Sitechecker	98.97	54.38	45.62
7.	Ionos SEO Checker	35.99	19.77	80.23
8.	Foxy SEO Checker	121.79	66.92	33.08
9.	Lighthouse mobile test	127.05	69.81	30.19
10.	Lighthouse desktop test	129.56	71.19	28.81

The spatial distribution of the website quality results for the municipalities of Małopolskie Voivodeship demonstrated that large urban municipalities, often tourism destinations, such as Kraków, Krzeszowice, Zator, Muszyna, or Tuchów, boasted better-designed websites (Figure 4). Moreover, municipalities situated near large tourism destinations such as Kraków, Łącko, Bukowina Tatrzańska, or Limanowa also scored high.

Fig. 4: Typology of municipalities in Małopolskie Voivodeship regarding website optimisation. Source: own research

There were relatively few websites with the lowest scores. The synthetic technical SEO score identifies websites in need of an in-depth quality analysis or an SEO audit that will pinpoint trouble attributes in need of optimisation.

Conclusions

Websites of local government units classified to type I (6.7 to 8 technical SEO points) were usually performance-optimised; their load times were short. What is more, they were optimised for use on mobile devices. It was possible to browse them comfortably on smartphones, tablets, and similar equipment. Websites of this type usually had a complete set of metadata. They had no objects advised against, such as iframes or Flash objects. Type I websites had a well-

designed profile of external links and usually a significant number of quality inbound links. Type IV websites, the ones that reached the lowest technical SEO scores, required a thorough optimisation or redevelopment. Note that these websites scored poorly in all the tests, which indicated the reliability of the assessment.

The research investigated the technical attributes of websites. Nevertheless, it is people who are behind the quality of websites. Many of the identified 'SEO flaws' could be easily fixed. With no qualified personnel and a quality assurance system in place, the implementation and development of e-services can be significantly hindered or even impossible. SEO is a process, and each website is dynamic if only because of new content. Hence, every website has to be reviewed regularly and corrected in terms of technical SEO attributes.

Websites of local-government units in Małopolskie Voivodeship exhibited a relatively high degree of search engine optimisation. An in-depth analysis of selected websites indicated that it was often just minor details that required improvements, such as meta information, which can be done by the municipal IT department. A large number of relatively easy to fix errors suggests that municipalities do not audit their websites. Insufficient knowledge regarding weak points of municipal websites can hinder the development of e-administration.

The results indicate that public administration websites are not given sufficient attention. Their fate depends on the strategy of the unit, knowledge about e-services, and the attitude towards databases and IT systems. What is also necessary is to implement a quality management system for both e-services and the website (or web application). An internal control system with a checklist can be useful to ensure the quality of websites and web applications. Efficient, functional, and convenient websites contribute to the perception of the office as customer friendly and helpful.

Expatriate Instructors in the Middle East: Adjustment to COVID-19

Ilya BYSTROV
University of Buraimi, Al Buraimi, Oman, ilya.bystrov@gmail.com

Brindha NATARAJAN
Sri Hayagreeva Arts and Science College, India

Abstract

The article is dedicated to the way instructors of higher education institutions have coped with the COVID-19 pandemic in two countries of the Middle East— the Kingdom of Saudi Arabia and the Sultanate of Oman. The research was carried out using qualitative design. Data were collected during semi-structured interviews with 15 respondents who work at higher education establishments of these countries. Observations were used as an auxiliary instrument. The results are summarized in the form of five cases that reflect different strategies and reactions of instructors to address the stressful emergency conditions. The research revealed the following behavioral patterns: Survivor, Victim, Skeptic, Promoter, and One of the Crowd. Coping strategies were differentiated through information consumption, information dissemination, assertiveness, and anxiety level. Respondents demonstrated shrinkage of planning horizons, caused by the pandemic and economic downfall. The research showed that respondents had increased levels of anxiety, which should be addressed by academic managers.

Keywords: COVID-19, SARS-CoV2, behavior pattern, GCC, expatriate instructors, social media, social interaction

Introduction

COVID-19 (SARS-CoV2) has caused major disruptions, and has resulted in significant upheaval in the everyday lives that many people have become used to and taken for granted for many years. Among such disruptions are restrictions of travel and movement, personal interactions, and interpersonal communications, resulting in impaired economic relations and supply chains. Globally, this has put dozens of industries — including education — under enormous stress, augmenting changes of routine and professional lives. Social interactions, and even social organization itself, has been affected; that is, a fundamental element of the biological environment has introduced changes to the socio-cultural level.

According to Meijer, Verloop, & Beijaard (2002), educators' mental processes mutually define what is happening with the learning environment. How well expatriate instructors can adjust to the environment depends on multiple factors. The goal of the present research is to reveal how instructors of higher education institutions have coped with the stressful conditions caused by the pandemic and how this situation has changed the behavior patterns that are part of their personalities.

Multiple studies have identified the psychological impacts of the current situation on people globally. According to Liu, Ren, Yan, Li, Xu, Yu, Qu, Wang, Tian, Yang, Yao, Tan, Jiang, & Tan (2020) evaluated more than 14,000 respondents from 31 provinces of China and concluded that the emergency medical health system needed to pay attention to the extent of stress and psychological distress among the general public during and even after the biodisaster, thus contributing to the timely and targeted psychological services put into effect.

A study from Italy (Favieri, Forte, Tambelli & Casagrande (2020)) suggests that the COVID-19 pandemic appears to be a risk factor for psychological diseases in the Italian population, in a situation similar to that of China. According to this study, about half of respondents reported a significant psychological impact. The study also confirmed the role of restraining measures in modifying lifestyles, social perceptions, and confidence in the institutions. Notably, this study of more than 1600 Italian residents revealed that 5.1% of respondents demonstrated post-traumatic syndrome distress symptomatology and 48.2% evidenced lower psychological well-being linked to COVID-19 diffusion.

The relationship between mental health, the current pandemic situation, and social media has also attracted the attention of scholars. Gao, Zheng, Jia, Chen, Mao, Chen, Wang, Fu & Dai (2020), conducted a cross-sectional study among Chinese citizens who were older than 18 years. Their findings show that there is a high prevalence of mental health problems during the COVID-19 outbreak.

As highlighted, the media element plays an important role. Earlier studies, e.g., Cameron, Wolf, & Baker (2011), demonstrated the effectiveness of dissemination of health-related information for the improvement of health literacy and reduction of mortality rates and hospitalizations. According to Casero-Ripolles (2020), who conducted an exploratory analysis of media usage before and during the current situation, the COVID-19 pandemic has a certain impact on the media system. His findings suggest the emergence of important developments, such as the resurgence of the role of legacy media, especially television, and the fact that citizens who usually maintain a distance from such information have reconnected with news sources.

The role of social media in anxiety-related phenomena has interested researchers since its introduction. For example, Hampton, Rainie, Lu, Shin, & Purcell (2015), stipulated that social anxiety can originate from managing a large network of social media friends, feeling jealous of others' lives, and the "fear of missing out" on activities in online interactions. Recent research, however, argues that, by itself, social media usually does not cause negative effects. According to Jiang and Ngien (2020), who explored the effect of usage of one of the social networks on social anxiety, its use did not directly increase social anxiety. Instead, social comparison, a proximal outcome, and self-esteem, an intermediate outcome, played mediating roles, supporting the complete mediation effects.

Relationships between human behavior and disasters, catastrophic events, and calamities interested authors prior to the current pandemic. Even without examining Ancient history, the Medieval Period, or the Renaissance, the 20th century has provided numerous examples of studies and analysis, produced by religious thinkers, philosophers and researchers. For example, almost 80 years ago, Sorokin (1946), tried to analyze the nature of the relationship between man and society, and shared his thoughts on the effects of war, revolution, famine, and pestilence upon the human mind, behavior, social organization, and cultural life.

Later studies (e.g., Lazarus & Folkman, 1984) provided an understanding that stress is faced differently by personalities with different characteristics. This research suggested two types of coping: problem-focused and emotion-focused. The former is focused on problem-solving and the circumstances leading to stress, whereas the latter presupposes the regulation of emotions and their expression. Leventhal, Leventhal & Contrada (1998) viewed a person as a problem-solver who responds to social, physical, and institutional environments in which he or she faces health threats. In a wider evaluation, they perceived these elements of the environment as the basis for efficient use of resources that allows implementation of coping procedures that, in turn, allow a self-regulating system to adapt.

Quarantelli (1999) summarized the preceding studies of disasters and made several important conclusions regarding the mechanisms by which disasters affect social behavior. Saleebey (2001) widened the scope of study and introduced the social element into consideration; in his analysis of human behavior he used a biopsychosocial approach.

More recent studies, e.g., Codreanu, Celenza, & Jacobs (2014), analyzed the effect of disaster education on behavioral changes. In the most recent studies, e.g. Pan, Dresner, Martin, Mantin & Zhang (2020), behavioral peculiarities related to catastrophes have been studied in a very utilitarian way—that is, from the perspective of consumer behavior.

The effect of existing global work conditions should not be ignored as well. Multiple studies demonstrate that the economic and organizational changes of the last decades have altered the productive processes (Carreri, 2020).

As can be seen, this topic has been studied relatively well. Our study will contribute to existing research by focusing on how expatriate instructors, a distinctive social and cultural group, have faced the stress related to COVID-19, and identifying their behavior patterns in relation to the use of social media and social contacts.

Methodology

For this research, we used a design similar to that applied by Romar & Frisk (2017) to study the influence of occupational socialization on novice teachers' practical knowledge, confidence, and teaching in physical education

and also similar to that applied by Bystrov, Natarajan & Mirza (2019) to study adjustment of expatriates. We paired semi-structured interviews with the participant observation method (when possible). The latter gave us an opportunity to study individuals in their natural environment and make observations that would either support or contradict their stories. The majority of interviews (9) were carried out in the place of the respondents' choice—either the respondent's home or the interviewer's home. Six interviews were conducted with the help of a videoconference application.

Respondents represented faculties of several higher education institutions located in Saudi Arabia and the Sultanate of Oman. None of the respondents had a medical or health science background. This was a conscious decision, in order to try to understand the processes and dynamics happening inside relatively educated communities and groups that, nonetheless, do not possess medical expertise.

We summarized the results of the conducted interviews as five cases, giving them names that best reflected their nature. While the behavior patterns described in the first four cases were encountered in only one interview each, the last case represented the most common pattern, and was met multiple times. In this way, the description of the last case is aggregative.

Results & Discussion

Upon completion of interviews, we were able to differentiate the following cases:

Case A—Survivor.

Case A was a male in his mid-forties. He was Muslim and originated from the Indian sub-continent. In the country of residency, he stayed with his family—wife and two children; both children were of junior school age. A was an MBA degree holder, but at the moment of interview was finalizing his PhD thesis.

When A heard about the outbreak of a new virus in China, he had some concerns. As he stated, "Asia and Africa are always giving headaches. They scared us with Ebola, SARS and MERS; now this COVID". He couldn't recall using any precautionary measures prior to the beginning of 2020. The turning point for him was the news announcement about the construction of temporary hospitals in China. Thereafter, he began to perceive the situation as dangerous.

Respondent A followed all recommendations issued by the local Ministry of Health. He went even further and implemented measures that were not requested. Prior to the announcement of lockdown in the country where he resided, he went to the hypermarket and created a reserve of products that would be enough for him and his family to last for two months.

A also reported that his family minimized contacts outside the home even before social distancing and isolation were recommended. It was arranged that both children stopped going to school and started home studies under the mother's supervision two weeks before schools were closed and reassigned to remote teaching. Once food reserves were created, visits for groceries were minimized to once every three weeks to replenish them. Such food runs to the hypermarket were carried out at times of minimal presence of other customers—immediately after opening or 30 minutes before closing.

When asked about the usage of social media, the first thing A mentioned was the communication group in one of messengers that he and other residents of his ethnicity (about a dozen families) organized. A evaluated the communication group especially highly for its support during a time of slight panic "… when hand sanitizers, gloves and masks were wiped out almost everywhere. A almost ignored all other media—he only mentioned a website with coronavirus statistics that he visited occasionally and a videoconferencing application to communicate with members of broader family.

A did not complain about any health-related issues, sleep irregularity, or increased level of anxiety. He mentioned, however, that he was worried that his family members could be infected; however, he perceived these only as a motivating factor for proper actions. It is worth mentioning that during the interview A expressed his concerns about his immediate family, broader family, and his local community multiple times, while never expressing worries about himself.

A did not think that there would be any consequences that would affect his long-term plans. His plan to stay with his current employer was unchanged. He still believed that his current place of residence was one of the most secure places in the world (due to culture, relative geographic isolation, and low number of population). However, he anticipated changes to the style of social contacts, especially in face-to-face mode, which would, in his opinion, "become a luxury". He also expressed some concerns regarding the state of the world economy.
Overall, A's character can be described as properly planned and ready to take on the challenges that life presents. He is calm in approach, practical, and slightly extra cautious. To a certain extent, his behavior can be characterized as assertive, which presumes a high degree of self-confidence and self-respect, and allows a maximum degree of self–determination. According to Pfafman (2017), assertiveness is also a social competence. Assertive people are comfortable with constructive criticism; they are planners and try not to blame anything unnecessarily. They are willing to explore other new solutions (Michel, 2008). In perceiving a pandemic, they try to determine the exact scenario and accept inconveniences for betterment without hesitation.

From the communication perspective, assertiveness is expected to coincide with polite performance. Thus, according to Jenkins and Dragojevic (2013), politeness is a socially and contextually negotiated subset of appropriateness determined by the inter-play between identity, context, and relationship. It allows people to make requests that are less invading of others while maintaining a positive relationship (Brown and Levinson, 1987). Both were demonstrated by A in his problem-focused behavior.

Case B—Victim.

Respondent B was an eastern-European male, in his early forties. He was married, but at the moment of the interview, his wife was staying with relatives in her home country and B resided alone. B had a doctoral degree; he was a Christian, but not very religious.

When B first heard mention of a new disease in China, he did not pay much attention to it. At the beginning of January, he and his wife travelled to his home country for a week. Later, when the situation had deteriorated, he did not object to his wife's visit home. On the day that he heard measures for containing the spread of the virus would include closure of the majority of non-essential businesses, he went to the hypermarket and secured some food reserves—mostly rice and canned food.

The social contacts of B did not change significantly. As an introvert (as he characterized himself), he did not require a large number of contacts. He still maintained connection with his elderly parents and wife via videoconference application.

When asked about his usage of traditional and social media, B noted that the amount of time he started to spend watching online videos, listening to broadcasts, or reading posts in messengers or social networks increased considerably once his employer introduced a remote mode of work. "Every day I start with checking online coronavirus statistics for three countries—my home country, country where I am now and country my wife is from… My wife has asthma, my parents are almost 80, I am myself an ex-smoker—we all are in the risk group". He continued, then: "During the day I read posts in social networks and messengers in groups that are related to the disease, and while I do this I listen to radio or TV broadcasts where medical experts give updates". When asked if he watched or read anything that was not related to the disease, B said that he could watch a TV show occasionally, but overall, more than 50% of his time was dedicated to pandemic-related content.

It appears as if B had become trapped in a loop: feeling anxious, he started to look for information that would ease his fears; finding predominantly negative information increased his anxiety and forced him to spend more time searching for positive information. This cycle started to repeat daily.

When asked about his physical condition compared with the time before pandemic, B said that it was hard to define. From one point of view, when "it got serious" he quit smoking and from that perspective he felt noticeably better. From another perspective, B mentioned that his sleep pattern changed in negative way. Since he began to work remotely, he stayed awake until 03:00 or 04:00 and then slept until 10:00–11:00. He also complained that it became much harder for him to get to sleep.

Finally, B characterized his state the following way: "I felt very irritated with everything. Lost a couple of chess games while playing online—hit my smartphone several times. My cat demanded something too loudly—I shouted back at it." The state of B clearly showed anxiety-related hyperesthesia, as he couldn't remember doing or feeling anything similar before.

Regarding his future plans, B took a time-out for a minute and then stated that he wished everything would get back to normal, but he doubted it. He mentioned that he was looking for a new job placement in another region, but "with globalization turned backwards" it would hardly be possible. He sadly admitted that he would have to stay with the same employer at least for another contract term, as the coming few years did not have good employment prospects.

Overall B presented himself as a "take it on the run" type of person, emotionally-driven and with fears about life. Within the assertiveness model, his behavior pattern and responses can be characterized as partially passive, sometimes even as passive–aggressive.

Case C—Skeptic

Respondent C was a male in his mid-fifties. He was Muslim, originated from the Indian subcontinent, and was a master's degree holder. He was married, with two children from his first marriage that were already living independently. At the moment of the interview, he resided alone, as his wife was staying with her parents in their home country.

Respondent C admitted that he did not believe that the disease was as dangerous as the majority thought. In his understanding, the virus definitely existed, people became sick, and some even died. However, he then asked the rhetorical question: "What are the odds? I am not afraid of flying back home, or going in the car to the campus – both activities are much more dangerous than this virus". His point of view was that the dangers were deliberately exaggerated too much. When asked to elaborate on that, C started by defining himself as an Islamic socialist. He then told the interviewer that "… the existing organization of the world economy couldn't last anymore… Politicians and big corporations don't want to assume responsibility for economic crisis of the century and quarantine measures give a good explanation for 20–30% downfall in world economy". It appeared that the picture of the world that existed in C's mind was very well thought out and explained well his behavior and attitudes.

This skeptical perception of events was reflected in the way C maintained his social contacts. He admitted that, in comparison with the pre-pandemic situation, his social interactions declined, although only to a little extent.

When asked about his usage of media, C specified that he was not a big fan. However, occasionally he communicated with his friends who mostly shared the same point of view. Respondent C said that they "… exchange links between each other that undoubtfully shows this "pandemic" is not as scary as media is trying to demonstrate".

The major concerns of C were related to economic issues. Although he admitted praying for the health of his relatives and friends, he also specified that this was the same as the routine he followed in the previous several years. The anticipated economic crash, on the contrary, made him much more worried—for the two sons that he had to support until they finished their education, as well as for his and his wife's parents.

Overall, C demonstrated an example of problem-focused behavior.

Case D—Promoter.

Case D was a central European male, with a PhD degree, who was a Christian. He was married with two children. His immediate family resided with him.

Initially, when cases of the new disease were reported only in China, D did not worry much. His concerns started to grow at the end of January, when cases were reported in multiple parts of the world, and reached their peak in the middle of March, when the European Union closed its external borders.

Speaking about changes in the structure of his social contacts, D mentioned that he read in one group chat that "the safest way to avoid being infected is to avoid people. When you don't meet anyone, you have no chance of getting this virus". Following this understanding, D minimized his face-to-face social contacts to an absolute minimum.

When asked about how did he use media during the pandemic, D immediately became excited. He shared with the interviewer that he spent a large amount of time using social media and messengers, collecting and then reposting information. When asked about the reasons for doing so, D exclaimed: "… What if it is true? In this case I can save people by warning them." Later he additionally clarified: "Doctors don't know any more than we do. Many of them

are just clueless about how to treat this disease. If I pass the word that this or another method can help, somebody will be able to survive". Case D was not an author of any of the facts or claims that he spread. Rather, he only propagated them, with good intentions. Another interesting point mentioned by D was that broadcasting of messages allowed him "to introduce some order in the chaotic environment, where no one knows what to do". Preference was given to messages that "originated" from a "respectable" source—"doctors from Wuhan", "Center for Disease Control", and similar. Such an approach creates an illusion around events, as analyzed by Kapferer (1989). He described the spread of a rumor that certain food products were dangerous and caused cancer. The rumor was in circulation across different European countries for a decade, which happened without social networks and solely by physical dissemination in shops or mailboxes. Even educated people—teachers and doctors—participated in this activity, because the initial document was made on behalf of a clinic that specialized in cancer treatment. Although occurring at a different time, and with different means of communication, this is the same phenomenon as that in evidence with D.

Speaking about possible changes in his future plans, D stated that he didn't anticipate major changes. Some changes might happen, he believed, to traditional means of interaction between people.

During the interview, D demonstrated traits that placed him between an assertive and aggressive personality. While being emotion-focused, he was engaged in dissemination of facts that sometimes were far from reality.

Case E—Part of a Crowd.

Case E was a collective case that reflects the results of more than two-thirds of the conducted interviews—11 interviews of 15. All respondents representing this case were either master's degree holders (four), or had completed their doctorate (seven). Male and female respondents numbered five and six, respectfully. Eight of these respondents were married, while three were either unmarried or divorced. Members of this group of respondents originated from the Indian subcontinent, Europe, and South-East Asia.

Initial estimations of the situation were largely similar among respondents of this group. As one of the respondents noted, "People pass away every day. If I think about every poor soul that dies, I get crazy". Another respondent formulated in the similar manner: "If something happens, but it doesn't directly affect me—let it be, I don't care much".

Respondents of this group were mostly concerned with themselves and their immediate families. Most often they mentioned the fear that they or their family members would be infected, while there was no effective scheme of treatment or vaccine.

All respondents that represented this case reduced their face-to-face contacts and shifted communication activities mostly to social networks and messengers. Half subscribed to groups and channels that either specialized in the distribution of news related to the current pandemic situation or represented official sources of information. However, their participation in the spread of information was limited.

All respondents that constituted this case were united with a high rate of conformism and exhibited susceptibility to a bandwagon effect. All respondents, at some stage, made similar observations: "… but when all around me started to wear face masks…"; or in the social network they were using "everyone became really scared".

The majority of respondents who formed the aggregate basis for Case E demonstrated verbal aggressiveness during the interview in their reactions. Experiences, behaviors, and responses they shared or demonstrated evidenced maladaptive aggression and predominantly emotion-based approach.

Conclusion

The conducted research allowed us to draw several major conclusions:

- Despite the limited number of interviews conducted, we were able to differentiate several distinct profiles of how respondents reacted to the pandemic danger: Survivor, Victim, Skeptic, Promoter, and One of a Crowd.

- Respondents demonstrated that they preferred to group together with respect to how they understand the current situation. Skeptics grouped with skeptics, survivors grouped with survivors, etc. This grouping was reflected

in respondents' preferences for social media. Sources and facts that supported their points of view were prioritized, while those that contradicted them were ignored.

- Cases C and D can be interpreted as demonstrating higher degrees of uncertainty, in which people do not know how the external environment will surprise them tomorrow. A feeling of loss of control over their own lives makes such respondents susceptible to conspiracy theories, which was reflected in their behavior.

- All cases that were different from the conformist majority were relatively more skeptical regarding the state of the post-virus economy. While the collective conformist Case E had mixed results in this respect—some were concerned, while others were not— the other four cases demonstrated explicit concerns in this regard that were also logically backed.

- The described cases and the revealed corresponding types likely cover the majority of pandemic reactions. Nonetheless, the existence of other types, particularly mixed types, is probable.

- During the pandemic, the planning horizons of respondents shrank. The circumstances meant that it became more complicated to plan for the future, taking into consideration both the medical and economic aspects.

- The conducted interviews showed that a majority of respondents had an increased level of anxiety, which, in some cases, was a reason to seek professional help. This should be understood by academic managers and appropriate measures should be taken.

- The obtained results of our qualitative study are consistent with the results of mass studies.

The implemented methodology allows us to formulate more accurate questions for the quantitative, correlational research that will follow, in which we plan to undertake quantitative evaluations to characterize the types revealed by this study.

An Overview of Corporate Sustainability in Malaysia: The Current Practices and Potentials

Nur Syuhada JASNI[1] & Haslinda YUSOFF[2]

Faculty of Accountancy, Universiti Teknologi MARA (UiTM) Selangor, Malaysia
nursy168@uitm.edu.my[1], hasli229@salam.uitm.edu.my[2]

Abstract

This paper provides the current practices and potentials of corporate sustainability in Malaysia: Based on carefully selected from high-performance Public-listed Companies (PLCs) in Malaysia, we present a detailed picture of the current state of this research. Therefore, this paper is aimed at exploring the readiness of Malaysian companies thus point to promising future directions. The present study found that quality management and managing stakeholders' expectations are essentials in contributing to corporate sustainability development. Quality management provides consistent and organised in sustainability effort, which facilitated by quality employees. The findings provide evidence that managing stakeholders also includes efforts on building ethics, i.e. data protection and engaging with meaningful social projects for positive returns. Investigating more complex multi-level corporate sustainability, including sustainability risks and stakeholders' pressures, are among the promising future research opportunities.

Keywords: Corporate sustainability, Quality management, Stakeholders' expectation

Introduction

The Malaysian government has been working with the primary sources of finance, i.e. investors and financiers from bank institutions with significant roles in a company's growth. As a government arm, the Malaysia Stock Exchange, Bursa Malaysia has established the Sustainability Index known as FTSE4Good Bursa Malaysia (F4GBM) Index with an international consulting company, i.e. FTSE Group in 2014. The aim is to meet the expectations of sustainable investors in the financial market. Companies listed in the F4GBM Index must be reviewed semi-annually to verify whether each company has met sufficient sustainability factors incorporated in the company. Meanwhile, another source of financing is the financier, whereby the bank institution has worked with the government. Recently, CIMB Bank has provided Sustainability-Linked Loans (SLLs) in which the borrower receives financial incentives in the form of interest rate rebates if the borrower can demonstrate that the company has achieved its Sustainability Performance Targets (SPTs). According to CIMB website, the initiative has become a catalyst for businesses to embed environmental considerations into their strategies. It is promising to see investors and financiers working together in promoting responsible corporate citizenship in Malaysia. In this sustainability development, companies need to work on sustainability strategies to win both sources of financing for their company's prosperity.

Consequently, at a company level, a study is needed to shed some light on issues that have not yet been resolved by identifying the root causes of challenges to implement successful corporate sustainability and to address them appropriately. The contributions can potentially assist companies in rethinking and recognising their way of doing business that is beneficial internally and externally in synergising between profit-making intention and sustainable development. Thus, sustainability problems can be mitigated before they become worse and unmanageable, besides supporting policies at the macro-level (country) and sustainable development progress over time.

Hence, to understand the current situation, this study conducted a preliminary study to explore the readiness of Malaysian companies in practising corporate sustainability. It has been a definite lack of research focus within this context. Semi-structured interviews were conducted with five representatives from the Sustainability Department of high-performance Public-listed Companies (PLCs) in between June 2019- October 2019. The PLCs (involve in

trading/services operation) are identified actively practising incorporate sustainability in Malaysia by Bloomberg's Environmental, Social, and Governance (ESG) Index.

Present and future view of corporate sustainability practices

This study offered some useful insights obtained from interviewees of this study regarding their view of corporate sustainability at present and the expectation of the future. The findings are discussed in the following:

Quality Management

Top-bottom approach is essential in assisting corporate sustainability to be more consistent and organised. Two of the interviewees ardently explained:

"I want to champion the company sustainability, and now I can say that I am pleased seeing how our management is putting the effort. They are becoming more aware, maybe through the exposure from our discussion, and maybe through their interaction, perhaps with other stakeholders, or maybe with other companies or investors. I am not sure. But now, it seems that they want us to move towards this direction. So, I think the future of corporate ESG in the company is looking bright because we don't acknowledge it before, but now, it is part of our corporate strategy..." (P1)

"Usually, the annual report is prepared by the communication group and the finance group. And, of course, corporate governance. But, since last year, or the last two years, we started to involve more relevant units—group strategy. Somehow we learn in a hard way. But it's getting better. We start within ourselves first, the idea began with Corporate Responsible, then Sustainability. Slowly, the idea to make the business sustainable has spread out. Not just for the community or environment. The other units are also aware of the need to be sustained. The concept also recognised among the leaders and the management. They will ask about how to measure, what the impact is, how it can be sustained. So, these kinds of questions have started flying around, which is good. Previously, when there is a new boss, there will be new initiatives. But now, by implementing the sustainability concept, the business becomes more consistent, organised, and develop good communication. When we manage a program, we leverage what we had. We are looking forward to how we can benefit more, how we can make it sustainable" (P3).

More companies established the Sustainability Department and taking sustainability seriously and adapt to changes from time to time. Two interviewees claimed:

"They appointed me to lead sustainability. To me, that is a major step for a company to decide that there is someone who will focus on sustainability. Not many companies want to invest in that, so for me, it is a sign that it is only going to grow, and I really hope that it is something that will continue to develop and improve at the company, or even not at the company. I like to see corporations, companies, or any organisation in general, to improve the way they address ESG matters" (P1).

"Corporate sustainability should not sit under the Public Relation (PR) department or Communication department. Then it becomes very, either very PR centric or sometimes it's a bit more of damage control. Oh yeah so it should be led by the management team that should be champion or advocate for the management team" (P2)

Meanwhile, one of the interviewees from, P5, clarified the academic background of the Chief Sustainability Officer:

"We have a Chief Sustainability Officer. His background is in Accounting. He is handling our corporate sustainability and also in the Board of Directors" (P5).

P5 added:

"Business growth has driven corporate sustainability commitments. In the Sustainability Department, we are focussing on sustainability management and have different units, for example, safety, certification, environmental, lean" (P5).

Results show that quality management includes the top-bottom approach, whereas, top management provides supports and direction leading to be more consistent and organised. Besides, it is an advantage for a company established their managerial autonomy, Sustainability Department that facilitated by qualified employees as it is contributing to the corporate sustainability development as well.

Managing stakeholders' expectations

Company internalising more compliance policies and tighten sustainability efforts to meet with stakeholders' pressures. P5 believes that:

"Talking about the future of sustainability, I think it will be even bigger because outsiders are attacking palm oil. So, we will be tightening our sustainability effort" (P5).

The company is aiming to become a trusted brand. Thus, more efforts on building ethics, for instance, data protection, as data privacy is part of good governance. The following interesting quote explains this situation:

"I think one main area for the future is ethics. Why did I say ethics? Because the forefront of technology that we are involved in, things like Big Data, Machine Learning, and AI, have a lot of ethical questions, which have not been answered yet. How much data privacy does one has? Obviously, we can actually capture a lot of data from all our subscribers; you know why there are people who want to buy, what they can do. All of these are related to ethics. So I think for us, we do see that as both an opportunity and a risk. If we don't do it well, it will be risks. But if you do it well, you will be seen as a leader and trusted by your customers" (P2).

The company is interested in reaching more people to find quality talent and build a strong base of satisfied customers. This quote explains the situation:

"We see that as a significant growth factor for the millennial relevance. Because technology is changing the industry, and you'll always take young people. Technology comes from them. So, we train talents and customers as very important. It's a risk and benefit for our reputation" (P2).

Consequently, corporate sustainability also related to social project. Hence, measuring the impact of the project is also crucial as engaging in a meaningful project will contribute positive returns. One of the interviewees, P3, believes:

"Based on the progress now, we already started the buy-in from the management. And somehow the culture has started. Everybody is asking, 'What's the impact?' 'How to measure it?' These kinds of questions don't even exist in past meetings. But, recently, all the bosses, they're not even bosses. Anybody can ask. What's the impact of this program? This is the kind of culture that we want to create. I'm sure this sustainability culture can grow in the company and can drive us towards business sustainability. If we do it correctly, we will stay in the industry. We'll survive, and we'll do better" (P3).

The findings provide evidence that managing stakeholders also includes internalising more compliance policies to meet with stakeholders' pressures and putting more efforts on building ethics, i.e. data protection. Furthermore, engaging with meaningful social projects in reaching more people to find quality talent and build a strong base of satisfied customers.

Conclusion

The ways Malaysian companies are taking corporate sustainability suggest that the continuous support from top management on corporate sustainability is crucial to encourage all employees to cooperate and adapt faster within the company. In the next few years, more companies are likely to set up the Sustainability department as their managerial autonomy and not sitting under other departments. It is no surprise that a manager leads the Sustainability Department with accounting qualifications, who has broad knowledge in this field. Therefore, it is generally accepted the nature and scope of accounting have diverse beyond account and reporting financial matters to manage non-financial on sustainability issues, such as Environmental, Social, and Governance matters. The purpose of central management is to measure sustainability in an organised and consistent way, hence convincing employees that sustainability is manageable and achievable. Recognition of successful corporate sustainability is believed to be a trusted brand that can create a significant influence in reaching more people, for instance, attracting quality talent and building a strong base of satisfied customers. In the light of sustainability risks and stakeholders' pressures, companies are driven to address the sustainability risks by tightening the efforts and communicating effectively with stakeholders.

Human-Centric Approach in Corporate Sustainability: The Changing Landscape

Nur Syuhada JASNI[1] & Haslinda YUSOFF[2]

Faculty of Accountancy, Universiti Teknologi MARA (UiTM) Selangor, Malaysia
nursy168@uitm.edu.my[1], hasli229@salam.uitm.edu.my[2]

Abstract

Today, a growing number of corporate behaviour studies are linking between human-centric approach and corporate sustainability. However, the critical elements of the human-centric approach that contributing to greater corporate sustainability have yet to be undertaken. This paper points the key elements that are important in a human-centric approach that is accelerating the integration of corporate sustainability into strategic management. The literature review revealed that greater corporate sustainability are achieved through: (1) ethical leadership that derived from endogenous (internal) or exogenous (external) events pressures; (2) managerial autonomy that centralised sustainability commitment; (3) trained employees with skills and knowledge that also driver of innovations; and (4) utilising internal and external communication tools. The contribution of this paper provides a summary of the most critical issues that emerged in this field to improve business excellence. The basis of the human-centric movement is demanded a more structured development, hence should be addressed by further research.

Keywords: Corporate sustainability, Human-centric approach, Strategic

Introduction

Today, many companies are transforming the way their business operates by alleviating humanity and restoring the ecosystem to be more human-centric to become successful resilient businesses. Dutch Lady, Honda, Toyota, and Samsung are among the Multinational Companies (MNCs) that actively promote and practice human-centric concepts in their business operation. The implementation of a human-centric concept is aligned with fulfilling stakeholders' social needs. Internally, companies proactively involve employees on matters regarding innovation, wellbeing, and wellness. At the same time, externally, they focus on customers that concerns a tactical blend of human values (e.g., connection, engagement, satisfaction, loyalty, care, and respect). The human-centric concept is also integrated with digital interaction to establish trust and provide assurance that satisfies certain parties. Furthermore, companies remain true to their vision, promptly deliver their promises, and ensure all employees embrace the organisational values. This human-centric idea rapidly nurtures from the core, which is powered from the inside out.

Elements that are contributing to greater corporate sustainability

This study identified a few elements that are contributing to greater corporate sustainability for strategic business purposes. In the following, our discussion will be restricted to a human-centric approach context.

Ethical leadership

Sustainability practices emphasise the role of human resources for the implementation that able to strengthen the company's reputation (Ali, 2014; Tang, Hull, & Rothenberg, 2012) and efficiency, reduction of waste, energy, and raw materials. A great deal of previous research in a human resource focused on how ethical leadership, for example, Chief Executive Officers (CEOs) and other top managers, can vitalise investments into company resources and capabilities. Meanwhile, Board of Directors is the primary functional body of the corporate governance mechanism that works on

Cite this Article as: Nur Syuhada JASNI & Haslinda YUSOFF "Human-Centric Approach in Corporate Sustainability: The Changing Landscape" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

monitoring corporate management activities, designs corporate strategies, resolve agency problems between the management and external shareholders and enhance the quality of business decisions (Hou, 2019). Therefore, BOD must contribute their on-going commitment to corporate sustainability. Ethical leadership is most commonly associated with the work of (Meyer, 1982), which pointed out that the motivation for ethical leadership change is derived from endogenous (internal) or exogenous (external) events pressures. Thus, internally, the commitment arises from the personal perseverance of a CEO. Although, or possibly external forces when the business takes stakeholder accountability very seriously. For instance, Nike received accusations about violations of human rights, resulting in Nike addressed the issues ethically and operating responsibly within the supply chain.

Managerial Autonomy

Ethical leadership is also influenced by the growth of corporate strategy and corporate governance structure in establishing managerial autonomy (Dill, 1958; Li, X., Gao-Zeller, X., Rizzuto, T. E., & Yang, F., 2018; Lioukas, Bourantas, & Papadakis, 1993; Xiao, 1991). Dill (1958) specified managerial autonomy independence in developing tasks or measures. Similarly, Hambrick and Mason (1984) explained that managerial autonomy potentially manages and shapes actions in the company. Prior studies supported managerial autonomy important position in promoting the effect of managerial leadership beyond traditional corporate performance (Dill, 1958; Lioukas et al., 1993; Xiao, 1991) and corporate social performance (Chung & Cho, 2018; Li et al., 2018). The rationale of managerial autonomy by hiring a Corporate Sustainability Officer (CSO) is to centralise sustainability commitment under the position; meanwhile, the CEO can retain sponsorship of the change (Henderson, Gulati, & Tushman, 2015). To date, several studies contributed to the improved sustainability-related decision-making, which balanced the concerns and needs of numerous stakeholder groups. These are resulting in improving long-term reputation, motivation and profits (Waldman & Siegel, 2008), sustainability strategy of employee wellbeing (Piccolo, Greenbaum, den Hartog, & Folger, 2010) and green supply chain management (Ardakani & Soltanmohammadi, 2019). By including directors with sustainability expertise or establishing board committees that centred on sustainability matters will enhance sustainability performance, hence, demonstrating their sustainability commitment to stakeholders.

Training

The moves to increase individual knowledge acquisition will make employees more motivated. Also, stimulating the internal motivations of the employees should be developed progressively as part of sustainability strategies (Li et al., 2018). Apart from that, employees' confidence increased by continuous training and development that increase knowledge and skills related to the job description (Egri & Hornal, 2002; Ramus & Steger, 2000). Previous studies of Langwell and Heaton (2016) and Jackson, Renwick, Jabbour, & Muller-Camen (2011) revealed the significance by measuring the return on investment (ROI) of the training programmes, resulting in the understanding of the training impact on human development and cost-effectiveness.

Accumulation of skills and knowledge is the driver of innovations (Altenburger, 2018a; Nidumolu, Prahalad, & Rangaswami, 2009). Innovative approaches restructured and reinvented products and services, making them for consumers (Henderson et al., 2015); hence, contributing to the development of a strong infrastructure, and building meaningful brands that offer sustainable and organic material (Altenburger, 2018b; Hoffman & Bansal, 2012). It is possible that innovation is not related to technical advancements only, but also the utilisation of technological know-how changes at a modest level in enhancement or expansion (Engert, Rauter, & Baumgartner, 2016). Meanwhile, investing in "experiments" will develop company capabilities in engaging multiple-player-based, critical sustainable changes (Henderson et al., 2015) that eventually lead to long-term success. For example, Samsung's philosophy, "inspired by humans, creating the future" guiding them to create human-driven innovations that enrich customer's lives and contribute to social prosperity and sustainable environment.

Communications

A critical study provided groundwork evidence of corporate communication of the World Business Council For Sustainable Development (2011), which utilised a particular tool of communication, whether for internal and external

communication. Besides, everyone, from the CEO to the janitor of the company, should be part of sustainability routines to understand the processes and goals and develop endless support for corporate sustainability. It was argued that leader alone could not create change; thus, the notion that organisational change occurs through social exchanges. Thornton, Ocasio, and Lounsbury (2012) stated that "social interactions provide the key motor that reproduces, alters, or transforms practices and organizational identities." While a CEO may initiate change by creating a new vision, it is the social interactions that create a common understanding and shared vision that predicate action (Henderson et al., 2015; Micklethwait & Dimond, 2017).

Conclusion

In summary, it was shown from the literature review that four key elements; ethical leadership, managerial autonomy, training, and communications are crucial in a human-centric approach that contributing to greater corporate sustainability. First, ethical leadership is derived from endogenous (internal) from the personal perseverance of a CEO and exogenous (external) when the business address stakeholder accountability ethically. Second, the specified managerial autonomy, i.e. Sustainability Department will manage and shapes proactive sustainability actions in the company. Third, innovation also related to utilisation of technological know-how and experimenting process. Fourth, communication involves internal and external, leading to endless support for corporate sustainability. The basis of the human-centric movement is demanded a more structured development from the company.

Abstract

This article attempts to systemize the results of existing research on the issues of lifelong education of adult population in Russia, based on the fragmented comparison of Russian education system with the lifelong learning system in Czech Republic to define key issues and opportunities for efficient engagement of main Russian economic entities in the lifelong learning process, namely adult population/households, training institutions and the state. The following desk research methods were used for study: content analysis and traditional analysis of data, collected in the framework of surveys of key entities involved in the process of lifelong education of adult urban and rural population in Russia in real time mode. Based on data analysis the authors highlighted the problems and prospects of lifelong learning in the future for the main Russian economic entities for the purposes of improving the wellbeing of adult population in Russia. In particular, the authors identified potential opportunities for greater engagement of adult population in the process of lifelong learning; exposed factors, hindering the efficient management of adult lifelong education by corporate employers; demonstrated positive changes in the activity of institutions providing lifelong learning services to adults; detailed main functions of the state in further development of the system of lifelong learning in Russia.

Keywords: Research, Participants of Lifelong Learning Process.

Introduction

Lifelong learning is one of the factors in the formation of human capital, and all economic entities interested in it should invest in it. From the authors' point of view lifelong learning is, on the one hand, an independent choice each person can make; on the other hand, it is a whole system based on the interaction of such economic entities as:

- adults / households with a demand for lifelong learning services;

Cite this Article as: Galina TIMOKHINA, Irina SHIROCHENSKAYA, Evgeniya ZHADKO, Emil VELINOV, Inga KORYAGINA and Venera KADEROVA" Issues and Prospects of Involvement of Economic Entities in The Process of Lifelong Learning in Russia" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

- employers who formulate the offer of educational services, indirectly consuming these services through their employees' competencies;
- educational organizations that create demand for training programs at various levels;
- the state acting as a regulator of relations between economic entities in the process of organizing and coordinating lifelong learning services.

Within the framework of the implementation of lifelong learning concept in the EU countries, as well as in Russia an information and analytical system has been created to collect and analyze information about the availability of lifelong learning services for various groups of population. In particular, monitoring studies on the problems of the population and organization participation in lifelong education have been carried out by the Federal State Statistics Service, the Higher School of Economics and the Levada Analytical Center (Levada-Center) in Russia since 2002.

Despite the active research carried out within the framework of this scientific direction, it should be noted that it is not sufficiently developed in the context of a systematic analysis of the problems of lifelong education, in the organization of which all interested economic entities are involved.

The purpose of this research is to systematize existing studies on the problems of adult lifelong learning in Russia, based on fragmentary comparisons with the system of lifelong learning in Czech Republic, to determine the possibilities of major economic actors to productively participate in this process.

Research hypothesis: systematization of existing research on the involvement of economic entities in the process of adult lifelong education over a fourteen-year period will identify problems and potential opportunities for the effective organization of this process.

The present study is based on the following methods of analysis: comparison, abstraction and generalization of primary data obtained by the Higher School of Economics within the framework of a series of monitoring studies in the field of educational economics. The following methods of desk research were chosen:

- content analysis for the systematization of analytical research on lifelong learning issues for the period from 2006 to 2019;
- traditional analysis of survey data of the main subjects involved in the process of lifelong education. The selected methods allowed us to analyze a large array of information over 14 years of research on this topic in order to systematize them; to consider the object under study from different angles with the purpose of determining the problems and opportunities for productive participation of economic entities in the process of lifelong adult education. Limitations of the desk research resulted in the need for more detailed verification of data relevance and reliability.

This study uses some fragmentary data on the organization of lifelong learning in Czech Republic. The authors found the comparison of approaches to lifelong learning in Russia and Czech Republic interesting from an applied point of view and due to the following considerations. A significant part of the adult working-age population of both countries grew up and formed under the domination of the socialist ideology and received education in a similar format system. This fact could not but affect the models of economic behaviour of the main economic entities, including the field of lifelong learning. However, after the collapse of the Council for Mutual Economic Assistance (COMECON), behavioural patterns of economic entities of both countries mutated along multi-directional paths, which probably influenced the organization of various social and economic processes, including the process of lifelong education.

The structure of the article includes a brief literature review on this scientific direction. The first Chapter contains the analysis of the Russian adult population involvement in the process of lifelong learning; the second chapter presents the results of analysis of employers' participation, as well as the participation of educational organizations and the state in the process of lifelong learning.
In conclusion, the article presents conclusions, identifies opportunities for effective interaction of economic entities for greater involvement of the adult population in the learning process throughout life, and provides directions for future research.

Literature Review

A brief review of scientific articles in the field of our research shows the interest of scientists in the issues and problems of the involvement of economic entities in the process of adult lifelong education.

Thus, Boeren (2017) discusses the multi-level nature of adult participation in lifelong learning, describes the roles and responsibilities of participants in the process: adults, education providers, and subjects of social educational policy in the country. Makino et al. (2017) investigate the issues of organizing lifelong education not only by economic entities, but also by social communities in order to create a new educated society. In their research Hafford-Letchfield and Formos (2016) raise the problems of a co-productive approach in providing lifelong learning services to elderly people.
A significant part of the research focuses on the involvement of working Russians in obtaining additional vocational education (Karavai, 2016; Galitskiy,2016). In her research, Pushkareva (2016) pays attention to various changing conditions of social. Kalimullin and. Shaidullina (2015) consider the possibility of training competitive personnel in the system of lifelong education in the context of various integration models of production and education.

Zeer et al. (2017), Popova et.al. (2020) focus on the importance of lifelong education in the process of professional development of an individual. Prikot and Vinogradov (2016) consider lifelong education as an "infinite" number of educational options for each individual. Sergeeva and Voskresenko (2016) believe that the optimal conditions for the development of lifelong education can be created precisely in universities as multilevel educational clusters.

Sabria-Bernado et al. (2017) and Vera-Toscano et al.(2017) identified the following determining factors that influence consumer demand for lifelong learning in higher education through empirical data: motivation, conflict / difficulty, and career development. These data can be used by educational organizations in building relationships with consumers of lifelong education services. Kiseleva and Anikina (2015), Kiseleva et al. (2016) further specify the possibilities et al. further specify the possibilities of building relationships with service consumers through the development of relationship models.

Summing up a brief literature review on lifelong education, we would like to stress a considerable lack of scientific articles devoted to the systematization of current research on the organization of lifelong learning by its main participants: the adult population, as well as organizations involved in this process, and the state.

In our opinion, the participants in the process of lifelong education are interested both in seeing the possibilities of developing lifelong education and in understanding the problems and ways to overcome them.

Research Results

Analysis of Russian adult population involvement in the process of lifelong learning

Content analysis and traditional analysis of survey results aimed at participants in the lifelong education process conducted by the Higher School of Economics from 2006 to 2018 in the framework of monitoring the economy of education showed a certain dependence of adult involvement in lifelong learning and the cyclical nature of the economy: during periods of recession, enrolment in lifelong learning decreases by about 5-6 points compared to a more stable periods in the country's economy (fig. 1).

Fig. 1: Dynamics of adult involvement in lifelong learning in 2006–2018, %
Source: Bondarenko, 2018, 12 (132)

From the data analysis received from the 2017-2018 survey results on a sample of 1,600 units, which included adults aged 25-64 years, it follows that in Russia there is a serious lag in involvement in formal and non-formal education for all age groups, as well as a differentiation between the involvement of the younger age group (aged 25-35 years) and the older age group (55-64 years), which in 2017-2018 was 2.5 times (for comparison, in Czech Republic about two times) (Bondarenko, 2018, 12 (132)), (Weiss-Gal, 2016).

A worldwide trend shows a more active interest in lifelong learning among population groups with a higher level of educational capital (Timokhina, et.al, 2017). In 2017-2018 Russian respondents with higher education participated in lifelong learning almost 1.5 times more often than those with secondary vocational education (Bondarenko, 2018,12 (132)). A significant differentiation in terms of involvement in lifelong learning between the least and the most prosperous groups of population is also worth mentioning: more affluent people were able to participate in the process twice as often as low-income groups. Moreover, a significant lag in low-income groups will persist steadily over the past 10 years.

According to monitoring studies, the structure of demand for formal education services does not change significantly in 2013-2017. In formal education less than 3% of the adult population completed secondary special education programs, and 1.4% completed higher education programs (1.4%).

Data on adult involvement in non-formal education confirms Russian and European trends in the growth of demand for lifelong learning services. Among the total population aged 25-64, 4% were enrolled in them, and of the employed reached 6% (Bondarenko, 2017, 5(104) p. 28; Bondarenko, 2017, 5(104) p. 1-23). At the same time, the most popular programs are advanced training and professional retraining for professional development as well as courses for obtaining a new profession. This is due to the low time and money spent by adults.

Secondary data analysis from the 2017-2018 survey results showed that the most common type of lifelong education is informal - self-education: 24% of respondents aged 25 to 64 inclusively engaged in self-education in 2018, which reduces last year's figures by 3 points. The adult population is increasingly using online technology: an increase of 12% in 2018 compared to 2006 (fig.2).

Fig. 2. Use of information and computer technologies in self-education in 2006-2018 (in % of the number of respondents)

Source: Bondarenko, 2018, 5(125)

Approximately the same number of adults is engaged in full-time and part-time self-education (15% and 17%, respectively), similar proportions are observed in the statistics of adult self-education in Czech Republic (Beloiu, et.al, 2015).

The systematization of the survey data of adults conducted by the Higher School of Economics for the period from 2006 to 2018-2019 allowed us to identify internal and external barriers to the provision of lifelong learning services to adults. As internal barriers, we highlighted the lack of a formed need for additional knowledge, unwillingness to develop professional and personal qualities (Malkina, 2017). As external barriers to education for adults who need it, we can identify weak financial and organizational support of students on the part of employer, the state; time constraints, difficulties of combining study and work, family responsibilities, as well as educational infrastructure.

Similar internal and external barriers to involvement in lifelong learning are observed among Czech adults, in particular, low motivation characteristic of the least educated adults, limited time due to family responsibilities (14% of respondents), employment at work (34%), high cost of training (17%) (OECD, 2019).

Analysis of adult involvement in lifelong learning in Russia allows us to identify the following problems that impede its development:

- differentiation between involvement in all types of lifelong learning of younger and older age groups, the

least and most affluent segments of the population, adults with different levels of educational capital;
- completely surmountable internal and external barriers for the adult population to receive lifelong learning services.

The authors see a solution to these problems by using potential opportunities to increase the degree of adult involvement in the process of lifelong education, taking into account the best European and, in particular, Czech practices. It includes the development of short-term training programs, the modular structuring of educational programs, the widespread use of digital learning technologies, the development of educational programs that are understandable and accessible to adults with a low level of education, the development of programs that are in demand on the labor market, the provision of flexible training schedules, financial support from the state and employers, the formation motivational incentives in adults for lifelong learning.

Analysis of enterprises (employers and educational organizations) participation and the state participation in the process of lifelong learning

In order to analyze the organization of lifelong learning by employer companies, we compared the companies' survey results in Russia and Czech Republic for the period of 2016-2017. A qualitative study through a rotation panel and face to face formalized interviews was conducted by Russian research companies in 2016 and 2017 on a sample of 511 company executives (Bondarenko, 2018, 2 (122)). Czech research companies conducted a quantitative study in 2016-2017 on a random sample of 402 units (Fajčíková,et.al, 2017).

Big businesses are the leaders in organizing in-house training both in Russia and in Czech Republic. Despite some differences in the classification of business by size depending on the number of employees, small businesses show less involvement in in-house training in both countries, however, Russian small-size businesses demonstrated a more significant lag behind the average indicators shown by large companies than in Czech Republic (fig.3,4).

Fig. 3: Training by Russian companies of various sizes (in % of the number of surveyed employers)
Source: Bondarenko, 2018, 2 (122)

Fig. 4: Training by Czech companies of various sizes (in % of the number of surveyed employers)
Source: Fajčíková,et.al, 2017

Planning, organizing and monitoring the effectiveness of employee training is carried out mainly by high-tech companies of Russian large businesses that have R&D expenses. Unlike Russian companies, most Czech employers have the practice of forming plans and budgets for organizing employee training. Significant differences were revealed when comparing the organization of training in Czech and Russian small businesses: in Czech Republic, even in very small enterprises of 1-9 people, staff training is carried out (22% of the number of surveyed employers) (fig.5).

Source: Fajčíková,et.al, 2017; Bondarenko, 2018, 2 (122)

Fig.5: Availability of an official detailed plan/ budget for organizing staff training in companies of different sizes in Russia and Czech Republic (in % of (in % of the number of surveyed employers)

In order to train personnel for their own needs, save time and money, as well as eliminate the disadvantages of training by educational organizations, companies conduct internal training, creating in-house training infrastructure. According to a 2018 study, one in three Russian companies creates its own educational infrastructure; less than 10% of companies form it together with educational organizations. The organization of staff training through the use of its own resources is typical mainly for large businesses: 47% of companies with more than 500 employees have training centers, and 36% of these companies have training courses.

Despite the development of in-house training environment, about 40% of high-tech companies demand lifelong learning services from third-party structures: 20% of companies apply to educational organizations, about 20% - to business partners, recruitment agencies, coaches. A weak level of interaction between Russian employers and employees on training and skills exchange issues can be noted: only 16% of companies conduct joint activities on training and employee skills exchange. As a rule, such cooperation is based on the principle of vertical integration. Although in European countries and, in particular, in Czech Republic, the cooperation of companies on staff training is carried out on the basis of horizontal integration.

Based on the results of a comparative analysis of employee training organization by Russian and Czech employers, the authors identified a number of problems:

- Russian enterprises of large, medium and small businesses underuse the practice of forming plans or budgets for organizing employee training;
- Russian small-size enterprises are quite limitedly involved in lifelong learning programs for adults;
- The interaction between employers, in high-tech sectors on issues of training and skills exchange between employees, as well as with educational organizations is quite limited.

Educational organizations make perhaps the most significant contribution to non-formal and informal adult education. However, a systematic study of the organization of lifelong learning in the field of continuing education was carried out seven years ago. The results of the 2018-2019 study of strategies, motivations and students' and teachers' economic behavior in 94 Russian universities allow us to draw very scanty conclusions on the organization of informal adult education (Rudakov, et.al, 2019).

Continuing adult education is implemented through professional development programs, increase of the professional level of adults in about 80% of educational organizations.

Analysis of teaching practices shows that in 2012-2017, teachers of educational organizations began to rely more often in teaching on their own curricula of continuing education and teaching aids: if in 2012 70% of respondents used their own curriculum, and 45% used academic aids, then 2017 - respectively 74% and 52% (Zborovskiy and Ambarova, 2016).

In the process of adult learning, electronic methods of presenting information are more often used: presentations, slides and handouts (57% of respondents in 2012 and 62% in 2017), digital libraries and scientific portals - 54% of

respondents.

It should be noted that in 2017, 10% of teachers used the materials from Massive Open Online Courses (MOOCs) for training. Over the period under review, the proportion of teachers reading professional literature in a foreign language increased significantly (from 29% in 2012 to 42% in 2017), the share of those who prepare texts for publication in a foreign language has more than doubled (from 13% to 28%).

There is a tendency towards a shift in demand for short-term programs lasting less than 72 hours in the form of seminars, training courses compared with long-term professional training programs with the duration from 72 to 499 hours (Zhadko, Popova, 2018).

The results of the data analysis allow us to draw the following conclusions:

- vocational training programs predominate in comparison with general education programs in the portfolio of continuing education;
- there is a tendency to increase the supply of short-term programs in comparison to long-term training programs in organizations of continuing education;
- educational organizations began to use educational programs of continuing education and manuals created by teachers to a greater extent; they began to use electronic methods of submitting information more often in the process of adult learning.

The lack of up-to-date data on the market of continuing educational services, monitoring of the current situation and problems in adult continuing education does not allow making adequate decisions to improve the effectiveness of lifelong education by market participants.

Systematic work in the field of lifelong education can be possible only with the direct participation of the state and its fulfillment of a set of functions: regulatory, expert, analytical, informational, coordinating, controlling, etc. In particular, the expert-analytical function should be carried out by organizing systematic and objective statistical observations monitoring the involvement of the main economic entities in the process of lifelong education.

The information function of the state in the field of lifelong education is implemented in the creation of a system for informing the main economic entities about the regulatory framework, market participants, educational infrastructure, targeted educational initiatives, mechanisms that ensure access to adult education, educational routes, etc. Within the framework of this function, the propaganda function of the state is also important, which consists in explaining and encouraging the population to study throughout life.

The coordinating function involves establishing a dialogue between the educational system and the owners of medium- and small-size businesses who find it difficult to create an effective system of lifelong employee training without state assistance (Kapustina, et.al, 2016). The state coordinating function will help to attract employers more actively to cooperation within the horizontal integration framework through modern forms of interaction, for example, the creation of innovative educational clusters.

The implementation of a set of functions becomes possible with proper funding of lifelong education by the state. However, the OECD 2019 research on lifelong education highlights that in almost all EU countries, adults and organizations invest more in the development of lifelong education than the state: public spending is 0.1% -0.2% of GDP against 0.4-0.5% of employer companies and 0.2-0.3% of individuals – those adults who are interested in lifelong education (OECD, 2019). Data of this kind in the Russian sphere of lifelong education is not available to the authors of the article, however, but we assume that these indicators have even lower values.

Conclusion

In conclusion, we would like to state that the research goals formulated in the article have been achieved, and the hypothesis put forward has been confirmed. Based on the systematization of existing research on engagement issues of economic entities: adults / households, training organizations and the state in the process of lifelong education, the authors revealed both the problems that impede its development and potential opportunities.

In the first chapter of the article, the authors identified the problems of involvement of adult population in lifelong education in Russia due to different indicators of involvement for different strata and the presence of completely surmountable barriers for adults to receive lifelong education services. The authors propose ways to solve the

identified problems by using potential opportunities to increase the degree of adult involvement in the process of lifelong education.

The authors believe that in order to increase the participation of the adult population in lifelong education, employers, educational organizations and the state need to work to reduce the disparity in indicators of involvement in training between the least and most educated and well-off segments of the population, and different age categories. Potential opportunities should be used to remove internal and external barriers to adult involvement in lifelong learning, taking into account the best European and, in particular, Czech practices.

The results of a comparative analysis of employee training organization by Russian and Czech employers, which were presented in the second chapter highlighted a number of problems in terms of the weak application of Russian enterprises to the practice of forming plans or budgets for the organization of employee training, limited interaction between employers and educational organizations. Domestic employer companies need to study foreign and Czech experience in organizing lifelong education for employees, and introduce it more widely. It is necessary to develop short-term training programs, structure them modularly, offer training programs with flexible schedules that are in demand in the labour market, etc.

The analysis performed by the authors confirms that it is necessary to integrate the efforts of all economic entities in order to increase the level of involvement in this process.
Along with the problems of organizing lifelong adult education, the authors show positive changes in the activities of organizations supplementary education. However, the authors emphasize the lack of research on the organization of non-formal education by educational organizations in dynamics over the past seven years.

From our point of view, the prospects for the development of lifelong education in the future will be determined by the systematic approach on the part of the state to the implementation of the concept of adult education throughout life and the performance of its set of functions. With a systematic approach to the organization of lifelong education, knowledge of the problems identified in the study will allow us to set targets for increasing the involvement of economic entities in this process.

Thus, the directions of future research may result in the study of system-forming factors that determine the effectiveness of interaction between economic entities in organizing the process of lifelong education of adults in Russia. The authors believe such research may be of scientific and academic interest to researchers, and will also have an applied nature. This will allow the interested parties to make effective decisions on integrating efforts in order to increase the needs formation of the Russian adult population in a conscious desire for further education.

Abstract

This article presents an original methodology of consumer assessments of satisfaction with the quality of a product / service based on N. Kano's model; the article describes a study of customer satisfaction with the technical quality of Moscow underground (metro) services carried out in accordance with the methodology developed by the authors aimed at justifying management decisions to increase the competitiveness of metro system. Within the framework of the author's methodology, the relative importance of product attributes, including rail transport services, was determined; the calculation of descriptive statistics indicators for each attribute was carried out; for each attribute, the indices of influence on passengers' satisfaction and dissatisfaction with services were calculated according R. Best method; the total index of attribute influence on consumer satisfaction; the matrix for interpreting quality categories developed by M. Timko was modified; as well as a comprehensive determination of the impact of an attribute on consumer satisfaction. This methodology makes it possible to highlight problem points in the competitiveness of services and make management decisions to improve them. The authors propose management solutions to improve the competitiveness of Moscow underground (metro) services based on the developed methodology: make capital investments in the introduction of important and attractive attributes of technical quality of Moscow underground (metro) services for consumers; reduce costs of introducing quality attributes that are indifferent to consumers; increase the presence of one-dimensional attributes of technical quality of Moscow metro services; monitor technical quality attributes of a service and study their perception by consumers.

Keywords: Competitiveness, Consumer Satisfaction, Underground Services, Methodology.

Introduction

In the context of intense functional competition of various types of transport services, an indisputable and extremely urgent task of market economic entities is to manage the competitiveness of these services. The competitiveness of transport services, in particular, rail transport services, is understood as a higher ratio of the aggregate of quality characteristics, costs of its acquisition and consumption, as compared to goods / services-substitutes, when they meet market requirements (Mokronosov, Mavrina, 2014, Sidorchuk & Skorobogatykh, 2015).

The results of international and Russian scientific research substantiate and confirm that the key factor in ensuring and improving the competitiveness of any goods and services, including rail transport services, is their compliance with market requirements, that is, the needs, expectations, preferences, and values of potential and actual consumers of these services (De Oña, R, et al 2016; Eboli, Fu, Mazzulla, 2016; Seifullaeva et al., 2018; Seifullaeva et al., 2018) and others.

Since the set of behavioral variables of each individual consumer is formed under the influence of a wide range of factors, consumer assessments of the same type of transport service made by different consumers may not coincide. Each consumer will assess the level of competitiveness of services, in particular, services of rail modes of transport, purely individually (Friman, Fellesson, 2009; Ivashkova, et al., 2009). The competitiveness of a service is determined, in contrast to its quality, by a combination of only those specific properties that are of clear interest to a given consumer and ensure the satisfaction of this specific need, while other characteristics of the service may not be taken into account.

Accordingly, the starting point in the formation and improvement of the competitiveness of services, including rail transport services, is the study of various consumer behavior variables, including passenger satisfaction of specific needs when consuming these services (Givoni, Rietveld, 2007).

World and Russian experience in measuring consumer satisfaction ratings with the quality of rail transport services is represented by a certain variety of methods and techniques that make it possible to highlight problem points in the competitiveness of a service and make management decisions to improve it (Geetika, 2010; Eboli, Mazzulla, 2012; Sidorchuk, Skorobogatykh, 2015; Sidorchuk, et al., 2015; De Oña, et al 2016; Fraszczyk, Marinov, 2017; Machado-Leóna, et.al., 2017; Seifullaeva, et al, 2018; Lukina et al., 2018; 2019; Ibrahim, et.al, 2020; Jomnonkwao, et. al., 2020). At the same time, due to the dynamics of scientific research and the emergence of new links and relationships between their components, the strategy of scientific search for methodology and research on the problems of providing and increasing the competitiveness of rail transport services based on the study of consumer ratings is changing.

Project Goals

The purpose of this research is to develop an original methodology for consumer satisfaction ratings with the quality of goods/services based on N. Kano model and to study consumer satisfaction with the technical quality of services of the Moscow underground (metro) according to the author's methodology in order to justify management decisions of increasing its competitiveness.

Author's Methodology

The authors developed an original methodology for consumer ratings of service quality based on a model for analyzing attributes and their impact on consumer perception of a complete product by N. Kano. According to N. Kano's methodology, based on the study of the consumer's reaction to the presence and absence of a product attribute (feature), it is determined how this attribute will affect the consumer satisfaction or dissatisfaction with the product as a whole (Cowell, 1984; Grönroos, 1998).

Kano's methodology involves classifying product attributes in order to determine the degree of their impact on customer satisfaction or dissatisfaction. Kano's model includes five quality categories

(dimensions), each of which characterizes a special relationship between the quality of performance of a product attribute and customer satisfaction / dissatisfaction, as well as the sixth category, which covers contradictory and questionable answers from respondents (Table 1).

Table 1: classification of product attributes by Kano Model

Category	
Must-be (basic)	M
Attractive (desired/factors of delight)	A
One-dimensional (attributes of quality	O
Reverse	R
Indifferent	I
Questionable result.	Q

The first three categories of attributes are considered basic, since their contribution to satisfaction / dissatisfaction can be indented. The category of "questionable" attributes is excluded from the analysis, since the respondents' answers are contradictory and impossible to interpret. A large proportion of reverse attributes that are irrelevant and questionable are likely to indicate errors in the preparation of the questionnaire: they are either too general or, on the contrary, too detailed in formulation (Berger, et al., 1993). The sequence of research by the Kano method is described in detail in a number of research (Berger et al., 1993; Tsysar, 2002; Lopatinskaya, et al., 2015).

In order to assign an attribute to a specific category, the authors developed an original methodology which consists of the following steps:

1) Determine the relative importance of an attribute. The Kano method does not directly assess the importance of attributes. However, we assume that those attributes whose perception is determined are more important. That is, when respondents can assign an attribute to one of three main quality categories: basic, one-dimensional, or attractive factors. Therefore, the important attributes are those for which the equation is the following: (O+A+M)>(I+R+Q).

2) Calculate descriptive statistics. Fractions, modes, and standard deviation were calculated for each attribute.

3) Calculate the indices of influence on satisfaction. For each attribute, the indices of influence on passenger satisfaction (SII) and dissatisfaction (DDI) were calculated according to the method of R. Best, as well as the aggregate satisfaction impact index (CSI).

4) Build a modified matrix for interpreting quality categories. The authors propose to expand the graphical interpretation of quality categories developed by M. Timko by including two additional indicators: the relative importance of the attribute (the total share of responses in categories A, O, M) and the consistency of attribute ratings, which will improve classification accuracy and the information content of the graphical presentation. In order to use it on an existing matrix, add the size of the point that characterizes the attribute position (the percentage of responses O+A+M) and the color of the point (the value of the standard deviation)

5) Comprehensive determination of the attribute's impact on satisfaction based on graphical analysis and descriptive statistics. Comprehensive determination of the impact of an attribute on satisfaction based on a graphical analysis and descriptive statistics.

Thus, the methodology developed by the authors will make it possible to determine consumer satisfaction with the technical quality of the underground (metro) services, which will allow to formulate recommendations for making management decisions in order to increase the competitiveness of the Moscow metro services.

For the study, passengers of the Moscow metro (46% of men and 247% of women) were selected as sample units, the sample size was 461 units.

Research Results

The survey showed that the average customer satisfaction with the technical quality of metro services is 3.8 points on a five-point scale. The share of satisfied respondents is 63.1%, including a quarter of respondents fully satisfied with the technical quality of metro services. More than half (56%) of respondents believe that there is enough equipment for cars and trains and/or nothing else they can offer.

According to the author's methodology, four groups of important attributes of the technical quality of Moscow underground (metro) services were identified, see table 2.

Table 2: importance of technical quality attributes of Moscow underground (metro) services

Attributes	**The total share of basic, one-dimensional and attractive factors according to Kano,%**
Most important attributes	Over 65%
Electronic display indicating the next station	85
Working air conditioner	81
Availability of Wi-Fi	73
Separation of side seats by configuration or partition	69
Sound insulation	69
Space for strollers, bicycles and bulky luggage	68
Important attributes	51-65%
Leaning seats	63
Seat type: soft, springy	61
USB charges for smartphones	60
Allocated space for standing	59
The scheme of allocation of seats	59
Informing about the load of cars for the arriving train	57
Feeling of air movement, light blowing	57
Pass-through between the train cars	57
Interactive panel for setting the route in the car	55
The least important attributes	41-50%
Window leaf or the possibility to open a window	47%
Separation of seats by handrails	46%
Type of finish seat leatherette or fabric	45%
Configuration: wider seat spacing	41%
Unimportant or questionable attributes	Less than 40% or with a high proportion of reverse factors
Temperature control in the car at the request of passengers	42 /27
Increased glazing area	37 /14
Additional vertical handrails: at the edges and in the middle of the sofas	36 /32
Adjusting the type of lighting	31 /25
Luggage racks above the seats	22 / 38
The vertical rail	22 / 19
Additional board on the side of the carriage indicating the terminal station	17 / 18
Opening doors with a button	8 / 67

The most important group includes six technical quality attributes of Moscow underground (metro) services with a total share of basic, one-dimensional and attractive attributes of more than 65%. The most definite were of passengers' opinions regarding the presence of an electronic display indicating the next station, working air conditioner and the availability of Wi-Fi. The important group includes

nine technical quality attributes of metro services, for which the total share of basic, one-dimensional and attractive attributes exceeds the share of questionable and reverse estimates.

Four attributes are considered the least important. Here, respondents' opinions are split roughly in half: about half of respondents classify these attributes as factors that influence satisfaction or dissatisfaction. And about the same number of respondents attribute them to uncertain, reverse, or questionable factors. Attributes that have little impact on passenger satisfaction and/or have a high proportion of reverse factors (more than 25%) are allocated to a separate group.

We classified the technical quality attributes of Moscow underground (metro) services Moscow underground (metro) services based on the Kano model. Of the 27 technical quality attributes of Moscow metro services, a group of three attributes stands out: "Air conditioning", "Electronic display indicating the next station" and "Availability of Wi-Fi". These are the most important attributes (the share of O + A + M is maximum), the estimates for which are most consistent (standard deviation <1). The CSI Satisfaction Index has a value close to zero, since these attributes have an equally strong influence on both passenger satisfaction and dissatisfaction. This clearly characterizes these attributes as one-dimensional according to the Kano model.

The following three attributes, which we also ranked as the most important – "Separation of side seats by configuration or partition", "Space for strollers, bicycles and bulky luggage", "sound insulation" - are evaluated in a similar way.

Consistency estimates for the "sound insulation" attribute are contradictory: if the presence of increased sound insulation is attractive to respondents, then the standard noise level is rated by some respondents as normal, and by others as unacceptable.

Therefore, the "sound insulation" attribute has a high share of ratings both as attractive and as a one-dimensional factor. Taking into account the mode values, we have assigned this attribute to the one-dimensional category.

Thus, six attributes of technical quality of Moscow underground (metro) services are classified as one-dimensional (table 3). These attributes affect passenger satisfaction based on the "more is better" principle.

Table 3: characteristics of a group of "one-dimensional" technical quality attributes of Moscow underground (metro) services

Attribute	**Base, people.**	**Mode**	**Standard deviation**	**Proportion of AOM, %**	**Proportion of Kano categories %**						**SII, %**	**DDI, %**	**CSI, %**
					A	O	M	I	R	Q			
Electronic display indicating the next station	458	O	0,8	85	16	48	21	13	1	1	65	-71	-6
Air conditioner	452	O	1,0	81	18	48	16	14	4	1	66	-68	-3
Availability of Wi-Fi	457	O	0,9	73	12	51	10	25	2	0	64	-62	1
Separation of side seats by configuration or partition	458	O	1,1	69	16	38	16	24	6	0	54	-60	-6
Sound insulation	459	O	1,2	69	30	33	6	18	8	5	67	-49	18
Space for strollers,	457	O	1,0	68	15	3	1	2	4	1	53	-58	-4

bicycles and bulky luggage						7	6	7					

Seven technical quality attributes of Moscow underground (metro) services were assigned to the "attractive" group (table 4). These attributes make a big contribution to the formation of satisfaction, at the same time, passengers will not be dissatisfied with the absence of such attributes. Attributes are relatively important for the "O+A+M share" indicator, although the share of "indifferent" estimates is high. Consensus level is average, except for seat type ratings, where the standard deviation is high.

Table 4: characteristics of the group of "attractive" technical quality attributes of Moscow underground (metro) services

Attribute	**Base, people.**	**Mode**	**Standard deviation**	**Proportion of AOM, %**	**Proportion of Kano categories %**						**SII, %**	**DDI, %**	**CSI, %**
					A	O	M	I	R	Q			
Leaning seats	456	O	1,1	63	27	27	9	30	5	1	55	-42	13
Seat type: soft, springy	459	O	1,2	61	31	26	4	28	9	2	58	-40	19
USB charges for smartphones	458	O	1,1	60	26	31	3	36	3	1	56	-38	19
Allocated space for standing	457	A	1,2	59	37	16	7	28	10	3	54	-33	21
Informing about the load of cars for the arriving train	457	O	1,1	57	31	23	4	36	5	1	54	-32	22
Pass-through between the train cars	459	O	1,2	57	32	20	5	33	7	3	54	-33	20
Interactive panel for setting the route in the car	456	I	1,0	55	30	22	2	42	3	0	53	-28	25

We should say that this group does not have uniquely attractive attributes in the sense that N. Kano referred to this category as "delight factors": the upper quadrant of the matrix (maximum SII with minimum DDI) is free, the group inclines to the zone of "indifferent" attributes.

The next group includes attributes that should or should not be used when consuming Moscow metro services: must-be factors and reverse factors. The category of "reverse action" is uniquely related to the attribute "Opening doors with a button", while the opinions of the respondents are quite consistent (standard deviation is average). Its influence on increasing satisfaction tends to zero, while its influence on the growth of dissatisfaction is maximal. If, following D. Shen's remarks, we recalculate the respondents' answers for the attribute with the opposite value ("Automatic door opening"), then such an attribute will fall into the first category - important one-dimensional attributes (table 5).

Table 5: characteristics of the "reverse" technical quality attributes of Moscow underground (metro) services and alternative (opposite in value) attributes

Attribute	Base, people.	Mode	Standard deviation	Proportion of AOM, %	Proportion of Kano categories %						SII, %	DDI, %	CSI, %
					A	O	M	I	R	Q			
Reverse													
Opening doors with a button	459	R	1,2	8	6	1	1	18	67	7	8	-74	-65
One-dimension													
Automatic door opening	459	O	1,2	67	25	31	12	18	8	7	59	-54	5
Reverse													
Luggage racks above the seats	457	I/R	1,4	22	11	8	4	38	38	2	18	-50	-32
"Indifferent"													
No luggage racks above the seats	457	I/R	1,4	38	6	22	10	38	22	2	28	-55	-27
Reverse													
Type of finish – fabric	458	I	1,2	9	4	4	2	28	61	2	7	-68	-60
"Indifferent"													
Type of finish – leatherette	458	I	1,2	45	15	19	11	41	8	5	36	-40	-4

Similarly, the attributes "Luggage Racks above the seats" and "Type of finish – fabric" can be classified as "reverse" attributes. However, they have a high percentage of" "indifferent" ratings. Therefore, when analyzing the alternatives "No Luggage racks above the seats" and "type of finish (leatherette)", the latter are more likely to be included in the group of attributes "indifferent" than "one-dimensional". It should be noted that in a qualitative study, respondents mentioned that the fabric wears out and gets dirty rather quickly, so even new cars with fabric seats can look untidy.

The "must-be" attributes were attributed to the climate control attributes in the car "Feeling of air movement" and "Window leaf/possibility to open a window", as well as "The standard scheme of seat allocation" (table 6).

Table 6: characteristics of the group of "basic/must-be" technical quality attributes of Moscow underground (metro) services

Attribute	Base, people.	Mode	Standard deviation	Proportion of AOM, %	Proportion of Kano categories %						SII, %	DDI, %	CSI, %
					A	O	M	I	R	Q			
Basic/Must-be													
Feeling of air movement, light blowing	456	O	1,2	59	12	28	17	32	17	1	41	-51	-15
Window leaf/possibility to open a window	456	O	1,4	57	13	23	10	36	17	1	37	-56	-14
The standard scheme of seat allocation ("sofas")	456	O	1,2	47	11	26	22	24	15	3	38	-64	-27
Reverse													
Seats are arranged one behind the other (as in buses)	456	R	1,2	15	13	2	0	24	58	3	15	-62	-47

The attribute "Seats are arranged one behind the other (as in buses)" was classified with the opposite value. As can be seen the "bus" seat arrangement is perceived as an attribute of reverse action and has a high potential for growing discontent.

The remaining attributes are included in the "indifferent" or "questionable" attribute group. For these attributes, the percentage of "indifferent" assessments are maximum, with an average consistency of respondents' opinions. This means that the introduction of these attributes will have little impact on passenger satisfaction, although this impact is positive (relatively high CSI index).

The group of "questionable" attributes included, firstly, the attributes on which the opinions of the respondents differed greatly. The range of answers is great (standard deviation > 1.4) for the attributes "Separation of seats with handrails", "Temperature control" and "Vertical handrail in the center of the car". Secondly, attributes with a high proportion of "dubious" (contradictory) assessments are included in the questionable group. In our opinion, this is due to the novelty of the attributes "Lighting control by time of day", "Additional handrails at the edges and in the middle of the car", 'Additional board on the side of the carriage indicating the terminal station".

These attributes were used by interviewers to provide most of the passenger explanations, who use the "old" cars. A more detailed assessment can be given by comparing passengers' responses – those who are already familiar with these attributes (sample for "new" cars) with the answers of respondents who learned about such an attribute from the interviewer.

Table 7 summarizes the results of the technical quality attributes of Moscow underground (metro) services classification based on the Kano model.

For convenience, additional alternatives are given for a number of attributes (for example, "Upholstery Type"), in italics.

Table 7: classification of technical quality attributes of Moscow underground (metro) services based on the Kano model

Category based on the Kano model	Technical quality attributes of Moscow underground (metro) services
Must-be (basic)	Electronic display indicating the next station Air conditioner Availability of Wi-Fi Separation of side seats by configuration or partition Sound insulation Space for strollers, bicycles and bulky luggage *Automatic door opening*
Attractive	Feeling of air movement, light blow-off air Window leaf/ possibility to open a window *The standard scheme of seat allocation ("sofas")*
One-dimensional	Leaning seats Seat type: soft, springy USB charges for smartphones Allocated space for standing Informing about the load of cars for the arriving train Pass-through between the train cars Interactive panel for setting the route in the car
Reverse	*Opening doors with a button* *Luggage racks above the seats* *Type of finish – fabric* *Seats are arranged one behind the other (as in buses)*
Indifferent	Configuration (wider seat spacing) Increased glazing area *No luggage racks above the seats* *Type of finish – leatherette*
Questionable	Separation of seats with handrails Temperature control Vertical handrail in the center of the car
	Lighting control by time of day Additional handrails at the edges and in the middle of the car Additional board on the side of the carriage indicating the terminal station

A comparative analysis evaluating the importance of attributes and assigning them to appropriate categories based on the Kano model (one-dimensional, attractive, basic, indifferent, reverse, questionable) allows to group the technical quality attributes of Moscow underground (metro) services according to the degree to which they need to be taken into account in order to increase competitiveness of underground services. We have identified five groups shown in table 8.

Table 8: degree the degree to which the technical quality attributes need to be taken into to increase the competitiveness of the service

Degree the degree to which the attributes need to be taken into	Technical quality attributes of Moscow underground (metro) services
Zero degree of necessity The strategy is not to introduce / eliminate	New scheme of seat arrangement: one behind the other (as in buses) Opening doors with a button Vertical handrail in the center of the car Luggage racks above the seats Type of finish – fabric
First degree of necessity Strategy: high priority implementation / monitoring the quality	Electronic display indicating the next station Air conditioner Availability of Wi-Fi Sound insulation Automatic door opening Separation of side seats by configuration or partition Space for strollers, bicycles and bulky luggage
Second degree of necessity Strategies: implementation in the second place, investment in the growth of satisfaction	Leaning seats Seat type: soft, springy USB charges Allocated space for standing Informing about the load of cars for the arriving train Pass-through between the train cars Interactive panel for setting the route in the car
Third degree of necessity Strategies: cost savings	Configuration - wider seat spacing Increased glazing area
Fourth degree of necessity Strategies: additional study of attributes	Separation of seats with handrails Temperature control Lighting control by time of day Additional handrails at the edges and in the middle of the car Additional board on the side of the carriage indicating the terminal station

Among the considered technical quality attributes of Moscow underground (metro) services, five groups of attributes are identified, the introduction of which can lead to an increase in passenger dissatisfaction. Attributes of the first degree of necessity are perceived as mandatory, must be present in metro and do not significantly affect the competitiveness of metro services.

Group of the second degree of necessity to consider attributes aimed to increase underground services competitiveness covers the technical quality attributes of services that increase customer satisfaction. They are the second highest priority for implementation, regarded as investments in events aimed at increasing passenger satisfaction, and can significantly increase the competitiveness of underground (metro) services.

The strategy for the third-degree group of necessity is to save costs, because from the passengers' point of view, it is good if these attributes are present, but they do not have a big impact on passenger satisfaction and competitiveness

The meaning of the attributes included in the fourth group is not unambiguous. To substantiate their impact on passenger satisfaction and the competitiveness of metro services, it seems necessary to conduct additional research.

Conclusion

The authors' methodology developed and applied in this study allows us to offer sound management solutions aimed at increasing customer satisfaction with the technical quality of Moscow

underground (metro) services as well as their competitiveness, taking into account the relative importance of attributes.

As a result of the proposed classification of attributes based on Kano model and the author's methodology, several management decisions are proposed to improve the competitiveness of Moscow metro services:

1. Increase the availability of one-dimensional attributes of the technical quality of Moscow metro services, and invest in monitoring the quality of their performance.
2. Invest in the implementation of important and attractive attributes of Moscow underground (metro) service quality for consumers.
3. Reduce the costs of introducing unimportant attributes, or introduce them gradually until, as the novelty for the market decreases, they will not pass into the category of one-dimensional or basic.
4. Further study attributes and their perception by consumers, the value of which according to the Kano method is not unambiguous. First of all, the authors suggest conducting experimental studies to determine the optimal car climate.

The results of the research conducted in the framework of the Kano model and the author's methodology showed that the life cycle of attributes within the framework of the Kano method is not enough studied in the literature (Lofgren, et.al., 2008). Over time, attributes can shift from one category to another. For example, Wi-Fi availability in metro cars belongs to basic or one-dimensional (mandatory) category; in Moscow Central Circle cars they are also likely to move from the category of attractive attributes to the category of basic ones, it was in metro.

Therefore, periodic measurements of passenger satisfaction with the service attributes will allow to predict changes in the contribution of technical quality attribute of underground (metro) services to the assessment of passenger satisfaction and adjust the level of technical quality of services and their competitiveness in advance.

Abstract

Specialist literature presents multiple factors that are believed to affect income inequality. Our study focuses on household type as a determinant of overall inequality since it employs household as the unit of analysis, and examines the extent of inequality among households by incorporating household income data. Therefore, apart from assessing the level of income inequality, the aim of the study is to verify the extent to which household type affects household income inequality. Moreover, we endeavour to answer the question of whether there exists any common pattern of the influence of household type on income inequality.Our study aims at expanding and updating the knowledge regarding the dimensions of household income inequality in European countries. We employ the latest available representative microdata derived from the EU-SILC study. This study builds upon the Mean Logarithmic Deviation (Theil L index) and its property of being additively decomposable to assess the effect of household type on household income inequality. Our results indicate that households in the EU-15 countries differ in structure, with the most noteworthy differences occurring between the Mediterranean and the Nordic countries. The situation of households run by a single parent is on average worse than in case of other households. Generally, households run by couples without children or couples with one or two children are best-off. The effect of differences in household structure on income inequality is the most noteworthy in the Nordic and in the Anglo-Saxon countries, while in Luxemburg and the Mediterranean region this effect is the least notable.

Keywords: Income Inequality, Household Type, Mean Logarithmic Deviation, Theil Index L, Gini Coefficient

Introduction

Among the factors that are considered to account for the dissimilarities and trends in income inequality, differences and alterations in the characteristics of households are also examined. Household composition reflects the structure of household members in terms of their number, age, and mutual relations (*e.g.,* parents-children). In income inequality studies, household composition plays a crucial role due to the fact that equivalised household income is calculated on the basis of the number and age of household members. Household structure is also worthy of note with respect to international comparisons. Iacovou and Skew (2010) point out that international differences in household structure reflect considerable discrepancies between societies: in culture and norms, in the cost and availability of housing, in the incomes of various social groups, and in social policy, where the dissimilarities in tax and benefit systems can lead to radically diverse patterns of household structure.

The effect of household type on income inequality is frequently examined in empirical studies.

Examples of such analyses can be found in the works of Papatheodorou (2000), Brandolini and D'Alessio (2001), Martin (2006), Muszyńska and Wędrowska (2018a, 2018b, 2020). Medgyesi (2014) documented a growing inequality between household structures from 2004 and 2007 in the EU-15 countries, with the exception of Greece and Sweden. His analysis suggests that stratification between family structures continued to increase until 2010 in countries such as: Portugal, Italy, Luxemburg, France, Germany, and the Netherlands. In turn, Robling and Pareliussen (2017) found that the altered household composition accounted for 16% of the increase in overall disposable income inequality in Sweden from 1987 to 2013. Nevertheless, studies taking into account household type as a determinant of income inequality should be continued due to constant changes in the population structure resulting from the development of societies.

Guerin (2013) indicates that household structures vary in European countries, which affects the scope and form of income inequality. The key reasons for these discrepancies include a growing proportion of men and women who remain childless, a decreasing stability of marriages, a rising number of divorces, and also an increasing prevalence of cohabitation without marriage, single-parent households and step-parenting. However, two fundamental issues emerge as projected effects of these changes on the growth of income inequality. The first one concerns an increasing share of households particularly exposed to poverty (such as single-adult households and single-person households of elderly people). The second is related to declining fertility and assortative mating (well-educated high-income people marry in the same income groups, which leads to an increase in their income, thus creating a stronger income gap between household types). Peichl *et. al.,* (2010) reveal that - in the case of Germany - the changing household structure is associated with increasing inequalities arising from a drop in the average number of people inhabiting a household. In turn, Burtless (1999) and Martin (2006) report a growth in the share of single-parent families among households as one of the factors behind the increase in inequality.

The impact of changes in relationship formation on the emergence of income inequality between different types of households in modern societies has been studied also by Blossfeld and Buchholz (2009) and Grotti and Scherer (2016). Their empirical results support the notion that, over the past decades, income inequalities between different types of households have increased substantially due to lifetime accumulation of resources in higher skilled couples.

Our study centres on household type as a determinant of overall inequality. Therefore, in addition to assessing the level of income inequality, the aim of the study is to verify the extent to which household type affects household income inequality. Furthermore, we endeavour to answer the question of whether there exists any common pattern of the influence of household type on income inequality.

The study is based on microdata obtained from the European Union Statistics on Income and Living Conditions (EU-SILC). We employed the Mean Logarithmic Deviation (MLD) to assess the effect of household type on household income inequality, whereas the Gini coefficient was used to measure and compare the level of income inequality between European households.

Data

The paper presents the results of a study conducted within the scope of the project 'Income and inequality of income of European households' (RPP 162/2018-EU-SILC). The analysis includes fifteen countries forming the European Union before the accession of new members in 2004, *i.e.* the so-called 'Old Union'. The study was conducted on the basis of income data from 369,740 individuals. Depending on the country, the sample varied in size from 10,431 (Luxemburg) to 54,806 observations (Greece).

The study employs the latest available microdata obtained from the European Union Statistics on Income and Living Conditions (EU-SILC) and extracted from the cross-sectional database of the EU-SILC 2018 (version as of September 2019). The microdata contains information on the income achieved by individual household members in 2017. This is due to the fact that in the EU-SILC

survey, for the majority of countries, the income reference period is the calendar year previous to the year of the survey. The only two exceptions are the United Kingdom and Ireland. In Ireland, the income reference period is the last twelve months, whereas in the United Kingdom the current income is annualised and reflects the present calendar year (Eurostat, 2020).

For the purpose of the study, income was defined as equivalised household disposable income per household member. Total household disposable income was calculated as a sum of gross personal income components for all household members and gross income components at the household level reduced by taxes, social insurance contributions and interhousehold cash transfers paid. To account for the differences in the size and composition of households, household disposable income was divided by the number of equivalent adults in the household, and then the equivalised value was assigned to each household member. When making an adjustment, we applied the OECD-modified equivalence scale.

It should be noticed that the measures of inequality reported in the study were calculated using personal cross-sectional weights, therefore they are equivalent to an extrapolation of the measures to the entire population.

In our study, while analysing income inequality, we focused on household type, which is understood as a description of the household according to certain characteristics of its membership, such as the number of household members, their age and the relation between them, as well as whether household members are over the retirement age, or whether there are dependent children living in the household. For the purpose of the study, we devised seven household subgroups, that is:

- a single person (H-5),
- a childless couple, both under 65 (H-6),
- other households without children (H-7 and H-8),
- a single parent (H-9),
- a couple with 1 or 2 children (H-10 and H-11),
- a couple with 3 or more children (H-12),
- multi-generation household (H-13 and H-16).

When assigning households to the subgroups, we based on the household types distinguished in the EU-SILC database, hence the EU-SILC denotations of the households types included in the distinguished subgroups in the brackets.

Methodology

In the study, we apply two measures of inequality that arise from different intellectual approaches to inequality. Our empirical analysis employs the Mean Logarithmic Deviation (MLD), which belongs to the family of the Generalized Entropy measures, and the Gini coefficient, which is based on the Lorenz curve. The MLD is also referred to as the Theil L index, therefore, later in the paper the term Theil L index will be used.

Both indices – the Theil L index and the Gini coefficient - meet the most highly desired requirements for any measure of inequality, namely: anonymity principle, scale independence, population independence and the Pigou-Dalton principle (Litchfield, 1999). The advantage of the Theil L index over the Gini is its property of being additively decomposable (Bourguignon 1979; Shorrocks 1980, 1984). This property allows overall inequality to be expressed as a sum of the inequalities existing within the subgroups distinguished on the basis of a specific population characteristic, and the inequalities existing between the subgroups. In our study, we employ this property to verify the extent to which household type affects household income inequality.

A weakness of the Theil L index is the lack of an upper limit (Theil, 1967). For this reason, we also employ the Gini coefficient as another measure of inequality. The advantage of the Gini index over the Theil L index is that it is bounded in the interval [0;1], and can be easily interpreted and

compared. In the study, we use the Gini index to assess and compare the level of income inequality between the examined countries.

For a population of n income units with mean income μ and income for unit i denoted as y_i, the Theil L index can be depicted with the formula:

$$\mathrm{L} = \frac{1}{n}\sum_{i=1}^{n} ln\left(\frac{\mu}{y_i}\right) \quad (1)$$

As already mentioned, the Theil L index can be additively partitioned into a sum of the inequalities existing within subgroups of the population and the inequalities existing between them. Assuming that all households are partitioned into K subgroups, the Theil index L can be decomposed into the two components, as follows:

$$\mathrm{L} = \sum_{k=1}^{K} p_k L_k + \sum_{k=1}^{K} p_k ln\left(\frac{\mu}{\mu_k}\right) = L_w + L_b\ , \quad (2)$$

where K is the number of subgroups, p_k is the population share of a subgroup k in total population, μ_k is the mean income of a subgroup k, L_k is the Theil index L corresponding to a subgroup k, L_w and L_b denote within-group and between-group components, respectively.

The within-group component describes the part of overall inequality that arises from inequality within subgroups, whereas the between-group component presents the extent of inequality arising solely from the differences in the mean incomes of subgroups. The ratio of inequality between subgroups to overall inequality reflects the extent to which the feature on the basis of which the subgroups are distinguished contributes to household income inequality.

The Gini coefficient of inequality can be expressed in various ways. One of them is to define the Gini coefficient as a half of the relative mean difference, i.e. the expected distance between two randomly selected incomes in a population divided by average income. In population of n units and mean income μ, the Gini index can be expressed as follows:

$$\mathrm{G} = \frac{1}{2n^2\mu}\sum_{i-1}^{n}\sum_{j=1}^{n}\left|y_i - y_j\right| \quad (3)$$

In other words, the Gini coefficient is the ratio of the mean difference between all pairs of incomes y_i, y_j, to the two-fold mean level of income μ (Pyatt, 1976).

Results

The descriptive statistics on equivalised disposable income and population of the examined households are presented in Table 1. Over the past decades, household structures have been changing across the EU-15 countries, and these alternations have been extensively documented in many studies. Evidence from the EU-SILC data shows that the proportion of the population living in different types of households varied considerably from one EU-15 country to another in 2017. In general, the proportion of couple-only households (where both partners are under 65) were higher in the Nordic and North-Western countries than in the Mediterranean countries, while the proportion of two-adult households with at least one adult at the age of 65 years or more was the highest in the Mediterranean region. There are important disparities in single-parent households: the proportion of single parents with minor children was also higher in the Nordic and North-Western countries than in the Mediterranean countries. These figures should not, however, be treated as indicative of the level of lone parenthood across the EU-15 countries since in Southern Europe single parents are more likely to live in extended-family households rather than in single units (Iacovou and Skew, 2011). The proportion of the population living in single-adult households differed widely across EU-15: it ranged from above 9% in Ireland, Greece, Portugal, and Spain to more than 20% in Sweden, Finland, Germany, and Denmark. In all countries (except Greece and Italy), the most common of the seven household types is a household run by a couple with one or two dependent children.

Households differ in size and composition, therefore a simple comparison of aggregate household income can be quite misleading with respect to the well-being of individuals in each household. This is why we focus on income inequality, and - in particular - on equivalised household disposable income as the income concept that best approaches individuals' and households' standards of living (DiPrete, 2003). The profile of equivalised disposable income by household type in all countries was noteworthy as the highest average income was achieved by households run by two adults, both under 65, with no dependent children. In Finland, Ireland, the Netherlands, and Sweden the average income of this group demonstrated the highest divergence from the national average (it was higher by more than 25%). The situation of households run by childless couples - both partners under 65 years of age - was on average more favourable than in other households without children. Our analysis shows that in all examined countries, except Italy and Greece, one-person households obtained lower mean income than the average income of all households. One-person households often consist of young, unemployed individuals or elderly retirees, both of which face higher risks of poverty. Guerin (2013, p. 11) emphasizes that poverty among single-person households can be higher than in two-adult households, where income pooling can facilitate responses to income shocks if they affect one of the two individuals.

Source: Authors' calculation using the EU-SILC data.

In all countries - with the exception of Germany - the situation of couples with one or two children was on average more favourable than in households with three or more minor children. The most unfavourable differentials for couples with three or more children were found in the United Kingdom and in Austria, while the opposite was true of Germany, where the mean income of households with three or more children was higher by 17.3%than the national average. Papatheodorou (2000) points out that children have a negative effect on the total equivalent household income. Children are usually not entitled to any income from labour, only from family and children related allowances, which are relatively low. However, the lowest income among all household types in each country was achieved by single parents with children under 18. This pattern can be observed in all EU-15 countries. The situation of single-parent households with one or more children appears to be the worst in the Anglo-Saxon countries (the mean income equalled only around 60% of the national average). Quite interestingly, in Greece and Portugal the group of one-parent families was not found to have a particularly low disposable income, as evidence shows in other countries. Research on poverty emphasizes an increase of single-parent families, and especially single-mothers, as they are economically distressed and concentrated at the bottom rungs of the income ladder (Martin 2006).

Average income varied from a household type to a household type, and this alone implies some inequality between the groups. Moreover, income varied inside each household type, adding a within-group component to total inequality. The Theil L index mentioned above can be used to assess the impact of household type on income inequality in different subgroups of the population. This subsection presents and analyses the results of the decomposition of the Theil L index, using STATA software. Total inequality is partitioned by household type into within- and between-group components based on equation (2).

The Gini coefficient reveals that equivalised disposable income appear to be more equally distributed in Belgium, Finland, and Sweden. The most unequal income distribution among the EU-15 countries was observed in the Mediterranean region, Luxemburg, Ireland, and the United Kingdom. Our analysis shows that the distinguished household groups also experienced a different extent of inequality (Table 1). Equivalised disposable income was more equally distributed among two-adult households than among one-person households in countries such as: Belgium, Germany, France, Ireland, Italy, Luxembourg, the Netherlands, Portugal, Sweden, and the United Kingdom. We observed that households run by two adults under 65 were characterised by a more unequally distributed income than in the case of other households without children (including households run by two adults, where at least one is 65 years old or more). This is not surprising since it is expected of the social security system to work towards a more equalised income distribution in the old age. However, it is difficult to establish a common pattern comparing income inequality among households with children and among those without children. Of course, the category 'households with children' also includes both couples and single parents.

Despite the significant differences in mean incomes by household type, there was in fact more inequality within household types than between them. The lighter shaded area in Figure 1 displays the amount of inequality within household types, and the darker area displays inequality between household types. Between-group inequality represents the extent to which various household types

are stratified by income. The impact of household type on overall income inequality varies across Europe. When the groups are identified on the basis of household type, between 2% (in Greece) and 14,5% (in Finland) of overall inequality can be attributed to a different composition of the population. In 2017 the effect of household type on income inequality was the highest in the Anglo-Saxon and Nordic countries. Our results demonstrate that between-household-types inequality was responsible for more than 9% of overall inequality (see Figure 1). Household structure was of negligible importance in Luxemburg and the Mediterranean region: it accounted for less than 5% of overall inequality.

Fig. 1: The Theil L index decomposition

Discussion and Conclusions

Household structure differed across the EU-15 countries, with the most significant differences between the Mediterranean and the Nordic countries. In this paper, we endeavoured to answer the question of whether the effects of these disparities on inequality in equivalised disposable income vary among countries. For the purposes of empirical analysis we employed the Theil L index, a measure of inequality that is additively decomposable. This paper uses data from the European Survey on Income and Living Conditions. The database covers information on income of 369,740 individuals achieved in the year 2017.

Decomposition of the Theil L index by household structure reveals disparities between the economic situation of different household groups across countries. In most cases, households run by one person and couples with three or more children obtained lower mean incomes than the average income of all households. However, the situation of households run by a single parent with one or more children was on average worse than the situation of other households. The households without children, or those run by couples with one or two children were generally best-off.

The effect of differences in household structure on income inequality was the most prevalent in the Nordic (especially in Finland and Sweden) and in the Anglo-Saxon countries. By contrast, the effect was the least notable in Luxemburg and the Mediterranean region. This conclusion is clearly in line with empirical research on the impact of household structure on the degree of income inequality in the EU-15 countries (Medgyesi 2014).

It may seem paradoxical that the Nordics, which have unrestricted economies, providing a high level of social protection while simultaneously encouraging a high labour force participation through various instruments of active labour market policies and the provision of extensive child care (Fuest *et. al.,* 2010), are characterised by the highest level of inequality between the subgroups distinguished on the basis of household type. Firstly, when compared with other countries, the Nordic countries had the lowest within-group inequality in each group. Secondly, the household structure in the Nordic countries differed considerably from that in other countries. In the Nordics, the shares of single-adult households and couple-households without children have risen from high initial levels since the early 1990s, especially in Sweden and Finland (Pareliussen *et. al.,* 2018, p. 37). This tends to amplify inequality between subgroups distinguished on the basis of household type due to the fact that such households often have relatively low equivalised disposable income, and because it reduces overall income sharing among household members. Pareliussen and Robling (2018) indicated that changing household composition boosted inequality substantially in the Nordics from 1995 to 2013. On the other hand, Brandolini and D'Alessio (2001) stressed that demographic changes are not exogenous, but they respond to socio-economic circumstances: the growth in the number of single-adult households, for instance, certainly reflects a lengthening of the average lifespan, but it is also caused by a modification of the parent-child relations, as well as by improved economic conditions and, in particular, improved social security.

The effect of differences in household structure on income inequality was the least observable in Luxemburg and the Mediterranean countries. It should be stressed that the dispersion of equivalised disposable income between household members in these countries was higher than in other EU-15 countries, of which the Nordic countries proved to be the most egalitarian. Luxemburg and the Mediterranean region had the highest income inequality in each subgroup of households, and the observed inequality stemmed mostly from heterogeneity within the groups based on household type (from 95.7 percent to 95.6 percent). A minor influence of household type observed in the Mediterranean region may result from a more composite household structure, where a number of generations and various sources of income often coexist. These countries are characterised by extended co-residence of adult children with their parents, and of elderly people with their adult offspring; these arrangements, together with a much lower incidence of lone-parent families, make for considerably larger household sizes (Iacovou and Skew, 2011, p. 467). This makes the classification based on the simple variables used here that much less significant than in other countries (Brandolini and D'Alessio, 2001, p. 23).

Abstract

As our world moves more and more into the online medium so does our data. This massive movement allows the analysis of financial markets using methods that would not have been possible 10 years ago due to a lack of sufficient data. In this paper, we review some basic ideas of stock market data handled as a time series, need of RNN (Recurrent Neural Network), survey previous works, and use a LSTM (Long Short-Term Memory) network to forecast stock value during and after the 2020 market crash. The prediction accuracy is calculated and investigated with reference to S&P 500, PHLX Semiconductor (SOX), and XLRE.

Keywords: Recurrent Neural Network; Time Series; Data Mining; Pattern Recognition.

Introduction

Time series arise from chronological measurements made at a constant time interval. Such type of data is frequently used in signal processing, mathematical finance, econometrics, sales forecasting, and many other applications. In deciding actions that involve uncertainty in the future, time series models are one of the most efficient methods of forecasting. The man's desire to make the future less uncertain has led to the development of more and better forecasting techniques. Following the increase in computational capability and the availability of data in the last 20 years, AI has been able to leap forward in time series forecasting. Artificial Neural Networks modelled after the human brain can now recognize patterns and can generalize them to predict future patterns. Today, NNs (Neural Networks) are considered a common Data Mining technique in science, economy, and industry.

In this paper we propose an analysis of the effects of the 2020 Market crash, caused by the Covid - 19 Pandemic, using RNNs. Our hope is to uncover whether there is a fundamental difference between the normal stock market and its daily volatility and the market undergoing a sudden dramatic decline. The possible implications of this paper are that maybe a market crash is not as unpredictable as we thought, and that historical data might be used in identifying such a crash. The research method is based on a LSTM network that is trained on pre-pandemic data to recognize patterns in the daily fluctuations of the market and then used as a forecasting tool on past-pandemic data. If the fundamentals behind the stock market change during a crash, then the LSTM model will have a poor forecasting accuracy. In our simulations, the exact opposite is observed, the forecasting accuracy seems to stay the same, and even increase as the pandemic progresses. The results seem to prove that there is no fundamental difference between a bull market and a crash and universal market forecasting tools can be developed.

The need of better tools for forecasting

Market Indexes

The stock market refers to the collection of markets and exchanges where regular activities of buying, selling, and issuance of shares of publicly held companies take place. The stock market can be best described by its chaotic nature and nonlinearity, where the extracted time series have structural breaks, are noisy, and random. Moreover, the stock market is influenced by several factors such as political events, currency exchange rate, general economic conditions,

Cite this Article as: Stefan-Razvan ANTON, Octavian POSTAVARU and Antonela TOMA "Performance Analysis of US Stock Market during the 2020 Market Crash using Recurrent Neural Network" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

trade goods worth, and so on. All of this makes the individual stock analysis useless and any prediction made on an individual stock will most likely be wrong. By instead analysing a market index, which should theoretically describe the behaviour of the overall market, we are able to achieve a forecast better anchored in reality. Other advantages of using market indexes are that they offer a historic perspective of stock market performance, that may be utilized by traders to gain better insight into their investment and that they provide a baseline that can be used for comparison when evaluating the overall performance of certain portfolios. In this paper, S&P 500, SOX, and XLRE are considered for stock market index evaluation and prediction.

The S&P 500 is a stock market index that measures the stock performance of 500 big businesses listed on stock exchanges within the United States, the top five S&P 500 stocks by index weight are AAPL 7.3%, MSFT 5.9%, AMZN 5%, FB 2.4%, GOOGL 1.7%.

The SOX (PHLX Semiconductor) sector is a Philadelphia Stock Exchange index composed of companies involved with the design, distribution, manufacture, and sale of semiconductors, the top five PHLX Semiconductors stocks by index weight are QCOM 9.55%, NVDA 9.44%, AVGO 8.44%, TXN 7.95%, TSM 5.47%.

XLRE represents the new real estate sector, composed companies involved in real estate, excluding mortgage, the top five XLRE stocks by index weight are AMT 15.2%, PLD 9.87%, CCI 8.86%, EQIX 8.84%, DLR 5.14%.

Literature Survey

An artificial neuron, as described by McCulloch (1943) is a mathematical function proposed as the computational equivalent of a biological neuron. The artificial neuron receives one or more inputs, sums them, and applies an activation function to produce an output. By stacking artificial neurons in layers, one obtains a basic neural network, or" B-type unorganized machines" as first proposed by Alan Turing. Although a single artificial neuron performs worse in time series forecasting than traditional methods, such as linear regression, exponential smoothing, and autoregressive integrated moving average, a neural network can outperform any traditional method many times over. Today, almost all time series forecasting models use some type of neural network. This is mainly to the fact that neural networks can approximate any complex continuous function given enough data and can recognize new patterns even after training.Hu (1964) proposed the idea of using a neural network together with time series in short-range weather forecasting, thus igniting the idea of using NNs for time series forecasting. Since then, many other neural network models for time series forecasting have been developed, with the most successful one being LSTM based ones. In 1999 Nag and Mitra attempted to evaluate the Signals approach and the ANN approach to identify a class of economic indications that can function as warning signals to an emerging currency crisis. Their findings were that while the signals approach has been widely used, in the context of the East Asian 1998 currency crisis, such models were found to be wanting in their predictive capability, and that the ANN approach managed to capture the nonlinear relationship between the economic fundamentals and the probability of a crisis.

Similarly, in 2008 Fioramanti used a NN model to predict the evolution of the debt crisis in less developed countries by using historical data from the time period of 1980 and 2004. In his study, he argues that NNs constantly outperform other classical analysis models due to the plasticity of the model and its ability to recognise patterns in highly nonlinear data.

Due to the unanticipated coronavirus disease 2019 (Covid - 19) pandemic, we are given the opportunity to measure the impact of an unexpected epidemic on the affected nations.

Qing He et al. (2020) found out that Covid - 19 had a small negative impact on the stock markets of China and other Asian countries that were affected during the early stages of the pandemic with the spill-over effect ton European and American countries being minimal. The considered indices underperformed after the epidemic, as opposed to the middle and late stages. In the later stages of the pandemic, as the spread of the disease in China has been stabilised, but with other countries being amid the global spread, China's stock market started to be affected by the spill-over effect.

In our paper, building o the previous work of Nag and Mitra (1999), Fioramanti (2008), Qing He et al. (2020), and many others, we investigate whether this nonlinear way of interaction between crashing markets is fundamentally different from regular day to day interactions.

LSTM Networks

First introduced by Hochreiter and Schmidhuber in 1997, LSTMs (Long Short-Term Memory Networks) are a special kind of RNN (Recurrent Neural Network), that are able to learn long-term dependencies, that is, remembering information for long periods of time. Since their invention in 1997 LSTMs have set accuracy records in multiple application domains, revolutionizing speech recognition, handwriting recognition, machine translation, language

modelling, and automatic image capturing. In LSTMs, LSTM cells are used in order to remember data from thousands or even millions of discrete time steps earlier. In an LSTM cell, there are extra gates added, namely the input, forget, and output gate that are used to decide which signals get forwarded to another node. The equations for a forward pass of an LSTM cell at time-step t, on layer l are:

$$\mathrm{f}_t^l = \sigma_g\left(W_f h_{t-1}^{l-1} + U_f h_{t-1}^l\right),$$

$$i_t^l = \sigma_g(W_i h_{t-1}^{l-1} + U_i h_{t-1}^l),$$

$$o_t^l = \sigma_g(W_o h_{t-1}^{l-1} + U_o h_{t-1}^l),$$

$$\widetilde{c_t^l} = \sigma_c(W_c h_{t-1}^{l-1} + U_c h_{t-1}^l),$$

$$c_t^l = f_t \circ c_{t-1}^l + i_t^l \circ \widetilde{c_t^l},$$

$$h_t^l = o_t^l \circ \sigma(c_t^l).$$

Where, f_t^l is the forget gate's activation vector, i_t^l is the input gate's activation vector, o_t^l is the output gate's activation vector, $\widetilde{c_t^l}$ is the cell input activation vector, c_t^l is the cell state vector, h_t^l is the hidden state vector, and where matrices W_k and U_k contain, respectively, the weights of the input and recurrent connections, where the subscript k can either be the input gate i, output gate o, forget gate f or the memory cell c, depending on which activation is being calculated.

Preliminaries

Data Preparation

The market data first needs to be processed. Each time period consists of date, open price, highest price during the day, lowest price during the day, close price, adjusted close price, and volume. In this paper, we will only need the date and the adjusted close price, which factors in things like new stock offerings, stock splits, and dividends. The data is first split into training, development, and test sets according to the following ratio 0.6:0.2:0.2, as can be seen in Table 1.

Table 1: Dataset distribution for S&P500, SOX, and XLRE

Year	Year Number	Total Number of time periods	Number of items in the training set	Number of items in the development set	Number of items in the test set
2016	1	252	152	50	50
2017	2	503	302	100	100
2018	3	754	452	151	151
2019	4	1006	604	201	201
2020	5	1187	712	237	237

In order to achieve better performance on the test set, the data on the training set needs to be normalized on the interval [-1, 1]. The effect can be observed in Fig. 1,2,3, where we plot the normalized data for S&P 500, SOX, and XLRE. This process is done in order to change the numerical values of the adjusted price, while keeping the overall characteristics of the dataset.

Fig. 1: Normalized data for S&P 500 on the period 4 Jan 2016 - 19 Sep 2020.

Fig. 2: Normalized data for SOX on the period 4 Jan 2016 - 19 Sep 2020.

Fig. 3: Normalized data for XLRE on the period 4 Jan 2016 - 19 Sep 2020.

Evaluation Criteria

For the forecasting problem, the best measure of performance is the prediction error.

$$E_t = Y_t - F_t \ ,$$

where E is the error at time t, Y is the actual value at time t, and F is the forecast value at time t. In order to achieve a robust evaluation of the results, one should consider more than one performance measure. In this paper we analyse the performance of the forecast using the following five general criteria:

Mean Absolute Error (MAE): $\frac{\sum_{t=1}^{N}|E_t|}{N}$

Mean Absolute Percentage Error (MAPE): $\frac{\sum_{t=1}^{N}|\frac{E_t}{Y_t}|}{N}$

Mean Square error (MSE): $\frac{\sum_{t=1}^{N}E_t^2}{N}$

Root Mean Square Error (RMSE): $\sqrt{\frac{\sum_{t=1}^{N}E_t^2}{N}}$

Percent Mean Absolute Deviation (PMAD): $\frac{\sum_{t=1}^{N}|E_t|}{\sum_{t=1}^{N}|Y_t|}$

Simulation Results and Performance Analysis

For this study, an LSTM network is used. The network contains one input layer, five hidden layers, and one output layer. In total, the network has 92251 trainable parameters that get updated each iteration in order to minimize the error between the forecast and the real data. The experimental procedure consists of:

1) Training the network separately for each of the three indexes to be analysed on the training set, corresponding to the time period 4 Jan 2016 - 31 Oct 2018.

2) Optimising the network parameters on the development set, corresponding to the time period 1 Nov 2018 - 9 Oct 2019.

3) Testing the network on the testing set, corresponding to the time interval 10 Oct 2019 - 19 Sep 2020, that is, on the early days of the Covid-19 Global Pandemic and on the 2020 Market crash.

After training and using hyperparameter optimization on the development set we have found that the hyperparameters that give the best accuracy are: 50 for the number of LSTM units per layer, 70 for the Number of Epochs (Number of passes through the entire training set), and 8 for the Batch Size (Number of examples used in one iteration). The forecast results for the period 10 Oct 2019 - 19 Sep 2020 for S&P 500, SOX, and XLRE are presented in Fig. 3, 4, 5. One can immediately notice that the network does a great job following each day trend, even in the highly irregular conditions of the 2020 market crash.

Figure 4: S&P 500 real price (green) and forecasted price (red) on the period 10 Oct 2019 -19 Sep 2020.

In fig. 4 it is clear that the initial crash of 1100 points takes place in approximately a month, with the rebound happening over a period of 5 months. For this whole period, the network closely follows each day trend and is able to correctly forecast the closing price with a daily average PMAD error of 1.8%.

Figure 5: SOX real price (green) and forecasted price (red) on the period 10 Oct 2019 - 19 Sep 2020.

In fig. 5 we see that the initial crash of 700 points takes place in approximately a month, with the rebound happening over a period of three months, two months quicker than in the case of the S&P 500. In the next two months, the trend maintains, and SOX gains another 250 points. For this whole rebound period, the network closely follows each day trend and is able to correctly forecast the closing price, but on the continued uptrend we see a decrease in inaccuracy. This behaviour is reflected in the daily average PMAD error of 2.9%.

Figure 6: XLRE real price (green) and forecasted price (red) on the period 10 Oct 2019 – 19 Sep 2020.

In fig. 6 we observe that after the initial crash of 15 points, the index does not manage to recover, seeing an increase of only 10 points over a period of six months. XLRE, having the most volatility of the three, is also the hardest to make accurate predictions on, having a daily average PMAD error of 4.9%.

The first experiment on the trained and optimized network is to find the influence of the number of days N, considered when making a forecast about day N+1. The results were that, usually, considering N between 2 and 5 gives the best accuracy, and particularly, the optimal number of days N, considered by the network when making a forecast about day N+1 is 4 for SP 500, 3 for SOX, and 5 for XLRE. In the following figures, both MSE, and MAE are scaled down by a factor of 120, in order to fit into the graph. Immediately a certain regularity arises, the errors seem to move with a certain rhythm, achieving peaks and valleys at an almost regular interval of 5 days.

Figure 7: Error Analysis on the number of days N used in making N+1 day forecast on the S&P 500.

In fig. 7 we notice that every local maximum of the error functions takes place at a regular interval of 3 days and every local minimum taking place at a regular interval of 5 days. The global minimum is obtained when N is 4, and the maximum when N is 16. It turns out that for S&P 500 medium-term fluctuations in price have a greater influence on the forecasted price than fluctuations that took place more than 5 days before the forecast.

Figure 8: Error Analysis on the number of days N used in making N+1 day forecast on the SOX.

In fig. 8 we notice that every local maximum of the error functions takes place at a regular interval of 4 days and every local minimum taking place at a regular interval of 3 days. The global minimum is obtained when N is 3, and the maximum when N is 14. For SOX, the most decisive factors seem to be in the last five days before the forecast, with the last day of the working week being the most influential.

Figure 9: Error Analysis on the number of days N used in making N+1 day forecast on the XLRE.

In fig. 9 we notice that every local maximum of the error functions takes place at a regular interval of 3 days and every local minimum taking place at a regular interval of 2 days. The global minimum is obtained when N is 5, and the maximum when N is 6. When we analyse the XLRE forecast error chart we notice a periodicity in the errors. The forecast seems to be most influenced by the fluctuations of the last week rather than the current one.

The second experiment is to analyse the influence of the instability of the 2020 market on the network's ability to make accurate forecasts. For this, we compare the MAE, MAPE, MSE, PMAD of the S&P 500, SOX, and XLRE indexes before and after the 2020 market crash.

As expected, S&P 500 and SOX having higher prices than XLRE, also have proportionally higher MAE, MSE, and RMSE. That means, only MAPE and PMAD can be used to accurately analyse indexes with big price differences.

One can immediately observe that a certain behaviour emerges. Even in a chaotic market by human standards, the LSTM Neural Network is able to make forecasts with a certain degree of accuracy. Surprisingly, in most areas, the network manages to achieve a better accuracy during and after the 2020 market crash than before it, when the general market trend was up. The largest improvement was noticed in the XLRE forecast, with all the error measures being two or even three times less than the before ones. This is undeniably a consequence of the network's ability to constantly learn and to find new emerging patterns.

Table 2: Forecast error analysis for before and after Covid-19 Global Pandemic and 2020 Market Crash.

Name	MAE	MAPE	MSE	RMSE	PMAD
S&P 500 Before	5133.8	0.018	3126.71	55.91	0.018
S&P 500 After	3861.67	0.0132	3808.48	61.71	0.012
SOX Before	4087.22	0.0285	2389.75	48.88	0.029
SOX After	3997.43	0.0226	2909.76	53.94	0.022
XLRE Before	167.21	0.0469	3.67	1.91	0.049
XLRE after	55.65	0.0163	0.81	0.9	0.015

Conclusions

In this paper, S&P 500, SOX, and XLRE are analysed via LSTM Neural Networks with regards to the before and after market conditions of the Covid - 19 Global Pandemic and 2020 Market Crash. Using MAE, MAPE, MSE, RMSE, and PMAD as means to measure the forecast accuracy, we manage to achieve satisfactory results on the time interval 10 Oct 2019 - 19 Sep 2020. Later by comparing the forecasting accuracy for before and after the Covid - 19 Pandemic, we arrive at the conclusion that the model is unable to detect any fundamental difference between a healthy and stable market and a market crash. This result implies that the underlying mechanism behind the stock market remains the same no matter the market conditions, in our case, between a bull run and a crash. This paper is useful in confirming that universal forecasting tools, that give an accurate answer no matter the market conditions, can be developed. Some limitations of the LSTMs are it's heavy need of high processing power, for a NN model to be able to compete with current algorithms for split-second decisions it needs more computational capabilities than an individual or a small investment company can manage, and the need of high amount of data in order to get an accurate forecast. We believe that, due to the natural increase of computational power due to Moore's law and the exponentially increasing amount of data available on the internet, these limitations will dwindle in time, leaving us with one of the most accurate forecasting model that exists.

Abstract

Early cost estimation is a common prerequisite for the profitability assessment of the development of complex products. Thus, the combination of numerous technical and economic factors poses a challenge for product developers when little more than the desired functionality of the product is known. In the field of medical devices, this issue is exacerbated by the fact that many devices should be custom products. The current research paper presents a detailed methodology for linking custom product architecture with cost analysis within the product design and development process for a posture correction orthosis. In order to make a cost estimation of hardware components for the posture correction orthosis, essential technical features and prices of typical components were identified via empirical research. The preceding selection of examined component categories was based on expert interviews, the analysis of finalized spinal orthosis projects and relevant literature. Several cost analyses were developed for each category of constructive solution. The most suitable constructive solution was chosen from these, based on their technical and economical characteristics. Nine constructive solutions for spinal orthoses were developed and several cost aggregates estimated using the presented method. The results were examined regarding their accomplishment of technical requirements and the value of estimated total cost. Costs were estimated for a built prototype that involved the chosen constructive solution shown in this study.

Keywords: Constructive Solutions, Product Architecture, Economic Analysis.

Introduction

According with Hägele (2011) the field of service robotics and medical devices is a comparatively young area that is expected to economically boom within the next decades into an economically significant multibillion Euro market. For this to become reality, the cost effectiveness of medical devices must be assured. However, only few studies have been published on economic aspects of medical devices and, in particular, of spinal orthosis. Most of these articles seem to focus on technical feasibility and solutions. Prassler (2010) mentioned that the lack of cost consideration has led to many product prototypes that were able to fulfil a certain purpose but prohibitively expensive. However, if profit-oriented enterprises are to engage in this field they must be able to predict the profitability of those undertakings that concern the development and marketing of a medical devices in order to make rational planning.

In the research study conducted by Bluemlein (2013) it is estimated that the development cost of a prototypical product is difficult for several reasons. Most technical cost estimation methods require more detail knowledge than is available at early development stages, thus reducing the appropriate selection of methods to expert opinion and comparison to similar products if possible. Also, robots represent complex systems where the costs cannot simply be reduced to material costs as is often the case for simple products; higher complexity entails an elevated development risk. Estimating the efforts and costs for developing a robot requires expertise not only in a variety of

technical fields such as electronics, systems engineering and software development but also an understanding of costing concepts and risk management. Furthermore, the cost of the estimation itself must not be prohibitively expensive as that would lead to abandonment of the attempt to predict project costs at all.

Hägele (2011) mentioned that often the estimation of manufacturing costs is based on the hardware structure. But nowadays, the software development has become equally as important for robots as the study on profitability of innovative robot applications has shown; because robots are complex systems the software development costs are considerable. This major cost block is incurred in preproduction phases whereas the direct software costs in the manufacturing stage are negligible. Therefore, the classical definition of production costs falls short for a complex product and cost intensive constituents of a system where hardware and software are equally important as it does not capture the indirect cost incurred in the development stage.

Ehrlenspiel et al (2007) says that the dilemma is exacerbated by the phenomenon that up to 90% of the life-cycle costs are determined in planning and development phases although the majority of the costs are incurred during production as depicted in Figure 1. This means that solid decision-making is highly important in early phases despite bounded rationality. At the time detailed product knowledge is available the possibilities of influencing costs will have decreased significantly.

Fig. 1: Influence on costs vs. incurrence of costs over product life-cycle [Blumlein, N. (2013)]

In a research study by Trivailo et al (2012) it is mentioned that enterprises interested in serving the market for complex products as robots require means to predict the profitability of such engagements. Ehrlenspiel et al (2007) considers that committing to the development of a robot that is technically feasible but economically not viable could result in profound financial losses therefore early cost considerations are the developer's responsibility. Cost estimates can also be used for comparison of variants, recognition of cost reduction potentials, production controlling or supplier cost examination.

According with Coenenberg et al (2009) the costing theory offers a wide range of cost terms. From a business-oriented point of view, costs are the consumption of goods and services incurred with the purpose of creating products or services, evaluated in monetary terms.

Considering the aforementioned, economic analysis of bespoke complex medical products is mandatory to the market viability of the developed concept. Hereafter, the authors propose a detailed methodology for economic analysis of a variety of construction options for a posture correction orthosis.

Product Architecture

Mortensen (2018) remarked that engineering design has traditionally studied and improved the development of single products. In order to increase ability to launch new products and strengthen the ability to launch on time, product architecture is one possible approach. The goal is to be able to make explicit and quantitative models describing the constitutive elements of a product architecture.

Ulrich (1995) presented the product architecture like a scheme by which the function of a product is allocated to physical components. This research paper further defines product architecture, provides a typology of product architectures, and articulates the potential linkages between the architecture of the product and the economic analysis of physical components.

Generally, orthoses for posture correction are composed from four systems: Software, Support, Data acquisition and Drive. Each of these systems contain few subassemblies and each subassembly is composed from components. In this study, the development of the Software system is not analysed and does not constitute a target of the study in the current stage. A general structure of the posture correction orthosis architecture is proposed in Figure 2, below.

Fig. 2: Posture correction orthoses architecture

Constructive Solutions

According to Ritchey (1998) the Morphological Analysis or General Morphological Analysis is a method that attempts to investigate all possible solutions to a multi-dimensional nonquantifiable complex problem in order to find the most adequate one by means of comparison. Ehrlenspiel et al (2007) said that the central concept is the use of a so-called morphological matrix. This matrix is constructed by setting different product aspects against each other along usually two or three dimensions, by mapping required product subfunctions to components as possible sub-solutions or by mapping product features to possible implementation forms as depicted in Table 1, for designing the posture correction orthosis.

In this stage of the analysis three of four systems are completed and constructive solutions are generated. The role of the Data acquisition system is to read the user's position. It is composed of a Vertebral body (VB) that simulates the user spine and the potentiometers that read the positions between two consecutive vertebral bodies.

Table 1: The morphological matrix for the solutions

	Positions reading	Vertebral body
Solution 1	Rotary encoder, MA3	Straight Vertebra
Solution 2	Potentiometer, 10k, continuously	Tappet Vertebra
Solution 3	Potentiometer, 10K, linear	Symmetrical Vertebra
Solution 4	Potentiometer, 10k, variable	-
Solution 5	Potentiometer, linear	-
Solution 6	Potentiometer, module	-
Solution 7	Potentiometer, EC 11, digital	-

According with the morphological matrix for constructive solutions shown in Table 1, seven commercial components were identified for Positions reading (PR). The constructive solution that will be chosen will be bought and integrated in the final prototype of the orthosis. For the Vertebral body, three custom designs were generated as the optimal solutions. Considering the specificity of the product, Additive Manufacturing (AM) technologies will be used to manufacture the final selected concept. The possible solutions for each component are shown in Figure 3.

Fig. 3: Posture correction orthosis constructive solutions

The technical data and the price for each of the analysed solutions were collected from the manufacturers' websites. Table 2 centralizes the characteristics of PR components that are relevant for technical and economic analysis. For reading the various positions of the user's spine it is necessary to be able to rotate the PR components at a maximum of 180°. Thus, all the proposed components are eligible, because the minimum value of the rotation angle is 300° for PR3 and PR4 (Table 2). The precision of components is given by the number of positions that can be read. The most imprecise component can register one reading at every 20°. This precision is not enough for a final product, but it can be considered for testing in the prototype stage. For the final product, this constructive solution will be replaced by the one that has the closest total cost.

Table 2: The characteristics of the analysed Position Reading solutions

Solution	Price [€]	Precision [pos./rot.]	Angle of rotation [°]
PR1	41.45	1024	continuous
PR2	2.86	120	360
PR3	2.89	60	300
PR4	0.51	18	300
PR5	1.24	24	continuous
PR6	2.06	36	continuous
PR7	1.03	24	350

Figure 4 presents all constructive solutions that were analysed from economical and technical point of view. This graph quickly identifies which solutions are better for a specific product depending on what technical precision is required. Figure 4a represents all constructive solutions that are analysed to see the difference between a very accurate component and its' price and other categories of components with same functions. This allows to decide if a more accurate component is necessary for this specific application. In order to identify the best solution for a posture correction orthosis, Figure 4b is generated, which zooms in ten times on the initial graph.

a) b)

Fig. 4: Comparation of Position Reading solutions

The Vertebral body (VB) is not a commercial component, thus the price for each option was calculated. Economic analysis is undertaken for VB2 in next chapter. All three vertebral bodies were designed using two types of construction options: asymmetrical and symmetrical. Full interchangeability between constructive solutions cannot be assured due to the different geometry of the PR components, which are commercially acquired. In this regard, Table 3 is put together to showcase the possible compatibility between different constructive solutions of VB and PR.

Table 3: The characteristics of the analysed Vertebral Body (VB) solutions

Solution	Price [€]	Type	Compatibility
VB1	4.01	Asymmetrical	PR1, PR2, PR3, PR4
VB2	2.36	Asymmetrical	PR1, PR2, PR6
VB3	2.15	Symmetrical	PR5, PR7

Hereafter, economic analysis is undertaken to determine if the separate lowest price component can lead to the optimum technical-economic subassembly.

Economic Analysis

Standard Cost

Mundhenk et al. (2003) describe a "low cost, high performance robot design utilizing off-the-shelf parts". In his opinion off-the-shelf parts led to the highest cost reductions and could ensure a good interchangeability rate. In this regard, a bill of materials (BOM) was put together for the posture correction orthosis (Table 4).

The BOM for the proposed posture correction orthosis was designed in a hierarchical way, to easily find identify subassemblies and specific components, if specific adjustments are needed. The last column of the table registers notifications, such as which components from final product is manufactured in house (own production). These in house manufactured components are specific and custom adapted to each end user of the spinal orthosis. For these components, the cost was calculated based on the methodology presented in the next subchapter, namely for Vertebral body VB2.

Table 4: Bill of Materials for the Posture correction orthosis

Product	System	Subassembly	Component	Qty	Unit Cost, €	Σ Cost, €	Notif.
Posture correction orthoses	Resistance	Jacket	Fabric	6	7.231	43.386

Total Cost [€]						**253.09**	

Cost calculation for Vertebral body VB2

For those components that are customized for each user the price included in BOM (Table 4) was calculated separately, as presented in the methodology below.

The total cost of the product consists of direct costs and indirect costs. Direct costs considered the plastic material from which the vest support piece was made (Figure 3). Indirect costs included the price of a 3D printer, salary costs for workers and administrative costs.

Fig. 5: Total cost scheme [adapted from Ulmeanu et al (2018)]

According with Andrei and Dragulanescu (1987) the manufacturing cost of a part is:

$$C = A_i + \frac{D_i}{n} \text{ [€/piece]} \quad (1)$$

where: A_i are batch independent expenses [€/piece];
D_d – expenses dependent on the manufacturing batch;
n – number of manufactured pieces.

$$A_i = c_m + c_s + c_{if} + c_{ind} \text{ [€/piece]} \quad (2)$$

where: c_m is the cost of the material of the part;
c_s – direct remuneration expenses;
c_{if} – expenses for the maintenance and operation of the equipment during the actual working time;
c_{ind} – indirect costs of manufacturing departments.

$$c_m = m_{sf} \cdot c_{sf} \text{ [€/piece]} \quad (3)$$

where: m_{sf} is the mass of raw material and m_{sf} = 0,029 kg;
c_{sf} – the cost of one kg of raw material, c_{sf} = 50.74 €/kg.

Thus, c_m can be calculated as c_m = 0,029 · 50.74 = 1,47 €/piece.

$$c_s = \sum_{i=1}^{k} \frac{\tau_{ui}}{60} \cdot s_{mi} \quad (4)$$

where: c_s are expenses with the salaries of the workers;
τ_{ui} – unitary time at operation "i", [min];
s_{mi} – expenses with the salaries at operation "*i*", [min]; expenses with the salaries for a plastics worker – 4.13 €/h.

Thus, c_s can be calculated as $c_s = \frac{5}{60} \cdot 4.13 = 0.34$ €/piece.

$$c_{if} = \sum_{i=1}^{k} \frac{\tau_{ui}}{60} \cdot a_i \quad (5)$$

where: c_{if} are the costs of maintenance and operation, respectively depreciation of the equipment;
a_i – the depreciation rate of the equipment as well as the repairs and maintenance.

$$a_i = \frac{2.3 \cdot C_{MU}}{A \cdot z_l \cdot k_s \cdot h} \quad (6)$$

where: C_{MU} is the price of the 3D printing equipment;
z_l – the number of working days in a year;
k_s – number of shifts;
h – duration of a shift.

VB2 was manufactured using a Zortrax M300Plus 3D printer, thus the depreciation rate can be calculated as: $a_i = \frac{2.3 \cdot 4038}{5 \cdot 245 \cdot 2 \cdot 8 \cdot 60}$ = 0,005. Also, the maintenance and operation costs are calculated as: $c_{if} = \frac{5}{60} \cdot 0{,}005 = 0{,}0004$ €/piece.

$$c_{ind} = c_s \cdot \frac{R_f}{100} \quad (7)$$

where: R_f are the administrative expenses, R_f = 150…200%;

Thus, the indirect costs of manufacturing are: $c_{ind} = 0.34 \cdot \frac{150}{100} = 0.51$ €/piece.

Considering the abovementioned, the independent batch expenses are A_i = 1.47 + 0.34 + 0,0004 + 0.51 = 2.32 €/piece.

Expenses dependent on the manufacturing batch consists of two categories:

$$D = B + C \tag{8}$$

where: B are the expenses with the preparation – completion of the manufacture and the administrative preparation of the launch of the lot;
C – expenses for the maintenance and depreciation of the equipment during the preparation-completion time.

$$B = (1 + \frac{p}{100}) \cdot \sum_{i=1}^{k} \frac{\tau_{pi}}{60} \cdot m_i \cdot s_{ri} \tag{9}$$

where: p is the administrative expenses, p = 25%;
m_i – number of equipment's working on operation "i";
s_{ri} – salary of worker at operation "i".

The expenses with the preparation – completion of the manufacture and the administrative preparation of the launch of the lot are: $B = (1 + \frac{25}{100}) \cdot (\frac{25}{60} \cdot 1 \cdot 4.13) = 2.15$ €/piece.

$$C = \sum_{i=1}^{k} \frac{\tau_{pi}}{60} \cdot m_i \cdot a_i \tag{10}$$

The expenses for the maintenance and depreciation of the equipment during the preparation-completion time are: $C = \frac{25}{60} \cdot 1 \cdot 0{,}0004 = 0{,}00016$ €/piece.

Thus, the expenses dependent on the manufacturing batch are: D = 2.15 + 0,00016 = 2.15 €/piece.
Considering that one batch was comprised of 50 pieces (n_0 = 50 pieces), the total cost for VB2 is as follows:

$$C_p = A_i + \frac{D}{n_0} = 2.32 + \frac{2.15}{50} = 2.363 \text{ €}.$$

Selection of the constructive solution

Economic Efficiency

From a technical perspective all the proposed constructive solutions are eligible to be used. One technical constraint which needed to be considered was that not all PR options could be assembled with all VBs. Thus, the selection of the cheapest option for the Posture correction orthosis had to follow this mandatory technical requirement. To select the most economically convenient solution percentual cost was established for each component and for all possible constructive solutions, using relation (11) below:

$$\Pi_{PC} = (CC*N/TC) *100 \tag{11}$$

where: CC is the component cost;
N – number of the same components used in a final product;
TC – total cost of the final product.

Using relation (11) and the values established in Table 4, the percentual costs for all PRs and VBs were calculated:

Π_{PR1} = (41.45*8/253.09) *100 = 131.02%
Π_{PR2} = (2.86*8/253.09) *100 = 9.04%
Π_{PR3} = (2.89*8/253.09) *100 = 9.14%
Π_{PR4} = (0.51*8/253.09) *100 = 1.61%
Π_{PR5} = (1.24*8/253.09) *100 = 3.92%
Π_{PR6} = (2.06*8/253.09) *100 = 6.51%
Π_{PR7} = (1.03*8/253.09) *100 = 3.26%
Π_{VB1} = (4.01*8/253.09) *100 = 12.68%
Π_{VB2} = (2.36*8/253.09) *100 = 7.45%
Π_{VB3} = (2.15*8/253.09) *100 = 6.80%

Based on relation (12) the percentage cost of all constructive solutions for the Reading subassembly is presented in Table 5 below.

$$\Pi_{CS} = \Pi_{PRi} + \Pi_{VBi} \tag{12}$$

Table 5: Percentual cost for constructive solutions of the reading subassembly

CS1	CS2	CS3	CS4	CS5	CS6	CS7	CS8	CS9
VB1-PR1	VB1-PR2	VB1-PR3	VB1-PR4	VB2-PR1	VB2-PR2	VB2-PR6	VB3-PR5	VB3-PR7
143.70%	21.72%	21.82%	14.29%	138.47%	16.49%	13.96%	10.72%	10.06%

Constructive Solutions Analyse

As shown in Figure 6a, the CS1 and CS5 constructive solutions have a higher cost (143.7% and 138.5%) than the total standard cost of the final product. These two solutions were eliminated and in Figure 6b the analysed solutions are presented.

a) b)

Fig. 6: Total costs for constructive solutions of the reading subassembly

For a PF component the lowest price is PR4, and for the VB component the lowest price is VB3. Because of technical requirements the combination between these two components is not possible. Thus a comprehensive graph is put together in Figure 7 to facilitate the selection of the optimal constructive solution.

Fig. 7: Constructive solution selecting graph

The constructive solution selecting graph allows the selection of the most appropriate constructive solution for a specific subassembly, system and even the constructive solution for a totally different version of a product. In our studied case, the optimum constructive solution cost is CS9.

Conclusion

Early cost estimation is a common prerequisite for the profitability assessment of the development of complex products. The combination of numerous technical and economic factors poses a complex challenge for product developers. In the field of medical devices, this issue is acerbated by the fact that many devices should be customised to the user's needs.

The paper presented a detailed methodology for linking custom product architecture with cost analysis within the product design and development process for a posture correction orthosis. Nine constructive solutions for spinal orthoses were developed and several cost aggregates estimated. The results were examined regarding their accomplishment of technical requirements and the value of estimated total costs. CS9 was chosen as the most suitable constructive solution based on technical and economical characteristics. From a technical perspective all constructive solutions were eligible to be used. Nevertheless, technical constraints regarding the assembly of VBs and PRs led to the selection of one particular constructive solution. If VB and PR costs were to be analysed separately, a wrong constructive could be selected. Thus, a selecting graph was put in place, allowing the designer to select the appropriate constructive solution for a specific subassembly, system and even the constructive solution for a totally different version of the posture correction orthosis.

Abstract

One of the basic goals of family businesses, determining the essence and uniqueness of these entities, is to last for generations. That is why successful succession is one of the most important tasks facing family businesses. Meanwhile statistics show that few companies pass into the hands of the next generations. The aim of this article is to examine the succession situation in Polish family businesses and to try to answer the question what factors may determine the failure of an intergenerational transfer. The research is based on two main secondary sources which are reports from studies conducted among Polish owners of family businesses and potential successors. Research results show that Polish family entrepreneurs make many mistakes that hinder the successful implementation of the succession process. These errors include, among others, insufficient knowledge of the time horizon of succession, lack of proper communication regarding succession, or lack of formal, written confirmation of succession. A very important factor affecting the low effectiveness of succession processes is the low interest of successors in taking over the family business. It may result from internal factors, relationships in family as well as factors from the social environment. To increase the chances of successful succession of Polish family businesses, it is therefore necessary to act in many ways. First, the owners' knowledge should be raised so that they can plan and then carry out the succession process. Secondly, it is necessary to convince potential successors that taking over the family business is a challenge that they can cope with and which will give them professional satisfaction. Thirdly, it is necessary to ensure the society that family businesses are a treasure of the national economy, and successors take over companies with a sense of well-understood duty and are able to contribute a lot to them.

Keywords: Failure in Succession, Family Business, Family Firms, Succession, Transgenerational Transfer.

Introduction

One of the basic goals of family businesses, determining the essence and uniqueness of these entities, is to last for generations. This multi-generational perspective is inseparably connected with the need to carry out the process of succession, i.e. the transfer of ownership and power to the next generation. Successful succession is one of the most important tasks facing family businesses and is necessary for their continuation for generations (Leotta et al., 2017; Hytti et al., 2017; Zhou et. al., 2016). Unsuccessful succession is one of the main reasons for the failure of family businesses or the loss of their family character. Statistics show that few companies pass into the hands of the next generations. About 30% of enterprises are successfully transferred to the second generation, about 10-15% to the third, and only 3% of family businesses to the fourth (Bizri, 2016). Therefore, it is very important to recognize the factors affecting the quality and effectiveness of succession and the main barriers hindering, and sometimes even preventing it.

The purpose of the article is to examine the succession situation in Polish family businesses and to try to answer the question what factors may determine the failure of an intergenerational transfer. This will allow recommendations to be made to facilitate the succession process in the future.

Literature Review

Succession is a specific and at the same time one of the most complex problems of family businesses. It touches the areas of enterprise strategy, personnel strategy, organizational culture and ownership structure (Sułkowski & Marjański, 2011). This is a broad topic and therefore it is not surprising that it is one of the most frequently discussed in the context of family businesses. Numerous authors are looking at such issues as the involvement of the senior in the company after the succession process (Ahrens et al., 2018), the key determinants which inhibit intra-family business succession (Lockamy et al., 2016), typology of next generation's future leadership projections (Lefebvre & Lefebvre, 2016), knowledge generation in the process of succession (Duh, 2014) and its transfer to the next generation (Boyd et. al., 2015; Pavel, 2013), new CEO selection and the skills that successors should possess (Schlepphorst & Moog, 2014), planning the succession process (Drury, 2016; Collins et al., 2015), influence of paternalistic management style on successors (Mussolino &. Calabro, 2014), management philosophy in pre- and post-succession phase (Steier & Miller, 2010), the importance of psychological aspects in the process of succession (Filser et al., 2013), influence of religion on succession intentions (Shen & Su, 2017), factors determining the choice of a successor (Luan et al., 2018; Bizri, 2016; Ansari et al., 2014), the impact of family relationships on succession (Soto Maciel et al., 2015), role of successor's involvement in the succession process (Peters et al., 2012), impact of taxes on succession (Vincencová et al., 2015), role and influence of external advisors and service providers (Cesaroni & Sentuti, 2016; Michel & Kammerlander, 2015). They are also often discussed Gender issues in the CEO successions of family businesses (Ramadani et al., 2017; Aldamiz-Echevarría et al., 2017; Deng, 2015; Ahrens et al., 2015; Glover, 2014; Remery et al., 2014; Overbeke et al., 2013; Humphreys, 2013; Otten-Pappas, 2013; Pyplacz 2013; Skačkauskienė et al., 2019) and there are also many studies indicating the succession in specific countries and industries (di Belmonte et al., 2016; Vassiliadis et al., 2015; Vassiliadis & Vassiliadis, 2014; Tirdasaria & Dhewanto, 2012; Lussier & Sonfield, 2012; Putri & Viverita, 2019). Despite such a wide range of interest, there are still many gaps that will probably be gradually filled in the coming years.

When considering issues related to succession, it is worth trying to define it, because as the scope of the topics related to it is wide, so are its definitions. Succession can be described as "the transference of ownership control and management to the next generation" (Woodfield et al., 2017). Corbetta and Priete capture it more broadly and define it as "a process whose goal is to ensure the continuation of the enterprise, i.e. its survival on the market. This process leads to a new ownership structure and changes in management in connection with the successor's takeover of both ownership and power in the company." (Roszko-Wójtowicz, 2014). Often is also defined as "the actions, events, and organizational mechanisms by which leadership at the top of the firm, and often ownership, are transferred" (Leotta et al., 2017). The literature also emphasizes that succession should be understood as a process, not just the moment when the transfer of the "baton" to the successor takes place (Lefebvre & Lefebvre, 2016). Budziak (2012) notes that "the problem of succession is the biggest challenge for the business family, the ultimate test of the sustainability of the entrepreneur's and his family's many years of effort. This is not a one-time event related to the opening of an inheritance or the transfer of shares and power in business to the next generation, but an element of a long-term business family strategy." One of the conditions for successful implementation of the intergenerational transfer process is a properly prepared succession plan. It should contain answers to such basic questions as: who, when and how will take over power and ownership in the family business (Sułkowski & Marjański, 2011). Ownership and power are two different issues, but they should be considered together - many succession processes have been unsuccessful because these issues were not transmitted in parallel (Winnicka-Popczyk, 2010). Drawing up a succession plan is not the only factor determining the success of the intergenerational transfer process. Issues related to the senior and successor also play a significant role. Seniors may be characterized by different levels of readiness to transfer ownership and power and acceptance of the successor's vision of running a business (Sułkowski, 2005). Often they constitute a significant barrier to effective succession. Their reluctance to surrender power may result in many factors, e.g. fear of losing the company and loss of authority in the family, strong emotional attachment to the enterprise, inability to reconcile with the passing of time and treating the resignation from active business as reconciliation with the inevitable death (Roszko-Wójtowicz, 2014).

No less important than the senior's willingness to leave is the willingness of the successor to get involved in managing the company. Financial security, the possibility of self-fulfillment, and trust on the part of the senior undoubtedly have a positive impact on the junior's attitude to taking control of the family business. The personal preferences of the potential successor and his professional interests also play a significant role. Family relations, which condition the successor's agreement with relatives, also affect succession success (Sułkowski & Marjański, 2011). The success of intergenerational transfer is determined by many factors, and disruption in any area may result in serious problems in the implementation of the succession process. Therefore, identifying and investigating

sources of disturbances can significantly contribute to improving the effectiveness of the succession process of Polish family businesses.

Research Methodology

The research is based on several secondary sources. The first is *Kody wartości. Diagnoza sytuacji sukcesyjnej w przedsiębiorstwach rodzinnych w Polsce (2013)* - the Synthetic Report on research carried out under the Kody wartości – efektywna sukcesja w polskich firmach rodzinnych project. The purpose of this study was to analyze the state of preparation of Polish family businesses for the succession process, and to identify key success factors for this process as well as to examine the emotions that appear among owners and potential successors. A total of 416 people took part in the study. As part of the research, comprehensive quantitative research (surveys) and qualitative research (diagnostic workshops and in-depth interviews) were carried out. In the quantitative survey conducted from January 7 to 28, 2013, answers from 332 respondents were obtained. The majority of respondents were owners - 250 people, while 82 respondents were potential successors. The qualitative research, conducted by a group of experts from the project, was divided into diagnostic workshops (took place on February 7, 2013, with 62 people from family businesses) and in-depth interviews (implemented from January 31 to February 9, 2013, with 22 people from family businesses).

The second source is *Barometr Sukcesyjny - ścieżki kariery pokolenia Next Generation w polskich firmach rodzinnych Report (2017)*, which was based on the largest successor survey in Poland, implemented by the Family Business Institute as part of the second Polish edition of the international GUESSS project (Global University Entrepreneurial Student Spirit Students' Survey) implemented in 50 countries on all continents. 50 universities from Poland took part in the survey carried out in 2016. 1471 successors were tested, who could potentially be owners of businesses currently run by their parents. The report also uses the results of the study from the first edition of the project, which were collected in October-December 2013 (11,860 students took part).

Results and Discussion

One of the most important issues regarding succession is its perception by both current family business owners and potential successors. According to the research (see Fig. 1), in both groups the majority of people in Poland are aware of the fact that succession is a very important process that should be planned and managed. However, it is worrying that approximately every fourth owner and successor underestimates the complexity of succession and believes that this process should be carried out spontaneously, depending on the circumstances.

Fig. 1: Perception of succession.

(Source: Lewandowska, 2013).

The literature very often emphasizes the need to plan the succession process. It seems that entrepreneurs also agree with this approach, because less than 15% of owners and successors do not see the need for succession planning. However, the majority of respondents believe that succession planning is a short-term process - according to only slightly more than 25% of owners and successors, it should last longer than a year.

Fig. 2: How long should a well-prepared succession process last?

(Source: Lewandowska, 2013).

According to specialists, succession should be discussed a lot and often in the family. This is necessary to be able to accurately determine and plan its course. Meanwhile, Polish family businesses talk about it rarely or not at all. Particularly worrying are the responses of the owners, among which over 20% indicated that succession is not discussed at all. Interestingly, the successors present a more positive picture of the frequency of succession conversations - 12% of them admitted that they do not talk about succession (9 percentage points less than among owners), while 17% indicated that succession is a very common topic of conversation.

Fig. 3: How often the topic of succession appears in conversations?

(Source: Lewandowska, 2013).

Research indicates a large discrepancy in the perception of succession phases between the owners and successors of Polish family businesses. Most owners are still in the succession planning phase (over 70% of responses), possibly seeking successors phase. Only 17% of owners believe that the process of succession is currently implemented in their companies. Successors have a definitely different view on this issue. Although almost 44% of them agree with the owners and believe that succession is only planned, but another 40% of successors believe that this process is already being implemented. Also, twice as many successors than the owners indicated that their family businesses are already in the post-succession phase.

Fig. 4: Succession process phases

(Source: Lewandowska, 2013).

For successful succession extremely important is the method of confirming it and informing successor about it. Meanwhile, almost half of the respondents (both owners and successors) indicated that the only form of confirmation of succession was an oral proposal to a potential successor. Moreover, 34% of the owners and 26% of the successors admitted that in their enterprises there is no formal way of confirming the succession. Only about 5% of surveyed family businesses use written forms of confirmation of succession.

Fig. 5: Way of confirming succession in family business.

(Source: Lewandowska, 2013).

The process of succession is not possible without the willingness and commitment of successors taking over the family business. Meanwhile, less than 10% of potential successors declare their willingness to become a successor in a family business. They do not see themselves in this role either immediately after graduation or 5 years after graduation. Although in the 2nd edition of the survey slightly more respondents expressed the desire to take over the family business, it is far too early to call this change a trend and draw far-reaching conclusions on its basis. There is no doubt, however, that growing up in the entrepreneurial climate has an impact on young people, because almost half of them, after working with others, would like to start their own business.

Fig. 6: Planned career path of the successor immediately after graduation and 5 years after graduation.

(Source: Lewandowska & Tylczyński, 2017).

Successors deciding to take over family businesses follow different motivations. Research shows that the most motivating factor to stay in a family business as a successor is a sense of responsibility for the work of ancestors. The desire to introduce changes in the company and the need to test own skills is slightly less important.

Fig. 7: Successor motivations for succession.

(Source: Lewandowska, 2013).

Conclusion

The research results cited in the previous section indicate that although the owners and successors of family businesses rightly believe that the succession process should be planned and managed, they make many mistakes during its implementation. These errors can significantly contribute to the failure of the succession process. The first mistake is the wrong perception of the time needed to carry out succession. Most owners and successors believe that it should last a year or less, while researchers indicate that for it to be truly effective it must last at least a few years. Succession is not a one-time act of transferring power and ownership, but a long-term process, during which the successor is selected and prepared to perform his duties and builds his own position and authority in the company. Another mistake is too rarely addressing the topic of succession in family discussions, whether between the owner and the successor. It is impossible to successfully carry out the succession process without talking about it and not establishing all the issues related to it together. This can lead to the situation observed in the quoted study in which successors and owners perceive the succession phase in which the enterprise is located differently. This can lead to many misunderstandings and discourage successors from succession. The lack of proper communication is associated with another mistake, which is the lack of formal confirmation of succession and informing all interested parties about it. Written confirmation of the successor's choice and transfer of authority is definitely clearer and binding than just an oral proposal. These errors are mainly due to the low level of knowledge of entrepreneurs about succession. Many mistakes in the process of succession also result from the guiding of emotions and family ties instead of competences (compare Roszko-Wójtowicz, 2013; Surdej & Wach, 2010). The successor should be the person who has the greatest predispositions for this, and not the one who is the oldest or

closest to the heart of the owner. Sometimes it may be necessary to look for a successor in the extended family or entrust the management of the company to an external manager (however, in this case some are already talking about losing the family nature of the business).The owners and successors intuitively feel the importance of the succession process, but they lack reliable, professional knowledge about its mechanisms and good practices. The way to increase the chances for successful successions is therefore to educate owners and successors and provide them with practical tips to avoid the most common mistakes. Such activities are already being carried out in Poland, primarily by associations of family businesses, so can be expect that more and more entrepreneurs will be able to successfully hand over companies to their successors.

The lack of willingness to take over the family business by potential successors is another and at the same time one of the most important reasons for the succession failure. No one can be forced to continue the family heritage, and no succession can be carried out without a successor. Therefore, factors that discourage the next generation from becoming involved in a family business should be considered very thoroughly. In many cases, this is the senior's reluctance to turn over power to the company and step into the shadows. This prevents the successor from building authority and realizing his own vision of running a business. In such situations, potential successors often prefer to start their own business than wait until the senior is finally ready to hand them over to the family business (research on the career path of the successors indicates this). Another source of reluctance to take over a family business can be the fear of responsibility and failure, disappointment of family and loss of family heritage built by predecessors (compare Więcek-Janka et al., 2016). Also, the inevitable comparison of the successor with the senior and judging the successor through the prism of the predecessor's achievements do not encourage participation in the succession process. It seems that in Polish reality, there are other important, but overlooked cause of reluctance of potential successors to take over the family business. They have their sources not in family relationships or a family business, but in its social environment. The first is the quite negative image of private entrepreneurship (which also includes family businesses) associated with selfish, soulless capitalism. This image grew on the basis of the previous political system prevailing in Poland and despite significant changes, one can still meet with maintaining its. Another reason is the negative image of the children of entrepreneurs (i.e. potential successors) in some local communities. Already at the school stage, future successors can sometimes meet with a negative attitude of the environment and mocking opinions in the style of “even if nothing can do, he does not have to worry, because he will take over daddy's company anyway”. Such opinions often result from jealousy and are the aftermath of the aforementioned negative attitude to private entrepreneurship, but they can have a big impact on successors. To prove their worth and free themselves from such perception, potential successors may forgo resigning from taking over family businesses. This is unfavourable for all parties, so it is important to eliminate this type of phenomenon. Therefore, it is important not only to change the attitude of potential successors and to show them that taking over a family business will allow them to develop professionally, but also to show the society that being a successor is not going on a easy task, but requires appropriate skills and competences.

The sources of unsuccessful succession discussed above do not exhaust the entire catalogue. For example, Więcek-Janka (2018) indicates differences in perception of the world and values between representatives of the BB, X, Y and Z generations. These differences significantly impede the cooperation of different generations in family businesses, and consequently negatively affect the succession process. Klimek et al. (2019) researching key determinants of succession attitudes of students indicate that knowledge of succession plans and knowledge of expectations about the successor have a positive impact on the choice of career path as successor. Therefore, it can be concluded that the lack of precisely defined succession plans and the requirements for successors are further factors hindering succession. Also Bieńkowska (2011), giving a catalog of determinants influencing the successor's motivation to take over the company, indicates automatically factors potentially hindering or preventing succession.

There are certainly many more sources of unsuccessful succession. This article is only an attempt to systematize the problem and an invitation to further analysis. Undoubtedly, its limitation is the lack of primary data that can extend the quoted data and confirm the presented theses. In the course of further research, it is worth focusing on potential successors and their feelings, especially regarding aspects that discourage taking over family businesses. Investigating the social factors of this reluctance seems quite reasonable and can significantly contribute to expanding knowledge about succession.

The Classification of Social and Cultural Risks

Anna MAYAKOVA

Senior researcher, SWSU, Kursk, Russian Federation
berryannett@yandex.ru

Abstract

The article introduces author's classification of risks that has been formed in virtue of the author's previous research as well as the works of scientists and specialists of economic (Batova I., Acharya V., Pedersen L., Philippon T., Richardson M., Semernik S., Cristea G., Constantinescu D.), sociological (Grimov O.A., Kamensky E.G., Shestopal E. B., Selezneva A.B.), technical (Khodydevskaya S.V., Khalin V.G., Chernova G.V.), psychological (Molokostova A.M.) and other scientific spheres. Within the framework of the study the characteristics of the classification (type of risk, the risk content, cause (source) of the risk, the direction of risk, degree of risk impact, the probability of the risk occurring, risk function, level of risk, the trend manifestation of risk, form of risk) and corresponding with them types of risk have been defined. The classification of social and cultural risks offered is a universal one to use in different spheres of science and for practical use.

Keywords: Risk · Social and Cultural Risk · Classification of Risks · Type of Risk · Characteristic of Classification.

Introduction

The development of classification of social and cultural risks is one of the most urgent problems of modern philosophy and science. It is possible to solve this problem basing only on the following concepts: the concept of comprehensiveness, which will enable to study this scientific problem multidimensionally, the concept of complexity in the framework of which the scientific problem under study is investigated with different interdisciplinary approaches as a whole, the concept of systematicity with the help of which we can trace the structural elements and evaluate the problem as an entire system of interdependent and interacting elements.

Results and Discussion

The global practice of risk management is contained in the developed regulatory documents, which contain elements of risk management. Recommendations of the European Union on risk management contain a general requirement, which is supported by the Russian Federation that is a detailed expert analysis to be carried out by employees engaged in risk management activities both within the same organization and at the state and interstate levels. Risk analysis supports this initiative. As can be seen from the risk analysis procedure, the whole methodology is based on the expert analysis principle. Along with expert analysis, international standards for risk management are similar in the dynamics of this process, its systematicity and consistency, focus on strategic goals, transparency and content. So, effective risk management allows not only more efficiently carrying out daily activities, but also planning and making strategic decisions on significant issues at various levels. Risk analysis within risk management is a documented process that enhances traceability of decision making.

In the framework of technical sciences there exists an extended ranging of risks into real, potential and " force majeure " ones (Hoodat, 2009). The appearance of a real risk leads to creating some correcting measures which can eliminate or minimize the risk, and then a system of measures to prevent risk is created. A potential risk is a risk that doesn't exist at the moment, but in can be anticipated, planned, forecasted. Force majeure is a risk that arises unplanned and unpredicted during some action. The main distinguishing feature of social and cultural risks is the absence of force majeure risk, respectively the classification of social and cultural risks by the type implies two types of risks: real and

potential ones. Potential social and cultural risks are the ones that can't be planned, anticipated and even imagined, because the scholarly knowledge in the sphere of risk arising is minimal or does not exist at all. Therefore, the evaluation of social and cultural risks is the evaluation of all possible assumptions (both positive and negative) about an event (development, implementation or usage of a technology). In general potential social and cultural risk is any possible risk with a minimal possibility of happening, even non-existent one.

Particularly such statement is applicable in the sphere of convergent technologies. It can be explained by the increased uncertainty of social and humanitarian perspective of development and the usage of convergent technologies which is connected with ambiguous end result in the framework of convergent technologies development: on the one hand the positive meaning and performance dynamic(creating a new technology), on the other hand a (potential) risk of using this technology for "non-positive" purpose. This risk is potential, because we cannot predict in what sphere a useful humanitarian elaboration will be applied. If such a prediction can be made, the risk is not potential anymore, it becomes a real one with low or medium possibility of arising (in the ideal case) and high or catastrophic degree of impact. The examples of risks with a high degree of impact can be the appearance of new qualities and characteristics of known materials (i.e. nanoparticles of gold < 2nm are toxic for humans); creating artificial materials generates anxiety of how the existing eco systems will interact with them and how humans will adopt to them.

In terms of introducing real and potential risks the author has mentioned two other criteria of risk classification: degree of impact and possibility of arising of the risk. These criteria of classification are also the criteria of risk evaluation when holding risk analyses with the help of risk management methodology. Classification of risks according to the criterion "the degree of impact" presumes the following types of risk: low medium, high or catastrophic degree of impact. According to the "the possibility of arising " criterion we can name such types as low, medium, high. With the purpose of more precise classification of social and cultural risks according to these criteria it is reasonable to apply the methods of SWOT-analyses (Gurel, 2017) and FME(C)A-analyses (Cristea, 2017).

One the key criteria of risk classification is the contents of risks. Basing on the sociological research of E. Shestopal and A. Selezneva (Shestopal, 2018) and a detailed analyses of the previous research in the sphere of risk management the following global threats have been pointed out:

- digitalization;
- westernization;
- massification;
- technification;
- virtualization of culture;
- moral crisis;
- deformation of channels and tools of spiritual heritage transmission.

Speaking about the sources of social and cultural risks mentioned above we can point out social division, identity crisis, structural misbalance in professional, ethnic and other social groups, in addition to psychological dysfunctions of the society, anomy, shortage of sympathy, discontented enquiry for social justice, state of uncertainty in the future, lack of long-term perspectives (Shestopal, 2018, Grimov, 2015, Kamensky, 2012). The chosen types of social and cultural risks are global, structured, the architectonic of each of them can be examined in more detail. The influence of risks on the quality of life is great, it can be proved by the analyses of social and cultural risks held by the author (Mayakova, 2019). Therein all risks can be minimized but cannot be eliminated because of their coverage. With the purpose to minimize risks for every of them the events that can and should be held are offered. Nowadays in Russia there exists a number of documents and initiatives that can help minimize social and cultural risks. The main condition of their execution is systematicity.

Bearing in mind the analyses of "risk contents" classification criteria we can make one more conclusion: the formation of a new classification criterion is a reason(source) of risk appearance. On the example mentioned above we can see the anthropological, economic and technological reasons. Speaking about the sources of risk appearance we should separately mention natural factors: earthquake, flood, extreme weather conditions and so on. It is natural that the reason of risk is seldom separate, that is why it is reasonable to introduce a "hybrid" source of risk appearance into the classification.

Taking into account different aspects of the concept of "social and cultural risk" it is relevant to introduce such criterion as "the direction of risk". Every direction reflects not only a social and cultural aspect, but also a field of philosophy and science, which is applicable in this discourse. Thus, taking into account everything mentioned above we can point out the following directions of risk:

- ethic;
- legislative;
- economic(technological);
- cultural(also esthetical);
- psychological;
- ecological;
- social
- hybrid.

The hybrid one implies the synthesis of several types of risk. Let us take the risk of "moral crisis" as an example that has a catastrophic influence on human and society in general. Taking into account the contents of the risk and the specific character of its influence(lowering the moral standards and the general cultural level of the society, dehumanization of all the spheres of human life, the development of destructive and illegal forms of behavior, lowering the general level of law and order, stability and security in the country and soon), this risk cannot be referred to a single particular direction. Consequently, this risk is a hybrid one, in the framework of which such directions as ethical, legislative, cultural, psychological, social are integrated. When necessary one direction can be split into several, being introduced as a complex system.

One of the most important characteristics of risk is the purpose of risk or its function. This or that event, action, technology, especially with an innovative meaning, some risks apriori. Thus, the function of risk is not necessarily negative, because the event examined in general leads to a positive effect i.e. profit. This concept was borrowed from the methodology of anti-crisis management where risk can be seen as a positive thing (Acharya, 2017). This type of risk is most pronounced in the sphere of some modernization. The transformation of something (system, technology, invention) is impossible without some risks, however the effect can overcome all our expectations. For example, within the framework of risks "Virtualization of culture" a threat of lowering communicative skills is identified, in other words, "failure of intercommunication", but this treat led to the development of new ways and types of communication. It is logical that if there is a risk that allows for profit, there must be identifies a type of risk that is opposite to it, the one that allows for losses. It is the most widespread type of risk.

Taking into account the fact that the problem of risks is important at different hierarchic levels of social order, it is necessary to introduce such criterion of classification as risk level (Batova, 2015). On the groungs of the meaning of "social and cultural risk" concept and the extent of its coverage let us define the following levels of risk:

- personal;
- group (small and medium group);
- sectorial/regional;
- institutional;
- governmental;
- international;
- global.

Most risks, especially of global threats, can be evaluated at each level of classification. This criterion of classification can be logically used as one of the stages of risk analyses, because it supposes all-round study of risk, we can say, its unfolding.

In order to have an opportunity to study one or several reasons, it is necessary for them to appear at some rate. Taking this into account, we complete our classification with such criterion as "the tendency of risk appearance". The risk can appear at different steps of one event or accompany it at every appearance of this event, then the risk will be objective (for example the discrimination of the idea of labor in the social and cultural context of economy centric society). If the risk can appear under the influence of subjective decisions, it will be classified as a subjective one (for example, risk

connected with responsible taking effort to rationally coordinate individual goals). Both examples of social cultural risks refer to the global threat of technification, in particular, in the direction of economocentrizm (Semernik, 2018). The risk, the appearance of which can be explained by some reasons (events, factors) is a motivated one. Consequently, if the motivation is not possible, the risk in unmotivated. As examples of motivated risks we can name the following: modern information technologies represent a powerful mechanism of conscience control, which contributes to substitution of values, destruction of cultural memory, change of identity (Khalin, 2018), i.e. the total manipulation of human sense; the risk(problem) of choosing unbounded self-development or self-protection (Molokostova, 2013). Finally, if the risk results into crime or leads to it, it can be called a criminogenic one. For example, the threat of criminalization of social relation emerging in the process of reforming the social -political system and the economic activity is such a risk.

The general classification is shown in Table 1.

Table 1: Classification of social and cultural risks

Characteristic of classification	Type of risk
1. Type of risk	1.1 Real 1.2 Potential
2. The risk content	2.1 Digitalization; 2.2 Westernization; 2.3 Massification; 2.4 Technologization; 2.5 Virtualization of culture; 2.6 Moral crisis; 2.7 Deformation of channels and mechanisms for transmitting spiritual heritage
3. Cause (source) of the risk	3.1 Anthropological 3.2 Technology 3.3 Economic 3.4 Natural 3.5 Mixed
4. The direction of risk	4.1 Ethic 4.2 Legislative 4.3 Economic(technological) 4.4 Cultural (also esthetical) 4.5 Psychological 46 Ecological 4.7 Social 4.8 Hybrid
5. Degree of risk impact	5.1 Low 5.2 Average 5.3 High 5.4 Catastrophic
6. The probability of the risk occurring	6.1 Low 6.2 Average 6.3 High
7. Risk function	7.1 Risk that allows for profit 7.2 Risk that allows for losses
8. Level of risk	8.1 Personal 8.2 Group (small and medium group) 8.3 Sectorial/regional 8.4 Institutional 8.5 Governmental 8.6 International 8.7 Global

9. The trend manifestation of risk	9.1 Subjective 9.2 Objective 9.3 Unsubstantiated 9.4 Reasonable 9.5 Criminogenic
10. Form of risk	10.1 Conceptual 10.2 Planned 10.3 Forecasted 10.4 Structured 10.5 System 10.6 Sudden

Conclusion

The classification of social and cultural risks offered is a universal one to use in different spheres of science and for practical use. The classification criteria and the risks corresponding to them are generated not only basing on the author's previous research, but also on the works of scientists and specialists of economic (Batova I., Acharya V., Pedersen L., Philippon T., Richardson M., Semernik S., Cristea G., Constantinescu D.), sociological (Grimov O.A., Kamensky E.G., Shestopal E. B., Selezneva A.B.), technical (Khalin V.G., Chernova G.V.), psychological (Molokostova A.M.) and other scientific spheres. The classification of social and cultural risks can be used in research work connected with further studying of the problem of risk in postnonclassical science and philosophy as well as in other spheres of fundamental and applied science.

Resumen

En este artículo se recopilaron todos los conflictos socio-ambientales presentes en Chile, para determinar a través de los datos levantados, los conflictos que se vinculan directamente con el uso, acceso y contaminación del Agua, y que además eran causados por la intervención de la Industria Minera. El objetivo de este trabajo fue en primer lugar, realizar una interrelación entre la Constitución Chilena de 1980, creada en el Gobierno Cívico-Militar, el Código de Minería y el Código de Aguas, para establecer algunas de las razones que facilitan los conflictos de Agua entre Empresas Mineras y las Comunidades circundantes y en segundo lugar, crear un Sistema de Información Geográfica, a través del levantamiento y localización de conflictos manifestados a través de varias fuentes: información bibliográfica, datos geo-referenciados y uso de imágenes satelitales, fuentes que luego se cruzaron para establecer el espacio territorial donde se producen los conflictos. Los resultados obtenidos mostraron una tendencia a la concentración de los conflictos socio-ambientales, sobre el uso del Agua, en los territorios donde se centraliza la Actividad Minera, a partir de ello, se discute y se reflexiona la relación sobre los principales desafíos que la industria y la comunidad deben sortear. El texto se estructuró en cuatro partes: (I) introducción al artículo, (II) los métodos y materiales, (III) Resultados y (IV) Discusión de los productos cartográficos y las principales conclusiones obtenidas durante el desarrollo de la investigación.

Palabras claves: Conflictos Socio-ambientales, Cartografía Social, Intervención Minera, Uso del Agua.

Introducción

Las regulaciones para el acceso y la gestión del agua en Chile están declaradas en el Código de Agua de 1981, donde se separa el dominio de la propiedad del agua con respecto a la Tierra, por tanto, alguien puede ser dueño de la tierra, pero no del Agua, lo que ha permitido un comercio de del recurso. Bolados et al (2017), indica que fue Chile uno de los primeros países en crear un Mercado entorno el agua, legitimando los usos productivos y energéticos, por medio de la separación de las Aguas Consuntivas y no consuntivas.

Cite this Article as: Leticia CAMPOS, Daniel ALVARADO, Andrés PARDO, Jorge ROJAS and Sergio Varas "Mapa de conflictos de Derechos de Agua Por Intervención minera en la Zona Norte de Chile" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

La Corporación Nacional Forestal (CONAF, 2017), informa que el 72% de la superficie del país ha sufrido sequía, provocada por el cambio climático, lo que ha hecho que exista un 15% menos de lluvia en los últimos 50 años, además de no contar con una robusta infraestructura hídrica, todo esto asociado a la condición mercantil del agua, donde la misma es privatizada, ha repercutido para que proliferen los conflictos por el uso, acceso y contaminación de las aguas, entre varios de los sectores productivos y las comunidades del país. Muchas de la problemáticas que se han producido son por la intervención de la Industria Minera, segunda actividad productiva que más aporta al país (13% del PIB nacional) y que atrae mayor inversión extranjera.

Esta industria utiliza una gran cantidad de agua en sus procesos y a pesar que según la Dirección General de Aguas (DGA), sólo ocupa el 3% del agua a nivel nacional, "contaminación, usurpación y envenenamiento del agua", son argumentos que se escuchan día a día en el país, por ser un sector altamente contaminante, según lo indica Valderrama et al (2019). La Sociedad Nacional de Minería, SONAMI (2013), establece que aún cuando el agua tiene un alto grado de reutilización en las operaciones mineras, no se puede volver a utilizar para el consumo humano, de la vida animal y vegetal, por lo que se acrecientan las expectativas negativas sobre los Proyectos Mineros que se quieren establecer en algún territorio.

La minería se ha planteado desafíos en relación al uso del agua, primero, asegurar la suficiente agua para satisfacer la producción, segundo, reducir el consumo de agua utilizada en los procesos mineros, y por último la comprensión de los vínculos entre el agua, energía y emisiones en una mirada integral.

La sustentabilidad del negocio minero, cuenta como factores críticos, como el uso de la energía, el territorio y el agua, siendo este último el polo de estudio de este trabajo, por lo que surgen las preguntas: ¿Es realmente la industria minera la que genera mayores conflictos con el agua en Chile?, ¿Cuál es la distribución territorial de los conflictos de aguas en el país?; ¿Cuáles son los conflictos entre Empresas Mineras y Comunidades en temas de conflictos de Agua?

Para afirmar que: "Los conflictos por el uso, acceso, aprovechamiento y contaminación del agua en Chile, se producen por la industria minera, asentada en la zona norte de Chile", surge la necesidad de crear un Sistema de Información Geográfico, que permita demostrar esta situación, para que las comunidades puedan visualizar lo que ocurre en sus territorios.

Materiales y Métodos

En primera instancia se realizó un estudio bibliográfico de la Constitución de 1980, el Código de Aguas de 1981 y el Código de Minería de 1983, para encontrar relaciones entre ellos, de esta forma poder analizar los conflictos desprendidos entre Comunidad y Minería.

En segunda instancia, se segmentó el territorio chileno en tres sectores principalmente asociados por la división política-administrativa de las regiones del país, su geografía, el clima y el índice de precipitaciones anuales.

En tercera instancia se realizó un levantamiento de todos los conflictos socio-ambientales que se han producido en Chile, durante los últimos 30 años, utilizando información del Instituto Nacional de Derechos Humanos (INDH), la Coordinadora de la Defensa de Agua y la Vida CDAyV y el Observatorio Latinoamericano de Conflictos Ambientales (OLCA).

En cuarta instancia, se construyó una base de datos con todos conflictos socio-ambientales, donde se seleccionaron solo los que tenían referencia a los conflictos de agua, distinguiendo los que tenían directa relación con el Área Minera, lo que a su vez permitió determinar su ubicación geográfica en el territorio.

En quinta instancia, se realizó el geo-procesamiento para la creación del mapa, con apoyo de un software GIS, para su posterior análisis espacial, utilizando los insumos obtenidos en las dos instancias anteriores, los cuales fueron integrados en un SIG representando cada conflicto ambiental como un objeto geográfico. Se utilizaron además imágenes satelitales del territorio, coberturas como los límites políticos administrativos, asentamientos humanos, aéreas climáticas, morfología del territorio y coordenadas Universal Transversal de Mercator (UTM) de los puntos en conflicto.

Figura1: Creación del SIG

Resultados

Constitución, Código de Aguas y Código de Minería

La Constitución Política de 1980, en su capítulo III: "De los derechos y deberes constitucionales", establece consideraciones para dos recursos naturales: El Agua y las Minas, con el fin de proteger el Derecho de la Propiedad Privada, este hecho tiene más una fundamentación más histórica, que jurídica, la nacionalización de la gran minería del cobre y la reforma agraria (Alburneque, 2001).

Estos dos Códigos, fueron promulgados bajo el Gobierno Cívico-Militar, el Código de Aguas en 1981, mientras que el Código de Minería 1983. En el primero separa la propiedad del agua del dominio de la tierra, pudiendo entregar el Estado los derechos de aprovechamiento de agua a privados de forma gratuita y a perpetuidad y en el segundo se establecen las consideraciones de la propiedad del estado sobre todas las tierras y yacimientos, además detalla los mecanismos para su concesión y explotación a privados. En la Tabla 1, se pueden apreciar todos los artículos que se vinculan entre el Código de Minería y el Código de Aguas en Chile, con una columna de síntesis, para saber de qué trata cada uno:

Tabla 1: Síntesis de artículos relacionados entre el Código de Minería y Aguas.

CÓDIGO	N°	SÍNTESIS		CÓDIGO	N°	SÍNTESIS
MINERÍA	3	Construcciones inmuebles		AGUAS	1	División de aguas
	17	Permisos especiales			4	Aguas inmuebles
	110	Aprovechamiento de aguas			5	Aguas bien nacional
	111	Aguas fuera de concesión			6	Derecho de aprovechamiento
	120	Gravámenes superficiales			7	Medida del aprovechamiento
					13	Derecho consuntivo
					14	Derecho no consuntivo
					16	Ejercicio permanente
					17	Dotación permanente
					18	Ejercicio eventual
					19	Ejercicio continuo
					27	Población

					41	Disposiciones especiales
					56	Pozos
					58	Aguas subterráneas
					62	Perjuicios
					122	Dirección General de Aguas
					132	Oposición
					147	Constitución del derecho
					173	Multas

Haciendo revisión de los dos textos legislativos, se encontraron las siguientes relaciones entre el Código de Minería y el Código de Aguas, en cuanto al uso de las aguas, se estipula en el primero, que el uso de las aguas que sean necesarias para explorar, explotar o beneficiar sustancias minerales se sujetará a las disposiciones del código de aguas y demás leyes aplicables (Artículo 111), específicamente en el artículo 110, se indica que el titular de la concesión minera tiene el *derecho de aprovechamiento de las aguas* halladas en las labores de su concesión, en la medida que tales aguas sean necesarias para los trabajos de exploración, de explotación y de beneficio que pueda realizar, siendo estos derechos inseparables de la concesión minera y que se extinguirán con ésta, esto mismo se establece en el Código de Aguas en su artículo 56. Con respecto a las construcciones que se pueden realizar dentro de los límites de la Concesión Minera, en el artículo 120 queda estipulado que se pueden construir tranques, canales, cañerías y demás construcciones, y que estos a su vez se considerarán bienes inmuebles (Artículo 3).

Por otra parte el Código de Aguas establece que su legislación sólo es para las aguas terrestres (artículo n°1), las que pueden ser superficiales o subterráneas (Artículo n°2), y que no rige a las aguas marítimas, una consideración de importancia, ya que *el uso de las aguas marítimas para la minería no está restringida por ninguna ley.* Para este código las aguas son muebles, esto quiere decir que pueden ser movidas, para ser destinadas al uso, cultivo o beneficio de un inmueble. El derecho de aprovechamiento es de dominio de su titular, quien podrá usar, gozar y disponer de él, pero en conformidad con la ley, este derecho se expresa en volumen por unidad de tiempo (m^3/seg) y además el que goce de este derecho puede hacer las obras necesarias para poder hacer uso de las aguas.

Sobre las disposiciones que entrega el Código de Agua, sobre la expropiación del derecho de aprovechamiento de aguas, cuando sea imprescindible ocupar estas aguas para satisfacer los menesteres domésticos (Articulo 27), la reserva del recurso para el establecimiento de la población, por no existir otros medios para obtener agua, recaen en que el presidente de la república podrá, mediante decreto fundado, con informe de la Dirección General de Aguas (DGA), disponer la negación parcial de una petición de derecho de aprovechamiento (Articulo 144). Finalmente en el artículo 173 se señala que toda contravención a este código que no esté especialmente sancionada, será penada con una multa de veinte unidades tributarias mensuales, además de otras responsabilidades civiles y penales.

Macrozonas de Chile

Chile, se divide política y administrativamente, según la Constitución de 1980 de forma descentralizada, en 16 regiones, 56 provincias y 346 comunas (INE, 2020). La Corporación del Fomento de la Producción (CORFO), a su vez divide al país con respecto a su Geografía Económica desde 1951 en 5 zonas naturales, el Norte Grande, el Norte Chico, Zona Central, la Zona Sur y la Zona Austral. Para fines de este estudio se reclasificó el país sólo en tres “Macrozonas”, según la naturaleza de las precipitaciones, clima asociado y actividad productiva principal, tal como se ve en la tabla 2:

Tabla 2: Reclasificación de Macrozonas

MACROZONA	REGIÓN	PRECIPITACIONES (mm/año)	CLIMA	ACTIVIDAD ECONÓMICA
Norte	Arica y Parinacota	87	Desértico- Semidesértico	Minería
	Tarapacá			
	Antofagasta			
	Atacama			
	Coquimbo			
Centro	Valparaíso	943	Mediterráneo	Agricultura y forestal
	Metropolitana			
	O´Higgins			
	Maule			
	Biobío			
Sur	La Araucanía	2690	Templado lluvioso, estepárico frío y polar	Forestal y ganadería.
	Los Ríos			
	Los Lagos			
	Aysén			
	Magallanes y La Antártica Chilena			

Chile cuenta con alrededor de más de 15 mil lagunas y lagos, 1.251 ríos a esto se le debe sumar el agua proveniente de las lluvias, lo que conlleva que cada persona en el país podrá hacer uso 53 mil m³ al año del recurso hídrico. Esto no es aplicable en todo el país, debido a diversos factores como aumento en la población, cambios climáticos, desarrollo económico y social, lo que ha terminado generando escasez hídrica en zonas o regiones específicas. A lo anterior se suma la heterogeneidad de las zonas geográficas que posee Chile, mientras que en el sur los caudales tienen un promedio de 100 mil m³ por persona al año, en la zona centro-norte alcanza sólo a 800 m³ por persona al año, lo que se encuentra bajo el promedio mundial que es de 1.000 m^3 por persona al año.

Chile tiene un déficit de agua de 82,6 m^3/s, y se piensa que aumentará a 149 m^3/s ya para el año 2030. La demanda de agua que requiere la industria minera llega a 24.95 m³/s, asociados a los Derechos de Agua que en comparación a la oferta hídrica la demanda es muy reducida según las cuencas hidrográficas donde estas actividades son realizadas. Para disminuir el uso de agua proveniente de ríos y cuencas de agua dulce, las industrias mineras comenzaron la implementación el uso de agua de mar mediante plantas desaladoras las cuales equivalen a un 15% aproximadamente de las aguas utilizadas en la industria minera.

Levantamiento de Conflictos

Al hacer el levantamiento de todos los conflictos socio-ambientales en Chile, se encontraron 118 casos, con esta información se creó una base datos dividida en 4 grandes elementos (ítems), sobre el Territorio, la Industria asociada al conflicto, los términos legales y sociales en que se encuentra el conflicto y por último el conflicto como tal.

Tabla 2: Estructura Base de Datos

- *Conflictos por el Agua*

Los Conflictos estaban ubicados de la siguiente forma con respecto a la división político administrativa del país 2 Conflictos a Nivel Nacional, 2 Conflictos Interregionales y 110 Conflictos Regionales. De estos 118 conflictos socio-ambientales, existían 36 conflictos por uso y/o contaminación del agua lo que representa 30,5 % del total nacional lo que se aprecia en la tabla 3:

Tabla 3: Conflictos geo-referenciados

N°	Nombre del Conflicto	Norte	Este

- ***Sector Productivo y conflictos de aguas***

Gráfico 1: Sectores productivos involucrados en Conflictos con temas de Agua

En este gráfico se puede apreciar que el 69,4% (25 casos) de los casos de conflictos por el agua en Chile se generan por intervención minera, seguido de la industria energética con un 16,7% y en tercer lugar la industria de la infraestructura con un 5,6%.

Analizando la situación por región, se detectaron 11 regiones afectadas por conflictos de agua, de las 5 primeras, 4 estaban ubicadas en la macrozona norte.

Tabla 4: Ranking de conflictos por región

Ranking	Región del conflicto	Cantidad	Porcentaje (%)	Macrozona
1°	Atacama	8	22.22	Norte
2°	Arica y Parinacota	7	19.44	Norte
3°	Coquimbo	7	19.44	Norte
4°	Araucanía	3	8.33	Sur
5°	Antofagasta	2	5.56	Norte

- ***División de los conflictos de agua por macrozona***

Gráfico 2: Macrozona de conflictos de agua

Conflictos de agua por actividad minera

Como este estudio se enmarca en el impacto que la minería tiene sobre el recurso hídrico, se trabajará con los 25 casos de esta área detectados a lo largo del país. Se estudiaron las causas, si existe afectación de tierras indígenas, en qué etapa se encuentran en el Servicio de Evaluación de Impacto Ambiental y en qué estado está el conflicto (latente, activo o cerrado).

- ***Causas del conflicto por actividad minera***

Tras el análisis se encontraron diversas causas del conflicto tales como; Extracción y desvío de aguas, Sobreexplotación de los recursos hídricos, Explotación de los recursos hídricos de reservas, Perforaciones que afectan a la flora y fauna, Disminución y contaminación de aguas, Extracción del recurso hídrico destinado a las comunidades, Contaminación de napas subterráneas, entre otros. Los cuales fueron agrupados en “macrocausas”; extracción, contaminación y residuos.

- Extracción: Extracción de aguas en lugares de exploración geológica o explotación de minas.
- Contaminación: Contaminación confirmada de recurso hídrico.
- Residuos: Probable contaminación por residuos, emisiones e inmisiones.

Tabla 5: Macrocausas que han producido conflictos de Agua.

Macrocausas	Cantidad de conflictos	Porcentaje (%)
Extracción	17	68
Contaminación	4	16
Residuos	4	16
Total	**25**	**100**

- ***Tipo de Empresa Involucrada en el conflicto de Agua***

Las empresas privadas involucradas en conflictos de Agua equivalen al 84,5% , mayormente de capitales extranjeros.

- ***Tierras Indígenas comprometidas***

Un dato relevante fue determinar que a nivel nacional el 55,6% de los conflictos, se generaron entre comunidades indígenas y la industria minera.

- ***Servicio de Evaluación de Impacto Ambiental***

El 84% de los proyectos mineros en conflicto (21) se habían sometido al Servicio de Evaluación de Impacto Ambiental (SEIA), 17 de ellos mediante un Estudio de Impacto Ambiental (EIA) y 4 con una Declaración de Impacto Ambiental (DIA). De los EIA, 14 estaban en calidad de aprobados y 3 en calificación, en cuanto a DIA, 3 estaban aprobados y 1 en calidad de "desistido", este último buscaba emplazarse en el río Colico Región de la Araucanía.

- ***Estado del conflicto***

El INDH realizó una clasificación de los estados de los conflictos socio-ambientales que ocurren en Chile según su repercusión mediática, lo que también puede ser aplicado a los conflictos de uso de agua.

- Activo: Manifestación del conflicto en la esfera pública mediante protestas, acciones judiciales o peticiones que hayan tenido repercusión en los medios de comunicación durante el último año.
- Latente: el conflicto sigue vigente pero no registra apariciones públicas.
- Cerrado: existe un acuerdo entre las partes o una resolución institucional que pone término al conflicto.

Del estudio se determinó que un 60% de los conflictos estaban activos (15), 36% en calidad de latentes (9) y solo el 4% que representa a 1 conflicto, estaba cerrado tras un acuerdo entre las partes.

Macrozona Norte lidera conflictos por uso de agua

El análisis arrojó que el 92% de los conflictos (23) se dieron en las 5 regiones que componen la macrozona norte y el 8% en 2 regiones de la macrozona sur, no evidenciándose ningún conflicto en la zona central, se puede apreciar estos resultados en la Figura 2: Mapa de Conflictos de Agua, por intervención minera e Chile.

Figura 2: Mapa de conflictos de agua

Discusión

En Chile existe un sinnúmero de eventos que causan daño al medio ambiente, tanto a nivel civil como a nivel industrial, una de las aristas más preocupantes tanto para el gobierno de Chile como para su población, es el daño que se produce día a día con el agua. La contaminación, el mal uso, y la sobreexplotación de este recurso vital se puede encontrar a lo largo de todo el territorio nacional, sin embargo, es en la macrozona norte donde se encuentran las principales y la mayor cantidad de problemáticas detectadas, específicamente por la minería.

En Chile existe un déficit hídrico de un 82,6 m^3/seg, donde sólo 4 fuentes de agua (ríos y cuencas) de la macrozona norte aportan 10 m^3/seg, el resto está bajo dicho valor alcanzando un máximo de 1 m^3/seg. La minería en tanto, demanda 24,95 m^3/seg, hay empresas que en la búsqueda de la reutilización y mejor aprovechamiento del agua, están incorporando agua desalada en sus procesos, tanto para alcanzar los indicadores de producción requeridos en el tratamiento del mineral, como por los conflictos generados con las comunidades circundantes debido a la extracción y contaminación del agua dulce.

El código de aguas actual que rige en Chile es un documento muy completo y claro que establece parámetros para el uso de agua dulce superficial y subterránea, pero no contempla normas ni restricciones para el uso de agua de mar, lo que pudiera con llevar a posibles nuevos tipos de conflictos con la comunidad, por lo que es necesario fortalecer el marco legal, institucional y regulatorio para el uso del agua de mar desde todos los puntos de vista que éste conlleva.

En la zona norte del país los conflictos de aguas se agudizan debido a la escasez de agua por su geografía (zonas áridas), lo que ha causado sobre-explotación de las cuencas, generando un clima de tensión entre las comunidades locales con las empresas mineras.

No sólo las empresas mineras presentan interés en desarrollar el sistema de Plantas desalinizadoras para mitigar la escasez hídrica que afecta al país, también el gobierno apoya esta iniciativa que representa una inversión millonaria, pero que a largo plazo sería una vía sustentable en la lucha contra la sequía en la zona norte.

Según el Observatorio Latinoamericano de Conflictos Ambientales (OLCA), las empresas trasnacionales tienden a aprovecharse de los débiles marcos regulatorios de países subdesarrollados, con proyectos que carecen de toda lógica ambiental.

La mayor de conflictos por derechos de agua se reflejen en esta zona de Chile, por el momento, ya que según todas las proyecciones del Consejo Minero, prontamente la minería se trasladará con todo su potencial a la zona sur del país, determinado por la gran cantidad de reservas de oro que han arrojado las campañas de exploración geológica de grandes trasnacionales y la cantidad de yacimientos polimetálicos allí presentes, por ende este % puede cambiar. Lo anterior en relación que en las regiones del sur se encuentran grandes depósitos de agua dulce, como ríos y lagos, lo que incrementará los problemas del uso del agua ligado a la biodiversidad presentes en esta zona.

Los mapas siempre ayudan a tener una visión por lo menos general, de los fenómenos que ocurren en un territorio; por lo cual este Sistema Información Geográfica, que particulariza los Conflictos de Aguas, por intervención minera, permite evidenciar la crisis producida por el extractivismo, presente no sólo en Chile, sino que en toda Latinoamérica y que afecta a muchas comunidades indígenas.

Reconocimiento

Agradecer a Sergio Varas y Jorge Rojas, quienes a través de su Tesis de grado, la que estaba enfocada en la importancia de la utilización de un Sistema de Información Geográfica en un caso de Estudio sobre Comunidad, Minería y Agua, obtuvieron los datos para esta investigación. De la misma forma agradecer a Nathaly Campos Olivares, quien fue la revisora del presente artículo, aportando a la difusión de la ciencia.

Impact of Technological Innovation on United Kingdom Labor Market

Piotr WIŚNIEWSKI

Nicolaus Copernicus University, Toruń, Poland
psw@umk.pl

Abstract

Idea of Industry 4.0 is presented as a next step in our development. The age of intelligent machines and full automation. This process will have an impact on economic development, but also on structure of labor market. Industry sectors are the most exposed to changes brought by Industry 4.0. The mainstream publications like Forbes tries to predict jobs that will be obsolete due to automation. (Expert Panel, Forbes Technology Council, 2019). Among them are warehouse and manufacturing jobs, production line etc. The purpose of this research is to analyze relation between employment in industry and services and technological progress in United Kingdom. Additionally, there will be presented context of wider economic growth by using GDP per capita as measure of it. All datasets are from World Bank database. Vector Aurogression was chosen as the method. Gretl software was used to perform the study.

Keywords: Industry 4.0, Economic Development, Industry Employment, Econometrics.

Introduction

Most of the current literature about impact of technological innovation on a society sees this process as something exclusively positive. The optimistic view sees the fourth industrial revolution as an opportunity for new types of occupations and industries to emerge, as well as chance to improving living standards. However, everything has assorted effects – not only positive ones for everything and everyone. Innovations had impacted employment in some sectors of economy in less positive manner. For industry workers automation means higher probability of losing their jobs. Also, robots can be viewed as substitutes for unskilled labor. The economic consensus is: the change is negative in short term for unskilled labor in industry, but has positive impact on welfare of whole society outweighs. A few factors were included in research as variables to determine how much they affect the declining demand for labor in industry. This narrower focus may help to understand how to act on behalf of unskilled workers. Even if the transition in country's economy is inevitable, it may be carried out in many different ways. The first step on the path to make this process as painless as possible is for workers to better understand it.

Technology, Society and Economy

Technology is not only determined by society, but also is able to influence social changes. These two are closely connected and coexistent. Social computing is the best example of the complexity of the relation between these factors.

Fig. 1: Relationship between technology and society

Source: Vannoy and Palvia, 2010

Vannoy and Palvia (2010, p. 150) presents concept of the co-determinization of technology and society. The idea is that societal change creates demand for new technologies and shapes the way for technology develops, but also technology has influenced how the society functions. The most prominent example is cybercrime. It is relatively new entity that was created as a result of new information technologies. Boehlke and Wiśniewski (2016, p. 60) have presented individual and institutional aspects that made cybercrime as profitable and widespread as it is. That includes increasing data value, different approach to ownership on the Internet and popularization of online banking.

The fourth industrial revolution has even more severe consequences for all aspects of life. Burgess and Connell (2020) quotes Schwab to highlight the ability of new technologies to change "…production, consumption, employment, industry structure and living standards." Past experiences with industrial revolutions from steam power to information technology always resulted in improvements on all these fields. New industries replace old ones and new types of jobs are created when others are becoming obsolete. Many low-skilled workers in industry are losing their jobs because of this process.

There is also some distrust to technological impact on economy. Both Keynes as well as Lentief have predicted that labor will become less and less important (Acemoglu and Resrepo, 2019). Previous industrial revolutions does not resulted in such scenario. Robotization has renewed these concerns for workers in both developing as well as developed countries. For developed countries it means that their work will become substituted with robots. In developing countries, on the other hand, there is danger of reshore. That means that developed countries will produce goods domestically using machines. In theory this should bring back to developed countries some of the jobs what was offshored before. In reality this means that unskilled workers will be exchanged for machines that will be operated by highly-skilled employees. In these terms the technological innovation will cost jobs, both in developed as well as developing countries. Robots have potential to fuel reshoring (Faber, 2020).

Industry 4.0 is defined by things it influences, that include changes in traditional models of production, trade and integration, as well as change in dynamics and configuration of work (Beliz et al., 2019). In theory, it should results in self-optimization and self-development. Computers would not be operated but communicated with. This deeply suggesting that changes will be most severe in industry sectors. Rifkin (2015) has hoped that positive results will include almost zero transactional costs, increased productivity and reorganization of society.

This opinions may be disputed, but in the end, it does not matter for currently employed in industry. What seems to matter is how this new structure of the market impacts their jobs and life. In the macroeconomic scale technological progress is definitely welcomed and positive. On the individual level this is not as easy to state. Did employee of industry sectors have a reason to be afraid of being replaced by machines?

Fig. 2: Employment in Industry between 1991 and 2018 in United kingdom.

Source: World Bank

Figure 2. has presented the employment in industry, which has been constantly decreasing since 1991. Du and Wei (2020) have presented two stands of research. The first one considers the aggregate impact of technological change on employment. The second one examines the impact of technological change on the skills and employment structure (Burgess and Connell, 2020). This research focuses on aggregate impact of this change.

Vector Autoregression Model

Figure 2. has presented the employment in industry, which has been constantly decreasing since 1991. Of course, raw data is not enough to draw any conclusions. This is the reason why in this article Vector Autoregression model will be use.

Vector Autoregression model (VAR) are based on these rules (Osińska, 2007 p.367):

- there is no a priory difference between endogenous and exogenous variables,
- there are no limitation as to variables value, including assumption that some variables are equal to 0,
- there is no prior economic theory that model is built on.

Basic model VAR:

$$Z_t = \sum_{i=t}^{q} A_i Z_{t-i} + \varepsilon_i$$

Where:
Z_t- vector of current values of variables Nx1
A_i-matrix of autoregressive operators of processes.
ε_i- vector of errors.
In the presented model, four variables were chosen. Patent applications are named in model simply as 'Patents'. Employment in industry (% of total employment) (modeled ILO estimate) is presented in model as 'Industry'. GDP per capita, PPP (current international $) is named 'GDPpc'. Employment in services (% of total employment) (modeled ILO estimate) is presented simply as 'Services'. World Bank data was used in model.
The first phase of building VAR model is to choose a lag.

In the VAR system, the maximum lag order is 3.

The asterisks below indicate the best (that is, minimized) values of the respective information criteria, AIC = Akaike criterion, BIC = Schwarz Bayesian criterion and HQC = Hannan-Quinn criterion.

Table 1: Choosing time lag based on information criteria

Lags	loglik	p(LR)	AIC	BIC	HQC
1	-363.01120		30.640896	31.615996*	30.911347
2	-343.03268	0.00079	30.322614*	32.077795	30.809427*
3	-334.21528	0.34571	30.897222	33.432484	31.600396

In this case I have chosen the lag based on Schwarz Bayesian criterion.

VAR system, lag order 1. OLS estimates, observations 1992-2018 (T = 27). Log-likelihood = -392.73908

Determinant of covariance matrix = 50641173. AIC = 30.5733, BIC = 31.5331, HQC = 30.8587 Portmanteau test: LB(6) = 105.638, df = 80 [0.0290]

Table 2: Patents applications ('Patents'), first equation

- Standard Deviation of dependent var= 4.116128
- Standard error of regression= 0.393875
- Adjusted R-squared= 0.990843

Autocorrelation of random process does not occur. There is no reason to reject null hypothesis of ARCH effect test at significance level of 5%. Result of Doornik-Hansen test is Chi-square(8) = 15.1726 [0.0559]. There is no reason to reject null hypothesis of this test at significance level of 5%. Presented model is good quality: there is no ARCH effect, residuals are normally distributed and there is no autocorrelation.

Fig. 3: VAR inverse roots in relation to the unit circle

VAR inverse roots are lower than 1. This means that process is stationary.

Fig. 4: Combined graph of impulse response

One standard deviation shot to employment in industry causes at first significant decrease in patent applications in the first 2 periods, but then it causes a significant increase that, in presented timeframe, not dissipates.

One standard deviation shot to GDP per capita causes at first significant decrease in patent applications that not dissipates in presented timeframe.

One standard deviation shot to employment in services causes at first significant increase in patent applications in the first 6 periods after which the effect dissipates.

One standard deviation shot to patent applications causes significant decrease in employment in industry in next 4 periods. After that, effect seems to start to dissipate.

One standard deviation shot to patent applications causes significant decrease in employment in industry in next 4 periods. After that, effect seems starting to dissipate

One standard deviation shot to employment in services causes at first significant decrease in employment in industry in the first period, after which the effect dissipates.

One standard deviation shot to patent applications causes significant increase in GDP per capita. Effect does not dissipate in presented timeframe.

One standard deviation shot to employment in industry causes at first significant increase in GDP per capita, but after first period it causes permanent decrease.

One standard deviation shot to employment in services causes at first significant decrease in GDP per capita in the first period, after which it has permanently increased.

One standard deviation shot to patent applications causes a significant, permanent increase in employment in services.

One standard deviation shot to employment in industry causes a significant decrease to employment in services. Effect is not dissipated in presented timeframe.

One standard deviation shot to employment in industry causes a significant decrease to employment in services in the first period, after which it causes permanent increase.

Number of patents applications, GDP per capita and employment in services have negative influence on employment in industry. At the same time, employment in industry has positive influence on number of patent applications and does not have permanent effect on employment in services. It has negative influence on GDP per capita. Why is that? It is easy to imagine that the more developed economy of United Kingdom is, the more processes are automated. More efficient industry sectors have more resources for research and development which results in more processes being automated. This explains both positive impact to number of patents applications as well as negative feedback in reverse. Increasing number of employees, for example, in a factory, it creates strong incentive to create technology; to cut cost and automate processes. The negative impact of employment in industry on GDP per capita may be explained by changing structure of developed countries. Industry is most prominent in developing part of the world. Developed countries are usually driven by high-technology and services.

This research confirms conclusions of Acemoglu and Restrepo (2020) work. In their research, they have found that one new robot reduces employment by six workers in United States. They also quoted Graetz and Michaels (2018) research that has stated that "… industrial robots increase productivity and wages, but reduce the employment of low-skill workers."

Conclusion

The problematic nature of employment in industry in relation to automation requires complex analysis and explanation. It is true that automation and Industry 4.0 will surely be the reason for further decrease in employment in industry. This process seems to be inevitable. People are more expensive than machines. Besides that, work in industry is usually not as safe as in other branches of economy. Trying to save jobs in industry would mean that welfare of whole country would be decreased (as presented industry has negative impact on GDP per capita). What to do with people who inevitably lose their jobs? This is beyond this research. True is that all developing and developed countries will face this problem. All of them need to find their own way to deal with it. Trying to forcefully keep employment in industry seems to be one of the worst solution for the economic system of the country as a whole.

Future Directions of Research

This research presents aggregated look on technological impact on employment in industry. Some aspects of reshoring were presented by not empirically confirmed. Next step of research should be either focused on reshoring and challenges for labor in developing countries or focusing on options for unskilled workers after fourth industrial revolution. Both options have their own set of challenges and difficulties. In terms of reshore, there is a question about scale of this process. How many industries can be automated and move back to developed countries? As well as how fast this will be possible? If only fraction of industries may be fully automated, then problem of reshore is less severe and developing countries will need to simply refocus on different industries. In case of automation in almost all types of industries, economies of whole countries may collapse. On the other hand, problem with unskilled workers after fourth industrial revolution is that it did not happened yet, or at least it is in early stage. Almost all aspects of fourth industrial revolution are speculative and it is hard to predict how they influence other aspects of economy. Both these research paths are viable and worth exploring.

Abstract

The production of organic crop products is a profitable direction for the development of agriculture in Russia. Most of the agricultural land in Russia is not contaminated with chemicals. Many vast territories are located in ecologically clean areas. Reasons that hinder the development of organic agriculture are the following: lack of targeted governmental financial support, farmers' lack of awareness about the difference between certified organic products and non-certified products et cetera. The authors of the article analyzed data from the National Organic Union of Russia, FiBL, IFOAM on the level of development of organic production in Russia and other countries. A more detailed analysis was carried out according to the Rosstat data in the context of the regions of the South Ural. Taking the present conditions of the Orenburg region and utilizing an optimization model, the authors substantiated the structure of production costs and assessed the economic efficiency of the production of winter and spring wheat with the usage of the traditional technology and of the methods associated with organic technology.

Keywords: Organic Products, Crop Production, Assessment, Economic Efficiency.

Introduction

The global market of organic products is currently in a state of dynamic development. The criteria for the identification of organic products were, for the first time, formulated internationally in 2006: «Organic food is to be processed by biological, mechanical and physical methods in a way that maintains the vital quality of each ingredient, the finished product, and nutritional value…» (Glossary on organic Agriculture 2009). During the period from 2000 to 2018, the global market of organic products grew from about 18 billion euros to about 97 billion euros. According to expert calculations, the market volume may reach $ 212-230 billion by 2025, which equals to about 3-5% of the global agricultural market (FiBL & IFOAM 2020). Organic products have to be certified, just like the farms (plots of lands) where such organic products are produced. As of the end of 2018, about 72 million hectares were certified globally, which, however, means, that in the world as a whole, no more than 1 per cent of land has been certified. As expected, the scale of the development of organic agriculture is different in different countries. For example, while more than 10% of agricultural land is certified in the EU, only about 0,1% of such land is certified in Russia. The statistics show that in the period from 2017 to 2019, the market of organic products grew by 8 to 10 per cent every year. At the beginning of the century, all of Russia's organic products were imported. By 2019, however, as much as 20% of all organic products sold on the Russian domestic market were produced in Russia (Organic market in Russia in 2020).

According to the Organic Union of Russia, 23% of organic products on the market produced in Russian consist of cereals, grain, bakery products (Fig. 1). A significant part of these products is intended for export. Particularly speaking, more than 60 thousand hectares of arable land have been certified in Russia for growing grain, oilseeds and, forage crops for export. The main exported crops are wheat, barley, oats, buckwheat, flax, peas, rapeseed, rye, triticale, soybeans, and broad beans. These products are currently sent to the countries of Western and Eastern Europe (Organic market in Russia in 2020).

SIUSIURA "Economic Assessment of The Efficiency of Organic Crop Production in The South Ural's Regions in Russia" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Fig. 1: The structure of Russia's organic producers by product type

Source: Organic market in Russia in 2020, National Organic Union of Russia [Online], [Retrieved August 20, 2020], http://rosorganic.ru/files/Analiz%20organic%20RF%202020%20г.pdf.

The development of organic production is hindered by the lack of state investment. Russian farmers are in a situation where they have to take all the risks associated with the production of organic products and rely only on their own resources. Practically speaking, there are only private investments in this area of agriculture. At the same time, a significant number of farmers who produce organic products in the EU receive direct and indirect governmental support. For example, the year 2020 is marked by a plan to allocate 200.9 million euros exclusively for the purpose of promoting European organic products to enter the markets (Organic farming). To be completely fair, it is necessary to note that the European approach is not based on market mechanisms, and the mechanism of organic farming promotion is based upon the top-down structures which don't always benefit local farmers. At the same time, organic production in a number of countries is exclusively export-oriented. (Stoeva S. 2016). Russian farmers are mostly focused specifically on organizing the production of environmentally friendly products to meet the domestic demand in large cities and of the international market. According to scientists, the introduction of innovative technologies related to environmental protection and resource conservation will be a deciding factor that will increase the public interest in the production and consumption of organic products (Ermilova M., Maksimova T. ets. 2019).

Reviewing the legal situation in this field in Russia, we can see that in 2018, a new law was published which came into force on the 1st January of 2020, named Federal Law N280-FZ "On organic products and on amendments to certain legislative acts of the Russian Federation" (Федеральный закон N280-ФЗ «Об органической продукции и о внесении изменений в отдельные законодательные акты Российской Федерации»). We should also note that state standards which determine the procedure for the production of organic products in Russia and the countries of the Eurasian Economic Union (a straightforward example would be GOST 33980-2016) came into force even earlier. It is also important to add that the year 2019 was marked by the state approval of the symbols of organic products and of the regulated procedure for their certification. The public interest on the part of agricultural producers is growing in this direction, although the mass introduction of this technology into practice has not yet been observed in the Russian Federation. In some of Russia's regions, such as the Republic of Bashkortostan, the Republic of Tatarstan, Belgorod Oblast, Voronezh Oblast, Kaluga Oblast, Tomsk Oblast, Yaroslavl Oblast, and the Krasnodar Krai the production of organic products is present the most. In the next paragraphs, we will assess the conditions and the efficiency of organic crop farming in the regions of the South Ural.

Research Design and Methodology

The authors analyzed the state of grain production in three key regions of the Southern Ural for the period from 2016 to 2018, utilizing the data provided by Rosstat. The calculations for the Orenburg region were carried out in the most detailed manner. The aim of the study is to substantiate the structure of production costs for winter and spring wheat according to

two options (traditional technology, organic technology) and to assess the economic efficiency of wheat production without the use of mineral fertilizers and chemical plant protection products in the Orenburg region. Research methods used consisted of optimization modeling and of the structure analysis method, as well as the method of time series analysis.

Results

Three regions of Russia are located in the South Ural: the Republic of Bashkortostan, the Orenburg Oblast, and the Chelyabinsk oblast. These regions share a similar economic structure. Agricultural production, and, in particular, the production of grain, plays a significant role in the regional economy. 11% of all sown areas in Russia are concentrated in these regions. Also, the Orenburg oblast is in third place in the country in terms of sown area (after the Altai Krai and the Rostov Oblast). 4246.2 thousand hectares in the Orenburg region were covered crops in the year 2018. (see Table 1).

Table 1: The main indicators of the production of grain and leguminous crops in the regions of the South Ural (in farms of all categories)

Indicators	Republic of Bashkortostan			Orenburg region			Chelyabinsk region		
	2016	2017	2018	2016	2017	2018	2016	2017	2018
The sown area of all crops, thousand ha	3069.3	3004.1	2952.8	4218.1	4225.2	4246.2	1858.6	1895.2	1918.0
Share of the area under grain, % of the total sown area	59.0	59.4	59.3	64.5	63.7	63.7	72.8	74.2	72.6
Weight of the gross harvest of grain after processing, thousand tons	3324.0	3782.7	3058.9	3138.6	4207.2	2033.6	1947.7	2307.3	1850.3

Source: Agriculture of Russia. 2019: Statistical Yearbook. / Rosstat. Moscow. 91 p. [Online], [Retrieved August 20, 2020], https://rosstat.gov.ru/folder/210/document/13226.

The structure of agricultural crops is dominated by cereals, of which wheat (winter and spring) are the most prominent ones. The climate in the regions leads to fluctuations in yields and gross grain harvests over time. 2017 was very favorable in terms of weather conditions, which made it possible to obtain a large grain harvest (4207.2 thousand tons, in the Orenburg region, with an average yield of 15.8 centners per hectare). One of the requirements for the production of organic products is the minimal use of mineral fertilizers and pesticides. For many years, only very small amounts of mineral fertilizers have been applied in the Orenburg region. The share of crops with mineral fertilizers applied in this region was only about 9.4% in 2018 (while in Russia as a whole it was about 61.1%). More than half of the farmland in

Russia is not treated with pesticides. In the Orenburg region, no more than 0.3 kg of pesticides are applied per hectare of crops. The noted circumstances make it possible to shorten the transition period and to begin certification of fields for organic matter in the shortest terms possible. Orenburg region has very favorable conditions for the production of organic products since the region has a large territory and the level of pollution of arable land with chemicals is low. Let us now consider the prospects for the development of organic crop production in the Orenburg region in more detail.

The Orenburg Oblast is located in the south-east of the Russian Federation, on the border with the Republic of Kazakhstan. The region itself is located in the dry steppe zone. Here, chernozem (black soil) and dark chestnut soil are the most widespread soils. The sharply continental climate of this area is characterized by its harsh winters and dry and hot summers. This means that a scientifically grounded farming is of great importance in this region, serving as the bases for a full realization use of the region's bioclimatic potential. As studies of Orenburg scientists show, a biologized agricultural system is indeed a preferred one for the region. Such a system involves carrying out snow retention procedures in winter, the use of crop rotations, usage of zoned varieties, a combination of crop and livestock production, etc. (Filippova, Petrova, Mikhina 2017). This is exactly the approach that is used in crop organic production.

The investments in agriculture in the Orenburg Oblast in 2018 amounted to 3,035.5 million rubles. (34.5 million euros). The value of agricultural products produced amounted to 107.9 billion rubles. (1.2 billion euros). Of this, 52% is the value of crop production, while 47% is animal husbandry. Large agricultural organizations produce 36% of crop production, while private farms produce 34%, and the region's population itself produces 30% (see Fig. 2). At the same time, agricultural corporations are the main grain producers.

Fig. 2: The structure of crop production in the Orenburg region in 2018

Source: Agriculture, hunting and forestry of the Orenburg region. Statistical Yearbook 2019 / Orenburgstat. Orenburg, 2019. 149 p.

We have conducted optimization calculations in order to assess the economic efficiency of grain production using organic technology for agricultural corporations in the Orenburg region. We took profit before tax as the target function of the optimization model, while also taking into account the following limitations:

- Limitations of the usage of resources, taking into account the availability of resources, requirements for crop rotation, and the maximum size of industries;
- Limitations of the needs of fodder for farm animals, taking into account the number and the animals' productivity, guaranteeing the structure of the diet, its nutritional value, and the optimal number of fodder and protein units.
- Limitations of the amount of crop production produced;
- Limitations of the amount of crop production held for sale.

Two models were created. The first model reflects the structure of production costs for growing winter and spring wheat using traditional technology with the use of mineral fertilizers and chemical plant protection products. The second model reflects the structure of production costs without taking into consideration the costs of purchasing mineral fertilizers and plant protection chemicals. The calculations for the first model take into account the actual area covered by crops: winter

wheat – 234068 hectares and spring wheat – 557891 hectares (data from the Ministry of Agriculture, Trade, Food, and Processing Industry of the Orenburg Region for 2019). The second model was created upon the calculations in which 20% of arable land will be allocated for the cultivation of organic products: winter wheat – 46814 hectares and spring wheat – 111578 hectares. (The area calculated for the region as a whole). The size of the plots in each agricultural corporation will differ based on its capabilities and choices.

As a result of the calculation, we can see the structure of production costs (see Table 2).

Table 2: The structure of production costs for growing winter and spring wheat using traditional and organic technologies (for agricultural corporations in the Orenburg region)

Expenditures	Winter wheat		Spring wheat	
	Traditional technology	Organic technology	Traditional technology	Organic technology
Salary	13.7	15.9	16.5	18.1
Seeds	14.2	16.4	21.9	24.0
Mineral fertilizers	6.6	0.0	2.7	0.0
Organic fertilizers	0.2	0.3	0.1	0.2
Pesticides and other chemicals	7.0	0.0	6.1	0.0
Electricity	1.4	1.6	1.2	1.3
Fuel	19.1	22.1	19.2	21.1
Maintenance costs of fixed assets	12.1	14.0	10.7	11.8
Insurance	0.1	0.2	0.2	0.3
Other	25.6	29.5	21.3	23.3
Total	100.0	100.0	100.0	100.0

Source: Authors' calculations.

If the condition that agricultural corporations will sell at least 75% of the grain produced in the time period and the price of organic products will be at least 7% higher compared to similar but uncertified products, then, according to our calculations, the profitability of organic wheat production will be higher even without the use of mineral fertilizers and chemicals (see Fig. 3). The level of profitability is calculated as the ratio of profit before tax to the total cost of production and the products' sales.

Fig. 3. The level of profitability of the production of winter and spring wheat using traditional and organic technologies, %

Source: Authors' calculations.

It is necessary to clarify that at the first stage of introducing organic technology without the use of fertilizers and plant protection chemicals, the yield of agricultural crops may decrease (on average, the yield is lower by 2 centners per hectare for winter wheat and 1 centner per hectare for spring wheat). This is probably the main obstacle to the introduction of technologies for the production of organic crops in Russian. Without due government support, these technologies can be implemented only either by large, financially stable corporations, or by those small manufacturers who are ready to take risks and have a guaranteed market for their more expensive products.

The size of the fields allocated for organic production in Russia varies from 2-3 hectares to 6000 hectares. The prices of organic products in the consumer market may differ from an uncertified counterpart by 20-30% (Organic market in Russia in 2020).

Conclusion

Thus, the regions of the South Ural of Russia can provide every opportunity for the introduction of organic agriculture. The main obstacles to this, in our opinion, are lack of targeted governmental financial support, high selling prices for organic products in the domestic market, and poor awareness of most farmers about how certified organic products differ from non-certified products. Another important problem is that the infrastructure for storing and selling organic products has not been formed. The main direction for the development of organic crop production for the Orenburg region can be the cultivation of grain crops, as well as fodder and industrial crops. It is important to add that at the initial stage of introducing organic crop production technology, with the complete exclusion of mineral fertilizers and chemical plant protection products, the economic efficiency of wheat production does not decrease due to an increase in the sales price of products.

YouTube Immersion as A Content Marketing of Experiences

Michal OTROCKI
University of Lower Silesia, Wroclaw, Poland
michal.otrocki@dsw.edu.pl

Abstract

This article describes YouTube as an immersive medium on a level not as much of interface operation as of communication practices driving attention engagement with the content as the main source of experiences. The operation of the service will be analysed with regard to both the interface along with the algorithm behind it, and user practices. This new approach — as compared to existing studies — is based on the proposition that immersion mechanisms be analysed through the lens of marketing pragmatics (content, organic and experimental marketing). Relying on critical reflection from the fields of media and cultural studies, one can identify certain technical and social factors to immersion — sensory activity but also engagement and absorption as a sort of game with the content. The predominant strategy for content dissemination, however, is to generate organic traffic. Content is understood here as an exchange medium for which the user's attention is an equivalent, while content experience should strive to build lasting relationships with the channel-brand and the latter's community.
Despite the great potential for the building of engaged communities, one can still note some negative consequences of building communication communities on the basis of the logic of market exchange — immersion can lead to the construction of a closed, inward-looking social-value system.

Keywords: Immersion, Content Marketing, Marketing of Experiences.

Introduction

The main goal of this article is to substantiate the claim that YouTube is an immersive environment. That is so not through the delivery of sensory experience, however, as much as through the implementation of attention economics proper to content marketing — for content is the base medium of the exchange.

This article joins the category of immersion developed in marketing to the perspective of media and cultural studies. The chosen method is critical analysis of literature — mainly concerning the concept of marketing of experiences, VR, and immersion in new media.

The operation of the service will be analysed on the level of both the interface and user practices. In the broader perspective one also has to ask about potential negative consequences of building communication communities on the basis of the logic of market exchange.

YouTube, one of the largest social media, is nowadays part of the mainstream (Burges and Green, 2007). According to the portal's own data used in advertising, in 2020 YouTube has more than two billion regular users, every minute 400 hours of unique video material is published, and the total daily video play time exceeds one billion hours. Additionally, YouTube is the world's second-most frequently used content-search engine after Google. This is because, unlike other large-scale social media, it continues to be more of a huge content repository than a messenger service. Its user engagement is predicated mainly on the availability of the various contents, including a gargantuan collection of knowledge in diverse fields. In spite of whatever exceptions one could take to the quality of information on the Internet, one has to grant that the Web — including YouTube — currently serves as the primary source of knowledge for the self-educating prosumer society.

By design, YouTube is an open and free service (bar YouTube Premium — ads are not displayed for paid subscribers, unlike in the free version; the portal shares the subscription proceeds with the participants of its Partner Programme), both for channel operators and for the user audience. It cannot escape notice that the portal — itself being a commercial enterprise and providing a platform for business operations for practically everyone —

currently relies on a mechanic tightly linked with marketing communication. As an advertising platform it allows publishers to profit from monetizing their videos, whether directly, rewarding the number of impressions of third-party ads while playing the video (YouTube enables profit to be made on video, graphical or textual ads displayed to the audience while watching videos on the basis of the users' interests and browsing histories), and indirectly, by constituting a medium for marketing activities of one's own. One can assume the majority of the users to be aware of this aspect and eager to participate in it. The results may include the adoption of activity patterns subordinated to the logic of content exchange along with the associated rewards even where the commercial aspect is not the main reason for using the portal.

Content — Experiencing — Immersion

The understanding of content as an exchange medium inscribed in a pragmatic communication model will be of key significance to our discussion.

This perspective could appear less than self-evident from the perspective of media and social-communication studies. Marketing, in being more practice than theory, is a field that still continues to supply cultural reflection more often with subjects than tools. As a practical discipline it formulates its theory in a doctrinal way and, sometimes irritatingly, in the form of recommendations. Although sometimes it merely assigns different names to phenomena already having their explanations in other fields of knowledge, it does so in a pragmatic spirit, for it reduces its claims in practice according to measurable criteria and indicators (e.g. conversion rates).

Traditionally understood marketing can be focused on sales goals, but a perspective based on participatory-culture patterns is gaining popularity; the overarching goal starts to be the creation of a positive image for the brand and stimulation of community activity focused around it. Long-term recipient relationships are the cornerstone here, not messages as unilateral actions.

This approach is the result of the evolution of a certain holistic concept (self-definition) of marketing as a discipline. When describing the changes in the perception of marketing-communication functions and contents in the successive 'eras' (versions) of marketing, one can draw upon the classic perspective of Philip Kotler (Kotler, Kartajaya and Setiawan, 2010, 2016):

1.0: Starting from the Industrial Revolution the focus had been on the product, with the message content mostly being the technical and functional description, and the customer simply a buyer making a rational decision.

2.0: Along with growing competition and access to information, customers began to be regarded as individuals making a choice. Messages were, therefore, reorientated on the consumer and the consumer's emotive sphere; the content was addressed to a specific target group according to the diagnosis of the problems and needs of its members.

3.0: Orientation on the customer, the customer's needs and values becomes in turn founded in the brand's mission and values. The company's goal is to improve the world and face up to social problems demanding to be solved. The company establishes a stronger connection with its customers thanks to identical values — with the values being responsible for the majority of communication content. The intention is for such activities to solidify companies market position in reliance on the social engagement around which they design their products and services. Charitable donations or a pro-ecological stance could serve as an example.

4.0: In terms of orientation, this approach should lead to a focus on building an engaged (digital) community around the brand. Communication is based on creating and publishing attractive contents, useful and interesting to a specific group of people for whom consumption is a motive to initiate discussion. In this way one enables the customers to participate in the refinement of existing services or products, or creation of new ones.

Let us note that in this area the evolution of content-based communication proceeds by the gradual deepening of the relationship through four spheres of impact (persuasion) — rationality (*logos*), emotion (*pathos*), values (*ethos*) and commitment to action (*kairos*).

The marketing founded on this perspective is an extraordinarily expansive practice nowadays, mainly thanks to its adaptability. It remains an important element of a strategy that enables brands to endure and improve recognition in the face of constantly changing trends and intensive evolution of technical solutions.

Here, one could distinguish three complementary perspectives-practices — content marketing, organic marketing and experimental marketing.

Content marketing provides a relatively simple explanation for the functional aspects of communication focused on content creation and management. According to an industry-popular definition, it is simply delivering the contents the audience seeks (Mandour, 2014). According to Joe Pulizzi (2020), founder of Content Marketing Institute: 'Content marketing is the marketing and business process for creating and distributing relevant and valuable content to attract, acquire, and engage a clearly defined and understood target audience – with the objective of driving profitable customer action.'

Organic marketing, in turn, focuses on techniques for stimulating and moderating interest. Organic traffic linked to certain content is often erroneously referred to as 'natural' and 'spontaneous'. Being the object of organic-marketing operations, after all, it can be neither completely natural nor spontaneous — to look no further, it is stimulated, for example, by appropriate content curation and positioning (SEO). The creators of organic marketing speak, on the one hand, about 'natural' interest, and on the other hand they claim it as their own personal merit; this, in a way, testifies to the inherent pragmatism of this discipline: 'we don't exactly know how it works, but it does work, so it's true to practice.'

The sphere of commitment to action is explored to the greatest depth by experiential marketing, which focuses on creating relationships with customers on the basis of their subjecthood and realistic, direct experiences. It is in this context that one speaks predominately of immersion as the most desired and effective — 'embodied' — experience abolishing the distance between the consumer and the relevant situation (Carù and Cova, 2007).

Sensory Immersion as An Aggregate of Content and Attention

In YouTube, as in any audio-visual medium, immersion occurs first and foremost through sensory impression, via image and sound. However, it would be at the very least a dubious claim to assert that YouTube is an immersive platform for virtual reality only on this particular level; the screen interface would be problematic, to look no further. One has to bear in mind that, according to the classic concepts of Michael Heim (1993) and Oliver Grau (2003), immersion continues to be described as multisensory immersion in an artificial virtual reality (VR), breaking off contact with the natural world, from which it follows that the screen as such leaves the spectator on the outside, preventing the sensory impact ('overwhelming') of virtual reality (Koszela, Kukiełka and Wantoch-Rekowski, 2016).

Other than the portal's — rather futile — attempts made since 2015 to popularize the 360 video technology (Smith, 2015), we are mostly dealing with a dynamic windowed screen wherein virtual reality is created by the fragmentized field of view (Manovich, 2001). This field-interface's dynamics constitute the space of immersion occurring in a different way from sensory illusion. As a psycho-social ('psycho-cultural') phenomenon, immersion can consist in: 'absorbing the consciousness of a spectator fascinated without limit with the message perceived (Pietrzak, 2016). The scope of immersion in this meaning can be broad, encompassing diverse and gradable forms of relationship with the presented world — the mediated presence itself, the process of engagement, the act of faith, the experiencing, and identification/projection or living out. Users entering the virtual world do so with a certain dose of trust, which makes them want to abide in such a reality (Prajzner, 2010).

Let us invoke O. Grau's intuition here (2003, p. 345) — 'perhaps the single most important factor is the possibility to access and exchange images via global data networks.' One can, therefore, conclude that immersion could also be found in mass-scale long-term participation in a network, manifesting itself in activities 'of often a very personal nature, contributing to the creation of an everyday [life] in the digital environment,' such as in social media (Ostrowicki, 2007; 2013, p. 13). Here, consciously participating in YouTube's specific *realis* would establish immersion of a depth depending on the quality and type of the interface; should one, therefore, grade immersion only on a scale from navigating an interface to experiencing the cyberspace, YouTube would be a technologically 'shallow' environment (Ostrowicki, 2006).

While discussing the mechanics of YouTube's operation, however, one has to consider not so much the interface (its multi-screen nature, audiovisuality and interactivity) as the non-transparent algorithms controlling it and with it any activity in the service. Inferences about their actual operation can be drawn only indirectly, by observing data and trends and remembering about YouTube's integration with other Google services (most importantly AdSense, a Google ad-distribution service enabling account monetization under the Partner Programme). Examples of immersion in YouTube can be observed with relative precision via its Analytics module, which provides insight

into summary data on related content use, mainly as a function of time and various forms of activity registered by the interface. The average single user session extends to 40 minutes play time of materials available on the platform. Though the analytical module does not provide insight into individual behaviours of individual users, there is still enough ground on which to assume personal conscious participation as the basis of activity. This is provided that the depth of immersion is even more dependent on attention economics than on the delivery of sensory experience.

The phenomenon of the immersion occurring in the YouTube environment can be described as a function of content and attention — for these two are the resources being exchanged on that medium. Creators and distributors provide contents, and spectators provide attention. Both share their experiences. Content engages attention, attention follows content toward desired sensations-experiences — and this particular phenomenon is the catalyst of the YouTube environment's immersion, of which organic traffic is the most desirable result and predominant distribution strategy in the service (this means content spread achieved without paid forms of promotion and either reaching potentially interested recipients or being found by them themselves via search engine). Organic marketing, therefore, is tightly linked to content, for the attractive content of a video is what enables organic publishing and reception, which is conducive to building experience and, in effect, an engagement-filled relationship with the brand.

Immersion as A Game — Engagement and Absorption

Immersion-deepening activities in YouTube could be described by analogy to reflection on video games (McMahan, 2010). There are three conditions for immersion to happen. Firstly, the topic must be compatible with the spectator's expectations. Secondly, the activities must significantly affect the digital environment — for example by debate-sparking comments, positive or negative ratings, flagging clips as harmful to the community. Thirdly, the relevant creation-environment must follow a consistent convention (a YouTube channel's audience will not be returning upon finding that the creator is neither trustworthy nor consistent).

Two dimensions can be distinguished — engagement and absorption (Brown and Cairns, 2004). Engagement, in a way, constitutes an entry level — just as a gamer must invest time and break the competence barrier in order to understand the rules of the game, the spectator must learn the specificity of the relevant YouTube channel's operation by watching a greater number of videos published therein. While in the case of games we can speak of an intuitive interface and ergonomic controls facilitating this, for YouTube that could be 'nice' audio-visual presentation (appropriate quality of sound, and legible audio layer) but above all interestingly, attractively delivered content.

Here, it is worth noting that care to the quality of the content influences its dissemination by the service and enables the chosen — and at once as numerous as possible — audience to be reached (Gonciarz, 2013). The most important element drawing the attention of a YouTube surfer, for example at the stage of choosing among the many clips featured by the portal on its main page, is the thumbnail or 'cover'. Among the main indicators Analytics names the number of impressions and the clickability of the thumbnails (the ration of thumbnail impressions to the number of times the video is played). The service provides a number of recommendations on how to improve thumbnail effectiveness, from title selection to graphical composition (YouTube, 2020). The recommendations use the marketing aspect as the main motivation for quality — 'Craft advertiser-friendly thumbnails and titles to help your monetization'. The appropriate title and description are elements of textual marketing and at the same time immersive action engaging the spectator's attention. Fitting and catchy titles and precise descriptions shedding light on the video's topic allow it to distinguish itself against the many alternatives and obtain better positioning in the search engine. Only appropriate (accurate) coupling of the title and content of a video improve the probability of immersion. A badly chosen or misleading title can create disappointment in visitors who were looking for something else.

The aforementioned entry barrier can result from the creator's chosen range of topics — those must catch the spectator's interest and hold the spectator's attention. The spectator can satisfy the need for entertainment and gain the benefits of watching the video, for example by learning useful information. Although options for holding spectator's attention are limited at this stage of immersion, overcoming the initial difficulties can reinforce emotional attachment, positive reception and willingness to continue to invest time in accessing the content.

In a virtual game absorption — the second degree of immersion — refers to plot consistency and cohesion of the presented world, while for YouTube materials it will be driven by subject, genre or narration consistency (e.g. in a history delivered by a serious of videos). At the stage of immersive absorption such factors as empathizing with the atmosphere of the perceived world and with the characters appearing in it increase the chance of successful

immersion, as the spectator becomes increasingly able to identify with the presented world. The claim that virtual sensory impressions are not the success driver could find support in the fact that a lot of materials are amateur-produced, with the quality of the sound and image leaving much to be desired, and yet they boast great popularity — the content is much more important to the audience than the audio-visual layer.

It is worth highlighting the absorption of attention focused on practical information-knowledge connected with action. One particular form of it can be the cognitive impact of the plot (content) — satisfaction of the need for the acquisition of certain competences such as problem solving or honing practical skills (Ermi and Mayra, 2005). The video form enables precise instruction (e.g. in correct exercise or cooking techniques), is more economic and more effective than textual descriptions (Garret, 2015). This is reflected by the popularity of vlogs containing tests, reviews, advice and tutorials but also specialized education materials and overviews — e.g. professional documentation of a multitude of medical procedures medical trainees and practitioners can use. The University of Iowa Hospitals and Clinics' Department of Surgery has conducted a survey showing 90% of people to prepare for their surgery by watching videos, with 86% doing so with YouTube (Rapp et al., 2016).

Emphasis is laid in this context on providing the audience with their desired experience in the form of the information they seek, for example how to solve a specific problem, without being intrusive (unlike an ad message, which usually discourages its viewers, preventing immersion). One person who willingly makes the informed choice to subscribe to the brand's blog, profile or YouTube channel — thus one who decides to stay in touch — is more precious than 100 leads generated using traditional methods of advertising (Dobaj et al., 2014).

Besides the delivery of information, narrative creations originating with a thought to the modern recipient engage that recipient primarily on the emotional and not the intellectual level — they are, therefore, conduits for experience building. Immersion could be regarded as engagement orientated on a product or topic but at the same time also living through something not in the nature of consumption — for example entertainment could be the goal.

The absorption process drives strong emotional attachment to characters (e.g. vloggers), translating into willingness to continue watching an ever increasing number of video materials relating to the person or brand. A similar phenomenon can be observed in users of popular Internet video platforms providing VOD services, where immersion takes the form of so-called binge-watching, that is the compulsive watching of a series (Jurgensen, 2012). Binge-watching is the result of an adaptive chemical reaction in the human brain (Doidge, 2007). Watching a history that is shown on a screen and interesting to the viewer generates a certain type of sensory-ideatory trance — in identifying with the characters and following the plot the spectator feels strong emotions. The desire to sustain such states triggers watching more episodes. Attempts to encapsulate this phenomenon have not so far resulted in identifying the minimum number of episodes watched or time spent watching — one can, however, recall the Netflix study in which as many as 73% of respondents-platform users claimed to watch anywhere from two to six episodes in a row, with as many as 61% admitting to uninterrupted watching in such a session.

In YouTube's case, binge-watching traces its source also to the effective algorithms embedded in interface functionality. This includes recommendations of videos for watching (the main page, 'recommended for you', 'see also', pop-up notifications of new videos on channels), playlists generated by the portal on the basis of similar contents (after a video ends, another, similar one is played in order to hold the viewer's attention) or enabling the viewer to interact with the digital environment (e.g. conversations in the comments section).

A similar role falls to the driving of recipient engagement by the video creators themselves — direct communication with audience members and creation of emotionally engaging content cause the immersion probability to grow (Witmer and Singer, 1998). Activities potentially influencing this dimension of immersion could include, among others, standard repeatable formulaic greetings; requests for subscriptions, 'likes' and comments; asking questions or for asking for the audience's topic suggestions. The greater the number of such activities undertaken by engaged users, the greater the increase of the video's potential impact; this translates not only into measurable monetization benefits but also into future audience absorption (YouTube Creators, 2017). Crowdsourcing understood as a design process involving the community certainly is one such immersive mechanic (Kasprzycki-Rosikoń and Piątkowski, 2013). Creators enable the viewer community to participate in the creation process, for example by asking — in the video — for comments with ideas for new materials; for example, the strangest questions asked in comments under the previous episode could be used as a basis for creation (Gonciarz, 2013).

Cross-appearances, or guest appearances by popular YouTubers in other channels, also deserve a mention as a practice calculated to increase the reach (Ptasińska, 2018). The goal of activities of this type is to reach potential

new audience already gathered in the host's and the guest's respective channels. In a certain sense this operates on the basis of recommendation — the favourite creator recommends another one as worth giving one's attention to.

All of the above activities are geared to leverage the potential enabled by YouTube's algorithm, some insight into the operation of which the user-publisher is given through the Analytics module. There, among other things, one can trace the number of impression and average viewing time and draw conclusions as to after what time and at which time the users gave up watching. Also the clickability ratio of impressions is important, in suggesting whether the video managed to engage the users enough to give it a rating and share their opinion or make a reference to the subject discussed. Finally, the module makes it possible to check have many people became permanent subscribers after watching the relevant material. One can surmise that a textbook case of immersion while watching YouTube materials occurs when the viewer watches the video from start to finish, with activity in the comments section and ratings confirming engagement. Films given the most time by users engaged in discussions and ratings reach even greater numbers of users potentially interested in the given range of topics (Missfeldt, 2017). Such videos are also capable of absorbing a viewer who interacts with the community interested in the subject and shares the video further (Gonciarz, 2013).

The mechanisms, as described here, on which the YouTube environment is based cause the recipients primarily to be reached by contents interesting to them within a specific subject range and therewith also personalized Adsense ads. As YouTube itself lets us know, the main assumption in the algorithm operation is content adaptation to the user so as to recommend potentially engaging videos. That is done by analysing each video for the most important variables — title, thumbnail, subject field, average play time (as percentage of total length), number of positive and negative ratings, and number and content of comments.

Discussion — YouTube as a closed medium

Already near the end of the 20th century it had been forecast that the following half-century would be characterized by constantly improving access of Internet communities to video production and distribution (Davis, 1997) — technological progress relating to network bandwidth and increasing accessibility of hardware certainly facilitated this. Internet 2.0 was supposed to provide everyone with the possibility of becoming not only a content consumer but also a content producer (Celiński, 2013). The creator was to become a publisher with ease, which Paul Levinson (2013) described in enthusiastic terms in his own time.

From the perspective of content marketing as a cultural practice YouTube appears as a near-perfect tool. The platform brings together video producers and viewers-users (who are especially valuable as subscribers building engaged communities). The former group includes professional media producers with corporate backing, copyright holders (TV outlets, publishing houses, film studios, etc.), advertisers, small and medium companies looking for an inexpensive distribution channel for their marketing materials, as well as cultural institutions and, last but not least, so-called YouTubers with an established personal brand, activists and amateur creators (vloggers). The latter share their knowledge absolutely free of charge or in exchange for the monetization of ads inserted by YouTube as part of its Partner Programme for creators. Very frequently amateurs are better than experts in their fields at successfully disseminating knowledge in a simple and friendly form adapted to the audience's level and age group. According to data from the last decade of the portal's existence, the greatest popularity (estimated on the basis of subscription and impression counts) is garnered by 'amateur' channels, which could be interpreted as a manifestation of bottom-up content generation (Burges and Green, 2009). Obviously, one also has to reckon with the adverse consequences of that trend, for which A. Keen (2007) offers the most complete description.

The content itself of the published video serves as the basic communication medium and catalyst for the creation of social groups. John C. Paolillo (2008) recognizes the platform's active users as its 'social core', for they create and share content and refer to each other's videos as a basis for critical analysis or concurrence in their respective opinions. He identifies the activities of YouTubers and other publishers as an important driver of the platform's attention economics with also an important role in shaping the YouTube culture. The contents are of assistance to solving the various individual potential or actual customers' problems, while YouTube itself, as a platform for discussions and comments (below the individual videos and on channels), creates a mutually beneficial communication channel for publishers and their communities.

One of the forms of generating organic traffic on the platform is the viral strategy; however, YouTube blocks (by restricting their reach) materials such as until-recently popular 'pranks' (practical jokes based on surprise and often intimidation or repulsion, set up on purpose and recorded as a video to be shared on the Internet). Attention is also drawn to YouTube's policy restricting the dissemination of contents that are socially harmful or misleading — the

platform encourages the user community to report them, which proves that automated blocking by the algorithm has not yet achieved perfection.

Communities form around a specific subject range, establishing mutual relations thanks to it. Thanks to the possibility to express their emotions by 'likes' or comments, YouTube contents as a *sui-generis*' common good' builds relationships between users (Homfokl, 2009).

YouTube thus presents as a medium supplying viewers with topics in a sort of general social debate, helping build a communication community (Bendyk, 2011). Burgess and Green (2009) go as far as asserting that the origin of YouTube's success lies precisely in the participatory culture enabling the publication and exchange of independent opinions and comments. As its welcome page proclaims: 'YouTube's mission is to give everyone a voice and show them the world.' The belief that the world becomes a better place when creators share histories and views on them is a value underpinning YouTube's activity. This enthusiastic and idealized vision, however, has to be subjected to realistic critical analysis. In the opinion of, among others, Jenkins, Ford and Green (2013, p. 48), even the concept of Web 2.0 itself, having emerged in 2004 (that is one year before YouTube's launch), quickly went on to become the cornerstone of the cultural logic of e-business — 'a set of corporate practices that seek to capture and exploit participatory culture'.

YouTube's operation model currently based on attention economics created for content marketing causes the use of the platform to acquire numerous characteristics of immersion. The immersive mechanic, in turn, is nothing else than the pursuit of corporate logic and pragmatism, successfully concealed.

In this context it is worth noting the thought given by M. Heim (1993) to the consequences of adopting a computer-search logic (contrasted with intuitive logic) for orientation forming in virtual reality. Communication based on content searched happens in an online environment governed by a logic of creation and sharing, an environment that registers, reinforces and multiplies the recipients' collective interpretation and appropriates their materials (Jenkins, Ford and Green, 2013). This clearly influences a certain pattern of thinking. The users generating contents in YouTube are proud of what they do — irrespective of the value they generate for the portal, whether they want it or not. They create videos as media contents out of a simple willingness to share, but each such type of activity has the characteristics of self-marketing. In this way, as Jenkins (ibid.) observes, they find themselves submerged in a value system used by companies for the evaluation of materials, as YouTube encourages them to treat interest in their contents as a sort of currency — the number of impressions their materials get will translate into social prestige. This being inside of a system is one of the potentially negative dimensions of the immersion discussed herein. This mechanism's failure to be transparent should inspire further studies into its social and cultural consequences. If one looks at the functioning of this medium as a sort of immersive content market, the fact that it creates a closed value system becoming increasingly difficult to leave can be quite concerning.

Abstract

Society's changes are jumping tremendously. Another leap is underway, and part of the planet is already approaching company 4.0. External and internal influences are preparing society 5.0. The one-child policy and the change in society's population's structure in the next 30 and 50 years the qualitative birth rate in the developed part of the world and quantitative birth rate in other places. There will be 16 billion people on the planet in 100 years, or 5 billion. Global sustainability of development. A change in society affected by the natural change, the end of the mantra of GDP. Changes in production and consumption. Nationalization instead of globalization in production with the help of Industry 4.0. Recycling as a phenomenon of the future. Changes in the education of people and the profession of the future. Why fundamentally change education towards the information society, not to the education of the new generation, but to a comprehensive opportunity to work with information and the ability to perceive the world in a holistic dimension. New understanding of medicine, holistic approach. Current cryptocurrencies only as an intermediate step to currencies owned by corporations. Artificial intelligence as a normal part of life. Security protocols of people in connection with cybersecurity and information society controlled by artificial intelligence. Political and military changes. Further changes to human rights and freedoms. We will have nature under control, or nature will again control us considerably.

Keywords: Artificial Intelligence, Future, GDP, Industry 4.0, Natality, Society

Introduction

When we deal with the society of the future, there are several possible avenues of development. One of them is the constant continuation of the current trajectory, only with the change of equipment and technological background.Or the society of the future as a new configuration of social systems, infrastructure, goals and its own functioning.Why are we dealing with the society and its big jumps? The society and its development can be similarly classified.Is it modern to adapt business companies to the level of Industry 4.0.where we have company 2.0, 4.0 ordoes the article refer directly to 5.0?Is this about science fiction? Or has development become so rapid? Looking at it all from a global point of view, humanity has really broken free from its chains. Then came the global "pandemic" Covid. It doesn't matter whether this virus is of natural or scientific origin. We expect according to the formula Industry 4.0, Labor 4.0 status Society 4.0.Company 4.0 should be characterized by a sociable change based on scientific and technological development, new discoveries and innovation of higher order.We expect vertical and horizontal integration, the interconnection of production, and distribution systems. It expresses a new vision, concept, a fundamental comprehensive society-wide change with overlap into a change in thinking.

Friedrich Nietzsche, for his part, states that another higher order of man, Übermensch, will be able to free one's need to follow the usual conventions and thus to follow social status, mammon, etc.This will allow Superhumans to break free from the cycle of constant repetition of history ("history is repeated all the time"), to find and pursue the achievement of higher goals through the "essential ego" (free from social conventions). Only then, inadvertently, will he reach a shift incl. Higher morale and ethical characteristics. Will simple evolution move us? But the development of the brain itself (i.e. a radical increase in the number of neurons of the gray cortex) , in terms of

human evolutionary development, is unlikely to make a significant shift any time soon, as it takes place very slow pace. After all, mankind has had virtually the same brain for about 300,000 years. What about bio-digital fusion, i.e., human-technology connections?This is likely to bring development and improvement rather at the level of the senses, i.e., enhanced perception, or an extension of the context of perception, or a closer connection to people. The question is how our brains are going to handle it. In any case, a significant change in the way humanity as a whole operates in the wake of the connection with technology is not to be expected. A radical change may be the arrival of ASI, i.e. "Artificial Super-Intelligence".The question, however, is whether human evolution will continue at all.

Vision of The Future Society

Contemporary society is governed mainly by economic laws, which are often illogically constructed, but supposedly support the logicality or illogicality of the behavior of mankind. Everything is tied to GDP (Strachotová et al., 2018a), which includes more and more distorted parameters.From the point of view of microeconomics, it is important that the work is delegated to suppliers or sold to customers, because what one does for himself is not quantified in GDP.Therefore, grown vegetables from the farmer are not sold in the immediate vicinity or consumed by the farmer himself but are transported, sold to intermediate warehouses (Dyntar et al., 2020), which store it and sell it to retail chains that use logistics chains to distribute it (Strachotová, Strachota, 2017). Control institutions that control economic processes or hygiene regulations watch over all of this. As a result, everyone realizes "added value", the price of the product increases, the product is unnecessarily transported over long distances, an incredible amount of natural resources are drawn. Moreover, from the point of view of natural resources, there is often a nonsensical drawdown just to increase GDP (Rozenský et al., 2019). The result is overcrowded highways carrying trucks of goods across Europe or the world. Nowadays, It is common for merchants who are transporting goods to pay for the ferry to take a significantly longer route around several continents, just because they will need it for Christmas and at the moment they have full warehouses, there is no cash flow to pay for these goods to suppliers. Distortions in both microeconomics and macroeconomics take place here. A common example is that, a bank or a small business charges the price of a product or service in full, as they have it in their price lists (Kutnohorská, Strachotová, 2019). You then have a registered discount amount in your account that makes the product cheaper. However, this discount must not be recognized in the accounts as a decrease in sales, as it would reduce all the economic parameters observed. This discount is billed as a "marketing expense".This will make the end customer's view of the sales price realistic. From an economic point of view, the discount is recognized as an advertising expense, which from the point of view of shareholders or the bank, is taken as a positive step because the supplier invests in advertising and thus promotes sales growth. Does that sound illogical? Franchise chains routinely transfer fees between the franchisee and the franchisees this way, so there is a dramatic increase in similar costs and revenues.The shareholder does not have a chance to unprop this even with a detailed examination, so he is satisfied, the value of the shares is growing or the dividend of them. There are estimates that in this way, at the macroeconomic level, they are deformed with the help of transnational corporations, budgets in the range of 5 - 15 percent of GDP. Everything is included in national budgets, including health insurance and social pensions, just to ensure that GDP's ratio to the national budget is correct, because that is what the price of debt service is all about at a given percentage of the state's debt.There are several countries in the world that do not follow GDP, but are mostly at the very bottom of the economic rankings of the entire planet. Already sustainability becomes important to many investors, and non-financial reporting is very strongly based on the CSR.

Society 5.0

Production, Industry, Services

Processes and production are deformed in the same way as GDP. For the correct economic calculation of the product or for the value of the company's shares (and subsequently its credit value, dividends, and others), it is necessary that the product is simply sold a given in the scheduled quantity. Banks and other institutions have segmentation according to how reliable manufacturers achieve this parameter. For example, the VW group has a 95% probability of selling its planned production in terms of car sales, whereas Fiat or Opel, for example, is normally only 50%. It is a parameter that subcontracting companies can use for their operating lending to the producers. But even companies with a high probability of meeting the plan no longer have these outlets. What about production? Products cannot be scraped, although it is stated that up to 15% of the production of newly produced vehicles are actually scrapped (Dyntar, Strachotová, 2015). Why doesn't the production get cheaper? All processes would be disrupted, as seen above when analyzing revenues and marketing costs. A decrease in production would only result in a decrease in total sales for the total production of the product or service concerned, followed by a decrease in the value of the manufacturer's shares, etc.The products are purchased by the subsidiaries of the manufacturer, the leasing company, the product is often leased for short-term or long-term leasing.In 2020, a

bankruptcy rent car was divested by Hertz, VW's market leader in car rentals. Will Hertz continue to buy 80,000 vehicles a year from the Ford Group?Certainly not, but the VW group has ensured who they will sell a large part of the products to, which have a worse application in terms of sales. At the same time, there will be a greater marketing concept, in terms of brand and other synergic ally effects. All of this has one major global impact. It's for the environment (Strachotová et al., 2018b). Unnecessarily manufactured products that do not find their real application and are soon scrapped or otherwise relatively ecologically disposed of are increasing in the long term. But building sand and most colored metals, we only have enough supplies for a few decades. That's why we're planning to go into space, to other planets, so we can continue to pillage because there's nothing to loot on Earth. In this dramatic way, the use of virtual products and services is also increasing. The actual videos were available 30 to 60 years ago, but one needed a video camera, a cutting device, then a computer, and most of the production thus produced ended in a home archive or photo album. For the past ten years, videos have been filmed by the entire population, stored on disk arrays by multinationals that continue to use them for marketing, and even share a few percent of the ad's revenue with their users. So, in addition to sharing content, there is a growing virtual race for the number of views. People are having fun; multinational giants are still growing with the amount of money they have. The estimate for free cash flow for Microsoft, Google, Apple, or Facebook is about $250 million for each. Companies do not even invest it. In their words, "there is nothing."What do they know about our future consumption or behavior when they know more about our lives than the secret services of the states in which we live? First of all, it's about changing the behavior of the population. Many of our future sales will be digital. The electronic footprint that we all leave behind is so vast that it is practically no longer necessary for people to be purging themselves of science fiction novels. This is actually happening or done by other means. Modern space races are underway, but it's no longer a China-US duel. Russia is already partially out of the picture. For this, Elon Musk has put into orbit a multiple of satellites for the spread of Internet connectivity and other services in 2020 than any country in the world in the last 50 years. All of this leads to many changes in society and our lives—industry, manufacturing services.

Industry 2.0

V4 economies are called the assembly plants of Western Europe. We qualified for this position. We have production here, often top production. Why are these economies weaker than their western part? Where the added value is hidden, the margins. Most of the population thinks they are hidden in export dividends from these businesses. The opposite is true. In Central Europe, there is a significantly smaller share of the pre-production part, i.e., the development and post-production part, i.e., trade and marketing.This is mostly retained by the producers' headquarters under their own supervision as part of the parent company (Strachotová, Pavlištík, 2017). Production margins are often only in single digits, and everything is catching up with the production volume. Development, trade, and marketing have a margin component, often several orders of magnitude higher—a key position in the area. For the last 30 years, foreign and Czech producers have loved the Czech economy for 3 factors.1) Discipline and low cost of the Czech workforce. Low mainly labor costs related to Western Europe or North America.2) Geopolitical proximity = neighboring with Germany, as Europe's industrial leader.3) Quality production. Within the VW Group, for example, the quality of production in Czech Škoda Auto plants is higher than in the parent VW. But these are factors for Industry 2.0. These 3 factors may be uninteresting within a few years, and foreign investors may begin to withdraw their industrial capacities during the current nationalization.

Industry 4.0 and influence on Society 4.0 and 5.0

Industry 4.0 is characterized by a high degree of robotization of production and individualization of production (Strachotová et al., 2019). This trend is already underway. A large manufacturer of railway vehicles, the Swiss company Stadler, decided to produce a large order of decker trains KISS (2010 and 2014) directly in Switzerland with the deployment of a high degree in robotization and automation of production.Siemens won previous competitions for similar trains and trains were produced in Prague, for example, which is characteristic of Industry 2.0. The manufacturer Stadler has its plants in Germany (Pankow), Poland (Siedlce), and many others, for the production of "cheaper" countries.This is the first example, as early as 2011, of the use of modern production lines in Europe.VW has taken a similar path, building a new electric car production line (EmDem) in Germany over the past two years, where instead of the classic few thousand employees, there are only about 100 technical engineers with tablets in their hands, which are controlled and adjusted by production robots, chatbots. Manually working human hands can only be found here minimally. Deploying robots and artificial intelligence costs a similar amount everywhere (Botek, Strachotová, 2018). But we do not need to educate thousands of employees for specific fields; a few dozen engineers and system specialists are enough to replace them. What will those thousands of lower-level employees do? From an environmental point of view, this is about saving resources for transporting intermediate

stages of production across the continent; from an economic point of view, this is precisely the threat to the employment of "manufacturing" not to the production countries.

Professions of the future

Which professions will remain, which will arise and which will disappear? Anything that is just routine work, described in an algorithm, will be performed by robots. We are already routinely sending so-called case from the Society 4.0, to production processes in India, where workers in Industry 1.0 produce or assemble products. The most common mistake that causes things to malfunction in our lives is that the following production step is not identified in the algorithm sent for production to India or China. Restart the computer. Then mark the step in green to check if the information system will start, and then turn it off and wrap it for submission. It seems normal for a standard European technician to wait 20 seconds after restarting to check that the product has started up.Management in the production countries has calculated the time it takes to produce the product and therefore do not count for the additional 20 seconds during which the worker waits at the production line to see if the product has run properly (and still draws an extra 20 seconds of electricity) (Strachotová et al., 2020). This thinking is important to society 5.0. The most common profession will be the profession of a programmer or an analyst. The customer will present to them their vision of what they would like to produce or obtain, and the programmer will have to carry out modeling for robots for individual production of the given product. The professions they replace are now unimaginable as a vehicle driver or accountant, where automated data processing will take place, and the accountant will be left with a role that is now called a tax advisor and solves optimization processes. All professions that demand creativity will surely stay. Robot and artificial intelligence, certainly, in the beginning, can not creatively prepare food, here the role of chefs will surely remain. Within 20 years, call center workers, telemarketers, telephone salespeople, insurance, and pension fund agents will disappear.

Education

Covid's situation has fundamentally changed education. At least 80% of pupils and students learn a different style of work. They were always ready to learn what they received from their teachers. Now pupils and students themselves have to learn based on what they already know. This is crucial for them in the future because they will learn to learn based on their own knowledge and skills. They will need this core knowledge and experience for the rest of their lives for their own lifelong learning (Hukal et al. 2018). We could call the 21st century a century of lifelong learning. It is no longer enough for us to acquire certain pumice of knowledge and skills by the age of 25, but we must learn to learn all our lives. Self-learning will become an organic part of our lives. From the point of view of the current model of education, thanks to the COVID crisis, there was a strong pressure not to draw a line between what the student should learn at home from common sources and what activities need to be implemented in the school team with the support of the teacher. All this had to be absorbed by the parents of pupils and students, where many of them understood that it is not only a problem in the teacher but to find a way to educate and motivate their children internally. This will also be helped by artificial intelligence, which does not replace the teacher in their complex role, but can correct written works for them.

Finance, banking

From a financial point of view, the world will change fundamentally. Physical money is likely to be abandoned with a switch to electronic money. Moving from traditional currencies to cyber currencies. The world's strongest companies will create their own currencies (Facebook = Pound). At the same time, these global companies have so much client information that they can offer targeted loans in better ways than existing banks. What happens when these financial giants pool their resources in parallel with the fall in the share price of today's "normal companies". They will gradually buy them. Ordinary companies will adapt their digital strategies not to a potential customer, but rather with the vision of getting as many customers as possible and we will sell our services to these multinational corporations (Facebook, Google, Apple, Microsoft and others). The use of these currencies will be a flexible and efficient tool for exchanging domestic and international payments characterized by low costs. Similar digital currencies can have far-reaching macroeconomic implications. First of all, they can change the position of traditional banks and the whole process of digital currency spreadmay , in the worst case, disrupt the process of intermediation and the stability of the financial. Some countries could also face declining demand for their domestic currency and capital outflows. In terms of macroeconomic impact, this is a situation similar to the process of dollarization.

Transport, logistics

Most of the main transport arteries have long been directed between large cities and conurbations. This is the cause of a paradoxical situation where regional settlements with several thousand inhabitants that also have a topographic isolation of 30 km from each other are dependent on public transport to the nearest metropolis and back from this metropolis, where a direct transport route either does not exist at all or only IAD is implemented (Dyntar et al., 2020). The society of the future expects different transportation and transport services. Now they still have no idea what the concept will be because they have no complete idea about it. For most of the population, nothing else was imaginable. Transport was represented by railways and horse-drawn stagecoaches. Cars were in their infancy, the road transport network next to the railway was in a deplorable state; most of the roads were unpaved, the asphalt or concrete surface of the roads did not exist. By asking the general population what kind of transport they would like now, 110 years ago, we got the answer that they would like faster horses. Now we get the answer: Faster cars, empty roads, comfort, or individuality. Cars, they did not know of planes, trains were relatively slow and often far from settlements. Cars then saved us from an environmental disaster in Manhattan because there was a lot of horse droppings everywhere. A similar change awaits us, because just faster cars, like 100 years ago, is not the answer. Even the New York subway, which runs in stop mode and speed, is not a complete solution. Capacity is obviously at the limit. Beijing is addressing this through the constant construction of additional subway lines, where dozens have been built over the past ten years, often running in parallel and at different heights.

Changing transport systems and preferences takes time. In agglomerations, it's in units of years. In small territorial units, it is often even decades. At least on a European scale, construction does not take place in the order of months, but in the order of years to decades. All approval processes are complicated and lengthy; there must be an EIA for everything, many institutions comment on the issue, and there are also many associations and lobby groups that boycott this.

Our traffic in terms of small-scale logistics has also grown significantly. Formerly one monopoly delivery service, set up by the post office, has competed in DHL, DPD, PPL, and courier services for the past 30 years. Formerly a thing for the B2B segment, today for everyone. In recent years, competitors have emerged on local or global platforms in terms of shipments in the C2C segment. On the one hand, these are services such as zaskovna.cz or the mentioned forwarding services that now have many collection points, often in the vicinity. On the other hand, Uber drivers today routinely deliver consignments or new food from the global platform. Often these services are another engine of further unnecessary traffic in agglomerations. Uber and others also pay drivers for so-called empty rides, which is when they drive and do not transport anyone, because they want to give the impression of the number of available means of transport and to reduce travel time to customers. In a million-dollar agglomeration of the Prague system, it is estimated that at least 500, rather 1,500 cars drive unnecessarily around the center this way. In larger systems, such as London, despite the toll for entering the city, it is many times higher.

Attempts to solve this using capacity railway transport by raising it to the level of the 21st century, with a modern signaling device of the ETCS level 2 type (3). We can reduce the interval between trains to the frequency of connections below 2 minutes, but the limit will still be the boarding and alighting of passengers. This is a technological limit. Even a wide door and a barrier-free level will not allow for a faster transfer of passengers. The railway solves this with the so-called fast and slow layer, when the slow layer of trains stops everywhere, only minimally fast, but the capacity of the lines is not infinite. The conversion of the station to a more modern concept takes countless years rather than months, and even this is not enough. It is important to understand this problem comprehensively. Measure the travel time from point A to point B. Door to door. It is not a problem to have a high-speed train that will cover a distance of 100 km in 25 to 30 minutes instead of an hour. However, it is then necessary to add the travel time to the train and especially the transfer times. The stations in the larger nodes are so extensive that even a change in the platform takes, for example, 5 minutes, a change in the means of transport, for example, 10 to 15 minutes, from the express train to the metro. During that time, however, the high-speed train traveled 50 km. Traffic at speeds of 200 to 320 km/h is more energy-intensive than at speeds of 120 km/h per hour, and this time savings are wasted by transfers. The concepts of direct connections, without transfers, and the principle of morning express from one metropolis to another and an afternoon back is long overdue. We have clock traffic in the interval of 2 hours, 1 hour, 30, 20, 15, 10, or even 5 minutes. This time loss caused by transfers has already been found in China, where until recently in the hunt for the highest commonly used speed of high-speed trains the speed was up to 380 km/h. Now, China, with regard to energy intensity, has forced itself to reduce the speed of trains to a maximum level of 300 to 320 km/h. A more important parameter is that the correct time block for transport from agglomeration to agglomeration occurs. To explain, when the transport between places A and B needs 4 hours and 15 minutes, it is economically more advantageous to rebuild the line or speed up the transport to 3 hours 50 minutes. In 10 minutes, the set can be brought to a state that it is ready to go back in 4 hours. If we cross this magical limit for an hour, even a few minutes later, we need another train for the same route. Which in world

conditions and prices ICE, AVE, AGV, Shikansenis approximately 25 million EUR per train. In addition to increased demands on service, additional maintenance (more trains), efficiency, more staff, etc.. The same problem, of course, is also with ordinary trains. To understand the tragedy of the situation.The famous completion of the third track and the subsequent reconstruction and reconfiguration of signaling equipment and stations on the extremely busy Hamburg Hannover train route at the cost of huge investments added a capacity of only 13 additional trains per hour. Why wasn't the four-track version built right away is supposedly a complicated thing with regard to land purchases, let's really look at construction and other lobbies behind it, because for another crazy amount, this will have to be redone anyway in the foreseeable future. This is clearly an agreement on the lobbying of individual car traffic, where traffic from point A to destination B can be just as fast, despite congestion and significantly lower traffic speeds. But there is no place to take up more space for the construction of other roads, the existing capacity is overloaded, the construction is lengthy, the synergy effects in terms of impact on nature are catastrophic. From a simple economic point of view, do we want a doctor, an IT engineer with an hourly salary of 500 EUR, to normally make a driver with a salary of 10 EUR per hour for the same amount time?

Artificial intelligence is already solving transportation of the future. UBER, Liftago and more integrate ride-sharing, shared cars, public transport and resources such as shared bicycles or scooters for last mile solutions. At the same time, it indicates the most endangered jobs. With the help of artificial intelligence and self-driving vehicles, we can handle equally efficient transport, but with a significantly smaller number of employees. Self-driving trains or self-driving subways are common in the world. It's just about prejudice and implementation and also about hundreds of thousands of jobs (political pressure).

Information society

Society 4.0 already contains elements of artificial intelligence. The timeline is poorly predicted, but the future 5.0 society will be more virtual than real. In everyday life, work life or private life, virtual assistants of the next generations will come to organize our day with us, monitor our life functions and health status, and help with future routine activities. They give us psychological support, they can translate between languages simultaneously. It will not be a robotic replacement for a human, but rather his software support. In today's form, it is, for example, Google Assistant, Amazon Alex, Siri from Apple. Smart dresses will change shape, look, structure. The human body will be serviced by nanorobots. For a long time, only emotional abilities, creativity and social intelligence remain.

Virtual reality penetrates our lives. There will be a small percentage of people on the planet who will have "real" experiences (estimated at 10% in 2050), 80% of the population will be able to afford the experience in a virtual environment and the rest will have none or no need. It is estimated that around 2040, 50% of the electricity produced on the planet will be used to run data servers with low or even unnecessary video content. The society of the future

The image of the future society will be reflected primarily in the degree of diversity of the society. The current society is not a homogeneous whole not only in terms of assets, income, regional distribution. Uniformity is not even desirable. It is a hierarchical structure of various individuals who form a social whole. Despite all efforts to prevent this effect, regional disparities within countries are deepening. There is a gradual convergence of levels between states in the economic and technical fields, but within the states, unpromising regions where poverty reigns are emerging. This internal tension between regions is a more significant risk than problems between states at the global level. The spread of scissors between regions further supports urbanization and the growth of global megacities, which are growing both in width and height. The concentration of the population is increasing. The younger, more educated and economically active part, which is crucial from an economic perspective, has always exacerbated internal disparities to have the best ability to migrate. Until 2020, we only knew this from the 1984 novels (Orwell, 1949). Then the global intervention of the Covid 19 virus, or SARS II, and suddenly most of the planet's population wore masks, the economies of the states stopped for a short time, there were global changes in the approach to life, education, travel. This is just the beginning, we know that human freedom has shrunk considerably again. Free of charge, and voluntarily. The short-term closeness of society has not been used for positive changes in relation to the environment of us, as the dominant animal species on the planet. Only the indebtedness of future societies has taken place and continues to take place everywhere, which is nothing more than a form of new vassalism and slavery.

Global Sustainability

Mankind can no longer solve current problems, which are collectively called climate change. These are whole continents of plastic floating in oceans, melting permafrost, deforestation of the planet (Siberia, South America),

pollution of drinking water, increase in CO2 (Hájek et al., 2019). We can only solve this with the help of very advanced technologies and artificial intelligence. Slovakia has developed technology that will produce carbon fuels from plastic. There are machines that can draw COx from the air and thus produce, for example, asphalt or electricity. These machines controlled by artificial intelligence will be common in a few decades. The German model of a sustainable society is based on quality agriculture that can produce quality food, so we have a healthier population that needs less medical care, where the resources saved are in prevention programs, which again save and improve the quality of life (Willow, 2020, Ibima). We can produce electricity in several ways and, above all, there will be newer methods of its accumulation, so there will be no problems with the construction of new or renovation of existing distribution networks. The whole ecological program of green Europe, which is the EU's vision for the years 2020-2030, has, in addition to opponents of electro-mobility, secret admirers from Asian agglomerations. In today's not only Asian agglomerations, mortality is high every year due to the increased content of particles in the air. There are hundreds of thousands more dead each year. Transport is one of the serious sources of these dust pollutants (exhaust gases, brake and tire wear), often significantly greater than from thermal power plants.

Artificial Intelligence

Society 4.0 can characterize the initial onset of change in working relationships and life reality models. (Mařík, 2018).We left our privacy for money, or in worse cases for free, to multinational companies and social network owners, who make a lot of money from it. For a large part of the population, social networks have become an electronic drug. However, they were not here at all 20 years ago. Society 5.0 will be characterized by virtual reality. An emerging phenomenon, today imaginable as a 5D cinema, but in real practical life it is already imaginable in many forms. In addition to self-driving cars, we have electronic assistants controlled by artificial intelligence. Artificial intelligence can, for example, design a new painting from thousands of scans of Rembrandt's paintings, which has a clear characteristic of the painting from this legendary painter. He can compose music by studying the Beatles style, speaking in the voice or image of politicians, so we don't have a chance to recognize at first sight or listening whether it's real news or a hoax. This phenomenon now starts under the term Deep Fake. It will be the next message from the president, broadcast on television, reality or it will be Deep Fake, Text messages are much simpler, today part of the content is compiled using algorithms and artificial intelligence, actually at the request of the target listener or reader segment. It will become a complete part of our lives, and we cannot distinguish between the real reality and the reality created by artificial intelligence. Artificial intelligence is now based on the use of neural networks and maps. Artificial intelligence does not yet understand the human context. When driving a vehicle, it is able to drive with maximum overload, which will be perfect in terms of time, but unusable in terms of the human body. Sci-fi is artificial intelligence at the human level, also called general artificial intelligence. Its risk to humanity is that this artificial intelligence can control itself and will not need humanity to do so. Then it will be exterminated because it draws an excessive amount of resources from the planet.

Political, military and power interests

The basic rule is that war is just a policy waged by other means. For more than 107 years, there was an empire, far larger than the legendary Roman Empire, reaching all continents. The British Empire = the sun does not set above it, and whose wealth in the global world was created by inserting 40,000 gold pounds several hundred years ago. It's been just rubble for over 75 years. During the last 100 years of World War II, there were several new political regimes that called themselves the power of the people, even though they were dictatorships and ruled a huge part of the world. However, this large part of the world has these regimes under their skin. Part of the population resists them; part sympathizes with them. The population of citizens who could not even physically experience them (USA, Western Europe) perceives them as the perpetrators of all evil, even though there were forms of racial segregation, oppression or totalitarianism in the territory of these states 2-3 generations ago. In many other territories, so-called proxy wars were fought, with the powers not fighting directly, but providing assistance to these parties. These were Russia, Spain, after 2WW Korea, Vietnam, Central America, the Middle East, Afghanistan, in the new millennium Iraq, Yemen, Syria, Mali. Forms of war conflicts gradually moved from the model of regular armies to all forms of guerrilla wars or wars in cities with strong involvement of the civilian population. It's just about money. It is estimated that the 9/11/2011 attack on New York cost only a few years of preparation, a few months of training, and a sum in the hundreds of thousands of USD. The direct damage is in the order of billions of USD, indirectly it is felt by the whole world in changing security rules in transport, tourism, war, and other areas. Due to its destruction, man has stopped building on weapons from the Second World War. The followers of the German war V2 rockets carried the first astronaut into space (CCCP) or to the moon (USA). A fundamental cultural difference was already visible here. Russian missiles are autonomously controlled or allow interference with control from Earth. American space rockets also allow manual control by humans. The military industry with an unlimited budget provides for things that the ordinary commercial world would not accept. Forty-five years ago, aircraft

flying at Mach3 speed, today 4-generation thermonuclear missiles were without a fallout as a successor to neutron bombs. But today, we don't have to occupy the territory; we just need to exterminate it. What the German army used for horses in 1941 and subsequently American or Soviet troops against it a lot of mechanization, there we now have self-steering drones that can perform espionage tasks much better than the legendary U2 (1960) aircraft, flying at altitudes above 20km. But this technique can no longer be controlled by ordinary operators and computers. Artificial intelligence is already used here. We have autonomous weapons that are not controlled by man. Their first version was actually supposed to be the legendary tsar bomb with a force of hundreds of thousands of kilotons. It was supposed to be like a ship, and if radioactive radiation of a certain intensity appeared over the Soviet Union, it would explode on its own because it was assumed that if the Soviet Union did not survive, it would have no right to survive the world. Fortunately, this project was suspended 20 years before the Chernobyl explosion. Today we envisage a ban on autonomous weapons of all kinds. But it is especially true in politics that we cannot ensure that these weapons are not produced illegally in the world. Only artificial intelligence can protect us from this form of weapon, controlled by artificial intelligence. The key conclusion, then, is who controls this artificial intelligence. Game theory tells us that we assume that our competitor is secretly developing this, so we have to do it too.

Artificial intelligence has been deployed for several terms, in fact, a model of management is already emerging, where there are no politicians with a vision, but only experienced marketers who follow social perceptions and trends. The current COVID crisis shows us this and sets restrictions on freedoms for the future that we could not have imagined 1-2 years ago, and we now accept them voluntarily. The global trend and the shift from democracy to a technocratic model of governance is everywhere. Majdan, yellow vests in France, a million moments in the Czech Republic, problems in Hong Kong, behind all of which hid the company Analytica, which managed to influence public opinions with the help of Deep Fake. Seventy years ago, radio broadcasting and leaflets or film weeklies were enough for this. After that, film and television were able to significantly influence public opinion; today, social networks, and next, it will be cyber-attacks that will eliminate the critical infrastructure of states.

Population Trends

People are the predominant animal species whose requirements for resources keep growing (Matos et al., 2020). In Europe (and other developed countries such as the USA, South Korea, Japan, Singapore etc.) we have seen depopulation for at least the past 30 years. Fewer babies are born than before. The average in Europe has been around 1.4 babies per mother in the past 30 years, the exception being rich countries such as Norway and Switzerland with an average near 3. In the USA, the natality growth is mainly due to the Hispanic minority that has historically always had more children. The fundamental difference is quite obvious. Africa and a large part of Asia prefer quantity to quality, while Europe, the USA, Russia, South Korea, Japan, Singapore are heading down the quality street. The policy of one child with the preference of a son was applied for decades in mainland China. Is it normal that we decided, on our own accord, to decrease the population in the northern hemisphere? No country from the G20, the most developed economies in the world, does not achieve - with the exceptions of aforementioned (Norway, Switzerland) - the reproduction value of 2.1. According to a new IHME study (Lancet, 2020), civilization will grow to 10 billion by 2050. In 2100, the original estimates were between 11 and 16.5 billion people on the globe (Vollset, 2019), with the dominant powers of India, Nigeria, China, and the United States. (United Nations, 2019). The new scenarios predict the end of population growth around 2064 of around 9.7 billion people, and the population will then start to decline. According to this scenario, in 2010, there should be about 732 million people in China, 1.1 billion in India, 791 million in Nigeria, 6.7 million in the Czech Republic, 2.5 million in Slovakia, 15.5 million in Poland, 7.8 million in Romania, Bulgaria 2.6 million, Serbia 4.4 million. The birth rate falls to Poland 1.17 and the Czech Republic to 1.37 children per woman. The average in Africa will drop from today's 4.3 to 1.8 children.

Healthcare

Artificial Intelligence processes a patient's diagnostics, but it cannot tell what disease it is, what are the prospects of healing and what are the consequences. Telling patients whether they are terminally ill or whether they will suffer

lifelong consequences depends only on a physician's empathy and approach. The Hippocratic Oath includes an ethical dimension. What does this dimension actually mean? The crucial dimension of ethicality in medicine is to do no harm to patients. There are still many diseases that do not need to be treated; the effort should only be to manage it. But it is often omitted that patients should be done no harm. How can this be achieved in the modern over mechanized times we are living in when everyone is extremely busy and doesn't have time for anything? By giving patients the time. The second crucial moment in medical ethics is the patient-physician relationship. What relationship can we actually establish when a patient only answers a physician 3-4 questions? This could be the solution to the problem: giving medical staff in the health care sector where everything is limited, and physicians are rather clerks who spend 3 minutes out of the 4 they have typed on their computer.

Health care costs keep growing. While it is to the joy of pharmaceutical companies, physicians often work extremely long hours and their job requirements are huge: their mistakes can damage patients' health fatally. Physicians should avoid prescribing statistically defined medicine that has no effect on solving a patient's problems whatsoever. This is non-ethical on the part of the physician, it yields no results, it is only a waste of resources. The economy is directly concerned (physicians' salaries, costs of medicine, operating costs of medical facilities) as well as indirectly when patients, instead of generating GDP, use up resources, often unnecessarily and with no use. (Monte, 2019) If holistic medicine is applied with the help of Artificial Intelligence, the total treatment time will reduce up to 40%, treatment costs will decrease and patients will recover soon in all aspects. Artificial Intelligence can make operations more considerate, shortening, in consequence, the time of hospitalization. In some cases, it might no longer be needed at all. Artificial Intelligence can also help with a personalized medical procedure as it will check all medicine used by a patient together with their contraindications. Personalized medicine, tailor-made to a given patient, can also be useful in the future. Estimates of decreasing medicine consumption are about 50 - 60% of current values. This economic dimension will often have a positive impact on the ethical dimension as these measures will significantly improve patients' quality of life.

Conclusion

How will we live with this and how will we resist it. Do we want to be in control? Or are we controlled? What can you do? It always starts with education. We need to have properly educated people at the right time in the right place and in the required quality producing the required activity or performance. It is still about investing in education, science and research and also the ability to apply this research in practice. Silicon Valley (USA) and Silicon Valley (Israel) are clearly the world leaders in connecting science and business. The largest artificial intelligence network we have in the world now has about 1 million neurons. The human brain has 86 billion of them. The architecture of the change of society has been very intensive thanks to mobile communication for the last 10 years. The architecture of the goals has changed priorities, opportunities and responses of society. At the same time, it blocks new opportunities for change. The difference between cause and effect in society's behavior has disappeared. We are more and more subject to fashionable technological waves, and we involve our own selves less as a defensive element. The security protocol of the people can protect us. It has its own cybersecurity. It can maneuver us in the information society that is controlled by artificial intelligence. We probably only have the chance to change for a few more decades. Then the chaining of processes will reach a turning point, beyond which change will be possible, but only at the cost of the implosion of society as we know it. The human species will survive this as well, but the question is the degree of futility and nonsense of the sacrifices it will bring. It is necessary to reflect changes in the conditions in which the society operates—both external = natural conditions and internal, which are in the hands of society itself. Natural change has its own autonomy and mechanism of functioning; human society must find a new way to homeostasis with nature. It is not a question of whether or not society is able to change and adapt to natural changes on the planet, but whether it is willing to do so. Even now, the popular bird flu affair (COVID 19) suggests that nature is able to eliminate humanity on the planet as a useless species, drawing vast amounts of sources of drinking water, clean air, and energy for survival.

Earnings Management and The Quality of Financial Statements After The transfer into IFRS. Case of Poland.

Agnieszka PIECHOCKA-KALUZNA

Poznan University of Life Sciences, Poznan, Poland
agnieszka.piechocka@icloud.com

Abstract

This article discusses one of the most important features of financial statement – its quality under different accounting frameworks. Although there is no sole criterion for measuring such quality, it is largely accepted that it may be assessed indirectly by examining the potential earning management and high-quality financial statements should show no signs of being managed in such a way. This paper presented results of studies on earning management measures related to a large sample of financial statements issued by companies listed on the Warsaw Stock Exchange which transferred their accounting framework from Polish local GAAP to International Financial Reporting Standards (IFRS) during the period 2004-2019. To measure it, the author used well recognized methods as well as a new approach based on xgboost (eXtreme Gradient Boosting).

Keywords: quality of financial statement, earning management, International Financial Reporting Standards (IFRS)

Introduction

Every well designed and well composed system requires certain frameworks in order to achieve its goals set. As Maciucia et al (2015) mentioned, within an accounting system, such conceptual frameworks ought to ensure some kind of triumph of good accounting practices over bad ones. Such triumph, in turn, is necessary to release appropriate financial reports of entities, that is reports of high quality that reflect their real financial situations and genuine results.

Since 2005, every company whose shares are quoted on the European Union (EU) regulated market must prepare its financial statements (on group level) under the International Financial Reporting Standards (IFRS), as endorsed by the EU Commission. According to Ho (2011) the IFRSs are built on a framework that provides an economic foundation for establishing accounting standards based on consistent concepts, rather than a collection of arbitrary accounting conventions such as conservatism, historical cost accounting, prudence, and matching.

The idea of international accounting convergence seems to be highly desirable by many academicals, regulators and capital markets participants (Alexander and Jermakowicz 2006). Moreover, most of these people point at IFRS as a set of regulatory frameworks that would best match their expectations. Especially their expectations related to the quality of financial reporting. The reason why a just IFRS set aspires to become the basis for future benchmark in accounting quality is that it has already been widely adopted around the world. In fact, as Ho (2016) observed, there are over 100 countries that require or permit at least IFRS while preparing the financial statements of entities.

It seems that the widespread adoption of a common, international set of standards will increase the transparency and comparability of financial reporting between regions, countries and corporations and will minimize global stakeholder apprehension. According to Rogdaki et al (2011) The international mandatory application of IFRS is a practical demonstration of the latest effort to ensure quality information.

Having realized that many companies have changed their accounting environment and transferred financial statements to meet the IFRS standards, it is worth using quality measurement to show whether the financial statements will be of higher quality after implementing the new (IFRS) standards in comparison with those prepared under the previous legal regime.

Case of Poland” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Review of literature on the quality of financial accounting

The measures applied in this paper refer to recognized models described in acknowledged literature on the quality of financial statements during the transformation to IFRS. These measures concentrate on one of the key areas potentially exposed to the risk of distortion, namely earning management. According to the theoretical expectations, high-quality financial statements should not bear any signs of earning management – neither earning smoothing nor tendencies towards achieving small positive results rather than losses.

In many recognized studies, ad Barth et al (2008), Chritensen et al (2015) or Lang et al (2006), earning management distortion was divided into two classes. First, it is a tendency for managers to smooth earning. In fact, direct measurement of smoothing is rather difficult to detect. Therefore, the studies should derive on indirect evidence. It is assumed that better quality standards will lead to higher earnings volatility. Since accruals are often use to smooth companies' earnings, it also worth analyzing the relationship between changes in the level of accruals and changes in operating earnings or changes in operating cashflows.

Another manifestation of earning management is management toward small positive net income rather than negative result (net loss). If there is room for some discretion in preparing the financial statement and a company is going to report relatively low loss, then there is a higher probability that management will use discretionary accruals to obtain even small but positive final result. Thereby the application of high-quality accounting standards (IFRS) should result in reporting small positive earnings with lower frequency than when employing local domestic (worse) accounting standards. Of course, the definition of such 'small' income or 'small' loss is extremely subjective, but most recognized studies, like Burgstahler and Dichev (1997) assume that 'small' refers to results giving return on assets (ROA) ratio in a range from -0.01 to 0.00 for net loss and from 0.00 to 0.01 for net income. According to Barth et al (2008) and Christensen et al (2015), the most appropriate models for the measurement of the smoothing of financial statements would be the following ones:

[1]

$$\Delta\mathrm{NI}_{it} = \alpha_0 + \alpha_1\mathrm{SIZE}_{it} + \alpha_2\mathrm{GROWTH}_{it} + \alpha_3\mathrm{EISSUE}_{it} + \alpha_4\mathrm{LEV}_{it} + \alpha_5\mathrm{DISSUE}_{it} + \alpha_6\mathrm{TURN}_{it} + \alpha_7\mathrm{CF}_{it} + \alpha_8\mathrm{AUD}_{it} + \alpha_9\mathrm{NUMEX}_{it} + \alpha_{10}\mathrm{XLIST}_{it} + \alpha_{11}\mathrm{CLOSE}_{it} + \sum_{k=1}^{11}\alpha_{k+11}\mathrm{IDUM}_{it} + \varepsilon_{it}.$$

[2]

$$\Delta\mathrm{CF}_{it} = \alpha_0 + \alpha_1\mathrm{SIZE}_{it} + \alpha_2\mathrm{GROWTH}_{it} + \alpha_3\mathrm{EISSUE}_{it} + \alpha_4\mathrm{LEV}_{it} + \alpha_5\mathrm{DISSUE}_{it} + \alpha_6\mathrm{TURN}_{it} + \alpha_7\mathrm{CF}_{it} + \alpha_8\mathrm{AUD}_{it} + \alpha_9\mathrm{NUMEX}_{it} + \alpha_{10}\mathrm{XLIST}_{it} + \alpha_{11}\mathrm{CLOSE}_{it} + \sum_{k=1}^{11}\alpha_{k+11}\mathrm{IDUM}_{it} + \varepsilon_{it}.$$

[3]

$$\mathrm{CF}_{it} = \alpha_0 + \alpha_1\mathrm{SIZE}_{it} + \alpha_2\mathrm{GROWTH}_{it} + \alpha_3\mathrm{EISSUE}_{it} + \alpha_4\mathrm{LEV}_{it} + \alpha_5\mathrm{DISSUE}_{it} + \alpha_6\mathrm{TURN}_{it} + \alpha_7\mathrm{CF}_{it} + \alpha_8\mathrm{AUD}_{it} + \alpha_9\mathrm{NUMEX}_{it} + \alpha_{10}\mathrm{XLIST}_{it} + \alpha_{11}\mathrm{CLOSE}_{it} + \sum_{k=1}^{11}\alpha_{k+11}\mathrm{IDUM}_{it} + \varepsilon_{it}.$$

[4]

$$\mathrm{ACC}_{it} = \alpha_0 + \alpha_1\mathrm{SIZE}_{it} + \alpha_2\mathrm{GROWTH}_{it} + \alpha_3\mathrm{EISSUE}_{it} + \alpha_4\mathrm{LEV}_{it} + \alpha_5\mathrm{DISSUE}_{it} + \alpha_6\mathrm{TURN}_{it} + \alpha_7\mathrm{CF}_{it} + \alpha_8\mathrm{AUD}_{it} + \alpha_9\mathrm{NUMEX}_{it} + \alpha_{10}\mathrm{XLIST}_{it} + \alpha_{11}\mathrm{CLOSE}_{it} + \sum_{k=1}^{11}\alpha_{k+11}\mathrm{IDUM}_{it} + \varepsilon_{it}.$$

where ΔNI is the change in net income, scaled by end-of-year total assets, ΔCF is the change in annual cash flow from operations, scaled by end-of-year total assets, ACC is the earnings less cash flow from operations, scaled by end-of-year total assets, CF is the annual net cash flow from operating activities, scaled by end-of-year total assets, SIZE is the natural logarithm of the market value of equity at the end of the year, GROWTH is the percentage change in sales, EISSUE is an indicator that equals one if the company issued equity, LEV is the end-of-year total liabilities divided by the end-of-year book value of equity, DISSUE is the percentage change in total liabilities, TURN is the sales divided by the end-of-year total assets, AUD is an indicator variable that equals one if the company's auditor is BIG4 (which means PwC, KPMG, E&Y or Deloitte), and zero otherwise, NUMEX is the number of exchanges on which a company's stock is listed, XLIST is an indicator variable that equals one if the company is listed on any US stock exchange, CLOSE is the percentage of closely held shares of the company reported by WorldScope, and IDUM are industry dummies.

A smaller variance of the change in net income in model [1], change in cashflow from operations in model [2], change in cashflow from operations, scaled end-of-year total assets in model [3] and change in earnings less cash flow from operations, scaled by end-of-year total assets in model [4] will be treated as an evidence of profit smoothing.

According to the study of Sun et al (2011), profit smoothing may be also detected using the analysis of absolute value of discretionary accruals:

[5]

$$\mathrm{ADAC}_{it} = b_0 + b_1\mathrm{XLIST}_{it} + b_2\mathrm{POST}_{it} + b_3\mathrm{XLIST}_{it}:\mathrm{POST}_{it} + b_4\mathrm{SIZE}_{it} + b_5\mathrm{GROWTH}_{it} + b_6\mathrm{EISSUE}_{it} + b_7\mathrm{LEV}_{it} + b_8\mathrm{DISSUE}_{it} + b_9\mathrm{TURN}_{it} + b_{10}\mathrm{CF}_{it} + \sum_{k=1}^{11} b_{k+10}\mathrm{IDUM}_{it} + \varepsilon_{it}.$$

where ADAC is the absolute value of discretionary accruals, XLIST is an indicator variable coded 1 for cross-listed companies and 0 for matched U.S. companies, POST is an indicator variable coded 1 for cross-listed companies in post-IFRS periods and 0 in pre- IFRS observations; for matched U.S. companies, POST has the same value as the cross-listed company it is matched to, SIZE is the company's size, measured as the log of market value of common equity, GROWTH is the company's growth, measured as the annual percentage change in sales, EISSUE is an increase in equity, measured as the annual percentage change in common equity, LEV is leverage, measured as the ratio of total liabilities to common equity, DISSUE is an increase in debt, measured as the annual percentage change in total liabilities, TURN is turnover, measured as the ratio of sales to total assets, and CFO is cash flow from operations, measured as cash flow from operations deflated by total assets. The key for the analysis of potential smoothing under different accounting regulations (pre- and post-implementation of IFRS) is factor $b_{3,}$ which represents incremental change in ADAC for cross-listed companies in the post-IFRS period relative to cross-listed companies in the pre-IFRS period.

Earning management may also lead to the targeting of the level of earnings. To calculate that type of measurement of earnings management, the following model [6] can also be used

[6]

$$\mathrm{POST(0,1)}_{it} = \alpha_0 + \alpha_1\mathrm{SPOS}_{it} + \alpha_2\mathrm{SIZE}_{it} + \alpha_3\mathrm{GROWTH}_{it} + \alpha_4\mathrm{EISSUE}_{it} + \alpha_5\mathrm{LEV}_{it} + \alpha_6\mathrm{DISSUE}_{it} + \alpha_7\mathrm{TURN}_{it} + \alpha_8\mathrm{CF}_{it} + \alpha_9\mathrm{AUD}_{it} + \alpha_{10}\mathrm{NUMEX}_{it} + \alpha_{11}\mathrm{XLIST}_{it} + \alpha_{12}\mathrm{CLOSE}_{it} + \sum_{k=1}^{11} \alpha_{k+12}\mathrm{IDUM}_{it} + \varepsilon_{it}.$$

where POST (0,1) is an indicator variable that equals one for observations in the post-adoption period and zero otherwise, while SPOS is an indicator variable that equals one for observations where net income scaled by total assets is between 0 and 0.01. A negative coefficient on SPOS, as Christensen et al (2015) mentioned, suggests that companies manage earnings less towards a small positive target in the post-adoption period.
The last facet of potential earning management refers to earnings persistence, and according to Dechow et al (2010), is important because more persistent earnings can result in better inputs to equity valuation models and to higher equity market valuations. Following Sun et al (2011), model [7] can be used to appraise persistence:

[7]

$$\mathrm{E}_{i(t+1)} = b_0 + b_1\mathrm{XLIST}_{it} + b_2\mathrm{POST}_{it} + b_3\mathrm{E}_{it} + b_4\mathrm{XLST}_{it}:\mathrm{POST}_{it} + b_5\mathrm{XLIST}_{it}:\mathrm{E}_{it} + b_6\mathrm{POST}_{it}:\mathrm{E}_{it} + b_7\mathrm{XLIST}_{it}:\mathrm{POST}_{it}:\mathrm{E}_{it} + \sum_{k=1}^{11} b_{k+12}\mathrm{IDUM}_{it} + \varepsilon_{it}.$$

where E_t is earnings before extraordinary items for year t, deflated by beginning-of-period market value of common equity. B_7 is the most interesting factor because it represents incremental effect on persistence for cross-listed companies in the post-IFRS period. It means that if IFRS leads to more persistent or higher-quality earnings, one should expect b_7 to be positive. Alternatively, b_7 could be positive if the decrease in persistence was less for IFRS than for the matched sample group.

Methodology and Sample Description

This paper examines a case study based on entities listed on the Warsaw Stock Exchange that transferred the framework of their financial statements (from the Polish Accounting Act to the International Financial Reporting

Standards). To evaluate if that kind of transformation led to preparing financial statements of higher quality, I applied the measures which are recognized as the most appropriate in assessing the value and quality of financial statements. This paper is the natural continuation and refinement of comparative research on companies conducted by Piechocka-Kaluzna (2018) and Piechocka-Kaluzna (2019) that prepared their financial statements under IFRS and local accounting regulations presented on separate samples in 2019.

A novelty in relation to the approach used in the literature is the use of the XGBoost method, which is discussed later in this section. In addition, various types of modifications were applied (which had not been seen before in the world literature), such as the use of a model with fixed effects instead of an unobservable effect model for panel data. I decided to take such a step where the procedure used so far in the literature gave uninterpretable results.

The sample consists of 2977 firm-year observations of Polish-based companies quoted on the Warsaw Stock Exchange – WSE (Poland) between 2004 and 2019. During the study, I used year-end standalone financial statements, auditors' opinions, share quotations that come from the Notoria base. Additionally, I analyzed data of the above-mentioned companies obtained from a court register. For each of these companies, I checked the accounting standards applied to the annual reports and designed a sample of 'switch companies' – companies that transferred their accounting framework from the Polish Accounting Rules (PAR) to the International Financial Reporting Standards (IFRS). These were all transfers to IFRS during the years 2004-2019 on WSE that referred solely to standalone financial statements. The sample excluded group financial statements. Table 1 and chart 1 present industry breakdown and year breakdown of the sample.

Table 1: Industry breakdown of the sample

Industry breakdown	Number of Firm-Year Observations	Percentage of Firm-Year Observations	Number of IFRS firms	Percentage of IFRS firms
Construction	232	8%	195	9%
Chemical	30	1%	30	1%
Energy	16	1%	13	1%
Mining	10	0%	10	0%
Information technology	153	5%	125	6%
Other	2259	76%	1475	71%
Media	59	2%	58	3%
Real Estate	74	2%	62	3%
Oil and gas	15	1%	15	1%
Food and drink	101	3%	78	4%
Telecommunication	28	1%	27	1%
Total	**2977**	**100%**	**2088**	**100%**

Fig. 1: Industry breakdown of the sample

In accordance with the well-recognized studies of Ball et al (2003), Ball and Shivakumar (2005), Basu (1997) and Barth et al (2008), I removed the outliers using the following empirical criteria for the variables:

- GROWTH > -100 or GROWTH < 100,
- LEV < 100 or LEV > -100,
- DISSUE < 100 or DISSUE > -100,
- BVPS < 100 or BVPS > -100,
- EPS < 100 or EPS > -100,
- ΔNI < 100 or ΔNI > -100,
- ΔCF < 100 or ΔCF > -100,
- ADAC < 2.000.000.

Table 2 presents descriptive statistics on all variables chosen for the analysis of accounting quality of the 'switch companies'. All of test variables and control variables were defined in a manner most similar to the corresponding formulas described in models [1]-[7], except the IDUM control variable for which (following the WSE methodology) industries were divided based on sub-indices:

- WIG-budownictwo – for construction industry,
- WIG-chemia for chemical industry,
- WIG-energia for energy,
- WIG-górnictwo for mining,
- WIG-informatyka for information technology,
- WIG-media for media,
- WIG-paliwa for oil and gas industry,
- WIG-spożywczy for food and drink industry,
- WIG-nieruchomosci for real estates industry,
- WIG-telekomunikacja for telecoms,
- others not included in any of the above sub-indices.

The significance of the means was calculated using the t-test (two-sided tests) and significance for medians was calculated using the Wilcox test (two-sided tests). The following are of material significance:

- ACC, SPOS, LNEG, P, DISSUE, XLIST for means significance of 1‰,
- ΔNI, EISSUE and CLOSE for means significance of 1%,
- CF and TURN for means significance of 5%,

- ΔNI, ΔCF, ACC, CF, SPOS, LNEG, P, LEV, EISSUE, DISSUE, AUD, XLIST for medians significance of 1‰,
- TURN for medians significance of 5%.

Table 2: Descriptive statistics

CLOSE	0,52	0,51	0,23	0,56	0,58	0,22	0,000***	0,000***

*where '***' means significance of 1‰ for p-value, '**' means significance of 1% for p-value, '*' means significance of 5% for p-value and '.' means significance of 10% for p-value.*

Each of the models applied was estimated twofold. First, for companies before transformation into IFRS (which was referred to as -pre); second, for the same companies but for periods after transferring into IFRS (which was referred to as -post).

For each of the 7 models used for measuring quality, there are estimated regressions with results (presented in tables) which depict the significance of particular variables on a given significance level ('***' for 1‰, ''**' for 1%, '*' for 5% or '.' for 10% significance). If there is no asterix or dot, it means that variable data was statistically insignificant in explaining the control variable.

Additionally, for measuring the significance of particular features, I applied the xgboost (eXtreme Gradient Boosting) method, as described by Chen et al (2016). The method refers to regression tree learning, characterized by Breiman et al (1984) and is widely used for classification, regression and ranking issues. Its undisputable advantage is the possibility of measuring the importance of the features (variables) used in the model. The importance is calculated separately for each tree as an improvement in the quality of the division in the tree and then it is weighted by the number of observations in nodes. Subsequently, it is averaged over all trees and scaled so that the most important feature has a measure of importance of 100. During model construction, 1000 regression trees were used for each model considered. The results are presented using graphs. If there is no such drawing for some models, it means that the tree with only one division was optimal and only one feature is important according to this criterion.

Results

Models [1]–[5] were applied to study earning smoothing within the sample.

Table 3-4 and charts 2-3 present results for model [1], which assesses earning management for companies before (-pre) and after (-post) the transfer into IFRS.

Applying the fixed effect panel model [1], I received the following parameters:

- n = 145, T = 1-12 and N = 388 (where n is the number of companies in the model, T means the number of years and N is the number of observations) for -pre companies,
- n = 205, T = 1-14 and N = 1223 for -post companies.

Table 3: Panel regression for model [1] – pre-transformation

	Parameter	p-value	Significance
SIZE	-0,05	0,003	**
GROWTH	0,01	0,314	
EISSUE	0,03	0,231	
LEV	0,01	0,092	.

wig_nrchom	0,00	0,980	
wig_spozyw	-0,22	0,045	*

The significant features for model [1] for companies in the years before the transfer to IFRS are the following variables:

- DISSUE, CF and CLOSE at 1‰ significance level,
- SIZE at 1% significance level,
- Food and drink at 5% significance level.

Fig. 2: Importance of features for model [1] – pre-transformation.

A ranking of importance estimated using the xgboost method indicates that the most important variables are CF, GROWTH, DISSUE and LEV, which is partially consistent with panel regression results for the same model.

Table 4: Panel regression for model [1] – post-transformation

	Parameter	p-value	Significance
SIZE	0,09	0,007	**
GROWTH	0,02	0,216	
EISSUE	0,08	0,243	
LEV	0,01	0,708

wig_paliwa	0,21	0,313	
wig_spozyw	0,31	0,336	
wig_telkom	-0,13	0,828	

The following variables were significant for model [1] in the years after the application of IFRS:

- CF at 1‰ significance level,
- SIZE at 1% significance level,
- TURN at 5% significance level.

Fig. 3: Importance of features for model [1] – post-transformation.

A ranking of importance estimated using the xgboost method indicates that SIZE is the most important feature, which is generally consistent with the outcomes of panel regression.

Tables 5-6 present results for fixed effect panel model [2], where, following Christensen et al (2015) approach, ΔCF is the change in year cashflows from operations scaled to net assets.

I received the following parameters:

- n = 145, T = 1-12 and N = 388 for pre-transformation companies,
- n = 205, T = 1-14 and N = 1223 for post-transformation companies.

Charts 4-5 show the importance of features calculated with the use of the xgboost method.

Table 5: Panel regression for model [2] – pre-transformation

	Parameter	p-value	Significance
SIZE	-0,01	0,664	
GROWTH	0,02	0,088	*
EISSUE	-0,02	0,335	
LEV	0,00	0,393	
DISSUE	-0,01	0,087	*
TURN	0,05	0,122	
CF	-1,02	0,000	***
AUD	-0,03	0,563	
CLOSE	-0,07	0,428	
wig_budow	0,03	0,647	
wig_energ	0,03	0,802

In model [2], for years after the transfer to IFRS, significant variables are:

- CF and TURN on 1‰ significance level,
- GROWTH on 1% significance level,
- variables construction and information technology on 10% significance level.

Fig. 5: Importance of features for model [2] – post-transformation

A ranking of importance estimated using the xgboost method indicates that CF is the most important feature in model [2] -post-transformation, which is partially consistent with the results of panel regression.

In model [3], the control variable CF, just like in formula [2], means year cashflows from operations scaled to net assets on the beginning of the year.

Tables 7-8 present results for fixed effect panel model [3] with the following parameters:

- n = 145, T = 1-12 and N = 388 for pre-transformation companies,
- n = 205, T = 1-14 and N = 1223 for post-transformation companies.

Charts 6-7 show the importance of features calculated with the use of the xgboost method.

Table 7: Panel regression for model [3] – pre-transformation

	Parameter	p-value	Significance
SIZE	0,00	0,815	
GROWTH	-0,01	0,256	
EISSUE	-0,01	0,740

According to model [5], the following variables are significant:

- constant value, POST, construction at the 1‰ significance level,
- XLIST, LEV, information technology and XLIST:POST at the 1% significance level,
- SIZE at the 5% significance level,
- CF at the 10% significance level.

Fig. 10: Importance of features for model [5].

A ranking of importance for model [5] estimated using the xgboost method indicates that the most important variables are GROWTH, LEV, CF and TURN, which is not consistent with the results of difference-in-difference regression.

Model [6] is a logistic regression for panel data described by Chan et al (2015). It was applied to estimate the potential earning management toward target profit.

According to Table 12, which presents the results for this model (where n = 221, T = 1 – 15 and N = 1611), the following variables are significant:

- SIZE, TURN, NUMEX, CLOSE, construction and information technology on 1‰ significance level,
- DISSUE and mining es on 5% significance level,
- XLIST and chemical on 10% significance level.

Table 12: Logistic regression for model [6]

As we can see, according to Table 13 the significant variables in model [7] are E:XLIST, XLIST:POST and XLIST:POST:E at the 1‰ significance level and E and XLIST at 5%.

Fig. 12: Importance of features for model [7].

A ranking of importance for model [7] estimated using the xgboost method indicates that only control data E explains its changes and none of the variable data is important.

Conclusions

The final results of increasing the accounting quality for companies after the transfer to IFRS is presented in Table 14. The volatility of the control data was calculated as the variance of the examined variable. An asterix ('*') means that it was based on residuals instead of raw data. Thanks to estimating models [3] and [4], it is possible to calculate the Spearman's coefficient between cashflows from operations and accruals. According to the accepted approach, the Spearman's coefficient level is interpreted as:

- weak correlation if it ranges from 0.00 to 0.29,
- moderate correlation if it ranges from 0.30 to 0.49,
- substantial correlation if it ranges from 0.50 to 0.69,
- strong correlation if it ranges from 0.70 to 0.89,
- very strong correlation if it is higher than 0.90.

According to recognized studies like Barth et al (2008), it is much more appropriate to examine the residuals of the models than the absolute value of CF and ACC. To test the equality of two variations (variances), the F-test was used. When testing other differences, the bootstrap test was used. It consists in drawing (with return) a sample of companies with the same number as the whole sample. For each such sample, the size of interest was determined and compared with the observed one. The whole procedure was repeated 1000 times. The percentage greater than the observed value shall be recognized as p-value. The match factor reported in the Table is an improved match factor that can serve as a measure of quality of the model if the number of explanatory variables is greater than 1. It informs us how many percent of the changes in the explanatory variable are due to changes in the explanatory variables.

Table 14: Accounting quality of financial statements

Earnings management	Pre-adoption	Post-adoption	Expected sign	Difference	Difference (%)	Level of significance

Small Positive NI (SPOS) (*N* = 1278)		-0,0100	–			No

Table 14 presents the outcomes of comparison of accounting quality in the period before (pre-) and after (post-) the transfer to IFRS in Poland, based on 804 pre- and 1802 for post-transfer observations. The variability of earnings (ΔNI) increases significantly in post-adoption periods, which is consistent with the expected decrease in earning management. According to Christensen, the change in the variability of earnings could also be driven by a natural change of scope or nature of activity (which is also accompanied by a change in cash flows from operations), rather than merely by a positive effect of the implemented regulations. However, an analysis of the variability of earnings relative to cashflows from operations (ΔNI/ΔCF) proves that it is not the case. My studies demonstrate that a positive change in the variability of earnings is a consequence of implementation of IFRS, because the variability of earnings is higher than the variability of cashflows from operations. Consequently, it strengthens the positive effects of implementation of IFRS on the quality of financial statements.

The negative correlation between accruals and operating cashflows in the periods before IFRS adoption changed significantly to a positive correlation, which is also argued to reduce earning management after the adoption of international standards while preparing financial statements. All of these changes were significant on 1‰ significance level.

The coefficient on small positive profits for model [6] is slightly below 0. Therefore, the inference about reduced earnings management towards target profit in periods after the adoption of IFRS is not allowed.

To sum up, it can be said that the analysis of the sample of companies quoted on WSE in 2004-2019 which transferred their accounting framework into IFRS is partially consistent with the prior research. In general, within the examined sample, there is a slight trend towards a decrease in earning management. However, some changes observed are not as strong as it would be expected given the results of previous studies. It demonstrates that IFRS are better than local Polish regulations (in terms of the quality of financial statement), but the difference was downright symbolic.
Consequently, this may lead to the conclusion that the prior local accounting regime (PAR) was on a fair level. However, consistent with the many caveats to this study, it can be concluded that the adoption of IFRS lead to even higher quality of accounting.

To summarize, the implications mentioned above support the conclusion that I contribute to the accounting literature on IFRS in the following ways. First, because no one has done such comprehensive research in the field of accounting in Poland before. The results of current studies confirm the outcomes of the research I conducted in earlier times (Piechocka-Kałużna 2019) on a broader but more general sample.

Second, my current studies exhibit the quality of financial statements prepared under IFRS in the same entities that had used Polish local GAAP previously. Even though the current studies are more detailed, targeted and objective than previously examined by Piechocka-Kałużna (2019) and Piechocka-Kałużna (2014), they still lead to the same conclusions. That in effect highlights the thesis that IFRS are rather of better quality.

Third, my studies generally prove that implementation IFRS as a framework for preparation of financial statements makes an improvement in accounting quality. Although they resulted in changes in accounting quality between the pre and postadoption periods, it is not a big difference. This leads to the conclusion that Polish accounting regulations should be considered as high-quality set of regulations as well. It likely explains why for many years the issue of IFRS implementation in Poland was approached with a distance. On the other way it may also justify why after using

IFRS in practice, many respondents to my earlier studies decided to change their attitude to IFRS. Like Frost et al. (2009), I do believe that academic research has a great role to play in the debate over the future of IFRS.

Moreover, I need to emphasized that accounting quality measures do not capture all possible benefits from IFRS adoption. Brochet et al (2013) find capital market benefits following mandatory IFRS adoption in the UK, which had previous domestic standards that are considered by Bae et al (2008) to be very similar to IFRS. According to DeFond et al (2010) and Wang (2014) the benefits are more likely to arise from changes in accounting comparability than changes in accounting quality.

Finally, I suppose that interesting, important and a novelty in relation to the approach used in the previous literature is also the innovative use of the XGBoost method. In addition, various types of modifications were applied (which had not been seen before in the world literature), such as the use of a model with fixed effects instead of an unobservable effect model for panel data.

I am confident that my findings should be of interest for research on financial statements' quality. This research might serve as a base for future studies on IFRS transfer on other markets. Furthermore, there exist considerable avenues for future research on the applying new approaches within financial reporting area as XGBoost.

A Different Approach to Inflection Points Detection In L-Shape Curves

Alexandra BAICOIANU
Transilvania University of Brașov, Brașov, Romania
a.baicoianu@unitbv.ro

Bianca A. LIXANDRU

andreea.lixandru@student.unitbv.ro

Abstract

This paper is organized around the problem of detecting the inflection point in a L-shaped curve. Nowadays, this problem is often encountered both in academic environment and in real situations, being found in fields such as engineering, mathematics and acoustics. This research study extends two specific procedures for detecting the inflection point in L-shaped curves: triangle method and optimal regularization method. A number of different experiments have been used to determine and recommend which method is superior and in which situations. We defined heuristics for which we defined an adaptive way of working given by the curve offered as input. Our research is focused on making both correct and efficient calculations, using parallel computation for example. In the following sections we will present the simplification of the curve, the methods, their results, the comparison between the two methods and all the conclusions.

Keywords: Inflection Point, SVD, L-Shaped Curve, Triangle Method, Simplified Curve, Optimal Regularization Method, Adaptive Algorithms.

Introduction

This article describes two ways of detecting the inflection point in a L-shaped curve. In order to solve this issue, we propose two procedures. The first solution is to simplify the curve and apply the algorithm for detecting the optimal regularization parameter, while the second solution is to simplify the curve and apply the triangle method.

Our algorithms need regularization and some of the most commonly used methods of regularization are: Singular Value Decomposition (SVD), Generalized Singular Value Decomposition (GSVD) [Rodriguez G., Theis D. (2005)], Tikonov Regularization and hybrid methods derived from the Krylov, Arnoldi, Lanczos techniques [Gazzola S., Novati P., Russo M. R. (2015), Sanders T., Platte R. B., Skeel R. D. (2020)]. Following research, we decided to use Singular Value Decomposition for regularization, since its main benefit is to reduce computational cost.

The preferred method is to use a simplified curve instead of a normal curve because it reduces noises and redundant information, examples in Fig1. (a) and (b), and hence facilities the analysis of derivatives. Also, it allows us to generate an accentuated curve and to identify the point more easily. For the points we used the logarithmic scale because this is a more efficient and compact way of displaying numerical data over a very wide range of values. Also, as we want to obtain only the significant points from the curve, we normalize all the data as to reduce large distances between points.

Fig. 1: (a) Curve without simplification

Fig. 1: (b) Curve with simplification

After the first stage of simplification, we need to apply the two algorithms. A very good practice to reduce noise and unnecessary points is to use a simplified curve to compute the algorithms. More than G. Rodriguez and D. Theis (2005) tried in their research study which propose an implementation for detecting the optimal regularization parameter [Rodriguez G., Theis D. (2005)], we tried to make a variadic selection to choose multiple or less points and see which constant is applied better. In their research, G. Rodriguez and D. Theis (2005) proposed a distance smaller than the distance between the first and last point divided by 2*number of points. We tried to divide by a number of 3*number of points, 5*number of points, 6*number of points and 10*number of points and obtained better results in almost all cases. As for the optimal regularization method G. Rodriguez and D. Theis (2005) had a different way to choose the inflection point. We chose the inflection point as the minimum wedge product, because we noticed that not all L-shaped curves have a wedge product of less than -0.5.

For the second algorithm, an excellent starting point was the triangle method proposed by P. Ch. Hansen, T. K. Jensen and G. Rodriguez (2007) [Hansen P. Ch., Jensen T. K., Rodriguez G. (2007)]. Though this algorithm satisfied a numerous cases, we tried to improve their method and ran the algorithm over the simplified curve which turned out to be a very good idea. Moreover, we used Adaptive Pruning Method on the simplified curve, but this technique did not show impressive results.

We also followed the research of A. Kerkri, J. Allal and Z. Zarrouk (2019), which presents their results on triangle method and adaptive pruning method [Kerkri, A., Allal J., Zarrouk Z. (2019)]. As for our own input, we improved triangle method and ran the algorithm over simplified curve. The results we obtained will be presented in the following paragraphs.

The technique by which A. Cultrera and L. Callegaro (2020) solve the issue of finding the inflection point in a L-shaped curve [Cultrera A., Callegaro L. (2020)] had a beneficial impact on this paper, being a good source for further research. Their algorithm includes the Menger curvature of a circumcircle and the golden section search method, which will not be presented in this research study.

Design and analysis of computational experiments

These notations are mostly used in the context of our research study:

n - initial number of values, integer value
p - number of points from simplified curve, integer value
ε_1, ε_2, ε_3 - tolerance, constant values, chosen
x - velocity, uni-dimensional vector
b - pressure, uni-dimensional vector
$|b - Ax|$ - residuals, uni-dimensional vector
$|Hx|$ - solution norms, uni-dimensional vector
P - point with x value equal to logarithmic value of residual and y value equal to logarithmic value of solution norm

We will compare optimal regularization parameter and triangle method and try to decide which algorithm is better. The main problem that arises when applying this kind of algorithms is that they will not provide the best solution in all cases. So, we used two adaptive algorithms that use heuristics rules to obtain a satisfactory result. Before running the algorithm we have to simplify the curve, after which we will apply the two algorithms in turn. All of these will be presented in the following sections, after which we will draw conclusions regarding the positive and negative aspects of the algorithms.

The stages of curve simplification

The first stage involves understanding whether the solution is roughly in the kernel of the regularization operator. If the condition is met, our curve is not L type and then the corner search is impractical. The above is possible through the detection of exceptionally small semi-norms, with a test of the type:

$$\frac{\min |Hx|}{\max |Hx|} < \varepsilon_1$$

The subroutine applies this test in conjunction with:

$$\min \left\{ \frac{|Hx_i|}{|x_i|}, i = 1, \dots, n \right\} < \varepsilon_2.$$

Whenever, the 2-norms of the regularized solutions are provided. The tolerances ε_1 and ε_2 are constants of the algorithm. Their values have been established to 10^{-12} and 10^{-4} respectively, working in double precision, while the results do not appear to be much sensitive to any changes in these parameters.
We then compute the points, P_i of the L-curve:

$$P_i = \{\lg |b - Ax_i|, \lg |Hx_i|), i = 1, \dots, p$$

and the vectors, v_i:

$$v_i = P_j - P_i, i = 1, \dots, p - 1, j = i + 1$$

As to remove clusters we remove all the "short" vectors, i.e. those used to validate the condition:

$$|v_i| < \varepsilon_3,$$

and assigning q acceptable vectors, with $q \leq p$. The constant ε_3, formerly established at $\frac{|P_p - P_1|}{2*p}$, is rather significant, because it allows the use of more or less vectors. When we divide to a value that is inferior to $2 * p$, we obtain less vectors. Alternatively, if we divide to a greater value than $2 * p$, we further the number of vectors in simplified curve. While considering lower values may provide very good results, it may also lead to risky over-estimates. Therefore, this is the reason why we decided to analyze the choice of ε_3.
To simplify the curve, we tried multiple approaches. An essential element for simplifying the curve is the number by which the value of the distance between the first and the last point is divided. This helps us keep track of the number of segments on which the algorithm will run.

The number chosen for division depends on the number of points in the curve. We will exemplify this for a curve with 100 points and the values 2, 5, 6 and 10.

Fig. 2: Curve with divide number 2 $*$ *p*

It can be seen in Fig 2. that the inflection point overlaps for both methods. Moreover, the point chosen is very high because as very few segments are chosen, an accurate choice would be practically impossible.

Fig. 3: Curve with divide number 5 $*$ *p*

It can be seen in Fig 3. that the triangle method provides a satisfactory result, but for the optimal parameter method, we notice that the inflection point is chosen on the right side which leads to the possible loss of important data.

Fig. 4: Curve with divide number 6 $*$ *p*

Fig 4. shows that the results are very good and that both methods propose some satisfactory inflection points.

Fig. 5: Curve with divide number $10 * p$

In Fig 5. many segments are already chosen and this produces an unexpected result for both algorithms.
As we saw in the previous examples an important role in determining the inflection point is the number of segments that we use as input for the algorithm. Therefore, based on the number of points, we need to decide which constant to use for division. With a large number of points, we will choose a smaller number. Conversely, with a small number of points we will choose a larger number. Thus, we may conclude that this is a problem-dependent heuristic and requires repeated attempts.

An adaptive algorithm for detecting the optimal regularization parameter

This section aims to introduce an algorithm designed to detect the optimal regularization parameter in truncated singular value decomposition (TSDV) regularization methods for the numerical solution of gravely "ill-posed linear systems" [Rodriguez G., Theis D. (2005)].

The considered algorithm merges a geometrical approach meant to identify the corner of the L-curve related problem with a set of experimental guidelines. A linear system of equation is $Ax = b$. We will refer to the state of "ill-conditioned when the condition number $k(A) = |A||A^{-1}|$ in a given matrix norm is of the same order of magnitude or larger than the reciprocal of the relative precision on the entries of the matrix A and of the right hand side vector b" [Rodriguez G., Theis D. (2005)].

Next, we apply the algorithm over the simplified curve and calculate the wedge product for each vector in the curve:

$$w_i = \det([v_i, v_j]), j = i + 1$$

We have to choose which is the point which represents the inflection point. We compute all the determinants between all consecutive vectors from curve (order of vectors is important) and the smallest wedge product is the inflection point we searched for:

$$point_l = \min(w)$$

For the given curve we will consider each two consecutive vectors in ascending order, which are defined by an angle $\propto \approx \frac{-\pi}{2}$. The corner exploration can be obtained by finding the minimum p-coordinates of the products with a w between two successive vectors.

Fig. 6: Identification of inflection point in simplified curve

In Fig 6. it can be seen that the vectors are oriented from right to left and that for every two consecutive vectors the point at their intersection is taken into account.

In addition to the algorithm proposed by G. Rodriguez and D. Theis (2005), we have modified the way in which the number of segments is chosen. Aside from that, we opted out the conditions containing ε_1 and ε_2 because we noticed that those values negatively influenced the results. For example, for some L-shaped curves, the algorithm predicted that they would not be L-shaped due to the condition with the ratio.

Using the adaptive algorithm proposed by us on multiple curves we discovered the following particular cases:

- If simplified curve contains just a vector, algorithm returns left point of the vector.
- If simplified curve contains two vectors, algorithm returns right point from first vector.
- If we use as input a curve with collinear points, algorithm returns right most point in the curve.

Triangle Method

Here, we aim to illustrate a robust and adaptive implementation of the L-curve criterion as to locate the corner of a discrete L-curve comprising a log-log plot of correlative residuals and solution norms for the regularized solutions describing a method with a discrete regularization parameter. First, we need to remove all the points with zero norm. Hence, let us consider the following tuple of L-curve points:

$$\left(P_{i_1}, P_{i_2}, P_n\right), i_1 = 1, \dots, n-2, i_2 = i_1 + 1, \dots, n-1$$

and determine the corner as the triple defined by a minimal oriented angle $\theta(i_1, i_2, i_n)$. When all angles $\theta(i_1, i_2, i_n)$ are greater than $\frac{-\pi}{8}$, then the L-curve is considered "flat" and the leftmost point is designated. Please consider that P_n, the leftmost point, is always included in the calculations.
We calculate the following vectors:

$$v_1 = P_{i_2} - P_{i_1}$$
$$v_2 = P_{i_1} - P_n$$

We compute for each pair of vectors:

$$\theta = \frac{-v_1^T * v_2}{|v_1|^2 |v_2|^2}$$

Also, we have to determine the weight computed as:

$$w = \det\left([v_1, v_2]\right)$$

Through these stages, we have to find the maximum θ which is bigger than $\cos(\frac{7\pi}{8})$ and have a weight smaller than 0. Also, the angle θ is very important because it should be bigger or smaller than a constant which allows us to predict that the angle between two segments is big enough to say that the intersection between that two vectors is the point we were searching for.

For the algorithm proposed by P. Ch. Hansen, T. K. Jensen and G. Rodriguez (2007) we tried several experiments with the $\cos(\frac{7\pi}{8})$ which provided very similar values and we obtained the same results. Like for the other algorithm, the simplification of the curve becomes very significant in obtaining a satisfactory result.

Through our experiments we considered several scenarios and we discovered some particular cases such as:

- If simplified curve contains only two points, algorithm returns first point.
- If curve contains three collinear points, algorithm returns second point.
- If curve contains multiple collinear points, algorithm returns a random point from right side.

Comparative Analysis of Algorithms

A helpful thing for these two algorithms is that we use simplified curve because simplification is beneficial for implementation. It helps us to remove the noise and redundant points from the curve which means that the simplified curve contains only significant points and more realistic data.

Following multiple experiments, we found that the optimal regularization parameter algorithm is better than the triangle method because this algorithm has satisfactory results even in cases where the curves are very noisy or not L-shaped.

We created an interactive interface by means of which we could see the results of the two algorithms in order to compare them and see what happens depending on the parameters we choose.

Fig. 7: Visualization of the division number of optimal regularization method

Fig 7. it is illustrated the interface which we used to do the all experiments. This shows an example in which the division number for optimal regularization method was set at value 6 and the angle for triangle method was set at 2.74 value, which is the equivalent of $\cos(\frac{7\pi}{8})$.

The project is medium in size and the implementation of the algorithms was done in C++ and with the help of the Python language we made a friendly interface with which we managed to see the results and call algorithms with various parameters much easier. One of the challenges encountered in carrying out the project was the optimization and one of the ways in which we performed efficient calculations was to solve the linear systems by parallel computation.

Our implementation uses Math Kernel Library (MKL) which is a library that has the following advantages: optimizations, efficiency and the possibility to have parallel computation. In developing our algorithms, MKL was very helpful because we managed to make calculations much faster due to the ability to make parallel calculations. We used this advantage of MKL to treat the following situations: multiplication of medium and large matrices, calculation of the inverse of a matrix.

Conclusions

We detailed new adaptive algorithms used to identify the corner of a discrete L-curve. It was shown that some L-curves are ill behaved due to particular features of the SVD coefficients. In such situations, any L-curve algorithms would fail to find the exact optimal solution, regardless of how it may have been implemented.

But using several numerical examples, we noticed that the optimal parameter method offers very good solutions in almost all cases. It is an algorithm that gives satisfactory results even when we are talking about collinear points. It is a fairly stable algorithm that provides a predictable result.

In most situations, the triangle method also returns a very good result. However, it is not desirable for this algorithm to be used for curves that contain only collinear points or points that are placed on an approximately straight line. In this case, the algorithm would be quite unpredictable.

In some particular cases you can configure the behaviour of the algorithm for both methods may be configured.

Escape Clauses vs. Strength of Fiscal Rules – Experience of EU Countries

Slawomir FRANEK

University of Szczecin, Poland
slawomir.franek@usz.edu.pl

Abstract

One of the criteria for assessing the strength of fiscal rules is the occurrence of escape clauses, which allow to provide fiscal rules with resilience to shocks and give those rules flexibility. The meaning of this criteria is demonstrated by the experience related with the sharp downturn of sustainability in public finances in the face of the COVID-19 pandemic. The following paper indicates that despite the still insufficient commonness of escape clauses in fiscal rules, their presence is a factor affecting the strength of fiscal rules. The studies conducted have confirmed that the real effect of including the escape clause in the fiscal rule on the Fiscal Rule Strength Index is admittedly not decisive, but noticeable enough that it allows to demonstrate statistically significant differences in the strength of fiscal rules in relation to the criteria of occurrence of escape clauses. It was pointed out, in addition, that a challenge for the fiscal stability of EU Member States will be determining the moment of return to the use of rules in relation to which the escape clauses have been applied in response to the crisis caused by the COVID-19 pandemic.

Keywords: fiscal frameworks, fiscal rules, COVID-19.

Introduction

Fiscal rules are understood as permanent constraints of the fiscal policy expressed in the form of a synthetic measure determining the permissible value of basic budgetary parameters (Kopits, Symansky 1998). In this way, the boundaries of fiscal policy are set, and they cannot be changed frequently. This would be on the assumption that rules are objectives established in the form of a legal act or a political obligation, which can rarely be revised (e.g. within an electoral cycle) and are binding for at least three years. In line with this approach, medium-term budgetary frameworks or expenditure ceilings treated as multi-annual projections that can be revised annually are not considered fiscal rules (Lledo et al. 2017). There is extensive literature on fiscal rules, covering both the characteristics of factors leading to their implementation and the consequences of their application. For example, using a heavy section of countries, Altunbas and Thornton (2017) investigate the economic, institutional and political characteristics of countries affecting the likelihood that the numerical rule will be adopted as part of a fiscal strategy to reduce public debt levels. Research on the consequences of applying fiscal rules indicates that they reduce macroeconomic volatility (Fatas and Mihov, 2006), decrease the procyclicality of fiscal policy (Bergman and Hutchison 2015), and cause public debt to be declined (Azzimonti et al. 2016), lower budget deficits (Caselli and Reynaud 2020) and mitigate the probability of government debt crisis (Asatryan et al. 2018). An analysis of a comprehensive sample of over 140 countries over the period 1985-2015 reveals that fiscal deficits averaged 2.1 percent of GDP in the absence of fiscal rules against 1.7 percent of GDP in the presence of fiscal rules (Caselli and Reynaud 2020).

More refined analysis, using the strength of the fiscal rule (instead of a dummy variable for the existence of a fiscal rule) - and correcting the endogeneity issues - reveals that only well-designed fiscal rules lead to more fiscal discipline (Caselli and Reynaud 2020). This means that in order for there to be efficiency in the application of fiscal rules, postulates regarding their construction should be formulated (Ayuso-i-Casals et al. 2009). They refer to such criteria as: enshrinement of the rule, monitoring system, system of sanctions related to breach of this rule, rules of waiving the rule.

Fiscal rules should set out in advance the procedures for suspension them (so-called escape clauses), especially in emergency situations such as natural disasters or a sharp deterioration of the economic situation. The credibility of the rule is demonstrated by the extent to which the possibility of abandonment of rule (or a temporary suspension) has been defined as a unique case and applied as a last resort and not as a situation that would find use in all conditions.

The aim of the paper is to establish the meaning of escape clauses for the strength of fiscal rules of EU countries, measured by the value of the *Fiscal Rule Strength Index.* In the analysis, information about fiscal rules included in the *Fiscal rules database* from 2008-2018 (provided by European Commission) were included. Additionally, a review was made of the escape clauses launched in the EU countries as a response to fiscal disturbances caused by the COVID-19 pandemic.

Flexibility of Fiscal Rules

Flexibility of the rule means the possibility of mitigating impact beyond the influence of the authorities through a well-formulated exit clause launched by a self-standing institution. When designing fiscal rules, escape clauses play a fundamental role in ensuring a proper balance between commitment reliability on the one hand and shock response flexibility on the other. It is generally acknowledged that the budgetary framework should be structured with sufficient flexibility to enable an appropriate response to large negative and unpredictable shocks. However, this should not jeopardize the discipline imposed by rules and benefits associated with ensuring the credibility of government commitment. Generally, it can be achieved thanks to well-defined escape clauses, which take into account the occurrence of such shocks. Careful design is important to avoid abusing escape clauses to circumvent fiscal rules. Research on the effects of escape clauses is not unequivocal. On the one hand, the use of escape clauses may lead to lower likelihood of compliance, contributing to an increase in public debt (Reuter, 2019). However, it also turns out that well-defined escape clauses make the fiscal framework less pro-cyclical (IMF 2013). Bova et al. (2014) indicate that flexible fiscal rules taking into account escape clauses and excluding public investment favor countercyclical fiscal policy. When it comes to their design, five main dimensions of escape clauses can be identified: (i) the nature and magnitude of future shocks; (ii) the magnitude of the budgetary response to the shock; (iii) the length of the period during which the rule would be relaxed or suspended; (iv) the path to full rule compliance; (v) and responsibility for clause activation and monitoring (Ter-Minassian 2010).

Only when escape clauses have predefined triggering conditions and defined mechanisms of returning to previously used rules, they meet the requirement of fixed rules and at the same time substantially limit discretion. The existence of an escape clause in a rule means fitting with a mechanism that enables systemic actions aimed at restoring the current macroeconomic balance.

A well-designed escape clause should therefore specify: 1) the reason for the application of the clause; 2) the relationship between this reason and the conditions defined in the applicable legislation; 3) suspension period of the rule; 4) conditions that should be met in order to return to the rule's application. It is also desirable that the activation of the clause be approved by parliament, both in terms of budgetary implications and to ensure the proper use of the clause (IMF 2020).

A few reasons justify that escape clauses must have country-specific elements. This is due to the type of shocks the country is most exposed to and the sensitivity of individual budgetary aggregates to them. Similarly, the available fiscal space for shock absorption depends on the situation of public finances in a given country (European Commission 2010). These factors are a sufficient argument to engage fiscal councils in the implementation of escape clauses. Therefore, it is proposed that truly exceptional circumstances allow for triggering of a clause. This means that their use is strictly limited to (i) harsh economic recessions or (ii) natural disasters or other events beyond the control of the government that have an overall adverse impact on a budget balance of at least 1% of GDP. The latter threshold ensures extraordinariness of the event and indicates a considerable impact on public finances; thus, its occurrence is exceptional (AIReF 2018). An independent fiscal institution should evaluate conditions based on a combination of macroeconomic indicators that trigger an escape clause. Creating institutions responsible for activating escape clauses is a key area where their involvement can contribute to finding a fair balance between flexibility and credibility of commitment. This is particularly important due to the fact that the state of the economic situation is assessed on the basis of the forecast of the output gap level. In practice, though, output gap revisions are quite frequent and ambiguous in the context of expansion and recession. Relying on real GDP growth projections is not conducive to the accuracy of the forecast cyclical position. Thus, it can be concluded that the revisions of the output gap are mainly due to errors in GDP growth forecasts, and not to corrections of potential GDP growth (Hernández de Cos et al 2016). This means that fiscal policy should be judged against the context of uncertainty of forecasts. Hence the need to involve an independent fiscal institution as an arbiter assessing the probability of achieving the assumed macroeconomic parameters.

The size of the allowed fiscal response to the shock should be decided on a case-by-case basis. In the event of a natural disaster, it may be sufficient that the derogation from the rule may be temporary. As regards a harsh economic recession, a more decisive fiscal impulse may be required. In any case, the size of the allowed fiscal impulse should also depend on the fiscal position of a given country's budget, i.e. the fiscal space available. In such case, it should

be sought that the escape clause has a specific period of validity, preferably no more than one year. In a situation where the fiscal conditions do not radically improve within this time, it will be possible to extend it, but after reassessing the fiscal outlook. For fiscal credibility, it is important to clarify the procedure to be followed in order to restore fiscal discipline. This implies an indication of criteria, whose achievement will mean a return to the application of the rule.

Escape clauses are designed to deal with the consequences of large but temporary shocks. More sustained trends (for example, a permanent reduction in growth potential due to the situation in the labor market or demographic trends; or a lasting change in a country's resources) require a permanent alteration in the purpose of the rule (or, in some circumstances, even the basis of the rule). Therefore, it is good when ex ante provisions concerning such changes are included in the provisions introducing the fiscal rule. This is useful for avoiding re-opening of political debates on the entire rule framework in the event of permanent changes. In practice, however, it would be speculative to predict all factors that may require a revision of the rule. That said, the continual recourse to escape clauses has nothing to do with designing flexibility, but is due to the demands of the political economy.

Methodology and Data

The research of the importance of escape clauses was conducted in two stages. First, the number of fiscal rules with built-in escape clauses for EU countries was analyzed. Secondly, the strength of fiscal rules with built-in escape clauses was compared with the strength of fiscal rules without escape clauses. For this purpose, the Mann-Whitney (two-sample Wilcoxon rank-sum) test was performed. The source of data for these analyzes is information on fiscal rules in EU countries published by the European Commission in the *Fiscal rules database*. These analyzes use the FRSI (Fiscal Rule Strength Index), which is a synthetic measure of the strength of the rules. The presence of an escape clause is one of the characteristics of a fiscal rule taken into account in measuring the strength of the rule. The methodology of calculating the strength of fiscal rules assumes the influence of five criteria: 1) legal base of rule, 2) binding character of rule, 3) monitoring bodies of rule, 4) correction mechanisms of rule, and 5) resilience to shocks of rule. The occurrence of an escape clause in a fiscal rule is one of the elements for the assessment of criterion 5 (the other criteria for resilience of shocks are: existence of budgetary margin defined in relations to the rule; targets defined in cyclically-adjusted terms, and exclusions from the rule).

Additionally, the legitimacy of launching escape clauses in response to the fiscal crisis caused by the COVID-19 pandemic was examined. The research in this area was based on the fiscal forecasts included in the EU countries' Convergence/Stability Programs. The fiscal effects of Covid-related fiscal measures approved in individual EU countries in 2020 are shown by differences in the forecasts of the core macroeconomic parameters between Convergence/Stability Programs from 2020 and Convergence/Stability Programs from 2019. The source of data for these analyzes are the texts of Convergence /Stability Programs for EU countries available on the website of the European Commission

The Importance of Escape Clauses in Fiscal Rules of EU Countries – Empirical Analysis

The recent global financial crisis (2008-09) has clearly revealed the shortcomings of a budgetary framework that does not contain appropriate escape clauses. At that time, only about half of the countries operating under the fiscal rule were able to conduct a counter-cyclical political response within the rule. Other countries had to either explicitly modify the rule or abandon its application (Ter-Minansion 2010). This meant that decisions on this matter were made ad hoc. However, while recent years have brought a noticeable increase in the number of fiscal rules across the EU, it has not resulted in a significant spread of escape clauses.

Tab. 1: Number of fiscal rules (including rules with escape clauses – EC) in EU countries

	2008		2014		2015		2016		2017		2018

Source: Own calculations based on Fiscal Rules Database, European Commission

Table 1 presents the number of fiscal rules in the European Union countries, with the division into: balance budget rules (BBR), debt rules (DR), expenditure rules (ER) and revenue rules (RR). Additionally, the number of rules with built-in escape clauses is listed for each group. The noticeable increase in the number of fiscal rules since 2008 has not led to a considerable increase in the importance of escape clauses. The share of rules containing escape clauses in the total number of fiscal rules in force across the EU has remained slightly above 30% in recent years, and was the highest in 2016 at 40%. This means that rules containing escape clauses are still not yet generally used. There is still a dominance of rules with no escape clauses. In 2018, in six EU countries none of the fiscal rules had any escape clauses still. These countries were: Czech Republic, Greece, Luxembourg, Hungary, Sweden, UK. It is pertinent to note that in the Fiscal Rules Database, the European Commission also takes into account subnational fiscal rules (unlike the IMF database, which only contains information about national rules). The problem of the lack of escape clauses mainly concerns the rules applied to local governments in EU countries. In 2018, out of all fiscal rules applicable to local governments, only two had an escape clause. This represented 8.3% of the fiscal rules used only in local governments. In the previous years, the share of rules with escape clauses among rules for local governments was even smaller.

Similar research conducted by Nandeleng and Ellyne (2020) based on the analysis of 20 sub-Saharan African countries identifies 57 fiscal rules in force in these countries in 1997-2016 and indicates that only 15 of them have escape clauses. Nandelenge and Ellyne also note that there is a lack of unambiguous criteria for activating and deactivating escape clauses in these countries.

The inclusion of IMF data (which cover 96 countries around the world) in the analysis shows that fiscal rules with built-in escape clauses are also uncommon on a global scale. At the same time, similarly to EU countries, the number of rules containing escape clauses has increased in the last decade. A comparison of data for 2008 with that for 2015 (the latest available in the IMF database) shows that in 2008, across the EU the share of escape clauses in the total number of national fiscal rules was two times lower than in the group of 96 countries listed in IMF statistics. Until 2015, both groups of countries saw a substantial deterioration in this share, with higher dynamics for the EU countries. Thus, in 2015 the share of escape clauses in the total number of national fiscal rules in EU countries was comparable to their share in 96 countries around the world.

Despite the still insufficient universality of escape clauses in fiscal rules, their presence is a factor for the strength of fiscal rules. Since 2004, the European Commission has published data on the FRSI constructed to capture the influence of institutional features of fiscal rules on effective containing of budgetary imbalances. The presence of an escape clause is one of the characteristics of a fiscal rule taken into account in measuring the strength of the rule. Table 1 demonstrates the differences between the mean FRSI value for rules containing escape clauses and the mean FRSI value for rules without escape clauses.

Tab. 2: Mann-Whitney U test statistics for Fiscal Rules Strength Index (sample 1 – rules with escape clauses, sample 2 – rules without escape clauses)

Source: Own calculations based on Fiscal Rules Database, European Commission

A comparison of the FRSI values over subsequent years shows that in each of the analyzed years the strength of rules with built-in escape clauses is higher than the strength of rules without escape clauses. The values of the Mann-

Whitney test (two-sample Wilcoxon rank-sum) confirm the statistical significance of the differences between the average FRSI values for rules with escape clauses and the average FRSI values for rules without escape clauses. Importantly, in each of the studied years, these differences were higher than 1 (usually higher than 2). This means that the strength of fiscal rules is not determined by escape clauses. Thus, the genuine effect of entering an escape clause in a fiscal rule on the perception of the rule's strength is not considerable, but it is noticeable enough to show statistically significant differences in the strength of fiscal rules against the criterion of the presence of an escape clause.

Escape clauses in fiscal rules of EU countries as a response to the fiscal crisis caused by the COVID-19 pandemic

Experiences of many countries show that the credibility and efficiency of escape clauses requires a precise definition of conditions for their activation, so that they cover events that are actually beyond the control of the government (Mbaye and Ture, 2018). An example of such an event is the COVID-19 pandemic. The scale of the fiscal effort needed to protect member countries from the consequences of the COVID-19 crisis required the use of more far-reaching flexibility under the Stability and Growth Pact. Hence, on 20 March 2020, the European Commission published a communication in which the general escape clause of the Stability and Growth Pact was activated based on the severe economic downturn caused by the coronavirus outbreak throughout the EU and the need for a sufficiently large fiscal response (European Commission 2020). On 23 March, the ECOFIN Council agreed with the European Commission that the conditions for applying the general escape clause of the EU fiscal framework had been met. It continued that this activation would allow member states to depart temporarily from the budgetary requirements that would normally apply, thus enabling them to tackle the economic consequences of the pandemic. Overall, EU member states approved more than 350 different Covid-related fiscal measures. Of these, nearly half are fiscal expenditures (EU Independent Fiscal Institutions 2020).

Chart 1: Differences of forecasts [in pp.] between CP 2019 and CP 2020 for EU-28 countries
Source: Own calculations based on Stability and Convergence Programs, European Commission

The fiscal effects of these activities in individual EU countries in 2020 are shown by differences in the forecasts of the core macroeconomic parameters between Convergence/Stability Programs from 2019 and Convergence/Stability Programs from 2020. Chart 1 shows the differences (in percentage points) between the forecasts for 2020 for the EU countries of such macroeconomic variables as: GDP growth, general government balance, public debt and general

government expenditure included in Convergence/Stability Programs (CP) of 2019 and 2020. In this way, changes in the expected macroeconomic situation caused by the COVID-19 pandemic have been shown. The sharp economic downturn caused by the lockdown has led to a deterioration in the expected fiscal indicators, forced by the need for rapid introduction of unprecedented economic measures. The scale of deterioration in the Member States' economic situation is evidenced by the fact that in 2/3 of the EU countries the public debt to GDP is assumed to increase by more than 10 pp., and in over 80% of the EU countries the budget balance will deteriorate by more than 5%. At the same time, in as many as nine EU countries the economic growth rate is to drop by more than 10 pp. compared to the forecasts from 2019, and every EU country forecasts an increase of at least a few percent in the general government expenditure/GDP indicator. In nine countries, the increase in public expenditure to GDP is expected to exceed 10 pp compared to the 2019 forecast. These data show the extraordinary nature of the changes in fiscal conditions of all EU countries. It shall suffice to indicate that in each of the EU countries, the economic downturn in 2020 is assumed to be more than 5 pp. compared to the forecasts for 2020 published in 2019. In addition, in five countries (Cyprus, Greece, Italy, Spain, Slovenia) in 2020 the public debt ratio is forecast to increase by over 20 pp. compared to the levels assumed in the forecasts a year earlier. These figures are sufficient evidence of the need for extraordinary measures in the fiscal sphere. Such extraordinary measures are escape clauses.

At the end of May 2020, 19 EU countries launched an escape clause suspending national budget restrictions. In some cases, this activation was automatic with the announcement of a general escape clause. This was the case in Portugal, France and Italy. Other countries have their own fiscal rules and escape clauses. For example, in Germany, parliament approved a supplementary budget by majority - with a large fiscal package - and suspended the debt brake rule. While most countries only have exit clauses in place until the end of 2020, some have suspended their fiscal rules for a longer period. For example, the Czech Republic raised the ceiling for the structural deficit from 1% to 4% for 2021, with its gradual reduction by 0.5% annually until 2027. This decision was the subject of almost a month of debate and was heavily criticized, also by the Czech Fiscal Council. Italy has accepted the possibility of deviations in the structural deficit by 2032. Finland has activated escape clauses for a shorter period - until the end of 2022 - suspending expenditure ceilings, which is expected to allow for greater public spending of around EUR 0.5 billion per year (EU Independent Fiscal Institutions 2020). In Poland, the Public Finance Act was amended (Act of May 28, 2020 amending the Public Finance Act), which made it possible to suspend the stabilizing expenditure rule and apply an escape clause in the event of a declared state of epidemic and a simultaneous considerable deterioration in the macroeconomic situation. The condition for activating the escape clause is, in accordance with the provisions of the Public Finance Act, a drop in the annual GDP growth by more than 2 pp. against the average dynamics of GDP in the period of the business cycle.

Amidst the current crisis, there are several factors that justify the use of exit clauses:

- The need to use significant additional fiscal sources, which would result in breaking fiscal rules.

- The decline in economic activity will significantly change the budgetary situation by limiting tax revenues and increasing expenditure both in the form of automatic stabilizers (unemployment benefits) and discretionary ones.

- The fall in commodity prices means a reduction in the income of those countries that are commodity exporters.

Obviously, the escape clauses activation strategy, together with the determination of the amount of deviation from the rule, depends on the impact of the shock on public finances (health expenditure needs, the economic condition of households and enterprises) and the limitations resulting from the available fiscal space. Depending on the individual national budgetary frameworks, the initiation of escape clauses, as well as their expiry, are carried out either by the government, parliament or self-standing bodies. In some countries, independent fiscal institutions are tasked with assessing whether the government's launching of an escape clause is justified. This was the case in countries like Austria, Belgium, the Czech Republic and Finland (OECD 2020).

Some EU Member States lack the "classic" escape clause for their national fiscal framework. For example, in Slovakia the public debt rule based on the Maastricht criterion, but stricter in terms of the debt limit, entails quasi-automatic sanctions when certain thresholds are reached. Exceeding the permissible debt levels triggers sanctions defined in the Slovak constitution. Although the fiscal framework shows exceptions to the imposition of sanctions (war, strong decline in nominal GDP, natural disasters), it still does not mean the same type of escape clause that exists at the European level (Eisl 2020).

Some escape clauses impose restrictions on how long fiscal policy may deviate from the objectives set out in the rule and requirements that must be met to return to fiscal goals. Specific requirements can make the framework more robust, but must strike the right balance between ensuring a quick reversion to the rule and avoiding sudden

corrections. Countries have adopted approaches with varying degrees of flexibility. The German constitution requires that the application of the escape clause in the event of a natural disaster or state of emergency is accompanied by the adoption of a "repayment plan" for additional loans "within a reasonable timeframe" (OECD 2020).

The economic impact of such a unique event as the current pandemic is associated with a high level of uncertainty and may require greater deviations or a longer return to the rule. For example, budgetary and economic forecasts in most countries are based upon standardization in the second half of 2020. Countries are now expected to follow the alignment path set out in the escape clause, in many cases anticipating a return to the rule within one or two years - in some cases there is no clear date as for EU activation, but this depends on the conditions. Considering the high level of uncertainty, countries should prepare plans based on the baseline scenario, activating the escape clause. Governments should be ready to reassess and use all the flexibility allowed under the framework, including the renewal or extension of escape clauses, if necessary. This makes it very important to keep the process fully transparent. A well-designed communication strategy has a fundamental meaning when launching escape clauses, to increase the credibility of the fiscal framework and avoid negative market reactions. An effective communication strategy should be based on simple and clear messages designed to inform the public and the markets about current economic developments and the assumptions behind fiscal forecasts and the uncertainties surrounding them.

Also, the possible extension of the use of an escape clause should follow the same principles that underlie the activation of escape clauses in the first place, including the revised plan to return to the rules. It is essential that this process is subject to external scrutiny and parliamentary approval, which will balance flexibility with credibility. This means that the EU countries will face a heated discussion on decisions regarding the coordination of fiscal policy, if the term of escape clauses is extended.

Conclusion

The presence of escape clauses in fiscal rules increases the flexibility of rules and their resilience to the appearance of shocks. Their occurrence supports the counter-cyclical impact of fiscal rules on macroeconomic conditions. However, the use of escape clauses requires careful prudence. The credibility of the rule is demonstrated by the extent to which the possibility of departing from it (or a temporary suspension) has been defined as a unique case and applied as a last resort and not as a situation that would apply in all conditions.

The analyses presented in the paper confirm that the recent years have brought a noticeable increase in the number of fiscal rules in the EU countries. Along with this increase, there has been no significant spread of escape clauses. The share of rules containing escape clauses in the total number of fiscal rules in force across the EU has been slightly above 30% in recent years, and was the highest in 2016 and accounted for 40%. This means that rules containing escape clauses are still not yet generally used. There is still a dominance of rules with no escape clauses. Similar trends occur in other countries of the world. Based on IMF data, the share of escape clauses in the total number of national fiscal rules in EU countries was comparable to their share in 96 countries of the world. The issue of the lack of escape clauses concerns especially rules for local governments.

At the same time, the presence of an escape clause is one of the characteristics of a fiscal rule taken into account in measuring the strength of the rule. A comparison of the FRSI values in the period 2008-2018 shows that in each of the analyzed years the strength of rules with built-in escape clauses is greater than that of rules without escape clauses. At the same time, research indicates that escape clauses are not the decisive factor that differentiates the strength of fiscal rules. This fact means that the genuine effect of entering an escape clause in a fiscal rule on the perception of the rule's strength is not considerable, but it is noticeable enough to show statistically significant differences in the strength of fiscal rules against the criterion of the presence of an escape clause.

The fiscal effects of the COVID-19 pandemic have contributed to the rapid activation of escape clauses for the fiscal rules of most EU countries. The initial point for these activities was the introduction of a general escape clause by the European Commission. However, actions in this respect may turn out to be insufficient. The macroeconomic uncertainty resulting from the COVID-19 shock may require further fiscal flexibility, including the renewal or extension of escape clauses. This means that EU countries will face sizeable challenges in the field of fiscal policy coordination if the escape clauses are extended.

Preferences of Rail Transport Passengers with Regard to Modern Technologies

Grazyna ROSA

University of Szczecin, Szczecin, Poland
grazyna.rosa@usz.edu.pl

Abstract

The aim of the article is to indicate and establish the hierarchy of the features of rail passenger transport services with regard to modern technologies most preferred by the service users, and their evaluation. In order to achieve this aim, a method of critical analysis of available secondary research results and a method involving a questionnaire in primary research were adopted. Own research was conducted on a representative sample of 331 young travellers.

Keywords: Modern Technologies, User Preferences, Passenger Transport, Rail Transport.

Introduction

Contemporary transport industry (including both passenger and freight transport services) is a part of the consumer market. The oversupply of services in the passenger transport industry stems from the development of private transportation which satisfies most of the demand for transport services on the market. The share of rail transport in passenger transport is small and amounts to approx. 3%, while car transport accounts for the remaining 97%. (Wykorzystanie i potencjał…, April 2017), (GUS 2019). The passenger transport industry is very dynamic and is undergoing various transformations which result primarily from changes taking place in the area of transportation. On the one hand, the phenomenon of congestion, heavy road traffic, and, as a result, longer travel time by means of private and national public transport (buses), and, on the other hand, a significant improvement of railway infrastructure, acquisition of modern rolling stock which enables spending travel time productively, gradual introduction of an integrated rail ticket, availability of electronic tickets additionally improve the competitiveness of railway companies in respect of road transport, mainly private transport.

This is chiefly reflected in the number of passengers, and in the case of rail transport in Poland it reached 280.3 million in 2015, which represented an increase of 4.2% compared to 2014 (269.1 million). The year 2016 saw an increase of 4.3% and ended with the result of 292.5 million passengers, while in the years 2017 and 2018 a further increase to 303 and 310 million passengers respectively was achieved. At the same time, these figures reflect that an average Polish resident travelled only several times in 2016, 2017 and 2018. (Wykorzystanie i potencjał…, 2017), (GUS 2019).

The aim of the article is to indicate and establish the hierarchy of the features of passenger rail transport services with regard to modern technologies most preferred by the service users, and to evaluate them. In order to achieve this aim, the method of critical analysis of available secondary research results and survey methodology, involving questionnaires in primary research, were applied.

Literature Review

Consumer behaviour on the market is limited by a number of factors, the most important of which include: consumer tastes and preferences; the amount of money available, i.e. an available budget, and the prices of alternative goods (Teoria wyboru konsumenta) [15.07.2019].

Preferences of consumers depend on their knowledge, opinions, emotions or beliefs; they are a reflection of their perception of a given product and brand. This perception is subjective (Rosa (eds.), 2015). Consumers' preferences result from the fact that they strive to satisfy their needs by selecting goods which are available on the market in

Cite this Article as: Grazyna ROSA "Preferences of Rail Transport Passengers with Regard to Modern Technologies" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

great numbers and which meet their expectations. These choices reflect their tastes, preferences and personalities; they are a determinant of demand, specifying the products consumers want to purchase. (Szymańska, 2012).

The analysis of the approaches to passenger transport presented in the literature reveals that for many years, common carriers and transport providers have assumed that if their services are relatively reliable and the condition of their vehicles (often outdated) does not pose an immediate threat to travellers, then the customers will be satisfied with the service provided (Bąkowski, Szewczuk (ed.) 2000), (Engelhardt, 2007, 2018), (Paprocki, 1996), (Wyszomirski, (ed.), 1994, 1998), (Tomanek, 2002). They considered price as the main instrument of competition. The analysis of the results available in the literature indicates that the capability to provide reliable services is insufficient to achieve and maintain a strong competitive position in a changing environment. The importance of standard services is diminishing. The role of knowledge, cooperation skills, entrepreneurship and innovation is growing. The importance of innovation in the field of transport service, technology as well as customer relations is recognised (Rosa, 2013, 2018), (*Koleje pasażerskie w województwach - dynamika zmian…* (b) kwiecień 2017), (Drewnowski 2019). The customers are increasingly demanding in respect of, for example, the quality of services offered, safety, provision of current information, the carrier's partnership approach, customer service, often even comprehensive logistics service on a national and international scale (Bocheński, Wojtkiewicz 2019), (Krawiec, Ćwiek, 2019), (Massel, 2019), (Mężyk, 2019), (Szałucki, 2019). Where these elements come to the fore, companies competing in the passenger transport market must carry out a professional analysis of the market and the preferences of customers in order to provide the values most appreciated by customers.

On the other hand, customer preferences in the field of modern technologies are a new subject which is insufficiently investigated in the literature (cf: Rosa, 2018.)

The preferences of passenger rail transport customers stem from the necessity to satisfy transport needs, which reflect their expectations and personality.

Research Method

The research was carried out from October 2017 to March 2018 on a random sample of 350 people from all over Poland, meeting the age requirement and thus constituting a homogeneous sample of “young adults” aged 18-29 years. Survey methodology involving a questionnaire was applied. The analysis of the completed questionnaires revealed that 19 of them were incomplete, and thus a sample of 331 persons was eligible for further study.

Table 1 presents the characteristics of the respondents based on the information contained in the particulars.

Table 1: Respondents' socio-demographic characteristics (N=331)

	Total (%)
Gender	
Female	50.61%
Male	49.39%
Education	
Higher education	18.54%
Secondary education	78.72%
Vocational education	2.74%
Household composition

City up to 99,000 inhabitants	32.22%
City with 100,000 to 199,000 inhabitants	14.29%
City with over 200,000 inhabitants	30.70%

Source: own work

The aim of the research was to select the key features of passenger transport services relevant to customers, and have these features assessed by the providers of rail passenger transport services in Poland in respect of modern technologies. In order to achieve the intended aim of the article, an attempt was made to answer the following research questions:

1. How important are characteristics of the services provided by railway companies in passenger transport in the context of marketing activities making up the modern technologies category?
2. What is the assessment of characteristics of the services provided by railway companies in passenger transport in the context of marketing activities making up the modern technologies category?
3. Which statistically significant socio-demographic variables correlate with the preferences of users of railway passenger transport services?

A hypothesis assuming that overall railway transport assessment grew along with increase in importance of particular categories of modern technologies to passengers was put forward in the research.

In order to answer the research questions and test the hypotheses, statistical analyses were carried out using the IBM SPSS Statistics version 25. The software was used to analyse the main descriptive statistics, characterise the respondents with the use of frequency analysis, as well as to carry out several Pearson's Chi2 correlation tests, student's *t* for independent samples, one-way analysis of variance, Pearson's *r* and regression analysis. The classical threshold of $\alpha = 0.05$ was designated as the significance level. The probability results of the test statistics at the level of $0.05 < p < 0.1$ were interpreted as significant at the level of statistical tendency.

Research Results

The respondents replied in the following scale: very important, important, less important, not important and expressed their assessment as follows: very good, good, bad, very bad. Analysis of the respondents' answers enabled drawing the following conclusions:

a) Basic descriptive statistics of the quantitative variables measured along with the test of normal distribution.

Firstly, basic descriptive statistics were calculated along with the Shapiro-Wilk test examining the normality of distribution of all measured variables on the quantitative scale. The result indicated that the distributions significantly deviated from the Gaussian curve. However, the skewness of all variables did not exceed the range of $-2 < Sk. > 2$, and thus it could be assumed that the variables have distributions close to normal.

Table 2: Descriptive statistics

Descriptive statistics	M	Me	SD	Min.	Max	Curt.	Sk.	S-W	p
Importance of modern technologies in rail transport services	**1.8**	**1.71**	**0.57**	**1**	**4**	**1.34**	**0.97**	**0.92**	**<0.001**
Assessment of the availability of modern technologies in rail transport services	**1.97**	**2**	**0.53**	**1**	**4**	**1.24**	**0.47**	**0.96**	**<0.001**
Overall assessment of rail transport services	2.1	2.09	0.49	1	4	1.74	0.2	0.96	<0.001

Source: own work based on primary research (N = 331)

b) The relations between socio-demographic variables and the preferences of the respondents regarding passenger rail transport services

In order to verify how socio-demographic variables, which are statistically significant, correlate with the preferences of passenger rail transport customers, student's *t-distribution* for independent tests and a one-way analysis of variance were performed. The examination concerned the existence of correlation between the assessment of the significance of modern technologies in trains and the socio-demographic variables, such as gender, education, household size, income, professional status, student status and place of residence. The *t* test for independent samples was used for socio-demographic variables with only two groups.

Table 3: Relations between preferences regarding railway transport and socio-demographic variables

		t	*p*	*d*	*95% CL*	
					LL	*UL*
Importance of modern technologies	Gender	-2.11	0.036	-0.01	-0.27	-0.1
	Professional status	0.16	0.874	0	-0.15	0.18
	Student status	-1.24	0.215	-0.01	-0.25	0.06

Source: own work based on primary research (N = 331)

In the next step, a one-way analysis of variance was carried out several times using the tested variables which were related to the opinions on the importance of modern technology as well as the price and time of travel in rail transport. A statistical analysis was carried out for grouping variables, which were on the qualitative scale and comprised more than two groups. These socio-demographic variables included education, household size, household income, and the place of residence of the respondents. The correlation was calculated using omega^2.

Table 4: Relations between travellers' preferences regarding railway transport services and socio-demographic variables

		F	p	ω^2
Importance of modern technologies	Education	2.18	0.090	0.01
	Household size	0.98	0.421	0
	Income	0.73	0.535	0
	Place of residence	2.46	0.063	0.01

Source: own work based on primary research (N = 331)

The relations between preferences regarding modern technologies and the gender proved to be significant. In addition, an interdependence between preferences concerning modern technologies and education, as well as place of residence was observed at the level of statistical tendency. All relations, both significant and those at the level of statistical tendency, were weak.

Due to the importance of the gender in the assessment of the significance of modern technologies, the preferences were investigated in detail and their relations with the gender were analysed in the following sections. Due to the uneven distribution of respondents in the groups in regard to education and the student status, this socio-demographic variable was not taken into account.

c) Preferences of travellers regarding modern technologies

In order to determine the preferences of the respondents regarding modern technologies, a factor analysis was carried out for all questions included in this category, namely:

1 Importance of being able to check information in social media;
2 Importance of obtaining additional services, such as Wi-Fi in rail transport;
3 Importance of being able to check railway connections on the Internet;
4 Importance of availability of an electronic ticket when using rail transport;
5 Importance of being able to purchase a ticket via the Internet;
6 Importance of being able to purchase a ticket via mobile devices;
7 Importance of being able to track the current location of the train using a mobile application.

In addition, Pearson's Chi^2 analysis was carried out to verify the relations between the gender and particular answers regarding the opinions on the importance of modern technology.

It was concluded that first of all the general preferences regarding modern technologies should be described. The average of the respondents was $M = 1.8$, with a standard deviation amounting to $SD = 0.57$, which meant that for the majority of respondents, modern technologies were important or very important, as the lower the score, the more important the given aspect was for the respondents. However, modern technologies were less important for women ($M = 1.73$, $SD = 0.5$) than for men ($M = 1.48$, $SD = 0.63$).

The importance of being able to check information in social media

In the next step, the importance of being able to check information in social media when using rail transport was assessed. Firstly, Pearson's Chi^2 analysis was carried out in order to verify the correlation between the gender and the respondents' assessment. It turned out that men and women responded so similarly that no statistically significant difference was observed between them [$\chi 2(3) = 1.46$; $p = 0.692$; $V = 0.07$].

In the next step, a frequency analysis was carried out for all respondents which concerned the responses to the question about the importance of being able to check information in social media regarding the use of rail transport.

Table 5: The importance of being able to check information in social media

	n	**percent**
Very important	56	16.9
Important	85	28.8
Less important	114	38.6
Not important	40	13.6

Source: own work based on primary research (N = 331)

According to the majority of respondents, being able to check information in social media regarding the use of rail transport is of little importance. The second most common answer was “important”. The option “not important” was chosen the least frequently.

The importance of obtaining additional services such as Wi-Fi in rail transport

In the next step, the importance of obtaining additional services such as Wi-Fi in rail transport was analysed. The analysis of the respondents' answers, taking into account their gender, proved that there was no statistically significant difference between men and women [$\chi 2(3) = 1.46$; $p = 0.701$; $V = 0.07$]. Therefore, it was decided to perform a frequency analysis for the entire sample without gender division.

Table 6: The importance of obtaining additional services such as Wi-Fi in rail transport

	n	**percent**
Very important	98	33
Important	115	38.7
Less important	66	22.2
Not important	18	6.1

Source: own work based on primary research (N = 331)

The majority of the respondents admitted that additional services such as Wi-Fi are important. Slightly fewer respondents considered this form of services to be very important in rail transport, and only a few considered it to be completely irrelevant.

The importance of being able to check railway connections on the Internet

As regards the opinions on the importance of being able to check railway connections on the Internet, the gender of the respondents, which slightly differentiated their opinions [$\chi 2(3) = 15.63$; $p = 0.002$; $V = 0.23$], proved to be statistically significant. Since the expected minimum value was less than 5, the Fisher's correction for Pearson's Chi^2 analysis was applied.

Table 7: The importance of being able to check railway connections on the Internet

	Women		**Men**		**Total**	
	n	**gender percentage**	***n***	**gender percentage**	***n***	**percent**
Very important	121	79.6	84	59.6	205	70
Important	23	15.1	35	24.8	58	19.8
Less important	7	4.6	16	11.3	23	7.8
Not important	1	0.7	6	4.3	7	2.4

Source: own work based on primary research (N = 331)

Generally, being able to check railway connections on the Internet was considered to be very important. Women answered “very important” relatively more often than men. Men were more likely to mark middle responses. In both cases, the least chosen option was “not important”, which was selected by more men than women.

In summary, being able to check railway connections on the Internet is usually very important or important for the respondents. Few people consider it less important and almost no one believes it is completely unimportant.

The importance of availability of an electronic ticket when using rail transport

In order to verify the importance of availability of an electronic ticket for the respondents, a frequency analysis was carried out. The results were presented for all respondents, without division into gender due to the lack of statistical significant correlation between the gender and the responses [$\chi 2(3) = 5.12$; $p = 0.163$; $V = 0.13$].

Table 8: The importance of availability of an electronic ticket when using rail transport

	n	percent
Very important	161	54.2
Important	90	30.3
Less important	33	11.1
Not important	13	4.4

Source: own work based on primary research (N = 331)

The majority of respondents indicated that the availability of an electronic ticket is very important. More than half of the respondents gave this answer. This option was considered to be completely unimportant by the smallest number of respondents. Moreover, the answer "less important" was chosen only by a small number of respondents. In conclusion, the respondents considered the availability of an electronic train ticket as significant.

The importance of being able to purchase a ticket via the Internet

Next, the importance of being able to purchase a ticket via the Internet was investigated. Due to the lack of a significant relation between the gender and respondents' answers [$\chi 2(3) = 2.52$; $p = 0.480$; $V = 0.09$], a frequency analysis without the gender division was once again carried out. It is worth noting that the test of the presented relation was carried out using the Fisher's correction, taking into account a breach of the condition regarding the minimum expected value equal to 5.

Table 9: The importance of being able to purchase a ticket via the Internet

	n	percent
Very important	182	61.3
Important	76	25.6
Less important	33	11.1
Not important	6	2

Source: own work based on primary research (N = 331)

Over half of the respondents confirmed the importance of being able to purchase a ticket via the Internet. It was significant for more than three quarters of the respondents. Few respondents have admitted that it is less important or completely unimportant.

The Importance of Being Able to Purchase A Ticket Via Mobile Devices

Furthermore, in the assessment of the significance of being able to purchase a ticket via mobile devices, the gender did not have a considerable statistical significance [$\chi 2(3) = 4.44$; $p = 0.208$; $V = 0.12$]. The lack of significant correlation was verified and calculated by carrying out Chi^2 analysis with the Fisher's exact test, taking into account the expected values below 5.

A frequency analysis of the importance of being able to purchase a ticket via mobile devices was carried out for the entire sample. The data was presented in the form of frequency and percentage of responses.

Table 10: The importance of being able to purchase a ticket via mobile devices

	n	percent
Very important	171	57.4
Important	84	28.2
Less important	34	11.4
Not important	9	3

Source: own work based on primary research (N = 331)

In this case as well, over half of the respondents marked the answer "very important". And as previously, it turned out that a small number of respondents indicated that this aspect is of little or no importance. For those who took part in the survey, being able to purchase a train ticket using mobile devices was important.

The importance of being able to track the current location of the train using a mobile application

The last question in the category of modern technology preferences concerned the importance of being able to track the current location of the train using a mobile application. In this case as well, no statistically significant gender effect was observed [$\chi 2(3) = 2.92$; $p = 0.406$; $V = 0.1$]. Therefore, it was decided to carry out a frequency analysis without a breakdown by gender.

Table 11: The importance of being able to track the current location of the train using a mobile application

	n	percent
Very important	117	39.3
Important	81	27.2
Less important	80	26.8
Not important	20	6.7

Source: own work based on primary research (N = 331)

The majority of the respondents declared that being able to track the current location of the train using a mobile application is very important. However, answers: "important" and "less important" were almost as frequent. As with other questions, the least common answer was that this aspect is completely irrelevant.

Conclusions from The Research on Travellers' Preferences Regarding Modern Technologies

A detailed analysis of travellers' preferences regarding modern technologies revealed that only the importance of being able to check the connections via the Internet is statistically and significantly different depending on the gender. As men and women gave sufficiently similar answers to the remaining questions, it was concluded that there is no statistically significant correlation.

Moreover, it was determined that in general the most important feature of modern technology was the ability to check rail connections on the Internet. The majority of respondents considered it to be very important. After converting responses to numerical values, with the lowest number representing the greatest importance of a given aspect, the average of responses indicating the importance of checking railway connections on the Internet amounted to $M = 1.43$, that is between the answer "very important" and "important", slightly closer to the "very important" answer.

The second important element of modern technology was the ability to purchase a train ticket via the Internet. Again, the majority of respondents considered it to be very important. After converting the variants of responses to numerical values, the average of responses was located between "very important" and “important” answers, slightly closer to the answer “important” *(M* = 1.54).

The ability to purchase a train ticket via a mobile device was the third significant feature of modern technologies. In this case as well, more than half of the respondents considered that this is a very important aspect of travelling by train. Moreover, this feature had the least number of answers: “not important”. Once again, after the responses were converted, the average between the “very important” and “important” answers was established, with slightly greater number of “important” answers *(M* = 1.6).

The “important” feature indicated by the respondents least frequently was the availability of an electronic ticket. After converting the responses to numerical values, the average *M* = 1.66 was obtained. This was the last feature of modern technology, whose average did not exceed 2, which meant a less important answer. Less than half of the respondents considered the availability of an electronic ticket as very important.

Provision of additional services such as Wi-Fi and being able to track the route and location of the train using a mobile application were definitely less important for the respondents than the above-mentioned issues. Both features were assessed similarly in terms of their significance, and after conversion amounted to an average of *M* = 2.01, which indicates a low importance of these two elements. As regards the importance of obtaining additional services, the majority of respondents declared that this was a moderately important aspect of rail transport services. However, the most common answer regarding the ability to track the route of the train during the trip was the “very important” option. The similar average of both features was significantly affected by a smaller number of “important” responses and a larger number of respondents who considered this to be a less important element than the provision of additional services.

According to the respondents, the least important feature was being able to check information in social media. As regards this feature of modern technology, the highest number of “not important” responses was recorded. At the same time, fewer respondents than in the case with other questions indicated that it was very important. After converting the responses, it was found that the average obtained is between the answers “less important” and “not important” *(M* = 2.47).

Summary

Services offered by railway companies should be tailored to the preferences of customers. The conducted research revealed that in the field of new technologies only four of the studied features are very important or important for young travellers.

The respondents considered the following features as the most important in rail transport services. The features are presented in order of importance:

1 checking railway connections on the Internet;
2 purchasing a train ticket via the Internet;
3 purchasing a train ticket via a mobile device;
4 availability of an electronic train ticket.

According to young travellers, the less important or unimportant features include:

1 provision of additional services such as Wi-Fi;
2 being able to track the current location of the train using a mobile application;
3 being able to check information in social media (least important).

The presented hierarchy is not conditioned by the gender of respondents – both men and women indicated the same order of individual characteristics. Only the ability to check connections on the Internet is statistically and significantly different depending on gender, which was reflected in the fact that for women this feature was much more often “very important”.

The research results demonstrate that railway companies should pay particular attention to reliable and up-to-date information on the Internet, facilitate the ticket purchase via the Internet and mobile devices as much as possible

and provide the availability of electronic tickets. In the event that the customer forgets or loses an electronic device, they should have constant access to their data on their devices.

Summing up, one should also emphasise that the implications and pace of modern technology development in railway transport in Poland differ from the global standard, as a result of which the solutions covered by the research are not the latest or state of the art ones from the global perspective, but they are adequate to the development standard of such services in Poland. Results of the analyses performed will be the basis for development of further, more extensive research in the future.

Acknowledgement

The project is financed within the framework of the program of the Minister of Science and Higher Education under the name "Regional Excellence Initiative" in the years 2019 - 2022; project number 001/RID/2018/19; the amount of financing PLN 10,684,000.00

Abstract

IoT technology represents an important segment for the next stage of the industrial revolution (INDUSTRY 4.0); in addition, it can be also seen as a way for the smart devices to communicate with each other within a modern enterprise, as also with employees and suppliers or customers in the future. In energy companies, the Internet of Things (IoT) mainly affects the logistics processes, especially their acceleration and overall streamlining. The aim of the article is to find out how benefits and limitations are included with implementation and use of technology IoT in decision-making at strategic, tactical and operational level in the energetics companies. The focus was on the field of logistics processes with regard to input parameters and restrictive conditions of the Slovak Republic. The results of primary survey carried out in cooperation with Slovak energy company GGE served as a basis for the creation of a general model of IoT technology for the energy sector in Slovakia. Methodological section includes results of interviews with the manager of GGE company and primary survey by observing current operation and management of logistics processes, synthesis, method of comparing critical success factors with best practice by Ipecon, induction in conclusion, deduction and summarization of knowledge in the form of own model. The results confirmed the positive impact of IoT not only in the field of distribution, but also on management and decision-making processes at all levels. Through the data collected from the sensors, managers have the real-time data available, provide fast feedback and ensure a quality power supply. The implementation of IoT technology thus represents a competitive advantage for energy companies, which generates a high added value for the customer. The impact of the implementation of the proposed model in practice is part of the following research activities.

Keywords: Industry 4.0. IoT. Logistics processes. Energy distribution. Management.

Introduction

Generating and analysis of Big Data needs support of new technologies including Internet of Things. The research trend has potential to make company´s processes more effective, whether in the field of logistics or support of decision-making in strategic, tactical and operational level. Sensors collect data from the external environment and distribute it through the network for analysis. With this the current state of activities is evaluated and relevant results are received for improvement of processes in the future. This results in savings in terms of time, human capital, but also the company's total funds. IoT can also be used in direct contact of employees with technologies, which help monitor the human work and control of machines. The new Industry 4.0 concept, which will be introduced into the industrial sphere from 2020, envisages shortening of all processes. This will be achieved by using new, better materials, but also by using the mentioned IoT. Artificial intelligence in these technologies will also help visually modeling the ongoing processes. The transition to IoT is also conditioned by the technological readiness of the company. At the same time, however, it will make the work of the systems used more efficient and will be able to interconnect them. A large number of devices can thus be interconnected by uniform systems, which will simplify their operation. IoT is also of great benefit in decision-making processes, as it gathers the information needed for the system promoting decision-making, or systems for architectural decision-making. In the end, it can

Cite this Article as: Gabriel KOMAN and Dominika ŠULYOVÁ "The Impact of IoT Technology on the Management of Logistics Processes in a Slovak Energy Company: GGE Case Study" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

be stated that IoT brings many benefits to companies; processes can be executed faster, which leads to valuable savings, especially time and financial savings.

Literature Review

In 2011, the German government, led by Angela Merkel, created a new concept, Industry 4.0. "Smart manufacturing" followed up on the previous three phases (steam, electricity, automation). Table 1 includes some definitions of Industry 4.0.

Table 1: Defining the Industry 4.0 concept

Author(s)	Definition
Science Direct	
Frank, et. all, 2019	It represents a new stage in the production systems by integrating technologies that add value to the product life cycle.
Ivanov et. all, 2020	The basic goal of I4.0 is to shorten lead times and prevent the "Bullwhip" effect (The accuracy of demand forecasting decreases).
Muhuri et. all, 2019	The overall transformation through smart engineering and digitization concerns the concepts of robotics, IoT or augmented reality.
Scopus	
Diez-Oliva et. all, 2019	"Smartization" of production processes, the Industry 4.0, is an implementation of the new ICT applied to industrial products.
Castelo-Branco et. all, 2019	A concept that represents the adoption of Cloud Computing, Big Data, IoT, and digitization to gain a competitive advantage of industrial enterprises at home and abroad.
MDPI – "Machines" Magazine	
Sanders et. all, 2016	It applies the principles of Cyber-Physical Systems (CPS), the Internet and the future-oriented technologies and smart systems with the improved human-machine paradigms.
Mabkhot et. all, 2018	The new concept of industrialization, at the heart of which is a "smart factory", uses the progress of ICT.

The definitions indicated in Table 1 have the common elements, which are mainly the global trends in the information and communication technologies (ICT), such as artificial intelligence, robotics, automation, "smart manufacturing, logistics or energy", Cloud Computing, etc. Sanders took a different view of the issue, as he included a man-machine communication relationship in this concept, indirectly indicating that even the most advanced technologies still need a human factor to run. Devices and sensors are able to collect the information and transform it into data; they facilitate management and decision-making; however, ultimately the resulting variant is selected and implemented by the manager. Within this article the term Industry 4.0 is perceived as communicating devices (device-to-device or machine-to-machine), element of artificial intelligence, robotics or sensors that mediate a digital form of business, together with trends such as Blockchain, Omni-channel, internet of things, industrial Internet of Things, etc. In the 21st century, automation (the 3rd wave of the industrial revolution) is far from enough. The fourth wave is no longer only in the corporate environment (production, logistics, energy), but it interferes with our daily lives in the form of "smart" mobile phones, homes, or entire cities. The main goal of this concept is to transform companies into a digital form and start using elements of Industrial IoT, i.e. the Internet of Things. Table 2 lists some definitions of IoT by foreign and domestic authors.

Table 2: Defining the IoT (Internet of Things) concept

Author(s)	Definition
IEEE Explore	
Siegel et. all, 2018	Sensors and action units can communicate and collaborate based on a concept that connects people, things, data and processes – IoT. The technology brings low costs, efficient systems and flexibility.
Li-Minn, Kah Phooi Seng, 2019	IoT is a technology composed of Cloud, Cloud Computing and sensors that influence the modern world and customer needs through platforms.
Wiley Online Library	
Samaila et. all, 2018	The concept was defined in 1999 by Kevin Ashton. IoT uses the standards, such as Zigbee, Bluetooth, Wi-Fi, NFC, for the network communication.
Paul, Jeyaraj, 2019	It combines Wi-Fi technologies and Internet protocols providing network communication and connects physical and virtual components.
Home Authors	
Jurová et. all, 2017; Soviar et all, 2019	The interoperability of cyber-physical systems in households, businesses or hospitals creates a precondition for IoT. The technology is used to monitor processes and control them.
Vaculík, 2018a; Vaculík, 2018b; Varmus et all, 2015	IoT was primarily concerned with tracking things through RFID technology; later, the concept was enriched with EAN codes, chip cards, NFC and QR codes.

Within the article is the Internet of Things a technological view of the interconnected things, people, processes, and data that together make up Internet of Everything (reflecting the purpose of IoT implementation). With the development of the Internet, the way of work, life, but also leisure time has changed. In an enterprise environment, the innovation simplifies the real-time data-based planning, management, and decision-making for managers. The Internet of Things is divided according to the area of implementation into the territorial, medical, animal tracking, mobile, nanotechnology, underwater, underground and waste consumption monitoring IoT (Li-Minn, Kah Phooi Seng, 2019). IoT technology has a significant impact on the company's production, logistics, information and communication processes. (Koman et all., 2018; Ferenc et all, 2017; Hittmar et all, 2015; Soviar et all, 2018; Jankalova, Jankal, 2018; Soviar et all, 2017; Jankalova, Jankal, 2016)

Internet of Things Architecture

The conversion of the information and operational technologies (M2M communication) brings managers cost savings, efficient production and logistics, fulfillment of business goals (profit, customer satisfaction, higher market share). The three basic implementation layers are described in Figure 1. The infrastructure layer consists of sensors and action units; it includes functions for automatic door opening, asset monitoring via RFID, real-time alerts and energy consumption measurement. The network layer mediates the acquired data to the next layer via the Internet (router and gateways). The application works on a client/server basis; data is stored on Cloud storage. (Calihman, 2017)

At present, large international companies are involved in the development and implementation of new architectures for the IoT area. A good example from practice is Google, which developed the “Brillo” platform; it can work with a large amount of memory and data is transmitted via Wi-Fi network or Bluetooth. Data applications are based on the Android operating system. (Bouhaï, Saleh, 2017).

Fig. 1: IoT architecture (Calihman, 2017)

The platform upgrade was named "Android Things"; it includes tools like Google Play or Cloud Platform. The interaction is provided by the "Weave" protocol, which Samsung and Philips also implemented into their devices. The "Brillo" architecture consists of a Linux Kernel (core); the middle layer consists of the HW API library, and the highest one of Android (Ličko, 2016). Huawei manufactures The Agile IoT platform for Samsung's Artik. Microsoft is currently joining the development trend with its new version of the Windows 10 operating system. (Bouhaï, Saleh, 2017, Kubina, Lendel, 2015)

Materials and Methods

The understanding of the issue was achieved by analyzing foreign literature for the field of Industry 4.0 concepts, IoT technology, which were enriched with own definitions. For the selection of relevant literature were used keywords as IoT, Industry 4.0, distribution processes in power engineering, Big Data, the Internet of Things in decision-making processes etc. The selection of the company was determined by cooperation on a project on the use of the Internet of Things in the field of distribution in the Slovak Republic. The best practice was selected with the help of the GGE´s manager who has many years of experience in the researched field. The research itself was conducted through interviews with the management of GGE, the Slovak energy company, by setting two research questions.

Research Questions

1. *Are there any energy companies in Slovakia that have successfully implemented IoT and Industry 4.0 into their processes?*

2. *What benefits has the implementation and use of IoT brought in processes, management and decision-making for managers and their employees?*

The primary survey was also carried out by observing the current situation of logistics processes, the activities of managers at all levels (strategic, tactical and operational) during the duration of the three-month cooperation. Observation took place in a standardized form, it means personally in the logistical and economic departments.

The documents on the Tedis information system were provided by Ipecon company. The company also carried out an illustrative demonstration of the system, its functioning and its contribution to distribution and decision-making processes. Critical success factors were selected, reviewed and evaluated in cooperation with the manager of GGE, who also participated in defining the mathematical basis of specified intervals and scoring. The article used the method of induction in the creation of the conclusion. In the whole case study was also applied deduction summarizing the results.

The comparation with best practice has the form of the critical success factors mentioned above. The obtained results served as a basis for the construction of a general model for the implementation of IoT technology for Slovak energy companies. Model verification in practice and its testing are part of other future research activities.

Results

The interviews show that the most important element of competitiveness is the precise regulation of energy (Table 3) with minimal deviations (according to the subjective scoring, it received 5 points, i.e. the maximum in a given interval).

Table 3: Critical Success Factor

Factor	Weight	Score (1 – 5)		Weighted value	
		GGE	Ipecon	G	I
Precise energy regulation	0.50	5	5	2.50	2.50
Lower operating costs	0.10	3	4	0.30	0.40
Predictive maintenance	0.15	4	5	0.60	0.75
Management and decision-making support	0.25	4	5	1.00	1.25
Total	1.00	Overall competitiveness		4.40	4.90

Defining the mathematical basis determined in cooperation with the CEO of GGE:

- Precise energy regulation, interval (0-15%) = 1 point; (16-31%) = 2 points; (32-66%) = 3 points; (67-94%) = 4 points; (95-100%) = 5 points; i.e. the upper regulatory limits are much stricter than the lower ones (according to the interview);
- Lower operating costs – (0-20%) = 1 point; (21-40%) = 2 points; (41-55%) = 3 points; (56-77%) = 4 points; 78 and more = 5 points.
- Predictive maintenance – Elimination of errors up to 10% = 1 point; (11-22%) = 2 points; (23-44%) = 3 points; (45-67%) = 4 points; 68% and more = 5 points.
- Decision-making management support – Effective use of documentation, (0-12%) = 1 point; (13-24%) = 2 points; (25-45%) = 3 points; (46-60%) = 4 points; 61% and more = 5 points.

It is essential for Ipecon to predict maintenance and provide management and decision-making support when designing systems and providing energy services. In both cases, the lower operating costs were not the primary success factor, but an associated positive effect (Table 4).

Fig. 2: Critical Success Factors of GGE and Ipecon

Observation of work with the Tedis information system by Ipecon

A branch of the energy company GGE in Považská Bystrica was observed. The goal of the observation was to determine the impact of IoT technology on the logistics and decision-making processes through practical demonstrations of work with the Tedis information system by Ipecon, to reveal the positive and negative aspects of IoT technology implementation and, upon the facts ascertained, to propose a model solution for Slovak energy

companies. Time span – February 2019; three meetings; documents obtained in the form of data from the interview, and the Act 657/2004 Coll.; a description of the Tedis system by Ipecon (more info on the website). Scope – Focus on the logistics processes and management and decision-making support. Location – Production/logistics department and management.

Observation Results

The information system contains 10 basic functions used by companies dealing with energy distribution in Slovakia, including the GGE branch in Považská Bystrica. IS manages and monitors the thermal units in real time – Information and simulation of inputs, outputs, sensors, alarms, GPS coordinates, data collection and their processing into graphs/tables. Control of energy units and a ¾ hourly maximum – Monitoring of turbines and power stations; setting the maximum allowed energy consumption. Energy balances and their processing – Calculation of daily and hourly sums of energy prices; comparison of the values measured and required; measurement of deviations and their elimination. Reports and their automatic sending via e-mail – Reports in MS Excel; a possibility of their immediate printing; transfer to the invoicing module in the company. Fault notification via SMS messages – To the mobile phone/tablet; possibility of quick repair and inspection; use of the GSM modem. Redundant system – Works 24/7 throughout the year; a redundant system serves as a backup against outage. Effect – Higher reliability and operability of the system. Diagnostics – Scans processes/D2D device communication; an activity control tool; visual processing and demonstrations; see the following figures.

Fig. 3: Preview of Tedis outputs and simulations (Ipecon, 2020)

A competent employee obtains data at the regular 1-minute intervals from sensors that collect data in the field and convert it into electrical signals. If the temperature is too high, the employee will command the active unit to turn on the fan. The movement is carried out pneumatically (Air pressure – Figure 3 and 4).

Fig. 4: Ventilation process through controller instructions (Ipecon, 2020)

Data is transmitted over the enterprise LAN through a router that is connected to a radio network. Servers and workstations are also included in the connection architecture. The demonstration was carried out directly at GGE; subsequently, additional information was provided by a telephone conversation with a representative of Ipecon, which supplies the Tedis system.

Main Results

The interviews provided answers to two research questions and from the methodological section. It was found that in Slovakia, there is a sufficient number of energy companies that have implemented new trends in the field and thus improved their processes. For example, GGE, based on the data collected via sensors and the Tedis system, can predict the future energy consumption, determine the quality of the mains, and adjust the prices offer according to customer needs (based on seasons, day vs. night). Based on the data, managers are able to make faster decisions and, with the real-time feedback, they can also evaluate the consequences of their actions. They know how to choose a most suitable alternative out of several possible ones, which creates a fact-based decision-making and management system. Reducing the costs of monitoring failures and maintenance (formerly in the form of daily trips of employees) brings the opportunity to invest free funds in other innovative improvements of the company. Employees feel safe at work (early warning system via sensors), and thus a pleasant working environment is provided.

The financial statement results showed that the deployment of IoT in the company increased profits by more than 100% (Table 4).

Table 4: Economic result after tax (before and after the implementation of IoT in the company GGE)

Year	GGE distribution, a. s.	
	2011 (Before implementing the Tedis system)	2012 (Year of implementation)
Economic result after tax	€ 17,438	€ 645,318

Finstat, 2020

In the interview, the CEO of GEE distribution confirmed that the number of printed documents decreased by approx. 50%. All data is clearly archived and backed up via the Tedis system. Information is disseminated through individual modules, e.g. billing across the company, which is efficient whether in terms of time, management, or cost.

The obtained information confirmed or refuted the importance and significance of the implementation of IoT technology in the company practice. The findings were used in the design of a general implementation model in the field of energy distribution in Slovakia, which can be used as a pattern for another energetic companies in the same geographical and industrial area. Methods of analysis, synthesis, critical success factors, comparison, induction, deduction and summarization were also used in the article.

General model of implementation of IoT technology into the Slovak energy companies

General implementation model (Figure 5) IoT in the observed company can be used as a reference point for the existing heat and energy suppliers in Slovakia. The starting part of the model are the houses and apartments of clients, in which the heat consumption probes and sensors are located. The data is automatically recorded on the Cloud storage via the Internet. Businesses access this data through a server and a computer. Internal processes (operational level in Figure 5) of work with the IoT system include diagnostics, real time-monitoring of thermal aspects, energy balances and their processing, reporting and fault notification via SMS messages. At the strategic level (a blue rectangle in Figure 5), data is transformed into information and knowledge that will enable managers to effectively manage and make decisions. Deviation analysis, monitoring and consequences of decisions are the basis for the implementation of feedback between the manager (company representative) and the client. Through the obtained data and decisions, the manager can improve the quality of, and optimize, energy consumption through the setting of sensors, respecting customer requirements and their preferences. The second feedback is between the logistics processes that connect the company and heat consumers. First, it is necessary to process the biomass to generate steam, which is then distributed through pipes to the heat exchanger.

Fig. 5: General model of IoT technology implementation in energy companies in Slovakia to support management and decision-making

The energy will be stored in a storage tank; it will be used to heat residential units and water. The sensors can be used to collect data in every single logistics process. When they return to the company via the Internet, they influence ICT and decision-making processes.

Discussion

The research carried out at GGE confirmed the positive impact of IoT technology on the support of management and decision-making in the energy industry, together with the associated negatives. Benefits of introducing IoT into the energy company upon from the conducted interviews are as follows:

- Work simplification; fast feedback; real-time data collection;
- Transformation of data into information;
- Management and decision support at all levels of the company;
- Lower personnel costs in the form of downsizing employees;
- Preventive maintenance and fault reporting;
- Stabilization of adequate quality of the electricity network;
- Minimum deviations; precise regulation of heat/water/electricity/gas;
- Efficient reporting;
- Optimization of the company's distribution processes, especially the activities of dispatching and distribution stations.

The benefits confirm the suitability of introducing the intelligent sensors and D2D (sub-component of Industry 4.0 and IoT) into the company, thus fulfilling the main goal, purpose, and task of research. However, in addition to the positives, the technology brings in practice and use also negative aspects, namely:

- Increased training costs;
- A manager with a strong personality is needed who can motivate people to change;
- Traditional processes are being replaced by new ones = frequent reluctance of employees to change established habits in the work environment;
- Hacker attacks on the system and data in it;
- Finance and time.

Ultimately, however, the benefits outweigh the barriers, as evidenced by the research questions met.

Conclusion

The results of the research conducted through an interview with the CEO of GGE, the energy company, formed the basis for designing a general model for the implementation of IoT technology in the logistics processes of Slovak energy companies. The main outcome was to offer a relevant proof of the benefits of IoT technology in the logistical support of management and decision-making through real-time data, and to support it with arguments. Based on the best practice of a selected company in Slovakia, GGE branch in Považská Bystrica, it was possible to design a general model that can be adapted to the needs of individual heat and energy providers in the conditions of the national market. The results of the observation identified ten key areas and/or processes that are based on the use of raw field data to be processed through a selected information system. The analyzed company obtains data through built-in sensors, and thus effectively manages the processes of diagnostics, monitoring of thermal aspects in real time, energy balances and their processing, reporting, and fault reporting via SMS messages. The implementation model includes both, the operational and strategic level, as well as feedback among individual actors, such as business managers, households (residents) and the relevant company. If necessary, some steps of the model can be modified, eliminated, or extended depending on the internal and external conditions that will affect the company that decides to implement IoT technology in its logistics and management processes. To anticipate and eliminate any potential problems, it is essential to focus mainly on changing the thinking and motivation of employees, on a participation in training, the correct setting of requirements based on an analysis of the current situation and the selection of an adequate supplier with sufficient experience with the issue. To achieve the maximum effect, it is beneficial to test the selected solution in practice and perform its subsequent modification, including the associated feedback between specific activities.

By elaborating the theoretical basis of knowledge of the given issue, the concepts from the given area were clarified, which needed to be understood for the implementation of research activities in practice. Trends and technologies, customer purchasing behavior, as well as the needs and motivation of employees are key factors that affect the company's performance and the ability to optimize the production and logistics processes. The funnel-like model reduced the information in order for it to be effectively used in the field of energy distribution in the conditions of Slovakia at a practical level in real conditions. By implementing IoT into business processes, the research shows that CSF mainly include precise energy regulation (quality with minimal deviations), safety, low costs, management, and decision-making support. Other benefits are in work simplification, fault reporting, predictive maintenance, real-time data collection, etc. Training, changing the mindset of employees, higher demands on the management of the company, hacker attacks and financially demanding investments are limitations that can slow down the successful introduction of new technologies or make it impossible. The elaboration of the article confirmed the assumption that IoT technology is beneficial for management and decision-making in complex

activities of the company and forms a competitive advantage in the current market of trends. Exploring the effects of implementing the model into practice will be part of the following research activities.

Abstract

This study aims at investigating the quantifiable effect of credit risk on the performance of listed banks in the sultanate of Oman over the period of 10 years (2010-2019). The analysis of this study is based on Secondary data extracted from the Muscat Securities Market (MSM). Panel data has been employed in this study. Return on Assets (ROA) and Return on Equity (ROE) are the performance indicators and Bank specific variables like Non-performing loans, size of the bank and oil price have been taken as indicators of inherent credit risk . The study employed Random effects model to analyze the time series data. The result showed that the quality of the assets on the balance sheet and the inherent credit risk have an inverse relation whereas the bank size had not significant relationship with ROA and ROE. Oil prices has an effect on ROE but not on ROA. As Oil prices cannot be controlled by the banks, they need to focus more on alleviating themselves by controlling, regulating and monitoring the non-performing loan book. Banks are recommended to adhere to highest standard of credit appraisal ensuring lending to credit worth borrowers with the highest ratings

Keywords: Commercial banks, Credit risk, Financial performance, ROE, ROA, Size of bank, Non-performing loans.

Introduction

The performance of the economic sector of an economy is considered imperative to the growth of a nation and hence the economic sector needs to be at the forefront in terms of performance. One of the most important economic segments of an economy is the financial services sector. This tertiary sector includes the most important and conventional financial service i. e. Banking. The dependency and importance of the banking sector for the developing and underdeveloped economies was reviewed with a view that these economies have less than 1/10th share of financial assets in financial sectors other than banking(ADB, 2013). Banks are responsible for the confidence and growth of an economy and hence this sector should be well structured. A well-structured banking sector would be viable, robust, and successful (Saeed and Zahid, 2016).

Banks being intermediaries have the primary function of accepting deposits and lending loans. The basic income generated by the banks is through credit lines on and off the balance sheet having intrinsic credit risk (Allen, 2012). Banks face risks that are classified as credit risk, liquidity risk, market risk, operational risk, nominal risk, and legal risks(Van Gestel and Baesens, 2009;W.Koch and MacDonald, 2009). Credit risk has the possibility of a borrower to default by failing to make payments as per his contractual agreement (Richard *et al.*, 2008). The Basel Committee on banking supervision (2000) explains credit risk as the possibility that the borrower of funds will be unsuccessful in meeting its commitments in line with the established contract. Such credit risk predominantly affects the lender and may cause a complete or partial loss of principal and interest, problems in cash flow, and higher collection costs.(Basel Committee on Banking Supervision, 2000)

In general terms, credit risk means the critical risk which shapes the financial performance of the bank. If a bank's balance sheet shows high level of non-performing loans, it means the profitability of the bank will be low which consequently will affect the performance of the bank. Banks' exposure to credit risk is more than any other risk. Thus, efficient credit risk management is vital for the very existence and progress of the banks (Ekinci and Poyraz, 2019).

Risks not only create negative impacts on operations and profits but also on the market value of the institution. Credit risk is regarded as the most important type of risk as it is contemporary to 8 out of 10 balance sheet items (Perera, Ralston and Wickramanayake, 2014). To ensure financial health, banks need to identify in time the potential credit risk as such leads to lower liquidity levels. Credit risk also arises in case of the banks' guidelines to risk management are frail and incomplete (Richard *et al.*, 2008).

Need for the study

Oman's banking sector has an overwhelming domination in the financial sector. Banking sector acts as a vital intermediary and also plays a fundamental part in the payment and settlement mechanism. Henceforth, the financial well-being of the banking sector is crucial for the economic stability and development of the country. (Central Bank of Oman, 2019).

The management of credit risk is vital as it explains the exposure banks have with counterparties and vice versa, whereby enabling the creation of mitigation techniques. Eminent studies have pointed out that inappropriate credit risk management coupled with excessive lending was one of the major causes of the global meltdown (GAO, 2013).

Only a strong and lucrative banking sector has the capacity to endure detrimental setbacks and can contribute to the constancy and reliability of the financial system. Any non-performance of banks will lead to the adverse impacts on the macro economy which would be extensive and mammoth.

Evaluating performances of banks are critical for the investors and for the sustainable growth of a nation (Pekkaya & Demir, 2018). Hence, this study has been undertaken to examine the impact of credit risk management on the financial performance of banks.

Review of literature

The credit risk is assessed based on three variables - doubtful loans, non-performing loans and loan loss. Panel data analysis of both fixed and random effect model and GLS was employed to know the impact of credit risk on the

financial performance of banks and found that that the credit risk has significant negative impact on Return on asset (ROA) and Return on Equity (ROE). The result also showed that the size of the bank and the total deposit have a positive impact on the financial performance of banks. (Al-Eitan and Bani-Khalid, 2019).

Credit risk has a negative relationship with the profitability of the banks. Poor asset quality to total assets in short run and long run has a direct impact on the profitability. Banks with high asset quality and low in non-performing loans are more profitable than the others. (Jane GathigiaMuriithi, 2016)

Decrease in capital adequacy ratio, total asset and interest ratio decreases the credit risk. Also the study reveals that there is a positive relationship between the unemployment rate and credit risk in Azerbaijani banks. (Shahriyar Mukhtarov, 2018)

The characteristics of banks play a major role in the risk taking capacity of Tunisian banks. The ratio of return on asset is positively influenced by credit risk and the ratio of capital adequacy negatively affect the credit risk. Moreover, the banks' profitability is correlated with the macro economic variables. (Nabila Zribi, 2011).

The effect of Credit Risk Management on the financial performance was analyzed by considering ROA as a financial performance indicator. Credit risk indicators include Default ratio(NPL/TL), Cost per loan asset (CLA) and Capital Adequacy Ratio (CAR). All the credit risk indicators have a negative impact on the financial performance on the banks taken for the study. The results further indicated that credit risk is the major determinant of financial performance of banks. (Poudel, 2012). The negative impact of NPL on financial performance is also confirmed by (Patwary and Tasneem, 2019). The study further mentions NPL as the main reason for the failure of majority of banks.

(Delis, 2005) in their study has taken ROA and ROE as profitability indicators of Banks. For measuring the credit risk, loan-loss provisions to loans ratio (PL) has been used. The loan-loss provisions to loans ratio (PL) has a negative and significant impact on the profitability indicating the need to minimize the NPL to increase the profits of the banks. (Titko, Skvarciany and Jurevičienė, 2015) analysed the drivers of bank profitability. The results of the study indicate that bank size, improved infrastructure and e-banking services positively affect bank profitability whereas operational efficiency has a negative influence on bank profitability.

Most of the studies examined have used either bank specific variables or macro-economic variables separately and some studies have used both bank specific variables and macro-economic variables like GDP, CPI inflation. But none of the studies have used oil prices as the macroeconomic variable along with bank specific variables in their study.
The main reason for including oil prices in the study is Sultanate of Oman's economy earns more than 70 per cent of its revenue from oil exports alone. As a result, any decline in oil prices would have a negative impact on the fiscal and external balance of the economy. This decelerating economic growth may adversely impact borrowers which may escalate non-performing loans and provisioning requirements. A study conducted by (Hesse and Poghosyan, 2009) shows that oil price has an impact on the banks' financial performance which clearly indicate the importance of oil prices on banks' profitability.

In order to find out whether bank specific variables and oil prices have an impact on banks' profitability , a study has been undertaken considering both the bank specific variables and macro-economic variables to evaluate the credit risk and financial performance of listed banks in Muscat Securities Market(MSM).

Data and Methodology

The current study focusses on the credit risk and financial performance of listed banks in Muscat Securities Market. In Muscat Securities Market(MSM), 8 banks are listed viz. Ahli Bank, Bank Dhofar, Bank Muscat, Bank Nizwa, Sohar International Bank, HSBC Oman, National Bank of Oman and Oman Arab Bank. Out of these 8 banks, financial reports are available for the complete period of this study(2010 to 2019) only for 6 banks as bank Nizwa was established only in the year 2012 and Oman Arab Bank was listed in Muscat Securities Market only in the year 2020. So, except Bank Nizwa and Oman Arab Bank all the other 6 banks are included for the study. The annual financial statements of these 6 listed banks which were audited and published in the Muscat Securities Market(MSM) (https://www.msm.gov.om/) was collected for the years 2010 to 2019.

The ratios and the variables used in this study was determined from extensive literature study and are listed below in table no.1.

Table 1: Ratios and variables used

S.No.	Variables	Name of the Ratios/ variables used	Explanation	References
1.	**Profitability indicators**	Return on Assets(ROA)	It is the ratio between the profit after tax divided by total or average assets. It aids in the determination of the efficient usage of banks assets and its capability to generate revenue from the assets	(Alshatti, 2015; Noman et al., 2015; Saeed and Zahid, 2016; Noor, Das and Banik, 2018; Sun, 2018; Al-Eitan and Bani-Khalid, 2019; Ekinci & Poyraz, 2019)
		Return on Equity(ROE)	ROE is calculated using the formula profit after tax divided by total/average equity. This ratio measures the competence of a bank in utilizing the investment made by shareholders to generate profit.	(Alshatti, 2015; Noman et al., 2015; Saeed and Zahid, 2016; Noor, Das and Banik, 2018; Sun, 2018; Al-Eitan and Bani-Khalid, 2019; Ekinci & Poyraz, 2019;Kajirwa and Katherine, 2019))
2.	**Influencers of profitability**	Non-performing loans to Total loans (NPL/TL)	It is used to measure credit risk. If the ratio is low, it indicates better asset quality and lower credit risk and vice versa.	(Taiwo et al., 2017; Mukhtarov, Yüksel and Mammadov, 2018; Sun, 2018; Abubakar *et al.*, 2019)
		Total equity to Total assets(TE/ TA)	The performance of the financial institution is well explained by this ratio	(Ekinci & Poyraz, 2019)
		Total loans to Total assets(NPL/TA)	This ratio is considered to be the good indicator of Asset quality of banks. As loans bring interest earnings which constitute the major revenue for the banks, higher the ratio means higher profits for the banks.	(Ekinci & Poyraz, 2019)
		Size of the bank(SOB)	Total assets of the banks are used to determine the size of the banks. Banks having larger assets are more probable to have larger diversified assets or portfolios. Hence, their opportunity to reduce the risks and increasing their profits are more.	(Zribi and Boujelbène, 2011; Saeed and Zahid, 2016; Mukhtarov, Yüksel and Mammadov, 2018; Ekinci & Poyraz, 2019)
		Oil prices	Evaluation of the effect of oil prices on banks' profitability reveals that the influence of the oil price shock on profitability is affirmative and substantial irrespective of the explanation of the oil price shock.	(Hesse and Poghosyan, 2009)

Return on Assets and Return on Equity which are the profitability indicators are taken as dependent variables. Bank specific variables like NPL/TL, TE/TA, NPL/TA, SOB are considered to be the determinants of profitability are taken as independent variables. (Hesse and Poghosyan, 2009) point out that macro-economic variables occupy a strategic

position on the performance of the banking sector. Hence, macro-economic variable oil prices which is likely to affect the bank performance is taken along with bank specific variables are taken as independent variables

The data was analyzed by using descriptive statistics, correlation and Regression. The adoption of this technique was inspired from (Kajirwa and Katherine; Ekinci & Poyraz; Abubakar *et al.*, 2019) and also from similar studies conducted on the bank credit risk and financial performace of banks.

Table 1: Descriptive Statistics

Descriptive Statistics	ROA	ROE	Bank size	Asset Quality	Capitalization	Credit risk	Oil prices
Mean	10	10	195357445	10	10	10	78.331
Median	9.95846	10.5516	25882169	9.91155	8.57171	10.1819	75.105
Std. Deviation	1.0040	1.9401	362353964.7	0.3894	3.2712	1.8575	25.4850
Minimum	8.6938	6.8237	17894529	9.4871	7.7697	7.4424	40.1
Maximum	11.6127	12.4346	943703683	10.7722	16.2657	12.5321	109.6

Table 1 shows that the means of ROA, ROE, Asset Quality, Capitalization and Credit risk are 10. The average oil prices are 78.331.

The capitalization ratio calculated on the basis of owned capital in the total capital structure appears to be good with a median of 8.57171684 and a standard deviation of 3. 27122027.Large ratio of owned capital means the managers of the bank have to simply follow the objectives set by the owners. Thus, when the owned capital is more the non-performing loans level will be lesser. (Bawa *et al.*, 2019).

Credit risk(NPL/ TL) has a median of 8.5717 and a maximum of 16.2657 shows that the Non-performing loans of the banks are less when compared with the total loans lend by the banks. According to (Bawa *et al.*, 2019), non-performing loans will have a negative impact on the banks' profitability.

Table 2: Correlation

	ROA	ROE	Bank size	Asset Quality	Capitalization	Credit risk	Oil prices
ROA	1						
ROE	.902**	1					
Bank size	.332	.432	1				
Asset Quality	-.039	-.130	-.735*	1			
Capitalization	-.800**	-.595	-.279	.085	1		
Credit risk	.906**	.935**	.502	-.130	-.562	1	
Oil prices	.847**	.657*	.249	.106	-.763*	.664*	1

Source: Authors' calculated results using SPSS
***. Correlation is significant at the 0.01 level (2-tailed).*
**. Correlation is significant at the 0.05 level (2-tailed).*

Correlation analysis has been done to show that there exists no robust correlation between dependent and independent variables (Al-Eitan and Bani-Khalid, 2019). The independent variables like bank size, Asset quality, Capitalization, Credit risk and Oil prices and the dependent variables namely., ROA and ROE shows a weak to medium relations in most cases which reveals that there is no correlation between them.

The Dicky-Fuller and Phyllis-Peron test was used to prove the stationarity of the time series of the variables taken for the study. This test also examines the stability of the time series for the study period as the time series instability will result in unrealistic regression results. (Al-Eitan and Bani-Khalid, 2019)

Table 3: The unit root results (Dickie-Fuller & Phillips-Peron)

t-statistics in Log First Differences		
	ADF (First differences)	PP
ROA	56.5531***	65.6018***
ROE	50.2603***	50.7365***
Bank size	30.2865***	36.1567***
Asset quality	44.7566***	44.4393***
Capitalization	59.6521***	64.9466***
Credit risk	38.8799***	38.0756***
Oil prices	42.3884***	42.2676***

Source: Authors' calculated results using SPSS
****, indicates significance at 1 %*

Table 3 shows the Dickie-Fuller & Phillips-Peron test. As the results in the level are insignificant and unstable, Dickie-Fuller & Phillips-Peron test was conducted for all the variables at first differences. The results at the first difference shows that the variables are stable and the null hypothesis of instability was rejected.

Regression Results and Discussions

Wald test was calculated to find out if the independent variables in a model are significant. The results of the Wald test show that it is significant. Hausman test was carried out to select between fixed effect or random effect method. If Hausman Test probability value is more than 5%, the method to be chosen is random effect.(zulfikar, 2018); (Al-Eitan and Bani-Khalid, 2019) As the Hausman test probability value for ROA is (0.9228) and ROE is (0.8624) which is more than 5%. Hence, Random effects model is used to analyze the data. The results of the Random effects model are presented below in Table 4.

Table 4: Random effects model

Dependent Variable: ROA		Dependent Variable: ROE	
Bank size(SOB)	1.81E-12 (2.34E-12)	Bank size(SOB)	0.027576 (2.05E-11)
Asset quality (NPL/TA)	-0.024217*** (0.006237)	Asset quality (NPL/TA)	-1.79E-11*** (0.051769)
Credit risk(NPL/TL)	-0.039399*** (0.012672)	Credit risk(NPL/TL)	-0.141153*** (0.106810)
Oil prices	2.45E-05 (1.56E-05)	Oil prices	0.309289*** (0.000136)
Capitalization(TE/TA)	0.004851*** (0.003215)	Capitalization(TE/TA)	0.000366*** (0.028182)
R-squared	0.691627	R-squared	0.716313
Wald Chi-square	93.899	Wald Chi-square	123.9412

Probability (Chi-square)	<0.00001	Probability (Chi-square)	<0.00001
Hausman Test (Prob.)	0.9228	Hausman Test (Prob.)	0.8624
Total Observations	60	Total Observations	60

*Source: Authors' calculated results using EViews 11. *, **, ***, indicates significance at 10 %, 5 % and 1 %.. standard errors are shown in parentheses.*

The Asset quality(NPL/TA) and also the credit risk(NPL/TL) has a negative relationship with both ROA and ROE and the results are significant at 1% level. This result is consistent with (Delis, 2005; (Jane GathigiaMuriithi, 2016); Al-Eitan and Bani-Khalid, 2019).

Bank size or the size of the bank has no significant relationship with ROA and ROE. This result is in contrast with the previous studies. Previous studies like(Titko, Skvarciany and Jurevičienė, 2015; Al-Eitan and Bani-Khalid, 2019) Ekinci & Poyraz, 2019) showed a positive and significant relationship between Size of the bank and profitability.

Capitalization ratio(TE/TA) is positive and has a significant relationship with ROA and ROE. This result is supported by (Ekinci & Poyraz, 2019). (Ekinci & Poyraz, 2019) reasoned that this strong relationship is due to the fact that well capitalized banks' dependence on external funding is less and as a consequence cost of funding will be less which ultimately results in huge profits.

Conclusion

The study evaluated the credit risk and the financial performance of Listed commercial banks in Sultanate of Oman. The result shows that Asset quality, Capitalization and Credit risk has an impact on both ROA and ROE. It indicates that the banks should be very careful in lending because more Non-Performing Assets in the bank's balance sheet will have a negative impact on its credibility. Oil prices has a positive effect on ROE but not on ROA which proves the impact of oil prices on banks performance. Even though oil prices have an impact on the Return on Equity, banks do not have the authority to control the oil prices.
As the Oil prices cannot be controlled by the banks, they need to focus more on alleviating themselves by controlling, regulating and monitoring the non-performing loan book. Banks are recommended to adhere to highest standard of credit appraisal ensuring lending to credit worth borrowers with the highest ratings. Apart from that, Bankers must have a clear understanding of the business environment, its current position and also must be able to forecast the business prospective in order to reduce the non-performing assets.

The data analyzed is only for 6 commercial banks of Oman due to non-availability of data for the period and also only 6 banks were listed in Muscat Securities Market during the period of analysis. As the data anlaysed is not sufficient to substantiate the results, it is difficult to generalize the results obtained. The authors recommend that data can be collected from the securities market of all the commercial banks functioning in the gulf countries in order to find a conclusive evidence for the impact of credit risk on the financial performance of commercial banks.

Abstract

Since the 1990s, the macro environment of passenger transport companies has changed radically. As a consequence of changing conditions, marketing is being atomised and the demand for new marketing instruments is rapidly increasing. In societies of abundance, consumers are better educated and more demanding, thus a need arises for new marketing activities and adapting products to the requirements of the target market, taking into account the individual needs of buyers. This article focuses on the literature concerning young people, especially the group of young adults (18-29 years old) who often travel and are considered an important target group for railway companies due to continuing education outside their place of residence, work or sightseeing. The research investigates passenger rail transport in regions and agglomerations in Poland. In order to achieve the research objective, the method of critical analysis of available results of secondary research and a questionnaire in primary research were used. Modern marketing in passenger rail transport services should therefore target areas where particular factors are related to travel times, service prices, customer service processes and availability of new technologies.

Keywords: Passenger Rail Transport, Customer Preferences, Marketing.
YEL codes: R41, M30. L92, N74, O18.

Introduction

The turbulent changes taking place in the global economy, especially at the beginning of the 21st century, have had and continue to have a strong impact on the perception of marketing and the definition of its role and principles in companies. These changes are related to a greater inclusion of marketing in the management of enterprises (e.g. orientation towards enterprise value, strategic management orientation, market orientation, increase in the importance of information technology, taking care of a positive image of the enterprise) (Pomykalski 2005, p. 3). The modern market for rail transport services (both passenger and freight) is a market oriented toward a service user. The oversupply of services in the passenger transport market results from the development of private transportation which satisfies most of the demand for transport services on the market and reduces the demand for the services in the public transport market. This situation forces railway companies to focus on customer needs and use modern marketing not only to convince customers to use the services, but also to ensure that the quality of the services provided is satisfactory and that the purchasing process runs smoothly and according to their increasing expectations.

The concept and nature of marketing of transport services derives from the nature of marketing and, more specifically, marketing of services. Marketing solutions and activities are constantly evolving. In the beginning, marketing was defined as: the art of selling products, then as the art of finding and keeping customers, and eventually as the science and art of establishing, maintaining and improving relationships with profitable buyers. In the above definitions, the orientation of marketing changes from a company to a customer. A change in the way marketing is defined may be observed in marketing concepts 1.0, 2.0 and 3.0. Product-oriented marketing is referred to in the literature as marketing 1.0, while its orientation towards customers as marketing 2.0 (Kotler, Kartajaya, Setiawan, 2010, p. 18). In marketing 2.0, which originated in the age of information, consumers are in

Cite this Article as: Grazyna ROSA, Izabela OSTROWSKA and Agnieszka TOMASZEWICZ "Study of Young Adults' Preferences in Passenger Rail Transport Services as A Basis for Marketing Activities" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

the limelight, however they are only perceived as passive recipients of marketing activities. The philosophy of marketing 3.0, on the other hand, focuses on specific behaviours of consumers and underlines that marketing activities should be related to human aspirations, values and spirit. In this sense, consumers not only meet their practical needs, but emotional as well. They are looking for goods and services (brands) which promote the pursuit of social, economic and environmental justice (Kotler, Kartajaya, Setiawan 2010, pp. 18-19). Another concept, currently the most up-to-date one, is the concept proposed by Ph. Kotler, referred to as Marketing 4.0. It involves a change from vertical to horizontal relations: inclusive and social. The originators of this approach describe marketing 4.0 as "deepened and extended human-centric marketing which addresses every aspect of consumer journey (Kotler, Kartajaya, Setiawan 2017, p. 15).

In the middle of the last century, the discussion on the then "service revolution" redefined services, going beyond the sale of "basic services". In this broader context, the emergence of a more distinct and autonomous marketing of services in areas such as transport, communication, education and e-commerce was recognised and envisaged (Gilmore 2006, p. 13). The marketing of transport services may be defined analogously as the way transport companies act in the market. Perceived through the prism of the process of rational stimulation and satisfaction of the needs reported by users, transport requires continuous adaptation of products and services to the changing market reality and customer requirements (Wyszomirski, Rucińska 2007 and Wojewódzka – Król 2007, p. 303).

The subject of passenger transport, including rail transport, is discussed in the literature by numerous authors such as (Bąkowski, Szewczuk (red.) 2000), (Engelhardt, 2007, 2015), (Paprocki, 1996), (Rosa, 2013, 2018), (Tomanek, 2002), (Wyszomirski, (red.), 1994), (White, 2016.), (Koleje pasażerskie…, 2017), (Cherkashin, 2018), (Abramovic, Sipus, 2019), (Drewnowski, 2019), (Bocheński, Wojtkiewicz 2019), (Krawiec, Ćwiek, 2019), (Massel, 2019), (Mężyk, 2019), (Szałucki 2019). The article focuses on the issue poorly examined in the source literature, namely young customers' preferences. The analysis will be based on the results of own research.

Customers' preferences in rail transport – current state of the art

Since the 1990s, the macro environment of passenger transport companies has changed radically. The internationalisation of the global economy, the creation of the European single market and the emergence of new competitors have consequently forced changes in transport companies. The main change, however, is the acceleration and proliferation of technical progress, which renders it necessary to introduce amenities for customers: to facilitate planning a journey, purchasing a ticket or providing a transport service. As may be observed, the ever-progressing and evolving digital age sets a new framework for marketing in the digital economy. The human element and the classic customer service allowing individual treatment are not used to a large extent, as opposed to self-service in the purchasing process and automation of the customer service process. As a consequence of technological changes, it is necessary to adapt all marketing tools to the changing nature of consumer journey leading to purchasing in the digital economy age (Rosa, 2020).

In societies of abundance, consumers are better educated and more demanding, thus a need arises for new marketing activities, for example customised marketing which involves specialising and adapting products to the requirements of the target market, taking into account the individual needs of buyers (Rosa 2020). Shaping and developing market orientation in this most recent approach – marketing 4.0, i.e. deepened and extended human-centric marketing, requires systematic recognition of transport needs, detailed research and analysis of needs, preferences and behaviours of transport users, taking into account their results in improving the products and services offered and building lasting relations with the market, internal and external environment of a company.

The market of transport services is undoubtedly a competitive market, thus the flow of marketing information, necessary in the decision-making process, concerning primarily marketing decision (Rosa, Mindur, 2014, pp. 583-588), is of great importance. Due to the specific nature of transport services, the main areas of research include: identification of transport needs and demand, customer preferences and competitive behaviour. The analysis of market share and competitive benchmarking is also crucial (Grzelec 2012, p. 108). The study of customer preferences enables extending the knowledge of transport needs and transport assumptions, and allows the determination of conditions under which these transport needs should be satisfied. The subject of this research are the users of freight or passenger transport services. It includes both studies of external phenomena (study of cultural conditions and freight transport practices), all elements of the marketing mix (mainly the transport service) and the evaluation of image of transport companies (customer survey) (Rosa, 2020).

As regards the transport situation in Poland, according to Eurostat data, in 2000-2016 the number of cars per 1,000 inhabitants in Poland increased from 261 to 599, which means that a potential rail transport customer in Poland may actually choose between a passenger car and a train. It should be noted that in many European countries this

indicator is at the level of 550, which means that in Poland it is higher than the European average by 35 (higher than in Italy, Norway, Germany, Austria, Luxembourg, Malta or Cyprus) (Bartosiewicz, Pielesiak 2019). At present, according to Eurostat and Statistics Poland data, the share of rail transport in passenger transport in Poland amounts to 7.3%. The EU average for trains is only 0.3 percentage points higher. Cars account for the largest share of land transport, with 81.3% in the EU and 77.2% in Poland. However, the share of bus and trolleybus services on the Polish market is higher than the EU average (Eurostat, 2019).

Table 1: Passenger transport in the European Union countries

Countries	Passenger transport			
	passenger cars	coaches, buses and trolleybuses	trains	trams and metro
	% of total passenger-kilometres			
EU-28	81.3	9.3	7.6	1.8
POLAND	77.2	13.9	7.3	1.6

Source: Eurostat, Road transport in Poland in the years 2016 and 2017, GUS, Warszawa, Szczecin 2019, s. 164.

The analysis of the global situation reveals that the rail network has been extended in countries such as China and Thailand, and has been reduced in countries such as Brazil, Japan, France and New Zealand. Certain railway companies (in USA, former Soviet Union countries, China and Mexico) mainly carry freight, which enhances efficiency and enables a "commercial" approach to prices and services. Other railway companies (in Sri Lanka, India and most of Western Europe) provide considerably more passenger services than freight services, which reduces productivity, increases costs and leads to political interference in transactions and pricing. As regards India and Western European railways, passenger transport services are, to a significant extent, provided to suburban passengers, which is both costly and generates only limited revenues (Banerji, 2017).

It is assumed that in rail passenger transport the basic factors influencing demand are: population size, location and density of settlements, level of economic development of the region, purchasing power of the society, time allocated to various forms of activity, operating costs of individual means of transport in relation to the prices of public transport services, the significance of particular preferences which affect the quality of services offered (Pielesiak, Bartosiewicz, 2019). It should be noted that the transport needs of the population related to the organisation of social life are determined by the location of: workplaces, educational institutions, shopping centres, leisure facilities, cultural and scientific institutions and public administration units. The movement of people may be additionally related to the maintenance of interpersonal relations (Kos, Krawczyk, Tomanek, 2018, p. 47). The behaviour of travellers is related to socioeconomic factors that characterise a given population, such as: age, education, car ownership, household size, income (De Witte et al., 2013, 329-341). As a result, the railway use varies across the European Union. The results, demonstrating the number of journeys per capita, are presented in Figure 1.

Fig. 1: The rate of railway use in selected European countries (Office of Rail Transportation 2017).

Switzerland has the highest rate of rail use in Europe, with nearly 70 journeys per capita per year. Travelling by rail in this country is characterised by (Urząd Transportu Kolejowego, 2017, p. 11):

- high availability of railway services (large number of trains per day and cyclical train timetable);
- reliability;
- travel comfort (comfortable and well-muted cars available even in regional transportation);
- well-organised connections with other modes of transport, as well as a wide range of services offered under a single ticket for all modes of transport.

Competition in passenger transport mainly involves instruments such as product (time, comfort and safety, physical accessibility and number of connections) and price. Competition in the market for passenger transport services is based on the substitutability of services provided by carriers representing different transport modes and offering different yet substitutional services for the transportation of passengers or cargo (Paprocki 1996, p. 62). The competitors in passenger transport may include (Engelhardt 2007, s. 171):

- mass transportation (rail and road carriers) and private transportation through cars;
- railway carriers and local municipal carriers (bus, metro, tram) providing services of short-distance transportation in urban agglomerations;
- railway and bus carriers providing services of short, medium and long distance transportation, the latter concerning in particular international connections;
- railway and air carriers (mainly low cost lines) providing medium and long distance transportation services.

Correct recognition of consumer preferences which influence purchasing behaviours often has a decisive impact on the market position of companies. This results from the fact that the consumer is under the influence of numerous factors of a subjective nature, which are difficult to specify as they stem from feelings and experiences which the consumer acquires throughout their life. Feelings of this type are defined as internal preferences which reflect consumer's tastes. Research on consumer preferences may be conducted on the basis of historical observations as well as data describing consumer intentions included in the methods of analysis of expressed preferences. They refer to market behaviours declared by consumers. Under this assumption, the primary source of information is data collected through direct and indirect surveys, which record consumers' purchasing preferences. (Ostrowska, Rosa, Tomaszewicz, 2019).

Consumers make decisions about the preferred means of transport in conditions of uncertainty. The variables known to the customer at the time of making the decision usually include travel costs, departure time and estimated travel time. When making a decision, they take into account the likelihood of such events as delayed departure and arrival at the destination, the need for a transfer, the risk of an accident or the occurrence of various inconveniences during the journey (e.g. heating failure, no seats available, fellow travellers causing inconvenience). There are studies investigating decisions made by the consumers when choosing means of transport, which enable the prediction of risks they are willing to take when choosing different means of transport (Rasouli S., Timmermans H., 2014). The authors stress that the consumer's decision is influenced by the routine, customary behaviour related to transportation, i.e. preferences based on their experience. Moreover, the choice of means of transport is contingent upon the consumer's disability and the fact that it might be difficult for them to travel independently, for example by train, and they must be assisted. It was observed that as the length of the journey increases, the likelihood of having to assist a disabled person during the journey raises. People with disabilities may travel more independently if they could use additional door-to-door services which are not offered by railway companies (Ermagum et al., 2016).

People attempt to make rational decisions in accordance with their preferences, which transform into attitudes and influence purchasing behaviour (Kroesen M., Chorus C. 2018). Recognition of consumers' preferences, existing and predicted ones, and their purchasing habits allows the preparation and implementation of an effective programme of influencing consumers (Szymańska 2007). Consumers' preferences are generally understood as subjective assessments or a system of assessments which is the basis for choices made in the purchasing process (Trojanek 2009, Black 2006, Rybicka 2003) which motivate consumer behaviour. Convictions are formed in a situation in which a consumer chooses a good or a service from a number of available options and prefers one product over others. Convictions (preferences) may be shaped by consumers on the basis of their opinions, knowledge, emotions or beliefs. They are a reflection of what the consumer thinks of a given product or brand. They are consumer's subjective feelings which reflect the consumer's tastes. Consumers are constantly extending their knowledge about the market, and as a consequence their preferences change. As a result of competitive activities, especially aimed at increasing customer value, even loyal customers may consider changing their current service provider (Gracz, Ostrowska 2014, Ostrowska, Rosa, Tomaszewicz, 2019).

Preferences have the following features:

- they concern specific objects of choice, i.e. tangible or intangible items;
- they are demonstrated immediately before or during the purchase;
- they very often reveal themselves in the purchasing decision process and are one of the factors determining the decision to purchase a particular product;
- their measurement depends on their type (internal and external preferences) (Trojanek 2009, Kaczmarczyk 2006, Ostrowska, Rosa, Tomaszewicz, 2019).

The preferences of passenger rail transport service users may be defined as the necessity to satisfy transport needs, which reflect their expectations and personality (Rosa, 2020). Preferences in the purchasing process usually translate into consumer behaviour on the market, which may also be exhibited when choosing transport services. Due to the availability of online services and information, the "digital traveller" has ever-increasing requirements and expects customised service (Nyurenberger, et al., 2019).

The analysis of consumers' preferences enables the identification of product characteristics which guide consumers in making their purchasing decisions, however the significance of individual factors in making these decisions varies. For that reason, studies of consumers' preferences are carried out (Rybicka 2003). These studies explain the motivation behind purchasing decisions in passenger rail transport as well. Therefore, identifying these factors is significant in the process of choosing a means of transport. In addition, the structure of preferences reflects the hierarchical structure of unrestricted choice of services offered on the market and indicates the order in which consumers choose individual services (Ostrowska, Rosa, Tomaszewicz, 2019).

Study Methodology

On the basis of the results of marketing research, the target segments (markets) for the researcher may be identified. The target market is the group of existing or potential customers of the company. Services on offer and other marketing tools are developed for this market (which may consist of several segments). Segmentation relating to passenger transport is the division of the market of service users into uniform, homogeneous groups which form units similar to each other in respect of, for example: travel destinations, distance travelled, type of transport, frequency of service use, having similar response to external stimuli as well as similar in respect of age, gender,

income, place of residence, etc. (Rosa, 2020). In the transport services market, there are segments to which transport companies target their marketing offer, differentiated in terms of scope and type, promotion and information, prices and distribution. An important segment of the passenger transport market is young adults, i.e. people aged 18-29 years.

The research was carried out from October 2017 to March 2018 on a random sample of 350 people from all over Poland, meeting the age requirement and thus constituting a homogeneous sample of "young adults" aged 18-29 years (50,61% females, 49,39% males). The analysis of the completed questionnaires revealed that 19 of them were incomplete, and thus a sample of 331 people was eligible for further study (error 0.03 and $\alpha = 0.95$). The aim of the research was to select the key features of passenger rail transport services relevant to customers, and have these features assessed by the providers of passenger rail transport services in Poland.

Table 2 presents the characteristics of the respondents based on the information contained in the particulars.

Table 2: Respondents' socio-demographic characteristics (N=331)

	Total (%)
Gender	
Female	50.61%
Male	49.39%
Education	
Higher education	18.54%
Secondary education	78.72%
Vocational education	2.74%
Household composition	
Single	9.37%
Two people	14.5%
Three people	23.26%
Four people	36.25%
Five and more	16.62%
Household net income/month/ per capita	
Very low income (<232 EURO)	9.24%
Low income (232-464 EURO)	39.81%
Medium income (465-696 EURO)	35.03%
High income (696 EURO<)	15.92%
Job status	
Employed	83.42%
Unemployed	16.58%
*Student	76.74%
Place of residence	
Countryside	22.80%
City up to 99,000 inhabitants	32.22%
City with 100,000 to 199,000 inhabitants	14.29%
City with over 200,000 inhabitants	30.70%

Results

On the basis of conducted research, Figure 2 presents a summary of the answers given to the question about the importance of different features of passenger rail transport.

Fig. 2: Ranking of features of passenger rail transport services (results of own study)

The most important features identified by respondents which influence purchasing decisions were punctuality and convenient times of connections, which were assessed as very important by 73 percent of all respondents. Slightly fewer people indicated that being able to check connections on the Internet and safety in means of transport are very important (70 percent). The following features were identified as the next most important features of rail passenger transport services (answers: very important) by young customers:

• ticket price (69 percent);
• number of connections (68 percent);
• travel time (68 percent);
• number of transfers (68 percent);
• quality of provided services (62 percent);
• being able to purchase a ticket online (61 percent).

These factors may be grouped according to specific types of preferences concerning:

a) the duration of the transport service;
b) price of the transport service;
c) customer service during transport service provision;
d) use of modern technologies in the process of service provision.

In order to determine the respondents' preferences concerning particular categories, a factor analysis was carried out for all questions included in a given category. The lower the average for a given category, the more important was a given aspect for the respondents. In addition, Pearson's Chi^2 analysis was performed to verify the correlation with gender and the significance of each category.

In the first category, factors related to travel time were grouped (Fig. 3). The category "travel time in passenger rail transport" included:

- convenient times of connections;
- the punctuality of trains;
- time of travel;
- the number of transfers;
- number of connections.

Fig. 3: Preferences in the duration of the transport service and its importance to customers (based on the results of own study)

According to the obtained average $M = 1.38$; $SD = 0.55$, travel time was the most important aspect in rail transport. Closer examination revealed that women were more concerned about travel time ($M = 1.21$; $SD = 0.33$) than men ($M = 1.48$; $SD = 0.53$).

The second category, in which the respondents' preferences were investigated, was the fare (Fig. 4). The category "price for passenger rail transport service" included:

- price of the ticket;
- special offers;
- guarantee of reimbursement due to delays.

Fig. 4: Preferences in prices for transport service and their importance for customers (based on the results of the own study)

According to the average obtained, this was the second most important aspect in rail transport(*M* = 1.57; *SD* = 0.57). In addition, a statistically significant difference was observed in the assessment of the significance of the ticket price, between women (*M* = 1.48; *SD* = 0.47) and men (*M* = 1.67; *SD* = 0.66). Women attached more importance to the price of rail travel than men.

The third category included aspects related to broadly understood customer service during transport service provision (Fig. 5). This category included:

- safety in means of transport;
- quality of services provided;
- being able to purchase a ticket in the train;
- information about the next station;
- equipment in the means of transport;
- competence of the service staff;
- direct communication with service staff;
- the way the offer is presented.

Fig. 5: Preferences in customer service in rail transport and its importance to customers (based on the results of own study)

The category average amounts to 1.73 and a standard deviation is 0.4. In this case, there is also a difference in the level of statistical trend between women and men [t(225) = -1.91; p = 0.57; d = -0.25; 95% CL(LL = -0.21; UL =0)], which means that women paid more attention to customer service aspects (M = 1.68; SD = 0.38) than men (M = 1.78; SD = 0.42).

The last category defined as "modern technologies in passenger rail transport" includes (Fig. 6):

- being able to check rail connections on the Internet;
- being able to purchase a train ticket online;
- being able to purchase a ticket using mobile devices;
- availability of an electronic ticket during the journey;
- being able to track the route and location of the train during the journey through the mobile application;
- provision of additional services, such as Wi-Fi;
- being able to check information in social media during the journey.

Fig. 6: Preferences in the use of modern technologies in the process of providing transport services and their importance for customers (based on the results of own study)

The average for this category was M = 1.8 with standard deviation SD = 0.57, which meant that for most of the examined categories the use of modern technologies in the provision of transport services was the least significant. In this respect, the use of modern technologies in the provision of transport services was less important for women(M = 1.73; SD = 0.5) than for men (M = 1.48; SD = 0.63).

Conclusions

As a consequence of technological changes, it is necessary to develop and adapt classical marketing to the changing nature of consumer journey, leading to purchases in the age of digital economy and the development of modern marketing, also in the passenger rail transport market. The ever-progressing and evolving digital age sets a new framework for marketing in the digital economy for passenger transport, including rail transport. Unlike the traditional approach, modern marketing should introduce new and advanced elements, so far not experienced by travellers, which are in the sphere of imagination or expectations.

Modern marketing of passenger rail transport services may be oriented towards factors relating to such areas as:

- travel time which has proved to be the most important for young customers. Convenience of transfers and punctuality of trains are of great importance to customers. In communication with customers, the competitiveness of rail travel distances compared to other modes of transport may be emphasised. Companies must ensure that their services are timely and may gain a significant competitive advantage in this respect.
- in the second place, consumers ranked the factors related to the price of services, which means that they compare different modes of transport in terms of the cost of the service. In their activity, transport companies should pay special attention to the level of prices, but also to the availability of special offers allowing price differentiation according to the age of the customer (special offers for students, seniors), length of the route, size of the group (family tickets, group tickets), travel time (weekend routes).
- the third most important category included the factors related to the customer service process. In this respect, the safety of passengers, the quality of service, being able to buy a ticket in the train, being informed about the next station and the competence of the service staff proved to be of great importance. The information

contained in traditional leaflets or folders is the least important for people searching for information on the Internet.

- the last group concerned the aspects related to the availability of new technologies. In this area, companies should develop professional passenger information systems – especially the online availability of information on connection times, travel times and possible holdbacks on the route. It is necessary to introduce modern forms of distribution of services (tickets) through online systems and ticket machines, treated as an important complement to traditional sales – ticket offices and on trains. Less important are solutions that enable tracking the route and location of the train during the journey through a mobile application, Wi-Fi services in the train or tracking information in social media during the journey.

In the transport services market, the concepts of marketing 3.0 are manifested in the fact that customers, striving for self-fulfilment and self-development, travel for a specific purpose or for specific reasons, at specific times, do not want to wait for the means of transport, but instead require constant online information, facilities, e.g. place for bicycles, suitcases, power sources, a comfortable and intimate place to sit, air-conditioning, according to the conviction that the goods and services they use should have the expected values (marketing of value). A further step in its development could be marketing 4.0 covering horizontal, integrative and social relationships in transport with a focus on social media, elimination of geographical and demographic barriers, development of new technologies and social networks integrating communities interested in tourism, sharing knowledge and their own travel experiences.

Abstract

The article examines the economic and social consequences of the COVID-19 pandemic. By constructing a multifactor regression model, the authors analyzed the economic and social indicators of development of Ukraine and Sweden, investigated the dependence of selected indicators on quarantine measures. In order to identify the basic patterns of development of economic and social processes under the influence of quarantine measures related to COVID-19, regression models of socialization of economic development were calculated. Indicators that during the correlation analysis revealed the greatest dependence on domestic policy and the level of economic development of regions in the conditions of COVID-19 were selected as dependent variables, namely: employment rate (%), average per capita disposable income (USD); indicators of economic development and financial condition of the regional budget: revenues of the regional budget per 1 person (USD), subventions from the state budget per 1 person (USD), gross national product per 1 person (USD), capital investments per 1 person (USD). The obtained regression parameters in the analyzed regions are equally targeted and show a direct relationship between the studied indicators of social development and regional budget revenues and inverse dependence on government subsidies, which confirms the reduction of this tool to influence the development of social sphere in the region under COVID-19. At the same time, there is a direct and stable relationship between local budget revenues and citizens' incomes. Regression models showed that in the conditions of COVID-19 both in Sweden and in Ukraine, the average per capita disposable income of the population directly depends on subventions from the state budget. Regression analysis showed a close link between quarantine measures related to the COVID-19 pandemic and the socio-economic development of Sweden and Ukraine.

Keywords: COVID-19, pandemic, economic and social consequences, public policy, Ukraine, Sweden.

Introduction

Today is characterized by a large-scale global crisis related to the spread of COVID 19, as evidenced by four main parameters: the rate of spread (the disease was first recorded on December 31, 2019 in Wuhan, China; on March 11, 2020 it was recognized by the WHO as a pandemic; as of August 28, 2020, more than 24 million confirmed cases worldwide) [2]; geographical scale (it is difficult to name a country or territory that would not be affected by the disease); their depth (consequences are observed in all spheres of life, all strata of society); unpredictability of the course and depth of influence (scientists have not reached the unity in their conclusions and forecasts. In the media there constantly appear explanations and recommendations that contradict each other).

At present, governments in most countries around the world are focused on effective countering the global threats of the COVID-19 pandemic. Effective tools to protect the population from infectious diseases include such measures as: "suspension of certain facilities, the introduction of restrictions to significantly reduce population mobility, social distancing and localization of centres of the infection" [2]. At the same time, the scale of restrictions, their prolongation over time negatively affect the daily life of the population, respect for rights and freedoms; functioning of public and state institutions, national economies. In addition, different countries have different socio-economic potential, respectively, face different consequences. Some researchers claim that the losses to the economy and society

Cite this Article as: Oksana MARUKHLENKO, Tetiana POSPIELOVA and Svitlana SOKOLOVSKA“ Economic And Social Consequences of The Covid-19 Pandemic: The Experience of Ukraine and Sweden ” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

from quarantine are much greater than the probable losses from a pandemic. This is especially true in regions with low socio-economic potential. Under these conditions, the study of the socio-economic potential of the region and its consideration in the development of state policy to counter COVID 19 becomes an extremely important issue. Waiting for the second wave of the pandemic further highlights this problem.

Actual scientific researches and issues analysis.

The search for scientific literature on the subject of this study was conducted in the international bibliographic databases Scopus (https://www.scopus.com/). The following data reflect the situation as of August 25, 2020. The analysis of 2,084 documents from the Scopus database showed that 2,079 documents were published in the current 2020. At the same time, almost 700 of them are still in press, ie published in the database in absentia. A significant percentage of publications (79.9%) are published in open access journals.

About 35% of all publications belong to authors from China, in second place (about 20%) researchers from the United States, followed by scientists from the UK (11%), Italy (7.5%), France (3.8%), Canada 3.7%), Australia (3.3%), Germany (3.3%), India (3.3%).

The largest number of publications is devoted to the origin, clinical characteristics, epidemiological analysis of the coronavirus. In particular, the most cited are the following publications: "SARS-CoV-2 Viral Load in Upper Respiratory Specimens of Infected Patients"; "Clinical course and outcomes of critically ill patients with SARS-CoV-2 pneumonia in Wuhan, China: a single-centered, retrospective, observational study"; «Clinical characteristics and intrauterine vertical transmission potential of COVID-19 infection in nine pregnant women: a retrospective review of medical records»; "Early epidemiological analysis of the coronavirus disease 2019 outbreak based on crowdsourced data: a population-level observational study"; «Nowcasting and forecasting the potential domestic and international spread of the 2019-nCoV outbreak originating in Wuhan, China: a modeling study».Despite the large number of studies on the problems of COVID-19 in the world, the socio-economic consequences of the pandemic remain unnoticed by scientists, which led to the study.

Despite the large number of studies on the problems of COVID-19 in the world, the socio-economic consequences of the pandemic remain unnoticed by scientists, which led to the study.

The purpose of the article is to study the economic and social consequences of the COVID-19 pandemic.

The Main Part

The COVID-19 pandemic has forced states to impose quarantine measures, including closing state borders, suspending transportation, shutting down a large number of service-related businesses, and imposing restrictions on businesses. There is a significant impact of quarantine measures related to COVID-19 on the social and economic development of EU countries. As a result, the world economy is plunged into a deep recession – countries with the most stable economic system are projected to lose at least 2.4% of their GDP by the end of 2020. There is also a decrease in the forecasts for the growth rate of domestic GDP for 2020 from 2.9% to 2.4%.

The Swedish economy lost twice less during the pandemic, compared to other European countries - 7%. And although this economic downturn is record-high for Sweden, it still has not had as significant impact on the quality of life of the population as it has had in other European countries. As for Ukraine, according to the updated data of the State Statistics Service, for five months of 2020, the real GDP of Ukraine decreased by 5.9%. The Cabinet of Ministers forecasts a possible decline in Ukraine's GDP in 2020 by 4-8% compared to 2019. The International Monetary Fund has downgraded its forecast for Ukraine's GDP to fall to 8.2% in 2020. This indicates that although GDP in Ukraine and Sweden fell significantly less in 2020 than in other European countries, the impact of COVID-19 on their social and economic indicators differs. The state policy of counteracting COVID-19 also differs. The state policy of counteracting COVID-19 also differs. Sweden has become the only EU country where the authorities have not imposed the strict quarantine in connection with the pandemic. That is why the article examines the experience of these countries. In further consideration the socio-economic potential of these countries will be presented in more detail. The trends in economic activity and budgetary capacity in Ukraine and Sweden are shown in Tables 1 and 2.

Table 1: Indicators of the social situation in Ukraine and Sweden*

Indicators of the social status of the region / Period	Total population, people	Employment rate, %	Average life expectancy at birth, years	The incidence of COVID-19, %	Disposable income per capita, %	average salary, $	The level of criminogenic danger
SWEDEN							
2015	9836003	65,2	81,9	0	41965,2	3497,1	15,342
2016	9836003	65,7	82,31	0	43188,0	3599,0	15,219

Analyzing the indicators given in Tables 1 and 2, it should be noted that both in Sweden and in Ukraine over the past five years there has been a positive increase in key economic development indicators, including: GDP growth per capita, capital investment per capita, increase of own revenues of local budgets per capita. The dynamics also shows a significant increase in subventions from the state budget for socio-economic development of separate territories.

However, if we consider the economic indicators in terms of a separate territory, we can see that there is a significant difference between the economic model itself. In Sweden, almost half of the population's income goes to the country's budget. Subventions from the state budget average about 14.5% of budget revenues. At the same time, capital investments account for almost 50% of budget revenues, which indicates directing funds to the development of the country's economy, its well-being and, as a consequence, the development of the country's social potential. Unlike Sweden, Ukraine's budget revenues are higher than those of the country's population. At the same time, subventions from the state budget per person are higher than revenues. This indicates a constant budget deficit. Great burden on business structures. Investments to the country's development are almost non-existent. That is, the bulk of the funds goes to provide the social component. With such an economic model, it is very difficult to keep economies at least at a satisfactory level, especially in times of crisis and under the influence of such global challenges as COVID-19.

Research Methodology

Quarantine conditions not only significantly affect the development of socio-economic potential of countries, but also cause profound changes in the economy and social sphere. The consequences of this influence have both positive and negative effects. The latter, first of all, includes the growing dependence of countries on changes on international markets, reducing the role of domestic sources of funding, accelerating the spread of global financial crises in the national financial and social environment and so on. Undoubtedly, all these effects are reproduced not only in the economic sphere, but also in social development. To ensure a decent welfare of the population, positive social dynamics, social and economic processes must be combined as a necessary condition for maintaining the correlation between opportunities and needs. This also applies to the impact of the pandemic on social development.

In order to study these effects, we were faced with the task of determining the impact of economic indicators on indicators that characterize the social component of the regions. For this purpose, a multifactor regression model was built:

$$Y(x) = f(x_1, x_2, \ldots\ldots x_{n-1}, x_n), \quad (1)$$

де X_i– variable economic factors;

n - number of factors.

Unquestionably, it is important to check the quality of the found parameters of the model and evaluate the model as a whole for adequacy to the real processes of social development and ensuring the welfare of the population. The solution of the two above tasks to assess the adequacy and quality of the model would allow to use the constructed econometric model to explain the results of the impact of the studied socio-economic factors. Moreover, it will provide an opportunity to model in the future the importance of socio-economic factors.

It should be noted that it is possible to formulate the general set of indicators that most reproduce the socio-economic potential, subject to the presence of previous research by scientists on this issue and available statistics.

Indicators that during the correlation analysis revealed the greatest dependence on domestic policy and the level of economic development of regions in the conditions of COVID-19 were selected as dependent variables:

- y_1- Employment rate, %

- y_2- Average per capita disposable income, USD

Indicators of economic development and financial condition of the regional budget are chosen as dependent variables:

- x_1 - revenues of the regional budget per 1 person, USD;

- x_2 - subventions from the state budget per 1 person, USD;

- x_3 - gross national product per 1 person, USD;

- x_4 - capital investment per 1 person, USD.

In this case, the total multicollinearity in the array is detected by the Pearson test ($\chi 2$) with a reliability of p = 0.95. The partial correlation coefficients that characterize the closeness of the relationship between two variables are determined later, provided that the third one does not affect this relationship. Then, with the help of e-statistics with a reliability of p = 0.95, pairs of factors are identified, between which there is multicollinearity.

After establishing stochastic multicollinearity, it should be eliminated if possible. One such method is the method of extracting variables (factors). Its essence is to remove (should be consistent with the purpose of the study and economic feasibility) one or more highly correlated explanatory variables from the regression. Then the new model is re-evaluated. To verify, several possible models are constructed and the value of the coefficient of determination R2 is calculated, which measures the share of variation of the indicator, which is explained by the relationship between the independent variable and factors and the calculated value of Fisher's criterion Fp by formulas:

$$R^2 = \frac{\sum_{i=1}^{n}(\hat{Y}_i - \bar{Y})^2}{\sum_{i=1}^{n}(Y_i - \bar{Y})^2}, \quad (2)$$

де $\hat{Y}_i$ - the estimated value of the indicator for the i-th observation;

Y_i - statistical value of the indicator for the i-th observation;

$\bar{Y}$ - sample average value of the indicator.

$$F_p = \frac{R^2}{1-R^2}\left(\frac{n-m-1}{m}\right), \quad (3)$$

де n - number of observations;

m - number of factors.

The closer the value of R2 to one, the better the statistics correspond to the constructed regression function. The value of Fp should be several times larger than the tabular one, then the regression will not only be significant, but also have practical value for forecasting.

After deleting one variable, a two-factor model is built. The coefficients of the regression equation Y = a0 + a1X1 + a2X2 are calculated using matrix operations by the formula:

$$\vec{a} = \left[[X]^T[X]\right]^{-1}[X]^T\vec{Y} \quad (4)$$

After finding the estimates of the regression parameters a0, a1, a2, the new model is checked for multicollinearity. If the result is positive, the adequacy of the model (regression equation) according to Fisher's criterion and the significance of the parameters (individual factors) of the regression according to Student's criterion are performed.

Then the forecast value of the indicator and the interval forecast (reliable interval) for the set values of factors according to formulas (4 and 6) are calculated:

$$DY = t_c S\sqrt{X_p[X^TX]^{-1}X_p^T + 1}, \quad (5)$$

де t_c - tabular value of the Student's criterion;

Xp - vector-string with predictive values of factors;

S - standard deviation of the estimate (measures the scattering of the value of the indicator relative to the line of the regression function) is the square root of the variance of adequacy:

$$S = \sqrt{\frac{\sum_{i=1}^{n}(Y - \hat{Y}_i)^2}{n-m-1}}, \quad (6)$$

$$Y_{\max\,(min)} = Y_p \pm DY, \quad (7)$$

де *Yp* - point forecast of the indicator.

The calculated partial regression coefficients indicate the average change of the dependent variable for a single change of the corresponding independent variable and the constant values of other independent variables. According to the known regression equation, it is possible to model the future parameters of the indicator when changing the values of one of the factors. Next, partial elasticity coefficients are calculated for the forecast.

Research Findings

In order to identify the basic patterns of development of social processes under the influence of quarantine measures related to COVID-19, regression models of socialization of economic development were calculated. In the process of regression analysis, statistical methods of analysis and a package of applied statistical analysis SPSS were used. Using the selected data given in Tables 1 and 2, a regression analysis of the impact of economic development factors of the regions in the conditions of COVID-19 on the development of social potential for Sweden and Ukraine was carried out.

As a result of calculations for ***Sweden*** on the first dependent indicator, the multiple regression equation was obtained: Y1 = 71.8165-0.000115X1 + 0.000344X2-0.00322X3 + 0.00349X4. Economic interpretation of the model parameters: increasing X1 by 1 unit leads to a decrease of Y1 by an average of 0.000115 units; an increase in X2 by 1 unit leads to an increase in Y1 by an average of 0.000344 units; an increase in X3 by 1 unit leads to a decrease in Y1 by an average of 0.00322 units; an increase in X4 by 1 unit leads to an increase in Y1 by an average of 0.00349 units. According to the maximum coefficient β4 = 16.113, we conclude that the greatest impact on the result Y1 (employment rate) has a factor X4 (capital investment per capita).

As a result of calculations on the indicator Y2 (average per capita disposable income of the population) the multiple regression equation was obtained: Y2 = 85637.6118-0.1065X1 + 4.2674X2-17.5706X3-7.3677X4. Economic interpretation of the model parameters: increasing X1 by 1 unit leads to a decrease in Y2 by an average of 0.107 units; an increase in X2 by 1 unit leads to an increase in Y2 by an average of 4,267 units; an increase in X3 by 1 unit leads to a decrease in Y2 by an average of 17,571 units; an increase in X4 by 1 unit leads to a decrease in Y2 by an average of 7,368 units. According to the maximum coefficient β2 = 9.016, we conclude that the greatest influence on the result Y2 has a factor X2 (subventions from the state budget per 1 person).

As a result of calculations for ***Ukraine*** on the indicator Y1 (employment rate), the multiple regression equation was obtained: Y1 = 49.5016-8.3E-5X1-0.03273X2 + 0.05048X3 + 5.0E-6X4. Economic interpretation of the model parameters: an increase in X1 by 1 unit leads to a decrease in Y1 by an average of 8.3E-5 units; an increase in X2 by 1 unit leads to a decrease in Y1 by an average of 0.0327 units; an increase in X3 by 1 unit leads to an increase in Y1 by an average of 0.0505 units; an increase in X4 by 1 unit leads to an increase in Y1 by an average of 5.0E-6 units. According to the maximum coefficient β3 = 10.457, we conclude that the greatest influence on the result Y1 has a factor X3 (gross national product per capita).

As a result of calculations of the indicator Y2 (average per capita disposable income of the population) the multiple regression equation was obtained: Y2 = 105.3154 + 0.02691X1 + 18.4021X2-18.5105X3 + 3.2835X4. Economic interpretation of the model parameters: an increase in X1 by 1 unit leads to an increase in Y2 by an average of 0.0269 units; an increase in X2 by 1 unit leads to an increase in Y2 by an average of 18,402 units; an increase in X3 by 1 unit leads to a decrease in Y2 by an average of 18.51 units; an increase in X4 by 1 unit leads to an increase in Y2 by an average of 3,283 units. According to the maximum coefficient β2 = 2.746, we conclude that the greatest influence on the result of Y2 has a factor X2 (subventions from the state budget per 1 person).

The statistical significance of the equations is verified using the coefficient of determination and Fisher's test. It is established that in the studied situation 99.26% of the total variability Y is explained by the change of factors Xj.

The obtained regression parameters in the analyzed regions are equally targeted and show a direct relationship between the studied indicators of social development and regional budget revenues and inverse dependence on government subventions, which confirms the reduction of this tool to the influence social development in the region under COVID-19. At the same time, there is a direct and stable relationship between local budget revenues and citizens' incomes. Regression models showed that in the conditions of COVID-19 both in Sweden and in Ukraine, the average per capita disposable income of the population directly depends on subventions from the state budget.

Based on the results of the analysis, the corresponding regression models were constructed and verified, which are shown in Table 3.

Table 3: Regression models of the dependence of the development in the social sphere on the economic indicators connected with COVID-19 in terms of the analyzed regions

Regression indicators	Economic indicators in the conditions of COVID-19				Multiple correlation coefficient, R	Adjusted coefficient of determination, R2	The greatest influence on the result of Y
	x_1	x_2	x_3	x_4			
Sweden							
Y_1	$Y_1 = 71.8165-0.000115X_1 + 0.000344X_2-0.00322X_3 + 0.00349X_4$				0,981	0,813	X_4
Y_2	$Y_2 = 85637.6118-0.1065X_1 + 4.2674X_2-17.5706X_3-7.3677X_4$				0,989	0,89	X_2
Ukraine							
Y_1	$Y_1 = 49.5016-8.3E-5X_1-0.03273X_2 + 0.05048X_3 + 5.0E-6X_4$.				0,985	0,846	X_3
Y_2	$Y = 105.3154 + 0.02691X_1 + 18.4021X_2-18.5105X_3 + 3.2835X_4$				0,996	0,963	X_2

The level of impact of COVID-19 on the socio-economic development of the region depends on the state policy for counteracting the pandemic. The main idea of the Swedish model of coronavirus control, authored by the country's chief epidemiologist Anders Tegnell, was the natural development of mass immunity to infection, serious support for the economy, minimization of restrictions.

Among the restrictions that have been introduced are the following: the transition of secondary schools and universities to distance learning; ban on visiting all places for the elderly; temporary (from April 18 to June 30) restrictions on meetings, closure of shopping centers, termination of transportation; ensuring the redistribution of drugs and medical equipment.

To mitigate the impact on the Swedish economy, a package of emergency measures has been proposed to overcome the crisis for small and medium-sized enterprises and employees. The total amount of the anti-crisis package is up to 300 billion kronas, or about 30 billion dollars. The IMF website, with reference to official data, provides slightly higher estimates: from 380 billion to 668 billion Swedish kronas (from 7.6 to 13.3% of GDP in 2019), depending on the depth and duration of the decline in economic activity. Under an agreement between the government, the Centrist Party and the Liberal Party, the municipalities and regions most affected by the ongoing COVID-19 outbreak will receive additional funding totaling SEK 22 billion. Prior to the epidemic, the amount of support for regions and municipalities was estimated at 5 billion kronas. This additional funding will be provided both in the form of an increase in state subsidies and in the form of an additional amount to cover additional costs for health care and social services.

Business Support

1. Guaranteed government loans. The main model of supporting Swedish business is to provide guarantees to banks that accommodate with loans. The central government will ensure that at least 70% of new loans are issued to companies that are experiencing financial difficulties due to the COVID-19 virus, but otherwise are sustainable. Financing will be issued to banks, which, in turn, will provide guaranteed loans to companies.

2. Temporary discount on the cost of rent in particularly vulnerable sectors of the economy. To reduce costs for companies experiencing significant hardship as a result of the spread of COVID-19 - in sectors such as the durable goods trade, hotels, restaurants and some other activities - provides support aimed at facilitating and speeding up rent revisions.

3. Tax benefits. There is a deferral of no more than 3 months for corporate social security contributions, VAT and payroll taxes for up to 12 months (SEK 27 billion if used similarly to GFC and SEK 315 billion if fully used by all firms), deferral of annual VAT (SEK 7 billion) and deferral of SME taxes (SEK 13 billion).

4. Support for individual entrepreneurs. The rules for allocating tax reserves have been temporarily changed, so that for individual entrepreneurs affected by COVID-19 containment measures, taxes have been reduced.

5. Support for culture and sports. The government plans to increase funding for culture and sports by SEK 1 billion (500 million kronas each). The funds are intended to compensate for the losses of these areas due to the restriction of fees and social distancing.

Employment support, unemployment benefits and other labour market measures

1. Support for underemployment and wage subsidies. As in many other European countries, the Swedish government, in a crisis caused by the spread of coronavirus, supports the preservation of employment by co-financing the cost of part-time employment. The government will cover up to 75% of business costs at the risk of reducing working hours or laying off employees. Employers will be able to halve wage costs under the so-called "short-term redundancies" programme, and employees will be able to receive 90% of their initial salary. In addition, there are additional costs for subsidizing wages for short-term leave.

2. Temporary reduction of employers' contributions to social insurance and individual contributions. For the period from March 1 to June 30, 2020, small businesses are offered a temporary reduction in employers' social security contributions so that companies can only pay old-age pension insurance premiums. It is assumed that this reduction should apply to no more than 30 employees and to the part of the employee's salary that does not exceed 25,000 Swedish kronas ($ 2,500) per month. This entails tax breaks of up to SEK 5,300 ($ 530). The value of this proposal for public finances is estimated at SEK 33 billion (USD 3.3 billion).

3. Unemployment benefits. The government is proposing to temporarily ease the conditions for joining the number of recipients of unemployment benefits. It is also proposed to increase the minimum and maximum amounts of unemployment benefits.

4. Education and training programmes. To expand the opportunities for study in higher education, it is proposed to increase the number of places, including summer courses. In addition, it is proposed to increase funding for universities to develop distance learning. Funds are also allocated for online education, also known as MOOC (Mass Open Online Courses), which are free and open to the public. To compensate for the increase in workload, it is also proposed to increase funding for the Swedish Council for Higher Education and the Swedish Council for Student Finance. Higher education programmes are available to anyone who has been notified of the termination of their contract.

It is proposed to increase funding for regional vocational education for adults. It is proposed to expand the number of budget places in the system of additional professional higher education; offer the population new short courses and packages of courses, as well as various types of pilot projects so that more people can improve their skills. It is proposed to expand the number of places in the public high school with full funding from the central government.

In addition, greater opportunities for distance learning are offered, partly through additional support for distance learning providers in vocational higher education, and partly through the provision of more distance learning courses in training associations.

5. Active policy in the labor market. It is proposed to increase funding for Arbetsf6rmedlmgen programmes (Swedish Public Employment Service) and active programmes in the labour market.

Support of the population by social insurance instruments

1. The qualification day for the payment of sickness benefits has been canceled (from March 11 to May 31, 2020). This decision means that workers will receive sickness benefit from the time they are absent from work due to illness, and the central government, not employers, will cover the cost of the first day of leave.

2. Self-employed people are also paid compensation due to illness for 1-14 days. The state pays for sick leaves for two months, until May 2020.

In contrast to Sweden, the Government of Ukraine has introduced stricter restrictive measures, in particular: closure of all educational institutions (by the end of May); restriction of passenger transport and public events; suspension of food, cultural, trade and entertainment establishments.

The Government of Ukraine has also approved a law providing for administrative consequences for violating sanitary and epidemiological requirements and increasing criminal liability for violating requirements aimed at preventing the

spread of an infectious disease. During this period, only citizens of Ukraine and people who have the right of permanent residence in the country, including accredited representatives of the diplomatic and international community, will have the right to enter the country. Long-distance transport and subway work were stopped.

The parliament has also introduced a number of measures to minimize the economic consequences for companies, including small and medium-sized enterprises [10], by amending the Tax Code. The President of Ukraine has ordered customs clearance of humanitarian goods within 24 hours, and in case of delay, the State Customs Service / Ministry of Reintegration of the Temporarily Occupied Territories must notify the relevant humanitarian organization.

Operational response. By Order № 185 of January 2020, the Ministry of Health provided technical recommendations for the preparation and response of the health care system. The government has stepped up health measures at intersections, expanded the dissemination of information and communication campaigns on the risks of infection, and strengthened the national epidemiological surveillance system to facilitate the detection of cases; has designated 51 medical facilities across the country as support facilities for responding to coronavirus infection COVID-19. The Ministry of Health and the WHO are conducting a joint assessment of the operational readiness of the designated medical facilities. Rapid response teams have been established at the regional level and training of epidemiologists and virologists has been launched at the national level by the Ministry of Health with the support of the WHO.

Clinical response. The Ministry of Health has developed a number of guidelines and recommendations for case identification, biological sampling, referral of patients for services, etc., and has established testing systems, with the National Virology Reference Laboratory Kyiv. The Ministry also provided the regional laboratories with reagent kits for polymerase chain reaction to detect cases of COVID-19 to increase on-site testing.

Accordingly, we can conclude that the state policy to combat COVID-19 in Sweden is actively preventive, uses mostly investment mechanisms and aims to support the socio-economic potential of the region and meets the regression model of dependence of social development on economic indicators connected with COVID -19. Unlike Sweden, in Ukraine the state policy for counteracting COVID-19 is mostly reactive, uses administrative and legal mechanisms and is focused on coordination and control. It contradicts the regression models of the dependence of social development on the economic indicators associated with COVID-19. It is clear that the budget opportunities of Sweden and Ukraine are different. In January-June 2020, the revenue plan of the general fund of the state budget of Ukraine was not fulfilled by UAH 38.4 billion, or 7.8% (according to the Chamber of Accounts), and accordingly the state does not have the funds to apply the investment mechanism to support socio-economic potential. Meanwhile, under such conditions, it is advisable to minimize restrictions for businesses and households and give them the opportunity to take care of themselves.

Conclusions

The construction of a multifactor regression model allowed the authors to establish the impact of COVID-19 on the social and economic development indicators of Sweden and Ukraine. Indicators that during the correlation analysis showed the greatest dependence on domestic policy and the level of economic development of regions in terms of COVID-19 were: the level of employment (%), average per capita disposable income (USD); indicators of economic development and financial condition of the regional budget: revenues of the regional budget per 1 person (USD), subventions from the state budget per 1 person (USD), gross national product per 1 person (USD), capital investments per 1 person (USD). The regression parameters for Sweden and Ukraine are equally targeted and show a direct relationship between the studied indicators of social development and regional budget revenues and an inverse dependence on government subventions. Under COVID-19, both in Sweden and in Ukraine, the average per capita disposable income of the population directly depends on subventions from the state budget.

e-mail: lao48@yandex.ru

Abstract

The study is devoted to assessing the activities of municipal sports schools from the point of view of the SROI concept. The study analyzed the financial support of sports schools, the availability of sports facilities in the management of a sports school, the number of athletes and results in sports competitions. As a result of the work done, sports schools were divided into four categories in terms of the ratio of cost to sports performance. The results obtained served as the basis for further optimization of the management of sports schools, and also showed the ineffective aspects of the use of budget funds.

keywords: SROI, sport, sports costs.

Introduction

Social sector developmental investments are designed to cover every system level (federal, regional and local), with the private partnerships being increasingly involved in the investment projects.

This process needs to be supported by the relevant toolkits for calculations and analyses of the relevant performance rates and criteria which, in their turn, require special calculation methodology being applied and tested in practice.

It should be noted that the social investment projects face a variety of challenges both in the public social disbursements and private investment management systems, particularly in the context of the modern business social responsibility concept.

It should also be mentioned that due to the challenges of the modern social investment processes on the whole and the sports sector investments in particular the above issues still need to be studied in more detail, with the relevant notions being further developed and sorted out whilst many conceptual issues are still being vividly discussed and also waiting for detailed analyses.

A key calculation problem of the social returns on investment projects is due to the difficulties in assessing the project benefits in sound monetary terms.

The traditional rates of investment project benefits are not always applicable, and this is one of the reasons for virtually every social project being now rated as economically inefficient.

On the other hand, sports are known to be highly beneficial for society in many aspects as they effectively cut down the public expenditures for health services and crime prevention services and facilitate integration of the human capital.

Cite this Article as: Andrey V. LITVIN and Dmitry P. ARKALOV " The Practice of Using the SROI Methodology for Assessing the Performance of Municipal Sports Schools: Russian Practice" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Thus, sport contributes to solving many problems for many government agencies and business circles, including promoting a corporate image, developing infrastructure, risks of preventing or mitigating the consequences of civil unrest, etc.

The modern SROI-concept-based investment benefit calculation technology is also not free of certain drawbacks that include the following:

1. need for a commonly accepted classification of the relevant social values;
2. the available project benefit interpretation and implementation algorithm is still underdeveloped and too complicated;
3. social benefits of the investment projects are rated by a limited range of indicators;
4. some project benefits can hardly be expressed in clear monetary terms.

The modern concept of social return on investments was primarily designed in the early 2000ies by a research team of Roberts Enterprise Development Fund (San-Francisco, USA) followed by the concept being further developed by the UK-based New Economics Foundation research team that made an attempt to harmonise the SROI concept with the existing social benefits reporting systems.

Currently, there has been little research on the application of the modern SROI concept to assess the social benefits of sports investment projects in Russia.

The purpose of the study was to develop an applied SROI model to clarify the methodology for calculating the social return on government resources invested in the sports sector as part of specific projects (Millar, Hall, 2013).

Methods and structure of the study

We believe that we need to further standardize the calculation technology within the frame of the base SROI concept and customise the outcome data including a set of special checklists being developed for convenience of the investment project management experts. The main contradiction that needs to be addressed is due to the need for monetary terms/ equivalents or some similar terms and procedures being applied to integrate and harmonise the diverse model characteristics and parameters that can hardly be quantified in practice. There are also many other aspects in the study subject that need to be duly addressed in the study. In the theoretical aspect, the study needs to factor in and analyse the relevant axiological, psychological, sociological, economical and legal components of the process. In addition, the formal calculation procedure cannot be designed unless supported by due mathematical and logical methods, including fuzzy logic methods. In the process management aspect, the study needs to thoroughly analyse the existing decision-making, reporting, planning and forecasting practices. It should be mentioned that the global studies in this area are still making the first steps and, hence, the theoretical basics are still insufficient. The study area may be expanded with time when new statistical data on the country-specific experiences and/or specific social investment projects are reported. Furthermore, studies of this problem need to be governed both by the general methodological principles and more specific ones developed within the concept under consideration. Ranked with the former (general methodological principles) may be the system-approach, determinism, development, relevance, humanism and the individual social responsibility principles. Ranked with the specific ones i.e. developed within the SROI methodology may be the stakeholders' commitment, change monitoring, importance, substantiality, adequate self-rating, transparency and verification principles; and some of the key corporate social responsibility principles (Kazakov and others 2017). Calculations under the modified SROI model will be based on the relevant investment impact and social return data. To further clarify the model itself, the researchers need to mine the statistical data relating to the traditional SROI model parameters. Having designed the new mathematical model, we can further clarify the list of the necessary parameters. These parameters (invested amount, for example) may be classified into two groups: expected and actual. The actual data may be mined from the official sources and by the relevant questionnaire survey (opinion polling) methods, with the questionnaire forms being distributed via email to speed up and save costs of the process. The expected data for each of the parameters may be also mined via polling, with the process outcomes being additionally discussed in the focus groups. A representative sample will include at least 50-60 respondents. The proposed procedure will be designed to ensure due authenticity, dependability and interpretability of the outcome data.

Research

We have conducted research to assess the social effectiveness of financing sports organizations based on the SROI concept (Litvin and others 2019). As an empirical base, data are used on sports schools in Izhevsk for 2017-2018 (table 1). The data was obtained on the basis of the state statistical reporting form 5FK «Information about the sports

school», and from the official open site for posting information on the financial and economic activities of state (municipal) institutions bus.gov.ru. To process the information, methods of calculating average values, grouping, correlation analysis, Data Mining were applied. The analysis showed that between sports schools there are significant differences in terms of the social efficiency of investments - the number of athletes and the number of gold medals per 1 ruble invested in financing sports schools of budgetary funds. From the position of the SROI concept, there is considerable potential for optimizing the financing of certain sports and in improving the performance of sports schools (Ponkin, 2017). A model for grouping sports schools according to the level of social efficiency of investments is formed, based on the available sample, four categories of sports schools with different parameters of social efficiency of investments in sports are identified. At present, it is important to improve methods for calculating indicators of the social efficiency of using funds allocated to specific sports facilities, sports, sports events, etc. These problems must find their place in the framework of training professional sports managers (Howard, Cromptonб 2018).

Table 1: Indicators of sports schools in Izhevsk

Sports School Code	The cost of maintaining a sports school, thousand rubles	Number of Athletes	Costs per Athlete	The ratio of athletes studying to «excellent» and «good» to the total number of athletes (Russian system for assessing knowledge at school)	The number of gold medals at the All-Russian competitions per athlete	The number of gold medals at the All-Russian competitions
1	17 936,20	984	18,23	0,58	0,021	21
2	14 655,70	555	26,41	0,63	0,000	0
3	20 717,80	753	27,51	0,63	0,008	6
4	19 250,30	949	20,28	0,21	0,005	5
5	11 130,80	705	15,79	0,48	0,000	0
6	10 181,80	732	13,91	0,70	0,003	2
7	33 699,00	826	40,80	0,40	0,011	9
8	12 267,90	312	39,32	0,53	0,054	17
9	10 701,00	259	41,32	0,41	0,000	0
10	7349,40	325	22,61	0,52	0,006	2
11	8920,90	531	16,80	0,58	0,064	34
12	10 395,90	355	29,28	0,59	0,006	2
13	5170,30	97	53,30	0,49	0,000	0
14	36 866,20	1156	31,89	0,44	0,007	8
15	10 329,60	407	25,38	0,76	0,000	0
16	3469,10	43	80,68	0,05	0,023	1
17	24 188,70	1590	15,21	0,89	0,000	0
18	16 177,50	621	26,05	0,54	0,031	19
19	19 083,50	492	38,79	0,82	0,026	13
20	8817,10	552	15,97	0,90	0,013	7

The costs of maintaining sports schools, the number of athletes, and the number of winners were obtained on the basis of the reported statistical information (statistical reporting form 5FK «Information about the sports school», the official website for posting information on state (municipal) institutions bus.gov.ru).

The share of students athletes who study «excellent» and «good» in the contingent of students is determined using a survey of the heads of sports schools. For the analysis of the social effectiveness of investments in the activities of sports schools for each sports school, the expenses for one athlete are calculated, as well as the number of gold medals at the All-Russian competitions for one athlete. In the future, the ratio of the number of gold medals to the volume of financing («the price of one victory») was also calculated. From the point of view of social efficiency, the correlation between the sporting success of a sports school (the ratio of the number of gold medals to the number of athletes) and success in getting an education at school (the share of «excellent students» and «good») is of interest. To conduct the study, traditional methods of applied multivariate statistical analysis Data Mining were used. The peculiarity of this group of methods is that they do not require preliminary formulation of hypotheses, for this reason they are referred to as «exploratory analysis».

Research Results and Discussion

All sports schools are divided into two groups according to the cost of one athlete (table. 2). The average cost is the median of 26.23 (twenty six thousand two hundred thirty rubles) The arithmetic mean value of costs in the 1st group is 19.02 (nineteen thousand twenty rubles), in the 2nd - 40.03 (forty thousand thirty rubles)

Table 2: Grouping of sports schools by the level of costs per athlete

Data	1st group	2nd group
Sports School Code	6; 17; 5; 20; 11; 1; 4; 10; 15; 18	2; 3; 12; 19; 8; 7; 9; 13; 16
Average costs for a group of sports schools per athlete, thousand rubles	19,02	40,93

The data in the table indicate that between the two groups of sports schools there is a double gap in costs per athlete, due to the difference in sports, and in differences in the effectiveness of cost management between sports schools. We will construct a similar table for the number of gold medals per unit of financing (Table 3). The median value in the sample is 0.26 (zero point two six). In this case, there is an eightfold gap between the two groups of sports schools, which indicates a very significant difference in the «price of victory». The reasons for this require further study. It should be noted that in the 1st group sports schools with mainly playing sports are concentrated.

Table 3: Grouping of sports schools by the number of gold medals per 1 million rubles of budget financing

Indicators	1st group	2nd group
Sports School Code	17; 5; 15; 2; 9; 13; 12; 6; 14; 4	7; 10; 16; 3; 19; 20; 1; 18; 8; 11
The average number of gold medals per 1 million rubles of budget funding for a sports school, for a group of schools	0,11	0,87

We summarize both tables in table 4.

Table 4 allows you to identify four categories of objects - with an efficiency higher than the average for two positions; with efficiency below average in two positions; two categories in an intermediate position. The most effective category (bottom left of the table) includes primarily individual sports, martial arts, athletics

Table 4: Grouping of sports schools by two indicators of social efficiency of investments

Indicators	The cost per athlete is below average	The cost per athlete is above average
The number of gold medals per 1 million rubles of budget costs is below average	6; 17; 5; 4; 15	2; 12; 14; 9; 13
The number of gold medals per 1 million rubles of budget costs is above average	20; 11; 1; 10; 18	3; 19; 8; 7; 16

It should be noted that the assignment of an object to one of the categories can be explained by both natural causes (for example, features of a sport) and the effectiveness of managing a sports school.
In any case, from the point of view of the SROI concept, special attention should be paid to those positions (sports, sports schools) that provide the highest return on investment.

Findings

There are significant differences between sports schools in terms of indicators of the social efficiency of investments. In this case, the gap in costs per athlete between the two groups of sports schools was 2 times, the discrepancies in the number of gold medals per unit of expenditure exceeded 8 times. From the position of the SROI concept, in this case, there is considerable potential for optimizing the financing of certain sports and increasing the efficiency of

sports schools. In the course of the analysis, a model for assessing the social effectiveness of investments was formed and four categories of sports schools with different parameters of the social effectiveness of investments in sports were identified. The factors that caused a particular school to fall into the appropriate category, as well as the necessary conclusions for management, require additional research. Our study did not confirm the hypothesis that there is a correlation between sports and educational success of athletes in the context of sports (the correlation coefficient was – 0.07). At the same time, it can take place within certain sports or among athletes in a specific organization.

Faculty of Tourism and Health Sciences, The Jacob of Paradies University in Gorzów Wielkopolski, Poland
E-mail: bstankiewicz@zut.edu.pl

Abstract

Observed global trends in behavioural changes in the contemporary tourism market indicate a tendency of tourists to seek new active forms of spending free time, based primarily on the need to explore the world combined with new and extreme experiences. On this basis, numerous new models and forms of tourism have been identified, often referred to as "niche" tourism to distinguish it from mass tourism. One such form of niche tourism is undoubtedly Backpacking. The aim of the study is to analyse the directions of backpacking trips and motives for their selection on the example of tourists from Poland and abroad. The basis for the measurement was a survey consisting of a total of 29 substantive questions, supplemented with socio-demographic questions. The research was also conducted in two ways: as field research (July-August 2018) and via the Internet (2018-2019). In the course of the study, statements by 290 backpackers were collected The results of the research indicate that the dominant model among the inhabitants of Western Europe were long journeys (i.e. those crucial for backpackers). Also indicated the differences between Polish and foreign backpackers when it comes to motivations to return or not to return to given countries. This publication is an attempt to capture the advantages of modern Backpacking and to answer questions about the directions of travel and motives for their choice by Backpackers from Poland and abroad.

Keywords: Backpacking, Niche Tourism, Themes of Choice, Travel Destinations.

Introduction

Backpacking entered the field of tourism in the 1980s, on the Australian continent. It found its way into the academic discourse owing to (Pearce,1990), who described, in the early 1990s, individual tourists called backpackers by the Australian tourist industry. Those were tourists traveling Australia who made particular choices and displayed a specific set of characteristics. Among the most essentials ones were: young age; independence (including free planning of routes and itineraries, using one's own geography of travel); low costs of travel, and thus a preference for cheap accommodation and meals; traveling for periods of time longer than the holiday entitlement at work; and also – which was their distinguishing feature – informal participation in various local forms of spending free time and interacting socially with other travellers and with residents of visited countries (Loker-Murphy,1996).

One of the first countries which noticed the backpackers' driving force for the local economy was Australia. In order to attract the biggest possible number of backpackers, they introduced innovative economic solutions which brought benefits not only in the economic, but also in the social sphere (Loker, 1991). Among other solutions, a migration visa program Working Holiday Visa (WHV) was adopted, aiming extensively at meeting the expectations of the backpacking market (Visa 2007), which merges this sector of tourism with many other branches of the industry. It was also in Australia (followed by Thailand, Indonesia, New Zealand) where the tourist industry was significantly targeting the needs of backpackers. The infrastructure (hostels, bars, pubs, gyms, nightclubs, taxi services, buses, stores) was expanded and diversified, catering specifically to the backpacking community. As a result, these countries became not only important destinations of backpacking travels, but also in a way their proverbial Mecca, especially for people beginning their adventures with backpacking (due to numerous conveniences and developed services offered by the tourist market). In Australia alone, an almost 5% increase in the

Cite this Article as: Wojciech LEWICKI And Boguslaw STANKIEWICZ "Backpacking Example of Niche Tourism- Analysis of Directions of Travel with A Backpack and The Motives of Their Choice" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

number of backpackers is recorded annually (for example, in 2013 the continent was visited by 571,000 backpackers ; they bring over 3 billion AUD into the country's budget (Jarvis & Peel, 2013).

After more than thirty years since the first attempts at capturing the phenomenon, the image of backpacking – hitherto a cohesive entity – breaks into many different portraits which escape homogenous classification. The way of backpackers' self-identification and their experiences are polarized (Hannam, & Diekmann, 2010). And although one might still search for features co-creating backpacking in general space, on the level of individual travel awareness different variables can be noticed, for instance in travel methodology or in classifying motivation. Van Vaals suggests that forms of tourism which emerge from backpacking and are currently barely visible will also develop with time and will become full-fledged types of tourism, among them the money-saving techno-traveller, the anti-tech glampacker, the primitive green backpacker (Van Vaals, 2012).

It cannot be ruled out that the model of backpacker formed in the twentieth century is slowly disappearing and being replaced by a new type, which is a product of contemporary mass and consumer culture. The following publication attempts to supplement the knowledge about the specifics of backpacking, characteristic for the nations who practice it, and so to demonstrate the experience of Poles against the background of foreign backpackers. The analysis of the literature on the subject has shown that such research is lacking, which additionally emphasizes the advisability of addressing this topic from both the scientific and practical side.

The aim of the study is to analyse the directions of backpacking trips and motives for their selection on the example of tourists from Poland and abroad. The article is organized in the following way. Chapter 2 contains a detailed description of the research method used in response to research questions. Chapter 3 describes the results of experimental research. Chapter 4 presents conclusions, at the same time indicating future directions of research in this area.

Materials and Methods

Conceptual Assumptions

The purpose of the entire research enterprise was to portray the contemporary Polish and foreign backpacker through characterizing their multi-dimensional subjectivity and describing their travel practices. Following this line of reflection, an attempt was made to answer the following research questions:

1.What are the directions of the first backpacking trips, grouped according to the main regions of the world, taking into account the preferences of Polish and foreign tourists?
2.What are the reasons for choosing a destination for your first backpacking trip?
3.What are the reasons for returning or not returning to previously visited countries for tourists from Poland and abroad?

Method of Sample Selection

In the context of the changing nature of foreign backpacking, and the still undefined specificity of Polish backpackers, selecting people with a backpacker identity based on objective criteria was not feasible because in the case of backpackers it is impossible to have a sample that would meet the requirements of a representative study based on a probabilistic method, especially one that would provide a greater than zero probability of the respondent taking part in the survey. And also one that would meet the condition that the probability would be the same for all units of observation (elements of the population). Due to these circumstances, the selection of respondents for research did not proceed in the representative scheme. Methodological arguments supporting this decision resulted from several premises:

- descriptive character of the research, and in particular the implementation of its cognitive purpose, which referred to the concept of comparative research through the recognition of the Polish and foreign tourism environment;
- significant heterogeneity of the backpackers' environment;
- the lack of opportunities to standardize access to respondents, and what is related to this - creating a homogeneous and effective sample survey.

Affirmative actions were taken in the selection of people for research, addressing them to the environments in which backpackers were present. Therefore, the criterion of consciousness was the main factor determining the

participation of a given person in the study – potential interlocutors were asked if they were backpackers. During the survey, almost all respondents (except one) agreed to be assigned such a role and responded positively to the first question asked for this purpose.

The selection of respondents for the research was carried out among many backpacker communities scattered around the world; they were found:

- during journeys made by the authors herself;
- through the use of places of traditional community meetings in the form of clubs, lectures;
- through the use of information about existing websites which act as forums for community contacts.

Due to the diversity of respondents in terms of travel experience, level of participation in backpacking and origin from different geographical regions of the world, two relatively independent research courses were conducted, with all the above-mentioned communication channels used in both Polish and foreign thread.

During the research phase, 290 interviews were collected. In view of the fact that the non-probabilistic scheme did not impose a predetermined sample size as the minimum, the adopted strategy was connected with the recognition of the sample as sufficient for the adopted analysis scheme and allowing comparisons between Polish and foreign backpackers.

The research in Poland was conducted in two ways. Firstly – at travellers' meetings in the period from September 2018 to July 2019. 40 respondents were included. The meetings were held in public places, recognized by the community as travellers' spots (in Wroclaw, Warsaw, Poznan, and Krakow). Secondly – via the Internet. In order to conduct research arranged on the Internet, available travel forums and Internet blogs were used as a medium of communication; information about the study was posted along with a contact request in order to complete a survey. The result of such a large-scale recruitment of backpackers were 139 answers to the survey. The reasons for refusals to participate in the study were most often planned or ongoing travels.

The research abroad was also conducted in two ways: as field research (July-August 2018, 98 respondents) and via the Internet (2018-2019, 13 respondents). As in the case of Polish research, Internet research was used in foreign surveys. On 47 forums, and backpacking and travel websites, information was posted about the study along with a participation request. Overall, the number of individual e-mails sent to members of foreign travel and backpacking groups was 304. The most common reason for refusal was lack of identification with the role of a backpacker. Eventually, in the group of foreign backpackers 111 respondents qualified for further analysis.

Description of the Tool

The basis for the measurement was a survey consisting of a total of 29 substantive questions, supplemented with socio-demographic questions. Due to the adopted concept of targeted research, the trial was carried out in two environments – Polish and foreign, using the same tool and question-based content. The group of survey questions was dedicated to the reconstruction of various backpacking practices connected with typical aspects of travel such as travel directions, preferences and practices concerning organization of a journey. The survey was closed with a standard set of variables describing the social profile of the respondent.

Analysis Scheme

In the course of the study, statements by 290 backpackers were collected. The method of empirical material analysis was based on quantitative and qualitative techniques which form generic analyses. Here we can distinguish: quantitative analysis, mainly through indicating and describing the distribution of responses to the questions of the survey in the studied collective of backpackers; typological (qualitative) analysis – accompanying the quantitative categorization of closed-ended questions and enriching this categorization with information on the qualitative context of facts; comparative analysis (schemes of intercategorical comparisons) – key from the point of view of the exploratory research objectives, based on the concept of analysing differences in percentage distributions and values of variables in comparison groups. The groups formed categories of respondents (subsets of observation), distinguished due to the distribution of features (variables) differentiating the respondents. The basic dimension of the studied differences was the status of a backpacker defined by his nationality. In the adopted scheme, two basic comparison groups were distinguished: Polish backpackers (179 observations – 61.7% of respondents) and foreign (111 observations – 38.3% of respondents). This system of comparisons was supplemented successively in the course of analysis with various variables, including: age of respondents, gender, number and time of travel, social and professional situation, material situation, etc. Unless otherwise stated, percentages were added up to 100 in each

(separated by variable values) independent comparative group (respondent category). In the case of multiple choice questions and more than one answer to a question, percentage distribution did not add up to 100, but were calculated in percent's by comparing the number of people giving a given answer to the total number of respondents. Technical comments on the method of data presentation were put in titles and footers of tables and figures. Since the respondents were not obligated to answer all the questions in the survey, the number of important answers varied, depending on the question, which influenced the variable size of comparison groups. Usually, numerical and percentage losses were not significant, but for orientation the total number of responses included in the analysis was given. Where order-based response scales were used, the intergroup comparison scheme was based on the average values of point scales**.** In each case, a point definition of the scale used was given. The layout of all analyses has been subordinated to the objectives of the study.

Results

The study showed that Europe was the most frequently chosen destination for the first backpacking trip (Fig. 1). Essentially, the dominance of Europe as the destination of the first trips was the result of the largest share of European nations in the surveyed population. Moreover, the domination of Polish respondents in the study was the reason for indicating Poland as the first destination for a backpacking journey. A previously unreported conclusion thus emerges that backpacking usually begins in one's mother country.

Fig.1: Directions of the first journeys of Polish and foreign backpackers

Source: own study, total n = 244 = 100%, Poles n = 176, foreigners n = 68

The analysis of the directions of the first trips of Polish and foreign backpackers differs significantly. While Poles, apart from Poland, mostly opted for European countries (total 58.5%), especially neighbouring ones (Czechia) and Southern Europe (Italy), the foreign backpackers' mecca was definitely Australia (40% of foreign respondents chose this destination for their first trip).

The differences in choices of the first destination were clearly marked in the motivations (Fig.2). While for foreigners their first journeys were definitely connected with cognitive aspects – exploring the culture and people of the country they went to (19%) combined with following a dream ("I've always wanted to"), in the case of Poles,

those motives remained important but the most essential motive was the proximity and friendliness of the country (33%).

Fig.2: Motives for the choice of destination for the first backpacking trip

Source: own study, multiple answers do not sum up to 100%, total n = 242, foreigners n = 75, Poles n = 167

Asked about their motives to return (Fig.3), they mentioned (albeit not too often – only 192 responses were received to this question) sentiment and positive experiences connected with a given country and direction of travel. Although the general structure of the motifs was similar as far as hierarchy is concerned, this element was more often indicated by foreign backpackers than Polish ones (59% against 41%).

Fig. 3: Motives for returning or choosing not to return to formerly visited countries for Polish and foreign backpackers

Source: own study, multiple answers do not sum up to 100%, total n = 192. Foreigners n = 59, Poles n = 133.

Respondents were asked to name places they rejected as tourist destinations (Fig.4). In this aspect, Arab countries took the lead, with 35% of respondents stating they would not like to visit them, Europe ranked as number two (23%). Other countries and regions were mentioned sporadically.

Fig. 4: Destinations avoided by Polish and foreign backpackers

Source: own study, total n = 120

Among the most often mentioned countries in this category were: Russia (7.6%) and India (6.9%). Equally often various Arab countries were selected. Among the countries whose character was described, there was those considered too cold or too hot. When asked to justify their choices, (number of responses = 120) indicated the following reasons: war, danger and life threatening conditions, unstable political situation, stereotypes of countries and residents; about post-communist countries: these are still wild countries) – 44.8% of respondents; too many cultural differences, intolerance (especially emphasized in relation to Arab countries):– 12% violence and crime (e.g. about Africa: bad experiences – 12.9%;discrimination against women; bad treatment and rapes – 8.6% poverty, illnesses, filth – 7.8%; expensive or boring – 6.9%.

It turns out that the main obstacle to visiting a given country or region of the world is first and foremost political instability, conflict (of different types: power, culture, religion), which incites fear – directly or indirectly – and poses a threat to safety. Most of these threats were associated with the Near East (52% of motives).

In the context of the discussed issue, it is worth taking a look at specific convictions and circumstances which might influence the decision not to undertake a backpacking journey (Fig.5).

Fig.5: Limitations in backpacking travels for both studied groups: Poles and foreigners

Source: own study, multiple answers do not sum up to 100%, total n = 285, Poles n = 176, foreigners n = 109

The analysis of distribution of answers (one could choose up to three main obstacles) partially overlaps with the answers about the avoided directions of travel. Fear of danger, according to the respondents, is the main reason limiting the freedom of traveling. Over 20% of respondents mentioned also: lack of money (53% total) – a major barrier especially for foreign backpackers - 66.1%, Poles 44.9%; professional obligations (42.5% total) – similar in both groups: Poles 44.3%, foreigners 39.4%; lack of time (28.1% total; Poles - 26.7%; foreigners - 30.3%); not knowing foreign languages (total - 41.1%) – indicated more often by Polish backpackers (48.9%) than foreign ones (28.4%).

The key issue in numerous threads of the study were directions and countries of traveling. The respondents were asked to list all the countries they had travelled to (no limitations). The names of visited countries were then classified into regions of the world (Fig.6)

Fig. 6: Directions of travels for Polish and foreign backpackers

Source: own study, multiple answers do not sum up to 100%, total n = 286, Poles n = 178, foreigners n = 108.

The analysis of the answers provided show that European travels were a standard for all respondents (Poles and Foreigners) however, countries of Northern Europe were chosen far less often than neighbouring countries and Southern Europe. Perhaps because the majority of respondents were Poles, while among the foreigners the most represented groups were the British, the Germans, and the French, Europe remained the dominant geographical region of travels. Foreign backpackers, unlike the Polish ones, chose Australia significantly often.

The dominance of Europe could be explained with the difference between an interest in a given journey and its actual realization in European countries, which causes a significant disproportion in quantity between the large number of declared European destinations and fewer indications of other directions. Southern regions of Europe were far more popular than northern ones. A similarly high percentage of people chose Asian regions, especially South-East Asia; it was chosen by both Polish and foreign backpackers. As the traveling experience of backpackers grew, the tendency to visit more exotic places also grew. Without a doubt, a special region for traveling was Australia - especially for foreigners, who made it an important element of their journeys (77% of foreign backpackers went there), while among Poles, the North of Europe - Scandinavia and the Baltic states - was very popular. At the next stage of the research, an attempt was made to identify the directions and the number of trips of tourists from Poland and abroad (fig.7).

Fig.7: Destinations versus number of trips of Polish and foreign backpackers.

Source: own study. Multiple answers do not sum up to 100%. N total = 259, 1-2 trips n = 68, 3-4 trips n = 72, 6-10 trips n = 73, more than 10 trips n = 46.

An analysis of the number of responses indicates that Australia was one of the priority regions, while the number of trips to Africa, Southeast Asia and the Middle East increased with the travel experience. All these regions, however, started to dominate only after at least 5 departures, unlike in Europe, where a sharp increase in the number of departures was recorded after just two departures.

Discussion and Conclusions

Although the Destinations of backpacking tourists were of interest to other researchers as well (Ross, 1997; Smith, 1994; Wilson, 1997; Hampton, 1998; Spreitzhofer ,1998; Paris & Teye 2010), It is in most cases that the effects of massaging backpacking trips to individual countries have been described (Mohsin & Ryan, 2003; Richards & Wilson, 2004; Liu et. al 2018).Or the dynamically developing tourist infrastructure, created mainly to meet the

specific requirements of contemporary tourists (Matthews, 2008; Visser 2003), was indicated. The results of the research indicate that the dominant model among the inhabitants of Western Europe were long journeys (i.e. those crucial for backpackers) by Wilson (1997). First of all, Australia has remained their Mecca, and it is difficult to formulate unambiguous opinions in the case of other destinations. However, it can be suspected that an important factor in the selection of individual countries and regions may be historical and cultural relations, because just like for Polish respondents, Scandinavia and the Baltic countries were interesting travel destinations due to their historical connections, for British backpackers the journey in the footsteps of the old British empire seemed obvious. For this reason, O'Reilly (2006) saw some neo-colonial and neo-imperial accents in backpacker travel and considered modern backpacking to be a continuation of the post-colonial behaviour of earlier generations. He maintained that there were significant similarities between them. The most important of these is the constant expansion of Western influence into the East through the presence of backpackers in the Orient world, although of course the intentions of today's backpackers are definitely different from those of former colonialists (Desforges, 1998). India is an exception. This country has hardly been chosen by the British backpacker despite the great historical and cultural importance this country has for them.

Symptomatic for the ongoing discussions about the nature of backpacking are the differences between Polish and foreign backpackers when it comes to motivations to return or not to return to given countries. It is Poles, more than foreigners, that can be attributed to the characteristics of stereotypical backpackers, i.e. people focused on searching and exploring, for whom an important reason for a potential return is more things to see and learn, but if they do not come back, mainly because repeating is a waste of time ; the time is too short to return to the same places; I am not coming back because there are still too many places and cities in this world that I want to see; I don't go back to places I've seen because I don't have enough time and I need something new. This is confirmed by the difference of 14.4 percentage points of the answers obtained.

Equally interesting research results were obtained when answering the question why backpackers wanted to return to certain countries or finding out why they did not want to travel to others. Backpackers did not choose some countries mainly because of various threats, such as weather disasters, natural disasters and diseases, hostility of the local community, acts of terror, crime, political unrest (Fesenmaier & Johnson 1989). Interestingly, foreign literature repeatedly emphasized that risk - inscribed in traveling - is an experience that backpackers themselves are looking for in their journey choosing (Beezer,1994). The authors agree with the thesis that backpackers decide to traverse unknown roads and virgin territories, penetrate different cultures through a conscious agreement to abandon the stability and routine of institutionalized tourism in favour of experiences bordering on risk (Elsrud, 2001;Walters, Wallin, & Hartley, 2019). And at least, as noted by Scheyvens (2002), seeking adventures, especially those involving risk, cannot be considered one of the features of the identity of backpackers, it should be noted that their behavior in visited places and readiness to face potential threats or daring actions, albeit not uniform, are very important for this group of tourists (Jabłonowska 2015; Chen & Huang, 2019)

To sum up, although the results of the research provide interesting conclusions on niche tourism such as Backpacking, there is a need for more extensive research, covering other factors such as the cost and financing of backpacking travel. This data can provide a broader context and insight into the analysis of backpacking destinations and motives for their selection. Therefore, such analyses will be the subject of future work in order to identify and identify the factors of development of Backpacking in the era of global changes in the contemporary tourism market.

Research on the Financing Sources of Start-Ups: A Case Study of Poland

Wojciech LEWICKI

Faculty of Economics, West Pomeranian University of Technology Szczecin, Poland.
E-mail:Wojciech.Lewicki@zut.edu.pl

Abstract

In today's market reality, nobody doubts that financing the activities of enterprises is a complex process influenced by many factors. It is obvious that a market entity with several years of experience and an established market position has different opportunities to raise capital, and a start-up that bases its strategy solely on assumptions that a given product will find its buyers in the future. The article presents selected research results on the sources of financing startups in Poland. The aim of the research was to gain extensive knowledge on the methods of raising capital by these entities. In particular, identification of business models, types of selected financing sources, determination of current needs and indication of barriers to obtaining funds. This research may contribute to the development of universal solutions in the field of financing startup activities especially in Central European countries. The presented and interpreted results can be the basis and incentive for further research on the topic related to the development of entrepreneurship and startup ecosystems, both at the local and global level.

Keywords*:* Start-Ups, Financing, Entrepreneurship.

Introduction

The dominant statement in the literature on the subject is that we live in the era of startups (Shane, Locke & Collins, 2012; Baron, 2004; Cui et al, 2016; Davila et al, 2015). Every now and then there is information about a new fantastic startup that will change our reality - examples include Google and Facebook, which were also startups in the past. One definition emphasizes that a startup is an enterprise created to search for a specific business model (Block et al, 2018). As many authors mention, the goal of such an organization is to search for new markets for the development of its product and to achieve quick financial success (Block et al, 2018;Gilbert, McDougall & Audretsch, 2006;Huynh, Petrunia & Voia, 2012) Many researchers see startups as the key to the development of entrepreneurship and innovative economy (Huynh, Petrunia & Voia, 2012; Hall & Lerner, 2010; Gartner & Carter, 2003). At the same time indicating that it is a form of business that was created to provide a new product, service, technology or process under conditions of high uncertainty. As it is commonly known, mature enterprises are usually characterized by a clearly defined purpose and specificity of activity and implement a plan that involves acquiring customers and generating revenues. By contrast, startups are only looking for a scalable and repeatable business model that would allow them to stay on the market and further develop. Therefore, the choice of both the right business model and, consequently, the sources of financing, may determine the market success of this type of entities on the contemporary global market.

Available reports OECD (2019) and research of the European Economic Commission European, (2017) indicate that the Polish economy is one of the most dynamically developing economies in Central Europe (Ministry, 2018). Although the concept of startup in Poland has been known for only a few years, in 2020 there are already around 3,000 startups in Poland. Thus, both the position and role of the startup sector in the Polish and EU economy is becoming more and more significant (Matejun, 2014; Gwizdała, 2017) and certainly requires analyzes and research.

The analysis of the available literature has shown that there are many publications on both the issues of identifying startup features and the description of funding sources available on the market. However, in most cases, these studies refer to the economies of Western Europe or developing countries (Info, 2016; IFC, 2017; Godke Veiga, & McCahery, 2019; McCann & Ortega Argiles, 2016). However, there are no publications describing the startup sector compared to the economies of Central European countries such as Poland and focusing on the analysis of selected business models, financing sources, or identification of barriers to obtaining financial resources by future startups. The presented study is therefore an attempt to fill the gap in the literature on the subject in terms of the above-mentioned research problems,
