while at the same time providing a basis for further considerations on startups, business models and their financing sources.

Therefore, this article has many important practical implications, both political and economic. Considering that the aim of the research is to gain extensive knowledge on how Polish startups raise capital. The article was organized as follows. Chapter 2 contains a detailed description of the purpose, scope and research method used to answer the research questions posed. Chapter 3 describes the results of experimental research and their interpretation. In turn, Chapter 4 discusses the results achieved by the author and presents conclusions - pointing to their limitations in the perspective of the research conducted so far and indicates future research directions in relation to the issue of startups and their sources of financing.

Materials and Methods

Conceptual assumptions

The aim of the entire research project was to obtain extensive knowledge about selected sources of financing startups in Poland. The description of the selected issue related to the start-up topic was therefore included in one basic aspect. In the research area, the focus was on identifying business models, the type of financing sources selected, current needs and barriers to obtaining funds by future startups - i.e. the first stage covering the ideation, vision and formation of a startup. Following this line of reflection, an attempt was made to answer the following research questions:

1.What are the most frequently chosen business models by future startup people?
2.Which sources of financing are most often chosen by future startup people?
3.What are the financing needs for future startups?
4. Which of the barriers, in the opinion of future startup people, limit the most obtaining financing?

Method of Sample Selection

Affirmative actions were taken with regard to the correct selection of people for the research, directing the questionnaire to the environment and future startups. Therefore, the awareness criterion was the main factor determining the participation of a given person in the survey - potential respondents were initially asked if they were future startups. During the survey, all respondents confirmed such a role and answered positively to the first question asked for this purpose. The selection of respondents for the study was carried out among the startup community, both related to academic entrepreneurship and those who start their startup activities outside the university. Due to the diversity of respondents in terms of age, gender, type of activity and market sector, one research course was conducted using one communication channel - the Internet.

In the research phase, 500 interviews were collected. Therefore, the adopted strategy meant that the sample was considered sufficient for the adopted analysis scheme and made it possible to answer the research questions asked.

Description of the Tool

The CAWI method (interviews conducted via the Internet) was used as part of the study. The questionnaire form enabling its completion by electronic means was available on the university's website. The survey was anonymous, which allowed for free expression of the respondents' opinions. The layout of the presented results reflects the completed questionnaires.

Analysis Scheme

In the course of the research, 500 completed answer sheets were obtained in electronic form through a questionnaire posted on the website. The research was conducted in Poland in the period from October 2019 to December 2019. The survey contained 10 questions (answers to 4 of them are presented in the article) related to the issue of financing sources of startups in Poland. In the adopted scheme, the questions asked concerned the selected business models, startup financing sources, startup financing needs and barriers related to obtaining funds. The questions were open-ended. The study consists of substantive comments and charts containing the results of answers to the questions contained in the forms. After entering the answers into the spreadsheet, the obtained research data was subjected to statistical and

content-related analysis. In order to improve the clarity of the obtained answers, the results are presented in the simplest form (percentage value) in individual figures 1 to 4.

Unless otherwise stated, the percentages were summed up to 100% of the surveyed group. In the case of multiple-choice questions and more than one answer to the question, the percentage distribution did not add up to 100%, but was calculated as a percentage by comparing the number of people giving the same answer with the total number of respondents.

Technical notes on the data presentation method are included in the titles and footnotes of the figures. As the respondents were not required to answer all the questions in the survey, the number of valid answers varied from one question to another, which did not affect the final result as the number and percentage losses were not significant. The layout of all analyzes was subordinated to the objectives of the study.

Results

In the first stage of the research, respondents were asked to indicate the concept of a business model, the one they are going to choose for their startup (Fig.1)

Fig.1: Startup business models selected by startups

Source: own study

The analysis of the obtained results showed that the most popular concept of a business model chosen among future startups is the B2B model, indicated by 50% of the respondents. As a result of the research, it was found that 15% of the surveyed startups declared to operate only in the B2C model. It is worth noting that 15% of startups will implement both models simultaneously. On the other hand, activities based on other business models were declared by as many as 20% of startups.

At the next stage, the respondents were asked to indicate sources of financing for their startups (Fig.2).

Fig.2: Startup financing sources selected by startup founders

Source: own study

The research shows that 68% of Polish startups will be financed from their own funds (including reinvested income). On the other hand, 30% of startups plan financing by Venture Capital. Funds from the European Union (37%) are equally popular as a form of financing startups. It is worth noting that 42% of Polish startups are planning funding by the Polish Agency for Enterprise Development or the National Center for Research and Development. The key role in financing startup activities of business angels was indicated by 26% of the surveyed respondents. Only 6% of Polish startups will benefit from crowdfunding. Only 9% of Polish startups will be financed from a bank loan, and 10% of startups will be financed by a strategic industry investor.

At the next stage of the research, respondents were asked to indicate the current needs of startups (Fig.3).

Fig.3: Current startup needs

Source: own study

The results of the answers obtained indicate that future startups most often declare the need for financial resources of 61% of respondents. The percentage of startups indicating the need for employees was 49%, and 41% of the respondents reported the need to expand their network of business contacts. On the other hand, 15% of respondents feel the need to increase the resources of specialist knowledge. Only 4% of the startups surveyed did not report any needs.

The last stage of the research included the answer to the question regarding the identification of barriers related to obtaining financing for starting a startup activity (Fig.4)

Fig.4: Barriers related to obtaining funds for startup activities

Source: own study

The results of the obtained answers indicate that the largest number of respondents, i.e. over 51%, indicate formal barriers, and over 39% - administrative barriers. Moreover, 32% indicated information barriers. On the other hand, 15% of respondents faced a barrier in the form of lack of business contacts. Only 10% of respondents did not report any barriers related to obtaining funds for startup activities

Discussion and Conclusions

The literature emphasizes that the sources of financing or the business model - apart from the very idea for business activity - are the most important condition for a startup's success (Atherton, 2012). The main aim of the research was to gain extensive knowledge about the sources of financing for startups in Poland. Future startup founders can choose between equity and foreign capital. Many researchers emphasize that the choice of a business model and financing source is related to the loss-up life cycle (Cassar, 2004; Paul, Whittam, & Wyper, 2007). Although there are many different approaches to identifying the stages of a startup's development depending on whether the development model relates to the customer (customer development model proposed by Blank and Dorf (2012), product (product development model proposed by Berman,. Dogrultan, Herrmann and Mamer (2011) or financing (investment development model proposed by practitioners from Deloitte, in this particular case the research referred to the first stage, that is the first phase - combining ideation, vision and startup formation. On the basis of the presented research results, it was found that future Polish startups most often choose a B2B business model, just like startup founders from Western Europe (Cucculelli & Bettinelli, 2015). The model in which they target their own goods and services to other enterprises. As one of the authors emphasizes, this sales channel is chosen for its benefits, as it is intended to generate higher earnings and faster growth (Leek & Christodoulides, 2011). Selling products and services only to the consumers (B2C) is more difficult. Research has shown that many future startuppers in Poland decide to choose a mixed model, that is B2B2C. The author agrees with other researchers, in this context that future startups focusing only, for example, on the purely consumer channel may lose due to the fact that more and more new product variants are launching, which tempt and distract from the current choices (Mingione & Leoni ,2020). Referring to the sources of financing startups at the sowing stage, classical sources of financing play a very important role. M. Zwilling (2015) noted that a specific source of startup financing at this stage is bootstrapping, that is financing from own savings, which is confirmed in the presented research. This form of financing is also indicated by other researchers (Čalopa, Horvat & Lalić, 2014; Saini & Plowman, 2007), comparative analyzes of the most frequently chosen sources of financing for startups in other countries. The author's research confirmed that. On the other hand, obtaining bank loans - due to the lack of collateral and high risk of project failure - is still limited. This is important information for the banking sector to analyze the current rules for granting financing for this specific form of activity.

As the author proves in terms of current needs, future startups from Poland most often declare the need for financial resources and business contacts. On this basis, the author agree with the thesis promoted by other authors (Colombo, Cumming, & Vismara,2016; Cosh, Cumming, & Hughes, 2009) that the knowledge of risk factors related to running a business or building cooperation with the business environment is crucial, especially in the initial stage of development, and these aspects were noted by the respondents in this study. The analysis of the responses collected from the respondents also allowed for the identification of barriers related to obtaining funds for startup activities. On this basis, the author put forward the thesis that along with the further construction of the systems of governmental and non-governmental institutions, the search for ways to eliminate formal and administrative barriers should be continued. Because, as suggested by many other authors, this restrictions may lead to blocking the opportunities and development path of startups, in particular in the SME sector (Davila et al. 2015, McCann, & Ortega Argiles 2016;Blank & Dorf, 2012). And as it is well known, the startup ecosystem in most cases determines the success of development. On this basis, the author conclude that effective cooperation between various groups of the business community will foster the emergence of innovative startups. The implementation of such a task should also be included in the strategy activities of the state administration.

As regards the assessment of conventional and alternative sources of financing for startups author remains in dispute with other authors of the research in this matter. External financing in the form of debt or external equity is often difficult to obtain for start-ups. This is confirmed by the research of Hazudin, Kader, Tarmuji, Ishak and Ali (2015), as well as Beck and Demirguc-Kunta (2006), Fielden, Davidson and Makin (2002). This thesis was partially confirmed by this study. Hence, bootstrap financing is a response to financial constraints faced by small companies (Winborg & Landstrom, 2001). In addition to the above-mentioned classic sources of financing at the sowing stage, among others, the following alternative sources are mentioned (Paschen, 2017): crowdfunding, business angels and venture capital (VC). As indicated by other research studies, donation crowdfunding is the most beneficial for the initial stage of a startup, as it is characterized by the greatest operational flexibility compared to other forms of crowdfunding (Argerich & Cruz-Cázares, 2017). Moreover, the role of business angels who invest their capital in the early stage of startup

development (Seed Stage) is crucial (Teker & Teker, 2016). In addition to financial support, they provide strategic consulting services and offer a network of business contacts. Many researchers also emphasize the role of venture capital. According to Davila, Foster and Gupta (2003), this type of financing is an important factor in the development of modern startups. However, as research in Poland has shown, this form of financing and the others discussed above are still not recognized by future startups. It should be noted, however, that comparing the selection of individual sources of financing by future startups in individual countries, e.g. the United States or Other Western European countries, would be a logical error, taking into account other economic conditions in these countries and the role of startup ecosystems in this process. Considering that in the realities of the Polish economy, operational programs from the European Union and funds from the Polish Agency for Enterprise Development and the National Center for Research and Development are of key importance. On this basis, the author concludes that state institutions should to a greater extent encourage future entrepreneurs to use also other forms of financing.

This document uses data from a survey on a specific research sample of 500 startups, so a much broader analysis is needed, in particular using the variability of time series, data taking into account the individual life cycles of a startup and case studies on specific industries and market sectors. In addition, further research in this topic should focus on issues related to the definition of motives and criteria determining the selection of both specific sources of financing and business models by startups, taking into account the role of government institutions in this process.

Summarizing the presented research on the sources of financing for startups in Poland case study, they do not fully exhaust the matter, but are an attempt to signal the complexity of the presented research problem. Although the conclusions of the research can be used by future startups and administrative authorities responsible for the development of entrepreneurship .Certainly, this subject requires further analysis and research to understand both the essence of startups themselves and the motives determining the selection of individual sources of financing by startups, both at the local and global level. Therefore, such analyzes will be the subject of future work to identify the factors of startup development and entrepreneurship

The Use of Reserves and Accrued Liabilities for Discretionary Shaping of Financial Results of Stock Exchange Listed Companies: Case of Poland

Anna STASZEL

Cracow University of Economics, Krakow
Poland, staszela@uek.krakow.pl

Pawel ZIENIUK

Cracow University of Economics, Krakow, Poland
zieniukp@uek.krakow.pl

Abstract

Reserves and accruals belong to the measurement category in which a lack of credibility is considered to be at a high-risk value. Due to subjectivity and possibility of choosing many premises during the valuation process, reserves and accruals are treated as instruments of aggressive accounting. Therefore, those items can influence the discretionary shaping of financial results that are presented in financial reports which pose as the final product of the accounting system. The main objective of the empirical research conducted by the Authors was to prove the influence of the decisions - taken by the management of companies listed on the stock exchange - regarding the establishment and release of reserves as well as accruals with the financial result value indicated in the profit and loss statement. The research sample consists of 68 companies listed on the Warsaw Stock Exchange which prepare financial reports in accordance with International Financial Reporting Standards (IFRS). The applied time period is 11 years - reports from 2007 to 2018. Theoretical considerations were conducted with the use of national and international literature regarding the subject, and applicable legal provisions concerning the accounting framework. A review of empirical research on the possibility of manipulating financial results through reserves and accruals was also made. The Authors analysed full versions of 748 financial reports with the inclusion of explanatory notes. T for the average and chi square tests were applied to confirm the statistical significance of the received results. Statistically significant dependences stem from the received results and confirm formulated research hypotheses that entities with high financial results do not avoid establishing reserves, but entities with low financial results release the previously established reserves and thus improve their profit levels. Conclusions that stem from the conducted empirical research take part in the discussion on the credibility of financial reports and on the possibility of using the items from reserves and accruals by the management in order to shape the value of the financial result in a discretionary manner. The results may be a prerequisite for conducting further empirical research that would consist of a larger research sample and that would take into account other tools that can be used for manipulating the value of financial results by companies listed on the stock exchange.

Keywords: Credibility of Financial Reports, Manipulation of Financial Results, Aggressive Accounting, Reserves, Accrued Liabilities.

Introduction

Both the establishment of reserves and accrued expenses, as well as their release, are associated with the creation of costs or revenues and affect the financial result. Decisions concerning the establishment and release of reserves are made on a discretionary basis and based on estimates. Therefore, they can be successfully used to manipulate the financial result. There are two main directions of manipulation: improving the image of the entity or showing a situation worse than in reality (Hońko, 2007, p.140).

Managers, while improving the image of an entity, may aim at e.g:

- receiving additional remuneration (bonus) from the profits made,
- increasing the share price on the stock exchange, in order to resell it,
- improving creditworthiness when applying for external financing,
- improving financial indicators and raising capital from the capital market (issue of new shares),

Cite this Article as: Anna STASZEL and Pawel ZIENIUK "The Use of Reserves and Accrued Liabilities for Discretionary Shaping of Financial Results of Stock Exchange Listed Companies: Case of Poland" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

- gaining new business contacts.

However, showing a situation worse than in reality may aim at:

- showing a significant improvement in the situation of the enterprise in subsequent reporting periods,
- reducing the number of dividends paid,
- reducing employees' claims if part of their remuneration depends on the profits made,
- understating the company's value before its acquisition,
- seeking to launch a recovery programme or initiating insolvency proceedings.

In economic practice, it has been accepted that financial result is one of the main measures of economic efficiency of the conducted business activity, however, it should be remembered that the amount of profit or loss depends not only on the course of real economic processes, but also on the adopted accounting principles in a given entity. Moreover, it is possible to influence the amount of the financial result through skilful selection of appropriate accounting instruments. The question is whether users of financial statements are aware of the limited usefulness of not only the category of financial result, but of the financial statements as a whole, not because of the lack of such attributes as reliability or trustworthiness, but precisely because of the possibility of legitimately influencing the content of the statements. Despite many limitations, it is the financial result and other reporting data that remain the primary measure of an entity's economic performance used for the purpose of making judgements and decisions.

The article presents the results of empirical research conducted on a sample of 68 companies listed on the Warsaw Stock Exchange over a time horizon of 11 years. The authors formulated the main hypothesis of the empirical research, according to which: changes in reserves are used by the Management Board to shape the gross financial result for a given period. In order to verify the main hypothesis, two detailed hypotheses were formulated:
H1:The values of changes in the balance of reserves depend on the financial results achieved by the entities.
H2: Decisions to establish and release reserves depend on the entity's gross financial result.

Both detailed hypotheses were positively verified by means of: ANOVA test. t for the average and chi square.

Literature Review

The research on reserves focuses primarily on the possibility of discretionary creation of financial result using this category. It is worth noting that such procedures as income smoothing, big bath or cookie jar reserves are based on appropriate manipulation of the size of reserves, because the effects of increasing or decreasing the balance of reserves, with only a few exceptions, directly correct the financial result of an entity, and most of the reserves are treated as estimates. It is therefore a category that can be successfully used to manage profits.

Analyses conducted by many authors show that the share of reserves in the balance sheet total of the studied business entities usually does not exceed 5%, and yet, they constitute an effective tool for the manipulation of the financial result. The authors noticed a correlation between the fact of establishing or releasing provisions and the financial result, financial indicators, including ROE. Research conducted by Polish authors also shows that entities are willing to establish excessive reserves, which they then use (reverse) to create higher financial result.

Empirical research conducted by A. Chraścina (2015) on a sample of 263 listed companies for the years 2010-2013 showed that:

- the average share of reserves was 4.64% of the average balance sheet total
- the level of disclosed reserves depends on the management and reporting factors, for example changes in the management personnel, the quality of audit or making the managers' remuneration dependent on the financial results of entities.
- Reserves are a tool for shaping financial results (earnings management) in order to smooth the financial result, apply the "big baths" strategy, avoid showing a decrease in the financial result and avoid showing a small loss.

Research conducted by A. Duraj (2004a, 2004b) confirmed that reserves are an important tool in the financial management of enterprises and that the increase in reserves is accompanied by a decrease in ROE. The research was conducted on a sample of companies from the metal industry sector for the years 1997-2002. Confirmation of the

use of reserves as a tool of discretionary shaping of the financial result also stems from the research conducted by E. Walińska and B. Bek-Gaik (2012) on companies included in the WIG20 index for 2007-2010.

On the other hand, research conducted by A. Staszel (2020) on a sample of 148 companies listed on the Warsaw Stock Exchange, for the years 2007-2014, showed that the statements prepared in accordance with IFRS are less reliable than the statements prepared in accordance with the Accounting Law. Statistically significant dependencies were found in the statements prepared in accordance with IFRS, indicating that entities shape their reporting data in a discretionary manner through the reserve policy

Many authors from Poland were interested in the possible use of reserves for discretionary profit management. In most cases, the hypotheses that reserves are a tool for profit management were confirmed. In particular, the research conducted by A. Staszel showed that reserves are a tool used to manipulate financial reporting. As part of the research on 1 036 financial statements, a distinction was made between statements prepared in accordance with the Accounting Law and statements prepared in accordance with IFRS. After the distinction was made, it turned out that statistically significant dependencies (indicating the use of reserves to manipulate reporting data) were observed in the group of entities preparing statements in accordance with IFRS. According to the knowledge of the authors, these were the first researches of this type in Poland, while abroad, more attention is paid to the differences in the reliability of statements prepared in accordance with local standards and those prepared in accordance with IFRS.

E. Peek (2004), while conducting research on Dutch companies covering the time horizon of 1989-2000, showed that reserves are used to shape profits, also confirming that entities have large reserves to smooth out current profits. Cohen, Darrough, Huang and Zach (2011) used a sample of 800 companies to show that reserves for warranty repairs can be used by managers as a tool to shape financial results.

The research concerning the impact of reserves on the financial results of entities operating in the banking sector should be considered as an interesting current of research in international literature. Leventis, Dimitropoulus and Anandrajan (2011) confirmed on a sample of 91 commercial banks that before the introduction of IFRS, the banks used the reserves for losses to shape their financial results. On the other hand, the introduction of the obligation to apply IFRS minimized the process of shaping financial results by means of reserves for credit losses. In turn, the Abou-El-Sood research (2012) conducted on a sample of 878 American commercial banks, for the years 2001 - 2009, shows that reserves for losses are a tool used to smooth out the financial results of banks. Before the crisis, banks reported higher reserves understating their financial results, while during the crisis they reduced the level of reserves in order to show higher financial results.

Both researches conducted in Poland and worldwide shown that with the use of reserves - constituting an estimated category - companies can shape the image of their property and financial situation (Poniatowska, 2013, p.119). Reserves can therefore be successfully used to shape the financial result in order to smooth it, apply a “big bath” strategy, avoid showing a small loss or avoid showing a decrease in financial results (Chraścina, 2015, p.53). Manipulation of financial reporting by means of reserves is possible due to the fact that their value is determined by means of estimates and they directly affect the financial result. Manipulation of the financial result is possible through: avoiding the establishment of reserves or understating their value, establishing excessive reserves or overstating their value, hiding real reserves under the category of contingent liabilities, or even releasing reserves despite an absence of circumstances justifying their release
Even the most precise reserve regulations cannot eliminate the elements of subjective choice. There are areas where the possibilities of manipulation are relatively small (for example, reserves on account of deferred income tax), as well as areas heavily exposed to the risk of distortion, such as reserves for retirement benefits.

The research conducted by A. Hołda and A. Staszel (2019) proved that a small 1% change in the assumptions used to estimate the discount rate (estimated using the CAPM or WACC model) causes a 1% change in the discount rate. These researches indicated that only a 1% change in the discount rate can cause a material change in reserves that could distort the reporting information.

Empirical Research

As part of the empirical research, it was decided to investigate dependencies between the reserves and the results of business entities. The analysis was made with a view to eliminate the impact of deferred tax. The analysis was made with a view to eliminate the impact of deferred tax.

For this reason, the research included the impact of reserves on the amount of gross financial result, which may be affected by both pension reserves and other reserves, regardless of the entity's activity (basic, other operating or financial).

Determination of the sample

The research was conducted on the basis of a detailed analysis of individual financial statements of companies whose shares are listed on the Warsaw Stock Exchange. The empirical research of the financial statements, due to their time-consuming nature, lasted from January 2018 to December 2019, while the research sample was finally determined in November 2018. After initial analysis of data, all those entities listed on the Warsaw Stock Exchange that have been preparing their financial statements in accordance with IFRS since 2007 were selected for further research.

From the initially selected pool, a significant number of companies could not be covered by the research: the financial statements had to be rejected from the research sample for objective reasons:

- banks, insurance companies and other financial institutions whose statements were prepared on different models,
- companies that provided only consolidated financial reports;
- companies that did not make their financial statements available for all the years covered by the research time horizon (i.e. statements from 2008 to 2017, data for 2007 were derived from comparative data of financial statements for 2008); this pool included:
  a) companies that entered the stock exchange in 2010 and beyond, and were therefore not required to provide their financial statements for earlier years,
  b) companies that entered the stock exchange before 2010, but:

  i) do not provide financial statements for the years under review,
  ii) make financial reports available, but they contain incomplete financial statements (for example, only the balance sheet and profit and loss account without any explanatory notes, or only selected financial data with selected notes).

Ultimately, only those companies that provided full financial statements together with additional information for all years from 2007 to 2018 were accepted as the sample. The main source of information was the financial statements published on the official company websites.

An Excel spreadsheet was used to collect data and to develop them. Statistical analyses were conducted in Statistica version 13.1 (t tests for averages, ANOVA tests) and in an Excel spreadsheet (Pearson's chi-squared test, averages, standard deviations, etc.).

Ultimately, the sample included 68 companies, i.e. all of the companies listed on the WSE that met the criteria set by the authors. For each financial statement, it was determined whether the entity:

- shows a gross loss, or
- shows a gross profit, but this is a small profit (below the general materiality for the financial statements as a whole, which is set at 1 % of the balance sheet total),
- shows a gross profit of a significant amount, which means that irregularities related to the reported gross profit may mislead users of financial statements.

The methodology used to calculate the materiality threshold (i.e. the amount above which omissions or distortions of reporting information are considered to have a material impact on the decisions made by the users of financial statements) at 1% is a materiality level very often adopted in the realities of Polish business entities, and the same materiality threshold, used in practice by auditors, was adopted for the purposes of this research.

Results of Empirical Research

It has been hypothesized that the amount of changes in reserves and accrued expenses reported in the financial statements depends on whether the entity reported a loss, an immaterial profit or a material gross profit. In order to

exclude the impact of the size of the examined companies, the annual change in reserves and accrued expenses divided by the balance sheet total was tested. Absolute values of changes in reserves and accruals were taken into account. The aim of the test was to verify whether changes in the balance (regardless of whether they were increased or decreased) depend on the results achieved.

In order to verify the assumed hypothesis, an independent t tests for averages was applied, which allows to verify whether generating a gross loss or gross profit by the company significantly differentiates the size of changes in reserves and accruals.

Table 1 presents the average values of changes in reserves and accrued expenses, divided by the balance sheet total, depending on the entity's performance. On the other hand, Table 2 presents the results of one-factor analysis of an independent t tests for averages.

Table 1: Average levels of changes in reserves and accrued expenses depending on the gross financial result achieved

Specification	The average absolute value of changes in reserves and accrued expenses divided by the balance sheet total
Reporting a loss in the statement	0.008514
Reporting gross profit	0.014576

Source: own elaboration based on data obtained from the conducted research

The information presented in Table 1 shows that in the case of companies that show a loss, the change in reserves and accrued expenses represents on average 1.5% of the balance sheet total, while in the case of companies that show a gross profit, the change in reserves and accrued expenses represents slightly below 1% of the balance sheet total. Whether the observed differences between the averages are statistically significant can be determined by means of independent t tests for averages analysis.

Table 2: Results of independent t tests for averages for the variants of proceeding in connection with the change in reserves as a factor differentiating the level of gross financial result

Independent t tests for averages	
Reporting a loss versus reporting a gross profit	
Mean Gross profit	0.008514
Mean Loss	0.014576
t-value	-2.00637
df	746
p	0.045177
Valid N Gross Profit	603
Valid N Loss	145
Std. dev Gross profit	0.027191
Std. dev Loss	0.049368
F-ratio variance	3.296240
p-value variance	0.000000

Source: own elaboration based on data obtained from the conducted research

The dependencies presented in Table 2 show that the gross financial result (loss or gross profit) is a factor significantly differentiating the amount of changes in reserves and accrued expenses. Statistically significant differences occur in average changes in reserves depending on whether the entity achieved gross profit or gross loss. To sum up, gross profit or loss is a factor significantly differentiating the amount of the change in reserves reported in the financial statements.

The hypothesis H1: "The values of changes in the balance of reserves depend on the financial results achieved by the entities" has been confirmed.

In order to verify whether the entities' policies with regard to reserves and accrued expenses (decrease in the balance of reserves or decrease in the balance of reserves, which is analogous to the increase or decrease in the gross financial result) depend on the achieved financial results, the authors created a table of multi-divisional frequency of increases and decreases in the balance of reserves, broken down into entities which showed a gross loss, immaterial gross profit or material gross profit. Table 3 contains a summary of the number of cases, with the percentage of cases given in brackets, calculated as a percentage from among the entities showing a loss, immaterial and material gross financial result.

Table 3: Dependency between decreasing or increasing reserves and accrued expenses and the nature of the achieved gross result

Specification		Loss	Immaterial gross financial result	Material gross financial result
Operations of the given year in companies	Decrease in reserves	72 (50%)	20 (43%)	220 (39%)
	Reserves remain unchanged	5 (3%)	6 (13%)	2 (1%)
	Increase in reserves	68 (47%)	20 (43%)	335 (60%)
		100%	*100%*	*100%*

Source: own elaboration based on data obtained from the conducted research

The information presented in Table 3 shows that among the entities that generate profits (both material and immaterial), 58% increase the balance of reserves, while 39% decrease the balance of reserves. On the other hand, in the case of entities that generated a loss, as many as half of them decrease the balance of reserves. This may be explained by the fact that the entity, by reducing the balance of reserves, wishes to improve its financial situation and reduce the size of losses.

In order to verify whether the frequency of increases and decreases in reserves depends on the achieved gross financial result, the Pearson's chi-squared test was applied. The value of test statistic is 50.29776 with a test probability of p=3,1292E-10, which means that the dependence in question is statistically significant at the level of significance of 0.05. Thus, the test result indicates that the policy in the scope of change in reserves and accrued expenses (increase or decrease in reserves) depends on the nature of the financial result (material result, loss, immaterial result) for a given period.

In order to verify whether the entities' policies with regard to reserves and accrued expenses (decrease in the balance of reserves or decrease in the balance of reserves, which is analogous to the increase or decrease in the gross financial result) depend on the financial results (loss or gross protit) an independent t tests for averages was also applied, which allows to verify whether the financial results in a year determine decision to increase or decrease reserves and accruals. Table 4 shows the results of independent t tests for averages.

Table 4: Results of independent t tests for averages for the financial result in connection with the change in reserves (decrease in reserves or increase in reserves) as a factor differentiating the level of gross financial result

Independent t tests for averages	
Decrease in reserves versus increase in reserve	
Mean financial result while decrease in reserves	99189.83
Mean financial result while increase in reserves	232395.9
t-value	-2.01560
df	746
p	0.044199
Valid N financial result while decrease in reserves	308
Valid N financial result while increase in reserves	440
Std. dev financial result while decrease in reserves	492117.7
Std. dev financial result while increase in reserves	1084114
F-ratio variance	4,853018
p-value variance	0.00

Source: own elaboration based on data obtained from the conducted research

The information presented in Table 4 shows that the average gross profit in entities which increase reserves is 232 395 900 PLN, while the average gross profit in entities which decrease reserves is about 2.5 times less: it is 99 189 830 PLN. The test probability (p-value) is 0,0000, so the hypothesis H2: "Decisions to establish and release reserves depend on the entity's gross financial result" has been confirmed. Indeed entities with bigger gross profit are more likely to increase reserves and accruals, and entities with lower gross profit or with loss usually decrease reserves, to show that way less costs and more profits.

Conclusion

The purpose of the research was to determine whether a category of reserves may be used to manipulate financial reporting. The answer to this question was attempted on the basis of an analysis of 748 financial statements of companies listed on the Warsaw Stock Exchange, preparing financial statements in accordance with IFRS, using triangulation of research methods.

The conducted research showed that reserves and accrued expenses constituted a small part of the balance sheet: only 4.2% of the balance sheet total. However, the annual changes in reserves (increases or decreases in reserves) constituted on average as much as 170% of the gross financial result of the examined entities. This fact proves that the change in the balance of reserves (which is accounted for as a result) has a significant impact on the data presented in the profit and loss account, and above all on the amount of the reported financial result.

It was then decided to verify whether the amount of changes in the balance of reserves (the amount of increases or decreases in the balance of reserves from year to year) is dependent on the financial results achieved by the entities. This dependence was statistically confirmed (in entities that show a gross loss, the change in reserves is almost twice as big as in entities showing profits). Moreover, it was possible to statistically confirm the dependence between the entity's policy regarding changes in reserves and accrued expenses (increase or decrease in reserves) and the nature of the financial result (material result, loss, immaterial result) for a given period. The entities that

generated a loss avoided increasing the balance of reserves (which generates costs), instead decreasing it (thus showing profits) more often than the entities that generated profits.

The main hypothesis, according to which: changes in the balance of reserves are used by the management board to shape the gross financial result for a given period, was confirmed.

The detailed hypotheses were also confirmed. Therefore, it can be concluded that the amount of changes in reserves depends on the financial results achieved by the entities, and decisions to establish and release reserves depend on the entity's gross financial result.

Interpersonal Conflict In Organizations: Handling Conflict Styles Between Peers In A Portuguese Public Organization

Paulo PINTO-MOREIRA

Coimbra Business School – ISCAC, Coimbra, Portugal
pmoreira@iscac.pt

Abstract

We live in a society that is highly evolved from the social and technological points of view, in which new trends in work organization and human resource management appear to move towards a growing level of behavioral requirements. There is a need for workers at different levels to learn and develop new behaviors, namely regarding interpersonal relationships with co-workers. This article focuses on the studies of conflict at the micro level more specifically the interpersonal conflict in organizational context. In order to evaluate interpersonal conflict handling styles, the ROCI-II Rahim Organizational Conflict Inventory was used in a sample of 181 subjects, workers from several hierarchical levels and departments from a Portuguese public organization. The main goal of this study is to deepen knowledge about interpersonal conflicts handled by peers themselves, establishing to what extent handling styles are determined by demographic variables – sex and level of education. The results indicate a greater predominance of the integrating and compromising styles, and that obliging, avoiding and dominating styles are less frequent. The subjects, whether they are men or women, share a very similar position regarding conflict handling. Subjects with higher levels of education qualifications are less avoidant.

Keywords: Interpersonal Conflict in Organizations, Handling Conflict Styles Between Peers.

Introduction

According to Ibañez (1988), the most relevant aspect in the definition of conflict is that it should stem from the social players' subjectivity, and more specifically from their cognitive representations, so as to differentiate it from other similar states of discord such as an objective counter-position or competition. Several conflict literature reviews show little consensus when it comes to accepting a generic definition of conflict. Cunha et al (2016), Lewicki, Weiss and Lewin (1992), Kolb and Putnam (1992) follow suit, noting that perspectives, as well as difficulties in defining conflict, abound - and, in general, no definition prevails over the others. According to Serrano and Rodriguez (1993), despite conflict being analyzed from several points of view, which correspond to different analytical perspectives and different phenomenon explanation levels, these are not, on principle, contradictory. Different scholars converge, arguing that conflict is an interactive process and may occur whenever two or more social entities (individuals, groups, organizations, nations) interact and their interests or goals are perceived as incompatible or dissonant. (Deutsh, 1994; Pruitt et al, 1994; Smith, 1966, Thomas, 1976; Ting-Toomey, Oetzel and Yee-Jung, 2001). Others add that the relationship between entities might become incompatible or inconsistent either when two or more entities seek the same goods or resources and these are scarce, arousing feelings of exclusivity towards said goods or resources between these entities, or when they have different attitudes, values, beliefs or abilities (Antonioni, 1998; Bercovitch, 1984; Cunha, 2001; Rahim, 2001 and 2002; Einarsen et al, 2018; Van de Vliert, 1985).

Cunha (2001) draws attention to the fact that to speak with authority in conflict, the parties in the litigation must understand the incompatibility of their goals, and that there are interdependent ties - either functional, structural or merely historical -, that prevent each party from achieving their goals without counteracting the other. On the other hand, Serrano and Rodriguez (1993) caution that there is subjectivity in terms of connotations of definitions centered on the incompatibility of the parties. They mention that partial or total incompatibility of the goals does not imply they really are so: regardless of what happens, incompatibility often stems from a distorted perception that accentuates the most diverging elements and not the common interests. Therefore, according to the author, the analysis of this dimension requires not only a motivational perspective, but also a perceptive one, given that any conflict carries with itself a particular background of stereotypes, prejudices, ethnocentric visions and biased perceptions of the opponent that curtail the supposed inability to reach an agreement.

Interpersonal conflict in organizations

Interpersonal conflict is a fundamental component of the organizational experience, in which one's individual goals, desires and expectations suffer interferences from others, creating diverging interests or the belief that each player's aspirations cannot be achieved simultaneously (Lee, 2002; Moberg, 2001; O´Connor et al, 2002; Ohbuchi and Fukushima, 1997; Pruitt et al, 1994). In a more enlightening manner, Rahim (1992 and 2001) mention that interpersonal conflict in organizations refers to manifestations of incompatibility or to disagreement between two or more people at the same or at a different hierarchical level, in a situation where one or more person's goals are mutually exclusive, creating hostile attitudes.

The subjectivity of the emergence of conflict very often arises from the fact that many people do not like engaging in conflict because of its negative consequences. The natural reaction is to avoid or end conflicts as soon as possible. The negative associations that exist towards conflict influence, without a doubt, how we face and respond to it (Jehn, Northcraft and Neale,1999). If conflict becomes intense, social players will stray from a convenient and sensible relationship and focus their efforts towards victory. Once the immediate objective of each of the parties is to win or have control over the situation, the interest in solving the problem(s) becomes less and less important. Therefore, the players are less predisposed to contribute to effective organizational goals (Rahim, 2002). According to Bergmann and Volkema (1994), interpersonal conflict between co-workers has the potential to divide a team and proliferate throughout the company. However, avoiding or suppressing conflict is often a mistake, and does not always meet the real interests of those involved. In that regard, Tjosvold (1997) argues that interpersonal conflict may develop each person's individuality, so as to feel satisfied and able, given that it provides an opportunity to express one's needs, opinions and stances. At the same time, there is an attempt to understand the other party's positions, which contributes to diminishing an egocentric attitude.

Given the aforementioned assumption – that conflicts are a consequence of one's own social interaction – the idea that the goal should consist in displaying adequate skills and tools to face them with a positive demeanor, should be reinforced. Beitler, Scherer and Zapf (2018); Deutsh (1994); Munduate et al (1993), Pruitt et al (1994) and Serrano & Rodriguez (1993) argue that the effects of conflict are positive when we know how to handle them properly, in a way that establishes relationships that are increasingly cooperative. This once again seems to reinforce the vision of Rahim (2000) regarding increased organizational learning, so as to boost people's efficiency in handling conflicts in a sustained manner.

Interpersonal Conflict Handling

According to Van de Vliert (1985), conflict handling is what those involved intend to do, as well as what they really do. It encompasses changes in attitude, behavior and in the organizational structure that allow members of the same organization to work with each other effectively, achieving their individual and/or group goals (Scherer and Zapf, 2018; Rahim, 1992; 2001; Yoko, Hartel and Callon, 2002). Despite the growing awareness that conflict in organizations can be functional, many of the recommendations continue to fall on the spectrum of mitigation, resolution or minimization, which is to say they promote conflict resolution and not conflict management. The difference between the two concepts is not just semantics (Robbins, 1978). What contemporary organizations need is conflict management and not conflict resolution. Conflict management does not necessarily imply avoiding, decreasing or ending conflicts altogether, it involves effectively outlining strategies to minimize dysfunctions and fostering constructive roles so as to increase organizational learning and efficiency (Rahim, 2001 and 2002; Kessler et al, 2013).

Organizational learning is of the essence, and many contemporary academics state that it is not a matter of wanting or not wanting to learn, but rather that organizations need to learn as soon as possible. The presence of tension and conflict seem to be essential characteristics of learning organizations, in which tension and conflict are underlined by questioning, unbalancing and challenging the *status quo* (Garvin, 1993, Schein, 1993, Senge, 1990). Argyris (1994) suggests that existing theories reveal processes of anti-learning, which can be better described as *quasi*-conflict resolution models. Several scholars mention the need to handle conflicts in a constructive way, to realize the collective learning potential. Thus, corroborating Rahim (2001 and 2002), the need to strengthen and consolidate conflict handling at the highest organizational levels is implied to encourage organizational learning and efficiency. Amason (1996), Jehn, Northcraft and Neale (1999), among others, suggest that conflict handling involves the acknowledgement of the following principles in regard to the performance of individuals and groups: certain specific types of conflicts may cause negative effects and should be diluted, these conflicts are generally caused by the actions and negative reactions of members of the organization, for example personal attacks, racial disharmony and sexual harassment; yet there are other types of conflicts that may have positive aspects, and such is the case of disagreements that spurred from tasks, action plans and other organizational issues. The members of the organization, in their

interactions with one another, will have to deal with their disagreements in a constructive manner, which leads to serious learning about how to use conflict handling styles to face different situations in an effective way.

According to Tjosvold (1997), well-managed conflicts are an investment for the future. People believe in one another, feel more powerful, effective and more prepared to contribute to their groups and organizations. In fact, in an organizational environment, individuals that handle conflicts effectively are seen as competent speakers and as having leadership skills (Gross & Guerrero, 2000; Luthans, Rosenkrantz and Hennessey, 1985). In line with Blake & Mouton (1978) and Thomas (1976), Rahim and Bonoma (1979) and Rahim (1983a) differentiate interpersonal conflict handling styles through two basic dimensions: personal interest, which explains the degree (high or low) to which a given subject seeks to satisfy their own interest, and the other's interests. These dimensions are subject to different combinations, resulting in five specific styles, designated as follows (Rahim 1983a, 1986, 2000, 2001 and 2002; Rahim and Bonoma, 1979):

- Integrating, which is characterized by a high interest both in one's own results and the other party. This style implies collaboration between both parties, exchange of information and an active search for an acceptable solution that works for both. Therefore, a direct communication between the parties is established, boosting the occurrence of creative solutions for both;
- Obliging, which is characterized by low investment in oneself, but high investment in the other party. This style implies the satisfaction of the other party's interests over one's own interests. When one of the parties adopts this style, they opt not to consider their differences towards the other and weigh in shared aspects seeking to satisfy the other party's interests;
- Dominating, which is characterized by high investment in oneself and low investment in the other party. In this style, one tries to achieve their own goals without caring for the other's interests;
- Avoiding, characterized by low investment in one's own results and in the other party's;
- Compromising, this style positions itself in the middle of the aforementioned four styles, characterized by an intermediate interest for oneself and other parties.

Empirical Study

The overall objective of this research is to describe the conduct of individuals in situations of interpersonal conflict in an organizational context among co-workers, and check how conflict handling styles are determined by the variables sex and level of education. The specific goals that we set are the following: identify profiles of interpersonal conflict handling between peers in each of the subjects; assess to what extent interpersonal conflict handling styles is determined by certain demographic characteristics.

Using the theoretical studies as a reference, we propose the following hypothesis:

H1 - The integrating and compromising styles are the most used in interpersonal conflict situations between peers – co-workers. On the contrary, avoiding, obliging and dominating styles are less frequently used.

H2 - In interpersonal conflict situations between peers – co-workers, the dominating style is more predominant in male subjects than in women.

H3 - In interpersonal conflict situations between peers – co-workers, the avoiding and obliging styles are more predominant in females than in mens.

H4 - In interpersonal conflict situations between peers – co-workers, subjects with a higher level of education integrate more and use avoiding less than those with a lower level of education.

Sample and Methodology

In this study, independent demographic variables and one dependent variable were considered - interpersonal conflict handling styles between peers in an organizational context.

Independent variables: Sex - the sample includes male and female subjects. Level of education - this variable is composed of three levels, Basic Education (up to 9th grade), Secondary Education (up to 12th grade/ K-12) and Higher Education (University degree). Years of professional experience - divided into five groups - up to 5 years; 6 to 15 years; 16 to 25 years; 26 to 35 years and over 36 years of professional experience.

Dependent variable: conflict handling styles. In this category we include the five interpersonal conflict handling styles between peers - co-workers in an organizational context: integrating, compromising, obliging, dominating and avoiding, using the approach suggested by Rahim and Bonoma (1979) and Rahim (1983a).

Measurement tool: To assess interpersonal conflict handling styles, we used the "ROCI-II, Rahim Organizational Conflict Inventory". (Rahim,1983b). This inventory has its theoretical basis in the two-dimensional approach of five factors by Rahim & Bonoma (1979) and Rahim (1983a). Thus, conflict management is considered on the basis of a two-dimensional model. On the one hand, there is the importance attributed to one's own interests and, on the other hand, the importance attached to the interests of the other party. This defines the five conflict handling styles: integrating, obliging, dominating, avoiding and compromise (Rahim, 1983a, 1983b). The tool consists of 28 questions and comprises A, B, C forms, through which we intended to measure how individuals handle interpersonal conflict situations with their superiors (A), their subordinates (B) and their peers (C). In this study we apply the C form referring to peer conflict - co-workers, comprised of 28 questions which are answered through a Likert scale with five potential replies, in which 1 corresponds to Strongly Disagree and 5 to Strongly Agree, and in which higher values represent greater use of a style and vice-versa. (Rahim, 1983c, 2001). ROCI-II also requests information regarding sex, level of education and profession.

With the translation and adaptation of the questionnaire's C form in mind, we used the original version of the questionnaire by Rahim (1983b) after being translated to portuguese. So as to test the interpretation and comprehension of each question, the questionnaire was trialed on 20 workers from the public organization where the sample for this study was collected later on. After revising it and consulting the original questionnaire also translated to Portuguese in the study by Cunha, Moreira & Silva (2003) with a national sample of 197, and it was submitted to a new trial with 41 workers. With data analysis and its respective conclusions in mind, several quantitative analysis were made using the SPSS - Statistical Package for the Social Sciences, version 16.0.

The study used a sample of 181 subjects, workers from several hierarchical levels and departments from a Portuguese public organization. There were 113 female subjects, which represent 62% of the total and 68 male subjects, who represent 38%. About half (49%) of the subjects have a university degree, followed by secondary education (36%9) and finally by subjects with only basic education, who represent 15%.

Analysis and Interpretation of The Results

Regarding the C form questionnaires of the "ROCI-II" inventory, we calculated an average value for each questionnaire and for each one of the five conflict handling styles, whose minimum value could be 1 and the maximum could be 5, which means 3 is the average value. From table 1, we ascertain that the predominant style is integrating, followed by compromise. Avoiding appears in the third position, followed by obliging, which is displayed in above-average values. The least adopted style is domination. The response scattering is more accentuated in the dominating style, followed by avoiding and obliging. There is less scattering in the integrating and compromising styles.

Table 1: Statistical data observed in the responses related to the five styles of conflict management

	Integrating Mean	**Avoiding** Mean	**Dominating** Mean	**Obligation** Mean	**Compromising** Mean
Valid N	181	181	181	181	181
Omississions N	0	0	0	0	0
Mean	4.1981	3.4954	2.7580	3.1096	3.9006
Median	4.1429	3.5000	2.6000	3.1667	4.0000
Standard deviation	.38817	.62987	.69857	.59014	.42547
Asymmetry	.064	-.332	.265	-.261	-1.056

Therefore, taking into consideration the results, we confirm our hypothesis #1, which mentioned a greater predominance of the integrating and compromising styles and that obliging, avoiding and dominating are less frequent. So as to verify the significance level of the differences between the values surveyed for both sexes, we used the *t-test*, preceded by the hypothesis test to the equality of variances. Table 2, presents .019 test values for integrating and .002 for avoiding, therefore less than 5%. Dominating registers .195, obliging .579 and compromising .277, with significance values above 5%. Therefore, dominating, obliging and compromising have the same variance, but integrating and avoiding do not.

Table 2: Significance of gender differences in conflict management style, preceded by hypothesis testing to the equality of variances

		Levene's Test for Equality of Variances		t-test for Equality of Means		
		F	Sig.	t	Df	Sig. (2-tailed)
I1_Integration Mean	**Equal variances assumed**	5.556	**.019**	1.663	179	.098
	Equal variances not assumed			1.731	159.087	**.085**
I2_Avoiding Mean	**Equal variances assumed**	9.707	**.002**	-.036	179	.972
	Equal variances not assumed			-.033	112.865	**.974**
I3_Dominating Mean	**Equal variances assumed**	1.695	**.195**	.251	179	**.802**
	Equal variances not assumed			.259	155.312	.796
I4_Obligation Mean	**Equal variances assumed**	.308	**.579**	1.246	179	**.214**
	Equal variances not assumed			1.234	136.802	.219
I5_Compromising Mean	**Equal variances assumed**	1.189	**.277**	1.626	179	**.106**
	Equal variances not assumed			1.732	168.012	.085

Taking into consideration these values for the *t-test,* we verify that test values are always above 5%, so they never allow us to reject the null hypothesis, which would be having the same variables for both sexes in integrating, avoiding, dominating, obliging and compromising or, in other words, that there are no differences between both sexes in what concerns conflict handling styles. This leads us to conclude that the subjects of this study, whether they are men or women, share a very similar position regarding conflict handling. Thus, we deny our hypothesis #2, which mentioned a greater prevalence of dominance in males, as well as hypothesis #3, that pointed towards a greater predominance of avoiding and obliging amongst the female sex. The analysis of variance - ANOVA (Table 3), allows us to see that for avoiding (.001), dominating (0.013) and obliging (.003), the hypothesis that the averages are the same across different levels of education is denied.

Table 3: ANOVA - Hypothesis testing for equality of Variances for educational qualifications

		Sum of Squares	df	Mean Square	F	Sig.
I1_Integration Mean	Between Groups	.820	2	.410	2.773	.065
	Within Groups	26.301	178	.148		
	Total	27.121	180			
I2_Avoiding Mean	Between Groups	5.809	2	2.905	7.881	**.001**
	Within Groups	65.604	178	.369		
	Total	71.413	180			
I3_Dominating Mean	Between Groups	4.164	2	2.082	4.429	**.013**
	Within Groups	83.677	178	.470		
	Total	87.841	180			
I4_Obligating Mean	Between Groups	4.071	2	2.035	6.180	**.003**
	Within Groups	58.617	178	.329		
	Total	62.688	180			
I5_Compromising Mean	Between Groups	.335	2	.168	.926	.398
	Within Groups	32.250	178	.181		
	Total	32.585	180			

Source: Own elaboration based on SPSS output

Hypothesis #4 is partially confirmed, when we point towards subjects with higher levels of education as less avoidant. Not confirming that the subjects with higher educational qualifications would be more integrators. There are no significant differences, which support this hypothesis.

Conclusions and Guidelines for Management

Through this study we conclude that men and women share very similar positions towards conflict handling, concurring with the results of studies conducted by Cunha, Moreira & Silva (2003), Munduate, Ganaza, and Alcaide (1993), Shockley-Zalabak, (1981) Sorenson, Hawkins and Sorenson (1995). The relation between gender differences and interpersonal conflict handling styles has been the subject of several studies, and the authors that encountered significant differences do not present unanimous tendencies. For example, Rahim (1986), obtained results that suggest that women use avoiding, integration and compromise more and obliging less than men; whilst studies by Brewer, Mitchell and Weber (2002) suggest that women use avoiding more and men use dominance more; studies by Baxter and Shepard (1978) and Hill, Henry and Green (1997) found evidence that suggests women prefer non-confrontational styles, while men prefer competition and controlling styles.

The registered predominance of the integrating and compromising styles and the lower frequency of avoiding, obliging and dominating styles in conflict situations between peers seems to concur with studies by Munduate Ganaza and Alcaide (1993), Lee (2002) and Rahim (1986), amongst others. As Lewicki, Weiss and Lewin (1992) mention, responses to conflict are a result of the subject's direct learning and relearning through behaviors and previous experiences, clearly influenced by individual perception and comprehension of the organizational context. This may lead those who are less experienced to adopt conflict handling styles in a less premeditated manner, according to the circumstances and the way they perceive them, probably due to greater irreverence, competitiveness and, mostly, less knowledge about all the implications it may have in an organizational context.

More than a succession of categorical conclusions, this article aims to draw attention to the social relevance of this issue. Being an exploratory research as well, it will restrict the extrapolation of the results to different organization realities. It seems pertinent, however, to make some management recommendations that could be extended to other organizational contexts. The first recommendation of this study refers to the acceptance, by organizations, that

conflicts are a consequence of social interaction itself, and that, beyond legitimate, they are inevitable, and therefore must be handled and not resolved (or mitigated). As Robbins (1978) refers, the difference between the two concepts is much greater than semantics. The challenge will be incorporating and promoting human resources management procedures and guidelines that reflect that reality. Creating tools and skills that allow handling interpersonal conflict properly, which according to Rahim (2001) should be achieved through the increase of organizational learning, so as to increase people's efficiency in conflict handling in a sustained fashion. Organizational learning is of the essence, and many contemporary academics state that for organizations it is no longer a matter of wanting to learn, but rather learning as fast as possible - given the importance that conflict has in an organization's life and the complexity associated with its handling, it is essential that workers across all hierarchical levels understand the contexts in which organizational conflicts occur, and know a variety of techniques to handle them. Corroborating Garvin (1993) and Rahim (2002), organizational learning, in what concerns conflict management, requires company cultures that support experimentation, risk-taking, openness to new points of view and a continuous attitude that questions and inspires, sharing information and knowledge.

Moving Average in A Binary Representation

Michał Dominik STASIAK

Department of Investment and Real Estate, Poznan University of Economics and Business, Poznań, Poland
michal.stasiak@ue.poznan.pl

Abstract

One of the basic methods of technical analysis that are commonly used in investor practice is the analysis of moving averages. Moving averages are appointed based on the candlestick representation of the price, which has the drawback of possible decrease in the informative value carried by the exchange rate trajectory data. Better results of course modeling can be obtained by using the binary-temporal representation. The article presents a new algorithm for calculating the weighted moving average for the quotations in a binary-temporal representation. The algorithm assigns each change of course trajectory in the binary-temporal representation a weighted average to form an extended binary-temporal re-representation, which in turn can be the basis to construct a state prediction model.

Keywords: Technical Analysis, Investment Decision Support, Moving Average, Binary-Temporal Representation.

Introduction

This section should follow keywords. Technical analysis and exchange rate modeling methods are created in order to support investors in decision making (e.g. indicators) or to fully automate the process of investing (algorithmic systems, HFT) (Aldridge 2013; Alonso-Monsalve et al. 2020; Nuti et al. 2011). The main goal of the following article is to propose an algorithm to implement one of the most popular methods of technical analysis – the average analysis – for a binary-temporal representation.

In majority of exchange rate modeling papers, the course trajectory is given in the so called candlestick representation (Burgess 2010; Lim 2015; Murphy 1999). Using this representation can lead to significant losses in the informative value of exchange rate trajectory data. Moreover, because of the different quotation frequency, the loss is variable in time and impossible to assess. Application of historical data formatted into the candlestick representation can, in consequence, lead to falsified results of the course modeling. A more precise and easier to interpret is the binary-temporal representation (Stasiak 2018).

In the paper we propose a new algorithm to determine the weighted moving average dedicated to the binary-temporal representation. The algorithm assigns every binary change an average calculated from previous n changes. The average construction encompasses both the information about the size of changes and their duration.

The article is organized in the following order. After a short introduction (section 1), the second section describes the binary-temporal representation, its advantages and properties. The third section recalls the methods for calculating averages in technical analysis. In the following section a new algorithm is proposed, intended to appoint weighted moving averages in the binary temporal representation. Also, a concept of extended binary-temporal representation is given, in which the representation includes information about averages and can be applied to construct prediction state models. The last section summarizes the research.

Binary-Temporal Representation

Courses of most of financial instruments change with a high frequency. Often few changes occur during even one second. Many of these changes oscillate around specific values, with small amplitude of 1-3 pips. Such changes have a

Cite this Article as: Michał Dominik STASIAK "Moving Average in A Binary Representation" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

character of random fluctuations (noise) and do not carry any informative value which could be used to model exchange rate trajectory (Neely & Weller 2011; Lo et al. 2000;). Therefore, applying so-called tick data to exchange rate analysis, that is data about each, even the smallest, change of the course, is ineffective because of both the size of data and the possible hindrances in the proper process of course analysis. For this reason, it is necessary to use proper formatting of historical data, which is equivalent to applying an appropriate data representation.

In the majority of scientific research, as well as in the investment practice, candlestick representation (Aldridge 2013; Gallo 2014; Nuti et al. 2011) is used in order to analyze the market. This kind of data presentation is offered by all broker platforms (e.g. Metatrader 4/5, JForex, etc.). In the candlestick representation the course changes in a given timeframe are described by four parameters: opening and closing prices, and highest and lowest registered prices.

The characteristics of the exchange rate given in a candlestick representation depend on the assumed time interval, but do not depend on the dynamics of the course changes. The amplitude of changes of night candles can be few or even few dozen times smaller than the one registered during presentation of important macroeconomic data (e.g. changes in interest rates) or during important geopolitical events (e.g. publication of elections outcomes). Because of these reasons, using candlestick representation can lead to a loss of important information about the frequency and direction of smaller changes, i.e. changes 'inside' the candle. This, in consequence, reduces the effectivity and precision of technical analysis. Mentioned drawbacks are especially significant in the construction of HFT systems, since decision making algorithms often wrongly determinate the outcome of a given transaction (i.e. they determine wrongly if the transaction would end with a profit of a loss) (Stasiak 2020).

As an answer to the problem of serious disadvantages of the candlestick representation and the need to filtrate the noise, in (Stasiak 2018) a binary-temporal representation was introduced. This kind of representation is free of mentioned faults and was inspired by the point-symbolic visual method (DeVilliers 1933) that was used prior to the candlestick one but was supplanted by it despite being more accurate.

The construction of the binary-temporal representation consist in assigning two parameters to each course change of a given value δ (the so-called discretization unit). First one, ε_i describes the direction of *i*-th change. If the exchange rate drops by one discretization unit, the algorithm assigns the value 0. If the course increases by one discretization unit, the change is assigned a '1'. The second parameter is denoted Δt_i and represents the duration of a given change, expressed in seconds. Hence, each *i*-th course change in the binary-temporal representation is assigned a pair $(\varepsilon_i, \Delta t_i)$. Therefore, the exchange rate trajectory from an arbitrary historical time period can be represented as a ordered sequence of pairs $\{(\varepsilon_i, \Delta t_i)\}_{i=1}^{N}$, where N denotes the number of observed changes.

Let us now take a look on the comparison between the two representations. Using the binary-temporal representation eliminates the periods of non-activity from the exchange rate analysis, such as nights. In the same time, it retains key information such as the direction and size of the course change and its duration. In the Figure 1 we can see different exchange rate trajectories represented by the same candle in the candlestick representation.

Fig. 1: Two different exchange rate trajectories 'inside' the same candle

As visible in the example above, the binary-temporal representation carries precise information about the size of change and its duration. The form and properties of the course in this representation depend only on one parameter – the assumed discretization unit. Too small value of this parameter leads to registering small fluctuations, majority of which can be considered as noise. On the other hand, a too big discretization unit results in a loss of the informative value of the data, losing information about the exchange rate trajectory. The algorithm in such case does not register significant changes, which is visible in the small number of registered changes in the researched time period. As a consequence, this may lead to less credible results of statistical analysis.

While analyzing the exchange rate there arises the question if the course changes are random as stated in the assumptions of e.g. theory of efficient market or random walks (Peters 1991). The assumption about the randomness of changes negates the possibility of predicting the direction of future changes based on the history of previous variations. In consequence, it denies the effectiveness of applying technical analysis methods in course modeling (Yao & Tan 2000).

In order to verify the assumption about the random character of course changes we can use means of statistical testing, e.g. by using three tests recommended by National Institute of Standards and Technology (NIST) to test random number generators in cryptographic modules (Bassham et al. 2010). The tests are: monobit test, series test and longest series in a block test (Bassham et al. 2010; Menezes, Van Oorschot, Vanstone 2018). These tests allow to verify the hypothesis of randomness of course changes on a given significance level (usually 0.01).

In the situation of assuming a too small discretization unit, the test results for noisy data show random character of the course changes. Similarly, when assuming a too big discretization unit, in the data that has lost its informative value the tests indicate a random character of changes. Hence, the assumed discretization unit should be possibly small, so that it would convey the character of fluctuation in the most precise way. In the same time, it should be big enough to eliminate changes considered as noise. In order to indicate an accurate range of discretization units for which the exchange rate in a binary-temporal representation does not have a random character, all representations were tested, starting from a 1-pip one. Next, the discretization unit was increased until the obtained representation was random. This way we obtained an interval of discretization units for which the course can be subjected to prediction analysis.

A detailed description of the tests and the process of determining the appropriate range of discretization units can be found in (Piasecki and Stasiak 2020). For selected discretization units, it is justified to use technical analysis methods aimed at predicting the direction of future exchange rate changes.

Moving average in a Candlestick Representation

In the applications of today's technical analysis, the averages are one of the basic tools in modeling exchange rate trajectories for financial instruments. Analysts make investing decisions using the ratio of the current rate to the average or averages from different observation periods. As the rate is traditionally presented in the candlestick form, the average is also derived from the candlestick representation. In practice, the most commonly used is the so-called moving average, determined based on closing prices from a given number *n* of periods (candles), preceding the current quotations. The oldest and simplest type of average is the so-called simple moving average (SMA), which is defined as an arithmetic mean of the closing prices of the *n* previous candles. Therefore, for the *i*-th candle, we can calculate a simple moving average using the following formula:

$$\mathrm{SMA}_i(n) = \frac{\sum_{j=0}^{n} P_{i-j}}{n} \qquad (1)$$

where P_i is the closing price of the *i*-th candlestick. Simple moving average is rarely applied, since it does not take into account the order of changes and, in consequence, the newest change has the same influence on the average as the oldest one. Starting from the assumption that the newest changes have the highest prognostic value, a weighted moving average was defined, in which each change is assigned a weight: the newest change has the biggest weight and the oldest one has the smallest. The most popular weighted moving average (WMA) uses weights decreasing in an arithmetic progress.

Hence, for the *i*-th candle, the weighted moving average can be determined by:

$$\mathrm{WMA_i}(n) = \frac{\sum_{j=0}^{n}(n-j)P_{i-j}}{\sum_{j=0}^{n}(n-j)}, \tag{2}$$

There are many other means of defining the weighted moving average, in which the weights are calculated by different methods, e.g. according to the exponential distribution (EMA), etc. The averages are used e.g. in analyzing and prediction of exchange rate trajectory changes in many techniques of today's technical analysis.

Defining the moving average in a binary-temporal representation

Let us consider application of averages in exchange rate analysis in a binary-temporal representation. A base for determining the average is information about the direction and size of the change and the time of its occurrence. As contrary to the candlestick representation, in the binary temporal representation the basic parameter is not the time but the change size. Therefore, in case of using the binary-temporal representation it is crucial to define a proper methodology of calculating the averages.

In papers pertaining the binary representation, usually the value '1' is assigned to an increase and '0' to a decrease in the exchange rate (Stasiak 2018). If after an increase we encounter a drop, then it would nullify the previous change. In order to map this property in the modeling of averages in the binary-temporal representation, a modified notation was adopted and the parameter representing the change direction *E* was assigned the value '1' for the increase and the value '-1' for the decrease:

$$E_i = \begin{cases} \text{If } \varepsilon_i = 1 \text{ then } \quad E_i = 1 \\ \text{If } \varepsilon_i = 0 \text{ then } E_i = -1 \end{cases}, \tag{3}$$

In the binary-temporal representation it is rather hard to indicate the value of a simple moving average (SMA). Defining the average only for the size of changes for *n* periods ($\frac{\sum_{j=0}^{n} E_{i-j}}{n}$) does not carry the information about the time of given change occurring. Assuming that the time is an important parameter of a prognostic value, defining the average without including the time parameter can lead to a not sufficient effectiveness of the prognostic models.

Let us now consider the concept of a weighted moving average, in which the closing price from each period is multiplied by a corresponding weight and then divided by the sum of all weights. We can assume the change value (*E*) to be the measure of the closing price, and the number of researched periods can be measured by the number *n* of analyzed changes in the binary-temporal representation.

Analogous to the case of WMA, time can be the base to determinate weights. In the standard method of appointing WMA parameter (formula (2)), the period of time (so time base of each candle) is constant, and so the weights are assigned according to the order of changes. In case of binary-temporal representation, it is important to include both the change order and the time of their occurrence. By considering *n* previous binary changes for *i*-th change we can determine the time in which the changes are currently analyzed T_i^n:

$$T_i^n = \sum_{j=0}^{n} t_{i-j} \tag{4}$$

We assume that the closest changes have the highest influence on the average, which means that the weights are inversely proportional to the distance, i.e. the shorter the time elapsed since the recorded change, the greater the weight assigned to the change. If for each *i*-th change the time will be registered in the moment where the change ended, then the last change can be assigned the highest value, that is '1'. The second to last change ended in the moment of the last change occurrence, i.e. exactly t_i seconds earlier. Therefore, for a given *j*-th change, when appointing an average for the *i*-th change, the weight can be determined by the following formula:

$$w_i^j = \begin{cases} w_i^j = 1 \; if \; j = 0 \\ w_i^j = 1 - \frac{\sum_{k=0}^{j-1} t_{i-k}}{T_i^n} \; if \; j \neq 0 \end{cases} \quad (5)$$

The weight calculated from (5) describes the ratio of the time that passed from the end of change to the present, to the duration of analyzed changes.

By applying the abovementioned method of weights calculation, we can propose a way to determine the average for the current change given in a binary-temporal representation:

$$BWMA_i(n) = \frac{\sum_{j=0}^{n} w_i^j E_{i-j}}{\sum_{j=0}^{n} w_i^j} \quad (6)$$

One can notice that in the formula (6) the average depends only on the assumed parameter *n*, i.e. the number of analyzed binary changes.

Let us now consider the construction of a binary-temporal representation extended by information about the average. The main idea of this representation is to add information about current average for each ensuing change. The construction of this method consists in assigning the direction of the change ε_i and two additional parameters to each i-th change in the binary representation: the duration of change t_i and the average value assigned to this change ($BWMA_i$ (n)), which is given by the formula (6)

Tab. 1: Binary-temporal representation extended by information about the average

i	…	512	513	514	515
ε_i	…	1	0	1	1
t_i	…	30	20	10	40
$BWMA_i(4)$	…	0.43	0.40	0.52	0.58

The form of the proposed representation is presented in the Table 1. It is dependent on the assumed discretization unit δ and on the number of analyzed changes *n*, based on which the $BWMA_i(n)$ average was determined – in the example presented in Table 1 the n equals 4. The extended (by the average) binary-temporal representation can stand as a basis to construct prognostic state models (Stasiak 2018), where the information about the average will be used to determine the probability distribution of the direction of future changes of the course.

Summary

In the paper we proposed a new concept of modeling exchange rate trajectory in the binary-temporal representation, with use of one of the most basic techniques of technical analysis, i.e. the moving average. We introduced a method that allows to determine the present value of the moving average for each change in the binary-temporal representation. Moreover, we suggested an extension to the binary-temporal representation, which includes information about the average. The representation can be used to realize adequate state models, that are crucial in constructing prediction systems for the future changes in course trajectory.

Paweł GŁODEK

University of Lodz, Lodz, Poland
pawel.glodek@uni.lodz.pl

Abstract

The paper presents a model that provides the framework for the analysis of the legal, organizational, and social context of science and technology commercialization at public universities. The model covers three levels of analysis: (1) systemic level, encompassing existing legal system as well as systems and environment for commercialization (2) organizational level, including universities, their authorities and institutions as well as departments directly responsible for the commercialization of science and technologies, and (3) social level, i.e. academic community, to include scientific workers, administration, students. All those create a square-shaped framework in which relationships between subsequent factors are analyzed, as a result of which the generic weaknesses of commercialization systems at public universities may be easily identified. Thus it is argued that the proposed analytical framework can be successfully used for the needs of identification of challenges and barriers for science and technology commercialization either at a single university, or concerning a group of universities in a specific socio-economic environment (e.g. region, or country). It can be also useful when comparisons between systems determining effective commercialization at subsequent universities or groups of universities with specific features, are in question.

Keywords: Commercialization, Universities, Barriers, Challenges, Model, Science Commercialization, Technology Commercialization, Knowledge Commercialization, Public Universities.

Introduction

Accumulation and the use of knowledge are becoming increasingly important in the development of the modern economy. According to the concept of the knowledge-based economy, knowledge is a key production factor that determines sustainable economic growth (Jasiński et al., 2019). For this reason, many scientific efforts as well as political aspirations are directed at the development of knowledge and an increase in the level of its commercial use. Universities play a vital role in this development process. First of all, they are an essential source of new knowledge (Raivio, 2008). Secondly, their involvement in the commercialization of science-based knowledge contributes to its transformation into marketable innovative products (Etzkowitz, 2003; Łobacz, 2018).

The commercialization of science and technologies is challenging for universities (Bianchi et al. 2013). They face numerous factors that influence their ability to operate effectively in this area (Migliorini et al. 2010). The literature focus on several of them (Etzkowitz, 2016). They are related to university structures, resources, and procedures, but also external regulations and cultural context. However, there is a need for an approach to provide a complex understanding of the phenomena and its' interacting components.

Thus, this paper aims to develop, present, and discuss the model that provides the framework for the analysis of the legal, organizational, and social context of science and technology commercialization at public universities. The model has been conceptualized based on literature review and expertise works and tested in practice.

Science and Technology Commercialization at Universities: Identifying The Issues of Concern

Commercialization of technology is related to all activities related to the transformation of knowledge (including scientific knowledge) into new products, technologies, and organizational solutions that have practical application and generate commercial value (Jolly 1997). This process relates to the technological innovation process, which by definition, refers to introducing a new idea, be it a technological solution, product, service, policy, or an organizational form, to the market (Mattila, Lehtimaki, 2016).

Universities are involved in the process of new knowledge creation as well as its commercialization. However high complexity of the knowledge commercialization process in the conditions of universities is emphasized (Zechner et al., 2011) and their competency in the commercialization of technology is of great concern. Thus the question, that may be raised here is, how the existing university commercialization systems may be analyzed and compared.

Literature focuses, among others on human resources (Migliorini et al., 2010; Criaco et al., 2014; Alibekova, 2019), university technology commercialization support structures (Bianchi et al., 2013; Fernandez-Alles et al., 2015; Kolymprisis, Klein, 2017), financial issues (Halt et al., 2017), university technology commercialization models (Etzkowitz, 2016; Głodek, Stawasz, 2017) or specificity of university knowledge (Karnani, 2013; Głodek, 2018). Organizational structures and procedures are directly affected by two forces defining how, in reality, the processes are applied, how decisions are made and executed, and, as result, how strong is science and commercialization system at public university.

The existing legal and social context should be mentioned. While the legal system defines the top-down framework of restrictions, obligations, and rights in regards to the organization of commercialization systems at universities, the academic community behaviors push organizational behaviors from the bottom-up perspective. In addition, the environment, in which the university operates, i.e. its location and relationships with the external environment strongly defines the opportunities for science and technology commercialization, and thus the results achieved.

Therefore, when the challenges and barriers of science and technology commercialization at universities are regarded, three problem levels should be taken into consideration: (1) the organizational level, which relates to internal university procedures and formal organization, (2) the systemic level – including in particular external environment, i.e. legal regulations and external stakeholders relationships, and (3) the social level, referring to typical behaviors, emotions, and peer-to-peer relations. All of these will be discussed below.

The Organizational Level

First of all, processes of knowledge commercialization require an efficient and flexible *decision-making system*. Thus, decentralization and bureaucratic nature of decisions related to technology commercialization and transfer (Shen, 2017); decentralization of decisions related to the financing of individual activities; lack of flexibility in researchers' employment and transfers, are perceived as barriers in science and technology commercialization systems (Tidd et al., 2005). The centralization of key decisions in the process of commercialization is justified by their importance and disposition of university assets (IP). But, the decentralization of financial decisions relating to the various stages of the commercialization process limits the speed of the decision-making process. A factor that indirectly hinders the process of commercialization is also the problem of the limited mobility of researchers (Whittle et al. 2018). This limits the process of acquiring new experience and knowledge exchange, which significantly affects the ability to generate new ideas with commercial potential.

The *attitudes of university authorities towards the commercialization* of knowledge and their active involvement in related actions are key factors affecting their effectiveness (Clark, 2008). There are many obstacles related to it, such as insufficient experience related to the science and technology commercialization; a lack of awareness of the need for undertaking activities related to commercialization; a lack of willingness to employ more risky management strategies; a lack of awareness of the complexity of the process or underestimation of existing problems. As a result, the science and technology commercialization-related activities may be marginalized or delegated to university bodies that do not have sufficient resources to perform it effectively, including financial resources, people, or knowledge.

The scope of employees' responsibilities and the motivation system. Due to the extremely great significance of the human factor at universities, resulting from the high independence of activities undertaken by researchers and a self-regulatory knowledge management system, *the scope of employees' responsibilities and the motivation system* affects

to a large extent their involvement in knowledge commercialization. The existing motivation system, reflected in internal evaluations, intensifies employees' activities which are most desirable for university authorities. A factor hampering the knowledge commercialization in this regard is a significant slowdown in the scientific career resulting from more intensive business work. If the system does not support the existence of cases of such a slowdown, it happens often that scientists cease to be academic entrepreneurs (Belkhodja, Landry, 2007).

Other factors limiting the efficiency of knowledge commercialization at universities are related to the *human resources policy*. Here two barriers are usually identified. The first one is the system of recruitment and dismissal which prefers scientific and teaching expertise and rejects entrepreneurial mindsets and business competences. The second one is an employment strategy recultant to employ in full-time research positions (favoring instead of employment in teaching positions).

Also, barriers resulting from the s*ettlement system between the university and its employees* are observed (Sá et al., 2011). Those include the demotivating role of the university surcharge system; and problems with defining clear rules for sharing profits derived from commercialization. University surcharge systems that constitute a significant burden for projects implemented for the business environment, should stimulate activities related to the commercialization of knowledge (Edler et al., 2011). A similar problem results from a lack of clear rules for sharing profits from commercialization.

Another problem is bureaucracy at universities and *administrative support and procedures*. Complex and time-consuming procedures towards IP protection, signing contracts with business organizations, etc. are additional barriers that inhibit significantly science and technology commercialization activities.

In addition, to facilitate science and technology processes, universities are entitled and very often encouraged to initiate and develop specialized bodies or departments directly responsible for the commercialization of knowledge. Those include Technology Transfer Centers (TTOs), Business Incubators (BI), and/or Science and Technology Parks (STP), created as internal structures or separate organizations (Bianchi et. al, 2013; Fernandez-Alles et. al, 2015). It is however argued that, regardless of formal conditions, these bodies need to be given good conditions to act effectively (Kolymprisis, Klein, 2017).

The first one is *the human resources capacities.* It was widely demonstrated that the possibility of active involvement of university technology transfer centers in the process of knowledge commercialization is essentially limited by the insufficient personnel potential. The problem is related to two factors in particular: relatively low employment (Matusiak and Guliński, 2010); and competence deficiencies of the employed staff. Both factors are to a large extent a consequence of financial constraints (including a lack of long-term *financial stability*). The lack of stable and adequate financial resources makes it necessary to concentrate the activities more on obtaining financing for their operations, than on operations themselves. The lack of financial stability additionally limits the possibilities of employing external specialists, both permanently and as experts and advisers, e.g.: in the field of assessing the commercial value of projects, creating business plans, etc. (Łobacz and Głodek, 2011). Additionally, this implies a lack of possibility of employing surrogate entrepreneurs (Migliorini et al., 2010; Lundquist, 2014).

The specificity of the functioning of higher education institutions in the context of their potential to commercialize knowledge may imply a large dispersion of information about the scope of activities and knowledge that can be commercialized, while *access to information* support science and technology commercialization (Galán-Muros, Plewa, 2016). In this area, key problems are a degree of openness of the scientific community to cooperation and knowledge sharing; a system of information acquisition; and a system of obtaining and sharing information.

The Systemic Level

A systemic level includes many barriers and challenges to science and technology commercialization at public universities that are highly dependent on the environment in which they operate, i.e. the existing legal system and directions of external environment development. Several conditions for effective operations can be defined in this regard. It can be anticipated that the existence of these factors differentiates the economic impact of universities located in different regions.

Firstly, with regards to *legal regulations governing the activities of public entities*, two issues seem to affect significantly the science and knowledge commercialization process at public universities (Hsu, Wu, 2012). The first one is the responsibility of authorities for commercial use of public funds. The second one is related to existing procedures of operation regulating business relationships of public entities with for-profit operating organizations.

The legal regulations here imply several issues associated especially with the valuation of intellectual assets, being a subject to commercialization (Siegel et al., 2004; Matusiak, Guliński, 2010).

Another group of barriers may be defined concerning *legal regulations governing the activities of universities.* Apart from overall legal regulations, which generally impose certain restrictions on public entities, universities are subject to additional regulations, which may also constitute a significant barrier to activities related to the commercialization of knowledge. These include in particular legal regulations regarding the creation of academic spin-off companies (Głodek, 2018) and legal regulations regarding the ability to manage the budget related to science and technology commercialization. The existing regulations may hinder long-term planning in terms of commercialization-related activities, for example, if subsidies that may be granted are purposeful and support only short-term projects with easily estimated indicators of success.

Systems and environment for commercialization play also a crucial role. Since the processes taking place at universities are influenced by the external environment, the high quality of the environment in which a given university operates may facilitate processes of commercialization, and vice versa – the limitations resulting from environmental deficiencies increase the challenges and problems that a given university faces in terms of commercialization. Here, the factors that can limit commercialization processes include the willingness of the environment to cooperate with universities, the proximity and availability of markets absorbing new solutions, the availability and quality of human and institutional resources related to knowledge commercialization and technology transfer, and the availability of funds that can be used to commercialize knowledge, and availability of behavioral patterns (the so-called success stories).

A Social Level

The social environment impacts the way people act and behave. Here, in regards to science and technology commercialization at public universities several issues are of great importance.

The first one is *the existing values hierarchy,* which includes values cultivated by the academic community (Gilsing et al. 2011). Barriers resulting from the mentality of scientific employees include in particular a lack of general acceptance of activities related to commercialization of knowledge and profits resulting from it; the perception of the superiority of basic research over applied research; the perception of the university as a unit generating knowledge and not transforming it into marketable products. Muscio and Vallanti (2014) underline a different perception of the research stage, expectations, and working methods by scientists and entrepreneurs.

The *existing patterns of behavior* have a similar significance to the cultivated value systems. For example, the existence of good practices in the field of knowledge commercialization and cooperation with business enables easy replication of existing patterns of behavior. The positive or negative behavior towards scientists who have been successful in business defines another pattern. As people tend to replicate the behavior of others, the more people with business experience work for the university, the more positive patterns towards their behaviors exist.

The above has a direct impact on *access to knowledge of what, how, and where to commercialize,* which is another important issue. Many scientists hold their business-directed actions as they lack knowledge on how to act and where to look for support. The main factors implying this lack of knowledge include lack of contacts with the business environment; a lack of skills enabling communication with enterprises; a lack of skills to translate knowledge into practical applications; a lack of skills in the valuation of commercial knowledge (Matusiak, Guliński, 2010).

A negative *perception of bodies responsible for knowledge commercialization* may create more barriers and concerns mostly the issue of trust. It concerns the belief is the goodwill of the institutions supporting the business activities of university researchers and their competences. If the trust exists, scientists are more open to sharing their ideas and thus the commercial potential of their technologies may be more adequately evaluated and further steps planned more professionally.

Methodology

Based on literature review as well as practical experiences of authors on science and technologies commercialization at different universities, there has been conceptualized a complex model providing a very insightful framework for the analysis of different aspects of organizational and legal factors which determine propensity for actions related to knowledge commercialization at the university and efficiency of those actions. Those aspects have been organized in groups and meta-groups according to the description of their features. Furthermore, all aspects have been shaped in a

way that enables analysis of relationships between subsequent aspects, thus helping in determining aspects and factors with higher influence and consequences of this influence.

The model distinguishes three levels of analysis: (1) systemic level, encompassing existing legal system and system environment (2) organizational level, including universities, their authorities and institutions as well as departments directly responsible for the commercialization of science and technologies, and (3) social level, i.e. academic community, to include scientific workers, administration, students. All those create a square-shaped framework with mutually related factors distinguished, which makes it clear and easy for results understanding. The framework enables analysis of relationships between subsequent factors, thus helping in determining aspects with the highest impact and consequences of this impact.

A Relation-Based Analytical Framework

The literature studies on science and technology commercialization reveal that the related systems at public universities are generally complex formations dependent on internal and external factors that are historically rooted or form a kind of overlay with new regulations more or less accurately concordant with existing procedures or formal and informal habits. This means that these commercialization systems are usually combinations of legal regulations, organizational procedures, and social behaviors, which in practice may not be consistent, thus providing inefficiencies in real actions, which – in the result – impede outcomes and impact. All that means that, if the barriers of science and technology commercialization at universities are to be removed, all of the factors which can be identified in all of the above-mentioned categories should be analyzed simultaneously and relations between them should be determined to understand the underlying causes of ineffectiveness.

The development of external systems, able to support or hinder actions related to the commercialization of science and technology defines the frames in which actions are pursued or stifled. This includes existing legal systems governing activities of public entities in general, as publically funded organizations, as well as the economic environment, in which those actions are taken, concerning the existing business environment and character of its links with universities.

As universities are knowledgeable organizations, where human capital is of key importance and people designate the quality and directions of undertaken activities, it must be recognized that values and behaviors of internal university stakeholders, directly involved in the process, as well as their knowledge and trust-related issues, shape the floor for science and technology commercialization. It has been acknowledged that the academic community (academic staff, university administration, students) represents diversified attitudes and behaviors towards science and technology commercialization and those have a significant impact on the propensity to knowledge commercialization as well as on real actions pursued towards active participation in actions required at various stages.

Thus it is argued that, if the challenges and real barriers existing at a given university are to be indicated, all of the factors mentioned above should be investigated and the relationships between individual factors clearly determined.

The three distinctive problem levels related to processes of science and technology commercialization at public universities with its problem areas and specific problem factors distinguished within each of the areas, define a framework, which can be used to analyze challenges and barriers to commercialization at universities in a particular environment. This framework has been summarised in Table 1. The framework summarises the literature studies, in which the main factors affecting the effective commercialization systems at universities has been determined.

Table 1: Problem factors and areas

Problem levels	Problem areas	Problem factors
A systemic level	The existing legal system and the systemic environment	Legal regulations governing activities of public entities
		Legal regulations governing activities of universities
		Systems and environment for commercialization
An organizational level	Universities, university authorities, and bodies	Decision-making systems
		Attitudes of university' authorities towards commercialization
		The scope of employees' responsibilities and the motivation system

		Human resources policy
		Settlement system between the university and its employees
		Administrative support and procedures
	Bodies responsible for activities related directly to the commercialization of knowledge (TTOs, BI, STP, etc.)	Human resources capacities
		Financial stability
		Access to information
A social level	Academic community (academic staff, administration, students)	Existing value hierarchy and behavioral patterns
		Access to knowledge of what, how, and where to commercialize
		Perception of structures responsible for commercialization

Source: own study

The approach presented here allows organizing the way of thinking about factors that may be important barriers to science and technology commercialization processes at public universities. The existence of links between the individual diagnosed problems means that there is a need to look for cause-and-effect relationships. Therefore all factors distinguished in the analytical model have been organized in a square-shaped framework, as presented in Figure 1.

An organizational level has been placed in the horizontal axis and all factors were divided into two groups: the first one covering all general issues related to university organization, and the second one concerning all factors that include development and operations of bodies responsible for activities related directly to the commercialization of knowledge (TTOs, BI, STP, etc.). On the vertical axis, on the other hand, the external economic and internal social factors have been compiled.

This kind of organization, very simple in its nature, provides a space in which all relationships between subsequent factors can be easily identified, and thus aspects with the highest impact and, furthermore, consequences of this impact can be easily determined. It is therefore a kind of a map of issues that is designed to facilitate a comprehensive analysis of the matter considered. It also gives an insight into small barriers existing at any level, which may however have a meaningful impact on other issues, thus slowing down the overall development of the culture of commercialization, and have serious consequences for the effectiveness of the whole system.

		A SYSTEMIC LEVEL				
		Legal regulations governing activities of public entities	Legal regulations governing activities of universities	Systems and environment for commercialization		
AN ORGANISATIONAL LEVEL 1	Decision-making systems				Human resources capacities	AN ORGANISATIONAL LEVEL 2
	Attitudes of university' authorities towards commercialization					
	The scope of employees' responsibilities and the motivation system		AREA FOR INTERACTION ANALYSIS		Financial stability	
	Human resources policy					
	Settlement system between the university and its employees				Access to information	
	Administrative support and procedures					
		Existing value hierarchy and behavioral patterns	Access to knowledge of what, how, and where to commercialize	Perception of structures responsible for commercialization		
		A SOCIAL LEVEL				

Figure 1: Links between the problem areas

Source: own study

The relationships between the problem areas are factors that can be easily determined by using direction pointing arrows, which determines the relationship. This kind of visualization is very clear in presenting the real sources of barriers that exist and challenges to face, naturally if it is preceded by in-depth narrative analysis. The example of this kind of analysis has been presented in Figure 2.

Figure 2: Links between the problem areas – example of analysis

Source: own study

The analysis presented in Figure 2, reveals that the main barriers associated with the science and technology commercialization at the university lie in the systemic and social level. The organizational behaviors defined are their consequence, and additionally, affect other organizational areas. The analysis of cause and effect relations also indicates that organizational determinants depend to a large extent on the mentality and behavior patterns found in a given entity. External factors are important as well, especially the ones connected with legal determinants (independent of the university) and systemic issues (the level of development of innovative systems capable of adopting new solutions and supporting their commercialization, e.g.: by providing capital).

Conclusions and Implications

Analyzing indicated factors and the whole model, one should nevertheless take into account dynamic changes occurring in commercialization systems at universities in recent years, resulting in different intensities of the above-mentioned problems at individual universities. However, it should be noted that even if some of these factors do not occur, or occur only to a small extent, at a given university, they may slow down the overall development of the culture of commercialization.

The proposed analytical framework can be successfully used for the needs of identification of challenges and barriers for science and technology commercialization either at a single university, or concerning a group of universities in a specific socio-economic environment (e.g. region, or country). The use of the model allows for a comprehensive analysis, taking into account different levels of factors, as well as the mutual relations between them. Thanks to this, it is possible to observe changes not only in individual factors but also their impact on the functioning of the entire model.

The developed model can be useful when comparisons between systems determining effective commercialization at subsequent universities or groups of universities with specific features, are in question. This might be especially useful when the comparison should be made between universities operating in different legal, organizational, and cultural contexts.

The Importance of Biophilic Cities for Local Communities

Marta SZAJA

University of Szczecin, Institute of Spatial Management and Socio-Economic Geography, Szczecin, Poland
E-mail: marta.szaja@usz.edu.pl

Abstract

The aim of this article is an attempt to show the relations between integrating green and natural elements into building, neighborhood and city design, and providing the basis for healthier lives and lifestyles, e.g. reduction in stress and increased levels of physical and mental health. This paper presents a research study which adopts a qualitative, inductive case study approach. The author used the following two methods to distil and connect research results focused on bringing nature into urban areas and its favorable consequences for local communities: literature review and case studies.
The literature review provides an insight into the existing experience in integrating nature into urban areas to provide health and well-being benefits for citizens. The article also considers four case studies of cities around the world. In each city the biophilic elements of the urban structure were used in various ways in order to improve the living conditions of the local community. This allowed to explore the processes through which urban nature was used as a strategic, mainstream measure to build livability in urban design and development. Analysis of presented examples shows that the biophilic cities go beyond mere provision of parks and preserving the nearby nature, but seek to actively entice and induce urbanites to enjoy nature and be part of it. Those kinds of solutions can help to provide in many ways the basis for healthier lives and lifestyles of local communities and should be considered more often in urban design.

Keywords city, biophilic city, biophilic urbanism, local community

Introduction

The concept of 'biophilia' was first popularized by Edward Osborne Wilson in the early 1980s with his seminal book of the same title. The author was using the term to mean 'the innately emotional affiliation of human beings to other living organisms'. (Kellart, Wilson 1995)

The biophilia hypothesis provides a theoretical basis with potential to explain and enhance health and wellbeing benefits of the urban nature. These benefits have the potential to substantially improve the livability of dense urban areas, and to provide economic benefits through reduced physical and mental healthcare costs. (Reeve, Desha, Hargreaves, Hargroves 2015: 215–233). Biophilia is now being applied to urban design, and leaders in this area such as T. Beatley, P. Newman and H. Boyer have created the field of 'biophilic urbanism', or 'nature loving cities'. (Newman, Beatley, Boyer 2009)

Now there is a growing body of evidence of the positive physical and mental health benefits associated with greenery and green elements in living and work environments. Research at the building scale shows strong positive relationships between the presence of natural daylight, fresh air and greenery, and increases in worker happiness and productivity. (Leather, Pyrgas, Beale, Lawrence 1998: 739–762). Similar studies show the positive power of schools that incorporate natural daylight and other green elements, to raise test scores of the students. (Herschong, Roger, Stacia 2002: 101–114)

Considerable evidence and research, dating to the 1980s, have suggested the healing and recuperative power of nature in hospitals and health care facilities (including Ulrich's classic study showing recovery from gall bladder surgery is significantly enhanced by views of nature). (Ulrich 1984: 421). Evidence of the power of the green qualities and features is also emerging at neighborhood community scales. Green neighborhoods and more natural living environments have been associated with reduction in stress and increased levels of physical and mental health. (DeVries, Verheij, Groenewegen, Spreeuwenberg 2003: 1717–1731; Nielsen, Hansen 2007: 839–850;

The aim of this article is an attempt to show the relations between integrating green and natural elements into building, neighborhood and city design, and providing the basis for healthier lives and lifestyles, e.g. reduction in stress and increased levels of physical and mental health.

What are biophilic urbanism and biophilic cities?

Biophilic urbanism is an important emerging design principle for buildings, featuring a suite of natural design features that address multiple pressures related to climate changes, increasing urban populations, finite resources, and our inherent need for contact with nature. The principle directs the creation of urban environments that are conducive to life, delivering a range of benefits to stakeholders including building owners, occupiers and the surrounding community (Definition developed by Peter Newman, Charlie Hargroves, Cheryl Desha, Angela Reeve, Omniya Bagdadi, Mariela Zingoni and Jana Soderlund, November 2012).

For the purposes of this article, biophilic urbanism was categorized into three scales: the building, neighborhood, and city scales (see Table 1).

Table 1: The main elements of biophilic urbanism

ELEMENT		FORMS	SPECIFIC BENEFITS	COMMON BENEFITS
BUILDING	Indoor Plants	Pot plants, on desks, around office, or in banks of pots. Indoor living walls, including pots within a mess frame (also see Green Walls). Indoor planted vegetation, such as atriums and large planted installations.	Reduces illness Increases productivity Improves air quality	Responds effectively to the growing need for densification of cities Revitalizes urban environments Alleviates urban heat island effect Improves air quality Improves microclimate Sequesters carbon/ reduces greenhouse gas emissions Increases biodiversity
	Green Roofs	'Intensive': Soil deeper than 200 mm and vegetation up to the size of trees 'Extensive': Soil up to 200 mm with ground cover vegetation	Improves building energy efficiency Water management Space efficiency Food production Sound insulation Increases roof/wall lifespan Vertical urban farming	
	Green Walls	*Panel System*: Pre-planted structural panels that are secured to wall and have an in-built watering system *Felt System*: Pre-fabricated structural panel with felt planting pockets that is planted onsite and kept moist *Container/Trellis System*: Pre-fabricated structural panel with planting pots		
NEIGHBORHOOD	Green Verges	Street trees and canopies chosen depending on physical properties Shade planting for buildings placed to remove heat load Green streets and alleys that create cool pervious greenways Rain gardens and bio-swales	Reduces traffic / encourages walking, and cycling Reduces building cooling/heating energy use Windbreak	

		integrated into stormwater management plan and consisting of pervious channels Green permeable sidewalks	Water management Food production	Improves water cycle management
	Green Islands	Urban parks and gardens placed close to transportation routes Community farms close to homes Residential backyards with space for food production Lawns and gardens reducing UHI effects Waterways and streams uncovered and rehabilitated	Reduces traffic/encourages walking and cycling Food production Reduces reflection Community sense Education	Provides amenity Enhances well-being/reduces stress Recreation
CITY	Green Corridors	Green corridors (biodiversity corridors) reaching outside the urban area Highway crossings and migratory routes Backyard commons that can be part of the green corridor Buffer protection from storms surges along coastal areas	Links biophilic elements Reduces traffic/encourages walking and cycling Connectivity Increases tourism Cognitive way finding	Reconnects with nature Revitalizes cities Increases property value
	Urban Farming	Community gardens City farms Urban and peri-urban agriculture	Food production Creates employment Education	
	Water Ways	Wetlands Constructed wetlands Ponds and lakes Day-lighted streams Vegetated swales and drainage corridors Infiltration basins Mangroves	Water management Water treatment Water storage Filtration / enhance water quality Protects downstream water bodies	Enhances tourism

Source: Beatley, T. (2010) Biophilic Cities: Integrating Nature into Urban Design and Planning; Island Press: Washington, D.C., USA; SBEnrc (2012), 'Can biophilic urbanism deliver strong economic and social benefits in cities? An economic and policy investigation into the increased use of natural elements in urban design,' Sustainable Built Environment National Research, Centre (SBEnrc), Curtin University and Queensland University of Technology, 8. doi:10.13140/RG.2.1.2137.2886; Girling, C. and Ronald, K. (2005) Skinny Streets and Green Neighborhoods: Design for Environment and Community; Island Press: Washington, D.C., USA.

The potential for application of building scale features is high. The proximity of these features to the infrastructure and people combined with the potential for widespread use is such that these features are likely to provide substantial overall benefits to environmental systems and individuals. The potential use of neighborhood scale features is high, given the proportion of urban spaces dedicated to streets and roads. These features need to allow for (and potentially enhance) other activities that occur in these spaces, such as car, bicycle and pedestrian traffic, access by emergency and service vehicles, parking, underground and overhead services, and in the case of pocket parks, potential property development. City scale features are large in size and difficult to retrofit into already developed urban areas other than in major land-use change situations. These features generally have lower technical and engineering design requirements, as these may be less connected to urban infrastructure and other land uses. They may provide opportunities for recreation, nature-based experiences and biodiversity conservation not possible

at the building or city-scale due to the size of individual features and separation from the built environment (Reeve, Desha, Hargreaves, Hargroves 2015: 215-233).

Biophilic cities are biodiverse cities, cities full of nature, places where in the normal course of work and play and life residents feel, see, and experience rich nature – plants, trees, animals. The nature is both large and small – from treetop lichens, invertebrates, and even microorganisms to larger natural features and ecosystems that define a city and give it its character and feel. Biophilic cities cherish what already exists, but also work hard to restore and repair what has been lost or degraded and to integrate new forms of nature into the design of every new structure or built project. Human beings need contact with nature, and the nature can take the form of shapes and images integrated into building designs (Beatley, 2010: 45; Bratman, Daily, Levy, Gross 2015: 41–50).

Cities and urban environments contain a variety of ecological and green assets, from parks to trees to rivers and riparian habitats, and increasingly, efforts are being made to further enhance the green elements and features of these living and work environments. Daylighting urban streams (taking them out of underground pipes and returning them to the surface), installing trails, planting new trees and forests, community gardens, installing green walls and vertical gardens, are among the many ways in which cities and urban environments can become greener (Beatley, Newman 2013: 3328-3345).

A biophilic city is not only a greener city but also a city in which residents are actively involved in experiencing nature – e.g., hiking, bird watching, sky-gazing, gardening, among many other activities. Furthermore, citizens in biophilic cities have abundant opportunities to be engaged in restoring and caring for the nature around them. Table 2 presents a more comprehensive listing of the key qualities, not just those of physical design, by which a biophilic city might be described or defined (Beatley 2010; Weinstein, Balmford, DeHaan, Gladwell, Bradbury, Amano 2015: 1141–1153; Carrus, Scopelliti, Lafortezza, Colangelo, Ferrini, Salbitano, Agrimi, Portoghesi, Semenzato, Sansei 2015: 221–228).

Table 2: Important dimensions of biophilic cities (with possible indicators thereof)

Biophilic Conditions and Infrastructure
– Percentage of population within a few hundred feet or meters of a park or greenspace; – Percentage of city land area covered by trees or other vegetation; – Number of green design features (e.g. green rooftops, green walls, rain gardens); – Extent of natural images, shapes, forms employed in architecture and seen in the city; – Extent of flora and fauna (e.g. number of species) found within the city;
Biophilic Behaviors, Patterns, Practices, Lifestyles
– Average portion of the day spent outside; – Visitation rates for city parks; – Percentage of trips made by walking; – Extent of membership and participation in local nature clubs and organizations;
Biophilic Attitudes and Knowledge
– Percentage of residents who express care and concern for nature; – Percentage of residents who can identify common species of flora and fauna;
Biophilic Institutions and Governance
– Priority given to nature conservation by local government; percent of municipal budget dedicated to biophilic programs; – Existence of design and planning regulations that promote biophilic conditions (e.g. mandatory green rooftop requirement, bird-friendly building design guidelines); – Presence and importance of institutions, from aquaria to natural history museums, that promote education and awareness of nature; – Number/extent of educational programs in local schools aimed at teaching about nature; – Number of nature organizations and clubs of various sorts in the city, from advocacy to social groups.

Source: Beatley, T. (2010) Biophilic Cities: Integrating Nature into Urban Design and Planning, Island Press: Washington, D.C., USA, 47–49.

It is important to recognize that biophilic cities are not simply green cities. The presence of abundant nature is a necessary, but not sufficient condition. In biophilic cities, residents are directly and actively engaged in learning about, enjoying and caring for the nature around them and have developed important emotional connections with this nature (Beatley, Newman 2013: 3328–3345; Silva, Rogers, Buckley 2018: 9545–9555).

Social Benefits of Urban Projects on Biophilic Urbanism – The Selected Case Studies

Biophilic cities deliver a host of positive benefits at an individual and family level that will help to enhance ability to successfully cope with and adapt to future stressors and shocks. Nature in cities delivers considerable and often underappreciated health benefits, furthering bolstering city's capacity and ability to adapt to stresses and shocks in the future. Residents of greener neighborhoods have been found to walk more and spend more time outside, in turn with considerable positive health effects (Schantz, Stigell 2008; Biedenweg , Scott, Scott 2017: 112–124; Frumkin, Bratman, Breslow, Cochran, Kahn, Lawler, Levin, Tandon, Varanasi, Wolf 2017: 075001; Markevych, Schoierer, Hartig, Chudnovsky, Hystad, Dzhambov, de Vries, Triguero-Mas, Brauer, Niewenhuijsen 2017: 301–317; Taylor, Hochuli 2015: 747–762).

The strong ecological tradition in Germany, with mainstream appreciation of the benefits of integrating nature into cities and towns, has been a key driver for Berlin's urban greening. It continues to ensure that the city preserves and even enhances its urban nature in the face of financial pressures and demand for urban development. Hence there is a good understanding of the social benefits of green space and features in the city. According to the Berlin Senate Department for Urban Development and the Environment: "The appearance of the city is defined as much by open space as by individual buildings or architectural ensembles. The size of the open spaces and the extent to which they blend harmoniously with the surrounding buildings make a first and lasting impression. They are responsible for the feeling of well-being and ease which the city provokes, and are crucial for the sense of identity the inhabitants have with their city. Open space brings to life the natural and cultural development of Berlin."(Senate Department for Urban Development and the Environment
The City of Berlin, German).

A study by Ryerson University identified a range of direct and indirect economic benefits from green roofs in Toronto (Banting, Doshi, Missios 2005). Benefits can accrue to the local municipality, such as through reduced stormwater flows, or to building occupants, such as at the Toronto Metro Central YMCA, where the green roof installed in 2009 has been used for conferences, movie nights, yoga classes, school classes, as well as for running, relaxation, and recuperation. According to Vice President, Property Management YMCA of Greater Toronto, there has been significant community engagement in the design, installation, and ongoing maintenance of the roof (City of Toronto 2011).

The City of Portland has investigated and developed metrics for the potential social benefits of urban greening, focusing on health and community livability. In the area of health these metrics consider air quality improvements (relating to particulate matter and respiratory illnesses) along with other impacts on physical and mental health. Community livability metrics consider improvements in amenity and aesthetics (including how these are reflected in increased property values), community cohesion (such as social capital and crime), access to nature (including the number of people affected by urban greening elements), and environmental equity (such as the share of urban greening elements in minority or low-income neighborhoods) (ENTRIX 2010).

The benefits of urban nature on people can be seen in Singapore's hospitals. The Alexandra Hospital was renovated to include a medicinal garden, fragrance garden and water features (Newman 2014: 47-65), and its success led to the biophilic design of the new Khoo Teck Puat (KTP) Hospital, which integrates food producing roof gardens, green walls, green balconies and a public garden, using the concept that 'nature would nurture' (Design Singapore Council 2011). The innovative design of this hospital is driven by the challenge of integrating nature within the constraints of minimal space, as the relatively small block (3.4 hectares) had to house the 110,000 m^2 building (Newman, 2014: 47-65).

Conclusions

Environment is crucially important for the lives and lifestyles of human beings. Local communities need contact with nature, and the nature can take the form of shapes and images integrated into building designs. Biophilic cities are biodiverse cities, places where in the normal course of work and play and life residents feel, see, and experience rich nature (i.e. plants, trees, animals). Their residents are actively involved in experiencing nature. They also have abundant opportunities to be engaged in restoring and caring for the nature around them. Biophilic cities nurture

what already exists, but also try to restore and repair what has been lost or degraded of every new urban structure or built project.

According to P. Newman "Biophilic urbanism is bringing tangible benefits to cities, ranging from improved stormwater management, reduced air-conditioning loads, reduced urban temperatures, improved health and well-being, lower crime rates, and increased productivity. It is providing a way to continue the great urban experiment which has created so much economic value by balancing the concrete and steel urban infrastructure with innovative and well-integrated forms of urban nature that ensure urban environments remain aesthetic, livable and attractive to existing and future residents" (SBEnrc 2012).

As T. Beatley and P. Newman indicate there are many more direct ways, in which green urbanism and biophilic urban design can create more healthful environments. Planting trees and installing green rooftops and walls, permeable paving, are all strategies that provide shade and cooling through evapotranspiration. These help to moderate urban temperatures. Trees help to ameliorate air pollution, and a robust and extensive network of storm water collection features (from permeable paving to rain gardens to urban forests) helps to reduce the problem of combined sewer overflow (CSO), a serious water quality problem that many cities are afflicted with (Beatley, Newman 2013: 3328-3345).

Biophilic urbanism can help to provide the basis for healthier lives and lifestyles in many ways. An extensive network of walking and hiking trails, the close physical proximity of large blocks of greenspaces to urban neighborhoods and an urban land use pattern of nearby parks, all contribute to at the least a possibility of a more physically active, healthier lifestyle. Gardening and food production opportunities in the city provide similar benefits: the opportunity to engage in an emotionally rewarding activity, but also one with substantial calorie-burning potential and the possibility of improving diets, as well (Cobb 2011; Bertram, Rehdanz 2015:139–152).

Along with the general increase in interest in ecological issues, there is a growing interest in environmental protection and sustainable development in shaping urban spaces. As a result of the adoption of the sustainable development paradigm by the city authorities and the local community, actions should be taken to contribute to the optimization of the urban design process and to obtain the most beneficial solutions in the name of optimal use of available resources (not only to save them, but also to maximize their usability).

Acknowledgment

The project is financed within the framework of the program of the Minister of Science and Higher Education under the name "Regional Excellence Initiative" in the years 2019 - 2022; project number 001/RID/2018/19; the amount of financing PLN 10,684,000.00

Abstract

The Government of UAE conducted many programs and incentives to support SMEs continuity. However, the current outcome does not meet the desired objectives. Research findings statistics shows that Emirati citizens are less motivated to start SMEs business, and generally, there is the uncertainty of success due to a lack of innovativeness and leadership skills. Furthermore, SMEs faced lots of obstacles consisting of creativity, synergy, technique completion, creating an attractive business, leadership, culture, technique, prioritizing your employees, systems and methods, determining performance. This study is to explore the impact of individual creativity and team creativity on business performance; with consideration of the moderation effect of leadership style among SMEs in UAE. The proposed conceptual framework of this study has individual creativity and team creativity as predictors of business performance. Along with six leadership styles, which are individually examined as moderators to evaluate the leadership style that has the greatest significant change in the relations between creativity factors and business performance. It is to hope that the proposed framework can be tested to evaluate the current scenario of creativity, leadership style and performance of SMEs in UAE.

Keywords: Individual Creativity, Team Creativity, Business Performance, Leadership Styles, SMEs, UAE.

Introduction

Small and medium enterprises (SMEs) are particularly important nowadays and are considered to be the core driver of any economy, whether in developed or developing countries (Ribau, Moreira, & Raposo, 2018). SMEs provide around 45% of overall employment and 33% of GDP in these countries, according to the Organization for Economic Co-operation and Development (OCED) (Hamilton & Beck, 2016). It has been viewed that in current times, there is a huge decrease in unemployment number in many countries around the world, and that has been a result of SMEs progression (Burns, 2016).

In UAE, SMEs role in advancing the economic development of the country is comprehensive, and the National Programme for SMEs has a big responsibility which involves more than 1,700 Emirati businessmen that possess the passion for exploring additional engaging opportunities in various aspects from around the world (Lasrado & Pereira, 2018). In United Arab Emirates (UAE), the government designed many programs that provide financial grants, technical support, and other forms of aid to creative young Emiratis who are willing to start a new business (PROF, Fadillah, & Ismail, 2018). SMEs in the UAE has proved to be the strategic operator of the nation and is predicted to have a vital role in the future. Based on reports from the Ministry of Economy, SMEs market includes more than 94% of the total number of active firms in the country, and it provides job opportunities to more than 86% of the employees in the private sector. Based on Dubai government reports (2017); micro, small, and medium enterprises constitute 95% of total registered firms, contribute to 40% of gross value add, and it helps in employing 42% of total workforce. The ministry is aiming to increase this contribution to reach 60% by 2021 (The UAE government portal, 2020).

Cite this Article as: Duha Hashim Ali ALKHAZRAJI and Wan Fauziah bt Wan YUSOFF "Individual and Team Creativity, Leadership style and Business Performance among SMEs in UAE: Proposed Framework" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The Government of UAE conducted many programs and incentives to support SMEs continuity. However, the current outcome does not meet the desired objectives. This suggests that the plan was not properly analysed, and risk factor was not fully weighed. As a result, fear of failing can possibly increase among native people which lead to more problems concerning entrepreneurship (Chabrak et al., 2017). Research findings statistics shows that Emirati citizens are less motivated to start SMEs business, and generally, there is the uncertainty of success due to a lack of innovativeness and leadership skills. Furthermore, SMEs faced lots of obstacles consisting of creativity, synergy, technique completion, creating an attractive business, leadership, culture, technique, prioritizing your employees, systems and methods, determining performance (Hanifah, Halim, Ahmad, & Vafaei-Zadeh, 2019). Therefore, this study is to explore the impact of individual creativity and team creativity on business performance; with consideration of the moderation effect of leadership style among SMEs in UAE.

Literature Review

SMEs Definition

SMEs are businesses that sustain earnings, properties or employees below a particular limit (Zhou, 2016) Each country possesses its very own interpretation of what is SMEs. In the UK, SME is a medium-sized or small enterprise with fewer than 250 employees. The EU defines an SME as a business with less than 250 employees, a revenue of less than EUR50 million, or an overall balance sheet of less than EUR43 million. There are three different types: medium-sized, small, and micro-businesses. These types are actually defined based on their turnover and number of employees. A medium-sized business possesses less than 250 employees and either a turnover of approximately EUR50 million or an annual balance sheet of up to EUR43 million. A small business has less than 50 employees and a turnover of around EUR10 million or an annual balance sheet of EUR10 million. At the same time, a micro-business has less than ten employees and a turnover of up to EUR2 million or a balance sheet up to EUR2 million. In Canada, SMEs are companies that have fewer than 500 employees, and any company that has 500 or more employees are considered to be a large organisation. In the United States, SMEs refers to companies with fewer than 500 employees (Müller et al., 2018). Small organisations are usually those with less than 50 employees, while micro-enterprises contains 10, or in many cases, five employees (Moeuf et al., 2018).

As the scope of the study is the Dubai SMEs market, then it is important to illustrate Abu Dhabi and Dubai's definition of SMEs. According to a mandate released by Abu Dhabi Executive Council on 30 June 2013, Abu Dhabi defines a micro-business as a business with less than five employees, and small business as a business that has more than five employees but a maximum of 19. in contrast, a medium-sized business is one with a minimum of 20 and a maximum of 49 employees. Having Said That, Dubai SME interpretation is detailed and divided into three types; trading, manufacturing, and services. A small business in the trading field, for instance, is one with nine or fewer employees and a maximum turnover of AED9 Million. In manufacturing, a micro SME is one with 20 or fewer employees, with a turnover of less than AED10 Million. In service, a micro business is one with a maximum of 20 employees and a turnover of lower than AED3 Million. Table 1 shows the SMEs criteria of Dubai.

Table 1: SMEs Definition in Dubai

Turnover, AED m	Trading	Manufacturing	Services
Micro	<=9	<=10	<=10
Small	<=50	<=100	<=100
Medium	<=250	<=250	<=250

Individual and Creativity

Creativity is described as the capacity of an individual or even group to offer new and unique ideas. It is a principal source for innovations, and it can highly influence business performance (Beghetto & Kaufman, 2017). Creativity is considered a significant prerequisite for innovation to a lot of organisations (Alayoubi et al., 2020). Creativity is very important in businesses that need continues improvement such as technology, but it is less significant in traditional business such as food processing (Aureli et al., 2019). Creative people are characterised by their ability to high adaptability, as some risks need this trait (Sica et al., 2019). Most of the creativity definitions conceptualise

it with bright ideas or new thought (Harris & de Bruin, 2018). Creativity suggests the application of innovation in companies, and creativity primarily defines the progression of concepts concerning practices, procedures, items, and/or companies that are (a) unique and (b) possibly valuable to a company (Lee et al., 2019).

Over the last few years, measuring creativity has shown to be an urgent task (Baer & McKool, 2009; Batey et al., 2010). The uncertainty encompassing the measurement of creativity is due to the lack of its own interpretation (Batey, 2012; Piffer, 2012). However, the majority of those scales are an adaption or a development to the root concept of creativity that proposed by Treffinger et al. (1971). These scales are normally categorized into four methods embodying the four main types of creativity definitions: process, trait, press, and product (Barbot et al., 2011; Couger et al., 1993).

- Press - focusses on the evaluation of the job environment or climate where creativity is recognized (Batey, 2012; Hennessey & Amabile, 2010). The measurement of these environmental factors is based upon the idea that there is an indirect relationship between these factors and creativity (Li et al., 2020).
- Trait - scale in this field were designed through investigating the attributes or passions of people that have innovative accomplishments (Pitafi et al., 2020). The created set of unique individuality traits include; featuring attraction to difficulty, higher energy, behavior adaptability, intuitiveness, mental variability, self-esteem, danger taking, perseverance, self-reliance, introversion, social grace, and endurance to vagueness (Barron & Harrington, 1981; Feist, 1998; Runco, 2007).
- Product- product strategy based analysis of creativity has been extensively suggested for evaluating creativity (Amabile, 1982; Baer, 1994c; Baer & McKool, 2009; Kaufman et al., 2012).
- Process - measurement focuses on cognitive processes and structures that contribute to imaginative production (Barbot et al., 2011; Finke et al., 1992).

Researches of individual creativity in different environments suggest that creative people possess a certain set of characteristics (Ribeiro et al., 2020). On top of that, creativity has a role in connecting individual creativity and company creativity (Gu et al., 2020). Employees are the source of bright ideas for solving a problem and making development and organisation convert those ideas into the process to generate services and products (Secundo et al., 2019). Creativity is adequately significant at the team level and should be examined using various techniques (Tu et al., 2019).

Business Performance

Performance is a frequent subject in many divisions of management (Chung-Wen, 2008). There has been a debate among researchers about the meaning of business performance (Aminu, 2015). Previous studies, which focused on business performance, failed to resolve several openings on performance conceptualisation. The reality of business performance as a multidimensional phenomenon may have contributed to the different opinions on business performance (Roslan, 2010). For many years, researchers on business performance have been preoccupied with discussions and debates on terminology, level of analysis and conceptual basis for assessment of performance (Arief, Thoyib, Sudiro, & Rohman, 2013; Arshad & Rasli, 2013). A balanced scorecard is a significant approach to measuring business performance. Taking the Balanced Scorecard strategy, there are four main aspects involved in strategy management: customer, interior processes (functions), knowing and growth (Human Resources), and financial (Mehralian, Nazari, Nooriparto, & Rasekh, 2017). Three categories are related to nonfinancial measures; however, firms normally choose a suitable strategy based on the business, environment, and management approach.

Leadership style

Leaders are necessary for any company and have various roles and contributions. Nowadays, the aim of any sort of institutions is to maintain its success through performance-enhancing. To enhance company performance, leadership has a vital role, therefore, to create the best product or services using accessible resources, leaders are the ones liable to the stakeholders of their companies (MITRA Madanchian & Taherdoost, 2017). Many studies have found that poor leadership of an organisation can lead to many drawbacks and affect business performance. For example, Ntenga and Awuor (2018) explored the impact of different leadership styles on employee turnover in different companies in Nigeria and concluded that poor leadership and management by fear in some organisation caused in increment and turnover intention and affect the overall performance of the organisation. Likewise, Gardanova, Nikitina, and Strielkowski (2019) revealed that managers lack critical leadership skills caused set-up-to-fail syndrome on their employees, which negatively affect employee and organisation performance.

According to Goleman (2000), there are six styles of leadership. Transformational leadership is when innovator habits affect followers and influence them to perform beyond their perceived abilities. Fans of these leaders usually attempt to mimic their leader as they tend to feel connected with them (Vallina & Guerrero, 2018). Within transactional leadership, there are two factors, contingent reward and management-by-exception. The contingent reward provides rewards for effort and recognises good performance (Barth & Benoliel, 2019). Autocratic leadership is a management style in which someone handles all the decisions and considers the opinions of very few people. Autocratic leaders make their decisions based on their very own beliefs and do not consider other people opinions (Patil, 2020). Democratic leadership, also recognised as participative leadership, is the kind of leadership where members of the team are more involved in the process of decision making (Caillier, 2020). Paternalistic leadership is an administrative approach that entails a controlling authority figure who acts as a patriarch, and handles workers, and collaborates as though they are members of a huge, extensive family. In exchange, the leader anticipates support from staff members, as well as compliance (Tang, 2019). The laissez-faire leadership concept is, in fact, at the opposite of the autocratic style. Out all the leadership styles, this style involves the minimum amount of leadership. Laissez-faire leadership is a hands-off style that lets followers set directions. However, this is mostly the leadership style that leads to the lowest productivity (Asghar & Oino, 2017).

Proposed Conceptual Framework

Based on the literature review, the proposed conceptual framework of this study has individual creativity and team creativity as predictors of business performance. In addition, leadership styles, six styles, are individually examined as moderators to evaluate the leadership style that has the greatest significant change in the relations between creativity factors and business performance. Figure 1 shows the proposed variables and their relations.

According to some researchers; such as (Al Mamun & Fazal, 2018; Awan et al., 2019; Castillo-Vergara et al., 2018; Cirella, 2016; Lussier et al., 2017; Rodríguez-Sánchez et al., 2017); In the workplace, the focus is usually on creativity as it always has a positive impact on the overall business performance. Furthermore, Hirst et al., (2011), in his research about individual creativity impact on business performance, concluded that creativity has a significant positive impact on employees performance. Another study of Ferreira et al., (2020) about dynamic capabilities, creativity and innovation capability and their impact on competitive advantage and firm performance discovered that creativity has the largest positive impact on improving the firm performance and competitive advantage. The same results are confirmed in a study by Munizu & Hamid, (2018) to examine the relationship between creativity and business performance at furniture industry in Indonesia, as they revealed that creativity is rapidly elevating business performance. In conclusion, the researcher can deduce that all studies related were expecting a positive direct impact of creativity on business performance in the workplace.

Fig. 1: Proposed Framework

Meanwhile, the leadership style is the leader's strategy of providing a path, applying plans, and encouraging individuals. Several leadership styles were proposed by many researchers as shown by pioneers in the political, business or various other fields. Overall, leadership style as a moderator has been explored in a lot of studies (Chellani, 2019; Daud & Hanafi, 2018; Desai & Srivastava, 2017; Kalsoom et al., 2020; Mahdinezhad et al., 2019;

Putra & Rasmini, 2018; Zheng et al., 2017). Previous studies of leadership styles concluded that there is always a positive moderation role in the relationships, which positively strengthen the impact between the variables within the relationship. In particular, to business performance, Ugheoke, 2019 and Yasmeen et al., 2020 discovered that those leadership styles are constantly having a positive role in improving the relationship between the proposed antecedents and business performance. As the outcome of this studies is compatible with the study hypothesis, we are expecting a positive moderating impact of leadership styles on the relationship between creativity variables and business performance.

Potential contributions

The proposed framework can be used:

- For management and practical side, the study is particularly beneficial to SMEs in UAE, as it highlights the role of creativity and leadership in the success rather than the traditional management and economic antecedents. Together, it could have dominant effects on various other fields in various companies, specialists, managers, selection analysts, manufacturers, and scholastics. Current investigation helps in understanding the productive factor of SMEs. Therefore, findings will be useful for the leaders of SMEs to have a better knowledge of the relations between the proposed variables.
- For Policymakers, The study is beneficial to decision-makers in funded programs in UAE or worldwide, because the study reveals that the success and failure in institutions could be related to something beyond financial and managerial structure Investigating variables related to individuals and group qualities, could make valuable add on to the information available for decision-makers to improve the future policies and requirement for the funds and grants offers.
- For theory and knowledge, discovering the role of leadership styles as a moderator towards the success of the organisation will increase the knowledge of these relations and will emphasise the importance of creativity and leadership to competitive advantages and improve the performance of organisations at SMEs.

Conclusion

The significance of medium and small business (SMEs) in increasing employment rate and in supporting the economic growth of a country has been recognised by governments and researchers. It is counted as the main source of creativity and innovation, which have significant effects on business performance. Individual creativity in the workplace and organisations has been the centre of interest in the past two decades in research. Individual creativity is using one's own mind to create something authentic, whereas team creativity suggests that a group of people interact with each other to increase the level of creativity. Leadership is both a topic of research and useful skill which includes the ability of an individual, group or an organisation to "lead" or direct other people, staffs, or whole organisations. There are four theories that contribute to the conceptual model; those include Goleman Leadership Styles Theory and institutional theory. The proposed conceptual model of this study has individual creativity and team creativity as predictors of business performance. In addition, leadership styles, six styles, are examined as moderators one by one to evaluate the leadership style that has the greatest significant change in the relations between creativity factors and business performance.

Abstract

The work is devoted to the development of the financial system and its institutions under the conditions of digitalization of the economy. Banks and their development prospects under the influence of the digital economy were also considered. Moreover, the advantages and disadvantages of using tools such as White Label and Big Data have been studied. There was considered a new financial institution - Fintech.

Keywords: Fintech, digitalization, Big Data.

Introduction

It is impossible to imagine our life without "smart" devices now, as well as without the Internet. Today it is not difficult to buy plane tickets online or pay in a store using a smartphone. All these actions are united by the concept of "digital economy". According to the World Bank, the digital economy is a system of economic, social, and cultural relations based on the use of digital information and communication technologies. The merger of online and offline spheres confirms the prospects for the development of the digital economy. However, the digital economy involves not only the online processes and transactions, but also the digitalization of almost all the aspects of business.

The key objectives of our research are:

- consideration of the main trends in the development of key financial institutions, such as banks, in framework of digital economy
- an overview of the appearance of such a phenomenon as Fintech in the Russian economy
- analysis of changes in the labor market in the digital economy.

Literature Overview

Columnists and authors from different countries include in their work the variety of areas: platform, business to consumer, mobile technology, business to business, retail banking, investment banking, financial transaction processing, financial data and analysis, corporate banking, risk management, compliance, asset management, blockchain, private banking, cryptocurrencies, insurance, cybersecurity (See Deloitte Report, 2017; Dasgupta et al, 2019; Divya and Murali, 2019; Oladapo and Rita, 2020).

The FinTech Book by Chishti and Barberis (2016) is the first crowdsourced book on fintech. 86 authors from 20 countries took part in its creation. About half of them are financial technology entrepreneurs, a quarter work in large financial or technology companies, and another quarter are companies engaged in the provision of professional

TITOV "The Concept of The Financial System in The Digital Economy" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

services. Users perceive these services positively. This all opens new opportunities for small businesses and small investors.

Study by Haycock and Richmond (2015) explores approaches to promoting customer service using mobile phones. The authors propose the new concept, it is an independent organization where leadership and headquarters are separate.

Note that five years ago BBVA chairman and CEO Francisco Gonzalez had pay attention that it would be increasingly difficult for banks to simplify invest in doing the banking business digitally. In the new world it is necessary to control a range of competencies, just one of which is banking (See Gonzalez, 2015).

The world-renowned Wikinomics author Don Tapscott and his son, former investment banker Alex Tapscott, examine is study Tapscott and Tapscott (2016) the impact of blockchain on the economy, governance, culture, access to financial services, and potential challenges.

To highlight the current situation in the fintech market, the Financial Times has published a special report, The Future of FinTech (See Financial Times, 2019). It contains several articles on various topics: the growing market for regulatory technology, the low adoption rate of blockchain in banks, and a call for green fintech.

Sironi (2016) describes the impact of using technology to provide more personalized advice on the work of financial advisors, who no longer sell a portfolio of specific products, but support purposeful investment.

Materials and Methods

The theme of digital economy got a clear outline in Russia only in 2016. At the same time, a strategic direction for the development of the digital economy was adopted. The digitalization of the economy forces both workers and employers to adapt to new conditions (See Smirnov et al, 2019). Soon, in a number of industries, human labour will be replaced by machine labour, which will create difficulties for companies and the state as a whole. The Russian labour market has never faced such changes before: according to the McKinsey Global Institute study, by 2036, from 2% to 50% of the volume of work previously expressed in man-hours will be automated. Businesses, educational institutions, and the state as a whole are required to take coordinated actions to retrain personnel. On the other hand, digital technologies also have a positive impact on the labour market, making it easier to find personnel, shortening the search time and increasing labour productivity.

On October 21, 2019, the McKinsey released a study of the banking industry, in which experts predicted the closure of many banks in the world (See McKinsey Global Institute Report, 2019). They will be replaced by IT and Fintech companies, analysts believe. The report was titled 'The last pit stop? Time for bold late-cycle moves.' According to experts, about 60% of banks in the world are unable to withstand the financial crisis and may disappear because of this. To survive, they need to "reinvent the business model" and follow the example of tech companies like Amazon and Ping. They attract customers with new solutions in the most profitable areas, for example, they pay special attention to acquiring, which has traditionally brought good income to banks. The study cites data according to which Fintech companies allocate more than 70% of the budget to technology development, while traditional banks - about 35%. So, banks should increase their investment in technology, gain weight through mergers, and also actively outsource.

In September 2019, PwC Luxembourg and the development agency Luxembourg for France also said that European banks and wealth managers should actively embrace 'Amazonization' and embed consumer technology driven by online platforms (See Pwc Report, 2019).

The formation in any country of ways of interaction between banks and Fintech companies directly depends on the policy of the financial regulator in relation to companies in this segment. Accordingly, it is worth noting the inequality in how regulators treat IT companies and traditional banks. In any country, lending institutions experience regulatory pressure from central banks. In particular, the regulator applies the requirements for the growth of equity capital to the bank, reducing the risk ratio, and forces it to abandon low-liquid assets.

Russia quickly appreciated all these challenges: The Bank of Russia highlights Big Data and Data Analysis, robotization and cloud technologies as the most promising financial technologies. The introduction of new technology must be accompanied by regulatory changes. The Department for the Development of Financial Technologies of the Bank of Russia identifies the following areas: regulation of marketplaces; development of blockchain technology (the

Bank is studying the market from the point of view of the possibility of using this technology); security and access rights of digital services; payment services; Big Data.

The modern banking system carries out most of its transactions through deposits, investments, and various lending operations. Every year the share of customers switching to using remote service channels is increasing due to the changing competitive environment in this industry with the emergence of Fintech companies, which will be discussed in more detail below. According to McKinsey study, 65% of Russian bank customers expressed a desire to buy banking products using tools such as mobile banking and internet banking. Russian banks' mobile applications have twice as many functions as their European counterparts, largely because Russian banks were already developing their competencies in the digital era, thereby making Russia one of the leaders in digital banking by 2018. This is a favourable condition for the rapid transition of Russian banks to digital services, even though Russia is still far from the Europe's level (60-70%).

Four main directions of development of the business model in the banking industry are being monitored at the current moment, taking into consideration the influence of the digital economy:

- Formation of own ecosystem
- Development of partnerships with other companies
- Provision of banking services under another's brand
- Creation of new lines of business based on blockchain

The transition to a financial ecosystem involves increased attention to consumer needs and building partnerships with other companies. Own ecosystem allows banks to increase loyalty and increase customer's base. An excellent example is the "Thank you" bonus program from Sberbank. The bonuses themself are not enough to attract customers, so the bank's management decided to supplement the program with such offers as "Thank you from Sberbank. Travel" and "Thank you from Sberbank. Impressions" to increase the interest and to attract the attention of customers. Such offers make the program unique and convenient for different categories of customers. Examples of outsourcing innovations, joint development and implementation of innovative solutions are the scoring systems of Alfa-Bank, Tinkoff Bank, etc. The banks' partners are social networks or cellular operators in these cases.

Another example is White Label (work under a foreign brand). It is used by banks when the long-term competitiveness of a bank is primarily determined by success in drastically cutting costs. White Label has both a number of advantages (focusing on the core business, additional income from the partner's program, etc.), and significant disadvantages: with a successful launch of the product, the reputation is not strengthened, additional resources are needed for technical support and product maintenance, etc. The largest banks in the USA and Australia can serve as an example of cooperation, which issue White Label cards for smaller banks, which can thus save on production.

Blockchain will also be able to dramatically change the banking sector. It can be noted that the use of blockchain will be effective in areas such as documentation and transactions already today. Nowadays, banking sector companies are faced with the task of optimizing transactions, so the implementation of blockchain can be an effective innovation that opens the opportunities and creates unique offers.

Let us move on to the concept of Fintech. Fintech (financial technology) is a technology that helps financial services and companies to manage the financial aspects of business. It includes software, applications, processes, and business models. Fintech also refers to an industry where companies use new financial technologies and solutions to compete with traditional financial institutions for clients. Fintech companies are very dynamic companies, often startups, focused on a specific innovative technology or process, covering everything from mobile payments to insurance. They attack the most profitable elements of the value chain. The latest PwC Fintech study indicates that Fintech companies could take at least a quarter of financial services business over the next five years.

The global investment in Fintech in 2019 is estimated to $ 53.3 billion showing a slight decrease of 3.7% compared to 2018. Thus, 2019 turned out to be the second in terms of investments since 2013 (see the Figure 1 below). The maximum in 2018 was achieved largely thanks to Ant Financial Services (known primarily as the owner of the Alipay payment system), which then raised a total of $ 14 billion. Without this number, investments in the Fintech sector in 2019 would have jumped by 29 % and updated the record.

Figure 1: Global Fintech investments

Russia is entered the top three countries in terms of the popularity of Fintech services. This is evidenced by the results of the EY study, released on November 21, 2019 (See EY Report, 2019). Experts estimate the penetration index of Fintech services in Russia at 82%. The higher rate is only in China and India (87%). The five top leaders also included South Africa (82%) and Colombia (76%). According to the forecasts of the development of perspective Fintech segments in Russia by 2035 (See EY Report, 2018):

- 96.3% of all transactions will be made using innovative services
- 9.8% of all insurance premiums will be paid by operators of Fintech services for insurance
- 36.7% of funds will be allocated through innovative financing services
- 46.1% of assets will be managed by innovative services for investment

The main drivers for the development of the Fintech market are the development of technologies, changes in consumer preferences and the growth of Internet penetration. The second factor can easily be attributed to such a factor as the low level of customer satisfaction with banking services or their inaccessibility. This is mainly due to the lack of banking infrastructure, the creation of which requires a significant amount of time and investment, as well as a low level of consumer commitment to traditional banking services and, accordingly, their willingness to use innovative solutions.

Let now outline several promising Fintech areas in Russia. The optimal platform will be the emergency response system in case of accidents "ERA GLONASS". According to experts of NP "Glonass", the Russian market is the most promising market in the world for the implementation of smart insurance solutions for vehicles. Note that NP "GLONASS" together with insurance companies are actively shaping the market for "smart" insurance services in transport, improving the legislative regulation of the sphere, organizing pilot projects to test technical solutions, equipment, platforms and business models for providing innovative insurance services.

P2P insurance can also be another promising area. As world practice shows, P2P communities may well be additional or independent channels for the distribution of insurance services and a way to form a positive customer experience. However, now the development of P2P insurance is still constrained by the lack of an appropriate legislative framework.

Let us dwell separately on one more direction, which is at the stage of emergence not only in the Russian Federation, but throughout the world - predictive banking. Today, banks have access to large arrays of client data, thanks to the analysis of which financial institutions not only know their clients well but can also offer the client possible subsequent financial actions.

It is also worth noting what impact the digitalization of the economy has on Russia's GDP (see table 1 below):

Table 1: Sources of GDP growth

Optimization of production and logistics operations	– Production line monitoring in real time – Logistic optimization and determining priority directions	1,4-4,0
Improving the efficiency of the labor market	– Effective and quick job search and filling of vacancies – Distant work – New workplaces	2,1-2,9
Improving equipment performance	– Reduced equipment downtime and repair costs – Equipment utilization increase	0,4-1,4
Improving the efficiency of R&D and product development	– Quality control – Big data analysis for product development and improvement	0,2-0,5
Reduction the resource consumption and production losses	– Reduced energy and fuel consumption – Reduction production losses of raw materials	<0,1

The main source of economic growth in the sectors of the economy is a multifactorial increase in the operating productivity of companies, the estimated effect of which is 1.6–4.6 trillion rubles. per year by 2025. Another factor affecting GDP growth from digitalization of the economy is an increase in the return on productive and non-productive assets. The introduction of the Internet of Things can allow companies to achieve an increase in finished product yield, reduce equipment downtime, and optimize the utilization of production facilities; the estimated effect of the implementation of these measures is from 0.4 to 1.4 trillion rubles. per year by 2025.

In general, by 2025, according to McKinsey [1], the digitalization of the Russian economy will increase the country's GDP by 4.1-8.9 trillion rubles. Digitalization will provide from 19 to 34% of Russia's GDP growth, and the share of the digital economy itself may amount to 8-10% of GDP. Now the share of the digital economy in Russia's GDP is 3.9%. According to the McKinsey digitalization index, Russia is included in the group of so-called active followers through investments in the expansion of information and communication technologies (ICT) infrastructure and the introduction of technologies in government agencies. Despite this, the country is still behind the leaders in this area - Singapore, USA, Israel, and Western Europe (Great Britain, Germany, Spain, Italy, etc.). As a result, the possibilities of supporting the competitiveness of Russian companies are lower not only on an international scale (insignificant volume of high-tech exports), but also domestically (displacement by foreign companies of Russian players in the segments of e-commerce, social networks, and search engines).

Discussion

So, to develop the financial system in digital era the creation and effective functioning of the Fintech ecosystem is required. This requires the development of technologies and increasing demand for Fintech services and products through comprehensive measures aimed at providing Fintech companies with access to finance, as well as improving the regulatory environment and the training process.

The imperfection of the structure of the financial sector leads to arising of risks that leads to ineffective functioning of financial institutions. In economic theory, all these problems have been sufficiently studied, but in the new conditions of the digital economy, financial intermediaries are more often faced with new risks.
Cyber risk management now is a complex and rapidly developing industry. Another risk is that digitalization is gradually blurring the line between banking and non-banking activities; the speed of creation of new payment instruments outstrips the adaptability of the banking environment to it. An important question arises also on consequences of technical failures. In case the external service provider dominates the market will be systemic risk, since the problem may already happen outside the financial industry - for example, through the introduction of cloud technology. And, of course, a huge problem is the lack of awareness of consumers about the proper level of protection of their data.

But it is possible to minimize the appearance of these problems in the financial sector with the necessary level of government regulation soon.

Abstract

Processes of social, economic, and regional development are of interdisciplinary nature and they are described by a host of definitions. The academic literature on the subject also emphasises the specific subjectivity of measuring such phenomena, predominantly determined by the lack of up-to-date and universal measures dedicated for this process. Analysing the literature on the subject as well as studies conducted on a national and international scale, it is possible to notice there is no measure dedicated for evaluation of a regional level of socio-economic development, which is adequate for Poland (or other countries at a similar level of development). This article aims at analysing the level of socio-economic development of individual regions in Poland. To this end, a relative coefficient of regional socio-economic development was constructed, which takes into account a broad, up-to-date set of factors of regional socio-economic development. The research study covers the years 2010 – 2018 and consists of three stages: preparing a comprehensive set of variables that describe regional socio-economic development, analysing the input data by means of the linear ordering method based on the data prepared with the zero unitarisation method and the relative coefficient of regional socio-economic development, and analysing the regional well-being ranking according to OECD, including verification of the correlation level of both rankings results. The analysis of the relative coefficient of regional socio-economic development demonstrated increasing discrepancy between the highest and lowest values for the individual regions is astonishing. The presented findings confirm the extreme ranking positions taken by the particular regions, as a result of applying various research methods.

Keywords: Economic Cohesion; Regional Policy; Economic Governance; Social Governance.

Introduction

Processes of socio-economic and regional development are often addressed in academic studies. The concept of a region as a research tool boils down to separating homogeneous areas where a certain feature or a set of features are observed, which are relevant from the point of view of the research problem in question (Chojnicki & Czyż, 1992, p. 2). EU policy identifies regions in Poland with Polish voivodeships (NUTS 2). Domański (2012, p. 18) emphasises that EU regulations apply the principle that vital development processes take place at the regional level, therefore the EU earmarks a considerable part of its budget for regional development, and it also runs research projects on economic development of regions. According to Regional Development Policy presented by OECD, regional development may be

perceived in most general terms as an effort made in order to decrease the regional disproportions via supporting business activity in those regions. The objective of a regional policy should be ensuring a possibility of development and high living standard to the inhabitants in various types of regions (OECD Regional Outlook 2016, p. 26).

Development is a process of positive changes comprising both quantitative growth and qualitative progress, where the quantitative aspect encompasses the concept of economic growth, while the qualitative aspect regards transformation of socio-economic structures, as a result of which they acquire new characteristics (Klóska, 2015, p. 14). Salecka (2018, p. 68) asserts that the result of development is the continuous improvement of people's living conditions. Parysek (2018, pp. 39, 41) emphasises that this is a multi-level and long-lasting process, nevertheless it seems that despite the complex and structured nature, it can be interpreted also in terms of changes of concrete properties of the individual constituents of the socio-economic system, i.e. its distinguished elements that are decisive for the developed structures. Analysing this phenomenon, it can be said that the condition necessary for any socio-economic development is economic development – the public in the first place must meet their basic needs which grow and implicate socio-economic development, whereas economic development is determined by the economic growth which at the same time is a derivative of the socio-economic development.

Over the recent years, many studies addressed the theory and determinants of regional and socio-economic development, methods and tools for managing the regional development (for more details please refer to: Aivazian et al., 2018, 2018; Florida et al., 2008; Herbst, 2007, 2012; Klasik & Kuźnik, 2017; Klóska, 2015; Nowakowska, 2015; Zakrzewska-Półtorak, 2012). However, according to the author of this article, there is no up-to-date study that accounts for the broadest possible scope of research regarding the level of socio-economic development, which is adequate for the regions in Poland. This study aims at analysing the level of socio-economic development of the regions in Poland. To this end, a relative coefficient of regional socio-economic development was constructed, which takes into account a broad, up-to-date set of factors of regional socio-economic development. This is particularly important in view of the fact that, at the moment, the COVID-19 pandemic is paralysing the global economy, which also affects all the national and regional economies. It is too early to evaluate the possible outcomes of this event, nevertheless in the future this study may constitute a basis for analysing the situation before the economy slowed down. Application of analogous computation methods will make it possible to objectively assess the changes in the levels of regional socio-economic development in Poland.

The Literature Review

The older studies generally applied the traditional measures of economic development, based on the national accounts systems (GDP, GNP, NNP), as the approximate, general indicator of the social development and across-the-board progress level (Obrębalski, 2013, p. 40). Kubiczek (2014, pp. 52, 53) emphasises that not all countries are interested in standardising the measures of development, as such indexes often demonstrate a lower level of the given country's development and adversely affect its image.

In the OECD analyses the data are broken down into five categories of socio-economic factors (Gross domestic expenditure on R-D by sector of performance and socio-economic objective, 2020): environment, energy, industrial production and technology, agriculture, education. Eurostat is based on 12 indicators demonstrating activities in 3 categories: economic development, competitiveness, innovations and eco-effectiveness and employment (Table 1).

Table 1: Socio-economic development indicators applied by Eurostat

Headline indicators	Operational indicators	Explanatory indicators
Real GDP per inhabitant	Economic development	
	Investments Disposable income of household per capita	GDP per capita Net national income Household savings
	Competitiveness, innovations and eco-effectiveness	
	Labour productivity increase	Eco-innovation indexes R&D expenditure Relative price and cost index Turnover from innovation Energy intensity of the economy
	Employment	
	Employment rate Young people neither in employment nor in education and training	Employment rate as per employment level Employment rate across regions Unemployment rate Labour cost to labour productivity ratio

Source: Zimny (2016, p. 76).

OECD also presents the tool: *Regional Well-Being: A Closer Measure of Life*, which makes it possible to measure the well-being level in a concrete region and compare it with 402 other regions (For analytical purposes, the OECD classifies regions as the first administrative tier of sub-national government. This classification is used by National Statistical Offices to collect information and it represents in many countries the framework for implementing the regional policies) on the basis of eleven key themes related to inhabitants' life quality. According to OECD, in order to better understand how the society functions, it is necessary to go beyond GDP level measurement and other economic statistics (OECD, 2018). The set of ratios illustrating the regional well-being level consists of three categories comprising from 2 to 6 topics:

1. material conditions:
   - household income per capita,
   - labour market (employment rate and unemployment level)
   - housing conditions (number of rooms per person),
2. life quality:
   - health (life expectancy, age-specific mortality rate)
   - education (percentage of labour with at least upper secondary education),
   - environment (estimated average exposure to air pollution with PM2.5 ($\mu g/m^3$)), assessed by means of satellite-based data,
   - security (homicide rate),
   - civic engagement (voter turnout),
   - availability of services (percentage of households with broad-band access),
3. subjective level of well-being:
   - community (percentage of people having friends or relatives they can rely on in case of need),
   - life satisfaction (average self-assessment of satisfaction with life, on a scale from 0 to 10).

An intersting set of indicators of Poland's sustainable development was proposed by the Central Statistical Office of Poland in the study *Wskaźniki zrównoważonego rozwoju Polski 2015* [Indicators of sustainable development of Poland] (GUS, 2015) (Figure 1).

Figure 1: Thematic areas of indicators of Poland's sustainable development, according to the Central Statistical Office of Poland.

Source: own study based on (GUS, 2015, pp. 54–297).

In the study entitled "Innovation and Regional Socio-Economic Development – Evidence from the Finnish Local Administrative Units" (2011), Makkonen proposes a set of 15 variables that describe innovations and socio-economic development (Table 2).

Malganova & Zagladina (2015), researching socio-economic development, distinguished three groups of factors determining the process, breaking them down into:

- positively affecting (e.g. daytime educational institutions per 1000 pupils, number of teachers in daytime general education institutions per 1000 pupils, provision of population with home telephones of urban and rural public network per 100 families pieces),
- negatively affecting (e.g. mortality per 1000 persons of population, mortality of infants at the age under 1 year per 1000 births),
- neutral (e.g. places in kindergartens provision for children of 1-6 of age per 1000 children, books in public libraries per 1000 persons of population.

Table 2: Chosen variables for depicting innovation and regional socio-economic development

Category	Variable
Patents	Patents granted/1,000 inhabitants
Population	Number of inhabitants
Population change	Net population change % (natural population change and migration)
Working population	Percentage of people of working age (between 15 and 64 years of age)
Unemployment	Unemployment rate %
Dependency ratio	Non-working population compared with working population
Gender structure	Number of women compared with 1,000 men
Education	Percentage of population with higher education (20 years and older)
Urbanization	Percentage of densely populated areas
GDP	Gross domestic product/inhabitant
GVA	Gross value added/inhabitant
Income	Gross income/inhabitant
Housing	Percentage of small and/or inadequate housing
Housing costs	Average cost of housing €/m²

Source: Makkonen, 2011, p. 34.

The study pertained to the Republic of Tatarstan (the Russian Federation), which is currently at a different stage of socio-economic development than Poland, therefore not all of the data are adequate to be applied in an analysis concerning Poland.

Among the factors taken into account in measuring the level of the socio-economic development in Poland, the predominant ones are those which characterise the condition and structure of the population and population-related processes, labour market, with a particular focus on unemployment level, pay level, quantity (and structure) of national economy entities entered in the REGON register (entrepreneurship), budget spending of local administrative units, prices level, investment expenditure level, GDP per capita, and aspects related to education, health protection and (more and more often) the broadly understood ecological awareness (Salecka, 2018; Stanny, 2012; Stasiak, 2016; Ziemiańczyk, 2010; Zimny, 2016). The literature on the subject emphasises that the population is a carrier of specific needs, and at the same time it generates labour force which will meet those needs (Kupiec, 2011, pp. 9–11). Human capital is a factor that affects the long-term economic growth rate – investing in human capital results in internal effects in the form of increased labour productivity, and also external effects in the form of increased productivity of material capital, therefore it may be deemed to be the key element of the contemporary economy, which stimulates the productivity in the economies where it is found (Korenik, 2008, p. 107).

As Ziemiańczyk (2010, p. 34) concluded: complex phenomena, which undoubtedly include socio-economic development, are very difficult to assess in an objective and unambiguous manner. Czyżycki (Czyżycki, 2012, pp. 22, 23) points out that preparing any types of rankings, and putting them in any sort of order in terms of socio-economic development, is to a certain extent subjective.

Based on the literature review it was found that the most relevant and broad set of indicators was proposed by the Central Statistical Office of Poland (GUS, 2015). When analysing the indicators that apply to social and economic governance, it is possible to notice that they are coherent with those applied by the aforementioned authors (however, no other author utilised them in such a broad array). The only study which to a partial extent proposed application of totally different indicators was the article of Malganova & Zagladina (2015), where the analysed data were inadequate to the current situation in Poland, such as e.g. quantity of landline telephones. Unfortunately, in the said study the Central Statistical Office of Poland did not present any analyses at the regional level – the study only addressed changes in the indicators over time and their values were compared to the analogous values for individual EU member states or general data describing the EU. In view of the above, for the purposes of this analysis the author decided to use the set of indicators proposed by the Central Statistical Office of Poland. Nevertheless, it was necessary to slightly adjust them, which was due to the data availability and the specific nature of the regional data – some of the data held by the Central Statistical Office were typical for characteristics on a national scale.

Data and Methodology

The methodology comprises the following sequence of stages:

1. preparing a comprehensive set of variables describing the regional socio-economic development: selecting and categorising the input data, preparing a comprehensive system of indicators;
2. analysing the input data by means of the linear ordering method based on the data prepared with the use of the zero unitarisation method and the relative coefficient of regional socio-economic development,
3. analysing the regional well-being ranking according to OECD, as well as verifying the correlation of the results of both rankings.

Based on the conclusions drawn from the literature review, the key measures of regional socio-economic development in Poland were selected. The input data used in the computations come from Bank Danych Lokalnych GUS [Local Statistical Data Bank] and pertain to the years 2010 – 2018. This period was determined by the data availability and the system of data presented by the Central Statistical Office. Where occasionally data were missing for a given year, interpolation methods were used to supplement them. The socio-economic development of the individual regions was characterised by means of 32 features assigned to 8 categories. Based on the analysis of the selected diagnostic variables, equal weights were attached. Table 3 presents the data applied in the study.

Table 3: Indicators of regional socio-economic development in Poland

s/n	Category	Indicator	Symbol	LTB/ STB
1	economic development	GDP per capita	x_1	LTB
		GDP dynamics per capita	x_2	LTB
		investment rate / GDP	x_3	LTB
2	employment and access to labour market	employment rate for people aged 20 – 64	x_4	LTB
		occupational inactivity rate for people aged 15 – 29	x_5	STB
		occupational activity coefficient	x_6	LTB
		registered unemployed/ working age population	x_7	STB
		employment rate for people with disabilities, aged 16 – 64	x_8	LTB
		number of national businesses per 10,000 of the working age population	x_9	LTB
3	innovativeness	net revenues from sale of innovative products/ total sales revenues	x_{10}	LTB
		number of people working in R&D/ total working population	x_{11}	LTB
		internal expenditure on R&D in relation to GDP (current prices)	x_{12}	LTB
		patents applications filed with the Polish Patent Office per 1,000,000 population	x_{13}	LTB
4	production and consumption patterns	percentage of certified ecological farms in total cultivated land	x_{14}	LTB
		total PM emissions per km^2	x_{15}	STB
		electric power consumption per inhabitant	x_{16}	LTB
		average monthly spending per person	x_{17}	LTB
5	demographic changes	fertility rate and gross reproduction rate	x_{18}	LTB
		migration balance	x_{19}	LTB
		rate of natural increase per 1000 population as per place of residence	x_{20}	LTB
		post-working age population per 100 working population	x_{21}	STB
6	poverty and life conditions	poverty ratio (% of people in households with spending below the relative poverty line)	x_{22}	STB
		average monthly disposable income per person	x_{23}	LTB
		residential units commissioned in the given year/ population aged 25 – 34	x_{24}	LTB
7	education	percentage of adults aged 25 – 64 participating in education or training	x_{25}	LTB
		percentage of children aged 3 – 6 years attending kindergarten – in total	x_{26}	LTB
		expenses related to Section 801 – Education, in relation to GDP per capita	x_{27}	LTB
		graduates of tertiary education institutions per 10,000 population	x_{28}	LTB

Source: own study.

The enumerated diagnostic variables are expressed in different units of measurement, which made any direct comparison impossible. In order to make them comparable and additive, they were transformed by means of the zero unitarisation method based on the span between the maximum and minimum values of the feature in question. Obtained values of the variables are positive and fall within the range from 0 to 1 ("1" stands for the most beneficial, and "0" for the least beneficial value of the examined variable). It was assumed that when a high value of the diagnostic variable for a given phenomenon is associated with beneficial growth, the feature is considered Larger-the-better (LTB), whereas in a situation where a low value of the variable is beneficial for the phenomenon in question, it is deemed Smaller-the-better (STB). The standardisation was carried out with the use of the following formulas (Ziemiańczyk, 2010, p. 34):

LTB:

$$Z_{ij} = \frac{x_{ij} - min x_{ij}}{max x_{ij} - min x_{ij}},$$

STB:

$$Z_{ij} = \frac{max x_{ij} - x_{ij}}{max x_{ij} - min x_{ij}},$$

where:

Zij – diagnostic variable, falling within the range from 0 to 1,
xij – the feature value for a given municipality,
min xij – the lowest value of the feature among the examined municipalities,
max xij – the highest value of the feature among the examined municipalities.
In the next step, a relative coefficient of regional socio-economic development was computed, by means of the following formula (Klóska 2015):

$$W_i = \frac{100}{k} \sum_{j=1}^{k} \alpha_j z_{ij},$$

where:

Wi – relative coefficient of regional socio-economic development,
k – quantity of variables considered in the study,
αj – weight of the jth variable,
zij – values of the statistical features xij considered in the study, standardised by means of the zero unitarisation method.
It was assumed that a higher value of the aggregate formula is associated with a higher level of socio-economic development. The analyses were carried out for each of the 16 regions over the years covered by the study (2010 – 2018), thus the input data in total included 4608 variables.

In the second part of the study, the regional well-being ranking according to OECD will be compared to the results of the analysis involving the relative coefficient of regional socio-economic development. The tool OECD Regional Well-Being: A Closer Measure of Life, which measures the well-being level in a concrete region and makes it possible to compare it to 402 other regions on the basis of eleven key themes related to inhabitants' life quality. The compared regional well-being measures offer a new way to assess the effects of policies implementation, and make it possible to take actions to attain a higher level of well-being for the citizens, also enabling a classification of regions both within any given country and in relation to regions in other countries (OECD, 2018).

Results and Discussion

The analysis of the relative coefficient of regional socio-economic development, which was computed for the individual regions in Poland for the years 2010 – 2018 (Figure 3) indicates stability of positions taken by individual regions, as well as considerable and persisting disproportions in the social and economic development between regions taking the positions at both ends of the ranking. Throughout the researched period, the top position in the ranking has been held by the region of Mazowieckie, whereas Świętokrzyskie has continually been in the weakest position. Slight changes between individual positions may be observed in the middle part of the ranking (Śląskie, Łódzkie, Zachodniopomorskie, Podkarpackie, Podlaskie), however, the changes tend to be incidental. What is interesting, the span between the highest and the lowest values of the relative coefficient of regional socio-economic development in the studied period rose from 37.2 in 2010 to 49.5 in 2018.

Figure 4 presents the regions ranking created by means of linear ordering of the value of the relative coefficient of regional socio-economic development for 2018.

Figure 4: Value of the relative coefficient of regional socio-economic development in Poland in 2018

Source: own study.

The analysis results may question the effectiveness of the EU regional programmes aimed at decreasing the disproportions between regions. On the other hand, the more developed regions keep developing.

The further stage of the study involved an analysis of the set of indicators illustrating the level of regional well-being, consisting of three categories comprising from 2 to 6 topics which were described in the Introduction to this article (for more details please refer to: OECD Regional Well-Being: A user's guide). The well-being indicators are expressed in various units. In order to make it possible to compare them on the same scale, they are standardised by means of the min-max method, bringing them to values ranging from 0 to 10. Table 4 presents 11 well-being indicators for the individual regions in Poland, against all the 403 regions evaluated by OECD. The values of the indicators specified by OECD for the individual Polish regions and for all the 11 categories vs. the values of the relative coefficient of regional socio-economic development computed for 2018.

Table 4: *OECD Regional Well-Being* indicators for the individual regions in Poland (scale from 0 to 10).

Region	Education	Labour market	Income	Security	Health	Environment	Civic engagement	Availability of services	Housing conditions	Society	Life satisfaction
Dolnośląskie	10.00	6.66	2.72	8.27	3.27	1.74	1.58	6.63	1.11	5.95	3.33
Kujawsko-pomorskie	9.71	6.17	2.18	9.14	3.33	2.25	0.96	5.65	0.00	8.06	2.96
Łódzkie	9.68	7.47	2.60	9.14	1.87	0.06	2.03	5.82	0.56	7.15	2.59
Lubelskie	9.63	5.59	2.06	8.40	3.73	1.82	1.49	6.14	0.56	8.78	2.22
Lubuskie	9.64	6.84	2.22	7.04	2.92	3.47	0.59	5.82	0.56	6.27	2.96
Małopolskie	10.00	6.84	2.40	9.88	4.89	0.33	2.70	6.63	0.56	7.86	2.59
Mazowieckie	10.00	7.63	3.24	8.89	4.03	1.00	3.48	6.79	1.11	7.59	2.96
Opolskie	9.75	6.63	2.32	9.51	3.83	0.00	0.28	5.98	1.11	6.51	2.59
Podkarpackie	10.00	4.96	1.88	9.63	4.84	2.07	1.78	7.60	0.00	8.78	1.11
Podlaskie	9.57	6.43	1.99	9.38	4.03	3.24	1.10	5.65	1.11	8.10	2.59
Pomorskie	9.75	7.11	2.47	9.38	3.88	4.14	2.09	7.27	0.56	6.63	3.70

Zachodniopomorskie	9.47	6.22	2.48	8.52	3.27	4.50	0.86	6.30	0.56	8.34	5.56

Source: own study based on OECD, 2018.

In both rankings, the highest values were attained by Mazowieckie and Pomorskie (1st and 2nd place), Podlaskie ranked in the middle (6th and 7th position), whereas the last two regions were Warmińsko-mazurskie (15th place) and Świętokrzyskie (16th place). In the case of some regions the evaluations are not that coherent, e.g. Zachodniopomorskie (4th and 9th place), Podkarpackie (7th and 12th place), Dolnośląskie (8th and 5th place) or Kujawsko-pomorskie (9th and 13th place). Still, the analysis of the findings with the use of Pearson coefficient demonstrates a significant correlation between the analysed variables (0.79).

Summary and conclusions

There is no ideal method to compute the level of social and economic development, nevertheless, this study attempts to analyse the available and up-to-date methods that are appropriate for conducting research studies at the regional level and make it possible to provide a broad array of variables. The subject tackled in this article is not novel and it is addressed in the literature on the subject, however, the presented way of measuring the regional socio-economic development was predicated on a thorough literature review resulting in a vast number of variables.

The time span covered by the study was 9 years, and the obtained findings demonstrated coherent values for all the years – to be more specific, the values of the relative coefficient of regional socio-economic development computed for a given region were not significantly divergent from each other over the subsequent years. This study does not contain any generalisations, and it was aimed at possibly the most detailed analysis of the level of the regional socio-economic development in Poland. In this respect, it is possible to notice disproportions between some regions, which persist over

time. On the one hand, the more developed regions have better conditions that facilitate further regional growth. On the other hand, the less developed regions are provided with support to enable their development. In this aspect, the increasing discrepancy between the highest and lowest values for the individual regions is astonishing. Pursuant to the assumptions of the EU Cohesion Policy, this value should be decreasing. One may consider whether or not it would be reasonable to quote more rankings kept by other institutions. However, in the opinion of the author of this article, this is not necessary, because – as already pointed out in the Introduction – not each type of ranking is appropriate for all countries (which also does not mean that it is not worth making an attempt to supplement the created indicator to cover other countries, e.g. within the European Union). On the other hand, the obtained findings are strongly correlated with the results of the study on the regional well-being level as per OECD's standards, which provides the grounds to believe that the variables applied in this study as well as the adopted methods are correct.

Acknowledgment

The project is financed within the framework of the program of the Minister of Science and Higher Education under the name "Regional Excellence Initiative" in the years 2019 - 2022; project number 001/RID/2018/19; the amount of financing PLN 10,684,000.00.

Abstract

This paper deals with digital integration in marketing strategies for B2B small companies. The use of digital technologies is widespread in creating the marketing strategies of small B2C companies, but small B2B companies before the pandemic denied the need to use digital technologies due to the lack of budget, time and human resources. The impact of the COVID-19 has dramatically changed marketing and business priorities. The efficiency of companies has dropped markedly due to working from home, reductions and social distance between people. This has prompted many companies to look for new innovative solutions to maintain their market positions. Since everyone moved to the online space, the digital transformation of their marketing strategies can be such a solution for small B2B companies. The goal of the work is to analyze the main prerequisites and reasons for the digital transformation of marketing strategies for small B2B companies in the context of economic instability caused by COVID-19. To test our hypothesis, it is planned to conduct in-depth interviews and online questionnaires among small B2B enterprises.

Keywords: COVID-19, pandemic crisis, digitalization, B2B, SMEs.

The starting point for changes introduced due to or in spite of COVID-19 can be considered December 2019. In other words, in some countries (for example, China), certain changes have been taking place for almost a year now.

During the pandemic, almost all countries managed to close all mass gatherings of people (shopping centers, gyms, universities, schools, etc.), postpone or cancel concerts, theater productions, etc.), close borders between countries, restrict movement between cities, and switch the maximum number of enterprises to distant or modification operation. Small businesses and individual entrepreneurs are closing down at a breakneck rate, and people are losing their jobs. According to the latest data From Rosstat (July 2020), unemployment in Russia is 6.3 %. This is the highest level of unemployment since the economic crisis in 2008.

In fact, the financial situation of the countries has "sunk" even lower than in 2008. Obviously, there is no hope that economic growth can be restored quickly after the Covid-19 pandemic (OECD 2020). At the same time, the economic recession inevitably leads to a decline in business activity in most companies (Ahmed et al. 2014). Today small businesses are closing both because of bankruptcy and needlessness, since the nature of demand is changing.

To survive the coronavirus crisis and gain competitive advantages, small companies have to develop innovative strategies. That means they should be more flexible in their marketing strategies. Companies are now more aware of their customers ' needs, and they are trying to use the pandemic situation to appeal to people's emotions, and marketing is a great tool for this. As the whole world has switched to online mode these days, you can see the abundant growth of social media marketing and other types of digital marketing.

However, B2C companies have much more opportunities to invest and develop innovative strategies using Internet marketing technologies and digital tools than B2B companies. The large number in the use of digital tools by B2C companies is due to the fact that B2B sales require an individual approach to customers, including the use of not only system, but also socio-psychological tools for sales and promotion. In this regard, when planning their presence on the Internet, B2B companies need to analyze the needs of their consumers in more detail at each stage.

Moreover, the lack of perception of the Internet marketing relevance, as well as the lack of budget, time and human resources for small B2B companies persisted until the beginning of the pandemic. The situation with the pandemic

Cite this Article as: Ksenia RAYTER and Olga KONNIKOVA" Impact Of COVID-19 On Digital Transformation in B2B Small Companies" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

has led to the tremendous changes around the world. Therefore, those companies that were able to quickly respond to the situation and start a digital transformation were able to maintain their position in the market, and some even made profits.

Small B2B companies are most vulnerable to the effects of COVID-19. In consequence of the transition to the online world, social distance between people, bankruptcy of companies, dismissals, reductions and transfer of workers in remote, the usual operation mode of B2B sales managers is almost impossible. Companies have to create short-term solutions and future-oriented strategies for their businesses and their customers. They have to be creative with their products, services and communications. They need to give the right message: that they can successfully work in a crisis.

In accordance with the article (Guo et al 2020), in the context of a crisis, the dynamic capabilities of companies can be divided into three aspects: sensing the crisis, seizing new opportunities in the crisis (Ballesteros et al. 2017; Teece 2007), and reconfiguring resources to cope with a crisis. Of course, it was impossible to anticipate the coronavirus crisis, but companies could rethink the ways to submit marketing campaigns and their content. For the majority, this means focusing spending in the survey, studying consumers ' lifestyles, and adapting their marketing strategies.

The results of an online survey of Chinese companies (Guo, H., Yang, Z., Huang, R. et al 2020) showed a high awareness of the need for digital transformation in all indicators: social, mobile, big data, cloud computing, IoT (Internet of Things), platform development, and Artificial Intelligence (Bharadwaj et al. 2013; Sebastian et al. 2017; Vial 2019).

Today, small B2C SMEs include in their marketing strategies an increasing use of social networks, online software, re-budgeting, monitoring business transactions and inventory (Winarsih et al. 2020). As for B2B companies, unfortunately, so far they mostly survive due to subsidies from the state and rapid cuts in expenses, both operational and organizational.

However, the crisis is a unique opportunity for the company's growth and prosperity (Civi 2013). Above all, B2B companies do not need to reduce their marketing budgets during a recession. (Rizomyliotis et al. 2017). The research has shown that increasing the marketing budget during downturns leads to a full return on investment, an increase in market share, and an increase in sales (Nickell et al. 2013).

Further research can be refined by checking the structure of the frame. To collect data, we will use the method of online questionnaires and in-depth interviews with stakeholders of small B2B companies. The results of this study are expected to provide recommendations for small B2B companies to implement and digitally adapt their marketing strategies to achieve sustainability.

Abstract

The article considers and systematizes the main prerequisites for the emergence of the global economic crisis in 2020. A comparative analysis of the crisis of 2008 and 2020 is carried out. The article describes the economic situation in Russia on the eve of the crisis in 2020, by taking into account national characteristics and geopolitical factors in the form of international sanctions which affect its development. The assessment of measures of state support to the Russian economy during the crisis is given. There are defined and well thought out the principles of companies' and corporations' activity in the current conditions.

Keywords: Coronavirus Pandemic, Financial Market, Economy, Financial Crisis.

Introduction

The relevance of the research of the scientific problem is due to the new economic crisis, the trigger of which for the first time in modern history was a coronavirus infection that brought down several industries and financial markets. The peculiarity of this crisis is that it is impossible to predict the depth of the recession in advance due to the dependence of its end date on the release and effectiveness of the vaccine.

Another significant problem is that against the background of the global crisis, geopolitical disunity between countries and regional associations come into existence and is in progress, which makes it difficult to join efforts in order to resist the pandemic and the crisis caused by it.

The purpose of this article is to conduct a comparative analysis of the global crisis of 2008 and 2020 on the basis of systematization of distinctive features and factors influencing their occurrence.

This purpose determines the assessment of measures to support the national economy, allowing to minimize losses in the recovery from the crisis caused by the pandemic.

STEPKINA "Dynamics of the World and Russian Economy in the Coronavirus Pandemic Context" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Degree of The Problem Development

Currently, many countries are conducting research on the impact of the coronavirus pandemic on the national economy (Tiirinki et al (2020), Finland; Higginson et al (2020), Australia; Norouzi et al (2020), China etc.), the global economy and industry markets. We analyzed the researches of the different authors, such as NICA (2020), Yue (2020) and Hiscott (2020). These research papers assess the possibilities of preventing and identifying risks, predict the impact of the crisis on various industries, and discuss the long-term global consequences of the crisis.

Analytics

The current economic crisis was predicted long before it began and was presented by expert communities as another classic cyclical crisis without any major disturbances. However, by the end of March 2020 The international monetary Fund (IMF) has officially announced a contraction in the global economy and the beginning of a recession. It was announced that the coronavirus pandemic COVID-19 was the main reason for this. For the first time (in the history of the modern world, an unprecedented situation has come about when a deadly disease has dealt a serious blow to the global economic and financial systems. However, it should be noted that the coronavirus was only a trigger, and not the main reason for the beginning of another crisis.

The main prerequisites for the 2020 crisis include the following

Slowdown in the Global Economy Growth

According to the Organization for Economic Cooperation and Development (OECD), the growth rate of the global economy in 2019 was the lowest since the financial crisis of 2008 and amounted to 2.3% (2008 – 4.1%).

By the beginning of 2020, a slowdown in economic growth was already observed in all leading economies: China 2019 – 6.1% (2008 – 11.4%), the EU – 1.2% (2.3%), Russia – 1.1% (7.5%). Over the past ten years, the probability of an economic downturn in the United States has increased at most (Fig. 1).

Fig. 1: GDP growth rate and forecast for 2021 (%)

(Source: compiled by the authors based on own research)

This existing situation allowed John Graham, a Professor of Finance at Duke University, to confirm that for the first time in a decade, no region of the world was in a strong enough economic position to become the driving force of the global economy.

According to a research study by Grishin (2020), the globality and uncertainty of the situation, the dynamics of the development of processes, the lack of precedents and social experience in resolving it makes it complicated to give real forecasts for the future.

High Level of Global Debt

In November 2019 the International Monetary Fund (IMF) reported that global debt has broken another record — 188 trillion US dollars, which is 230% of the value of all goods and services on the planet. Despite the fact that the economy is considered unstable even with a debt exceeding 80 % of GDP (Fig. 2).

According to the IMF estimates, under the baseline scenario, public debt on a global scale is expected to reach its historical maximum in 2020 – 2021 and exceed 101% of GDP, an increase of 19 percentage points compared to the level of 2019.

At the same time, a significant threat to the global economy is the US debt of almost 70 trillion US dollars, of which 22 trillion US dollars (106% of GDP) are accounted for government loans. Economists estimate that by 2028, the United States will spend a fifth of the state budget on interest payments alone. The situation is complicated by the fact that almost 40% of the national debt belongs to foreign investors who are losing confidence in American assets.

Aggravation of Foreign Trade Conflicts

In the recent years, the US foreign economic policy has been characterized by an aggressive form of promoting national interests and protecting the domestic market through an uncoordinated increase in import tariffs on goods involved in international trade. This resulted in an ongoing standoff between the United States and China, which arose after the signing of the Memorandum "On Combating China's Economic Aggression" by the US President in 2018.

Fig. 2: Government debt-to-GDP ratio (%)

(Source: compiled by the authors based on own research)

The sanctions that followed were mainly directed at Chinese industrial products, while China's response (primarily) was directed at agricultural products. The conflict resulted in a redistribution of goods flows on the world market.

Falling Prices for Raw Materials and Energy

The growth of oil reserves in storage facilities and the constant increase in its production by oil-producing countries (including at the expense of shale oil in the United States) led to a decrease in its cost. In addition, this was affected by the fall in the growth rate of the world's leading economy and the main oil consumer of China. So, if the average price for Brent crude oil in 2019 was $ 63.59, then at the beginning of the pandemic and the transition to self-isolation in March 2020, it was $ 26.35.

Restrictions imposed in various sectors of the economy related to countering the spread of a new infection, as well as the termination of the OPEC + deal, and the continuation of price wars have served as catalysts for a decline in global oil demand and, as a result, an oversupply of raw materials on the market and lower oil prices.

The Russian economy, as an integral part of the global economic system, generally follows global trends, as can be seen in Figures 1 and 3.

Fig. 3: Russia's GDP growth rate and forecast for 2021 (%)
(Source: compiled by the authors based on own research)

However, along with global trends, that affect GDP growth, the Russian economy has its own characteristics that hinder its progressive development. These characteristics are the following:

- raw material orientation of export. Exports of mineral resources, metal and wood account for more than 80 % of the Russian trade balance;
- weak competitiveness of domestic producers' products. Low share of exports of high-value-added goods, such as Mechanical engineering and Metalworking, which decreased from 20 to 5 %;
- technological lag in a number of industries and low labor productivity;

The most important factor, hindering the country's development, is the anti-Russian sanctions imposed by a number of foreign countries since 2014, which make it difficult not only to attract foreign investment, but also to enter international financial markets. As a result, the sanctions affected almost a fifth of Russia's GDP. Experts from the Analytical Credit Rating Agency (ACRA) estimated that the restrictions covered 54 % of the banking sector's assets, 95 % of the revenue of oil and gas companies, and almost all enterprises of the military-industrial complex. Every year, sanctions lead to Russia losing 1.5 % of GDP growth.

The negative impact of sanctions primarily affects the activities of companies and enterprises in the real sector of the economy and the financial sector. Restrictions on Russian companies' access to the international capital market have significantly reduced their business activity, forcing them to limit themselves mainly to the resources of the domestic market (Fig. 4).

Fig. 4: Structure of Russian companies' borrowings on the domestic market (in billion rubles)
(Source: compiled by the authors based on own research)

Under these circumstances, the implementation of national projects financed from the budget should have provided significant support to the real sector of the economy and the social sphere. However, the cost of fighting the pandemic has required the Government to reduce costs, including on national projects. For example, Federal budget expenditures on the National Project "Comprehensive Plan for Modernization and Expansion of the Main Infrastructure" will be reduced from 158 billion rubles to 92 billion rubles. by optimizing the cost of building seaports (by 54 billion rubles) and communications between economic growth centers (by 38 billion rubles).

Thus, the world and Russian economies came to the beginning of a new crisis with a certain load of unresolved problems.

In Russian and foreign scientific and analytical publications crisis 2020 is often compared to the previous financial crisis of 2008 (Table 1).

Table 1: Comparative analysis of economic crises 2008 and 2020 years

Criterion	2008 year	2020 year
Trigger	Crisis in the US mortgage market	The COVID-19 pandemic that started in China
Nature	Financial Global	Event-driven Global
Degree of exposure on the economy	Bankruptcy of major banks and financial institutions; The depreciation of the currencies of developing countries; Rising oil and gold prices; Job cuts and rising unemployment; Decrease in real incomes of the population; The drop in consumer demand	Closing or restricting the operation of public catering, tourism, passenger and cargo transportation companies for the period of quarantine and self-isolation, which affected their financial condition up to bankruptcy; The depreciation of the currencies of developing countries; Falling oil prices and rising gold prices; Job cuts and rising unemployment; Decrease in real incomes of the population; The drop-in consumer demand
Support measures economy	Support of significant financial institutions by national governments and Central banks; Lower interest rates.	Support by national governments and Central banks for small businesses and the public; Lower interest rates; Reducing the tax burden on businesses; Reducing the regulatory burden on financial institutions
Main factors influencing the recovery from the crisis	Reform of the financial system (financial markets and financial institutions)	The likelihood of a second wave of the pandemic and the introduction of repeated restrictive measures; Creating a vaccine

(Source: compiled by the authors based on own research)

Using previous experience, leading experts, analytical agencies and international institutions try to make forecasts on the timing and depth of the recession, determine the impact of the crisis on the global and national economies, develop new models of the post-crisis economy and financial markets, and etc. At the same time, they take into account existing global threats and risks.

The International Economic Forum in 2020 prepared a Report on Global Risks, that may affect the world in 2020 and in the next decade (Table 2).

Table 2: Risk map 2020

Risks	Content
Geopolitical instability	The national policies of many countries show strong divisions combined with increasingly unstable international relations. This volatility is likely to continue
Economic problem	As economic confrontations between powers grow, the global economy shows more signs of slowing down
Climate	Weak international agreements contradict the growing involvement of society in climate change issues. Public pressure on the government against the backdrop of many natural disasters will make 2020 a turning point for accelerating processes aimed at significantly reducing emissions and increasing investment in this area
Biodiversity reduction	Many ecosystems are in decline or at risk of extinction. The loss of biodiversity will have irreversible consequences for society, the economy and the health of the planet
Digital fragmentation consequences	Geopolitical and geo-economic uncertainty, including the possibility of fragmentation of cyberspace, threatens to hinder the full potential of next-generation technologies
New pressure on health systems	Health systems around the world are at risk of becoming unusable. New vulnerabilities resulting from changing social, environmental, demographic, and technological patterns threaten to offset the significant gains in well-being and prosperity that health systems have sustained over the past century

(Source: compiled by the authors based on own research)

Announced March 11, 2020 the beginning of the coronavirus pandemic and subsequent measures to combat it in conditions of restrictions and self-isolation by the World Health Organization (WHO) have made significant changes to the risk map, changing priorities and causing tension in society.

The beginning of the coronavirus pandemic and subsequent measures to combat it in conditions of restrictions and self-isolation which was announced by the World Health Organization (WHO) on March 11, 2020 have made significant changes to the risk map, changing priorities and causing tension in society.

At the same time, even in the pre-crisis years, problems related to disagreements in society caused by property and social inequality, political splits, etc. were growing. Key global trends in 2019. were recognized the following:

- deglobalization, the growth of nationalist sentiments and selfishness, the increasing obsession of the authorities to support state interests. Previously, the trend towards globalization was supported by the leading Western countries, which are now closing in on themselves, turning to protectionism (for example, Brexit);
- destabilization of the liberal economic order;
- expected global tightening of tax regimes in almost all countries;
- the growth of geopolitical unpredictability.

Grishin (2020) mentioned that the crisis of 2020 in the context of a pandemic has only strengthened these trends, and the globality and uncertainty of the situation, the dynamics of development processes, the lack of precedents and social experience in resolving it make it difficult to make real forecasts for the future.

Despite this fact, various international institutions, expert communities and individual governments publish forecasts for economic recovery after the crisis caused by the pandemic. First of all this is necessary for developing measures to support national economics, the social sphere, the formation of budget policy, etc. According to the World Bank experts, it will take 5 years for the global economy to fully recover. The Russian government believes that the country's economy will recover in about 3 years, but the rate of return of various industries to the indicators achieved before the pandemic can vary from one year to five years or more. We should also take into account the fact that the recovery of the national economy is impossible without the support of the state and the Central Bank.

Therefore, since the beginning of the crisis in Russia, unprecedented measures have been taken to support primarily small businesses, the most affected by the crisis and the population. This is evidenced by the adoption of a number of

resolutions by the Government of the Russian Federation and the approval of a Plan to Overcome the Economic Consequences caused by a New Coronavirus Infection.

The state's participation in overcoming the consequences of the crisis in the economy can be represented as a system (Fig. 5).

Fig 5: Support system for the Russian economy to overcome the consequences of the crisis
(Source: designed by the authors based on own research)

Consistency and targeting are the main factors determining the effectiveness of state support for all participants in the economic process. A more detailed structuring of the system will allow monitoring cash flows and the provision of non-financial support measures.

Along with priority support for small businesses and the population, the state pays considerable attention to corporate business in the non-financial sector as a support for the formation of a new post-crisis model of the economy. At present, almost all large companies and corporations were forced to change their business strategy under the influence of the crisis (regardless of the reduction, suspension or continuation of activities in full). The analysis of the existing experience of companies' performance during this period allowed us to identify the main principles of organizing their activities in the new conditions:

- diversification of the company's activities (offline and online) which allows to generate profit;
- temporary or final closure of a business that creates the possibility of opening another one;
- reduction of expenses (at least for the next three months) in order to determine the future prospects for business development;
- creating new products that attract the interest of customers.

Restrictive measures have effectively stopped the work of mass-consumer-oriented industries. Although recovery is relatively rapid after the quarantine is lifted, in the event of a second and subsequent waves of pandemics and repeated restrictive measures, the development of such sectors may again be at risk.

Exporting industries were not subject to large-scale restrictions during the anti-epidemic measures and continued to work throughout the first half of 2020. However, their return to 2019 indicators may be slow due to possible systemic problems or a significant imbalance in supply and demand. Several industries and companies have benefited from the crisis such as pharmaceutical and medical companies, manufacturers of medical equipment and inventory, IT-services, online sales, delivery, etc. These sectors of the economy include agriculture, because the issue of food security is a strategic one for each state.

Conclusion

There has never been a time in modern human history when a pandemic established the economic and social strategy of a society. In order to understand how long and how exactly we will get out of this situation, we needed to assess how much the current crisis is similar or not similar to the previous one (2008), which, according to many experts, still continues to have a negative impact on various areas of our lives. The analysis of previous experience and

prerequisites for the 2020 crisis allows us to assess the effectiveness of the state plan to support the Russian economy and get out of the crisis.

The main purpose of the plan is to overcome the recession caused by the epidemic and achieve a stable GDP growth rate, which will allow for a stable increase in real incomes of citizens. However, the atypical crisis that has protracted nature, and the influence of specific factors on its manifestation (the possibility of the second wave of the pandemic, forthcoming development of the vaccine and its effectiveness, health care situation) will force the Government to make adjustments in the approved plan. At the same time, at all stages of its implementation, it is necessary to observe the consistency and targeting of state support measures, as well as to carry out constant financial and public control.

In addition, it should be borne in mind that the current crisis is developing at the end of the current globalization cycle and, due to its features (quarantines, self-isolation and other restrictive measures imposed by individual countries), leads to the "regionalization" of the world economic system. Therefore, any state, including Russia, needs to learn to live in a new reality, where there will be a high degree of competition and uncertainty.

The Development of Products with Personality and Co-Created Products

Teodora-Iustina TUDOR

Polytechnic University of Bucharest, Romania
tr.iustina@yahoo.com

Nicolae IONESCU

Polytechnic University of Bucharest, Romania
ionescu_upb@yahoo.com

Abstract

The purpose of this paper is to assess the importance of co-created products and products with personality and people's reaction to them. In a world in which people want to stand out and be unique, this kind of products gain increasing importance by eliciting emotions and pleasant feelings. Thus, strong bonds are created between users and these types of products, and some of them end up being preserved long after they are unable to fulfil their primary functions. Products with personality and co-created products will become the future of design, because people have a growing desire to be surprised and intrigued.

Keywords: Product with Personality, Co-Created Products, Design, Emotions.

Introduction

The first contact between man and object – which is predominantly visual - sets the tone of his experience with the product design. Man reacts emotionally to everything around him, without necessarily interacting with people - tending to develop thoughts and emotions. We attributes human characteristics, states and feelings to things in our environment such as objects, plants, and animals.

Norbert Bolz describes how the emotional design strategy is used to endow objects with the illusion of depth and feeling. A designer aims at aesthetically modeling the product by integrating state-ofthe-art technology in an intuitive way, and putting the user first and the object second. Emotional design participates in the transfer of "interpersonal" values in the world of things, to induce a state of well-being and familiarity to the user. [Bolz, 1994]

The different ways in which designers treat things allows them to be inspired by the empathy for the emotional experiences of people who use with their product in their day to day life. From this idea emerges the concept that the user can and should be a key factor in the design process. [Sanders, Dandavate, 1996] This can take place in a context that generates the experience the consumer has with the product. It is necessary to plan in advance some scenarios of human - product interaction that involve all the senses and result in a pleasant experience which is intended to be repeated.

Not long ago, the emphasis was on the optimal functioning of the product and its ease of use. Now, these objectives began to give way to the pleasant experience that man derives from the product. This experience can simply mean a visual contact with the product or a complex interaction, but regardless of type, its sole purpose is to satisfy all human senses. However, the many challenges of research focused on the user's emotion, product personality and the user's contribution to the creation process led to this topic being vaguely and fragmentarily addressed. The few related studies of the last 20 years are sectoral approaches and do not fully address issues connected to the personality of products and their co-creation.

The role and importance of experience and emotion in design

Andrei Dumitrescu claims that the experience of design can be defined as a contact, even if only a visual one, with a product. According to him, the experience of a product falls into two broad categories: casual and projected experience. The user may have a casual experience when the creators only focus on product functionality and

Cite this Article as: Teodora-Iustina TUDOR and Nicolae IONESCU "The Development of Products with Personality and Co-Created Products" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

ergonomics, but the experience of the product (albeit ignored) exists, and it can be either felicitous or infelicitous. The projected experience generates a series of pleasant emotions such as satisfaction, pleasure or delight [Dumitrescu A., 2013].

In the past, designers devoted all their resources to make the product easy to use, ergonomically sound and eye-catching. In the last 30 years, they focused on positive experiences that the user can gain from interacting with the product. With new generations being captivated by the product's response to their reactions (even those of confusion), the consumer shows a general tendency towards surprise and amusement and seeks to relive this experience. This reaction has an important role in the purchase decision. At the foundation of this concept lies man's inclination to react to all things around him through emotions.

Another important aspect is the very wide variety of products nowadays, compared to the offer from 100 years ago, when the first products appeared. This forces designers to find new ways to differentiate their products from their competitors, focusing more on the emotional responses and experiences in the user-product relation, leaving functional benefits in the background [Diener, Lucas 2000].

Pieter Desmet argues that “skilled designers understand the strong appeal of emotions and have used their intuition and artistic skills to exploit this aspect” [Desmet, 2002]. For them, the design process that arouses increased interest on the user side comes from creating products that involve emotion in design, by bringing together two contradictory terms. As William Green says, design involves order and reason, while emotion brings irrationality and spontaneity. [Green, 2002]

Man's perception of his objects changes throughout time. If at first, it is more or less a necessity, as the years go by, the object gains emotional value, through the memories and emotions created around it. This feature cannot be given by a designer, it is a personal contribution that goes beyond the traits predefined by the creator. Norman reinforces this idea by stating that the objects in our environment represent much more than material possessions, they gain a value through the meaning they bring to our lives, becoming a symbol. [Norman, 2004].

The century we live in is constantly developing, consumer expectations increase day by day. Whether they are influenced by marketing strategies, trends or advertisements, the requirements for consumer products have changed. If until recently, designers and users appreciated the functionality, ease of use and attractiveness, now these qualities are taken for granted. Moreover, they have higher expectations from everyday products. The task of the designer is hampered by new standards, because the consumer doesn't only expect a product to perform all its functions correctly and quickly, but he also looks for a message to respond to.

The emotional response is the result of an interaction that takes place in a given context between an individual and a product. Donald Norman argues that the emotional aspect of the product can replace functional ones stating that “... there is also a strong emotional component of how products are designed and used, more critical to a product's success than its practical elements" [Norman, 2004] .

Desmet and Hekkert launch three key concepts designed to outline the process of triggering emotions, being represented by a series of stimuli that come from a product: concern and appreciation. [Desmet, Hekkert, 2002]. Unfortunately, analyzing these models we can identify an important element that is missing, namely, the designers' lack of preoccupation for the characteristics of the object to which the subject will react. Chakrabarti and Gupta thus remark that “the subject is capable of a variety of responses and it is unlikely that those consistent patterns between them and objects will be found" [Chakrabarti, Gupta, 2007]. Psychologist Robert Plutchick has created a model that includes eight universally valid human emotions as follows: acceptance, anger, anticipation, disgust, joy, fear, sadness and surprise. [Plutchik, 1980] Based on these eight emotions and the three basic states of arousal established by Ekman, Chakrabarti and Gupta developed the “Emotional Response Model” - ERM, representing the characteristics of the object that are stimuli for the user. The subject's preferences trigger one or more emotions. They argue that "emotional traits provide the bridge between object traits and primary emotions." [referinta] The model of the two stipulates that a number of characteristics of the object have direct relationships with the emotional traits, that in turn have a specific relationship with the eight primary emotions, the evaluation process being facilitated by the structure of the model [Chakrabarti, Gupta, 2007].

The attachment for the product is defined as the power of the emotional connection experienced by man with a product, thus involving the existence of an emotional connection between a user and an object with a significance for him. [Schifferstein and Pelgrim 2004] Creating the emotional relationship in design is based on a series of moderate emotions of surprise, delight, satisfaction and pleasure, so that the user can decide what matters to him; there is no need to arouse high-intensity emotions that are experienced on the first contact with the product, but rather numerous small pleasures [Andrei Dumitrescu, 2013]. Due to the personal nature of the emotions, the user has complete freedom

regarding their type and degree of intensity. There is no valid general relationship between the appearance of the product and the emotion it generates.

The experience can also be induced through advertising. The manufacturer simulates a possible situation in which the buyer lives a pleasant experience in relation to the presented product, which triggers an emotional relationship with it.

Fig.1: Hornbach's advertisement that induces emotion by simulating an experience [1]

Experience is equally important for designers who may have informative personal experiences that make it easier for them to understand current issues and feel greater empathy for the people who will be influenced by their decisions. The ability of designers to access buyers' experiences through a number of methods such as listening, observing and deducing customer wishes gives them the satisfaction of generating pleasant emotions [Sanders, Dandavate, 1999].

After building the sentimental relationship between man and product, the occurrence of several disruptive factors can decrease consumer satisfaction with the product, one of which is perceptual wear and tear. This happens after the purchase, when the person sees the product very often, thus the emotions that stirred him at the beginning have diminished now. The buyer compares the new product purchased with the old purchases or with the best similar alternatives on the market, because the objects in his life represent much more than simple material goods [Andrei Dumitrescu, 2013]. He identifies with the success of purchasing the best product to experience positive emotions such as feelings of pride, self-esteem and achieving a goal by buying something useful. Sometimes, for the sake of reliving these emotions and changing his mood, the buyer may exaggerate, purchasing several similar or unnecessary products.

Fig.2: Varied range of products that are part of the same family[2]

The comparison can be made before the purchase, when the buyer shapes an opinion about the product, looking for as much information as possible about similar offers on the market. The comparison stirrs feelings of confusion and disorientation due to the multitude of varieties on the market. Advertising is of major importance in this case. It provides the buyer with a series of selective information that highlights the product and presents its functions. Although superficial, it gives the buyer confidence and can have decisive power in choosing the product.

Fig.3: Advertisement presenting selective information about the product[3]

Although these two rules can work for many products, on the market, there are inventions that have failed to generate an emotional relationship with the user, despite their intense and long-term use. The telephone and the computer are two of the most indispensable products nowadays, used consistently throughout the day, either at work, or - most frequently - during spare time. Despite the fact that phones gained a remarkable importance in social relationships and can also generate strong emotions when being used, Norman notes that the product fails to instill affection. [Norman, 2004]

The typologies of emotions can be classified in terms of the feelings it arouses. Desmet initiated several methods to quantify the emotions transmitted by products. He relied on numerous researches which show that facial expression and body language are universal, and to support this assumption, he used photographs and short animations that suggest the expression of emotions using his face, hands and body. These 14 emotions established by Desmest make up an instrument called "PrEmo", and fall into two main categories: negative emotions and positive emotions. The conclusions of the study conducted by Pieter Desmet is that that "there is no one-to-one correspondence between design and the emotion the product produces; it is not a mere emotion, but the meaning that the product has for the customer". [Desmet, 2002] However, many products manage to induce such strong emotions that some people end up loving them, and others deeply disliking them. It follows that different products will succeed in satisfying one type of people, while failing to do so for another type.

Numerous studies have shown that attractive products keep their function longer, because they are used with more care. The variety of emotions aroused by the product can fuse into a strong feeling of affection called attachment, which differs from the others by increasing in intensity over time.

Attachment is defined by Mugge as "the strength of the emotional connection that the consumer experiences for a certain product" [Mugge, 2007]. An important advantage of this attachment is the lasting connection between man and product, which prevents him from giving up the product even when it breaks down or no longer fulfills its default functions. Belk states that when a person is attached to a product that belongs to him, it is very possible to treat it with care, postponing the replacement of the product by repairing it when it breaks down" [Belk, 1991].

Emotions help us perceive the environment beyond the rational elements, after we go through a physical perception through our senses. They are meant to create relationships based on how we feel around an object, being or person. Depending on the experience, the user tends to associate a product with memories, feelings and emotions. This information is difficult to identify and manage for each individual, and even more so for the masses. Nonetheless, its impact is difficult to neglect. Based on a series of general emotions encountered, researchers in the field have come to the conclusion that by managing and dosing the positive and negative emotions generated by products, the decision-making process can be influenced to a great extent. Thus, the buyer is impressed by products that stir positive emotions and kindle his interest through the complexity of its features put together in an attractive and intuitive way, while being discouraged by products that seem difficult to use and don't have an appealing appearance.

Products that stir emotions are sustainable, because they determine the user's attachment over time and his inability to give up the product easily, postponing its replacement by consecutive repairs or keeping it for years despite not being used anymore.

Definition and classification of the personality of the products

In the promotion and sale of products, three different practices are encountered: product personalization, customized products and product personality. The common goal of these is the adaptation of marketing strategies to the user's

interest by improving his experience in relation to the product, but also include a number of elements which differentiate them.

Product personalization “aims to create individual communication with a single consumer or consumer segment". [5] The customized product differs from the product available on the market in that it is individually designed and has a unique character depending on the customer's need. Thus, it stands out from the standard product through shape, size, material and even components. Personalization uses basic demographic information, behavioral patterns, and buying preferences with respect to craft marketing experiences for a specific audience segment [5].

Customization is initiated by the user according to his preferences and claims to the product expressed directly through target information to meet his own needs, for which he is willing to pay more [6]. Customization responds to a real need that the customer cannot give up or satisfy through the rest of the standard products on the market. Stan Davis provides a complete definition of the term "customization", described as "the process of delivering goods and services on the broad market that are modified to meet a specific customer need" [5].

The personality of products, unlike customization and personalization, involves characteristics of the human personality and attributes them to the products man comes into contact and identifies with. Thus, that product passes from the sphere of mass-produced goods, to that of a different product, enriched with human-like qualities and features, that the consumer can identify with and treat with care and attention.

The product can be defined as a lifeless object produced as a result of a design activity, with a predefined shape, functionality and appearance. The product can be devoid of personality in the first stage of its existence. Over time through contemplation and usage, it manages to create an emotional relationship with the user, thus gaining a personality similar to thiers.

Pascalle Govers states that “Product personality is the profile of personality traits used by people to describe the specifics of the product and differentiate it from other products” [Govers, Mugge 2004]. Patrick Jordan considers that it represents a set of characteristics of the human personality used in the description of the specificity of a product [Jordan, 1997].

Bloom argues that personality is "a process that changes the functionality, interface, information content, or distinctiveness of a system to increase personal relevance to the individual" [Blom 2000].

Andrei Dumitrescu offers a more comprehensive definition stating that “the personality of the product is the set of strongly outlined features of the human personality used by man to distinguish the product from others and to justify the sentimental relationship with it” [Dumitrescu, 2013].

The congruence theory launched by Patrick Jordan in 1997 in the article "Product as Personalities" argued that the personality of future buyers is reflected in the design of new products that will achieve success [Jordan, 1997]. After launching this theory, many other authors have stated that the similarity between the personality of the products and that of the user have a beneficial contribution on the attachment that occurs between the buyer and the product. Among them are Govers and Mugge, who claim that the process of identifying a person with the personality of a product determines a positive influence in the perception and evaluation of the product [Govers, Mugge, 2004].

As Congruence Theory holds, people tend to make a comparison between the concept of self and the image of the product, preferring those products that have an image compatible with their self. They identify their own personality traits and look for products consistent with themselves [Aaker, 1999] and [Govers and Schoormans 2005].

The development of the relationship between user and product has a significant positive contribution to the success of the product and the extension of its life. The most precious objects of a man are not necessarily those with a significant material value, but the things that could be difficult to replace, to which he becomes strongly attached. It is not the material loss of the product that the owner regrets, but the emotional loss that he suffers as a result of investing time and developing feelings about the product [Schultz, Kleine and Kernan 1989]. An emotional relationship between a person and a product requires similarity of personality, so that they become more attached to products with a personality congruent to theirs, thus strengthening the theory of congruence and the concept developed by Schultz, Kleine și Kernan. [Ruth, Hendrik and Jan, 2005].

Dumitrescu classifies the relationship determined by the personality of the product into two broad categories: either perceived at the individual level or at the general level. At the individual level “the personality of the product is the result of the interaction of each user or contemplator with the respective product”, and at the general level “the personality of the product is generated by the creator and producer”. Thus, the personality of the product stands out when considering aspects related to the appearance and dynamics of the product [Dumitrescu, 2013].

Thus, the role of designers in designing products with personality becomes very important, because it can stimulate the attachment to the product and extend its life, provided it has a classic rather than a modern design.

One of the potential problems that arise in the design of products with personality is given by the fact that designers and users may perceive the meaning of products differently [Hsu et al., 2000].

Wishing to perfect the design process to make products with personality, many authors have developed a series of methods to analyze people's perception of the product personality in relation to their own personality. A convenient method is the statistical survey in which a number of subjects are asked to associate different personality traits with a predetermined product. If there is unity in the subjects' opinions, then the product is considered to have personality. Otherwise, if opinions are strikingly different, it results that the product does not have a clearly defined personality. Janet Finch believes that the surveys come with a series of formulation and coding constraints around the questions, which aim at predicting a series of actions based on the answers provided by the participant. The scenario method yields much better results provided the purpose is obtaining general images, and not details.

Patrick Jordan builds a rather controversial model considered difficult to understand and apply, it was based on the model from psychology called Briggs-Myers. It was considered difficult due to its cumbersome terminology, making it increasingly difficult for ordinary people who had no contact with the field of psychology to deepen it. [Jordan, 2002].

Andrei Dumitrescu proposes a model inspired by that of Jordan, based on an experiment that confirms the validity of the concept and the analyzed personality traits. The experiment achieved its goal, with the first objective being that of successfully testing and validating the concept of product personality and not evaluating the personality of the products used in the experiment [Dumitrescu, 2007]. This scale has the advantage that it can be used to compare different products belonging to the same category - necessary to evaluate a product in relation to its competitors, as well as products belonging to different categories. This comparison contributes to the creation of a database of reference products which have different personalities - a source of inspiration for designers.

The user tends to invest more time analyzing the product to determine how it works and pays more attention to it. Janlert and Stolterman argue that this interaction is greatly influenced by the appearance and personality of the product. [Janlert and Stolterman, 1997]

Product personality can help determine the user anticipate how to use and interact with the product. Intuitively, the user shows involvement in interacting carefully with a product that has a delicate, sensitive personality and design.

The user's preference is guided by his own personality which he involuntarily seeks in the things and objects around him to confirm his identity [Govers and Mugge, 2004; Govers and Schoormans,
2005]. The desire to express his personality and find it in the things around him is also supported by Jordan: "it is about people's desire to assert their individual identity in an increasingly impersonal world" [Jordan, 2000].

Today's consumer is in a constant search for objects to help him stand out, and to satisfy his desire to be noticed and appreciated in a group. Sirgy states that possessions of personal identity are particularly important, as the use of products is a means of defining and symbolically expressing ones' identity [Sirgy 1982]. The user gains a state of comfort by the fact that his products help him to stand out in society. Sener and Kurtgozu explain that products can be useful in increasing our emotional communication, self-expression and other personal traits. [Sener and Kurtgozu, 2008]

It is known that some people invest impressive amounts of money in products that reflect their personality and help them improve their mood, shifting from a necessity to a means of expression.

Products become a tool through which people express their personality in front of others and the fastest way to stand out in a group. Objects enable them to connect more easily with new people and reconfirm their unique character in front of acquaintances, giving them confidence and balance. A product with personality stands out and is immediately identified by the user. It is also analyzed and labeled as appropriate or not to his own personality. The consumer's behavior changes in relation to a particular product, stirring his interest and causing him to handle it with more care. Products with personality are given a remarkable importance by the user. He comes to interact with them much more than with other products in the same category and that do not have a clearly defined personality.

3.Definition and classification of co-created products

At the foundation of the growth and continuous improvement of a company that wants to become a key player in the market lies the process of developing new products. Since a large volume of innovative ideas is required to properly meet the wishes and needs of customers with the possibility of reducing the huge costs of study and research, more

and more companies choose to use the concept of co-creation. It is a process of designing a product or service in which the consumer is actively contributing with their own ideas and suggestions, bringing uniqueness and innovation to the product.

In an article, Jhon Czepiel suggests that the customer's input can lead to greater satisfaction [Czepiel, 1990]. Authors Kelley, Donnelly, and Skinner bring to the forefront a number of benefits that arise from customer involvement in the production process, namely: quality, employee performance and emotional responses [Kelley et al., 1990].

Consumption is an extremely symbolic cultural activity through which consumers give subjective meanings to products and services. Thus, from the cultural perspective of consumer studies, cocreation pushes companies to be responsible for setting the value of goods and services [Holbrook and O"Shaughnessy 1988, Belk et al.1989].

Michael Schrage points out that the ability of clients to provide valuable ideas and suggestions should not be neglected, but it cannot be considered a valence present in every client, implying a selection is needed [Schrage, 1995].

The co-creation process helps firms improve the growth and profitability of companies by enabling customers to play an active part [Prahalad and Ramaswamy, 2000]. At the same time, it is acknowledged the importance of marketing a product based on the process of co-creating its value through the exchange of knowledge and opinions. This takes place between customers and partners who develop a service orientation based on common values creation. [Vargo and Lusch, 2004] In the process of collaboration, exchanges of opinions and arguments take place, unique experiences are created and are meant to bring consumers and companies closer in a collaborative relationship, with benefits on both sides. [Prahalad and Ramaswamy, 2004]

Aric Rindfleisch and Matt O'Hern defined co-creation as a collaborative NPD (product development) activity in which customers actively and constantly contribute to the selection of content for a new product offer to be launched on the market. It consists of two stages: customers' contribution with ideas/suggestions, and the rigorous selection of the best input. Thus, customers become "essential participants in the product development process and in some cases, are able to create new products with little help from companies" [O'Hern and Rindfleisch, 2008]. The authors reinforce this definition by offering as examples successful computer applications such as Apache, Linux and Firefox, which are projects managed exclusively by communities organized by volunteer programmers.

Companies seek to surprise their consumers with a series of interactive challenges that enable customers to customize the products they purchase. For example, www.nike.com provides customers with a Nike By You page that allows them to customize their own shoes, choosing from a wide range of colors and details.

Fig.4: Example of products that can be customized by consumers[4]

For a healthy evolution of the product development process, two types of fundamental information are needed: 1-information about customer needs and 2-information about how these needs can be met [Thomke and von Hippel2002; von Hippel 2005]. Manufacturers have solid and accurate knowledge of how they can meet customer needs, investing

and working constantly to do their best. A shortcoming of information about customer needs has steered large investments go into marketing research with the purpose of shedding more light in this area.

Von Hippel and his colleagues have found a way to deal with this imbalance between known and hard-to-obtain information, by providing customers some knowledge and tools to actively participate in product development [Thomke and von Hippel 2002; von Hippel 2005; von Hippel and Katz 2002].

Starting from the idea supported by Belk, Richins and Dawson, that material objects do not have the capacity to respond to intrinsic psychological needs. Psychologists in the field claim that only by stimulating creativity these needs can be met [Csikszentmihalyi, 1996]. Thus, bringing customers in the product creation process gains more ground and is facilitated by the development of the Internet.

Contribution and selection are two key processes which underline co-creation and are presented by O'Hern and Rindfleisch. They give rise to a conceptual typology of four forms of co-creation. The contribution process trains the public to offer the company a series of ideas, while the selection process picks the most promising contribution. The four types of co-creation are: collaborating, tinkering, co-designing and submitting, which are delimited according to the control exercised by the company or the public over the two components of the co-creation process.

This classification of the co-creation process represents a real progress compared to the traditional approach, first in the way customers are viewed and treated, and secondly by the role they play. [O'Hern and Rindfleisch, 2008]

The co-creation process benefits both the consumer and the company that adopts such a process for its services. Thus, we can distinguish the collection, classification and analysis of consumer preferences in order to provide real-time information, as well as make them known to the merchant. Reviews are another source of useful information for both parties. Reviews are designed to provide honest opinions and information to prospective buyers, as well as a feedback to the company [Zwass, 2010].

Conclusions Regarding the Strategies Studied

The concepts elaborated in this article represent an important starting point in terms of strengthening the relationship between user and product. This also brings to the table ideas like the user's emotion, the product's personality and the user's contribution in the creation process, with the benefits of discovering a fresh perspective on this topic. I believe that emotion in design is closely related to the user experience, leading to attachment and then nostalgia. Research has shown that the emotional product-consumer bond improves personal satisfaction and life quality. The personality of the product has a pertinent contribution in terms of the user's self-esteem, making him stand out from the crowds that use mass products. Thus, co-creation is the missing link in a complete strategy regarding the optimal product development process in which the customer brings his personal touch to a product that manufacturers are now so eager to bring forth. I consider that the studied concepts play a role in creating the best version of products for consumers and if combined, they can meet their goal better than independently.

Design of Payment Rates for Pollutant Discharge into Water Bodies

Maria P. IVANOVA
National Research Tomsk Polytechnic University, Tomsk
Russia, margo-sea@yandex.ru,

Tatiana O. TAGAEVA
Novosibirsk State University, Novosibirsk, Russia
to-tagaeva@rambler.ru

Abstract

While understanding that the environment is a set of components allowing for provision of environmental sustainability, special priority should be given to the issues of adverse impact on nature, particularly, the problem of quality deterioration of water bodies when polluted with harmful substances in the process of socio-economic development. In this case, an indispensable component of thorough treatment of the issue is solution of the problems in the sphere of rental resource management, namely, monitoring of payment rates for pollutant discharge into water bodies. Numerous investigations in this sphere allow for efficient treatment of the problem of the negative impact on the environment, providing favorable environmental condition. The above mentioned issue necessitates a throughout consideration of multiple calculation principles of payment rate for pollutant discharge into water bodies. Thus, the authors suggest an auxiliary principle of calculating such payment rates using simple logarithmic equation.

Keywords: Water Bodies, Payment Rate, Environment, Pollution, Equation.

Introduction

The present paper focuses on the issues of environmental protection via paying for adverse consequences in the process of chemical discharge polluting water bodies. In this case, much attention is paid to reasonable and adequate functioning of appropriate mechanisms for calculation of adverse impacts on the environment.

In the process of interacting with the nature, there appears a risk of negative impact on it. To date, consideration and analysis of such issues is rather topical, since quality of water bodies is strongly influenced by thorough treatment of this problem (Ryumina Ye.V, 2019, Ershov D.N., 2019).

For example, in Tomsk Oblast there is regular monitoring of surface water condition. The results of such monitoring are reflected in annual state reports (State reports "On the state and protection…", 2014-2018). According to the monitoring results on water body pollution (within the period from 2014 to 2018) presented in these reports, one can observe the dynamics of changes (table 1, table 2).

Table 1: Dynamics of water body pollution growth with harmful chemicals in Tomsk Oblast

Pollutants	2014/2018	Pollutants	2014/2018
Boron	+174%	Nitrites	+35%
Phenols	+120%	Urea (carbomide)	+19%
Sulphates	+63%	SSAS (synthetic surface-active substances)	+16%
Ammonia nitrogen	+54%	Fluorine	+10%
Zinc	+53%	Chromium 6+	+7%

Source: Author creation (2020)

Table 2: Dynamics of decrease in water body pollution with harmful chemicals in Tomsk Oblast

Pollutants	2014/2018	Pollutants	2014/2018
Phosphates (P)	-1%	COD (chemical oxygen demand)	-24%
Dry residue	-2%	Suspended substances	-26%
Nitrates	-4%	BOD full (biochemical oxygen demand)	-32%
Formaldehyde	-7%	Manganese	-45%
Copper	-10%	Petrochemicals	-60%
Iron	-15%	Nickel	-78%
Chlorides	-19%	Aluminum	-100%
Lead	-23%	Methanol	-100%

Source: Author creation (2020)

Despite the dynamics of water body pollution growth in Tomsk Oblast, there are some substances which significantly decreased over 5 years (starting from 2014) (table 2, fig. 1).

Fig. 1: Trend chart of pollutant discharge decrease in water bodies of Tomsk Oblast (2014-2018)
Source: Author creation (2020)

In terms of some components their discharge into water bodies of Tomsk Oblast increased over the recent 5 years (from 2014), which is shown in the chart (fig. 2).

Thus, according to Table 1 and chart 2, one can state that a large volume of harmful substances are discharged into the surface water bodies of Tomsk Oblast without special treatment (State reports on condition and environmental protection in Tomsk Oblast", 2014-2018).

Fig. 2: Trend chart of pollutants discharges into water bodies of the Tomsk region (2014-2018)
Source: Author creation (2020)

The above studies indicate the need to monitor additionally negative discharges into water bodies and, first of all, by means of the methods used to charge payments for these consequences.

Results and Discussion

Due to the fact that one of the economic control instruments is considered to be the methodology to determine the payments rates for a negative impact on the environment, a deeper assessment is necessary to present an alternative concept for calculation of such rates, since the detailed study of such calculation methods will influence the state of nature as a whole.

If we consider some regulatory documents in relation to environmental quality control, we can identify different kinds of discrepancies in the data concerning the amount of pollutants and the possibility to charge fees for these substances in the process of the negative impact on water bodies. Thus, the document (Resolution No. 78, 2017) regulates the values of maximum permissible concentrations (MPC) of 1363 substances in the water of water bodies for drinking and household and amenity needs of water use. While, according to the document (Resolution No. 913, 2020), there are payments rates for discharges of only 159 pollutants into water bodies. Thus, about 90% of all MPC of substances discharged into water bodies does not seem possible to take payments in case of negative consequences.

For this reason, the authors offer to consider an alternative approach to the existing calculation algorithm of the payments rates for the negative impact on water bodies, in the discharges process of pollutants into water bodies, taking into account the MPC, thanks to which an appropriate assessment of real environmental hazard is possible.

To define an alternative approach for determining the payment rates, the data of the maximum permissible concentrations of chemicals in the water of water bodies for drinking and household and amenity needs of water use, and data of the payment rates for discharges of 46 polluting substances were used. Due to the fact that the linear display of data in Figures 1, 2 would not show a proper visual understanding of the problem of the ratio of payment and the quantitative discharge of pollutants, and to display the data, decimal logarithms of the necessary indicators were used (Fig. 3).

Fig. 3: Dependence of MPC and payment rates for 1 ton of polluted water
(Y is the payment rate for 1 ton of pollutants, X - value of MPC of pollutants)
Source: Author creation (2020)

The results of the dependence analysis of the existing data on the payment rates and the maximum permissible concentrations of chemical substances in the water of water bodies of drinking and household and amenity needs of water use can be estimated in Figure 4.

It became possible to show the formula during the experiment (Fig. 4).

The straight line shown in Fig. 3 can be described by the following function:

$$\lg Y = -0.8955 * \lg X + 3.5269, \quad (1)$$

where Y is the payment rate for 1 ton of polluting discharges into water bodies,
X - value of MPC of pollutants.

Fig. 4: The change trend of MPC and payment rates for 1 ton of polluted water (Y is the payment rate for 1 ton of pollutants, X - value of MPC of pollutants)

Source: Author creation (2020)

Formula 2 (based on formula 1) is an equation to calculate the non-available payment rates for discharges of harmful substances into water bodies.

$$Y = 10^{(3.5269-0.8955*\lg X)}, \quad (2)$$

where Y is the proposed payment rate for 1 ton of polluting discharges into water bodies,
X is the value of MPC of pollutants.

Conclusion

According to the problem studied in the article, we obtained the data based on the analysis to conclude that in some documents the data is inconsistent. Considering the above, it can be proposed that a detailed study of this problem has made it possible to present an alternative approach to charge fees for discharges of pollutants. The definition of such an approach to the study allowed the authors to show an additional principle for calculating the rates at which fees are charged for discharges of harmful substances into water bodies. This approach became possible due to the logarithmic equation, with the hazard of each substance to be taken into consideration during calculation.

Thus, the application of the concept mentioned above will provide the possibility to eliminate the disadvantages related to the absence of payment rates for discharges of pollutants into water bodies.

Abstract

The article deals with the analysis of economic, financial, scientific and technological conditions for regulating clustering processes and innovative development of the Volga region. The subject of the study is innovative transformation of the regional economic space. The aim of the work is to analyze the processes of innovative transformation of the economic systems of the Volga region regions. The scientific novelty of the work lies in the method of complex analysis of the potential of innovative development of regions. The proposed methodology includes both indicators for assessing the factors of formation of a new innovative economy, and indicators of the effectiveness of innovative development, which form the technological and resource reserve for further economic development of the region. The advantage of using proposed methodology is the possibility of separating for each economic district and interregional cluster the leading regions, which acts as the center of innovative transformation of the economic space of the neighboring regions. It is concluded that the key regions for innovative transformation are Samara region and Republic of Tatarstan.

Keywords*:* Clusters, Institutional Development, Innovative Potential, Scientific and Technical Development.

Introduction

In modern conditions, increasing the region's competitiveness through innovative transformation is a fundamental element of development strategies in most of the majority of countries (Solvell, Lindqvist & Ketels, 2003). At the same time, support for cluster initiatives becomes an important factor in innovative development (Porter and Ketels, 2009). A network of innovation clusters is also being formed in the Russian Federation on the base of the experience of the world's leading economies. Despite the fact that the distribution of cluster initiatives covers all Federal districts of the country, their number in the district, the scale and level of development differ significantly (The concept of long-term socio-economic development of the Russian Federation, 2008). The economic space of the Volga region is also significantly differentiated by the level of innovative development and the degree of production clustering (Bodrunov, 2013). The distribution of successfully implemented cluster initiatives by Federal districts is shown in table 1.

Table 1: Number of successfully implemented cluster initiatives in the Federal districts of the Russian Federation

Note the high cluster activity of the subjects of the Russian Federation that are part of the Volga Federal district. The most developed regions of the Volga region in terms of cluster formation and development are traditionally considered to be the republics of Tatarstan and Bashkortostan, Perm, Samara, Ulyanovsk and Penza regions (Maksimov, 2014). At the same time, it should be emphasized that the pace of activity in implementing cluster initiatives has decreased since 2014-15, both in Russia as a whole and in the Volga region.

A significant number of works by leading researchers and research teams are devoted to the study of clustering economy (Hart, 2006; Lindqvist, 2009; Ketels, 2013). At the same time, the processes of innovative development in the Volga region and their relationship with the cluster policy of regional development remain insufficiently studied. The need for a detailed assessment of the processes of changing the innovation potential of the Volga region regions at the first stage of implementing cluster policy in the Russian Federation determined the purpose and objectives of this study.

The purpose of the study is to analyze the processes of innovative transformation of the economic systems of the Volga regions, as well as the features of the spatial distribution of the potential for the formation of an innovative economy in the context of cluster policy. The study set the following tasks:

- development of a system of indicators for evaluating innovative regional innovation systems;
- analysis of the potential for innovative development of the Volga region regions in the context of clustering features of their economic systems;
- defining the features of innovative transformation of the Volga region's economic space.

Research Methodology

To assess the innovative transformation of the economic systems of the Volga region regions, the author developed a method for a comprehensive analysis of the potential of innovative development of the regions. The proposed methodology includes both indicators for assessing the factors of formation of a new innovative economy, and indicators of the effectiveness of innovative development, which form the technological and resource reserve for further economic development of the region.

The final index of the region's innovative development potential (IRIDP) is formed on the basis of four sub-indices that reflect the key factors and directions of development of the innovative economy. These four sub-indexes include the following:

- index of economic potential of innovative development (IEP-1);
- innovative development human resources index (IHRP-2);
- the index of financial potential of innovative development (IFP-3);
- index of scientific and technological potential of innovative development (ISTP-4).

These subindex in turn are formed from the second level subindexes and separate indicators of innovative development of the region, calculated by Federal state statistics service of the Russian Federation. Indicators and subindexes of the potential for innovative development of regions are presented in table 2.

Table 2: Indicators and sub-indices of the region's innovative development potential

Indicators and sub-indices of the region's innovative development potential	Convention
1. Economic potential of innovative development of the region	IEP-1
1.1. Economic development of the region	IEP-1.1
1.1.1. Gross regional product per employed resident of the region	IEP-1.1.1
1.1.2. The coefficient of renewal of fixed assets in the region	IEP-1.1.2
1.2. Effectiveness of innovative development of the region	IEP-1.2
1.2.1. Share of innovative goods, works, and services in the total volume shipped by industrial enterprises	IEP-1.2.1
1.2.2. Share of innovative goods, works, and services new to the market that have been newly introduced or have undergone significant technological changes in the total volume shipped by industrial enterprises	IEP-1.2.2
2. Personnel potential of innovative development of the region	IHRP-2

2.1. Human resources potential of the knowledge-intensive and high-tech sectors of the economy	IHRP-2.1
2.1.1. Share of employees in high-tech industries in the total number of employees	IHRP-2.1.1
2.1.2. Share of employees in knowledge-intensive service industries in the total number of employees	IHRP-2.1.2
2.2. Educational potential of the region	IHRP-2.2
2.2.1. Share of the population with higher education in the total economically active population of the region	IHRP-2.2.1
2.2.2. Number of students enrolled in higher education programs by 10 thousand. inhabitant of region	IHRP-2.2.2
2.3. Personnel potential of regional science	IHRP-2.3
2.3.1. The ratio of the average wages of employees engaged in R&D in the average salaries in the region	IHRP-2.3.1
2.3.2. Share of employees engaged in R&D in the average annual number of employees in the region	IHRP-2.3.2
2.3.3. The share of young researchers total number of researchers in the region	IHRP-2.3.3
2.3.4. The ratio of researchers with a degree in the total number of researchers in the region	IHRP-2.3.4
3. Financial potential of innovative development of the region	IFP-3
3.1. Budget financing of innovative development of the region	IFP-3.1
3.1.1. Share of expenditures on civil science from the consolidated budget of the region in the total amount of expenditures	IFP-3.1.1
3.1.2. Share of expenditures of the consolidated budget of the region in the total amount of expenditures on technological innovations	IFP-3.1.2
3.1.3 Ratio of Federal subsidies for the development of innovative infrastructure to the gross regional product	IFP-3.1.3
3.2. The R&D funding at the expense of own funds of organizations	IFP-3.2
3.2.1. Internal costs on research and development in % to gross regional product	IFP-3.2.1
3.2.2. Internal costs on research and development per researcher in the region	IFP-3.2.2
3.2.3. Share of expenses of commercial organizations in the total volume of internal expenses of organizations for R&D	IFP-3.2.3
3.2.4. Intensity of expenditures on technological innovations by industrial enterprises	IFP-3.2.4
4. Scientific and technological potential of innovative development of the region	ISTP-4
4.1. Scientific potential of innovative development of the region	ISTP-4.1
4.1.1 Number of published scientific articles per 10 researchers in the region	ISTP-4.1.1
4.1.2. Number of patent applications for inventions per 1 million of the economically active population of the region	ISTP-4.1.2
4.1.3. Number of advanced production technologies created per 1 million people of the economically active population of the region	ISTP-4.1.3
4.1.4. The ratio of the volume of revenues from technology exports to the gross regional product	ISTP-4.1.4
4.2. Technological potential of innovative development of the region	ISTP-4.2
4.2.1. Share of industrial enterprises that implemented technological innovations	ISTP-4.2.1
4.2.2. Share of industrial enterprises that implemented organizational and marketing innovations	ISTP-4.2.2
4.2.3. Share of industrial enterprises that have developed and implemented technological innovations on their own	ISTP-4.2.3
4.2.4. Share of industrial enterprises implementing joint research projects	ISTP-4.2.4
4.2.5. Share of small enterprises that implemented technological innovations	ISTP-4.2.5

Developed by the author

When calculating the region's innovation development potential index (IRIDP), as well as sub-indices of both levels, all indicators are used with equal weight coefficients. At the same time, the initial values of indicators should be normalized in order to be able to use them within a single methodology. Accordingly, the region's innovation development potential index (IRIDP) is calculated using the following formula:

$$\mathrm{IRIDP}^r = \frac{1}{n}\sum_{i=1}^{n}\frac{x_i^r - x_i^{min}}{x_i^{max} - x_i^{min}}$$

IRIDP^r – index of innovative development potential of the *r*-th region;

n – number of indicators of the region's innovative development potential used for calculating the final index (*n*=28);

x_i^r – value of the *i*-th indicator of innovative development potential in the *r*-th region;

x_i^{max} – the highest value of the *i*-th indicator of innovative development potential in the analyzed sample;

x_i^{min} – the lowest value of the *i*-th indicator of innovative development potential in the analyzed sample.

Information base of the study

In addition to official statistical data from Rosstat (2020), data from «Rating of innovative development of the subjects of the Russian Federation» (Gokhberg and others, 2020) published by the National Research University Higher School of Economics (HSE) were used as an information base for calculating the region's innovation development potential index (IRIDP). The indicators used to compile the Rating, as in the proposed methodology, are formed on the basis of official statistics. Methodological benefits of using a HSE rating is: balanced (normalized) for all 85 subjects of the Russian Federation of the values of indicators of innovative development, estimation of degree of asymmetry of a distribution relative to the average value. It is worth noting the large amount of work done by the team under the leadership of L.M. Gokhberg, as well as the ease of using the information provided for further research. The disadvantage of this rating is the lack of data for 2016, while based on the dynamics of clustering processes (table 1), a methodological assumption is made to use data from 2013 to 2015 (the "third wave" of clustering of the Russian economy) and 2017 as the result of five-year development.

The grouping of regions was carried out on the basis of the author's model of clustering of the economic space of the Volga region, within were identified 2 macro-regions (Volga-Kama and Volga-Ural); 4 districts (Volga-Vyatka, Kama, Middle Volga and South Pre-Ural), as well as 4 interregional clusters (Nizhny Novgorod, Kazan, Samara and Saratov).

Research Result

The analysis of clustering processes in the Volga region regions revealed a significant differentiation of the economic space in terms of institutionalization of clusters. The uneven distribution of clusters by region, as well as differences in the level of their development, considered in table 3, are explained both by objective economic and geographical prerequisites and by the effectiveness of regional authorities in the framework of federal programs.

Table 3: Level of institutional development of clusters formed in the Volga region regions

Region	The number of cluster on level of institutional development		
	low	medium	high
Nizhny Novgorod region	1	0	0
Republic of Mordovia	0	1	0
Republic of Tatarstan	3	2	1
Republic Of Mari El	0	0	0
Chuvash Republic	1	0	0
Kirov region	0	0	0
Perm region	1	2	0
Udmurt Republic	0	0	1
Samara region	1	1	0
Ulyanovsk region	0	0	2
Saratov region	0	0	0
Penza region	3	1	0
Republic of Bashkortostan	0	0	1
Orenburg region	0	0	0

Calculated by the author based on data from the Russian Cluster Observatory of the Higher School of Economics

It can be concluded that the most active cluster policy is implemented by such regions as the Republic of Tatarstan, Perm, Penza and Ulyanovsk regions. Cluster initiatives are noted in such traditional economic centers of the Volga region as the Nizhny Novgorod and Samara regions, the Republic of Bashkortostan. The" outsider regions " in the implementation of cluster policy include the Republic of Mari El, the Kirov and Orenburg regions. We can observe a similar distribution of regions into leaders and outsiders when analyzing the dynamics of the regional innovation development potential index (IRIDP) presented in table 4.

Table 4: Index of innovative development potential of the Volga region regions

Calculated by the author

The author combined the Volga regions into macro-regions, districts, and interregional clusters based on previous research. In each group, you can identify the "leading region" and lagging regions. We can conclude that there is a fairly strong heterogeneity of regions in terms of the average level and direction of the dynamics of the index values. The high value of the index and its positive dynamics over the analyzed period are demonstrated by only two regions: Nizhny Novgorod region and the Republic of Tatarstan. Consider the dynamics of the economic potential of the Volga regions, the subindexes of the economic potential of innovative development are presented in table 5.

Calculated by the author

Consider the dynamics of the second-level subindex "1.1. Economic development of the region", which includes indicators of the gross regional product per employed resident and the coefficient of renewal of fixed assets. For all regions, there is a significant increase in the values of the subindex in 2015 and an equally significant decrease in the software in 2017 compared to 2015. For the second-level sub-index " 1.2. Effectiveness of innovative development of the region "(characterizes the share of innovative and newly introduced goods, works, and services), there are generally similar trends with more stable growth over the analyzed five-year period.

Comparison of regions based on quantitative values of indicators included in the second-level subindex "1. The economic potential of innovative development" and their dynamics allowed us to draw the following conclusions. We note the key role of the Republic of Tatarstan for the innovative development of the entire Volga-Kama region, as well as the activation of innovative effects within the selected Kazan interregional cluster. Tatarstan is also one of the most active regions of Russia in implementing cluster initiatives. The high performance of the Republic of Mari El is explained by the system-forming role of large high-tech enterprises, including the military-industrial complex, for the economy of a small territory and population of the Republic. The Chuvash Republic is characterized by a developed electrical engineering cluster and a number of cluster initiatives in the field of high-tech manufacturing industries.

Rather high values of subindixes for the Republic of Mordovia against the background of the more developed Nizhny Novgorod region are due, among other things, to the active development of the electrical industry. These regions have sufficient economic potential for interregional integration and the formation of both independent and joint cluster initiatives with other regions. In the Kama region, we note the leading role of the Perm region, which also shows sufficient activity in the cluster policy of economic development, while the Republic of Udmurtia is characterized by the concentration of large-scale production within a single machine-building cluster.

In the Middle Volga district, the leading role is played by the Samara region. The Saratov and Orenburg regions lag behind other regions both in terms of the economic potential of innovative development and in the use of cluster mechanisms for economic growth. We also consider the values of the subindixes of human resources potential for innovative development of the Volga region regions, presented in table 6.

Calculated by the author

The values of the subindex "2.1. Personnel potential of the knowledge-intensive and high-tech sectors of the economy" show growth in most regions of the Volga region, with the exception of the Penza and Orenburg regions. The Samara region, despite a significant decrease in the subindex values, retains a leading position. The situation with the educational potential of the Volga region is much worse, the Republic of Tatarstan and Mordovia demonstrate growth over the past 5 years, and the Samara region also retains a leading position. This situation is explained by a general decrease in the number of school graduates and, consequently, students, as well as the outflow of applicants to large agglomerations and the capital region.

We note the growth of the values of the subindex "2.3. Personnel potential of regional science" for the analyzed period for all regions of the Volga region, with the leaders being the Nizhny Novgorod region and the Ulyanovsk region, whose scientific and educational centers are Ulyanovsk and Dimitrovgrad. Values of subindixes of the financial potential of innovative development of the Volga region regions, presented in table 7.

Calculated by the author

Based on the values of the subindex "3.1. Budget financing of innovative development of the region", it is possible to identify regions that widely attract budget financing to the sphere of science and innovation at different stages. These regions are Nizhny Novgorod, republics of Mordovia, Tatarstan, Chuvashia; Samara, Ulyanovsk and Penza regions, the Republic of Bashkortostan. It should be noted that all the listed regions of the Volga region, in contrast to those lagging behind in this indicator, have a more active policy in the field of creating cluster initiatives within the framework of various federal programs. The values of the sub-index "3.2. R&D financing at the expense of organizations 'own funds" indicate that the following regions have significant internal R&D financing potential: Nizhny Novgorod region, Republic of Tatarstan, Perm region, Samara and Ulyanovsk regions, Republic of Bashkortostan. Next, we will consider the values of the subindexes of the scientific and technological potential of innovative development of the Volga region regions, presented in table 8.

Calculated by the author

In terms of scientific and technological potential, the following leaders were identified among the Volga regions, which showed an increase in the values of the first-level sub-index "4. Scientific and technological potential of innovative development of the region" for the analyzed period:

– Republic of Tatarstan, steady growth of science and innovation performance indicators in the analyzed period;
– Nizhny Novgorod region, growth rate by 2017, high level of development of science and innovation in production.

The rest of the Volga region and the Federal district as a whole show a decline in science and innovation indicators by 2017. The situation remains relatively good in the regions that implement cluster initiatives. The republics of Mordovia and Chuvashia, as well as the Penza region, are characterized by a decrease in the values of the subindex, while we note the preservation of high innovation activity of enterprises and organizations. Samara and Ulyanovsk regions, on the contrary, demonstrate a significant excess of scientific potential over technological. In 2017, there was a significant decrease in the scientific and technological potential of the Perm region and the Republic of Bashkortostan, which held leading positions in 2015.

Discussion

Based on the results obtained, which certainly have a debatable nature, it is possible to expand the scientific and practical discussion in relation to the chosen research problem. In particular, we can draw a conclusion about the correctly chosen goals and objectives of Russia's strategic development in the framework of an innovative scenario of economic growth (The concept of long-term socio-economic development of the Russian Federation, 2008). At the same time, it should be concluded that the implementation of cluster policy is insufficient for the innovative transformation of the economy of Russian regions. We also note the concentration of these strategic documents on the already industrialized territories without due attention to the processes of interregional cooperation in order to equalize the pace of socio-economic development (Forecast of long-term socio-economic development of the Russian Federation, 2013).

The results obtained allow us to suggest hypothetical directions for refining the spatial development Strategy of the Russian Federation (2019). In particular, add the Ulyanovsk region (Ulyanovsk-Dimitrovgrad) to the list of promising research and educational centers of economic growth in Russia. Also," raise the level " of Saransk from group III to group II, considering it as a promising development center that will contribute to the economic growth of the Russian Federation from 0.2 percent to 1 percent annually.

Acknowledgments

This research was supported by Grant of Russian scientific Foundation No. 19-78-00056 " Cluster model of Volga region development in the conditions of innovative economy"

Conclusions

Thus, we can observe an increase in the economic potential for the formation of an innovative economy in the Volga regions (sub-index 1). At the same time, it is necessary to note the positive impact of cluster development programs and complementary projects on the dynamics of performance indicators of innovative development in the region (sub-index 1.2), in particular for such regions as the Penza region, the Republic of Mordovia and Bashkortostan. The dynamics of indicators that characterize the financial potential of innovative development allows us to conclude that it is more effective to attract innovation financing for regions that have an active cluster policy. A key constraint for drawing conclusions about the impact of cluster policy on the innovative transformation of the Volga region economy is the fact that at the first stage of clustering, competitive industries in large economic and scientific and educational centers were subjected to clustering. At the same time, the relationship between innovation potential, innovation and cluster activity is traced.

Quite interesting conclusions follow from the interpretation of the results obtained within the author's multi-level model of the Volga region economic space. For each economic district and interregional cluster, a leading region is traced, which acts as the center of innovative transformation of the economic space of the neighboring regions. In the Volga-Kama macroregion such leaders at the level of "pairwise" comparisons of three regions: Nizhny Novgorod, Perm and Tatarstan. Despite the presence of two clear leaders (Nizhny Novgorod region and the Republic of Tatarstan), the key region for innovative transformation is Tatarstan, which has two transformation centers: the Kazan and Kama agglomeration. The first is considered as a potential point of growth of innovation activity and cluster initiatives for the republics of Chuvashia and Mari El, the second – for the Vyatka-Kama zone (Kama district and Kirov region).

In the Volga-Ural macroregion the Samara interregional cluster (Samara and Ulyanovsk regions) can be identified as the space with the greatest potential for innovative development. This territory is of key importance for the transformation of the economic space of the entire Middle Volga district and adjacent territories. Note the Penza region, which has a higher value of a comprehensive assessment of innovation potential in comparison with the Saratov region, as well as the Republic of Bashkortostan in comparison with the Orenburg region. The obtained conclusions can serve as a basis for the formation of spatial contours and vectors of a new stage of clustering of the Volga region economy, the implementation of the complementary nature of innovation and cluster activity in the regions.

Abstract

Since the beginning of the 21st century, the issue of cultural intelligence has been gaining in importance. It is particularly topical and relevant from the perspective of management in a multicultural work environment. At present cultural intelligence is described and analysed in numerous sources, often in the context of managers' attitudes and behaviours and their tasks or responsibilities in the area of managing multicultural teams.
Cultural intelligence (or Cultural Quotient-CQ) is defined as the skills and qualities that allow effective functioning in a multicultural environment and considerably influence the understanding and acceptance of cultural differences. It is particularly helpful in the process of adapting to diverse cultural conditions, which are frequently characterised by totally different values and rules as well as the ways of acting, thinking, and solving problems. Cultural intelligence, especially managers' cultural intelligence, supports the effectiveness of multicultural teams. It leads to employees' greater openness and tolerance to cultural diversity, acceptance of different views, attitudes, and behaviours of co-workers. Above all, it is conductive to developing sensitivity and flexibility in building positive, intercultural relations.
The study described in the article (individual in-depth interviews conducted with the use of IT tools) investigated the role and importance of cultural intelligence in a multicultural work environment and was conducted among Polish and Spanish managers. The main aim of the article is to identify the role and importance of cultural intelligence in multicultural environments from the point of view of managers who participated in the study.

Keywords: Cultural Intelligence, Cultural Quotient (CQ), Managers, Multicultural Work Environment.

Introduction

In today's globalized business world, managers' work increasingly often involves managing multicultural teams which comprise employees from diverse cultural backgrounds.

Modern companies expand their international business activity, which leads to the dynamic growth and development of intercultural interactions. Therefore, being aware of the role and importance of cultural intelligence (CQ) is particularly important for those managers in these companies who are responsible for the functioning of multicultural teams and for maintaining intercultural relationships, both with employees and customers.

Cultural intelligence, understood as the ability to effectively adapt to various cultural contexts and to understand the complexity of functioning in a multicultural environment, affects managers' ability to act efficiently and to achieve the goals set for their teams and, consequently, for the whole organization.

Managers who work in intercultural environments should realise that the same values may not be shared across cultures and that some of them may be obvious and understandable in one culture but not in others. Hence, they should be ready to continuously expand and update their knowledge about other cultures as well as be open to new ideas, ways of working, and business practices.

The theoretical part of the article defines the concept of cultural intelligence, describes its role in managing multicultural teams, and outlines the components of cultural intelligence.

The empirical part presents the results of the study conducted by the author. This qualitative study (16 individual in-depth interviews) was conducted among Polish and Spanish managers (8 interviews with managers of each nationality) who work in multicultural environments and manage culturally diverse teams.

The aim of the article is to present managers' views on the role and importance of cultural intelligence in a multicultural work environment.

Bearing in mind the above premises and the aim of the article, the following research question was formulated: Do managers who manage multicultural teams possess knowledge about cultural intelligence and how they perceive its role and importance in a multicultural work environment?

Cultural Intelligence (CQ) - definitions, importance, and role in managing multicultural teams

In our globalised world, contemporary companies do not limit their activity to one country but develop their international operations in search of new markets and growth opportunities.

Companies which operate on international markets find it necessary to establish and maintain intercultural interactions and develop trading ties in the international business environment. In order to successfully cooperate with companies from other cultures, employees must acquire and deepen their knowledge about these cultures (Sozbilir&Yesil 2016; Day 2017). Thus, the role and importance of cultural intelligence as a skill that is needed in modern management in the global market is systematically growing. Cultural intelligence is of particular significance for managers who work in multicultural environments and manage culturally diverse teams.

Since the beginning of the 21st century many authors have investigated the issue of cultural intelligence in their studies. These include: Earley, 2002; Earley & Ang, 2003; Peterson, 2004; Thomas & Inkson, 2004; Earley & Mosakowski, 2004; Ang, Dyne, Koh, &Ng, 2004; Earley, Ang, & Tan, 2006; Ang&Van Dyne, 2008; Crowne, 2009; Lee&Sukoco, 2010; Creque&Gooden, 2011; Engle&Nehrt, 2012; Ang, Van Dyne & Rockstuhl, 2015; Brancu, Munteanu, Golet, 2016; Simpson, 2017; Fang, Schei&Selart, 2018; Hu, Wu&Gu, 2019; Knap-Stefaniuk&Sowa-Behtane, 2020; Knap-Stefaniuk, 2020).

Cultural intelligence (CQ) refers to a person's capability to adapt and function effectively in culturally diverse contexts (Ang and Van Dyne, 2008; Earley and Ang, 2003). This adaptation requires skills and capabilities quite different from those used by people within their own cultural context. Cultural intelligence is also defined as "multifaceted competency consisting of cultural knowledge, the practice of mindfulness, and the repertoire of behavioral skills" (Thomas and Inkson, 2004).

CQ is also considered to be an ability that allows individuals to understand and act properly in many cultures (Thomas, 2006). Earley, Ang &Tan (2006) define CQ as the ability to successfully and effectively adapt to new cultural environments, that is, these previously unfamiliar conditions that can be attributed to another cultural context. CQ is also described as a system of knowledge and skills, linked by cultural meta-cognition that allows people to adapt to, select and shape cultural aspects of their environment (Thomas, Elron, et al. 2008).

Engle and Nehrt believe that cultural intelligence is a person's ability to successfully engage in relationships in culturally diverse environments (Engle, Nehrt, 2012). Khodadady and Ghahari point out that CQ is "the ability to interact effectively in multiple cultures" (2012, p. 22). In the organizational context, from the perspective of the tasks faced by contemporary managers who manage multicultural teams, cultural intelligence is also defined as the ability to effectively deal with cultural differences in an organization (Hu, Wu, et al., 2019).

Cultural intelligence is also described as an ability of managers who are involved in intercultural interactions to effectively operate in a globalised environment (Fang, Schei, et al., 2018). It is worth noting that the concept of CQ helps to explain why some managers are able to adapt their behaviours to various cultures more easily than others (Van Dyne, Ang and Livermore, 2010). Culturally intelligent individuals are described as competent and effective in many cross-cultural interactions (Ang & Inkpen, 2008; Ang et al., 2015), which is particularly important for managers who work with multicultural teams.

Summarizing the above considerations, it can be said that cultural intelligence reflects a general set of capabilities that facilitate efficiency in diverse cultural environments and makes some individuals more

successful in effective adaptation to various cultural contexts than others (Ang, Rockstuhl, Mei Ling Tan 2015, p. 433; Brancu, Munteanu, et al., 2016, p. 336).

It should be emphasized that cultural intelligence of managers who manage multicultural teams can be defined as the ability to effectively adapt to new cultural realities and the skills necessary to successfully function in environments characterized by cultural diversity of employees.

If contemporary companies want their managers to be successful on a global scale, they must try to attract people who possess the right skills and experience and must attend to their systematic development, especially in the area of cultural intelligence (Alon, Higgins 2005, p. 510). Such managers are indispensable because in contemporary organizations multiculturalism is reflected in a number of areas which are affected by differences in values, behaviors, and beliefs of people who come from diverse cultures (Griffin, 1996, p. 178).

Being aware of and possessing knowledge about cultural differences is a must for managers working in multicultural environments. Sensitivity to their employees' international diversity and knowledge about intercultural determinants of their teams should be part and parcel of modern managers' work. Managers who function in multicultural environments should try to understand the differences between employees and behave tactfully and patiently in intercultural relations (Glinkowska 2016, p. 58).

Managers' attitudes and behaviours, including their cultural intelligence, to a great extent shape the effects of cultural diversity, which may be both beneficial and unfavourable for the functioning of multicultural teams. Negative effects of cultural diversity include dysfunctional conflicts, decreased productivity, and difficulties in reaching agreement and achieving team goals. Positive effects of employees' cultural diversity primarily result from the knowledge base which covers a whole range of various cultural experiences, knowledge of different markets and customers' behaviours and needs, and greater willingness to expand company's activity to other countries and cultures.

It is worth noticing that the effects of cultural diversity in the workplace (positive or negative) depend primarily on managers and their effectiveness in managing multicultural teams (Martin 2014, p. 90). These effects, in the author's opinion, to a great extent depend on managers' cultural intelligence (their adaptability, openness, commitment to intercultural interactions, and an ability to build positive relationships with employees from other cultures). This intelligence plays a key role in creating positive effects of cultural diversity.

"Managers – especially those who work in a culturally diverse environment – play a vital role in modern management and the achievement of organizational goals. The challenges they face and responsibilities they shoulder result from the need to reconcile different ways in which employees from various – sometimes poles apart – cultures think and behave" (Burkiewicz, Knap-Stefaniuk 2020, p. 7474).

Managers who manage multicultural teams should create such working conditions (atmosphere, communication, relations between people) and solutions within a team (motivating employees, attending to their development, fair evaluation of their achievements) that will make employees from other cultures feel at ease and comfortable. It is important that they feel they can openly present their ideas and proposals, share their native market experiences, and propose new solutions.

Dealing with cultural differences is based primarily on respecting all the values represented by employees of multicultural teams (Glinkowska 2016). Managers' cultural intelligence affects the effective functioning of culturally diverse teams. It facilitates understanding and acceptance of those cultural norms, principles, and values which are held by employees from different countries. It also shapes managers' greater flexibility in selecting and implementing the best management style, working methods, ways of building relations with employees, and is conductive to efficient communication and differentiation of methods used to motivate employees.

A high level of managers' CQ is crucial for the company's successful functioning in a culturally diverse environment. Thus, cultural trainings and workshops are necessary to develop cultural awareness and sensitivity of managers who are responsible for the work of multicultural teams.

Components of Cultural Intelligence

"CQ helps people to understand other cultures" (Joost, Bücker, et al 2014, p. 2070). Based on the work of various authors (Ang, Van Dyne, et al., 2006; Van Dyne, Ang, et al., 2009; Ng, Van Dyne, et al., 2012; Ang,

Van Dyne, et al., 2012; Ang, Van Dyne, et al., 2015; Brancu, Munteanu, et al., 2016), the following components of cultural intelligence can be listed.

Metacognitive CQ is a mental capability which allows a person to acquire and evaluate their cultural knowledge. This component focuses on becoming aware of and monitoring the cognitive process in relation to one's own cultural identity and that of others when interacting with them (Simpson 2017). "Metacognitive CQ makes people more alert looking for explanations of unexpected reactions or behaviors of the person they are interacting with" (Joost, Bücker, et al 2014, p. 2070). Metacognitive CQ stimulates the formation of novel heuristics for intercultural interfaces and promotes the questioning of one's own cultural suppositions (And, Van Dyne, 2011).

Cognitive CQ is a component that refers to a person's general knowledge and the structure of their knowledge about cultures and differences between them (Simpson 2017). "Cognitive CQ stimulates thinking about other cultures and searching for explanatory models that bring a certain order in cultural differences" (Joost, Bücker, et al 2014, p. 2070). This component represents a person's knowledge about other cultures, examples of which include customs, standards, and values (Van Dyne et al., 2012).

Motivational CQ is a person's internal motivation to make an effort to function effectively in a culturally alien environment (Simpcon 2017). This component portrays the leader's, manager's desire to acclimate interculturally (Van Dyne et al., 2010). "Motivational CQ helps people to develop self-efficacy; it gives them energy to put effort in a cross-cultural situation and to develop the trust needed to enable control of the unfamiliar situation" (Joost, Bücker, et al 2014, p. 2070).

Behavioural CQ is the ability to respond appropriately – verbally and non-verbally – when dealing with representatives of other cultures. This component denotes the adoption and display of culture-appropriate actions (Ang, Van Dyne 2008). "Behavioral CQ supports individuals to use certain verbal and non-verbal behavioral repertoires which enable them to take initiative and act in an interaction" (Joost J.L.E. Bücker, et al, 2014, p. 2070).

Methodology

The qualitative study described in the article was conducted by means of the interview method (the interview was semi-structured) and the technique of individual in-depth interview. A special research tool (interview scenario) was developed to be used in the study, in which most questions were open-ended ones, and those closed-ended only verified the respondents' familiarity with the term "cultural intelligence" and their knowledge of components of cultural intelligence. The interviews were conducted using ITC tools (ZOOM and Microsoft Teams), which was motivated by the epidemiological situation and the inability to conduct interviews at face-to-face meetings. The author had planned to conduct these interviews with managers during her two research trips (to Spain and the Czech Republic) in the period between March and July 2020 (Spain, Czech Republic). Unfortunately, the situation related to COVID-19 changed this plan. So far, interviews have been held with Polish and Spanish managers, and the ones with Czech managers will take place in the near future.

Respondents, i.e. managers working in multicultural environments, were recruited through social networks (the snowball sampling). The search for them was initiated in several different places to avoid narrowing down the group of respondents only to those linked, for example, by professional ties. The key criterion for recruiting suitable respondents (managers) was their employment in international companies, their managerial position, and their managing a culturally diverse team (minimum 3 years at a managerial position; employees of minimum 3 different nationalities in the team). The author assumed that after such period (minimum 3 years) a manger has enough knowledge and experience in managing a multicultural team. In her previous study, the criterion was teams with employees of at least 2 different nationalities, however, in this study, it was changed to 3, as the author wanted to obtain the opinions of managers who have contact and experience in working with employees who come from more than 2 different cultures and thus have a broader perspective on issues related to those investigated in the article.

The interviews (16 individual in-depth interviews) were conducted with Polish and Spanish managers (8 interviews with managers of each nationality) who work in multicultural environments and manage culturally diverse teams. Originally, the author intended to conduct 20 interviews (10 with Polish managers and 10 with Spanish managers), unfortunately, due to organizational reasons, it proved impossible.

The interviews took place between March and August 2020. One interview lasted from 50 to 65 minutes. Before the beginning of each interview, the respondents were informed about the aims of the study, the way in which the interviews were to be conducted, the confidentiality of the study (the empirical material will be used only for publications, the respondents' anonymity will be respected). Not all respondents (managers) agreed to have their interviews recorded with ITC tools (4 Polish and 3 Spanish managers gave their consent). The interviews were conducted in Polish with the Polish managers and in English with the Spanish managers.

During the interviews the author tried to create a friendly atmosphere so that the respondents felt comfortable (this way of conducting an interview was a completely new situation for many of them). The data collected during the interviews were transcribed, coded, and categorized, and served as the basis for qualitative analysis of the respondents' statements. The empirical material was also subjected to quantitative analysis.

The respondents participating in the interviews included 8 Poles, aged between 33 to 45 (3 women and 5 men) and 8 Spaniards, aged between 35 and 48 (1 woman and 7 men). The aim of the interviews was to discover the opinions of managers from two different cultures on the role and importance of cultural intelligence in a multicultural work environment.

Cultural intelligence - The Results of The Study

The author conducted 16 in-depth individual interviews with 8 Polish and 8 Spanish managers who work with multicultural teams.

The specific aims of the study (interviews) was to find out whether the respondents know, understand, and can explain the term "cultural intelligence", whether they know the components of cultural intelligence, and whether they are able to determine which component(s) are the most relevant to their work and why. Other aims were to discover the respondents' opinions about the role of cultural intelligence in managing culturally diverse teams (in general contexts and with reference to managers' CQ) and to find out whether the respondents have participated in workshops on cultural diversity, CQ, and management of multicultural teams and whether they have participated in trainings during which their cultural competence (including cultural intelligence) was developed, as it may have an impact on their knowledge or lack thereof in this area.

One of the first questions asked during the interviews concerned the respondents' knowledge of the term "cultural intelligence". Taking into account the qualitative nature of the empirical material, the author provides the quotes of managers' answers (in the order in which the interviews with respondents were held).

All Polish managers were familiar with the term cultural intelligence (8 people confirmed that they knew and understood the term). When asked what cultural intelligence means, the respondents replied as follows. Manager 1 (female, 38) – "Cultural intelligence is the ability to understand people, employees from other cultures". Manager 2 (female, 40) – "It is the ability to work in conditions of cultural diversity". Manager 3 (male, 43) – "Cultural intelligence is the ability to understand and accept cultural diversity in social contacts and at work". Manager 4 (male, 33) – "It is openness to people from other cultures and acceptance that their culture may be completely different from ours". Manager 4 (female, 41) – "It is sensitivity to the other person and to the other culture from which he comes, even if this culture seems alien and unknown to us; it is tolerance and tact towards this otherness, which we sometimes do not understand". Manager 5 (male, 35) – "It is freedom and a certain ability to be flexible in relationships with co-workers and subordinates from other cultures". Manager 6 (male, 45) – "Cultural intelligence is the ability to act effectively in an environment of cultural differences". Manager 7 (male, 40) – "It is the competence of managers who work and have experience in working in an intercultural environment; it is easier for them to accept other cultures and working style or communication of employees from other cultures". Manager 8 (male, 43) – "I have knowledge of cultural intelligence because for a long time I have been working in an environment where there are employees from different cultures; it is simply about being able to deal with cultural differences in your daily work, especially when you are a manager and have employees of different nationalities in your team".

Also all Spanish managers were familiar with the term of cultural intelligence (8 respondents gave a positive answer to this question). They all confirmed that they understand this term and can explain it. Their answers are quoted below.

Manager 1 (male, 42) – "Cultural intelligence is about being open, kind, and tolerant to employees from other cultures". Manager 2 (female, 35) – "It is a smile and kindness to employees who come from a culture different than mine; it is an attempt that even if sometimes we differ a lot, together we realize the goals of the team; it is

also an ability to cooperate, despite these differences. Manager 3 (male, 48) – "After many years of work, I believe it is an ability to accept cultural differences, to be open to them and willing to learn, but also to share knowledge with employees from other cultures and seek the best solutions together". Manager 4 (male, 43) – "I think it is the effectiveness in managing a team that comes from being able to work with people from cultures other than yours; you know how to listen to them, appreciate what they do, build good relationships, although we often differ due to cultural backgrounds. Manager 5 (male, 45) – "Cultural intelligence means understanding and accepting people from other cultures with whom you work; it is flexibility and an ability to act in difficult situations when we are very different in our approach to work, in the way we perform our duties, in our different ideas of how to achieve goals in a team". Manager 6 (male, 43) – "Cultural intelligence comes from our experience; once you have experience of working with other cultures you are usually more tolerant, you try to understand other cultures, you act more flexibly". Manager 7 (male, 44) – "It is a skill to adapt to a team where you have employees from different cultures; you accept that they are different, you are tolerant". Manager 8 (male, 38) – "Cultural intelligence is a set of qualities and skills that makes work easier when you lead a team with different people, employees from different countries; you try to respect them, not to offend them because of their culture; you are tolerant and open-minded; you know how to act in such conditions".

During the interviews, managers were also asked about the components of cultural intelligence, whether they know them (or have heard of them before), whether they can name them, whether they can explain or define them briefly, and whether they can describe their role and importance in managing multicultural teams. This part of the interview was difficult for the respondents and yielded very few positive answers. Managers, both Polish and Spanish, answered that they "heard something" about components of cultural intelligence, but these were very general answers, which revealed that they lacked knowledge from this area. Two Polish managers (both females, 38 and 41) and one Spanish manager (male, 38) heard about the components of cultural intelligence and were able to name them correctly.

During the interviews, the author listed the components of cultural intelligence (metacognitive CQ, cognitive CQ, motivational CQ, and behavioural CQ), briefly described them and asked the respondents which of them seem the most significant in managing multicultural teams. The Polish managers most frequently chose cognitive CQ and motivational CQ (7 answers both), while the Spanish managers valued motivational CQ (8 answers) and behavioural CQ (6 answers) the highest.

The aim of the study was also to find out the respondents' opinions on the role of cultural intelligence (in general contexts and in terms of managers' CQ) in managing culturally diverse teams. All Polish managers (8 respondents) and all Spanish ones (8 respondents) stated that cultural intelligence generally plays a very important role in relations with other cultures and in the functioning in culturally diverse environments. It facilitates understanding other people and adjusting one's behaviour and communication to various cultural requirements. As far as working and functioning in a culturally diverse environment and managing multicultural teams is concerned, the respondents believed that cultural intelligence: helps to achieve goals (7 answers from Polish managers; 7 answers from Spanish managers); facilitates conflict resolution (7 answers from Polish and 8 answers from Spanish managers); improves the effectiveness of motivating employees (7 answers from both Polish and Spanish managers) and communication in the team (8 answers from both Polish and Spanish managers); builds positive atmosphere at work (6 answers from Polish managers; 7 answers from Spanish managers); influences the formation of intercultural relations within the team (8 answers from both Polish and Spanish managers); and facilitates effective cooperation and search for new solutions (based on the knowledge and experience of employees from different cultures) (7 answers from both Polish and Spanish managers).

During the interviews, the respondents were also asked questions about the ways in which they acquired knowledge on cultural intelligence and in which they developed it. The managers, both Polish and Spanish, primarily listed the Internet sources and articles, and trainings and workshops in which they participated.

Another aim of the study was to obtain information whether the respondents have participated in workshops on cultural diversity, CQ, multicultural team management and whether they have participated in trainings in which their cultural competence (including cultural intelligence) was developed. 6 Polish managers took part in workshops devoted to multicultural team management and 4 of them also participated in cultural trainings, and 5 Spanish managers took part in workshops on cultural differences organised in their companies.

During the interviews, Spanish managers pointed out that the analysis of the role and importance of cultural intelligence for managers who manage multicultural teams, or simply the importance of cultural intelligence in general, should also be analysed from the perspective of the cultural diversity of the population concerned (e.g. Spaniards, employees or managers, depending on the objectives of the study, who live in different regions of the country, e.g. in Madrid, Catalonia, Andalusia or others).

Summing up, the interviews confirmed that the respondents (all Polish and all Spanish managers) know the term "cultural intelligence". They encountered this term before at work or/and during workshops or trainings. Some of them, in order to develop their knowledge of CQ, read articles on the subject, although the Internet was the main source of information. The respondents (Polish and Spanish) notice and understand the link between managers' cultural intelligence and their effectiveness in managing multicultural teams (e.g. in achieving goals, sharing knowledge and experience, implementing new solutions, looking for innovative ideas, evaluating employees' individual achievements or successes achieved by teams).

Discussion

The data obtained through the interviews allowed to answer the research question formulated in the Introduction: Do managers who manage multicultural teams possess knowledge about cultural intelligence and how they perceive its role and importance in a multicultural work environment?

As a result of individual in-depth interviews conducted with 8 Polish and 8 Spanish managers, the author collected empirical material which demonstrates that all Polish (8 respondents) and all Spanish (8 respondents) managers know the term "cultural intelligence" and are able to explain and describe it. In the author's opinion, the respondents gained this knowledge while working in a multicultural environment for several years (5 to 12 on average) and managing culturally diverse teams (for 4 to 10 years).

Most managers were unable to list and describe the components of cultural intelligence. Only 2 Polish managers and 1 Spanish manager had some knowledge on this subject. After listening to descriptions of particular CQ components, the Polish managers declared cognitive CQ and motivational CQ to be the most important in effective management of culturally diverse teams, whereas the Spanish managers pointed at motivational CQ and behavioural CQ.

The respondents, both Polish and Spanish managers, acknowledged and were able to explain the significant role played by cultural intelligence, both in general contexts, in intercultural relations, and in working and managing multicultural teams. As far as the management of multicultural teams was concerned, they mentioned its positive effects in the following areas: goal achievement, conflict resolution, employees' motivation, communication, work atmosphere, team relations, cooperation, knowledge and experience sharing.

Some Polish and Spanish managers have participated in trainings and workshops directly related to their work in multicultural environments, during which they gained knowledge about cultural intelligence. Managers broaden their knowledge in this area by mostly reaching for the Internet sources.

As an extension and complement to this study, the author intends to conduct individual in-depth interviews with Czech managers and to expand the empirical material collected so far with new nationalities.

Limitations and Recommendations

The greatest limitation of this study is linked with the fact that it was based on a convenience sample. The sample was selected using the snowball sampling, based on the author's social and professional contacts. However, in the author's opinion, due to the epidemiological circumstances, it was a reasonable way to find people who meet the criteria set in the study.

The interviews were conducted by means of in-depth interview technique, using ITC technologies, which could also be a certain limitation. Direct contact with respondents (especially in qualitative research) creates better opportunities and freedom in going deeper into the issues of interest to the researcher, in asking respondents for details, and in establishing more direct contact with them.

The study was qualitative in nature. The author is aware of the fact that the scope for generalisation of the results of such studies to the population as a whole can be limited. It should also be mentioned that the interviews with Spanish managers were conducted in English; the fact that interviews are not conducted in native tongues can be an additional difficulty for both respondents and researchers.

The author intends (everything depends on the epidemiological situation) to conduct a similar study among Czech managers (as was the original plan). It might be worth considering whether to conduct a more detailed study on cultural intelligence among managers of different nationalities that accounts for cultural diversity of a given population (for example, cultural differences between various regions in Spain, such as Catalonia, Andalusia or others; in Poland - Mazovia, Silesia or others; and in other countries). Adding more variables (e.g.

the values held by managers) may enrich the empirical material on the role and importance of cultural intelligence in a multicultural work environment.

Conclusions and Future Research

The analysis of the subject literature and interviews with Polish and Spanish managers allowed the author to demonstrate the role and importance of cultural intelligence in a multicultural work environment (from the perspective of managers of two different nationalities).

Cultural intelligence is very important, especially for managers who are responsible for the work of multicultural teams and the achievement of goals. This intelligence affects managers' attitudes and behaviours in their contacts and relations with employees from other cultures, their ability to accept and quickly adapt to cultural differences, and their way of building relationships and effective cooperation at the meeting point of different cultures. Managers who work in a culturally diverse environment should continuously develop their cultural intelligence (their company's support is necessary here, e.g. by providing workshops, trainings, or coaching) and expand their competences in all components of cultural intelligence.

Further research in the field of cultural intelligence should focus on, among other things, the components of CQ and their role and importance in effective management of people in a multicultural work environment. It is worth expanding the scope of the study, for example, by adding quantitative research, by using a larger sample, by using different methods and techniques, or by including other nationalities (managers from Italy or Portugal). Moreover, when analysing the cultural diversity of a given population, it might be useful to take into account not only the country but also the region of managers' origin.

Summing up, managers' cultural intelligence facilitates managing people who come from different cultures and who differ in terms of values, beliefs, norms and principles, who prefer different ways of communication, who have different working styles and different perceptions of time or relationships in professional life. In order to increase the effectiveness of cooperation in intercultural relations (in multicultural teams), modern companies should focus on recruiting managers who understand the role and importance of cultural intelligence in their work and possess a high dose of cultural awareness and sensitivity.

Abstract

Online learning allows offers a variety of advantages amongst which can be mentioned: increased productivity, learner customization, content flexibility, targeted features etc. Nevertheless, most learning management systems are subscription-based and can prove to be quite expensive. For educational purposes in academic activities, freemiums and open source LMS solutions are readily available. The current research study follows the development of a pilot course using Talent LMS e-learning platform, which fulfills current requirements for new teaching methods that are more attractive and interactive. The importance of e-learning tools is exacerbated in the current socio-economic environment, which is currently dominated by the SARS-Cov2 epidemic. Authors propose a customizable learning environment using ready to use design tools, but also CSS code for a targeted user experience. The methodology for designing a Web Development for 3D Printing Start-ups pilot course was thoroughly presented, highlighting the main structural components. Implementation was undertaken during a seven-day intensive summer school held at POLITEHNICA University of Bucharest from Romania. Received feedback helped improve the contents, presentation and the structure of the course.

Keywords: E-learning, Teaching Methods, Adaptability, Gamification.

Introduction

As the world changes, continuous progress is made with the purpose of offering a better quality of life. Technology is increasingly available and advanced, with many advantages and disadvantages as well. Newer generations embrace a new way of thinking and develop different life-principles.

Recent studies conducted by Nagashibaevna Y.K. (2019) have shown that students have progressively lost interest in studying and that is mainly since some areas of education do not keep up with modern teaching technologies. Although many students use technology daily, they seem to agree that there is a lack of innovative and technology appropriate learning content.

In June 2020 the European Data Portal (2020) concluded that the current socio-economic environment caused by the SARS-Cov2 epidemic is forcing the shift of learning experiences from face to face into an online environment. This also made the Commission to review the Digital Education Action Plan in 2020, which was intended to

support the development of online learning at different levels of education across Europe. The necessity of cohesive and reliable e-learning tools is felt more astringently than ever before.

According to Eurostat (2020) in 2019, four in five young people (80%) aged 16 to 24 in the European Union (EU) had basic or above basic digital skills. Among EU Member States, Romania had the lowest share of individuals aged 16 to 24 with basic or above basic overall digital skills (56%). This shows that almost half of young Romanians do not have the necessary digital skills to access educational services online. To support the global efforts of maintaining an adequate educational process the European Commission (2020) offers a wide range of online learning resources for learners, teachers and educators during the outbreak of COVID-19.

Rapanta C. et al. (2020) concludes in his research that universities, now more than ever, should invest in teacher professional development of their faculty, for them to be updated on effective pedagogical methods with or without the use of online technologies.

Considering the abovementioned, the authors propose the design of an intuitive pilot e-course for sustainable development of e-learning tools. The course addresses *Web Development for 3D Printing Start-ups* in an attempt to create an interactive learning experience for users and encouraging participative development of educational e-tools.

Study Background and Methods

The current study proposes the development of a pilot course module using the online Talent LMS e-learning platform. The pilot course was designed and implemented within an intensive summer school program financed through a partnership Erasmus+ project. *TecHUB 4.0 - Technology and Entrepreneurship Education for Bridging the Gap in Smart Product Development*, is an international project with POLITEHNICA University of Bucharest (UPB) from Romania as the project leader, and partnering up with three other universities: Czestochowa University of Technology (PCz) from Poland, Lancaster University (LU) from the United Kingdom of Great Britain and "Lucian Blaga" University of Sibiu (ULBS) from Romania. TecHUB 4.0 aims at delivering, with methods based on modern teaching technologies, especially based on web-based platforms and digital technologies – e-learning and interactive platforms, the knowledge of professors, industry specialists, researchers, managers, and entrepreneurs to young students wishing to become entrepreneurs in the additive manufacturing (AM) area. To address this main target, the pilot course on *Web Development for 3D Printing Start-ups* was custom designed using CSS coding within Talent LMS.

Most learning management systems (LMS) are subscription-based and can prove to be quite expensive, reaching up to four figures a month. For educational purposes in academic activities, freemiums and open source LMS solutions are readily available. Aside budget considerations, another reason for opting for a free LMS is the size of the application area. For small businesses with small staff, for example, the features of a free e-learning platform are more than satisfactory.

According to Chang J. (2020) from Finances Online TalentLMS is the top free solution for e-learning (Figure 1). It is a very flexible cloud hosted LMS designed to help users simplify how they facilitate online seminars, courses, and other training programs. The cloud powered LMS solution does not need installation, upgrade or a back-up, thus being very user friendly even for a beginner admin.

Figure 1: Talent LMS main e-learning platform features

The key features that made TalentLMS the optimum choice for TecHUB 4.0 implementation and pilot course development were the comprehensive analytics service, the gamification of content and the availability of feature customisation through CSS coding.

In association with Talent LMS, WIX was selected as the designated website builder, mainly due to its' competitive advantages for beginners through advanced designing tools, as stated by Jenner N. (2018). Using WIX learners created a personal website by using the Artificial Design Intelligence (ADI) that the platform provides. A step-by-step learning process revealed how to create a website, add and edit content for a 3D printing start-up business.

Pilot Course Development

TalentLMS can be deployed with an open Application Programming Interface (API), but it is also an excellent solution when using Cloud hosting. It can support various languages, so that the developed pilot e-course could be not only delivered in a native language, but also administrated and designed that way by admins and, respectively instructors. TalentLMS as the main web platform for designing and delivering the pilot e-course mainly due to the open source characteristics and the available pricing plans. It is one of the very few platforms which can run cloud based, can offer a free pricing plan, has an open source on CSS coding and also has a variety of interactive content design and development tools. Five registered users and unlimited unregistered users were available and divided in several ways throughout the pilot e-course development process, as follows:

- 1 super admin and four instructors (registered users) – initial design and development stage;
- 1 super admin, 1 instructor and 3 learners (registered users) – first testing stage of the e-course;
- 1 super admin and 4 learners (registered users) – pilot testing during the focus group;
- 1 super admin, 4 instructors (registered users) and 100 learners (unregistered users) – pilot testing during the intensive summer school.

Figure 2: Module Structure for the module Web Development for 3D Printing Start-ups

The pilot e-course can be completed by an unlimited number of students, without having to open a specific TalentLMS user account. Nevertheless, the capabilities of the platform allow the development of very large data bases, the main customer types targeted ranging from freelancers and small businesses to large enterprises. The e-learning platform supports a series of common devices, like Windows, Linux, Android, iPhone/iPad, Mac, Web-based, Windows Mobile. This facilitated the adaptation of the pilot course to mobile devices.

The structure of the *Web Development for 3D Printing Start-ups* pilot course uses five different content types, namely: chapters, assignments, quizzes, presentations, and feedback questionnaires. As Talent LMS offers users three main roles as administrator, instructor and learner, the interface for each one is different. The content interface of an instructor for the *Web Development for 3D Printing Start-ups* module is presented in Figure 2. A learner will see a similarly structured interface, apart from the editing menu of each content type.

Each module starts with an introductory chapter, where a short description regarding the purpose and objectives of the module was made.

The main challenge in developing the pilot e-course was how to design it in a manner that will arouse curiosity and intrigue students in learning while doing practical work at the same time. Thus, an informal approach with the students was chosen, in order to make the studying process more relaxed and fun while making short funny jokes with the use of gifs, you tube videos and other custom features. CSS programming was undertaken in several set-ups of tables, pictures and gifs, but the most important ones were for exemplifying certain aspects with the use of "buttons" that lead to other websites and embedded videos, where a re-dimension and re-position of the frame was necessary (Figure 3, Figure 4 and Figure 5).

<center>
```

Figure 5: CSS code for embedded videos with dimensioning and repositioning of content – instructor interface An informal addressing method was used, for a "friendly environment". Students seemed to be more attracted by subjects that are taught in a friendly manner, rather than a strict and serious method.

The pilot e-course follows a simple structure, where students were encouraged to develop their skills in web design. Nevertheless, the proposed pilot e-course was implemented throughout the seven-day summer school together with

three more modules, namely: Product Design and Development of Smart Products; Business Plan Development for The Future Engineer as an Entrepreneur; Smart Product Computer Aided Design and 3D Printing. Thus, while completing the e-course, students were asked to develop a business plan, design and manufacture 3D printing applications, and also develop their own website where they must "sell" their 3D printed products.

Web Development for 3D Printing Start-Ups was used as a pilot-course mainly to gather information and feedback for the optimization of the other three modules such as structural optimization, information layout specific requirements, uploading assignments (Figure 6) and pop-quiz tasks (Figure 7). Thus, for the best optimization, the ongoing feedback method was chosen. Depending on what type of module students completed, they encountered assignments, pop-quizzes (Figure 7) and ongoing feedback forms (Figure 8).

The final e-course assignment was designed using CSS and allowed learners to upload: a text reply (own web page link); a file (PPT presentation of the start-up); video (demo pitch presentation of the start-up); audio (motto of the 3D printing start-up). After assignment completion learners can receive feedback from their instructors, make the appropriate amendments and reply (Figure 6).

Figure 6: Assignment 1 in CSS code – instructor interface; a) learner options before submitting answer; b) learner options after submitting answer

The pop-quiz was designed using several types of questions, such as: multiple choice answers, gap filling, ordering answers, drag-and-drop, free text and randomized. Thus, the instructor could choose bespoke methods for each group of learners (Figure 7). Instructors can define the question type and edit the content of the question using CSS code. Also, both questions and answers could be arranged in a specific order or randomized for each individual learner. Each of the questions had equal weights. The duration of the quiz could not exceed 15 minutes and learners would pass if they achieved 80% of the score. A maximum of two attempts were allowed on the test with a five minutes delay between attempts. In order to start the test a password was required, which students received during live online sessions with the instructors.

Figure 7: Pop-quiz within course content – instructor interface

The feedback form was designed based on the same rules as the pop-quiz, and it included open answer questions (Figure 8).

Figure 8: Ongoing feedback form – instructor interface

The key role of the feedback form was to establish if the proposed approach was more suitable for learners than traditional delivery of learning content. Throughout the pilot e-course, learners found the course rather interesting, funny and easy to follow. Moreover, as learners gave feedback on certain aspects, optimizations and modifications within the content and information layout was made.

Talent LMS has an integrated gamification process, where learners can get points when completing modules, pop-quizzes and registering. Instructors can also modify the gamification options and view student's progress, either individually or either the whole class. Thus, with interactive courses and current or new topics of interest, students should improve their activity within daily courses.

Conclusion

With no doubt, the future of teaching will be linked to e-learning tools and adapted to student's evolving needs. The designed pilot e-course could be used simultaneously with current teaching methods, focusing on advantages like:

- Presentations can be made within the e-learning Talent LMS platform, without any other specialized software;
- The physical attendance under certain specific aspects may no longer be mandatory;
- Learners can propose throughout the e-course feedback on what aspects can be further developed and improved;
- Learners can become involved in the active development of their own e-courses by learning how to use CSS code to customize their favorite features.

It seems that the conventional teaching methods need upgrade and an adaptation to the current requirements must be made.

Influenced by the current socio-economic developments caused by the SARS-Cov2 epidemic, the teaching process has greatly shifted in the online environment. Practice has shown that not all educational systems were ready for such a mass exodus, but they all made a real effort to adapt in a very short amount of time. Thus, an online attractive, intuitive and interactive platform must be used and adapted according to the current requirements, which shall also encompass the already existing platforms, all in one place. Students should access one platform for online meetings, course studies, pop-quizzes and uploading homework.

Abstract

Implementing a successful technology transfer is essential for universities, companies, the national economy and society at large. For universities, technology transfer can bring additional revenues that can be used for further scientific research, and also contributes to the recognition of scientific achievements of scientists, which, in turn, can help in attracting grants. For companies, the benefits of technology transfer include the ability to use the results of intellectual activity without spending on internal research and development, as well as the introduction and development of new technological processes that can contribute to the success of their business. For the national economy, technology transfer is a key growth factor through the development of high-tech companies, increasing the number of jobs and the production of innovative products. For society as a whole, the benefits of technology transfer are incalculable in terms of improving the quality of life, environmental conditions, technical advances that provide not only new opportunities, but also stimulate the development of the national and global economy through digital transformations. Digital technology solutions accelerate technology transfer, and one such solution is a technology transfer platform that facilitates networking.

Keywords: Technology Transfer, Results of Intellectual Activity, Intellectual Property, Innovation, Digital Platforms, Innovative Economy.

Introduction

One of the key factors in the current development of the world economy is the intensive exchange of scientific, technological and productive information at the regional and transnational levels. Educational and research institutions provide an enabling environment for the creation of innovations that change lifestyles. There are many new products and inventions on the market every year. Since the turn of the millennium, the world has witnessed the emergence of social networks, smartphones, autonomous vehicles and autonomous aircraft. Society is nearing the point where life has completely immersed itself in digital technology. The storage devices are smaller, but they can store huge amounts of data. Unmanned vehicles, robotic complexes, artificial intelligence, 3D printing and 3D manufacturing are just some of the inventions that everyone.

About Technology Transfer

Technology is the result of scientific research. However, the availability of technology, even if revolutionary, is not enough. The value of a technology is reduced if it cannot be transferred to a user who intends to use it to obtain a tangible production benefit. Universities and research institutions need assistance in moving the results of research, development and technology to the stage of creation of the final product or service, so the importance of technology transfer cannot be overemphasized.

Technology transfer is a process that combines exchange operations (between inventor and recipient) with production functions (measurement during start-up operations, individual testing, adaptation of equipment to specific operational conditions, repair of faults, refinement of technology) to reduce transaction costs and value addition.

Technology transfer is both a one-time technology transfer (patent commercialization) through a certain communication channel from one entity (technology owner) to another (technology implementer) and a technology transfer in several stages, depending on its specification and purpose and in accordance with the stages of technical development and contractual arrangements.

Technology transfer can be expressed in the form of transfer of results of intellectual activity, transfer of objects of intellectual property, realization of patentless inventions, exchange of scientific and technical information, implementation of joint research and development design and technological outputs.

Main activities of TT

Assessing the effectiveness of technology transfer implementation is a complex task that requires an integrated approach to identifying the economic, social, environmental, technological and other impacts derived from the introduction and deployment of knowledge-based development.
Technology transfer includes the following activities:

- technology selection, search and identification;
- performing technical and economic analysis and conducting expert work;
- the determination of the methods of dissemination of non-patentable ideas and inventions;
- search for technology partners and strategic investors;
- consulting support for an innovative project;
- creation of academic and corporate alliances for the implementation of high-tech projects;
- formation, incubation and positioning of innovative companies;
- attracting talented teachers, staff and students to innovative activities.

Technology transfer involves the transfer of material knowledge (technical data and drawings, design prototypes, instructions, inventions, utility models, industrial designs, software, and trade secrets) from one organization to another. The technology transfer mechanism is determined by the organization's policies and values.

Technology transfer in the context of research institutes involves a process in which high-tech developments created in the laboratories of these institutions are commercialized through licensing of patented intellectual property objects and the creation of start-UPS, and transformed into high-tech products.

Domestic and foreign practice of TT

The participation of the industrial complex of the economy in the transfer of technologies includes various constructive actions aimed at combining the efforts of manufacturing companies and scientific organizations for mutual benefit. Participation can be one-time – the implementation of a project/scientific and technical initiative, or it can include a so-called "strategic partnership", in which the University and the company work together on a continuous series of projects and activities: attracting teachers and students to innovative activities, developing curricula, performing research, training staff, and much more.

Domestic and foreign practice shows that there are various ways of interaction between industry and research organizations, ranging from the exchange of results of research, development and technological work, participation in joint project work, and ending with financial support for basic research . Industry is often a key source of funding and practical experience, which can speed up the process of creating material knowledge in the research environment. Constructive economic relations that arise between participants in innovation activities can complement joint research programs and investment mechanisms designed to synthesize new knowledge and make scientific discoveries.
For manufacturing companies, commercial relationships with research organizations can present a number of problems that are not obvious to the academic sector in relation to a particular technology or development. Therefore, it is important for representatives of science and industry to interact with technology transfer entities, which help identify possible difficulties, risks and problems at the early stages of implementing a joint innovation project.

Subjects of technology transfer have a culture of academic cooperation and have experience in strategic partnership with representatives of the real sector of the economy, which allows you to build a chain of effective interaction "University-industrial enterprise", contributing to the generation of material knowledge and their implementation in innovative products.

Qualified specialists working in the field of technology transfer help accelerate the processes of technological transformation in various spheres, complexes and sectors of the economy. They contribute to the successful management of innovation, involving companies in the innovation process, the protection and licensing of intellectual property, to market of science intensive products, the creation of new start-UPS and development of high-tech enterprises.

Technology transfer specialists interact with lawyers for the protection of patent and other intellectual property rights, evaluate the commercial potential of inventions, promote technologies to potential licensees and partners, train researchers on the principles and strategies of commercialization, participate in partnership negotiations and licensing agreements, and help create innovative ecosystems that contribute to the innovative development of the economy, promote the development of educational programs in the field of innovative entrepreneurship.

Personal contacts and trusting relationships between technology transfer specialists and developers/implementers of intellectual activity results are of particular importance in the implementation of technology transfer. The emergence of digital technologies that convert analog information into digital format has greatly simplified and accelerated the process of such relationships.

Digital technologies in TT practice

Digital technologies provide a better view of performance and results in real time by integrating structured and unstructured information, providing a better overview of the organization's data and data from external sources. One of the digital technological solutions in the field of innovation dissemination is a platform for technology transfer.

The technology transfer platform is a web resource where registered users can post technology requests and offers, exchange information, and search for experts, technology partners, and strategic investors.

The functional advantage of the technology transfer platform, in addition to constantly updated information, is an intelligent communication system for technology suppliers and recipients. The platform accumulates data on the technological resources of technology suppliers who seek to commercialize the results of intellectual activity, informs about the needs of technology recipients who are interested in acquiring innovative solutions, and offers expert resources that can be used in the process of technology transfer.

Abstract

This paper aims to analyze the importance of quality and customer satisfaction in the Portuguese mobile market as variables leading to customer loyalty. Several attitudinal and behavioral drivers of brand loyalty were examined, as well as the possible relationship between them and how they impact in lasting relationships between consumers and mobile brands. Previous literature supported the development of a set of hypotheses. The model was tested on an empirical study based on a survey to 231 Portuguese consumers, with questions measuring the main concepts (brand loyalty, trust, involvement/engagement, satisfaction and quality). Statistical analysis included descriptive statistics (means, standard deviation, Cronbach's alpha), paired-samples T-test, data reduction techniques and hierarchical regression analysis. Results reveal that repurchase intention, as a proxy to brand loyalty, is influenced by all the considered concepts. However, brand trust and brand involvement impact on brand commitment and seem to be stronger predictors of brand loyalty. Since this article considered brand loyalty as the sum of repurchase intention and brand commitment, expected quality is not relevant for neither of them. Trust seems to impact on brand commitment but not in repurchase intention. Performed Quality is statistically significant but through consumer satisfaction. Therefore, Satisfaction and Involvement/Engagement lead to strong brand commitment and repurchase intention and performed quality is also an independent variable that leads customers to brand loyalty in the mobile market. Results are discussed in light of the consumer-brand relationship theory. Despite some limitations (our study is only limited to Portugal, to a sample of young consumers mainly from the north of the country), this study offers a reasoned view on consumer-brand relationship. Aiming to identify the role of quality and customer satisfaction in the Portuguese telecommunication market, we hypothesized customer satisfaction as a mediator to involvement/engagement, trust and brand loyalty. To keep customers' attention and achieve brand loyalty (commitment + repurchase intention), any Portuguese telecommunication player needs to satisfy clients by betting on perceived quality in time and to involve them, offering accurate information on products and services. If so, consumers will feel satisfied, trust and develop a strong feeling towards the brand.

Keywords: Quality; Satisfaction; Involvement/Engagement; Trust; Brand Loyalty.

Introduction

Customer loyalty is generally accepted as very important to companies, consisting in the individual positive attitude towards a certain brand, a personal identification with its products/services and positioning and the predisposition to defend and recommend it to others (Caruana, 2002; Rai and Srivastava, 2012; Bhatti et al, 2017). Retaining clients goes on being one of the companies' main concerns, due to aggressive competitors always surprising consumers and getting their attention in time (Bharadwaj et al, 1993; Bon and Tissier-D., 2000; Ray and Srivastava, 2012). Opposite, getting a new customer is understood as a more expensive process (Bon e Tissier-D., 2000; Edward and Sahadev, 2011; Bhathi et al, 2017); all the brands' efforts to keep clients with them affect their results (Santouridis and Trivellas, 2010; Edward and Sahadev, 2011; Bathi et al, 201). Wanting to act in global and competitive markets,

The Case of the Portuguese Mobile Market" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

approaching sales estimations to real demand and betting on differentiation as the way to cope with competitors made customer loyalty a crucial issue in companies' strategies (Fournier and Yao, 1997; Santos-Vijande et al, 2018; Asch and Bowman, 2017; Hill and Alexander, 2017).

This research tries to understand the antecedents affecting customer attitudes and loyalty in mobile telecommunication, pointing out for some already studied variables -customers' satisfaction, involvement/engagement and trust. Bearing in mind that service quality has a positive impact on customer satisfaction (Steenkamp, 1990; Spreng and Mackoy, 1996; Bhatti et al, 2016), we also included this variable in the study.

This paper is structured as follows: Section 2 presents the theoretical framework, with related work on the loyalty concept. Section 3 presents conceptual model and hypothesis to be tested. Section 4 presents findings and Section 5 present main conclusions, some limitations and recommendations for future research.

The main contribution of our work is helping the Portuguese mobile brands to better understand what makes a customer choose for a certain player, stay with it and learn what to do in order to increase retaining rates. Results reveal that trust and involvement impact on brand commitment, therefore being stronger predictors of brand loyalty; furthermore, for our sample, Expected Quality is not relevant but Performed Quality is statistically significant through consumer Satisfaction. I.e., satisfaction and Involvement lead to strong brand commitment and repurchase intention and performed quality is also an independent variable that lead customers to become loyal.

Theoretical Framework

Several studies were developed on brand and customer loyalty and their importance on companies' revenue and competitiveness: the higher the consumers' loyalty, the lower the marketing costs (Jacoby and Chestnut, 1978; Assael, 1992; Bloemer and Kasper, 1995; Hallberg, 1997; Bon and Tissier-D., 2000; Know and Walker, 2001; Kuo et al, 2009; Bathi et al, 2017). Loyalty is about products/services (Reichheld, 1996; Bon and Tissier-D., 2000), about the company's employees (Macintosh and Locksin, 1997; Bon and Tissier-D., 2000; Butsher, S., 2017), their points of sale (Carmen, 1970; Rousseau, 2008) or any other factor (ex.: promotions – Payne et al, 1998; Mações, 2015). Being also the way for consumers to show their satisfaction with a product or service (Bloemer and Kasper, 1995; Han et al, 2018), some related concepts must be considered (Payne et al, 1998 and Kearney, 1998): differentiation, promotion, efficient distribution, after-sales services and communication.

The main purpose of any company must be establishing a true relationship of trust with consumers, satisfying, meeting and even exceeding their expectations, gradually creating a trust shield (Lehu, 2000; Kotler and Armstrong, 2012; Esterik-P. P.W.J. and Raaij, 2017; Kotler and Armstrong, 2017; Han et al, 2018). Kang et al. (2011) believed that it is important to create a sense of trust if brands want to have positive reactions from their clients; positive attitudes and favorable behaviors are the basis for a good relationship in time (Ganesh et al, 2000). To trust a brand, clients' need to see its effort to meet and exceed their expectations through time (Anderson and Sullivan, 1003; Caruana, 2002; Husasain et al, 2015), reducing any perceived risk (Delgado-B. and Munuera- A., 2005; Kamaruddin et al, 2017; Frasquet et al, 2017; Manni and Singh, 2018; Zakzuk and Núñez, 2018). Building trust in a buyer–seller relationship is crucial and a background of loyalty (Morgan and Hunt, 1994; Fournier, 1995; Gurviez, 1996; Chaudhri and Holbrook, 2001; Harris and Goode, 2004; Chiu, Huang and Yen, 2010; Hong and Cho, 2011; Kang et al, 2011; Paparoidamis, 2019; Khadim et al, 2018).

In work founded, loyalty has different meanings and approaches. Being much more than repeated purchases, it should be understood in three main approaches: (1) Behavioral, (2) Attitudinal (Dick and Basu, 1994; Dekimple et al, 1997; East, 1997; Bhatti et al, 2017) and (3) Integrated approach (Cross and Smith, 1995; Griffin, 1995; Mowen, 1995; Fournier and Yao, 1997; Bon and Tissier.D., 2000). Also referred as brand commitment, it considers the consumer's participation and connection with the brand offers (Mowen, 1995; Bon and Tissier-D., 2000; So et al, 2014; Vivek et al., 2012; Rhadita et al, 2017), joining two other concepts: band engagement and brand involvement. Engagement has recently emerged in both academic literature and practitioner discussions as an important brand loyalty predictor (So et al, 2014): a truly engaged customer reveals a psychological connection with a brand and a connection with its offers (So et al, 2014; Vivek et al, 2012). Involvement shows the level of brand interest and its significance to the consumer (Guthrie and Kim, 2009).

Satisfaction and quality seem to lead to competitive advantages (Steenkamp, 1990; Aaker, 1991; Cristopher et al, 1995; Ganesh et al, 2000; O'Shaughnessy, 1995; Spreng and Mackoy, 1996; Chi et al, 2009; Vinita et al, 2015; Bhatti et al, 2016; Nyadzayo and Khajehzadeh, 2016; Raditha et al, 2017). Satisfaction is, to a considerable number of authors, an important antecedent for brand loyalty (Kotler and Dubois, 1989; Selnes, 1998; Ganesh et al, 2000; Bloemer and Odekerken, 2002; Hussain et al, 2015; Ashraf et al, 2018; Kamarudding et al, 2018; Saham et al, 2018),

since consumers need to feel satisfied to consider buying again. One may say that satisfaction is an antecedent for repeated purchases and or use of a product/service, leading to positive word of mouth and/or recommendations (Shaham et al, 2018). The consumers' degree of satisfaction influences their subsequent behavior: when satisfied, consumers tend to buy again; if unsatisfied, they have an opposite reaction, probably speaking negatively about a brand, product and/or service (Kotler and Dubois, 1989; Samson, 2006).

Satisfied clients develop a relationship through time –loyalty-, feeling committed and wanting to buy again (Carmen, 1970; Vinita et al, 2015; Nyadzayo and Khajehzadeh, 2016; Paparoidaimis, 2017; Raditha et al, 2017).

Methodology

The research model follows a quantitative approach; hypotheses were drawn from the literature review. We established relations and variables were measured using already validated constructs.

Customer loyalty is increasingly understood as one prime factor inducing a long-term relationship between consumers and brands, therefore positively influencing a company's financial performance (Carmen, 1970; Reicheld, 1996; Hong and Cho, 2011; Mallika et al, 2014; Nyadzayo and Khajezadeh, 2016; Frasquet et al, 2017), therefore being crucial to clearly understand its antecedents (Chuah, 2017; Frasquet et al, 2017). This paper aims to analyze the importance of quality and customer satisfaction in the Portuguese mobile market as variables leading to customer loyalty. Since consumers' perception of quality is the result of their assessment of the general superiority of a brand vis-à-vis other brands (O'Shaughnessy, 1995), it seems to exist a direct relationship between quality and loyalty (Aaker, 1991; Christopher, 1995; Vinita et al, 2015; Nyadzayo and Khajehzadeh, 2016; Raditha et al, 2017). The higher the consumer's quality perception, the higher the level of satisfaction, the higher the connection with a brand, the bigger the possibility of ending up trusting and the greater the probability of becoming loyal, establishing a relationship in time and repurchase intention.

Fig. 1: Theoretical Model

When consumers choose a product, they care about perceived quality (Chi et al, 2009):

H1. The mobile consumer' satisfaction towards a brand depends on how he/she perceives its products and services' quality: *there is a positive association between perceived quality and mobile consumers' satisfaction*.

Some authors believe that the higher the brand's capacity to surprise consumers and offer them products and services capable to exceed expectations, the higher the positive perceptions they create and the greater the brand's image

(Ganesh et al, 2000). It has become very important for organizations to act in order to exceed consumers' expectations (Anderson and Sullivan, 1993; Kandampully, 1998; Caruana, 2002; Hussain et al, 2015):

H2. The mobile consumer' satisfaction with a brand depends on its capacity to exceed his/her expectations: *there is a positive association between exceeding expectations and the mobile consumers satisfaction with brands.*

Various studies have looked for the relationship between satisfaction, involvement/engagement, trust and brand loyalty: LeClerc and Little (1997), Park (1996) and So et al (2014) found that brand loyalty was also the result of involvement/engagement. Therefore, the higher the consumer's involvement/engagement, the more he/she becomes to trust a brand and to develop a loyal behavior:

H3. The effect of mobile consumer Satisfaction on the development of brand trust is higher, the greater the degree of involvement/engagement (Steenkamp, 1990; So et al., 2014): *the higher the consumers' connection and intensity of interest with a brand, the higher probability of becoming loyal.*

Trust is one of the backgrounds of loyalty for a considerable number of authors (Morgan and Hunt, 1994; Fournier, 1995; Gurviez, 1996; Chaudhri and Holbrook, 2001; Harris and Goode, 2004; Chiu, Huang and Yen, 2010; Ganesh et al, 2000; Hong and Cho, 2011; Kang et al, 2011; Khadim et al, 2018):

H4. The higher the mobile consumer's degree of satisfaction with a brand, the higher his/her psychological connection and level of interest and the higher the probability to trust: *there is a positive association between a high degree of satisfaction, involvement/engagement and the mobile consumer's brand trust and purchase intentions.*

Satisfied customers are good sellers (Kotler and Dubois, 1989; Bon and Tissier, 2000); the main purpose of any company must be to establish a true relationship of trust with consumers, creating a trust shield (Lehu, 2000; Kotler and Armstrong, 2012; Esterik-P. P.W.J. and Raaij, 2017; Kotler and Armstrong, 2017; Han et al, 2018). Larzelere and Hunt (1980) and Morgand and Hunt (1994) understood Trust as a central construct of any long-lasting relationship. Satisfaction leads to Brand Trust and this leads to the mobile consumer's willing to have a relationship in time and go on buying. There is a positive association between Satisfaction, Brand Trust and the mobile consumer's intention to keep coming back.

To many authors, trust is one of the backgrounds of loyalty (Morgan and Hunt, 1994; Fournier, 1995; Gurviez, 1996; Chaudhri and Holbrook, 2001; Harris and Goode, 2004; Chiu, Huang and Yen, 2010; Hong and Cho, 2011; Kang et al, 2011; Khadim et al, 2018); therefore, it is expected that:

H5. The higher the mobile consumer trust a brand, the higher the probability to develop a relationship with it and become a loyal client: t*here is a positive association between Trust and Brand relationship in time.*

When a brand is capable to keep a client committed, trusting and having repurchase intentions, it has created the ideal scenario for that client to become a satisfied person, predisposed to pay more, act as a kind of lawyer and buy more often (Carmen, 1970; Assael, 1992; Bloemer and Ruyter, 1997; Ganesh et al, 2000; Chaudhuri and Holbrook, 2001; Fullerton, 2005; Doorn et al, 2010; Mallika et al, 2014; Vinita et al, 2015; Messaoud and Deboki, 2016; Nyadzayo and Khajehzadeh, 2016; Kumar, 2016; Paparoidaimis, 2017; Raditha et al, 2017):

H6. The higher the brand trust, the higher the mobile consumer's intention to repurchase and to become a loyal client: *there is a positive association between Brand Trust and Repurchase intentions.*

Results

Data collected was the result of a questionnaire applied in 2018 (December) to a non-probability purposive sample (budget constraints), composed mainly by higher education students, in a total of 231 respondents. A pre-test was done to a convenience sample of 20 individuals; consequent analysis allowed some layout improvements, but did not imply changes regarding main variables. Final questionnaire was developed using the variables that met the bibliography research done in related concepts: Quality- gap between reality and perceptions, to evaluate the basis of satisfaction and consequent brand loyalty, using the SERVQUAL model (Zeithalm et al, 1985, 1988 and 1990) and its 5 dimensions: Tangibility, Trust, Answering Capacity, Warranty and Empathy. We used a Likert 7 points scale (Totally Disagree to Totally Agree). For Satisfaction, we used Spreng et al. scale (1996): satisfaction is the result of the consumer's evaluation of the use and/or previous experience with the brand. We used a 7 points' Likert scale (Very Dissatisfied to Very Satisfied). Involvement/Engagement were measured according to Zaichkowsky (1985),

trying to evaluate perceived risk; 7 point's Likert scale (Nothing Important to Important)**.** For Trust**,** we've used Delgado and Munuera scale (2001), with the following items:

a) Offers me a product/service with a constant quality level;
b) Helps me solving any problem that may occur with the product or service;
c) Offers me a variety of new products always adapted to my needs;
d) Is worried in satisfying me;
e) Values me as a customer;
f) Gives me support and advices on how to better use its products and/or services.

For Commitment (intention to keep a relationship) and considering it as an affective and/or emotional process, we based ourselves on Beaty and Kahle (1988), Bloemer and Kasper (1995) and Muncy (1996) studies, developing some questions trying to represent the main characteristics of a possible relationship between a consumer and a brand (ex.: I consider myself loyal to X brand; for me X brand is surely the best one in the market; I intend to go on buying X brand's product). A 5 point's Likert scale was used (Totally Disagree to Totally Agree), as the authors suggest. For repurchase intention, we based ourselves in some questions used by some authors (Morgan and Hunt, 1994; Fournier, 1995; Gurviez, 1996; Chaudhri and Holbrook, 2001; Harris and Goode, 2004; Chiu, Huang and Yen, 2010; Hong and Cho, 2011; Kang et al, 2011; Khadim et al, 2018) and developed 12 questions which content allow us to prove the consumer's intention to go on buying through time and his/her degree of certainty.

We then added two more complementary questions: (i) to confirm the respondents' intention to go on using their mobile operator's goods and services; (ii) to understand the needs that lead respondents to use mobile telecommunications.

Hypotheses vs Dimensions vs Questions

Table 1

Hyp.	Dimension/Variables	Questions vs Sources
1	**Quality** (Expectations) (Actual Performance)	1-22 23-44 (SERVQUAL, Zeithalm et al, 1985, 1986 and 1990)
2	**Satisfaction** (Consumer's evaluation - experience)	45-54 (Spreng et al, 1996)
3	**Involvement** (How important is the product and the decision process to the consumer)	65-70 (Zaichkowsky (1996)
4	**Trust** (Consumer's degree of certainty about the brand's characteristics described)	55-64 (Delgado and Munuera, 2001)
5	**Commitment – Brand's Identification** (Consumers' degree of certainty about staying with the brand)	71-81 (Bethy and Kale, 1998; Bloemer and Kasper, 1995; Muncy, 1996)

6	**Commitment – Repurchase Intention** (Consumers' degree of certainty about repurchasing)	82-93 (Morgan and Hunt, 1994; Fournier, 1995; Gurviez, 1996; Chaudhri and Holbrook, 2001; Harris and Goode, 2004; Chiu, Huang and Yen, 2010; Hong and Cho, 2011; Kang et al, 2011; Khadim et al, 2018)

Data analysis and Results

Statistical procedures were as follow: a confirmatory factor analysis was conducted in the scales used to measure the constructs; hypotheses were tested using SPSS. A set of validated scales taken from the academic literature were used.

Our sample is made of 51.9% of male respondents, ages between 17 and 24; the majority of the respondents stated a monthly household income until 250 euros, as already expected since they are all students. Table 2 shows their degree of education:

Table 2

Education Degree

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Until the 9th year	2	,9	,9	,9
	10º - 12º year	48	20,8	20,8	21,6
	University Frequence - Graduation (attending)	174	75,3	75,3	97,0
	Graduatin (done)	4	1,7	1,7	98,7
	University Frequence - Master	3	1,3	1,3	100,0
	Total	231	100,0	100,0	

EFA was used to validate the measurement models consisting of six constructs measured:

Table 3

	FACTORIAL ANALYSIS
EXPECTED QUALITY	One Factor, accounting for 33,4% of variance.
PERCEIVED QUALITY	One Factor, accounting for 45,5% of variance.
SATISFACTION	One Factor extracted accounting for 71,6% of variance.
TRUST	One Factor extracted accounting for 57,8% of variance.
INVOLVEMENT	One Factor extracted accounting for 66,4% of variance.
BRAND COMMITMENT	2 Factors extracted accounting for 64,4% of variance.
REPURCHASE INTENTION	2 Factors extracted accounting for 67,5% of variance.

Regression was also done to find Inter-correlations:

Table 4

	EXPQUAL	PERFQUAL	SAT	TRUST	INVOLV	BCOMM	REPINT
EXPQUAL							
PERFQUAL	.73						
SAT	.114	.610**					
TRUST	.485**	.309**	.317**				
INVOLV	.147*	.633**	.767**	.289**			
BCOMM	.135*	.576**	.755**	.293**	.836**		
REPINT	.097	.551*	.722**	.225**	.801**	.906**	

**. Correlation is significant at the 0.01 level (2-tailed)

*. Correlation is significant at the 0.05 level (2-tailed).

Reliability was tested by examining the Cronbach's Alpha coefficients; findings show that Expected Quality is not relevant for Brand Commitment, neither for Repurchase Intention (altogether assumed as Brand Loyalty in this study). Trust seems to impact on Brand Commitment but not in the Repurchase Intention (therefore contributing in a moderate way). Performed Quality (real performance) is statistically significant, but through consumer's Satisfaction (when we introduce Involvement, Performed Quality stops having statistical significance and/or direct impact on Brand Loyalty):

Table 5

	BCOMM		REPINT

Conclusions

The goal of this study was to examine brand loyalty antecedents in the Portuguese mobile consumers, considering some of the most common variables related to the concept. Based on the consumer-brand loyalty theory it was assumed that Quality and Satisfaction are important for inducing positive feelings on consumers, making them want to repurchase a brand's products and services and, at the same time, feel committed to it (loyalty).

In this research, we assumed Quality as an important variable to make consumers feel satisfied; once satisfied, consumers will feel connected to the brand, interested on it, therefore assumed that the higher the consumer's degree of involvement/engagement, the more he becomes to trust a brand and develop a loyal behavior. When individuals get more involved in the buying decision process, being capable to gather reasonable and accurate information, they begin to trust the brand (and trust is one of the backgrounds of loyalty for a considerable number of marketeers and authors). The higher the consumer trust a brand, the higher the probability to become loyal to it (committed and with the intention to buy again).

Table 6

Hypothesis	Final Results
H.1	Accepted
H.2	Rejected
H.3	Accepted
H.4	Accepted
H.5	Accepted
H.6	Rejected

According to data obtained, only Perceived Quality seem to impact on customer satisfaction and, as a consequence, on brand loyalty (performed quality is statistically significant, affecting satisfaction and, through it, leading to brand loyalty).This conclusion looks contrary to the main aspects referred to in the literature review (pointing for both perceived and performed quality), but we have to notice that our sample, mainly composed by young consumers, may impact in these findings.

As far as telecommunications are concerned and for the Portuguese mobile consumers, involvement/engagement are a result of satisfaction, leading to brand trust. Trust seems to impact on brand commitment, but not in the repurchase intention; i.e., for the mobile consumers, a brand that induces trust is a brand that they will go on paying attention through time, even if that attention does not lead to a purchase situation. This may allow us to assume that trusting a brand is crucial for the customer to feel identified (committed) and, if receiving the right stimulus, to consider repurchasing their products or services.

Our study is only limited to Portugal and, specifically, to young consumers from the north region, which limits extrapolating conclusions; therefore, comparative studies are recommended, to generalize findings to individuals of different ages, to allow establishing direct comparisons and have a wider understanding of the Portuguese mobile consumer behavior. Also extending the topic under review to other products, services and within an international context could be of consideration in future research.

Abstract

The purpose of the research is to study the role of consumption in the processes of ensuring economic dynamics and social development and to reveal the specifics of consumption of the Russian population in the period 2013-2018, as well as to identify existing contradictions. The authors made international comparisons and revealed a low share of final household consumption in Russia's GDP in comparison with similar indicators of developed consumer society models in the leading countries of the world. The authors studied the Russian dynamics of changes in the structure of GDP by expenditure. The article analyzes the conditions and factors that determine the structure of final consumption of households in Russia. It is determined that the structure of consumption in Russia is characterized by an extremely low share of services in comparison with developed countries and rapidly developing BRICS countries. It is proved that the decrease in final consumption in the period 2015-2017 is due to a drop in real disposable income of the population and a reduction in personal consumption opportunities.

Keywords: consumption, GDP, household expenditure, final household consumption, income inequality, Russia

Introduction

The role of consumption in the processes of socio-economic development is multifaceted. On the one hand, consumption and its characteristics are an indicator of the standard of living and well-being of the population. The quality of life of the population depends on what needs consumers ' incomes are spent on, what goods and services they purchase, and what the structure of these purchases is. The amount of income determines the ability of people to meet their needs and, accordingly, sets the framework for spending money. The growth of household consumption expenditures is possible if the population's income increases, confidence in the future and trust in the state increases, access to credit resources increases, and savings can be formed.

On the other hand, the expansion of consumption transforms the relationship between consumers and producers: growing consumer demand creates prerequisites for increasing production volumes, grow production capacity, raise employment, and enhance profits. Thus, consumption stimulates the business activity of producers and provides positive economic dynamics.

Cite this Article as: Gulnaz F. GALIEVA, Luiza I. IL`INA, Sergey V. PONOMAREV, Bella O. KHASHIR and Evgeniya K. KARPUNINA "Consumption as a Growth Factor of the Russian Economy" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

However, not all countries are characterized by a balanced structure of consumption, and consumer demand is not always the engine of economic growth. As a rule, in developed countries (the United States, the United Kingdom, etc.), a high level of consumption, provided by constant income growth, a healthy labor market and high credit activity of the population, contributes to economic growth.
Meanwhile, the share of final household consumption in Russia's GDP and the structure of population consumption are radically different from the European or American ones. How do these factors affect the country's economic dynamics? How does the structure of household consumption change during crisis periods? These issues require special research attention.

Methodology

The purpose of the study is to establish the relationship between population consumption and the processes of ensuring positive economic dynamics, as well as to identify the specifics of consumption of the Russian population in the period 2013-2018.

Research objectives:

- determine the share of final household consumption in Russia's GDP in comparison with other countries;
- analyze the dynamics of changes in the structure of GDP by expenditure in Russia;
- identify conditions and factors that affect household final consumption;
- analyze the consumption structure of Russian households and its changes.

The theoretical basis of the research is the works of Keynes (2013), Kudinova (2014), Struchenevsky (2018), Zombart (2005), Kapelyushnikov (2013), Zubarevich and Safronov (2019).

Keynes (2013) claims that consumption is a function of real income. Income is a source of satisfaction of people's personal needs and determines the level and structure of final consumption.

Kudinova (2014) explores the role of personal consumption in economic growth and cyclical processes. The author refutes the thesis that consumer actions aimed at maximizing personal satisfaction create prerequisites for economic growth regardless of the existing institutional conditions.

Takmakova (2010) argues that in order to revive the economy, it is necessary to form effective demand by increasing part of the population's income in GDP.

Zubarevich and Safronov (2019) analyze the transformation of consumption in the regions of Russia and identify its dependence on the level of income of the population of the regions, adjusted for the cost of living, and the level of poverty.

Struchenevsky (2018) emphasizes that population consumption is one of the main factors that ensure GDP growth, along with investment and exports.

Ovcharova and Popova (2013) note that Russia is far from developed European countries in terms of household consumption. Zemskova (2009) proves that in Russia, where a quarter of all expenditures are spent on food purchases, both the industrial and post-industrial orientation of the national economy is blocked.

Research methods: theoretical analysis, comparative analysis, economic analysis, system approach.

The research is based on materials from the Federal state statistics service of the Russian Federation, the Analytical center under the Government of the Russian Federation, United Nations, and the World Bank.

Results

International comparisons on the indicator “share of consumption in the country's GDP”

The share of consumption in a country's GDP (the share of household final consumption expenditure in GDP) can be considered one of the most important indicators of the population's well-being.

As a rule, the consumption rate is higher in developed economies than in developing ones (table 1) (Analytical center under the Government of the Russian Federation, 2019a).

Table 1: Structure of nominal GDP of the world's economies by expenditure, % of GDP, 2018

The group of economies	Final consumption		Fixed capital formation	Net export
	Households	Government		
World	56,52	16,23	26,13	0,7
Emerging economies	50,89	14,36	32,89	0,94
Transition economies	51,96	16,36	23,42	7,07
Developed economies	60,61	17,51	21,61	0,25
Russia	49,6	17,5	22,9	10,0

Source: compiled by the authors according to Unctadstat (2020)

The share of household consumption in global gross output in 2018 was 56.52%. In developing countries, the share of household consumption was 50.89%, while in developed economies it was 60.61%.

In 2018, the leaders in this indicator were the United States (68.4%), Mexico (67.3%), the United Kingdom (66.0%), Argentina (65.0%) and Brazil (64.3%). The US and the United Kingdom are characterized by a developed consumer society and low gross domestic savings. Argentina, Brazil, and Mexico support the level of consumption by public spending on social policy, optimizing the labor market, and increasing real incomes (Unctadstat, 2020).

The share of final household consumption in Russia in 2018 was 49.6 % of GDP, which is 7.3 percentage points lower than the average for the G20 countries (ECLAC, 2018).

Dynamics of changes in the structure of GDP by expenditure in Russia

In the structure of Russia's GDP by expenditure, there was a noticeable reduction in the share of household expenditure on final consumption of goods in the period 2014-2018 (table 2).

Table 2: Dynamics of changes in the structure of Russia's GDP by expenditure

Year	GDP, in current prices, billion rubles	Final consumption		Fixed capital formation	Net export
		Households	Government		
2013	72985.7	53,2	18,7	23,6	4,5
2014	79030.0	53,8	18,0	22,4	5,8
2015	83087.4	52,7	17,7	22,1	7,5
2016	85616.1	53,2	18,5	23,1	5,2
2017	91843.2	52,9	18,2	23,6	5,3
2018	104629.6	49,6	17,5	22,9	10,0

Source: compiled by the authors based on their own calculations and data from the Federal state statistics service of the Russian Federation (2020a)

As can be seen from the table, the decline in household final consumption expenditures began in 2015 (52.7%) and continued until 2016.in 2017, the dynamics leveled off, and in 2018, household final consumption expenditures fell again to 49.6% of GDP.

The quarterly dynamics of the contribution of GDP elements by expenditure to GDP growth shows that the main contribution to GDP growth in 2018 was made by consumer spending of households (+1.2 p. p.), gross fixed capital accumulation (+0.6 p. p.) and net exports (+0.8 p. p.) (Analytical center under the Government of the Russian Federation, 2019c)

The analysis of social conditions influencing final consumption of households.

The size of final consumption is determined primarily by the size of the population's income. Therefore, we will analyze the sources of formation of consumer budgets in Russia, as well as the nature of income distribution (table 3).

Table 3: Size and structure of personal income of the population

Year	Total monetary income, million rubles	Including as a percentage:				
		income from business and other production activities	wage of employees	social benefits	property income	other money receipts
2013	44, 230.6	7,0	55,1	18,7	4,7	14,5
2014	47,309.2	7,0	54,9	18,2	4,8	15,1
2015	53,153.2	6,5	52,8	18,2	5,1	17,4
2016	54,325.3	6,4	54,0	18,8	5,1	15,7
2017	56,205.1	6,3	55,1	19,3	4,6	14,7
2018	58,458.7	6,1	57,4	19,1	4,6	12,8
2019	62,080.1	6,1	57,9	19,0	4,4	12,6

Source: compiled by the authors according to the Federal state statistics service of the Russian Federation (2020a)

Most of the monetary income of the population in 2019 was generated by wages (57.9%). The second largest share of income comes from unofficial wages (calculated as the difference between consumption, savings growth, and officially earned income) (23%) (Struchenevsky, 2018). The dynamics of the population's income is also determined by social payments (pensions and surcharges to pensions, social assistance, scholarships, insurance indemnities), the amount of which in the period 2013-2018 showed growth dynamics, in 2018 they amounted to 19% of GDP.

Since 2013, the country has seen a decline in the real disposable income of the population. Only by 2018, the growth rate of real monetary income of the population reached a positive value, but real disposable income increased by only 0.1% (figure 1).

Fig. 1: Dynamics of disposable income of the population, real wages, real retail sales, and real household expenditures, %, 2013-2018 (compiled by the authors according to the Federal state statistics service of the Russian Federation, 2020b)

Figure 1 shows the decline dynamics in real retail sales and real household consumption expenditures due to a sharp drop in real monetary incomes and wages after the 2014 crisis (due to a sharp drop in world oil prices, which caused, among other things, a reduction in retail lending and an increase in the savings rate) (Struchenevsky, 2018). In addition, the figure shows that the monetary income of the Russian population significantly lags behind real wages

due to the fact that a large segment of the population is unofficially unemployed, or organizations overestimate data on the wage fund.

The growth of indicators in 2018 was due to several reasons: 1) higher wages for public sector employees and the minimum wage; 2) low inflation (2.2-2.4% per year) (Analytical center under the Government of the Russian Federation, 2019c); 3) growth in the number of the labor force and an increase in its level of education (Struchenevsky, 2018). In addition, in the period 2013-2014, the level of differentiation of monetary incomes of the population decreased – the value of the Gini coefficient in 2013 was 0.417, in 2018-0.411, this is evidence of positive dynamics in the socio-economic sphere. (Analytical center under the Government of the Russian Federation, 2019c). Thus, the decline in final consumption is due to a drop in real disposable income of the population and a reduction in personal consumption opportunities.

Consumption structure of Russian households and its changes

The World Bank classifies Russia as a group of high-income countries. This allows us to hope for future qualitative changes in the structure of consumer demand. However, changes in the structure of monetary income of population in the period 2013-2018 shows a significant reduction in the proportion of purchases of goods and services in the total amount used in income and increase in savings (associated with declining consumer confidence and negative consumer expectations in the post-crisis period) (table 4).

Table 4: Structure of the use of monetary income of the population of the Russian Federation, 2013-2018

Year	Total income used, %	Including as a percentage			
		Purchase of goods and payment for services	Payment of mandatory payments, contributions, and other expenses	Increase (+), decrease (-) in household savings	Increase (+), decrease (-) in cash on hand in rubles and foreign currency in ruble equivalent
2013	100	80,8	14,8	3,8	0,6
2014	100	82,0	15,3	0,3	2,4
2015	100	77,2	13,7	10,1	-1,0
2016	100	77,5	13,8	6,6	2,1
2017	100	79,1	14,1	4,6	2,2
2018	100	80,7	15,1	1,7	2,5

Source: compiled by the authors according to the Federal state statistics service of the Russian Federation (2020b)

Let's look at the content of the population's expenditures on the purchase of goods and payment for services (figure 2).

Fig. 2: Public expenditures on purchasing goods and services, in % , 2013-2018
(Source: compiled by the authors according to the Federal state statistics service of the Russian Federation , 2019)

Most of the population's expenditures (59.7% in 2018) are spent on the purchase of goods. The consumption structure in Russia is characterized by an extremely low share of services-below not only developed countries, but also their BRICS partners. In 2013, the share of public expenditures on services was 17.3%, and by 2018, it had increased to 18.1%.

The low share of services in the structure of public spending is characteristic of those countries where the supply of services is not developed, and their cost is also high; the population saves on services for the sake of purchasing goods; has a wide range of free services provided by the government; the shadow sector in the service sector is developed, the state of which is not reflected in official statistics.

The structure of household expenditures on the purchase of goods and services also includes the component "payments for goods and services produced abroad", the dynamics of which makes it possible to clearly identify the period of the collapse of the national currency of the Russian Federation in 2015. Prior to this period there is a steady state of this segment of 3.1-3.2 percent in 2013-2015. Due to the sharp weakening of the ruble, in 2016 there was a strong reduction in spending on the purchase of goods and services abroad (up to 2.2%), which indicates a reduction in the effective demand of the population.

The structure of final consumption of households is an indicator of the standard of living of the population and the nature of economic development. The factors that determine final consumption involve the structure of production, the state of the country's foreign trade on the supply side, the size and stability of the population's income, and the level of social inequality (Analytical center under the Government of the Russian Federation, 2019a).

In the period 2005-2014, with oil prices still high, household final consumption grew rapidly. For example, in 2008, the share of durable goods accounted for 16.7% of total purchases of goods and services, and in 2017 it decreased to 12.0%. As a result of the crisis in the Russian economy, the share of short-term goods in 2017 was 49.2%, and services 31.7%.

In times of crisis, the structure of consumption changes: discretionary expenditures are reduced, and food expenditures increase (mostly among low-income segments of the population). The structure of retail sales is also changing, as well as the ratio between individual product groups - food and non-food products, paid services of the population.

The results of a sample survey of Russian households allow us to assess the change in the structure of consumption of the Russian population in the period 2013-2018. (Fig. 3).

Fig. 3: Structure of population consumption, %, 2013-2018

(Source: compiled by the authors according to the Federal state statistics service of the Russian Federation, 2020c)

Russia has high income inequality and one of the highest shares of expenditures on durable goods – transport, furniture, household appliances, electronics, and construction materials. In 2013, the share of expenses for the purchase of vehicles was 10.2% of the total expenditures of the population, the population spent 5.6% on furniture and home equipment, and -1.3% on construction materials. By 2014, the cost of purchasing transport increased to 10.3%. The crisis year 2015 made significant adjustments to the structure of population consumption: the share of expenditures on the purchase of transport (5.3% - in 2016), the purchase of furniture and household appliances (4.5%), and construction materials (1.0%) sharply decreased. Thus, there is an increase in negative consumer expectations of the population, as well as an increase in pessimistic moods of consumers in assessing their personal financial situation and the economic situation in the country (Financial agency of the city of Moscow, 2014).

Only in 2017, the economy began to recover slowly, and spending on durable goods increased (spending on the purchase of transport increased to 8.2%). Also during the crisis of 2015, household expenditures on recreation and travel, purchasing alcohol and eating out decreased.

According to the World Bank, an indicator of slowing consumer demand is a reduction in the consumer credit market. Thus, in 2016, there was a sharp reduction in the volume of loans granted to individuals (by 32%): in 2015, loans were issued in the amount of 8,629,722 million rubles, in 2016 only 5,861,351 million rubles (Zotova and Tyurina, 2018).

As for short-term goods (primarily food products), their share in the expenditures of the Russian population is disproportionately large in comparison with developed countries. For example, in 2017, the share of food expenditures in Germany was 8%, in the United Kingdom - 13.5%, in the US – 5.9%, in Russia-more than 30% (The Federal state statistics service of the Russian Federation, 2017).

The development of the existing consumption model in the future could be based on a gradual increase in the share of paid services closer to the indicators of developed countries. This would keep services accessible to the lower strata of society. The increase in population with higher income should lead to a decline in the share of food expenditure in the poor layers and to reduce the share of food purchases by all households.

Conclusions

The authors conducted international comparisons on the indicator "share of household consumption in GDP", which showed that developed countries are characterized by a model of a developed consumer society and a low level of gross domestic savings. It is revealed that the share of final consumption of households in Russia is significantly lower than the average for the G20 countries.

The authors studied the Russian dynamics of changes in the structure of GDP by expenditure. A noticeable reduction in the share of household expenditure on final consumption of goods in the period 2014-2018 was found, which is associated with the currency crisis of 2015.

The authors studied the conditions that affect the final consumption of households: the income of the population and the nature of their distribution. It is revealed that most of the monetary income of the Russian population is formed by wages. It is determined that the decrease in final consumption in the period 2015-2017 is due to a drop in real disposable income of the population and a reduction in personal consumption opportunities.

The authors analyzed the structure of consumption of Russian households and its changes in the period 2013-2018, consisting in a significant reduction in the share of purchases of goods and services in the total amount of income used and an increase in household savings. It defines the specific structural characteristics of the consumption of the population in Russia.

Abstract

The problem of responsibility of own health, health of other people, healthy lifestyle and prevention of health-related problems are important topics in modern society as health is determined by both current state of the healthcare system and personal attitudes towards one's health. With the spread of the covid-19 pandemic, it is becoming more and more relevant to study the attitude to health of various population groups and behavioral practices to maintain a healthy lifestyle. Nowadays health depends not only on the state of healthcare but also on the psychological characteristics and person's attitudes towards health. Therefore finding differences in health attitudes among various socio-economic and age groups could provide more efficient approaches to health preservation among individuals and in society, which in turn requiring more studies of students' health preservation behavior management in educational organizations from psychological perspective. In this study, psychological characteristics of health and healthy lifestyle attitudes among state university students were studied. Total of 177 participants (49 male and 128 female students aged 18 - 41) had participated in the study. The article highlights results of these students obtained with Attitude towards health questionnaire (Berezovskaya R.A., 2005) and Violation of healthy behavior questionnaire (Lutzenko E.L. & Gabelkova O.E., 2013). The major question of the study was the effect of educational form on attitude towards health and specific healthy behavior violations, as well as which of these forms has the greatest potential for developing and maintaining healthy behavior of students. The results of comparative analysis of full-time and extramural students are provided.

Keywords: University students, health attitude, psychological characteristics, healthy lifestyle disorders, age differences, extramural and full-time education differences.

Introduction

The problem of responsibility of own health, health of other people, promotion of healthy lifestyle and prevention of health-related problems are important topics in modern society. In adolescence this problem is even more important as this age is critical for development of attitude towards one's health and lifestyle in general.

Cite this Article as: Anna N. ZAKHAROVA, Evgeny L. NIKOLAEV, Denis V. HARTFELDER, Galina S. DULINA, Elena Yu. LAZAREVA and Tamara V. TALANOVA "Psychological Features of Attitude Towards Health and Violation of Healthy Lifestyle in Russian University Students" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Nowadays attitude towards health is being studied by specialists in various fields – medicine, sociology, psychology etc. The psychological characteristics of attitude towards health is currently being studied in the framework of clinical, psychological and social studies as an interdisciplinary topic.

Russian psychology considers attitude towards health as a system of personality's selective interrelations with surrounding reality that considered either as beneficial or threatening for health and also being the determinants of physical and mental state assessment for the person (Nikiforov G.S, 2003; Berezovskaya R.A., Nikiforov G.S, 2003). According to Kulikov, attitude towards health as predisposition to preservation or wasting health could be considered a personality trait (Kulikov L.V., 2011).

The structure of health in the framework of the personal model of health includes: attitude to one's own body; personal understanding of the essence of health and the goals of its preservation; knowledge of body functioning principles and limits of volitional regulation; individual attitude towards diseases, including development of ability to actively search ways to recover from disease; expressiveness level of personal attitudes and motives in the process of recovery (Serzhantov V.F., Korolkov A.A., 2006).

The most common integral indicators of individual attitude towards health are: self-esteem of health characterized by temporary and territorial stability; value of health as one of the top items in the hierarchy of values of various population groups; health satisfaction closely related to life satisfaction; care for one's health with relevant activities and practices (Sokolskaya M.I., 2008).

The concept of “attitude to health” integrates all psychological categories, within the framework of which the concept of the internal picture of health is analyzed: this is knowledge about health, awareness and understanding of the role of health in the process of human life, its impact on social functions, emotional and behavioral reactions (Vasilieva N. Yu. ., 2014).

Attitude to health, possessing all the characteristics inherent in a mental attitude, has several main components: cognitive, emotional, value-motivational, behavioral.

Serious contradictions are hidden in many people's attitudes towards health: on the one hand, the value of health is also quite high in the ordinary mind, without reference to scientific evidence. At the same time, in the attitude towards maintaining health, the severity of an effective, behavioral component does not correspond to either the volume of knowledge about health, or the strength of emotional reactions to its weakening (Sokolskaya M.I., Rubanova E. Yu., 2008).

The psychological attitude to health in the process of personality development does not remain unchanged, it is constantly changing based on new life experiences (Berezovskaya, 2010). Currently, special attention of researchers is attracted to various aspects of the problem of attitudes to the health of student youth (Zakharova A.N., Talanova T.V., et al, 2018). Health problems at the student age are associated with high educational, informational, psychoemotional stress, systematic malnutrition, daily routine disturbances, exam stress, insufficient material security, a lot of time spent at the computer, physical inactivity, the spread of alcohol, smoking, and smoking mixtures among some young people. . Media propaganda of unrealistic models of the physical body, standards of physical attractiveness, leading to psychological problems of dissatisfaction with one's own body, to which young people are most susceptible also plays a role (Vasilieva, O.S., Filatov F.R., 2001).

Attitudes toward health can now be considered as a significant factor in determining the psychological well-being and quality of life of students, which have their own cross-cultural and sociocultural characteristics associated with traditions and the transformation of modern society, value meanings, identity, religious orientations (Zakharova A.N., Dulina G.S., Gartfelder D.V., Semenov V.L., 2018).

The study of the cultural and psychological characteristics of the attitude towards the health of Chinese and Russian students showed the relationship with positive attitudes towards health in both samples with indicators of social capital such as the level and radius of trust, the significance of ethnic and civic identity (Lebedeva N.M., Tatarko A.N., Chirkov V.I., Liu Ts., 2007).

In the study of Lebedeva N.M., Bushina E.V. (Lebedeva N.M., Bushina E.V., 2011; Bushina E.V., 2009), existing cultural and gender differences in attitudes and health-related behavior in Russian and Canadian students were identified

An assessment of the predicted values of a wide range of lifestyle options for positive mental health and mental health problems among German and Chinese students revealed the presence of specific effects for different countries. A positive prognosis for mental health problems among Chinese students was more frequent drinking of alcohol, whereas for German students this characteristic may indicate better mental health (Velten, J., Bieda, A., Scholten, S., Wannemüller, A., & Margraf, J., 2018).

Neglect of health, low commitment to healthy behavior, and high stress among medical students can be factors in the development of depressive and anxiety disorders (Hoying, J., Melnyk, B. M., Hutson, E., & Tan, A., 2020). Suboptimal diet, decreased physical activity combined with stress (McSharry, P., & Timmins, F., 2017) can lead to mental and somatic health problems in first-year students. A study by students at Jazzan University showed a high prevalence of overweight and obesity among students, which is in most cases due to unhealthy eating habits (Mahfouz, M. S., Makeen, et al, 2016).

Comparison of differences in knowledge about maintaining health and their practical application showed that knowledge about a healthy lifestyle does not necessarily lead to better following healthy behavior (Sajwani, R. A., Shoukat, 2009). Another study found that female dietetic students have a lower prevalence of eating disorders and an intermediate level of healthy behavior (Alkan, S., Ersoy, N., Eskici, G., & Ersoy, G., 2017).

Students' attitude to health is determined by their motivation to maintain health and follow healthy behavior habits. Identified gender differences in habits and motivation for healthy behavior among students show the presence of the most healthy habits and high stress exposure among female students, unlike male students who are more likely to have unhealthy diets and low physical activity (Von Bothmer, M.I., & Fridlund, B., 2005; Tirodimos, I., Georgouvia, I. et al, 2009; Badger, J., Quatromoni, P.A., & Morrell, J.S., 2019).

There is evidence showing significant differences in student health responsibility in terms of spirituality, body mass index, and marital status (Mehri, A., Solhi, M., Garmaroudi, et al, 2016). At the same time, the characteristics that contribute to increasing students' commitment to healthy behavior are the desire for self-realization, a sense of responsibility for their well-being, while habitual exercises have the lowest rates (Çalışkan, C., Arberk, K., & Üner, S., 2017).

A study of the value attitude to health and healthy lifestyles among students showed that most students have a critical (low) level of formation of these values (Imas, Y., Dutchak, M., Andrieieva, O., & Kensytska, I., 2019). The focus of students' internal health control is interconnected with healthy behavior through self-efficacy in maintaining health, while external health control reduces students' sense of self-efficacy and negatively affects students' healthy behavior (Açıkgöz Çepni, S., & Kitiş, Y., 2017) .

A person's attitude to his health, on the one hand, reflects the experience of the individual, and on the other hand, has a significant impact on his behavior. Therefore, it can be considered as one of the main “targets”, on which the psychocorrectional effect should be directed. Moreover, a differentiated approach to psychocorrectional work should be based on a comprehensive study of the characteristics of people's attitudes to their health.

In modern conditions, health depends on the state of medicine and healthcare, as well as on the psychological characteristics of attitudes toward health.

Currently, the most urgent problem requiring further research is the study of the relationship between the characteristics of the social situation of education (Zalevsky G.V., Kuzmina Yu.V., 2010), with the process of transforming knowledge of healthy behavior into personal meanings of students' healthy life (Yugova E.A., 2016).

Researchers focus on the fact that in order to manage the health-saving behavior of students, it is necessary to take into account the characteristics of student youth associated with the age period, the active process of social, cultural adaptation, inclusion in social and working life), the formation of a value orientation, since the transfer of the value of health in individual and social measurement occurs during the socialization and upbringing of the young generation (Puzanova Zh.V., Vyalov I.S., 2013).

In a study of the values that influence the attitude to health among three generations of modern Russia (Fedotova V.A., 2019), it was found that young people's attitudes toward health are more positive than among representatives of other generations of Russians.

Thus, identifying differences in perceptions of attitudes toward health in different social and age groups will help to find more effective ways to maintain the health of the individual and society as a whole (Bovina I.B., 2007).

One of the least disclosed areas in the psychological aspects of the attitude of young people to health and disorders of healthy behavior, in our opinion, is to study the specifics of students' attitude to health, taking into account the form of their education at the university. At present, distance learning forms are becoming more and more popular, which do not require students to attend the lesson daily. When fulfilling the requirements of the curriculum by correspondence, students can receive only part of the knowledge in direct contact with teachers. They get the rest of the knowledge, skills and abilities during independent tasks, being in constant contact with the teacher through modern information and communication technologies, including the use of distance education. The main feature of distance learning is the combination of distance learning methods, full-time studies, where there is an adjustment and discussion of insufficiently understood topics and sections. In this connection, questions arise about the extent to which a student's educational form in a university affects his attitude to health, how much a learning form is associated with certain health problems of students, and what form of learning has the greatest potential in developing and maintaining healthy behavior for students.

The purpose of this work is to study the specifics of the psychological characteristics of the attitude to health and the disturbances in the healthy behavior of university students belonging to different age groups and forms of education.

Research hypothesis - full-time and part-time students have differences in the psychological characteristics of their attitude to health and violations of healthy behavior.

Methods

The study was conducted in Chuvash State University (Cheboksary, Russian Federation). The study involved 177 participants (49 male and 128 female, aged 18…41), 117 of them (66.1%) were full-time students and 60 (33.9%) were extramural students.

The following methods were used in the study: theoretical analysis of scientific literature on the research problem, systematization and generalization of the information, empirical methods (questioning, testing), statistical methods (descriptive statistics, T-student test for means). The following psychdiagnostic tools were used:

1) Attitude towards health questionnaire by R.A. Berezovskaya for determination of psychological characteristics of attitudes towards health (Berezovskaya R.A., 2005). The questionnaire consists of 10 questions which forms four scales: cognitive scale, emotional scale, behavioral scale and value-motivational scale.
2) Violation of healthy behavior questionnaire by E.L. Lutzenko & O.E. Gabelkova for determination of specific healthy behavior violation (Lutzenko E.L., Gabelkova O.E., 2013). The questionnaire has such scales as craving for smoking, poor nutrition, neglect of safety, craving for alcohol, pursuit of a fashionable image, low self-control, emotional incompetence, self-destructive behavior and summary score representing general tendency of healthy behavior violation.

Results and Discussion

Student t-test for independent samples had revealed statistically significant differences between full-time ($n = 117$) and extramural students' ($n = 60$) psychodiagnostics results.

The analysis of Attitude towards health questionnaire by R.A. Berezovskaya was concluded by individual sections, main scales and levels (cognitive, emotional, behavioral, value-motivational). Comparison of the individual sections turned out to be more informative compared to integrative indicators.

The value-motivational component determines the role of health in the hierarchy of terminal and instrumental values of a person and also describes the features of motivation in healthy lifestyle sphere.

Comparison of the questionnaire results for the value-motivational component in full-time and extramural student's had shown that the former have higher mean scores for all values in the questionnaire. For some of these values – "Independence (freedom) " (5.82 ± 1.3 for full-time students, 5.15 ± 1.41 for extramural students; $t = 3.1580$; $p = 0.0019$), "Faithful friends" (6.05 ± 1.24 and 5.42 ± 1.41; $t = 3.0716$; $p = 0.0025$), "Health" (6.36 ± 1.2 and 5.72 ± 1.6; $t = 3.0050$; $p = 0.0030$) and "Happy family life" (6.15 ± 1.29 and 5.6 ± 1.86; $t = 2.3139$; $p = 0.0218$) – the differences are statistically significant (Table 1).

Table 1: Differences between full-time and extramural students' results of Attitude towards health questionnaire: section 1 (values)

Values	Full time	Extramural	t	p
Happy family life *	6.15±1.29	5.6±1.86	2.3139	0.0218
Financial well-being	5.96±1.26	5.55±1.4	1.9601	0.0516
Faithful friends **	6.05±1.24	5.42±1.41	3.0716	0.0025

We may conclude that of all the values the full-time students consider more important those that are associated with subjective personality-oriented signs of well-being, while for the values associated with successful career there're no differences between full-time students and extramural students.

The similar results were found for achievement success in life: full-time students had higher scores for factors considered important for success and for most of the factors statistically significant differences were discovered, except for "Good education" and "Useful social connections (supporting friends and acquaintances)" factors. Both full-time and extramural students has the highest means scores for "Persistence and hard work" factor, 6.3 ± 1.33 and 5.55 ± 1.87 respectively (Table 2).

No statistically significant differences between full-time and extramural students were found in reasons for lack of health self-care scores, except for expensiveness of the costs (4,02 ± 1.97 and 3.4 ± 1.92 respectively; t = 1.9886; p = 0.0483), is mostly due to the difference in economic situation and income level of the students (Table 3).

The ***cognitive component*** of the attitude towards health mostly depends on the psychological competence of the individual, which in turn defined by peculiarities of the common knowledge about psychology and psychohygiene in society or ethnic group to which the person belongs. The cognitive component is used for evaluation and classification of one's knowledge of health; it determines the understanding of the role of health in person's life and reveals knowledge of the main factors that have both negative and positive effects on health.

Comparison of indicators of cognitive component parts revealed some differences in the sources of attitude to health concept: while most of the information sources scores has no significant differences for full-time and extramural students, the former consider doctors (5.69 ± 1.37 and 4, 77 ± 1.62; t = 3.9894; p = 0.0001) and popular science publications (5.09 ± 1.58 and 4.55 ± 1.36; t = 2.2361; p = 0.0266) being more informative (Table 4).

The influence of various factors on the state of health were statistically significant higher for full-time students compared to extramural students. The most influential factor are lifestyle (6.31 ± 1.21) for full-times students and nutritional characteristics (5.5 ± 1.32) for extramural students (Table 5).

Table 5: Differences between full-time and extramural students' results of Attitude towards health questionnaire: section 5 (factors affecting health)

Influence of the factor	Full time	Extramural	t	p
Quality of medical care*	5.95±1.35	5.47±1.52	2.1509	0.0329

The ***emotional component*** of attitude towards health implies experiencing one's good or bad health and very significant in the context of a person's overall self-esteem, in determining one's life line, life plan as well as life style. The emotional component reflects the feelings of a person that are associated with the state of his health, as well as emotional state caused by the deterioration of a person's physical or mental well-being.

The emotional component of the questionnaire consists of questions about severity of feelings in case of having and not having worries about one's health. In the absence of diseases full-time students had statistically significant higher scores than extramural students for feelings of calmness (6.26 ± 1.09 and 5.67 ± 1.64; t = 2.8479; p = 0.0049), satisfaction (6.23 ± 1.13 and 5.65 ± 1.56; t = 2.8294; p = 0.0052), happiness (6.21 ± 1.14 and 5.67 ± 1.41; t = 2.7890; p = 0.0059), safe (6.06 ± 1.25 and 5.58 ± 1.39; t = 2.3106; p = 0.0220) and self-confidence (5.86 ± 1.38 and 5.38 ± 1.46; t = 2.1495; p = 0.0330), while feeling of indifference had statistically significant lower scores (3.22 ± 1.92 and 3.83 ± 1.87; t = 2.0243; p = 0.0445). With exception of the latter indicator, the greater vividness and intensity of sensations in the absence of health problems is typical for full-time students compared to extramural students, although the distribution of certain types of sensations in both groups are almost identical for lower mean scores. (Table 6)

Table 6: Differences between full-time and extramural students' results of Attitude towards health questionnaire: section 6 (the absence of health problems)

The severity of the sensation/feeling	Full time	Extramural	t	p
I am calm**	6.26±1.09	5.67±1.64	2.8479	0.0049
I am satisfied**	6.23±1.13	5.65±1.56	2.8294	0.0052
I am happy**	6.21±1.14	5.67±1.41	2.7890	0.0059

** - statistical significance level p<0.05;*
*** - statistical significance level p<0.005*

The most statistically significant differences of mean scores in the presence of health problems are feeling of regret (4.52 ± 1.47 for full-time students, 4.02 ± 1.62 for extramural students; t = 2.0915; p = 0.0379) and sense of shame (3.36 ± 1.81 and 4 ± 1.69; t = 2.2794; p = 0.0239), with former being higher and latter being lower for full-time students. Unlike the situation with no health problems, the ratio of mean scores and distribution of sensations for full-time and extramural students are different and there is no clear tendency for greater manifestation of sensations in no one of these groups (Table 7).

Table 7: Differences between full-time and extramural students' results of Attitude towards health questionnaire: section 7 (the presence of health problems)

The severity of the sensation/feeling	Full time	Extramural	t	p

The ***behavioral component*** of the questionnaire characterizes the health-related behavior, as well as the degree of commitment to healthy lifestyle and behavior in case of deterioration of health.

Analysis of the behavioral component revealed that full-time students are more likely to take preventive measures such as bad habits rejection (mean score 5.48 ± 1.82 for full-time students, 4, 8 ± 1.64 for extramural students; t = 2.4267; p = 0.0163), physical exercises (5.34 ± 1.61 and 4.78 ± 1.56; t = 2.2071; p = 0.0286), sauna (5 ± 1.81 and 4.37 ± 1.81; t = 2.1986; p = 0.0292) and body weight control (4.74 ± 1.76 and 4.15 ± 1.63; t = 2.1448; p = 0.0334) to maintain health. The most preferable way of health maintaining for extramural students is yoga, gymnastics and other wellness systems, while for full-time students this measure is the least popular (4.25 ± 1.4 and 3.49 ± 1,96 respectively; t = 2.6844; p = 0.0080). (Table 8)

Table 8: Differences between full-time and extramural students' results of Attitude towards health questionnaire: section 8 (regular measures to maintain health)

Measures taken to maintain health	Full time	Extramural	t	p
Engaged in physical exercises (exercise, running, etc.) *	5.34±1.61	4.78±1.56	2.2071	0.0286

*** - statistical significance level p<0.005*

There are no statistically significant differences of behavioral strategies in these groups in case of health problems. It could be noted that for extramural students of the strategy of independent adoption of certain measures based on their past experience is more preferable (mean score of 4.92 ± 1.27 for extramural students and 4.48 ± 1.56 for full-time students). It can be concluded that overall full-time students take more intensive measures to maintain their health, or at least perceive certain types of their behavior as such. (Table 9)

Table 9: Differences between full-time and extramural students' results of Attitude towards health questionnaire: section 10 (strategies in case of health deterioration)

Behavioral Strategy	Full time	Extramural	t	p

Analysis of results obtained with ***Violation of healthy behavior questionnaire*** by E.L. Lutzenko & O.E. Gabelkova revealed more frequent occurrence of such violations in full-time students compared to extramural students for both specific types of violations (scales) such as self-destructive behavior (full-time students 5.0 ± 1.67, extramural students 6.08 ± 2.41; t = 3.5010; p = 0.0006), craving for alcohol (13.92 ± 5.8 and 16.77 ± 5.98 respectively; t = 3.0561; p = 0.0026), Craving for smoking (12.24 ± 5.85 and 14.63 ± 6.83; t = 2.4339; p = 0.0159) and eating disorders (15.4 ± 3.7 and 16.77 ± 3.11; t = 2.4497; p = 0,0153) and integrative score (111.15 ± 18.81 and 122.63 ± 23.42; t = 3,5300; p = 0,0005) (Table 11).

Table 11: Differences between full-time and extramural students' results of Violation of healthy behavior questionnaire by E.L. Lutzenko & O.E. Gabelkova

Violation of healthy behavior questionnaire	Full time	Extramural	t	p
Craving for Smoking*	12.24±5.85	14.63±6.83	2.4339	0.0159
Eating Disorders Scale*	15.4±3.7	16.77±3.11	2.4497	0.0153
Safety Neglect (Risk Behavior) Scale	22.92±4.2	23.55±5.58	0.8379	0.4032
Craving for Alcohol**	13.92±5.8	16.77±5.98	3.0561	0.0026
Pursuit of Fashionable Image Scale	19.11±4.03	20.28±3.28	1.9478	0.0530
Low self-control scale (impulsiveness)	9.81±3.91	10.92±3	1.9163	0.0570
Emotional incompetence (inability to cope with stress)	12.74±3.23	13.63±3.15	1.7480	0.0822
Self-Destructive Behavior Scale***	5.0±1.67	6.08±2.41	3.5010	0.0006
Total Points***	111.15±18.81	122.63±23.42	3.5300	0.0005

** - statistical significance level p<0.05;*
*** - statistical significance level p<0.005;*
**** - statistical significance level p<0.001*

The emotional incompetence factor consists of statements that describe ineffective strategies for dealing with stressful situations, such as somatization of anxiety and the formation of a hypochondriacal disposition to one's health, depressive response, as well as concentration on negative emotions.

The factor of self-destructive behavior includes individual traits that encourage participation in life- and health threatening activities, such as drugs abuse, dangerous experiments and unprotected sex.

It can be concluded that in along with higher probability of having health problems due to older age, extramural students more often note their own bad habits and self-destructive behaviors of varying severity and regard them as healthy behavior violation.

Conclusions

The motivational-value component of the attitude to health among students has its own specifics for full-time and part-time students, characterized by more pronounced personality-oriented signs of well-being and a large number of factors for achieving success in life among full-time students.

By the values associated with a successful career, the factor of getting a good education and acquiring the necessary connections, differences between full-time and part-time students were not revealed. This may be due to the various age stages of development of full-time and part-time students. So for full-time students, the relevant values at this stage are building their own lives, they have expressed a desire to gain independence from significant adults, they pay more attention to finding a life partner, building social contacts for which students tend to keep themselves in good shape, be healthy, successful, purposeful, financially secure. Most part-time students have already formed social contacts, have families, so career values, recognition and respect, getting a good education and acquiring the necessary connections that are expressed in the same way as full-time students are more relevant values.

Moreover, insufficient health care for full-time students may be due to the need for high material costs, which are impossible due to the unstable economic situation of these students. Therefore, in general, full-time students have a large degree of formation of motivation for maintaining and strengthening health.

The cognitive component of the attitude to health in full-time and part-time students is characterized by various sources of awareness that form an idea of health. Full-time students are more oriented to information received from doctors and from popular science publications compared to correspondence students who are more likely to trust doctors, friends, and acquaintances relative to other sources of information. The largest factors affecting the state of health, full-time students are called lifestyle, and correspondence students are called nutritional features. These features largely depend on the beliefs and perceptions of students due to previous life experiences and the characteristics of the community to which they belong.

The emotional component of the attitude to students' health is characterized by an increased intensity of experiencing positive emotions associated with the absence of a disease in full-time students compared to external students. The emotional attitude to the situation of health problems in full-time students is manifested in a more pronounced feeling of regret and a less pronounced sense of shame compared to students in correspondence. According to the results, there is no clear tendency to a large intensity of manifestation of emotional experiences in a particular group of students. The emotional attitude to health is determined by the individual characteristics of the lifestyle and self-esteem of the person.

The behavioral component of the attitude to the health of students characterizes the features of commitment to a healthy lifestyle. In full-time students, it is more manifested by behavior aimed at avoiding bad habits, engaging in physical exercises, controlling body weight and visiting the sauna. For correspondence students, behavior toward classes in special wellness systems is more characteristic. In the event of health problems, students in both full-time and part-time studies have the same behavioral strategies. In general, part-time students more often take measures to overcome health problems based on past experience, and part-time students assess the measures taken to maintain their health as quite active.

An analysis of the identified characteristics of a violation of healthy behavior in full-time and part-time students shows a more frequent occurrence of such violations in part-time students compared to full-time students. It can be concluded that in addition to the more likely for older people the likelihood of health problems, correspondence students more often note the presence of malnutrition, craving for bad habits and self-destructive behaviors of varying severity.

A comparative analysis of violations of healthy behavior showed greater severity among students of part-time education (compared with full-time students) indicators on the scales "Craving for alcohol", "Craving for smoking" and "Eating disorders", "Self-destructive behavior."

Thus, students have formed motivation to maintain and strengthen health, more pronounced among full-time students. Full-time and part-time students use various sources of information that form an idea of health. The emotional component of the attitude towards health is characterized by the absence of a clear tendency towards a high intensity of emotional experiences in connection with health problems in a particular group of students. Part-time students are more likely to take measures to overcome health problems based on past experience, while they often have impaired healthy behavior than full-time students.

On the basis of the study, the relevant "targets" of psycho-correctional work have been identified, psychological and pedagogical recommendations have been developed for the formation of a healthy lifestyle in the educational space of the university, aimed at the psychological correction of students' health-saving behavior, factors of healthy behavior that impede the formation and maintenance of a healthy lifestyle, having specifics for university students of various forms of education and age.

Abstract

Research background: Financial and economic status of Russia between developing countries in Europe and Asia. **Purpose of the article:** Determine the financial and economic role and development opportunities of Russia as a border between developing countries in Europe and Asia. **Methods:** The research is based on a systematic approach using methods of descriptive statistics and cluster analysis. **Findings & Value added:** The article describes the need to determine the conditions and opportunities for the financial and economic development of modern Russia, taking into account the economic and geographical location and international economic cooperation. The development of Russia is considered not only as a criterion, but also as a category for countries that are borders between different socio-economic formations. The study revealed the overall dominant indicator-the GDP deflator, which reflects the activity and instability of the price index. Developing countries have consistently low values relative to Russia, and the Russian GDP deflator is the limit. Asia, with a less capital-intensive economy of the countries, is more stable in the growth rate of the corresponding indicator. Russia has been identified as a source of price index instability and a marginal benchmark for developing countries in Europe and Asia. The main causes of instability are public administration and GDP. As a result of the study, significant groups of instability between Russia and the countries of Asia and Europe were identified. The success of Russia's development as a border between developing countries in Europe and Asia is determined by the correspondence between the limits of economic relations and the existing structure of the Russian economy. This correspondence is the current financial and economic situation of Russia, defined as its status and opportunities for successful development.

Keywords: Border, Instability, Development Limit, Growth Rate.

INTRODUCTION

The relevance of the research is related to the need to determine the conditions and opportunities for the financial and economic development of modern Russia, taking into account the economic and geographical location and

EFREMOV " Russia Between Developing Countries in Europe and Asia" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN : 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

international economic cooperation. The concept of financial and economic status (formation) appears as a generalizing form of development of a set of economic relations in the process of creating and using funds of money.
The problem is considered at a higher level than just the economic and geographical location and international economic cooperation. The development of Russia at this level is considered not only as a criterion, but also as a category for countries that are, in fact, borders between different socio-economic formations.

So, for Russia, as the border between the developing countries of Europe and Asia, the main criterion for the limit of economic development is a stable socio-economic formation of a primitive raw material structure of the economy, in accordance with the interests of the ruling class (Smirnov V., et al., 2019), which is unable to overcome the barrier that separates the developed countries from the developing ones. This is facilitated by the developing countries of Europe and Asia themselves, perceiving Russia as the border of various socio-economic formations.

LITERATURE REVIEW

The analysis of the financial and economic situation of Russia as the border between the developing countries of Europe and Asia is based on the problem of ensuring sustainable GDP growth (Miller C., 2020). At the present stage of development of the world economy, high values of GDP growth dynamics are demonstrated by developing countries in Asia. The source of this dynamics is resource-intensive (labor-intensive) production, which is associated with a sharp increase in energy consumption and emissions of pollutants, as well as a decrease in the stability of the structure of the economy, due to accelerated development (Li J., Lin B., 2019).

But this dynamic is gradually losing its strength due to the rising cost of labor in developing countries and the decline in the cost of capital in developed countries. The loss of economic growth rates directs Asian economies to move to capital-intensive and resource-saving production. This, in turn, leads to the need to adjust the economic interests and policies of Asian countries in the context of the benefits of joint development with European countries with high-tech capital.

Mutually beneficial international cooperation helps reduce the impact and eliminate the consequences of cyclical global economic crises. In particular, adding the Chinese total investment portfolio to the European market in the medium term reduces the risk before and during the periods of the global financial crisis and the Euro zone sovereign debt crisis (Mensi W., et al., 2017; Kannadhasan M., Das D., 2019).

High values of economic growth dynamics in developing Asian countries indicate accelerated development, which causes an increase in the asymmetry of the exchange rate to consumer prices, thereby reducing the elasticity of demand and competition (Narayan S., Rehman M.U., 2017). High exchange rate volatility is associated with capital inflows to Asian countries. In this situation, capital control should become an effective tool for stabilizing the foreign exchange market (Caporale G.M., et al., 2017).

On the one hand, restrictions on capital inflows to Asian countries will positively affect the stability of the exchange rate, on the other hand, these measures go beyond investment flows. Restrictions on flows in one direction can affect flows in the opposite direction. Restrictions on one asset class can affect the flows of other asset classes (Jongwanich J., 2019). For example, China's two-way exchange rate, both on land and at sea, as well as the macroeconomic climate in the long term, largely determine the yuan as a regional factor that affects the exchange rate of the Japanese yen and the Korean won (Chiappini R., Lahet D., 2020).

Against this background, there is inevitably a General deepening of ties between the Asian market and the rest of the world. Many of the Asian markets are linked to global markets through key markets. The increased integration of Asian financial markets into the global financial network is clearly evident during periods of stress (the Asian financial crisis of 1997-1998 and the global financial crisis of 2008-2009), and the decrease in the number of connections in post-crisis periods. Many of the Asian markets ceased to be linked to global markets through key markets (such as Hong Kong), and over time developed stronger direct links to external markets (Chowdhury B., et al., 2019).

The stock market is becoming more integrated in a crisis. In turn, this has led to increased volatility between stock markets and financial markets during times of crisis. Negative shocks generate more instability than positive shocks of the same magnitude. Integration between financial markets (in terms of volatility overflow) implies low potential diversification opportunities for investors (Jebran K., et al., 2017).

Financial factors began to have a greater impact on stock returns. Thus, the global business cycle has become a priority for predicting stock returns. From the point of view of intra-industry relations, developed stock and currency markets demonstrate a strong connection with emerging Asian stock markets due to the integration of financial markets (Dong, X., Yoon, S.-M., 2019).

In General, the disadvantage of financial markets in Asia is a pronounced conservatism, including the difficult secondary trading of assets. In comparison with Asian countries, Russia's problems lie in the lack of conservative institutional investors (Smirnov V., et al., 2019).

Europe is showing a growing unemployment rate in economically weak countries against the background of a General normalization of unemployment and high wages in the strong countries of the Euro zone. The stability of the European financial system is higher than it was 10 years ago, which allows us to strengthen the policy of quantitative easing and asset purchases to maintain stability in the Euro area and save the Euro as a single European currency.

The most important direction for the development of the Eurasian economic integration is the emergence of a common market for financial and banking services. The principles, structure and content of measures of the concept of forming a common market for financial and banking services take into account the peculiarities of national economies and financial systems.

At the same time, the European market is not self-contained. Sentiment in Europe affects emerging market sentiment in both the short and long term. At the same time, emerging markets affect the mood in Europe only in the long term. A bi-directional causal relationship between the moods of emerging markets and developed markets in Europe in the long term suggests that the sentiment index of the two economies may feed each other during crisis periods (Dash S.R., Maitra D., 2019).

European markets are full-fledged receivers, while North American and Asia-Pacific markets are high-order risk transmitters (Brio E.B.D., et al., 2017). The peculiarity of the modern development of European markets is related to Bank lending. It is Pro-cyclical in the eight new (non-Baltic) EU countries, which includes the initial credit boom (2005-2007), followed by the global financial crisis (2008 and 2009) and the beginning of the Eurozone crisis (2010). Bank lending was negatively affected by both crises, but the two types of foreign banks behaved differently. The Big six banks remained committed to the lending behavior of national banks that support the idea of a second domestic market. Others were involved in fueling the credit boom, but then sharply reduced their lending during crisis periods (Bonin J.P., Louie D., 2017).

A significant role in assessing the creditworthiness of forms has become played by the ownership structure, which is unusual for European countries. However, from the point of view of firm management specifics, indicators of ownership structure and aggregate financial indicators are the most economically significant factors associated with increasing the probability of firms ' survival in European emerging markets (Baumöhl E., et al., 2019).

Although the European sovereign crisis was triggered by the deteriorating financial conditions of developed countries, the sovereign debt markets of developing countries outperformed the CDS markets of peripheral EU countries in terms of information transfer in the short term. This is due to the fact that in a developing country with less openness to international trade and a higher market value of sovereign debt, the country's sovereign debt is more vulnerable to EU sovereign risk (Wang A.T., 2019).

For the Russian reality, the value drivers of a credit institution are: high margin of safety for compliance with the Bank of Russia capital requirements, the availability of opportunities to attract funds at a reasonable cost, a reasonable balance between the profitability and riskiness of the loan portfolio, effective management of operating expenses. In General, managing the Bank in order to maximize its value and ensure sustainable operation in the future.

So, the differences in the conditions of existence of developing countries in Europe and Asia, whose border is Russia, actualizes the need to analyze its financial and economic situation and role in the development of dividing socio-economic formations.

METHOD

To analyze the financial and economic situation of Russia as the border between developing countries in Europe and Asia, we apply descriptive statistics methods, including processing of empirical data, systematization, visual

representation in the form of graphs and tables, and their quantitative description by means of basic statistical indicators (King A.P., Eckersley R.J., 2019; Brownstein N.C., et al., 2019). Tables, charts, and summary metrics are used to describe the behavior of each variable. Tables, charts and graphs are built using "MS Excel", "IBM SPSS Statistics Software" (Fávero L.P., Belfiore P., 2019). Descriptive statistics assesses an array of data by statistical indicators.

Statistical analysis will serve as a method for collecting, studying and presenting large amounts of data based on features () (Lazar J., et al., 2017) and data relationships (Schofield S. 1993), correlation relationships of spatial and time series of indicators, while preserving the research methodology.

The use of cluster analysis is due to the fact that statistical methodologies rely on a probabilistic understanding of causality (Urlacher B.R., 2020) and require justification of the connectivity of changes in the estimated indicators.

ANALYSIS

Analysis of financial and economic situation of Russia between developing countries in Europe and Asia is based on the results of evaluating the median (Me) and the asymmetry of the distribution relative to the average (AD), as well as their growth rates (Rates of gain, RG) of financial and economic indicators: current account balance; General government gross debt; General government net debt; General government net lending/borrowing; General government primary net lending/borrowing; General government revenue; General government total expenditure; Gross domestic product, constant prices; gross domestic product, deflator; gross national savings and total investment according to the International Monetary Fund, World Economic Outlook Database.

The result of the analysis of the dynamics of financial and economic indicators of developing countries in Asia and Europe is their hierarchy (tables 1 and 2) and the overall dominant indicator – GDP, deflator, i.e. the activity and instability of the price index.

Table 1: Hierarchy of developing countries in Asia, 2000 – 2024 гг.

Indicator	Country	Me > 5,0%	The asymmetry of the distribution relative to the average, AD
General government gross debt	Timor-Leste	73.47	0.74
Gross domestic product, deflator	Timor-Leste	9.12	-0.76
Gross domestic product, deflator	Russia	8.44	1.55
Gross domestic product, deflator	Mongolia	7.74	1.94
Gross domestic product, deflator	Myanmar	6.95	0.79
General government gross debt	Kiribati	6.54	2.97
Gross national savings	Maldives	6.44	1.93
General government primary net lending/borrowing	Indonesia	6.41	3.84
General government structural balance	China	6.39	2.09
Gross domestic product, deflator	Nepal	6.12	1.68

Source: calculated in "SPSS Statistics" based on data ©International Monetary Fund, World Economic Outlook Database, https://www.imf.org/external/pubs/ft/weo/2019/01/weodata (02 March 2020).

Table 2: Hierarchy of developing countries in Europe, 2000 – 2024 гг.

Indicator	Country	Me > 5,0%	The asymmetry of the distribution relative to the average, AD
Gross domestic product, deflator	Turkey	11.32	2.26
Current account balance	North Macedonia	9.10	4.11
Gross domestic product, deflator	Russia	8.44	1.55
General government gross debt	Kosovo	8.37	-0.04
Current account balance	Turkey	7.08	2.69

Gross national savings	Montenegro	6.93	1.18
General government primary net lending/borrowing	Albania	6.33	2.18
Gross domestic product, deflator	Turkey	11.32	2.26
Current account balance	North Macedonia	9.10	4.11

Source: calculated in "SPSS Statistics" based on data ©International Monetary Fund, World Economic Outlook Database, https://www.imf.org/external/pubs/ft/weo/2019/01/weodata (02 March 2020).

The difference lies in the level of this indicator for the leading countries of Asia and Europe, namely, in the dynamics relative to the average median values and the asymmetry of the distribution of the relative average value: Asia-average Me = 4.33% and AD = 0.79; Europe-Me = 4.49% and AD = 1.68.

Russia is the second largest country in Europe and Asia. But if we consider that Turkey is only 5% (Thrace on the Balkan Peninsula) located in South-Eastern Europe, and 95% – "Anatolia" (Asia Minor or Asian Turkey), then Russia ranks first in Europe.

So, Russia is a source of price index instability for developing countries in Europe and Asia. The main reasons for the instability of the Russian price index are General government primary net lending/borrowing and Gross domestic product, constant prices as the dominant in the hierarchy of the ratio of growth rates of absolute Me values to the distribution asymmetry relative to the average for Russia (table 3).

Table 3: Hierarchy of relations between the growth rate of absolute Me values and the distribution asymmetry relative to the average for Russia, 2000 – 2024 гг.

Indicator	**Me, %**	**The asymmetry of the distribution relative to the average, AD**	**ABS (Me / AD)**
General government primary net lending/borrowing	-23.19	-0.03	806.77
Gross domestic product, constant prices	-4.55	0.17	26.78
General government structural balance	-54.45	-4.73	11.52
General government gross debt	-1.18	-0.12	10.17
General government net lending/borrowing	-44.33	-4.99	8.88
Gross national savings	-1.18	0.16	7.40
Gross domestic product, deflator	8.44	1.55	5.45
Current account balance	-11.45	2.61	4.39
Total investment	0.42	0.16	2.58
General government revenue	-0.24	0.15	1.56
General government total expenditure	0.21	1.23	0.17

- close countries: Bosnia and Herzegovina, Croatia and North Macedonia.

So, Russia, dividing the developing countries of Asia and Europe, significantly affects and depends (mutually dependent) on public administration, the overall structural balance and gross national savings of Asian countries –

China, Bhutan, Brunei, Maldives, the Marshall Islands, Micronesia, Samoa, Solomon Islands and Tonga, as well as the management of the total public net debt of European countries – Bosnia and Herzegovina, Croatia and North Macedonia.

DISCUSSION OF RESULTS

The results of evaluating the median (Me) and the asymmetry of the distribution relative to the average (AD), as well as their growth rates (Rates of gain, RG) of the main financial and economic indicators that determine, corresponding to these indicators, the position of Russia between the developing countries of Europe and Asia indicate the overall dominant indicator-GDP, deflator, namely, the activity and instability of the price index.

Europe has higher values of price instability than Asia. At the same time, Russia, being a source of instability in the price index for developing countries in Europe and Asia, conditionally shares the causes of instability – for Asia, public administration, the formation of a common structural balance and gross national savings, and for Europe, the management of a common public net debt.

CONCLUSIONS

The problem of the success of Russia's development in the state of the border between developing countries in Europe and Asia is a burden on the current structure of the Russian economy, which is still unable to overcome the barrier that separates developed countries from developing countries. This is facilitated by the developing countries of Europe and Asia themselves, perceiving Russia as the limit of economic development.

This explains the overall dominant indicator of the GDP deflator, which reflects the activity and instability of the price index. Developing countries have consistently low values relative to Russia, and the Russian GDP deflator is the limit. Asia, with a less capital-intensive economy of the countries, is more stable in the growth rate of the corresponding indicator.

In General, Russia is a source of price index instability and a marginal benchmark for developing countries in Europe and Asia. The main causes of instability are public administration (net lending / borrowing) and GDP (constant prices). The study identified significant groups of instability between Russia and the Asian countries: China, Bhutan, Brunei, Maldives, Marshall Islands, Micronesia, Samoa, Solomon Islands and Tonga – public administration, the overall structural balance and gross national savings; Europe – Bosnia and Herzegovina, Croatia and North Macedonia-managing total public net debt.

Abstract

The present paper considers the whole of experience of sociological and socio-philosophical understanding of digital reality phenomenon in the categories of its temporal coordinates. The article discusses the influence of digital technologies' temporality on their social construction practices, as well as the main parameters of representation in various discursive spaces. In conclusion, the experience of predicting the development of digital technologies in the aspect of their riskogenics is presented.

Keywords: Digital Reality, Digital Technologies, Social Construction, Discourse, Temporality, Risks, Predictive Scenarios.

Introduction

High rates of technological development, including those connected with the emergence of digital reality, cause significant social, political, economic, and in a broad sense, existential consequences. The process of new reality formation, described in terms of digital discourse, has become the object of numerous studies that consider the content of the process itself and assess its consequences. At the same time, the theoretical and methodological question of determining how the process of social construction of digital reality, its discursive representations, and what their temporal coordinates are remains insufficiently clarified.

The technological transformations taking place in the context of the modern society formation and the consequences caused by them are currently ahead of the dynamics of public control and the degree of scientific reflection. However, each artifact of digital technological reality is reflected in various discursive spaces (scientific, everyday-practical, artistic, etc.) in various forms - in the form of a myth, an ideologeme, a pattern, etc. As a result, the meta-theoretical problem of studying the common logic and temporal dynamics of digital reality representations in various discursive spaces is important. Not only the content of representations is significant, but also the principles of their development and changes, considered as part of time dynamics.

Results and Discussion

The initial intuition of the analysis carried out in this study is the assumption that the temporal parameter is embedded in the very semantic essence of technological development. It is obvious that each technology as a fact and object of social reality is caused by a number of reasons of social and scientific and technological nature: that is, it has the past, relies on users' practices in the present, and is limited to a certain horizon in the future. This horizon is potentially distant, but unavoidable; outside of it, the functioning of an artifact or technology will cease to be relevant, or at least lose its instrumental modality. Thus, a chain of three temporal modalities is built: past - present – future. However, behind this obvious fact there are also less obvious temporal aspects of technological and more broadly – digital development.

Digital technologies form special temporal loci in the common physical and social chronotopos. This trend is noted by a number of modern sociologists [1, 2, 3]. Also, within the framework of synergetics, the concept of

Cite this Article as: Anna MAYAKOVA and Oleg Grimov "Digital Reality: Temporal Aspects of Discursive Representation, Social Construction, Predictive Experience" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

tempoworlds – the loci of the world provided by the existence of a special temporal order is developed. That is, explaining this idea, we can say that a tempoworld is interpreted as an autonomous fragment of the world with its own internal time, running independently of the rest of the world – other tempoworlds, due to restrictions or lack of interaction with them. In different tempoworlds, the pace of time can be radically different.

The overall growth of research interest in the problem of time is largely due to the role of modern technologies. It is their development that defines the form and content of temporality in a new way, expanding classical ideas about the linear nature of time, its irreversibility, etc. Since conceptualization of engineering and technology gets widespread as an independent actor with genuine subjectivity (e.g. in the framework of actor-network theory), there should be analyzed the status of technology and time symbiosis as equal subjects in the structure of special technotemporality. We can observe various configurations of this technotemporality. The practical aspects of this question are clear when analyzing time budgets and trying to isolate the actual technological time, or, on the contrary, considering technological time as an important aspect of social time. The solution of this issue will have both social and applied economic meaning. V. A. Artemov and O. V. Novokhatskaya ask the question: "...is it not necessary to reject only the 'human' time itself and include the functioning of everything that is created by man in social time to facilitate his work, its high productivity, release his time for new activities, etc.? [4]. In other words, should we not include in the social dimension of time those technological aspects that shape it, in particular, accelerate or save?

Discussing the issues of technologies' temporality allows us to assess their prospects, as well as their general profile. Using the terminology of R. Kozellek, we can evaluate "the space of experience" and "the horizon of expectations" of technologies [5]. Technologies that are relevant to their time (in our case, digital ones) have unique temporal characteristics at various stages of their manifestations. The main temporal parameters of technologies are "the space of experience" – a set of routine practices of application and, as a result, of technology domestication, as well as "the horizon of expectations" – a hypothetical description of the experience of technologies' application in terms of their prospects and risks.

Another important aspect is the issue of temporal organization of discursive representations of engineering and technology. It is obvious that these representations are temporally based and limited. Any stable forms of discursive representation are related to the actual experience of social actors and their temporal strategies. Representations have an objective temporal goal and an inevitably limited temporal horizon (although it may be relatively distant and / or blurry). The influence of time as a context or resource can be reflected in various myths and ideologies, program texts that show the temporal organization of technologies in the concentrated form of hopes, fears, and instrumental patterns caused by them.

The multiplicity of discursive spaces of digital reality technologies representation correlates with the general understanding of multiplicity in modern scientific knowledge as an important categorical framework that fixes the ontological diversification of an object, its structural mechanisms, practices, and optics of its analysis. An important manifestation of multiplicity is the phenomenological idea of the multiplicity of worlds by A. Schutz [6]. This idea is important for a common understanding of the processes of social construction of scientific knowledge and technology. A. Schutz notes the existence of a number of relatively autonomous worlds of finite values, each of which has its own reality and level of significance (as well as imperativeness) for the individual. The ultimate reality according to A. Schutz is the reality of the everyday world. The idea of multiple realities can be transposed to the idea of representing scientific knowledge and technology in various forms and discursive spaces. As a result, their special configuration forms the landscape in which technological artifacts function.

The phenomenological idea of the social constructionist nature of reality has been developed in a number of sociological theories. Thus, the representatives of sociology of science and engineering B. Latour, S. Woolgar [7] and emphasize the social nature of scientific fact production. The content of scientific knowledge is determined by social practices of its production. The production of scientific fact, as is said by the representatives of the actor-network theory, involves both material and non-material, both human and non-human entities. Together, these entities, as well as actions and interpretations affordances they define, form a material-semiotic network.

The sociological theory of the Social Construction of Technology (SCOT) analyzes the processes of building the image of technology that eventually becomes familiar or, conversely, is rejected by practice. An important principle of this theory is to consider any technology or invention as the result of interaction between different social groups. Any inventions, whether successful, well - established, or not fixed in real practice, are analyzed. The process of social construction of technology is complex and is provided by the so-called conceptual framework, which includes:

- related social groups – social groups that are connected with or related to a technological artifact. Their function is to give this artifact a social shell, to determine its degree of utility to society;

- interpretative flexibility – a set of ideas of different social groups about a technological artifact that determine its successful or unsuccessful implementation, as well as its evolution and the entire course of its development;

- closure and stabilization are two aspects of social construction that describe the use of technology in everyday practices. Closure means reducing the possibility of interpretation of an artifact and finally recognizing its social necessity in relations between groups. Stabilization means the same process within a group and leads to the formation of technologies for different social groups [8].

It may be added that the practice of applying and accepting technology is largely related to the experience of previous legitimation of previously conducted practices of its application. In the process of applying the technology, its public discussion, etc., its final image is polished. This is relevant both for relatively simple artifacts and for complex phenomena, which include digital technologies that hold a valuable place not only in the field of economy, production, institutional communication, etc., but also in the field of leisure and interpersonal user communication. In other words, a significant amount of practices in the use of modern technologies is not necessary, which in its own way distorts the original utilitarian orientation of technologies and reflects the consistent experience of their domestication. Thus, the public discourse builds an image of technologies and the range of acceptable practices for their application. Some issues of this kind are particularly acute and are resolved within the framework of ethics and legal practice (for example, the issue of electronic chipping of citizens, trust in a robot- judge, etc.). The practice of public discussion is extremely mobile and, in fact, is the Overton window, which defines corridors of legitimate social actions and interpretations related to this technology. In the course of public discussion, not only the affordances of actions (practices) are crystallized, but also the affor-dances of meanings and values that reflect the value-normative parameters inscribed in the technology.

One of the important temporal aspects of social construction is the prediction of possible scenarios for the development of events, including risk-related ones in the digital world. There are a large number of classifications of forecasts, but the most popular one is the division into search and normative forecasts. The search forecast determines the probable states of the studied processes and phenomena in the future. Past and present trends are extrapolated to the future, without regard to possible subjective actions that can change and destroy existing trends. The normative forecast formulates goals, standards, incentives, and ideals in advance, and develops the most effective ways and rates of achieving the likely target states of the studied processes. Depending on the situational orientation of the methods under use and the characteristics of organization, various types of forecasts can be developed - target, planned, program and project ones, and by time coverage - operational, short - term, medium-term, long-term and very long-term ones [9].

The peculiarity of scenario forecasting lies in the parallel study of several development options with characteristic opportunities and risks, subjective and objective, internal and external factors, criteria and indicators. According to Herman Kahn, one of the founders of the scenario method, when solving such problems, one should “avoid simple extrapolations and thinking by analogy, which are also undoubtedly important, but do not provide the level of separation from reality that is characteristic of strategic thinking” [10]. Scenarios allow researchers of “yesterday’s», «today’s” and “tomorrow’s” risks to be focused on establishing a personal perception of the future in order to make effective strategic decisions. As well as scenarios in theatre and cinematography, social scenarios are “stories based on carefully constructed plots” [11], which, owing to the possibility of execution, become important in terms of minimizing potential risks, dangers and threats.

Variants of the conditions under which the expected development of the analyzed, evaluated or projected system is carried out are an assumed sequence of events created in order to focus attention on key points in the development of social processes [12, p. 1 38-139]. Kahn said that “a scenario is understood as a dynamic sequence of possible events that focuses attention on the causal relationship between these events and decision points that can change their course and the trajectory of movement in time of the entire system under consideration as a whole or its individual subsystems” [13, p.97].

In accordance with the ideas of H. Kahn and A. Wiener, which are expressed in one of the scenario studies “The Year 2000: A Framework for Speculation on the Next Thirty-Three Years”, scenarios make it possible to perform several functions at once [14]. They draw attention to a wide range of possibilities by dramatizing and illustrating them; force you to work with details and dynamics; focus on the interaction of social, political, psychological, and

military factors; identify problems; and can be used to analyze alternatives of the likely consequences of past and current crises.

The main advantage of the scenario analysis is a comprehensive assessment of all development options, research of structural features and potential consequences of implementing solutions. These advantages will be realized owing to methods and a number of unique techniques for obtaining and processing multi-scale special information from experts who represent various fields of science and management.

When applying the scenario approach, various types of difficulties arise, which are due to the subjectivity of judgments and expert assessments. These difficulties include the following:

1. “representativeness hindrances” (caused by insufficient representation of factors and information about them);
2. “accessibility hindrances” (when what is known or what is easier to imagine is considered as the most possible and is evaluated for all practical purposes);
3. “confirmation interference” (when experts consciously or unconsciously “look for” evidence of their judgments and deny information that does not correspond to their ideas);
4. “retrospective interference” (manifestation of excessive confidence in previous opinions as clearer and more accurate than they actually are).

Building a “Problem tree” and/or “System map” is a common technique for categorizing problems with complex interactions. This construction is an ordered record of the analysis and solution components. The problem formed at the top level of the tree is generally divided into specific problems that allow the use of well-known methods of solving (economic, political, technological ones, etc.). To consider the hierarchy of problems and causes, well-known quality management tools are used, for example, “Ishikawa chart” (“fishbone graph”) and “Cross-diagnostics” [15, p.28]. We shall consider the application of “Problem Tree” on the example of one of the socio-cultural risks of digitalization, taking into account possible scenarios for the development of events in the aspect of social construction – “Culture virtualization” [16].

Fig.1: Problem tree of potential digital risks “Culture virtualization”

Conclusion

Summing up, we can make the following conclusions:

1) the issue of digital development is one of the most popular in modern technological discourse and is reflected in a variety of discursive spaces;

2) a significant influence on the representation and social construction of digital reality images is exerted by their temporal coordinates, described in the categories of real experience and the horizon of expectations.

Acknowledgment

The research is financed by the Russian Science Foundation, project No №19-18-00504 “Sociotechnical environment of digital reality: ontological matrices, ethical and axiological regulative structures, roadmaps, and information support for management decision-making”

Abstract

As the national economy transits to a resource saving model the need for tailoring managerial methods, principles and approaches for the strategic goal becomes urgent. With that in mind, this research analyses resource saving efficiency of producing systems at the macroeconomic level, including analysis of changes in energy intensity of the economy; we cite depreciation indicators of fixed assets of high, medium and low degree of technology; we have calculated the coefficient of fixed assets upgrade in the Russian Federation; we outline the dynamics of creation, utilization, neutralization and disposal of production and consumption wastes in Russia; changes in the environmental operating costs in the Russian Federation; we have calculated the share of R&D costs on the priority directions of science, technology and engineering in the total spending on R&D for the country in general; we have defined innovation activity of the Russian companies; the share of companies with technological innovations; the number of created advanced, new and fundamentally new production technologies in Russia; the share of energy resources produced with the use of renewable energy sources in the total volume of the Russian Federation's energy resources. We have formulated a conceptual goal of spurring up Russia's resource saving activities by way of conclusion.

Keywords: Economy, Management, Resource Saving, Mechanism, Effectiveness, Intensification, Research

Introduction

At the moment the bulk of concepts of the national economic development strategies aim at ensuring sustainable economic growth, solving engineering, technological, social and production problems with the help of spurring up the use (speed) of the existing resource potential (natural, technological, labour, financial, innovation, intellectual, scientific, educational and others). This model creates an inefficient practice of resource use, which is in conflict with the growing international problem of their deficit.

The negative consequences of environmental damage, ill-considered and uncontrolled use of natural resources, globalization of ecological problems are building up forcing the modern society to take a fresh look at the problems

Cite this Article as: Irina P. BOGOMOLOVA, Elena I. KRIVENKO, Maria B. CHIRKOVA, Julia N. VORONTSOVA And Elena S. STRYAPCHIKH "Improving the Efficiency of Macroeconomic Systems by Spurring up Resource Saving" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

and push forward with looking for new qualitatively new environmentally balanced models of economic development.

For instance, a Concept of Sustainable Social Development to ensure comprehensive solution of socio-environmental, industrial, technological, financial and economic problems has been developed. Part of the concept is creation of resource-oriented economy, where:

first, international ecological indicators (minimal emissions and wastes, the highest safety level and the level of waste recycling) of industrial facilities, transport, household activities are met;
second, the resources are used to maximum effect (the maximum effect with minimal resources, minimization of losses and waste);
third, existing (hidden) resource potential is revealed;
fourth, ecologically clean technologies and renewable sources are used as much as possible.

Literature Review

In the last 5 years, the ideals and models of building a resource oriented economy are widely discussed not only by specialized local and foreign scientists, but also by industry specialists and experts. The urgency of such initiatives is conditioned by a growing frequency of the market economy mechanism crises and stiff competition on the world market, when quality, price and production costs account for 85% of competitiveness. It is the resource saving technologies together with innovations that render an economic model due competitiveness. The modern society is increasingly interested in transformation of old and the appearance of new economic models, where the society will not be forced to pay for new material wealth with rising environmental risks, the lack of natural resources and increasing social tension.

One of the key goals of the transfer is a shift of the national models 'production-consumption' towards resource saving.

Research by such scientists as M. Aliyev (2007), V. Baranovskaya (2011), A. Bassi (2005), A. Bondar (2014), B. Burkinsky (2009), T. Galushkina(2016), M. Johnson (2010), I. Zalygina (2009), V. Klyuchenovich (2015), Yu. Lapshin (2018), K. Podvorskaya (2009), G. Saskevich (2010), P. Sukhlev (2016), R. Ayres (2003), etc. deal with the creation of a theoretical and practical basis of macroeconomic models' shift towards higher resource effectiveness. R. Balashova (2015), O. Veklich (2016), H. Daly (2015), N. Konishcheva (2017), D. Meadows (2015), L. Melnik (2010), I. Ippolitova (2016), S. Polovnikova (2010), S. Skokova (2014), N. Kondratenko (2017), V. Tarady (2014), etc closely, with the use of a comprehensive scientific approach researched resource saving as one of the promising directions of modern economic transformation. Despite the scientific works, researchers have not yet formulated a universal comprehensive approach and method towards the resource saving process in the national economic systems complicating implementation of the modern development concept seriously.

Research Question

The goal of our research is to develop an algorithm of comprehensive mechanism of resource management at the macroeconomic level based on the analysis of problems of implementing resource-saving processes in the national economy and providing for the use of chiefly economic regulation methods.

We should note that the goal of transformation of national production and consumption models is very pressing not only for Russia, but also for many developed states with high resource intensity.

For example, the resource intensity indicator of the national economy fell in 2019, but was still higher than the world average by more than 50%, and by 100-150% of the indicator of the developed states.

At the moment resource and energy saving is acknowledged one of Russia's state policy's priorities, but the speed of resource saving measures implementation remain insufficient to ensure development of a breakthrough type. Here some statistics will come handy.

Figure 1 demonstrates depreciation indicators of fixed assets of high, medium and low degree of technology.

As we see, fixed assets depreciation is growing steadily -- in 2008 the indicator amounted to 43.4%, while in 2018 it stood at 49.4%. The growing wear is directly proportional to resource efficiency of production systems and the whole producing sector of the national economy.

Like we have said before, one of the basic ideas of the Concept of Sustainable Social Development is strict compliance with the international ecologic indicators.

The data in Tables 1 and 2 point to strong dynamics of production and consumption wastes growth in our country. However, financial and organizational levels of utilization, neutralization, disposal, storage and burial of wastes leave much to be desired and lag behind waste formation.

Fig. 1: Depreciation indicators of fixed assets of high, medium and low degree of technology

The 2019 coefficient of fixed assets upgrade amounted to a mere 4.6% (Fig 2), which is also too little for deep industry modernization.

Fig. 2: Coefficient of fixed assets upgrade in the Russian Federation

Table 1: Formation, utilization, neutralization and disposal of production and consumption wastes in Russia, mln tonnes [9]

Year	Wastes formation		Dangerous	Utilization and neutralization of wastes	Placement of waste at enterprises	including:	
						storage	burial
2005	3,035.5		142.5	1,265.7	2,077.3	1,670.9	406,.5
2010	3,734.7		114.4	1,738.1	2,227.5	1,634.5	593.0

2019	374,411	63,760	174,921	102,396	16,348	354	639	8,266	219	7,506

The share of internal costs on R&D on the priority scientific, engineering and technology directions in the total volume of internal costs in the country is shown in table 3.

Table 3: The share of internal costs on R&D on the priority scientific, engineering and technology directions in the total volume of internal costs in the country, %

Types of economic activities	**Years**								
	2010	**2011**	**2012**	**2013**	**2014**	**2015**	**2016**	**2017**	**2018**
Total	56.5	59.2	67.6	65.5	67.9	68.6	71.0	70.5	69.8
High-tech	-	-	61.3	66.3	60.6	76.7	76.4	72.4	56.8
Medium-tech	-	-	47.3	59.0	65.2	46.3	65.1	49.9	79.6
Science-intensive	-	-	68.2	65.9	68.2	69.0	71.5	71.4	70.4

Innovation activities of Russian organizations is shown on Fig 3.

Fig. 3: Innovation activities of Russian organizations

The data show that between 2017 and 2018 innovation activities of Russian companies increased albeit insignificantly. For example, in 2018 the indicator amounted to 12.8%. Absolute figures are very low and call for a significant increase.

Despite the diversity and urgency of the problems, we believe that the primary issue that determines containment of the resource saving processes and requires prompt resolution is the insufficient level of economic interest of companies due to the lack of comprehensive mechanisms for managing resource conservation in the country.

The share of companies implementing technical innovations has more than doubled recently (Chart 4). This means that the situation has changed seriously, but the share of the companies involved is still insufficient.

Fig. 4: The share of companies implementing technical innovations

The number of advanced, new and fundamentally new production technologies developed in Russia is shown in Table 4.

Table 4: The number of advanced, new and fundamentally new production technologies developed in Russia, units

Types of technologies	Years					
	2014	**2015**	**2016**	**2017**	**2018**	**2019**
Advanced production technologies	1,409	1,398	1,534	1,402	1,565	1,620
Advanced production technologies that are new for the Russian Federation	1,245	1,223	1,342	1,212	1,384	1,403
fundamentally new production technologies	164	175	192	190	181	217
The number of advanced production technologies in use	204,546	218,018	232,388	240,054	254,927	262,645
The number of new production technologies acquired by organizations	28,705	24361	64,914	20,042	22,678	-

The share of fundamentally new developed advanced production technologies is very small.

Chart 5 demonstrates the share of energy resources produced with the use of renewable sources in Russia's total energy resources. This resource efficiency criterion, also mentioned in the Concept of Sustainable Social Development, has been at 17.2% for the last four years in our country. All these points to inertia of transformations in this resource saving segment.

Fig. 5: The share of energy resources produced with the use of renewable sources in Russia's total energy resources

Discussion and Results

Industry resource saving and energy efficiency have recently become a pressing issue for the Russian economy and management. We can identify the following resource saving instruments:

first, optimization of resource consumption by setting consumption norms not only in the technological production processes, but also in business processes;

second, assessment of restrictions in the production, consumption and operation systems;

third, analysis and evaluation of resource saving in each economic system element;
fourth, the principle of continuous improvement through introduction of the best production and management technologies.

Our analysis of the causes of the situation, which accounts for investment in the economy revealed the following key problems in the sphere:

1) the imperfect and declarative nature of the legislative and regulatory system for regulating and stimulating resource saving activities;
2) the absence of sufficient financial resources for resource saving measures, R&D and introduction of innovative resource saving developments;
3) the absence of working financial schemes for resource saving projects in various economic areas;
4) the absence of modern and well-developed market of resource saving, development of its infrastructure;
5) the absence of working economic mechanisms to stimulate resource saving that would ensure economic interest of its participants;
6) the shortage of information of the population, company managers about resource saving machines and technologies, resource efficient products, the possibilities of saving resources of various types;
7) the lack of resource management professionals, the absence of such services at companies, etc.

Analysis of expert assessments of the problems with raising the efficiency of macroeconomic systems based on faster resource saving processes in Russia helped us formulate recommendations aimed at solving the current problems.

1. Formation of an effective resource saving policy at all levels of economic system management, which will require a revision of industries' development strategies;
2. A transfer to a new model of resource consumption and distribution;
3. Formation of a modern management system at economic producing subjects.
4. A search for a reproductive component in the resource consumption model not only during production, but also consumption and operation.
5 Development of new instruments of state regulation of resource saving, which should fit into the united mechanism of economic modernization.
6. The resource saving process should be considered as part of the economic system, thereby directing it to sustainable development that focuses not only on resource saving but also on application of the principles of resource rationing with the available technology that will stimulate rational use of resources in the system.

7. Take into account industry specifics, resource intensity indicators of different industries.
8. Constant comparison of the resource consumption share at different production stages with the best available technologies to reveal the industries with the highest resource intensity and the industries with a resource saving potential.
9. Creation of necessary and sufficient prerequisites at companies to ensure the resource saving measures with maximum social, ecologic and economic effect on a national scale. The experience of developed states show that economic incentives are the best, if they are technically feasible. However, there should be understanding of the amount of funds the government can allocate to motivate resource saving and how they should be distributed among the industries to achieve the best social, ecologic and economic effect of resource saving at a national level.
Thus, misallocation of resources in conjunction with the existing environmental, social and economic problems poses the task of a manifold increase of the resource use efficiency, introduction of energy saving technologies with active support of the state. Here introduction of innovative resource saving technologies as one of the key factors able to ensure a breakthrough of the national economy is important.

At the same time, a transfer to a resource-oriented economy calls for creation of some necessary and sufficient prerequisites:

first, creation of the legal basis;
second, implementation of such initiatives as part of state policies;
third, development and use of economic stimulation instruments;
fourth, creation of infrastructure (scientific, educational, engineering and technological, social, informational and consultative);
fifth, organization of the world market.

Abstract

Stakeholders play a fundamental role in carrying out planned tasks, achieving goals and managing them effectively, therefore it is important to know and collect opinions from a wide group of them. Limiting interpersonal relations resulting from the pandemic, as well as costs of business, lead to a rapid increase in the use of information technology in the contacts of organizations with their stakeholders. Consequently, effective speech quality management is essential to ensure the smooth running of ICT-supported stakeholder engagement and consultation processes. The main purpose of this paper is to propose a model based on selected AI methods supporting quality management in stakeholder consultation through online interview based on audio recordings. This model fills the gap resulting from the lack of such solutions used during stakeholder consultation, which requires the collection of audio content of an appropriate quality from the digital space. The correct course of consultations and the effective use of their results depend on the quality of the speech data gathered. The proposed model makes it possible to support quality management and eliminate data that does not meet the requirements for the level and legibility of the recording. Audio data from individuals or fragments of illegible records may be automatically identified and deleted. In addition to theoretical considerations and the model, the results of empirical research are also presented in this paper, including a discussion on the errors in the classification of empirical speech data. The considerations are supplemented with the results of a comparative analysis of models based on two methods: Gradient Boosting and Fully Connected Deep Neural Network.

Keywords: stakeholder management, stakeholder consultation, speech quality management, online interview, AI methods.

Introduction

Stakeholders play an essential role in carrying out planned tasks, meeting targets and managing them effectively. Appropriate stakeholder management has a significant impact on the level of various types of trust (intuition, integrity, and competence) in project environments and therefore project managers should undertake effective actions related to communication with empathy and consultation in environments of projects (Francisco de Oliveira & Rabechini, 2019). Proper stakeholder engagement and taking their opinions into consideration are critical success factors for most contemporary projects (Achterkamp & Vos, 2008). Therefore, it is important to know and collect the opinions of a wide range of stakeholders who support and oppose results and have bias or maintain a neutral attitude. It is necessary to strengthen effective stakeholder engagement, conduct consultations with them, collect contextual knowledge from them (regardless of the existence of conflicting interests), allocate project resources in accordance with the designated priorities of conflict areas, as well as integrate various stakeholder points of view with the goals of the project management team (Bahadorestani, Naderpajouh & Sadiq, 2020).

Recently, there has been a rapid increase in the use of information technology in contacts of various types of organizations with their stakeholders, which are implemented on several levels: organizational, regional and global. Research on engaging citizens and stakeholders is undertaken by applying ICT to political decision-making processes, service delivery and others (UN, 2020). In interactive online communication and consultation processes between organizations and stakeholders it is essential, among others, to ensure quality of citizen-centric online environment to justify e-participation efforts (EC, 2009). Stakeholders' opinions may be collected in the form of

Cite this Article as: Tadeusz A. GRZESZCZYK and Michal K. GRZESZCZYK "Speech Quality Management in Project Stakeholder Consultation through Online Interview" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

text or audio recordings using the following ICT-supported methods: virtual/distance platform for stakeholder engagement, co-creation methods (e.g. based on online public consultations, social network analysis), online surveys and web discussion forums (Routzouni et al., 2019). A significant increase in the interest in recording statements in audio form is expected as it is a convenient form of providing feedback from stakeholders. Effective speech quality management is therefore essential to ensure the smooth running of ICT-assisted stakeholder consultation processes.

During the project stakeholder consultation through online interview, large datasets on speech content are to be collected. The proper conduct of such consultations and the effective use of their results depend on the quality of these datasets. On their basis, manual or automated transcription software of audio recordings (automated speech recognition technologies) is used. It is possible to identify the challenges and limitations of solutions applied in this field, as well as to analyze the development opportunities of audio recordings automated transcription (Stonehouse, 2019). The existing solutions in this field are insufficient, because they do not ensure the appropriate quality of speech recognition and automatic elimination of recordings that are not legible human statements. Using such recordings during online stakeholder consultations is a relatively new idea. Hence, it is necessary to develop new models to fill the gap related to the lack of quality management support when conducting stakeholder interview and consultation through online interview.

Attempts are made to use selected AI and machine learning (ML) methods in stakeholder analysis and management, e.g. Random Forest (Grzeszczyk, 2020), Convolutional Neural Network (Perez-Poch, 2019) and Fuzzy Cognitive Map (Sperry & Jetter, 2019). Taking advantage of advances in AI and ML could be also useful while expanding the set of existing quality management approaches, methods and models during online consultation with stakeholders. The main purpose of this paper is to propose a model based on selected AI methods supporting quality management in stakeholder consultation through online interview based on audio recordings. Two experimental implementations of this model, empirical verification studies and a comparative analysis of the obtained results were based on two methods: Gradient Boosting (GB) and Fully Connected Deep Neural Network (FCDNN). The choice of these two methods is justified by the fact that it is difficult to decide a priori which of them is more suitable for this type of analysis. GB is one of the ensemble methods which are based on multiple learning algorithms, while FCDNN is one of the more well-known and very challenging types of artificial neural networks. At the end of the paper, the limitations of the proposed model and the carried-out research are signaled. The obtained research results constitute a solid basis for the development of further research in this field.

Stakeholder Management, Engagement and Consultation

In the case of classic definitions, stakeholders are individuals or groups that are or may be influenced by the achievement of different goals of the organization (Freeman, 1984). Today, it is rather assumed that stakeholders are people, groups or organizations that have a significant interest in the implementation and operation of specific projects or programs (Rossi et al., 2019). Thus, they are people, groups of people or organizations that directly or indirectly, positively or negatively affect the results of projects or may be influenced by selected projects or programs (EC, 2005). Appropriate stakeholder management, engagement and consultation can help explain the existing local and regional problems and needs, and are also a reliable basis for social justification of the necessity to implement specific projects. Such credible justifications enable planning and setting goals in line with stakeholder needs.

The results of literature studies on project management confirm that stakeholders are of key importance for achieving the planned goals and it is necessary to focus on appropriate stakeholder engagement, proper consideration of their stakeholder influences and interests, improvement of stakeholder management processes, as well as development of stakeholder analysis approaches and methods (Mok, Shen & Yang, 2015). Stakeholder engagement and consultation are critical factors that bind critical decision steps and final project outcomes (Yu, Leung & Jiang, 2020). The course of consultations carried out in a traditional way can be documented using stakeholder surveys and questionnaires, daily field notes, video recordings, photographic evidence as well as audio recordings of stakeholders' opinions and views.

Taking into account the guidelines and good practices presented by international financial institutions and by United Nations agencies (e.g. UNDP - United Nations Development Programme), environmental and social security policies and legislation in many countries, the principles of civil society and opinions of academic communities, the following principles of meaningful stakeholder consultation can be formulated (Kvam, 2017):

- the consultation process should be carried out continuously and iteratively repeated throughout the project cycle,

- as a result, the main stakeholders should be identified and involved - individuals, groups, as well as formal and informal institutions operating at local and regional levels,
- it is necessary to reserve sufficient resources needed for the proper implementation of consultations, which include the budget, human resources, involvement of project authorities prepared to take the results of consultations seriously, and possible modifications to projects in line with the views expressed by stakeholders who have equal opportunity to present their views,
- consultations need to be transparent, based on facts and clearly reflect design decisions resulting from various stakeholder opinions,
- the process is to ensure a fair, non-discriminatory approach and collect the opinions of also less vocal stakeholders,
- consultations should be preceded by the effective provision of clear and comprehensive information to stakeholders about the most important aspects of the project, which are essencial for specific groups participating in these processes,
- it is vital to respect all stakeholders, not to impose specific views, any critical voices against the project should be protected,
- if it is necessary, the confidentiality of information from selected stakeholders must be ensured,
- avoiding too lengthy consultations without logical justification, excessive discussions that do not lead to results achieved within a reasonable time is essential,
- the results obtained ought to be systematically documented, and in the case of projects financed from public funds, the more important aspects should be made public.

When recording the consultation process, it is also necessary to take into account ethical aspects. Stakeholders should be informed about the objectives of the consultations, the fact the consultations are recorded and the possibility of withdrawing at any time. Audio recordings and their possible transcriptions need to be encoded to ensure anonymity and the lack of traceability of their origin.

Web technologies create real opportunities for online text and audio recording-based consultations regarding, for example, citizens' participation in decision-making processes related to the improvement of development strategies and determining the assumptions of various types of policies. Online text consultations supported by ICT tools can be conducted using websites, social networking sites or blogs, and concern, for example, commenting on proposed regulations or acts on which work is currently underway, etc. (Pulfrey-Taylor et al., 2011). Various types of ICT tools are designed with built-in reference models and argumentation schemes to support online consultation and enable stakeholder views to be exchanged during public policy discussions. Such tools can automate reasoning about the arguments used by stakeholders and pose relatively simple questions to improve consultation processes based on text (Wyner, Atkinson & Bench-Capon, 2011).

Effective quality management of audio recordings is essential to ensure the smooth running of online consultation processes, stakeholder engagement and ICT-assisted consultation. It is necessary to develop research on methods and systems supporting quality management and eliminating audio data that do not meet the requirements for the level and readability of the record. One possibility is to rely on AI models in this field, which can ensure the collection of audio content of appropriate quality from the digital space. The developed models can be based on single AI methods or mixed intelligent systems (Grzeszczyk, 2018).

Among the AI methods that can be used in the discussed case, for example, GB and FCDNN deserve attention. GB models are built based on decision trees that are trained subsequently mainly with data which had been incorrectly recognized by previous trees. Such models are characterized by fast learning and great suitability for solving classification problems, but are sensitive to even relatively small changes in training datasets and for these reasons the obtained results are sometimes difficult to explain (Akerkar, 2019). Similar limitations related to the difficulties in explaining the obtained results also apply to neural networks. Despite these limitations, neural networks find numerous applications, and in this case it was decided to use FCDNN to build one of the tested models. A detailed mathematical description of GB models as well as vast information on neural networks, FCDNN in particular, are abundantly available in the literature, e.g. (Beysolow, 2017; Aggarwal, 2018; Ghatak, 2019).

Methodology

The basis for the selection of an appropriate research methodology and methods is the pursuit of the main goal of proposing a model based on selected AI methods supporting quality management in stakeholder consultation through automated online interview. The following research methods and techniques were used: literature studies,

non-participatory unstructured observations of stakeholder's consultation, models based on selected AI methods (GB and FCDNN) and comparative analysis of the obtained results of computational experiments.

For computer calculations, hypothetical audio recordings prepared by the authors for the planned experiments were used (ninety 15 seconds long recordings were created). Ten recordings contain clear audible speech simulating interview process of answering questions asked through ICT system. Other sample recordings are a set of different background noises obscuring the speech e.g. working coffee machine or traffic. Among them, ten quiet recordings were prepared to increase difficulty for AI methods. Finally, recordings imitating the human speech that sometimes is played in the background of the interviews, like TV or radio, were added. During recording of the samples, the average level of noise was measured additionally.

a) b)

Fig. 1. Distributions of noise levels: a) all recordings, b) speech recordings
Source: own graphic representation

The level of noises was assumed in the range from 40 dB (quiet) to 90 dB (the maximum level of machine operation or heavy traffic). The sound intensity for a stakeholder consultation speech was specified in the range 50-60 dB. The following two decision classes were defined: *Speech* and *Other*. The class labeled as *Speech* involves a recording of an appropriate level, audible speech that can be used in stakeholder consultation processes related to specific projects and programs. In Figure 1, the distributions of noise levels among all samples extracted from prepared recordings are presented. Speech recordings are placed in the center of the distribution of all recordings, which could be another struggle for AI algorithms.

Having been gathered, the recordings had to be preprocessed to prepare the dataset for further training. All the recordings were sampled with 22500 sampling rate resulting in around 1400 samples for each of the recording. All of the rows were transformed to 13 Mel-Frequency Cepstrum Coefficients (MFCCs) producing 13 features for each of the rows. After preprocessing the dataset contained more than 126000 samples for training and testing (all samples from single recordings were given classes and treated as separate samples – the recording was not considered as a whole). During the training process it was guaranteed that samples from one recording were in a single set (training or testing) to avoid the situation in which samples from one file would appear in both sets and disrupt the validity of accuracy measurements. Finally, all examples were normalized so that the whole dataset had zero mean and unit variance (in order to assure stable learning).

Two tasks were solved during the experiments. GB and FCDNN classifiers were used to develop and compare two different AI methods to classify if the sample from the recording was of *speech* type. GB is an ensemble ML technique during which small weak models (e.g. decision trees with small number of splits) are combined in order to produce powerful classifiers. Multiple connected weak models allow to build ensemble models and achieve better results compared to using single models. The advantage of FCDNN is that by stacking many layers it acquires the ability to find meaningful relations between features and expected class/predicted noise level by optimizing a large number of parameters during the training process. Both methods can be used for regression tasks, therefore, additionally, the second conducted experiment was a prediction of noise level of samples. Automated measurements of the noise level can help indicate that the stakeholder's speech is inaudible or background noises are too loud. 10-fold cross validation was used during training to visualize that experiments are repeatable (the training set was composed of around 85% of the dataset, the rest was used as testing set in each fold). GB and FCDNN algorithms were used with standard parameters from Scikit-learn Python package (Scikit-learn, 2020).

Results and Discussion

Table 1 presents the results obtained from 10-fold cross validation with the use of two types of studied classifiers and regressors: GB and FCDNN.

Table 1: Comparing the results of GB and FCDNN classifiers and regressors

	GB		FCDNN	
Fold	**Accuracy**	**R-squared**	**Accuracy**	**R-squared**
1	0.95	0.93	0.97	0.94
2	0.95	0.82	0.98	0.88
3	0.98	0.87	0.99	0.92
4	0.97	0.92	0.99	0.93
5	0.92	0.93	0.98	0.95
6	0.95	0.94	0.98	0.95
7	0.95	0.97	0.98	0.96
8	0.96	0.91	0.97	0.95
9	0.91	0.89	0.92	0.92
10	0.95	0.92	0.95	0.94
Average	**0.95**	**0.90**	**0.98**	**0.93**

Source: own calculations

The obtained values of classification accuracy (for classifiers) and the statistical measure R-squared (for regressors) are at satisfactory levels, which confirms the appropriateness of the selection of AI methods for this application. On average, GB achieved 95% accuracy and FCDNN - a better result of 98% on average. The better results of FCDNN are also visible in the confusion matrices. Regressors created basing on GB and FCDNN also reached high scores with 0.90 and 0.93 measured by R-squared metrics respectively. Slightly better results of FCDNN than GB might appear due to higher complexity of the method which usually surpasses more traditional approaches. It is worth mentioning that measurement tools used during dataset creation were not 100% accurate, therefore some samples could differ with their dB values from the given label. Hence, results higher than 0.9 indicate that regressors were predicting precise values.

Table 2: Confusion matrix for GB

True label \ Predicted label	Speech	Other
Speech	957	450
Other	267	13785

Source: own calculations

The confusion matrix of GB and FCDNN classifiers (for the two defined classes) can be seen in Tables 2 and 3 (presented tables are results from the first fold of 10-fold cross validation). The values shown in these matrices prove the proper functioning of the tested classifiers and correct properties of models based on both selected methods. It can be seen that the defined decision classes can be easily separated from each other. This also confirms the usefulness of such models even with relatively few cases from the training set. This is especially worth noting regarding FCDNN because, as it is known, neural networks usually require large sets of training data, which is not always reasonable for many practical applications.

Table 3: Confusion matrix for FCDNN

True label \ Predicted label	Speech	Other
Speech	1211	196
Other	140	13912

Source: own calculations

The results for the FCDNN-based model are better, which is a bit surprising as GB models tend to perform better for small datasets compared to deep learning models. At first sight it might look unpromising that more than 200 samples were misclassified. However, this is due to the fact that classifiers were not being trained on whole recordings, but on 13 MFCCs for each of the samples which represented a very short part of the recording. Thus, some parts of the speech recordings might have had pauses (summing up to 1 second for the whole recording). This property results in shown misclassification (label of class *Other* was indicated by model, but label of class *Speech* should have been given). In future experiments this might be used for automated cutting of the recordings to make them shorter. On the other hand, some samples were classified as *Speech* when they should not have been. This is due to the fact that some example recordings contained TV or radio sounds. Therefore, in some of them background speech could be noticed. This misclassification of human speech and audio from TV or radio could be also made by humans.

Table 4: Classification metrics for GB and FCDNN

	GB		FCDNN	
Label	**Precision**	**Recall**	**Precision**	**Recall**
Speech	0.78	0.68	0.90	0.86
Other	0.97	0.98	0.99	0.99

Source: own calculations

Since the prepared dataset is imbalanced, accuracy measures do not always display the results that show the whole performance of the ML algorithms. Therefore, it is worth using such classification indicators as precision and recall. The results are again shown for the first fold. In Table 4 the advantage of FCDNN over GB is clearly visible. FCDNN achieved high metrics for both classes and proved to be better for this type of experiments and solutions. Slightly lower recall and precision for *Speech* class for both algorithms results from the reasons that have been described in the previous paragraph. Additionally, due to a high number of samples from the class labeled as *Other* the achieved metrics are also very high and promising for further research.

The good results obtained for FCDNN provide a solid basis for further development of various types of AI methods and classifiers based on them using deep learning, as well as for the formulation of reliable conclusions. During creation of the business solution there would be much more recordings prepared for training process, which would result in even higher metrics. The proposed method allows for an automated quality management of the collected recordings from the stakeholder consultation processes. In case of inaudible recording or too quite/loud speech with lots of background noises, a stakeholder might be automatically asked to repeat the interview in better conditions. This allows for a higher quality of services, feedback and communication between collaborators.

Conclusions

Audio recording-based consultations and online interviews will become more and more common. In this kind of stakeholder consultation, it is necessary to collect large datasets on the opinions expressed, and the proper conduct of the consultation and the effective use of its results depends on the quality of the data collected. The solutions existing so far are often insufficient, do not ensure adequate quality of speech recognition and automatic elimination of recordings that are not legible human statements. Thus, it is worth paying attention to the possibilities of filling this gap by using the development of AI methods.

The main purpose of this paper has been achieved and a model based on selected AI methods has been proposed, which enables effective support for quality management in stakeholder consultation through online interview based on audio recordings. The practical usefulness of this model has been confirmed by two experimental implementations, empirical verification studies and a comparative analysis of the obtained results. The use of this analysis made it possible to conclude that the FCDNN-based model provides a smaller classification error compared to the GB model (even for relatively small training datasets). The proposed model enables the automatic elimination of recorded audio data that are not identified as legible recordings of human speech. Fragments of illegible recordings are also automatically removed, while retaining the remaining content.

Performing computational experiments for only two types of AI methods is a significant limitation of the research carried out, therefore it is necessary to look for other AI and ML methods that can be used. It is also worth increasing and diversifying the sets of empirical data used in future comparative analyzes. Further development of research may also be related to the identification and real-time online transmission to stakeholders of the most likely

causes of deletion of recordings originating from them. Improved models may enable the determination of the type of disturbance, e.g. caused by passing cars, home appliances working in the background or other noises.

Abstract

In enhancing the performance of civil services, the Government of Malaysia has taken extensive change initiatives to continuously reform the administration of the public sector in Malaysia. The transformation programme has been introduced to improve the overall performance of civil personnel and to improve the delivery of services towards the public at large. Among other change initiatives taken is strengthening the Performance Measurement System (PMS) towards improving the performance of civil personnel and public sector organizations. The purpose of this study is to provide an extensive review of past literatures regarding financial management reforms in the Malaysian public sector organization which brings to the establishment of PMS. This study also aims to explore the pattern of senior management commitment in predicting their readiness towards public sector transformational change. A total of 40 useable responses were collected from May to August 2015 using a web-based survey. Data were analyzed using Rasch measurement and Winsteps@ 3.72.3. The study showed that the public sector managers seriously recognize the role and commitment of senior management as an important driver towards the successful implementation of change in Malaysia. This study also found that longer-tenured managers with several numbers of working experience are more committed to change than less tenured managers with limited experience. Findings from this study are expected to benefit the authorities by assisting them in executing their roles to ensure the public sector managers accept change and able to improve their performance as to support the government aspiration.

Keywords: Performance Measurement, Public Sector Organization, Rasch Measurement Model.

Introduction

Background of the Study

Globalization has placed strong pressure on the organization to compete for trade flows, investment, and resources (Auditor General, 2007; Goyal, 2006). Since then, the process of reforming the public sector was also known as Public Sector Reform (PSR) has taken place to replace the traditional administrative structures (Siddiquee, 2010; Norhayati & Siti Nabiha, 2009). The movement is known as the New Public Management (NPM) has sought to solve the problem of inefficiency with its emphasis on managing for outcomes and results as one of the ways to improve performance in the public sector (Siddiquee, 2010). Auditor General (2007) further points out that it is

Cite this Article as: Nazirah AZIZ, Emmarelda Maswesi AHMAD, Zamalia MAHMUD and Jamaliah SAID "Commitment of Senior Management Towards Public Sector Transformational Change: A Rasch Analysis" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

important to have a high quality and excellent public sector delivery system as a poor delivery system can damage investors' confidence to do business and invest in Malaysia.

The process of reforming the public sector in Malaysia was addressed by the previous Prime Minister of Malaysia towards emphasizing "Performance Now" as the new administration's tag line. This indicates that the government is seriously focusing on improving performance towards achieving Vision 2020. Performance management is a key agenda in public sector change on the basis that it will help them meet improvement targets. In addition, the government has established a Key Performance Indicators (KPIs) system. The aim of establishing the transformation program is to improve public services and to help the government to achieve the ideals of a developed nation. Recently, the current government has established the *Wawasan Kemakmuran Bersama* 2030 (Shared Prosperity Vision 2030) as the new transformation program introduced by the government to improve performance and service delivery towards the public at large. This Vision focus on the commitment of the government to make Malaysia a nation that achieves sustainable growth, and equitable wealth distribution across income groups, ethnicities, regions and supply chains.

One of the main issues addressed by previous scholars regarding change efforts is resistance to change (Hameed, Roques, & Ali Arain, 2013; Pryor, Taneja, Humphreys, Anderson & Singleton, 2008). Resistance to change emanates from many sources, including lack of information, lack of perceived benefits, lack of management commitment and motivation and lack of adequate resources to implement ideas (Al-Alawi et al., 2019; Liu & Zhang, 2019; Self & Schraeder, 2009). A group of researchers has argued that resistance to change will lead to high losses in government, and change is often resisted (Northcott & Taulapapa, 2012; Pryor et al., 2008).

The present study asserts the significance of inculcating managers' Perceived Readiness for Change (PRC) towards improving public sector performance. So far, however, there has been little discussion on the role of PRC in enhancing the efficiency and effectiveness of public sector performance. The present study explores the pattern (based on the response pattern of respondents on the Person-Item Distribution Map of Rasch Analysis) managers' PRC after the implementation of the change program.

Findings from this study are expected to benefit the government by enhancing their awareness of the importance of inculcating the readiness among public sector managers towards change. This in turn would help the authorities executing their roles to ensure the public sector managers accept change wholeheartedly and able to improve their performance to support the government agenda of the Shared Prosperity Vision by 2030.

Motivation and Objective of the Study

Prior researchers have attempted to identify the underlying reasons that caused a failure in organizational change. According to Burnes (2003), it is important to understand the causes of failure and drive for success in managing organizational change. It is necessary to have the right people to lead the organization with skills, competencies and aptitude to implement the guidelines for successful change. Hoag, Ritschard, and Cooper (2002) indicate that the failure of management is the strong factor that contributed to the failure of change. Previous research acknowledged the important role played by senior management in change effort (Kitsios & Kamariotou, 2017; Boukenooghe, Devos, & Broeck, 2009; Cinite, Duxbury, Higgins, 2009). However, no studies offer psychometric measurement in exploring readiness towards change, especially in measuring the commitment of senior management towards change. Do managers agree that commitment of senior management is essential during the change process? And, what are other factors (i.e. Age, tenure, or gender) that might contribute to this agreement?

This study aims to explore the pattern of senior management commitment in response to public sector transformational change. This study also aims to examine the commitment of senior management in the public sector towards successful change efforts. It is important to note that the senior management received information from the policymakers, and then they are responsible for disseminating the information to the middle management and staff.

Contribution of the Study

The contributions of this study are significant in the literature of performance measurement practices and readiness for change in the public sector. Other than that, the present study also contributes to the development of psychometric measurement using the Rasch Measurement Model. In addition, the findings of this study are expected to contribute to policymakers in enhancing the role played by the senior management towards successful change.

An extensive review of the literature in management accounting change studies in Malaysia revealed a connection with the reform and the public sector change (Atan & Yahya, 2015; Azmi & Mohamed, 2014; Danilah & Siti Nabiha, 2011; Nor Hayati & Siti Nabiha, 2009). However, studies that offer explanations for the readiness of managers for such reform is currently limited (Siddiquee, 2010; 2006; Norhayati & Siti-Nabiha, 2009). Hence, this study aims to assess senior management commitment as a new approach in the successful implementation of change initiatives with specific attention to management accounting change. This study employs a psychometric measurement, namely the Rasch Measurement Model to assess the readiness of public sector managers towards change through the commitment of the senior management. This is the first attempt to use Rasch analysis in a management accounting change study in Malaysia. In line with the transformation programs introduced by the government, this study seeks to draw inferences from the evidence about senior management's commitment to change concerning the effectiveness of transformation programs.

Organization of the Paper

The remainder of this paper is organized as follows. Section 2 develops an understanding of the readiness for change and discussion on the commitment of senior management towards a successful change. Section 3 discusses the methodology employed for the study. Section 4 reports the analysis and results of the study. Finally, a summary of the findings and conclusion of the study is presented in Section 5.

Literature Review

Readiness for Change

Previous scholars viewed the success and even the mere survival of an organization is depending on their ability to adapt to change (Greenberg, 2005). Change occurs first at the individual level, and then, at the organizational level (Elias, 2009). The readiness of individuals working in an organization reflects the readiness of the organization towards transformation. Individual readiness is an important driver for successful change in an organization (Burnes, 2004; Armenakis & Harris, 2002).

Change denoted not only members' belief in subscribing to change, but also members actively engaging in practices that will lead to its successful implementation (Cinite et al., 2009; Burnes, 2004). Cinite et al. (2009) further added that the announcement of transformation is not sufficient enough to persuade employees that the organization is ready to implement the change. If the organization failed to persuade or ensure that the change is needed, then the employees might feel that the organization may fail to change (Norhayati & Siti Nabiha, 2009; Cinite et al., 2009).

Prior researchers had attempted to identify the underlying reasons that caused the failure in organizational change. Burnes (2003) emphasized that it is important to understand the causes of failure and drive for success in managing organizational change. It is important to have the right people to lead the organization with skills, competencies and aptitude to implement the guidelines for successful change. Hoag et al. (2002) indicated that failure of management is a strong factor that contributed to the failure of change.

Hence, it is important to understand the s to change management implementation in public sector organizations (Adel Ismail Al-Alawi et al., 2019). As summarized in Kitsios and Kamariotou (2017), public sector servants have dealt with several changes, but there is a lack commitment from the management, unclear vision, and insufficient training.

Commitment of Senior Management towards Change

Scholars have identified that trust plays an important role in change management research (Hodges, Abrahamson, Agarwal, Bhargawa…, 2019; Michaelis, Stegmaier, & Sonntag, 2009). Employees' trust in the change agents is crucial to establish readiness towards change. In the case of reforming the public sector organization in Malaysia, the top management has been identified as the change agent that plays an important role to create readiness towards change. Michaelis et al. (2009) addressed that top management that has leadership qualities will promote trust from the employees and consequently improve employees' affective commitment towards change.

The extensive review on the discussion of the change models as provided by Pryor et al. (2008) indicates that Jick's Model (2003) and Mento, Jones and Dirmdofer's Model (2002) highlighted on the importance of the commitment of senior management in facilitating the change process. Mento et al. (2002) addressed the importance of establishing a change leadership team to direct the change initiatives. In addition to this, Jick's Model (2003) also demanded strong support from the leader in implementing change. Cinite et al. (2009) also addressed the need of establishing a 'champion' to direct the change. Thus, this study proposes that there is a need for leaders that are committed to ensuring successful change initiatives. It is important to note that the senior management is responsible to define the course of change to their subordinates and demonstrate their commitment to change through their behaviors. Moreover, senior managers are responsible for taking an overview of the presents and future direction and activities of their organizations (Burnes, 2003). Hence, organizations that want to be perceived by their employees to be ready for the transformation should pay close attention to the commitment of senior management.

The commitment of senior management plays a vital role in ensuring successful change initiatives (Bouchenooghe et al., 2009; Cinite et al., 2009; Pryor et al., 2009). This is very important to ensure the subordinates have trust in their leaders as their work culture is normally shaped by the action and the words of those leaders (Hodges et al., 2019). The public sector reform literature highlighted the importance of the commitment of senior management in the implementation of PMS in public agencies (Cavalluzzo & Ittner, 2004). The commitment of senior management is crucial in the process of implementing PMS as those leaders are responsible for resource allocation, strategies on the initiative, and to motivate subordinates who resist changing (Liu & Zhang, 2019). Subordinates who received strong support from top management are more likely to accept change compared to those who did not receive strong support from their leaders (Hodges et al., 2019; Cavalluzzo & Ittner, 2004). Consequently, top management commitment will influence the subordinates to contribute towards improving their performance and subsequently achieving organizational objectives.

This study viewed the commitment of senior management as an important driver to drive government agencies and civil personnel towards successful implementation of PMS practices in the public sector organizations in Malaysia. This study found that the role of readiness towards change, especially measured by the commitment of senior management is still under-explored.

Methodology

This section describes the research method employed by this study. A brief explanation on the use of the Rasch Measurement Model also been outlined in this section. In addition, this section also exhibits the measurement of variables used in this study.

Research Method

This study employed a survey method to gather information from 40 managers working in various public sector organizations using convenience sampling. Managers were randomly selected from the database available on Prime Minister Office's website (www.pmo.org.my). Four ministries agreed to be involved in this study. There are Ministry of Housing and Local Government (MHLG), Ministry of Health (MOH), Ministry of Domestic Trade, Cooperatives and Consumerism (MDTCC), and Ministry of Tourism (MTour). Only senior managers (grade 48 and above) and hold the position as Head of Department were chosen to be involved in this study as it is believed that the senior managers aware of performance measurement system of their department. In addition, it is believed that this group of managers is also responsible for disseminating information on change efforts made the policymaker to their staff. Managers were assessed on their perceived readiness towards change where they need to respond to nine items based on a 5-point Likert scale ranging from (1) strongly disagree to (5) strongly agree. The data collection process was conducted between May to August 2015 using an online digital questionnaire. The the draft questionnaire has also been sent to the Deputy Director of Audit Department in Ministry of Finance to get an expert opinion regarding the content validity of the instrument. In addition, the questionnaire was also subjected to reliability and validity analysis using selected Rasch measurement tools via the WINSTEPS$^{@}$ 3.72.3 software.

Rasch Measurement Model

The Rasch measurement is based on a probabilistic model which originates from the Linear Hierarchical Logistic Model (Zakaria, Abdul Aziz, Mohamed, Arshad, Ahmad Ghulman, & Masodi, 2008). In the Rasch philosophy, the data have to comply with the principles, or in other words, the data has to fit the model. From Rasch point of view,

it is required to test whether the data allow for measurement on a linear interval scale specifically in a cumulative response process (Zakaria et a., 2008). Following the measurement theory, it has been addressed that a scale should demonstrate that all items in the questionnaire belong to the same construct, and has monotonically increasing steps, and these properties can be illustrated by the Rasch model (Pinyopornpanish, Pinyopornpanish, Wongpakaran, 2020).

Based on the Rasch rating scale model, we will estimate P_{ni1}, the probability of person n choosing "disagree" (category 2) over "strongly disagree" (category 1) on any item *(i)*. D_i is the difficulty of item *i* and F_1 is the difficulty of the first threshold on item (*i*). The rating scale model is illustrated in Eq. (1):

$$P_{ni1}(x = 1 / B_n, D_i, F_1) = \frac{e^{(B-[D_i+F_1])}}{1+e^{(B-[D_i+F_1])}} \qquad (1)$$

Measurements of variable

The commitment of senior management towards transformation was measured using 3-items adopted from Cinite et al. (2009), and 3-items adopted from Allen and Meyer (1990). A further 3-items were adapted from Bouckenooghe et al. (2009) and used in this study. The choice of the scale from these three prior studies was due to their suitability with the context of the present study, which is to explore the pattern of senior management commitment towards public sector change. The first 3-items and the last 3-items has been tested in both private and public sectors (Cinite et al., 2009; Bouckenooghe et al., 2009); while the other 3-items has been widely used in change management research (Allen & Meyer, 1990). Respondents are required to answer by way of 5 point Likert scale from "5" strongly agree to "1" strongly disagree.

Analysis and Results

This section provides the descriptive statistics of the respondents' profile, the assessment of the validity and reliability of the data using the Rasch Measurement Model, and followed by the discussion of the output in Person-Item Distribution Map (PIDM).

Respondent Profile

Table 1 below presents the profile of respondents, including the gender, age, ministry, managerial tenure in the department, and size (represents by the number of employees under supervision). Referring to Table 1, 13 respondents were from MHLG, 12 respondents were from MOH, 12 respondents were from MDTCC, and 8 respondents were from MTour. The majority of the respondents were female (57.5%). 75% of the respondents were 40 years old and below, while 25% of managers were more than 40 years old. Slightly half of the respondents (52.5%) have been working in the department for less than 5 years. In addition, the majority of the respondents or 80 % supervised less than 200 employees in their department.

Table 1: Respondent Profile

Description	Frequency	%
Gender:		
Male	17	42.5
Female	23	57.5
Age:		
Less than 30 years	17	42.5
31-40 years	13	32.5
41-50 years	7	17.5
51-60 years	3	7.50
Ministry		
MHLG	13	32.5
MOH	7	17.5
MDTCC	12	30.0
MTour	8	20.0
Tenure in the Department		
Less than 2 years	7	17.5
3-5 years	14	35.0
6-8 years	10	25.0
9-11 years	6	15.0
More than 11 years	3	7.50
Number of employees		
Less than 100 employees	20	50.0
100-200 employees	12	30.0
200- 500 employees	8	20.0
More than 500 employees	0	0.00

Person- Item Distribution Map (PIDM)

The heart of Rasch analysis is provided in Figure 1, which is the person-item distribution map. Referring to the person-item distribution map (PIDM) in Figure 1, Managers with ID 1-13 were from MHLG, managers with ID 14-20 were from MOH, managers with ID 21-32 were from MDTCC, and managers with ID 33-40 were from MTour. Items and persons (or respondents) share the same linear measurement units known as *logits*. Referring to Zakaria et al. (2008), a logit is a unit derived from transforming ordinal data into an interval scale. Each person and item have its logit value that represented their ability and difficulty.

Figure 1 demonstrates unidimensional variable that was intended to measure the level of readiness of Malaysian public sector managers. As can be seen in the map in Figure 1, the person and the items are located along the line. The items at the top are more difficult to endorse or to agree with; and the persons at the top of the line are more able (agreed/ endorsed to most difficult items). As the items were scrolled down the line, those items became easier (to endorse/ to agree) and the persons became less able.

As can be seen in Figure 1, 40 managers are mapped on the left side of the map under the heading 'persons'. The distribution of respondents' positions is on the left side of the vertical dashed line in increasing order of ability. Those at the upper end of the scale agreed with more items and agreed strongly. On the map, we can see that 57.5% (n=23) of the managers fall above of all 9 items. This group of managers also agreed that the senior management people in their organization pay attention to the ideas brought to them by the middle managers and employees (*refer to item Commit_5*). Managers with ID number 14 and 26 are found to have agreed completely with all the items, followed closely by managers with ID number 25, 19, 23, 37. Manager with ID 14 are from MOH, while a manager with ID 26 are from MDTCC. Both managers shared almost similar characteristic, i.e, both are male, aged in between 31-40 years old, and tenure in the department for 9 to 11 years. Manager with ID 14 supervised 100 to 200 employees, while manager with ID 26 supervised less than 100 employees.

About 42.5% (n=17) managers did not find all items to be important driver to reflect the commitment of the senior management towards transformation (ID number 22, 07, 33,…08). As can be seen on the map, managers with ID 27, 35 and 32 fall below -7logit. This indicates their disagreement with almost every item measuring the commitment of senior management towards change. Further investigation has been done by checking with their

profile reveals that both managers with ID 35 and 32 are from MTour, while a manager with ID 27 is from MDTCC. Manager with ID 35 is female, while managers with ID 32 and 27 are male, all aged less than 30, tenure less than 2 years and supervised less than 100 employees. Hence, it can be assumed that these managers are less experienced, and may not have enough exposure or information regarding the change process in the public sector organizations.

Figure 1 reported that the readiness of managers with ID number 34, 17 and 36 matches items Commit_4 and Commit_8. This indicates that these three managers neither agree nor disagree that there is a champion of transformation at the most senior level in their organization (*refer to item Commit_4*). They also have a neutral agreement that the senior management team in their department is actively involved with the transformation (*refer to item Commit_8)*.

Those managers who are mapped above Item Commit_6 agreed that all these items or constructs are important drivers to improve readiness towards transformation through the commitment of the senior management.

There is also an indication of redundancy among the items as shown on the map. These items are labeled as Commit_1, Commit_2 and Commit_3. Commit_1 is measuring whether managers agree that the senior management is decisive with respect to organizational goals, priorities and strategies concerning the transformation. Commit_2 is measuring whether the senior management themselves have brought into the transformation and promote it by behaving in a manner consistent with the transformation. Item Commit_3 is measuring whether senior management defines the course of transformation to their subordinates.

Figure 1: Person-Item Distribution Map (PIDM)

Discussions and Conclusions

This section provides discussions on the findings, implications of the research, limitation of the research and suggestions for future research. In addition, this section also provides a summary and conclusion of the study.

Discussions

The public sector reform literature highlighted the importance of the commitment of senior management in the implementation of PMS in public agencies (Cavalluzzo & Ittner, 2004). The commitment of senior management is needed in the process of implementing PMS as those leaders are responsible for resource allocation, strategies on the initiative, and to motivate subordinates who resist changing. Subordinates who received strong support from top management are more likely to accept change compared to those who did not receive strong support from their

leaders (Hodges et al., 2019; Cavalluzzo & Ittner, 2004). Consequently, top management commitment will influence the subordinates to contribute towards improving their performance and subsequently achieving organizational objectives. The present study asserts that the commitment of senior management during public sector transformational change is crucial towards achieving the government aspiration.

The main findings of the present study exhibited in PIDM. This study found that slightly half of the respondents (57.5%) agree that the commitment of senior management plays a vital role in ensuring successful change initiatives. This proves that the commitment of the leaders towards improving organizational change engagement is essential to gaining management buy-in as well as to ensure that employees, and other stakeholders to engage with change (Hodges et al., 2019).

Based on a further investigation with the respondents' profile reveals that longer-tenured managers are located at the top position on the map, while less tenured managers (working with the same department for less than 2 years) are located at the lower position on the map. As noted in Hameed et al. (2013), as tenure increases, individuals develop a better understanding of the practices and routines of the organization, and their own roles in the organization. Thus, the present study suggests that as the tenure of the manager increases, the positive effect of the use of PMS increases, and the managers can easily adopt change.

The findings of this study lead to argument that less tenured managers might not receive adequate information regards to change initiatives implemented by the policymaker. Kitsios and Kamariotou (2017) claimed that public sector servants's reluctant to change could emanate from lack commitment from the management, insufficient information about change, and insufficient training to adopt change.

Another possible reason that could lead to this pattern is due to a lack of experience with their working environment. Further investigation with the respondent profile also reveals that managers aged less than 30 years old are located at the bottom position on the map. This issue needs to be tackled by the policymaker to ensure managers receive adequate information regarding any program introduced by the government. This can be done by providing proper training and improve communication channels. As summarized in Kitsios and Kamariotou (2017), public sector servants have dealt with several changes, but there is a lack commitment from the management, unclear vision, and insufficient training.

Implications of the Research

An important implication of the findings of this study is that they serve as a reminder to the Malaysian government to concentrate on having the senior management that is committed in the change process. By focusing on this issue, this could improve the senior management to be more supportive, decisive and participative in the change process.

The findings are useful for the Malaysian government and its agencies, including the Malaysian Administrative Modernisation and Management Planning Unit (MAMPU), Malaysia Productivity Corporation (MPC) to find new approaches in improving the performance of individual managers and organizations through strengthening the readiness for change. The Malaysian government, through MAMPU, MPC and other agencies, have done so much in providing training in the aspects of skill development, capability enhancement to change initiatives introduced by the government. However, the focus of the training should be provided on how to improve the values of readiness towards change through strengthening the commitment of senior management towards change.

This study employs Rasch Measurement Model to explore the importance of the commitment of the senior management team in the public sector change as an alternative method to management accounting change research as most researchers used classical ways of analyzing, namely SPSS. Rasch Model applied the use of psychometric measurement to establish more insights for the present study, which help provide a more comprehensive conclusion. Thus, the attempt made by this study could be emulated by other researchers in the future to use Rasch Model with more rigorous analysis, that is to do subtest on each item so that the gap between items could be traced and therefore, new items could be identified and added to the instrument more accurately.

Limitations and Directions for Future Research

Among the limitations of this study were a small number of respondents, where the respondents were mostly working with Federal tier located in Putrajaya. In the future the number of participants of public sector managers from different tiers (including government agencies outside Putrajaya, the state and local government) should be increased because they might have different views on the issue of the commitment of senior management towards

change. A wider geographical area should be considered for better generalization of the results to the overall population, thus producing a more convincing conclusion. It is also suggested to increase the number of sample sizes to produce better results as cross-validation can be done by dividing the large data into a few files to cross-validate. From here, comparisons could be made to confirm the validity of the instrument and the model. The larger sample size could generate more convincing results (Field, 2009).

This study is basically an exploratory in nature. There was no hypothesis or relationship between variables to be tested. Hence, this limits the discussion on the impact of the commitment of senior management towards change during the reform process. Future research can be undertaken by adding more variables, i.e. to test the effect of the commitment of senior management towards change on the individual or firm performance. This can be done by extending the analysis through the use of Hierarchical regression, or structural equation modeling (SEM) techniques such as AMOS or PLS any other methods that suit to test those relationships.

The use of bilinguals is advised for research involves responses from the managers working with public sector organizations in Malaysia. Many respondents suggested the researcher use both English and Bahasa Melayu for the questionnaire. One of the reasons is that there are familiar and feel more comfortable with Bahasa Melayu as the language is being used in their day to day working environment including preparing the reports, conducting the meetings and so on.

Conclusion

In enhancing efficiency and effectiveness in delivering public services, the Government of Malaysia grapples with various issues concerning continual administrative reforms, in particular, issues pertaining to the improvement of performance. Consequently, several transformation programs has been established, as change is essential for success. As such, the purpose of this study is to explore the role and commitment of senior management towards successful change efforts made the government of Malaysia, which is to emphasize on improving performance through enhancing the current Performance Measurement System (PMS). This study asserts that the senior management team plays a very important role in ensuring the successful implementation of change efforts.

Data were collected from 40 managers working in the public sector organizations, specifically in the federal government. Rasch analysis determined the validity and reliability of each item (*questions in the survey*) and the person (*the respondents*). The results imply that a larger number of respondents are needed to improve the reliability of the item used in the survey.

This study has shown that the measurement of managers' response towards readiness for transformation can be precisely measured using the Rasch probabilistic model. More than half of the respondents indicated their agreement to almost every item in the dimension of the commitment of senior management to the transformation. The result is also consistent with the previous study where the commitment of senior management is seen as an important driver for successful transformation.

Abstract

Health and social security is the two most momentous parts of every human being. In this concept following the India government was formed Employees' State Insurance Scheme (ESI) this scheme was inaugurated in Kanpur on 24th February, 1952 (ESIC Day) by then Prime Minister Jawaharlal Nehru. According to the section 46 of the employee states insurance act envisage following six social security Medical related benefits, Sickness related benefits, benefits of maternity, disablement related benefits, benefits of dependant's, and other benefits. It is a self-financing social security. ESI is a health insurance scheme for Indian employees who get below 21,000 salaries or remuneration. This scheme is mainly focused on the middle-income category of the employees'. The main motive of this study is found the reason for beneficiaries are opting private hospital rather than ESI hospitals. This study is mainly finding out the satisfaction level of who is using the specialist consultation and specialist treatment in both private hospitals and ESI Hospitals. After that find out the major problems to meet ESI Hospitals and find out the reason for why beneficiaries are opting private hospitals rather than ESI hospitals. This is mainly focused on the comparative analysis of ESI Hospital at Udyogamandal Ernakulum and Private Hospitals in Ernakulum, Kerala. The sample consisting 60 beneficiaries randomly collected in ESI Hospital Udyogamandal Ernakulam District. The conclusion of this study is the private hospital is providing more satisfaction compare to ESI hospitals Udyogamandal Ernakulam District.

Keywords: Employees state insurance out patient satisfaction, private hospital outpatient satisfaction, social security, medical protection.

Introduction

Employee state insurance scheme is the most important social security scheme of an India. This scheme is helping to employees for helping to ensure medical and social security. It was inaugurated on 1954 February 24th (ESIC Day) and the services were launched simultaneously in Delhi. Employees' State Insurance (ESI) Scheme is a social security scheme in India. The ESI provides social security and medical protection to beneficiaries and dependents. The ESI Act 1948guaranteed to good health and medical care, social security survivors of dead enrolee and their family member's.

According to ESI Act 1948, if any institutions or workplace is work 10 or more than persons work, they are eligible to join ESI scheme. The textile shops, restaurants, education institutions, hospitals are eligible for this scheme. The ESI provide medical care through ESI dispensaries and ESI Hospitals, Diagnostic centres. If any case of medical emergency the ESI provides super speciality facilities. After the new renovation, the wages limit is increased to Rs.21, 000. Earlier the limit is Rs.15, 000 per year. The ESI is providing health security and social security for all beneficiaries and their dependant.

This study is mainly finding out the satisfaction level of who is using the specialist consultation and specialist treatment in both private hospitals and ESI Hospitals. After that find out the major problems to meet ESI Hospitals and find out the reason for why beneficiaries are opting private hospitals rather than ESI hospitals. This is mainly

Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

focused on the comparative analysis of ESI Hospital at Udyogamandal, Ernakulum and Private Hospitals in Ernakulum, Kerala. The sample consisting 60 beneficiaries randomly collected in ESI Hospital Udyogamandal Ernakulam District. This study is help to increasing the efficiency of the services provided by ESI hospitals.

Need for The Study

The study was conducted to compare the satisfaction of services provided by ESIC Hospital and Private Hospital based on Consultation of outpatients 'services. The ESI beneficiaries are including the middle-income category that means below 21000 salaries. If this categories people face lot of problems in meet hospital expenses and caring health. It's very difficult to meet their hospital expenses according to their income. If the similar circumstances the ESI schemes are very useful to employees and their dependents. But the majority of beneficiaries are still not aware of proper use and it's potential. Majority of the beneficiaries' are used to private hospital for treatment. This study is mainly finding out the satisfaction level of who is using the specialist consultation and specialist treatment in both private hospitals and ESI. After that find out the major problems to meet ESI Hospitals and find out the reason for why beneficiaries are opting private hospitals rather than ESI hospitals.

Objectives of The Study

- To identify the satisfaction level of beneficiaries and their dependants in ESI Hospitals and Private Hospitals based on doctor's consultation.
- To find out the factors of influencing satisfaction of doctors' consultation services.
- To compare the satisfaction based on doctors consultation in ESI Hospitals and Private Hospitals.

Research Methodology

The study adopted the descriptive type and evaluating the comparative analysis of ESI Hospitals and Private Hospitals. And find out the major problems and find out the reasons and solutions. The questionnaire is a major tool of this study. The sample consisting 60 beneficiaries randomly collected in ESI Hospital Udyogamandal Ernakulam District.

Sources of Data

The primary data were collected from who is comes in ESI Hospital Udyogamandal in Ernakulam District with the help of questionnaire. Secondary Data were collected from various sources like books, newspapers, magazines, internet and journals.

Sample Size (Target Population)

The insured person (IP) and their dependant have been selected as respondents for the samples. The sample size consisted of 60 randomly selected beneficiaries and sample frame is whose comes in ESI Hospital in Udyogamandal Ernakulum District.

Research Tools

The questionnaire contains the information about both Private Hospitals and ESI Hospitals. In this study they use Likert scale (Highly Satisfied /Satisfied/Average/Dissatisfied/Highly Dissatisfied) Closed-Ended Questions for analysis of the data, SPSS was used. Reports' Codebook is used to refine data. Cronbach's alpha is used to reliability of Likert questions in the survey.

Reliability of The Study

In this table No 1.1 show that Cronbach's Alpha is .913. Which indicate a high level of internal consistency of this study. Cronbach's Alpha is the most commonly used measure of find internal consistency. And it helps to measure the quality of questionnaire and reliability of the questionnaire.

Table 1: Reliability of Study

Cronbach's Alpha	Cronbach's Alpha Based on Standardized Items	Number of Items
.913	.912	10

Item-Total Statistics

This column presents the value that Cronbach's Alpha. It was help to delete the irrelevant question. After the analysis of reliability test reduce the irrelevant questions and variable from this study.

Type of Hospitals	Variables	Scale Mean if Item Deleted	Scale Variance if Item Deleted	Corrected Item-Total Correlation	Squared Multiple Correlation	Cronbach's Alpha if Item Deleted
ESI Hospitals	Behaviour of Doctor	31.7333	24.741	.793	.895	.897
	Quality of communicatio n	31.7333	25.453	.837	.938	.894
	Waiting time for consultation	33.0167	27.779	.635	.833	.907
	Privacy of Consultation	33.1333	27.745	.545	.756	.912
	Time spent with Doctor	31.8167	26.017	.738	.949	.900
Private Hospitals	Behaviour of Doctor	31.6333	24.779	.820	.941	.895
	Quality of communicatio n	31.6333	27.931	.692	.868	.904
	Waiting time for consultation	31.5333	28.524	.491	.614	.914
	Privacy of Consultation	30.9333	28.029	.592	.611	.909
	Time spent with Doctor	31.7333	26.640	.672	.791	.904

Limitations of Study

Study is restricted to the city of ESI Hospital in Udyogamandal Ernakulum. While the findings can be replicated in cities similar o ESI Hospital in Udyogamandal Ernakulum, the same probably cannot be deduced for tier. This study is limited to only 60 peoples who are using both ESI Hospitals and Private hospitals.

Analysis of Satisfaction Variables

Waiting time for consultation, Behaviour of doctor, Quality of communication, Privacy of consultation and spending time with doctor are the main satisfaction variable of in this study.

Table 2: Analysis of Demographic Variable

Demographic Variable	Scale	Percentages
Gender	Male	48.3%
	Female	51.7%
Marital Status	Unmarried	33.3%
	Married	65.0%
	Widow/Widower	1.7%
Education	SSLC	10.0%
	Plus Two	31.7%
	Degree	40.0%
	Above Degree	18.3%
LOCATION	Below 20km	33.3%
	20km-30km	43.3%
	30km-40km	23.3%
	40km-50km	0.0%
	Above 50km	0.0%
Status of Beneficiaries	Insured Person	65.0%
	Dependent	35.0%
Frequency of Visit	Once in a While	56.7%
	Frequent User	33.3%
	Rarely User	10.0%
Taking Regular medicine	Yes	53.3%
	No	46.7%

Table 3: Waiting Time for Consultation in ESI & Private Hospitals

Variables	Scale	ESI		Private Hospitals	
		Frequency	Percentage	Frequency	Percentage
Waiting Time For Consultation	Highly Satisfied	0	0%	12	20%
	Satisfied	0	0%	30	50%
	Average	31	51.7%	18	30%
	Dissatisfied	23	38.3%	0	0%
	Highly Dissatisfied	6	10%	0	0%
	Total	60	100%	60	100%

The table No 3 shows that comparing of waiting time for consultation in ESI Hospital and Private Hospital. Waiting time for consultation is a lead to patient satisfaction. In case of ESI Hospitals, there is nobody rating for highly satisfied or satisfied. In case of Private Hospital, there are 70% of peoples satisfied with waiting time for consultation. The ESI Hospital 48% of peoples are dissatisfied with the waiting time for consultation and in case of Private hospitals, there is nobody rating for dissatisfaction. This analysis shows that Private Hospital is better than ESI Hospital in the context of waiting time for consultation

Table 4: Behaviour of Doctor in ESI Hospitals & Private Hospitals

Variables	Scale	ESI		Private Hospitals	
		Frequency	Percentage	Frequency	Percentage
Behaviour of Doctor	Highly Satisfied	12	20%	12	20%
	Satisfied	24	40%	30	50%
	Average	18	30%	12	20%
	Dissatisfied	6	10%	6	10%
	Highly Dissatisfied	0	0%	0	0%
	Total	60	100%	60	100%

It could be seen from the table No 4,that the level of satisfaction perceived by the behaviour of doctors in ESI Hospital and Private Hospital. From the analysis concluded that the beneficiaries are more than 60% of peoples are satisfied in ESI Hospital and 70% of peoples satisfied in private hospitals. In the case of ESI Hospitals and Private Hospitals, there is nobody rating for Highly Dissatisfied or Dissatisfied.

Table 5: Quality of Communication in ESI Hospitals & Private hospitals

Variables	Scale	ESI		Private Hospitals	
		Frequency	Percentage	Frequency	Percentage
Quality of Communication	Highly Satisfied	6	10%	6	10%
	Satisfied	36	60%	36	60%
	Average	12	20%	18	30%
	Dissatisfied	6	10%	0	0%
	Highly Dissatisfied	0	0	0	0%
	Total	60	100%	60	100%

It is highlighted from the table No 5, there is a nominal difference between in Quality of Communication on ESI Hospitals and Private Hospitals. There are 10% of beneficiaries are dissatisfied in the quality of communication in ESI Hospitals and nobody rating for Highly Dissatisfied or Dissatisfied Private hospitals.

Table 6: Privacy of Consultation in ESI Hospitals and Private Hospitals

Variables	Scale	ESI		Private Hospitals	
		Frequency	Percentage	Frequency	Percentage
Privacy of Consultation	Highly Satisfied	0	0%	36	60%
	Satisfied	5	5%	18	30%
	Average	14	14%	6	10%
	Dissatisfied	35	35%	0	0%
	Highly Dissatisfied	6	6%	0	0%
	Total	60	100%	60	100%

To find out the difference between ESI Hospitals and Private Hospitals in the category of privacy of consultations in comparative analysis is shown the table No 6. This analysis is the most significant category. This table highlighted that the major problems lead to beneficiaries are opting private hospitals rather than ESI Hospitals. The privacy of the patient is the most important right of a patient. This analysis shows that 41% of patients are dissatisfied with the privacy of ESI Hospitals and nobody rating for Highly Dissatisfied or Dissatisfied Private hospitals.

Table 7: Spending Time with Doctor in ESI Hospitals & Private Hospitals

Variables	Scale	ESI		Private Hospitals	
		Frequency	Percentage	Frequency	Percentage
Spending Time with Doctor	Highly Satisfied	6	10%	6	10%
	Satisfied	31	51.7%	36	60%
	Average	17	28.3%	12	20%
	Dissatisfied	6	10%	6	10%
	Highly Dissatisfied	0	0%	0	0%
	Total	60	100%	60	100%

It is identified from the table No 7, there is no significant difference between ESI Hospitals and Private Hospital in the category of spending time. There are only 10% of respondents are rating in dissatisfied and highly satisfied in both ESI Hospitals and Private Hospitals. There are 52% of beneficiaries satisfied in ESI Hospital and 60% of patience satisfied in Private Hospitals.

Suggestions

The ESI is a social security scheme of Indian employees. The ESI is providing so many benefits for their beneficiaries and their dependents. According to the analysis of the study the ESI Hospital faces some drawbacks compare to private hospitals. The waiting time is a one of the major drawback of ESI hospital. The proper administration and management can improve these issues. We all are know time is very precious than money. They reducing waiting time and it help to increasing patient satisfaction.

The privacy is another negatively influenced the factor of this study. The confidentiality of a treatment is a right of a person. The confidentiality and privacy protect patient rights. The patient has right of keep his or her medical records and health information. The ESI is negatively affected privacy compare to private hospitals. The proper manual queue system or automatic queue system is help to reducing the effect of this factor.

Discussions and Conclusions

In the analysis reveal that Private Hospital is better than ESI Hospitals In some category. This study is mainly focused on the outpatient treatment on the basis of doctors' consultation. Waiting time for consultation, behaviour of doctor, quality of communication, privacy of consultation, spending time with doctors' those are the main variables to find the satisfaction of ESI Hospitals and Private Hospitals for in this study.

According to the first objective of the study the analysis shows that the private hospital is lead to more satisfaction in doctor consultation. The ESI Hospital is less satisfaction compare to Private Hospitals. This conclusion is made by the help of data analysis and interpretation of questionnaire.

The second objective of the study is related to factors affecting influence of satisfaction of doctor's consultation. The literature review is help to and finding relevant satisfaction variables. Waiting time for consultation, quality of communication, Behaviour of doctor, spending time with doctor and privacy of consultations are the basic factors of influencing satisfaction of patients.

According to the third objective of this studies finding, the privacy of consultation is the major drawback of ESI Hospitals. In the case of private hospitals, they provide more privacy for patients. Patient privacy is the most important factor of lead to patient satisfaction. The every patient is very conscious about the privacy of treatments and history of treatment. This is the major reason for ESI beneficiaries choose private hospitals rather than ESI hospital. If the ESI Hospital provides more privacy to patients the beneficiaries are more opting ESI Hospitals for the treatments.

In case of waiting time for consultation, the ESI beneficiaries are face lot of problems rather than private hospitals this is the another reason for the ESI beneficiaries choose private hospitals. The time consuming is a relevant factor of lead to patient satisfaction. If the proper administration and best queuing systems are helping to improve to reduce the waiting time for consultation it helps to increase the level of satisfaction and the beneficiaries are more opting ESI Hospitals for the treatments.

The Behaviour of doctor, quality of communication and spending time with doctors are face nominal problems lead to dissatisfaction of beneficiaries' compare to private hospitals. The proper management and administration team can help to improve these difficulties. The proper training helps to increase the efficiency of medical and non-medical staffs. These are the main suggestion and conclusion to this study. This study helps gain knowledge and finds out the problems and solution to the most important social security schemes in ESI.

Abstract

Climate and environmental challenges are a serious concern of our generation. Along with inequalities, the negative effects of environmental degradation are a barrier to a fair and modern economy as well as a sustainable future. The European Green Deal is an ambitious and serious strategy that the EU has taken on to reduce these negative effects as well as to ensure green convergence. In order to be politically feasible and socially acceptable, the European Green Deal's objectives have to respond to economic and social needs of the EU Member States, to eliminate greenhouse gas emissions, to improve social and economic conditions, as well as reduce social inequality throughout Europe's regions.
The main aim of this article is to intensify the debate in terms of addressing the relationship between inequalities and the Green Deal, as well as to suggest some improvement measures and to find some alternative solutions.

Keywords: Green Deal; inequalities; climate change;

Introduction

Climate and environmental challenges facing the world have become increasingly pressing, and we need to take urgent measures to combat environmental degradation and climate change. To meet these challenges, the European Commission is committed to making a significant contribution to mediating the issues by launching a new growth strategy, the European Green Deal. The implementation of this strategy marks the change of the paradigm of economic growth based on consumption, thus, the aim is to move to a sustainable economic growth, based on the efficient use of natural resources. The main objectives of the European Green Deal are: i) the elimination of greenhouse gases by 2050; ii) streamlining the use of resources and decoupling them from economic growth (eliminating the dependence of economic growth on the use of resources); iii) as well as the commitment to "leave no one behind", an objective that involves eliminating inequalities and creating a favorable framework for all EU citizens.

A fair transition from which everyone can benefit requires a well-developed strategy as well as a consistent budget for the necessary investments. Thus, the implementation budget is a significant one of about 1000 billion Euros, for the next 10 years. These transition funds depend on the authorities' ability to develop projects and how they will manage their implementation.

At its meeting on 17th-21st July 2020, the European Council agreed to allocate € 1 824.3 billion to the Multiannual Financial Framework and the Next Generation EU recovery instrument. Of this amount, 30% will go to climate change projects, in particular with the goal of eliminating greenhouse gases by 2050 (EU climate target for 2030) and the Paris Agreement.

The most important objective of the Green Deal refers to the decarbonization of the energy sector because over 75% of greenhouse gas emissions are produced by the use of energy in economic sectors. This is a matter of concern among member states, who point out that the lack of alternatives for carbon-intensive sectors or a too abrupt transition will lead to job losses and regional inequalities.

Cite this Article as: Tamara-Maria NAE and Narcisa- Alexandra PANIE "Inequalities in the European Green Deal context" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The effects of climate change are being felt unequally in the world . The areas in which we live influence the way we are affected by environmental degradation. Environmental degradation generally affects more disadvantaged and vulnerable people and households living in areas prone to drastic climate change or with limited access to environmental quality (green spaces, fresh air, fresh food), thus contributing to increasing poverty and inequality.

Inequality has been a constant concern in the climate change debate. From the perspective of responsibility for tackling climate change, there is inequity between countries because they are countries with a low carbon footprint, but from which significant indirect contributions can be sought that could deepen existing inequalities. Development gaps between countries or regions risk placing a much greater burden on certain categories of vulnerable citizens who cannot easily find alternatives or adapt to new changes due to geographical factors or specific robust skills, and conversion difficulties professional.

What is clear is that for less developed countries, such as Central and Eastern European countries, the European Green Deal must not be a choice between development and combating climate change, but this pact must connect the improvement of the economic and social situation with actions to fight against environmental degradation.

The purpose of this article is to generate debate on the link between the Green Deal and inequalities and how we can propose policy measures and recommendations to combine the objectives of a green economy with reducing inequalities.

Literature Review

The concept of climate change is not a new one, but it has recently become more widespread in the context of the European Green Deal. The risks to which the entire globe is exposed due to these changes are both on the health of the environment and the population, and on the economy. Thus, extreme climate change as well as calamities affect the economy on the one hand, by degrading crops and reducing trade, as well as the health and well-being of the population by reducing the quality of life. Excessive use of natural resources is also a major concern for Europe's sustainability, but also for the quality of life of future generations.

Not surprisingly, in terms of climate change, the most disadvantaged are low-income and vulnerable people with no or limited recovery capacity. There are numerous studies that have analyzed the negative effects of climate change on the economy and society. Climate change has been analyzed as a major concern for poverty reduction (World Bank, 2002; Skoufias 2012). Since poverty, analyzes have expanded rapidly in the field of inequality, and it has been analyzed and demonstrated that the link between climate change and inequality forms a vicious circle, so that existing economic and social inequalities contribute to the unequal distribution of environmental degradation then generating greater inequalities. (WESS, 2016; Islam et. Al, 2017).

Other studies such as (The Intergovernmental Panel on Climate Change, 2014) conclude that climate change “exacerbates inequalities”. The explanation is that in disadvantaged regions in terms of geographical location, as well as infrastructure, there is a high risk that a burden of climate change will further disadvantage people living in those regions. The study also shows that people in countries facing significant social inequalities are more affected by climate change.

With regard to the Green Deal objectives, there are concerns that some countries cannot easily cope with the transition period and that complementary policies are needed to deal not only with reducing the effects on the environment but also on the economy and society. “We must understand that ecological and social progress go hand in hand. We cannot end poverty and build a fairer society by letting the ecological crisis destroy our planet. However, we also cannot end the ecological crisis while high levels of poverty and inequality persist.” (Sassoli, 2020)

According to some authors (Pianta, Lucchese and Nascia 2020), the European Green Deal will generate an expansionary fiscal policy that will end the period of stagnation in Europe due to fiscal constraints. This new fiscal policy is needed to increase the demand and investment needed for sustainable production systems. If this does not happen and only give up old polluting production without increasing investment, current spending on environmental goods and services, there will be a reduction in jobs and incomes.

Green deal and the other EU's policies

The adoption of the European Green Deal is the European Union's responsible response to climate change that affects us all and, implicitly, our future. The consequences of climate change affect important issues such as public health, quality of life, and even life expectancy. Article 3 of the Lisbon Treaty states that “the Union shall establish an internal market. It works for the sustainable development of Europe, based on balanced economic growth and price stability, a highly competitive social market economy, which aims for full employment and social progress, as well as a level of high level of protection and improvement of the quality of the environment. " (Treaty of Lisbon) and that “In its relations with the rest of the international community, the Union affirms and promotes its values and interests and contributes to the protection of its citizens. It contributes to peace, security, the sustainable development of the planet, solidarity and mutual respect between people, free and fair trade, the eradication of poverty and the protection of human rights, and in particular the rights of the child, and the strict observance and development of international law, including compliance with the principles of the Charter of the United Nations. "(Treaty of Lisbon).

Thus, the sustainable development of Europe as well as the sustainable development of the planet includes three main components, the economic, the social and the environmental. The European Union is proposing an ambitious environmental policy plan and intends to place the Community in a position of global leadership in reducing greenhouse gas emissions. To achieve these results, the budget for the European Green Plan is significant, amounting to around € 1 trillion over the next 10 years. Negotiations on the EU's long-term budget for 2021-2027 have shown political support for this plan due to large sums allocated.

The European Green Deal is directly related to Cohesion Policy, in which investment in regional development will focus on two objectives. Specifically, the European Commission wants 65% -85% of European Regional Development Fund and Cohesion Fund funds to be focused on developing a smarter Europe and developing a greener Europe. We point out that the European Green Deal promotes the objective of cohesion policy, reducing the disparities between different regions and more disadvantaged regions, through the Mechanism for a Fair Transition. Thus, we want to move to a green economy but without this process creating gaps between regions and inequalities in society. Many regions that have industries that are based on processes with a high carbon dioxide emission factor that generate greenhouse gas emissions or whose workers are part of these fields could suffer heavy losses if they are not taken into account in defining measures. One initiative is the Fair Transition Mechanism, which will pay attention to the regions facing the greatest challenges and which will have 3 indicators on which to allocate funds: the extent of the challenge posed by the transition for regions with a dioxide emission factor; high carbon and greenhouse gas emissions; the social challenges posed, on the one hand, by the potential loss of jobs in industry, in the sector of oil shale mining, coal and lignite mining and peat production and, on the other hand, by the need for further retraining of workers to be able to find a new job; the level of economic development and investment capacity of the Member States. The identified regions will benefit from around € 30-50 billion between 2021 and 2027, for every € 1 invested through the Fair Transition Mechanism Fund Member States will contribute a minimum of € 1.5 and a maximum of € 3 from the European Development Fund and the European Social Fund Plus, to which will be added the national co-financing of cohesion policy.

Green Deal and inequalities

Climate change is negatively affecting the lives of each of us and for some it makes it even more difficult. The challenges that climate change offers us are as important as the problem of inequalities, both of which are manifested globally, and there is even a relationship between them. This implies the need for ambitious policies, both at EU and global level, because only through the active and serious involvement of both policy makers and citizens will we be able to develop a sustainable future. The European Green Deal is the EU's response to climate challenges, and involves tracing the current economy and society on a more sustainable and inclusive path.

One of the objectives of the European Green Deal is to reduce greenhouse gas emissions by at least 55% by 2030 compared to 1990 level, making Europe the first neutral continent of greenhouse gas emission in 2050. At the level of the European Union, Greenhouse gas emissions have been on a downward trend since 1990. Peak values are marked by either extreme climatic phenomena (1996 - very low winter temperatures that led to increased heat demand), or the adverse effects of the financial crisis (2009) that affected the plants generating strong greenhouse gas emissions. In 2018, the amount of greenhouse gas emissions has decreased considerably compared to 1990 and is constantly decreasing. (Fig.1)

Fig. 1: Greenhouse gas emissions (including international aviation, excluding land use, land use change, and forestry, EU-27, 1990–2018 (Index 1990 = 100)

Source: Eurostat

Among the EU countries, the highest reductions in greenhouse gas emissions from 1990 to 2018 were registered in Lithuania (-57.36%), Latvia (54.05%) and Romania (53.16%), and the countries with the highest level were Cyprus (53.81%), Spain (19.74%) and Portugal (18.90%).

Fig. 2 : Greenhouse gas emissions (difference 2018-1990)

Source: Eurostat

The relationship between inequalities and greenhouse gas emissions has been the subject of numerous specialized studies. Environment Kuznets Curve (EKC) hypothesis describes an inverted U-shaped relationship between economic development and environmental degradation. He asserts that environmental quality deteriorates as per capita income increases at the initial stage of development but improves after a certain threshold of per capita income (Magnani, 2000). Most studies are based on the relationship between income inequality and environmental quality**.**

Another theory about the relationship between inequalities and the environment concludes there is a difference between social classes on environmental pollution. (Boyce, 2007). The rich class pollutes the environment more because they consume more goods and they own polluting firms. Under Boyce's political economy model, the political class can avoid environmental laws that would bring them additional costs by influencing politicians. He demonstrates that the wealthy class can use their economic and political bargaining power to undermine policy makers' efforts on environmental protection. Scruggs (1998) launches a hypothesis that demonstrates that environment is a normal good, an increase in per

capita income could be associated with the same level of preference for environmental degradation. But, if we define environment as a superior good, an increase in income will determine a preference for a cleaner environment because the wealthy prefer a clean environment consequently they will promote strict measures.

Another area of action of the European Green Deal is agriculture and nature. Climate change is affecting agriculture, there are areas where due to rising temperatures the soil is desertifying or we have situations where crops have been destroyed by the increasingly present extreme phenomena. The most affected are the small producers for whom the income from agriculture is the only revenue in the family, many of them also having credits for the necessary equipment or materials. There were 10.5 milion farm in the EU in 2016, the majority of these classified as family farms (95.2). According to Eurostat, in 2016, a third of the EU farms are developed in Romania, followed by Poland, Italy and Spain. Although about 65% are farms with an area of less than 5 hectares, about 7% of farms with an area of 50 hectares or more have cultivated 68% of the EU's agricultural area. Many small farms are characterised by the fact that farm holders may struggle to make a living. A characteristic of very small farms is that they are often subsistence households. These small farms can play an important role in reducing the risk of rural poverty, providing additional income and food. Thus, climate change tends to aggravate income inequalities by affecting crops that leave farmers with no income and only expenses. Romania, the country that in 2016 had the most farms in the EU, was hit in 2020 by one of the strongest droughts that destroyed most of the cereal crops. This will lead to a decrease in supply and an increase in prices amid high demand, which will worsen the financial situation of vulnerable low-income people.

Another problem facing the European agricultural sector is the widespread use of pesticides that affect human health. Countries such as France and Spain have sales of more than 35 million kilograms of pesticides per year, according to Eurostat. The use of pesticides aims to keep the plant healthy, but at the same time produces negative effects, they infiltrate in the soil and water. In the long run, this may mean destroying soil biodiversity and making it impossible to use it in the future. At EU level, the number of organic farms is very low, as can be seen in the graph below, with an average of 8%. Austria, Sweden and Estonia have the highest results.

Fig. 3: Organic crop area (% of total utilised agricultural area)

Source: Eurostat

The objectives proposed by the European Green Pact are to reduce by 50% the pesticides used in agriculture by 2030, to increase the area of organic farms and to invest in research and development in agriculture to develop sustainable agriculture. The European Commission proposes that 40% of the budget allocated to the common agricultural policy should contribute to combating climate change and 30% of the Fisheries and Maritime Fund should contribute to climate goals.

Mobilizing the industrial sector for a green and circular economy is another objective of the European Green Deal. European industry continues to be highly dependent on newly extracted, marketed materials, which then end up in

landfills. According to the European Commission, in 2017 the world extraction of materials had tripled compared to 1970 and continues to have an upward trend. As can be seen in the figure below, the generation of waste is very high, which indicates a waste of resources. Romania, Sweden and Bulgaria have the highest amounts of waste. The storage of this waste, sometimes illegal, causes some areas where there are landfills to suffer numerous losses. From soil and river contamination to the release of pollutants into the atmosphere, landfills cause consequences that intensify regional inequalities.

Fig. 4 : Generation of waste- Mining and quarrying

Source: Eurostat

The solution would be to recycle and reuse materials in production processes. At this point, the situation at EU level on recycling can be seen in the figure below. We can see that countries that are at the top of the ranking at the level of waste, such as Romania or Bulgaria are at the bottom of the ranking in terms of waste recycling. The European Green Deal aims to stimulate a green economy, based on renewable resources and the reuse of materials and products. Consumers will also be encouraged to recycle more and give up buying single-use or limited-use products.

Fig. 5: Recycling rate of municipal waste

Source: Eurostat

Last but not least, the objectives and areas of action of the European Green Deal are designed to develop a sustainable growth model conducive to inclusion. The transition can affect many people and regions, leading to growing inequalities. Also, not all member state will have the same starting point, some will have to implement many or even more drastic measures and for others, who have adopted environmentally friendly measures for years, the transition will be smoother. It is important that people always be at the forefront of taking action, as well as managing the process to take into account

difficulties and prevent them. The challenges of climate change can be turned into a unique opportunity to transform the economy into a more environmentally friendly one, create new and better paid jobs, and improve the health of citizens and their lives daily.

Policy Recommendations

The implementation of the Green Deal has both beneficial effects for the environment and the population and challenges that are felt differently for European Union countries, so we propose a series of policy recommendations in order to achieve the most efficient objectives of this project, without creating new problems and without aggravating the existing ones.

- **Profound changes in technologies and production process.** There is a need to replace old and polluting production technologies with new and efficient ones, improved in terms of resources used. It is also necessary to transform the capacities and abilities of the population in order to be able to use and develop new production technologies.
- **Interconnection of environmental and industrial policies.** A common approach to environmental and industrial policy is closely linked to the fiscal, monetary, competition, trade, technology and labor and wage policies that need to be considered.
- **Ensuring social equity.** The participation of all citizens in the transition activities and the equal distribution of benefits is essential for the implementation of the Green Deal.
- **Identifying alternative solutions for the specificity of each region affected by the transition.** It is necessary to identify alternative solutions taking into account the industry specific to each region, identifying a single alternative solution without taking into account this aspect can increase the burden for certain groups of people.
- **Collective practices**. The government must ensure that all citizens are involved in combating climate action. It also aims to create a mix of appropriate policies to ensure that the achievement of ambitious climate change goals will not intensify economic and social problems but mediate them.
- **Public and private investments.** It is recommended to boost demand for private and public investment, current public spending on environmental goods and services, and exports and consumption. On the contrary, eliminating old polluting production would simply lead to a reduction in production, jobs and income, destroying the consensus for the Green Deal.

Concluding Remarks

In the current pandemic context, climate change policy can be seen as an opportunity for economic recovery, but the unequal effects of society as well as regions must be taken into account. Otherwise, the Green Deal will not be able to meet the inclusion target.

In terms of social inequalities, they pose risks both in the context of climate change and in the attempt to combat climate change. Thus, I think that it is absolutely necessary that inequality be at the heart of economic recovery policies as well as at the heart of Green Deal policies.

Regarding gas emissions, the evolution at EU level has not been uniform, with some countries managing to reduce gas emissions while others have increased them. This issue leads to climate change that affects agriculture and creates social and economic inequalities. As presented above, most farms in Europe are classified as family farms. Thus, the present increasingly of extreme phenomena destroy cultures and leave many families without income. Another major problem is the exess use u of pesticides and the low number of organic crops. At EU level only 8% of the total agricultural area used is organic. In addition, the European Green Deal also aims to increase recycling. In the EU, countries such as Romania and Bulgaria have the highest levels of waste generation. In terms of municipal waste recycling, Slovenia and Germany are the countries that recycle the most, while the EU average is around 45%.

Investment, both public and private, is the key to a successful transition for EU countries, but the management of the Green Deal depends on each country's absorption capacities and their ability to develop feasible projects that can be financed through the European Commission’s instruments.

Abstract

Paper presents results of research taken to define and analyze the cyberspace and cybersecurity with use of achievements of theory of systems and cybernetics. Introduced models of cyberspace and cybersecurity refer to them as complex systems that remain in relations and system dependencies, which enables them to carry out a common mission. Their functioning has been illustrated within models by separate elements (components). The structures of systems create appropriate functional and safety configurations. Which when properly designed can minimize the effects of cyber incidents and reduce the set of risk factors of the nature of cyber threats or cyber attacks.

Keywords: Cyberspace, Cybersecurity, Security Configuration, Functional Configuration, Modeling.

Introduction

The current challenges related to cyberspace threats that must be faced by each entity of action (e.g. the European Union, state, organization) and the general development of the situation in the world require constant commitment on the part of security specialists and continuous improvement of solutions in area of cyberspace and cybersecurity. The increasingly global scarcity of cybersecurity skills makes it essential to develop and implement new or improved cybersecurity models. Another issue is a need to develop competencies and raise awareness across all sectors of cybersecurity engineering. Creating trustworthy cyberspace is crucial to increasing its overall resilience.

Cyberspace has become a new security environment. Thusly the necessity to make numerous changes, both in the pragmatics, legal and organizational dimensions of the functioning of security systems in the world and in the approach to constructing various models of cybersecurity. In this context, it is particularly important to understand the dynamics of changes in this environment.

Progressive development of information technologies application in almost all areas of life, business and administration makes crucial to determine what cyberspace actually is. This step allows to take further considerations on cybersecurity, as an area of research. This area is widely explored since years, but literature review demonstrate that taking into consideration the perspective of systems theory and cybernetics in this field is not common approach among researchers. Nevertheless there could be found a few of recent research delivering valuable results with use of this approach like Alqurashi et al (2013), Anjaria et al (2017) and Silhavy (2020).

Generally the cyberspace can be treated as an entity that transforms certain external and internal factors into specific goods. The effectiveness of this process is essentially the product of proper control and circumstances. Control means the process of making decisions in various spheres, which often have a different time horizon. It is done on the basis of the information provided. Their important source are various types of system analyzes, most of which concern only certain selected spheres of cyberspace operation, rarely covering cyberspace as a whole.

Digital systems, as the basic elements of cyberspace, have become so complex that it is impossible to prevent all cyber attacks. This problem can be solved by ensuring rapid detection and response. These in turn is only possible if we have adequate models of cyberspace and cybersecurity. Meanwhile, cybersecurity has not yet been fully integrated into the into management systems of the entities of action (e.g. existing EU-wide crisis response coordination mechanisms, national cybersecurity systems, nor organization's security management systems). A tool

that can significantly support cybersecurity management is a comprehensive model of cyberspace and cybersecurity.

The system and control theory assumes the possibility of application an universal theoretical framework for various concepts in the field of security engineering. This may be an useful paradigm to order the discussion on cybersecurity, which allows to combine results of interdisciplinary research of various scientific disciplines. The system approach enables modeling of changes taking place both in the cyberspace and elements of its environment. Results of these changes or effects of interactions between previously mentioned elements might be unsatisfactory due to the adopted criterion. Therefore there is a need to introduce a mechanism to enable the control of the usability properties of cyberspace in such a way as to achieve the goal of the operating e.g. an acceptable level of security.

Presented paper is an attempt to present a general way of modeling cyberspace, which would allow to describe and study its functioning in terms of utility, security and risk assessment. System approach to description of cyberspace, have been treated by authors as a starting point allowing to elaborate proposal a cybersecurity model. This in turn will enable the measurement of the state or level of security of individual domain systems in cyberspace and will ensure the maintenance of an acceptable level of cyberspace security.

The necessary process of building and expanding the cybersecurity management system should take place as part of a dialogue between all cyberspace stakeholders, in which the cybersecurity service should play the role of a coordinator and catalyst of cooperation between interested parties.

Cyberspace Model

Cyberspace is a time-dependent set of interconnected information systems and people that interact with these systems like in research study by Sienkiewicz (2015) or in documents released by the Cabinet Office (2011). It is the entirety of connections between human activity and information communication technology. It is a virtual object, devoid of geographical parameters, immeasurable and unlimited. Its boundaries are determined by the level of the current development of information technology and the degree of communication network development of the world. In the system approach, cyberspace is treated as an open system (Fig. 1).

Fig. 1: Illustration of basic objects of the production system and their relations.

The openness of the system lies in the fact of exchange the information, energy or matter with the environment as presented in the book by Morgan (2005). A system approach to the analysis of cyberspace forces it to be treated as a compact structure with various inputs and outputs. Inside this structure there are smaller elements that are treated as systems or subsystems that enable the processing of inputs to outputs in accordance with the goals of cyberspace. The most important elements of cyberspace are the regulation (management) subsystem and the operational (execution, transformation) subsystem (Fig.1).

The regulation subsystem consists of the following elements: organizational structure, organization's values, goals and tasks, management subsystem. The literature in the field of cybernetics contains a very extensive discussion of the issues of regulation (control), distinguishing its three basic methods: compensation of deviations, compensation of disturbances, elimination of disturbances, like in book by Regulski (1974). Apart from the technical and technological subsystem, the elements of the operational (transformation, execution) system are also the social subsystem.

The essence of the exchange between cyberspace and the environment is to provide the environment with products, services, values and the current level of security (output factors) resulting from the activities of cyberspace (i.e. the result of transformation of input factors). In turn, the environment provides cyberspace, in addition to tangible and intangible resources (input factors), which allow it to continue its operations, also disruptions in the nature of cyber threats and cyber attacks.

Respecting the above, model of cyberspace in terms of systems theory has been stated as follows:

$$CS =< \mathbb{S}, \mathbb{R} \subseteq \mathbb{S} \times \mathbb{S}, \mathbb{E}, \mathbb{U}, \mathbb{IC} > \tag{1}$$

where:

$\mathbb{S}$ – is a set of cyberspace systems,
$\mathbb{R}$ – is a finite set of relations defined on the set $\mathbb{S}$,
$\mathbb{E}$ – is an cyberspace environment,
$\mathbb{U}$ – is a set of cyberspace usability features,
$\mathbb{IC}$ – is a set of cyberspace security indicators.

Set of cyberspace systems is given by following formula:

$$\mathbb{S} = \mathbb{S}^K \cup \mathbb{S}^I \cup \mathbb{S}^T \cup IoT \tag{2}$$

where:

$\mathbb{S}^K$ – is a set of computer systems,
$\mathbb{S}^I$ – is a set of information systems,
$\mathbb{S}^T$ – is a set of telecommunications networks,
IoT – Internet of Things – is a network of everyday objects equipped with hardware, software and sensors so that they can connect and exchange data via the Internet.

Set $\mathbb{R}$ of relations defined on the set $\mathbb{S}$ is given by following formula:

$$\mathbb{R} = \mathbb{R}^{SS} \cup \mathbb{R}^{SE} \tag{3}$$

where:

$\mathbb{R}^{SS} \subseteq \mathbb{S} \times \mathbb{S}$ – is a set of relationships between systems responsible for performing of specific actions,
$\mathbb{R}^{SE} \subseteq \mathbb{S} \times \mathbb{E}$ – is a set of relationships between systems and elements of the cyberspace environment.

The cyberspace environment consists of all internal and external factors as well as the input and output factors of cyberspace, what has been stated as follows:

$$\mathbb{E} = \mathbb{E}^{CW} \cup \mathbb{E}^{CZ} \cup \mathbb{E}^{WE} \cup \mathbb{E}^{WY} \tag{4}$$

where:

$\mathbb{E}^{CW}$ – is a set of internal factors,
$\mathbb{E}^{CZ}$ – is a set of external factors,
$\mathbb{E}^{WE}$ – is a set of input factors,
$\mathbb{E}^{WY}$ – is a set of output factors.

Set $\mathbb{U}$ of cyberspace usability features is given by following formula:

$$\mathbb{U} = \mathbb{U}^{CF} \cup \mathbb{E}^{CR} \cup \mathbb{E}^{CS} \cup \mathbb{E}^{CE} \cup \mathbb{E}^{CN} \cup \mathbb{E}^{CB} \tag{5}$$

where:

$\mathbb{U}^{CF}$ – is a set of features related to the attribute of cyberspace functionality,
$\mathbb{U}^{CR}$ – is a set of features related to the attribute of cyberspace operational rationality,
$\mathbb{U}^{CS}$ – is a set of features related to the attribute of cyberspace efficiency,
$\mathbb{U}^{CE}$ – is a set of features related to the attribute of cyberspace operational effectiveness,
$\mathbb{U}^{CN}$ – is a set of features related to the attribute of cyberspace operational reliability,
$\mathbb{U}^{CB}$ – is a set of features related to the attribute of cyberspace security.

Set $\mathbb{IC}$ of cyberspace security indicators has been stated as follows:

$$\mathbb{IC} = \mathbb{IC}^1 \cup \mathbb{IC}^2 \cup, \dots, \cup \mathbb{IC}^s \cup, \dots \cup \mathbb{IC}^{\overline{\mathbb{S}}}, \tag{6}$$

where:

$\mathbb{U}^s$ – is a set of security indicators related to the s-th cyberspace system,
$\overline{\mathbb{S}}$ – is the number of distinguished systems in cyberspace.

Set $\mathbb{U}^s$ of security indicators related to the s-th cyberspace system is defined by following formula:

$$\mathbb{U}^s = \{b_d^s : d = \overline{1, D^s}\} \tag{7}$$

where b_d^s is an d-th security indicator related to the s-th cyberspace system.
The main goal of modeling cyberspace is to prepare such operating procedures that will allow for optimal management of it or its elements, in the sense of the adopted usability indicator which is the criterion function.

Cybersecurity Model

In ISO/IEC 27032 cybersecurity or cyberspace security is defined as the protection of privacy, integrity, and accessibility of data information in the cyberspace. But actually cybersecurity is wider concept, which refer to different domains of security i.e. Communications Security, Operations Security, Information Security, Physical Security, Public/National Security.

While considering the protection of cyberspace key resources we assumed that it should be carried out using the Cyberspace Security Management System (CSMS). From a system theory perspective, this subsystem is defined as a coherent, hierarchical organization (structure) aimed to maintain the required level of security for all systems included in cyberspace as mentioned by Mrówka (2015). In the structure of cyberspace, the CSMS takes a supporting role against the priority needs and requirements of cyberspace. Formally it can be stated as with following formula:

$$CSMS = \langle \mathrm{O}_{CSMS}, O_{CSMS} \times O_{CSMS} \rangle = \langle O_{CSMS}, \{R_{CSMS}\} \rangle \tag{8}$$

where:

O_{CSMS} – is a set of elements of the organizational and functional structure of the CSMS,
R_{CSMS} – is a set of system relationships and protection tasks implemented for the maintain required level of cyberspace security.

For the purposes of building a cybersecurity model, the CSMS will be represented in the cybernetic system convention, so written as a Cartesian product of: inputs (security system needs), outputs (CSMS capabilities) and decisions:

$$CSMS \subseteq \{P \times D_{CSMS} \times M_{CSMS}\} \xrightarrow{P_{CSMS}(t)} F_{CSMS} \tag{9}$$

where:

P – is a cyberspace needs in terms of security and protection of its sensitive resources (e.g. cyberspace security requirements specification),
D_{CSMS} – are decisions controlling cyberspace security management processes,
M_{CSMS} – are execution capabilities of the cyberspace security management system,
$P_{CSMS}(t)$ – is a function of cyberspace security management,
F_{CSMS} – is an objective function (effectiveness, usability) of cyberspace security management.

Wherein functions $P_{CSMS}(t)$ and F_{CSMS} are given by following formulas:

$$P_{CSMS}(t) : P \times D_{CSMS} \longrightarrow M_{CSMS} \tag{10}$$

$$F_{CSMS} : D_{CSMS} \times M_{CSMS} \longrightarrow R^+ \tag{11}$$

where: R^+ is a set of real numbers (indicator of quality or usefulness of cyberspace security management system).
The CSMS, as one of the cyberspace support systems, is responsible for maintaining and supporting the functioning of basic cyberspace systems. In the functional sense main task of CSMS is the preparation and maintenance of the required cyberspace security potential ($\Phi_O(t)$. In cyberspace security structures it is transformed into operational potential ($\Phi(\mathrm{t})$). The balance equation of the operational potential $\Phi(\mathrm{t})$ w in terms of cyberspace security can be written as below:

$$\Phi(\mathrm{t}) = \Phi_P - \Phi_Z(t) + \Phi_O(t), \tag{12}$$

where:

$\Phi(\mathrm{t})$ – is current operational potential at time t,
Φ_P – is initial operational potential at time t,
$\Phi_Z(t)$ – is spent cyberspace security potential,
$\Phi_O(t)$ – is recreated potential of cyberspace security.

As can be seen from equation (12), the operational potential $\Phi(\mathrm{t})$ is a function of, on the one hand, the intensity of destruction of the cyberspace security potential $\Phi_Z(t)$, on the other hand, a function of the intensity of its reconstruction. Its third independent variable (relatively constant) is the initial value of the operational potential Φ_P, so we can give it as follows:

$$\Phi(\mathrm{t}) = g(\Phi_P.\Phi_Z(t), \Phi_O(t)) \tag{13}$$

The cybersecurity management process is a continuous process and must be conducted with appropriate intensity, reliability, efficiency and with rationally justified material (O_M),, time (O_T) and financial (O_F) expenditures.

The conditions and needs pointed above impose certain requirements and restrictions on the CSMS, which must be met often while critical conditions occurs (e.g. during crisis situations). The cybersecurity management process (PR_{CSMS}) can be formally defined as the transformation of cyberspace potential ($\Phi_O(t)$) into operational potential ($\Phi(\mathrm{t})$), the highest form of which is the cyberspace security potential ($\mathrm{A}(\mathrm{t})$) understood as for specific tasks:

$$(PR_{CSMS}|O_M, O_T, O_F) : \Phi_O(t) \longrightarrow \Phi(\mathrm{t}) \longrightarrow \mathrm{A}(\mathrm{t}) \tag{14}$$

The CSMS is a dynamic system that must keep up with the rapidly changing needs of cyberspace systems, according to the actual geopolitical situation. The rational shaping of the organizational and functional structure and its operating procedures is a particularly complex and responsible task. Therefore, its development and improvement takes place through both theoretical and practical modeling. Simulation modeling and specialized tool software turn out to be particularly useful in this respect.

The cybersecurity models are only a certain approximation of a specific reality and illustrate only some aspects of the general structure of the real cyberspace security system. Successively developed and increasingly closer to reality models contribute a closer knowledge of the actual state of affairs and to attempts to improve this state and improve functions and processes.

One such model is the cybersecurity model. It is a formal model given in the form of logical-mathematical rules with the use of symbolic expressions, functions and formal structures. According to the general assumptions of system analysis and the sciences of systems theory and cybernetics, the Cybersecurity Model (CM) has been stated as follows:

$$MM_{CM} = \langle PD_{CM}, PC_{CM}, C_{CM,} \mathrm{B}_{CM}, \{D_{CM}, R_{CM}\}, ZZ_{CM}, \boldsymbol{Q_{CM}} \rangle \tag{15}$$

where:

PD_{CM} – are an entities of action, which are management bodies and functional persons responsible for the efficiency, reliability and safety of objects, domain systems, devices and installations included in cyberspace,
PC_{CM} – is a matter of action, which includes: objects, systems, devices and installations in relation to which the required level of security must be maintained,
$C_{CM,}$ – is the goal of the cybersecurity management system,
B_{CM} – is the cybersecurity policy for cyberspace,
D_{CM} – is the domain of cybersecurity management system,
R_{CM} – are relationships in the cybersecurity management system,
ZZ_{CM} – are rules of operation of the cybersecurity management system,
Q_{CM} – control subsystem regulating the usability properties of cyberspace and cybersecurity configurations.

Set PD_{CM} of entities of action could be decomposed as follows:

$$PD_{CM} = PD_{CM}^{OK} \cup PD_{CM}^{WŁ} \cup PD_{CM}^{SB} \tag{16}$$

where:

PD_{CM}^{OK} – is a set of management bodies responsible for the efficiency and reliability of cyberspace,
$PD_{CM}^{WŁ}$ – is a set of owners of domain systems, objects, devices and installations in cyberspace,
PD_{CM}^{SB} – is a set of decision-maker appointed within the structure of the cybersecurity staff.

In relation to individual elements or systems of cyberspace and the possibility of adjustment the current level of their security, the matter of action is a set of $e_j \in \mathbb{S}$ elements. The desired state of such elements can be determined by the decision-makers (authorized cybersecurity staff). The elements of the set $\mathbb{S}$ (Fig. 1) can be i.e.:

- domain systems of cyberspace,

- telecommunications networks,
- key business processes,
- information processing processes,
- information resources collected or processed within domain systems,
- software.

The main goal of the CSMS is to minimize cyber threats and maximize the security level of cyberspace domain systems. Its mission (goal) can be considered on several levels (e.g. strategic, tactical and operational).
The operational goal is the implementation of dynamic cybersecurity management processes in the critical infrastructure of cyberspace in a three-dimensional space including: cyber threats or cyber attacks, space and time. It is a transformation of cybersecurity management processes into schedules of operational protective activities in relation to cyber threats:

$$C_{CM}^{O} : \ \Phi_{CM} \longrightarrow H_{CM} \subseteq X \times Y \times T \tag{17}$$

where:

C_{CM}^{O} – is the operational goal of cybersecurity management system,
Φ_{CM} – is the operational potential of a cybersecurity management system,
H_{CM} – are a cybersecurity management process schedules
$X \times Y \times T$ – is the cybersecurity management space.

A cybersecurity policy is a document containing the assumptions and requirements of a given cyberspace in terms of security of its critical elements. It is a key element of the protection of cyberspace domain systems without which the use of even the most advanced technical, software or organizational security is not able to ensure a sufficient level of security of cyberspace.

The set of cybersecurity policy requirements for the system $S \in \mathbb{S}$ is a finite and countable set given as follows:

$$W_S = \{w_S^j : j = \overline{1, J^s}\} \tag{18}$$

where J^S is the number of cybersecurity policy requirements for the s-th cyberspace system.

For each of the requirements $w_S^j \in W_S$, we define the priority of the requirement in relation to a given domain system using the number $p_S^j \in \{0, \dots, 5\}$, where: 0 - means that the requirement has lowest importance to the $S \in \mathbb{S}$, system, 5 - means that the requirement has highest importance to the $S \in \mathbb{S}$, system.

The concept of the domain of cybersecurity management system D_{CM} will be considered in several aspects, according to various classification criteria. Most generally, the domain of D_{CM} model is a set of elements that a given system consists, which are possible to distinguish with respect of the adopted rules of topological division. Due to the dynamic and interactive nature of the analyzed system, the model domain was divided into two classes relating to the external and internal environment. The external system environment D_{CM}^{Z} includes all factors and external elements of the economic, social, political and military environment that affect the implementation of the cybersecurity management process. Internal environment D_{CM}^{W} of the cybersecurity management system, there are all factors and elements that make up the internal organizational and functional structure of the cybersecurity management system. For organizational and technical reasons, the separated internal elements operate in specific organizational and functional structures that can be identified with autonomous cyberspace systems.

One of the basic determinants of the cybersecurity management system is the set of $\boldsymbol{R_{CM}}$ relationships which define the relationships and dependencies between cyberspace objects, systems, devices and services. Due to the complexity of the cybersecurity management system and the very extensive scope of the $\boldsymbol{D_{CM}}$ domain mean that the set of relationships and connections between its elements and the environment is also complex and intricate. Relationships in the cybersecurity management system can be divided into two main groups as follows:

$$R_{CM} = \{R_{CM}^{S}, R_{CM}^{I}\} \tag{19}$$

where:

R_{CM}^{S} – is a set of system relationships including internal and external dependencies,
R_{CM}^{I} – is a set of cybersecurity management relationships.

The control subsystem for the usability properties of cyberspace and cybersecurity configurations will be formally defined by following expression:

$$Q_{CM} = \langle\, PM_{CM}, \Delta_{CM}, KF_{CM} \xrightarrow{\delta \in \Delta_{CM}} (KB_{CM} | L_{CM}), F_{CM}, S_{CM} \rangle \tag{20}$$

where:

PM_{CM} – is a decision subject,
Δ_{CM} – is a set of control decisions or directives,
KF_{CM} – is a set of cyberspace functional configurations,
KB_{CM} – is a set of cyberspace security configurations,
L_{CM} – is a set of cyberspace protection constraints,
F_{CM} – is a general functional reconfiguration function for cyberspace,
S_{CM} – is a set of cyberspace protection scenarios.

The subject of decision-making is a set of PM_{CM} functional persons who are members of the security staff of individual domain systems of cyberspace, playing various roles in the cybersecurity management process and having the right to make steering decisions.

The set of control decisions Δ_{CM} could be decomposed as follows:

$$\Delta_{CM} = \Delta_{CM}^{ZW} \cup \Delta_{CM}^{WU} \cup \Delta_{CM}^{AB} \tag{21}$$

where:

Δ_{CM}^{ZW} – is a set of control decisions for sensitive resources,
Δ_{CM}^{WU} – is a set of control decisions for establish usability properties of cyberspace,
Δ_{CM}^{AB} – is a set of control decisions for establish level of security attributes properties of sensitive resources.

The functional cyberspace configuration $KF^{k,l} \in KF_{CM}$ is given as follows:

$$KF^{k,l} = \langle Z^{k,l}, O^{k}, ZT^{l} \rangle \tag{22}$$

where:

$Z^{k,l}$ – is a set of tasks (activities or functions) that can be performed in a specific cyberspace with a specific functional configuration,
O^{k} – is a set of resources involved in the execution of tasks from set $Z^{k,l}$,
ZT^{l} – a set of technically efficient hardware and software resources used to appoint a kl-th functional configuration.

The cyberspace security configuration $KB^{m,n} \in KB_{CM}$ is given as follows:

$$KB^{m,n} = \langle ZW^{m,n}, O^{m}, MB^{n} \rangle \tag{23}$$

where:

$ZW^{m,n}$ – is a set of sensitive resources secured by kl-th security configuration;
O^{m} – a set of cybersecurity staff involved in ensuring the security of sensitive resources from a set $ZW^{m,n}$,
MB^{n} – a set of security mechanisms (technical or organizational) that make up the kl-th security configuration.

The cognizance of the security configuration $KB^{m,n}$ makes it possible to assign to each set $ZW^{m,n}$, a corresponding set of O^{m}., with a security mechanisms defined by set of MB^{n}. The cyberspace security configuration $KB^{m,n}$ is realized if and only if the set $ZW^{m,n}$, with certain elements of the set MB^{n}, can be assigned such a set O^{m} that will ensure the maintenance of the required security level of a set of sensitive resources $ZW^{m,n}$. Assuming the above, a result set $ZW^{m,n}$, for a given the set MB^{n}, is related to the set $ZW^{m,n}$, i.e. $ZW^{m,n} \times KB^{m,n} \times O^{m}$. Thus, we can consider the cyberspace security configuration (23) as an analog of the transformation system described in terms of theory of Mesarovic (1976), in which the inputs are resources from the set $ZW^{m,n}$ and outputs are elements from the set O^{m}.

The subsets of $ZW^{m,n} \subseteq ZW_{CM}$ constitute sensitive cyberspace resources and relate to the basic material and non-material categories used by cyberspace. The key sensitive resources are IT systems and telecommunications

networks. They constitute a kind of operational media that are the essence of cyberspace protection processes in the dynamics of operational activities. Effective protection of cyberspace systems requires the effective use of both tangible and intangible resources to prevent crisis situations and prepare for adverse events (e.g. cyber attacks or cyber threats, reacting during the destruction or disruption of individual domain systems), as well as when restoring cyberspace to operation. All these activities lead to the cybersecurity management system becoming ready and launch operational processes to protect the key elements for assure required level of the cybersecurity:

$$ZW_{CM} \times MB_{CM} \longrightarrow PP_{CM} \tag{24}$$

where:

ZW_{CM} – is a set of sensitive resources of cyberspace,
MB_{CM} – is a set of technical and organizational security means,
PP_{CM} – is a set of protection processes that guarantee the implementation of tasks in the field of cybersecurity.

Set PP_{CM} of protection processes could be decomposed as follows:

$$PP_{CM} \subset \{PP_{CM}^{A}, PP_{CM}^{Z}, PP_{CM}^{ZZ}, PP_{CM}^{OD}\} \tag{25}$$

where:

PP_{CM}^{A} – are processes of preparing cyberspace for cyber attacks,
PP_{CM}^{Z} – are processes of preparing cyberspace for cyber threats,
PP_{CM}^{ZZ} – are processes of preventing the disruption of critical elements of cyberspace,
PP_{CM}^{OD} – are processes of cyberspace restoration.

The implementation of cyberspace protection processes requires the fulfillment of a number of necessary and sufficient conditions relating to the internal and external environment of the cybersecurity management system. The set L_{CM} of system constraints and conditions can be decomposed as follows:

$$L_{CM} \subset \{L_{CM}^{S}, L_{CM}^{Z}, L_{CM}^{W}\} \tag{26}$$

where:

L_{CM} – is a set of cyberspace protection restrictions,
L_{CM}^{S} – is a set of system constraints,
L_{CM}^{Z} – is a set of constraints generated by the external environment,
L_{CM}^{W} – is a set of constraints generated by the internal environment.

The scope of the functional reconfiguration (F_{CM}) of the cyberspace security management system includes the following elements:

$$F_{CM} \subset \{F_{CM}^{E}, F_{CM}^{N}, F_{CM}^{S} | L_{CM}^{S}, L_{CM}^{Z}, L_{CM}^{W}\} \tag{27}$$

where:

F_{CM}^{E} – is function of effectiveness,
F_{CM}^{N} – is function of reliability,
F_{CM}^{S} – is function of security.

In order to create the possibility of equalize the loss of an acceptable level of cyberspace security, it is required to define, at the stage of designing cyberspace, a set of permissible control decisions (directives), with the help of which the cybersecurity management staff would be able to determine such current properties of the functional configuration and security configuration whose enable or ensure the achievement of the required cybersecurity state as a research study by Hoffmann and Stanik (2017).

Family of sets for acceptable safety configurations is given as follows:

$$\mathbb{KB} = \left\{KB_{dop}^{v}, v = \overline{1, V}\right\} \tag{28}$$

where V is the number of distinguished types of crisis or emergency situations in cyberspace.

The transition from the state "loss of the required security state" to the state "acceptable level of cybersecurity" can be described by the following projection:

$$F_{CM} : \mathbb{KB} \longrightarrow \mathbb{KB} \tag{29}$$

given as:

$$F_{CM}\left(\mathbb{K}B_{dop}^{w}\right) = \mathbb{K}B_{dop}^{v}, \;\; w, v \in V, w \neq v \tag{30}$$

where:

$\mathbb{K}B_{dop}^{w}$ – is a set of a set of acceptable security configurations before the occurrence of a crisis or emergency situation with the number $v \in V$,

$\mathbb{K}B_{dop}^{v}$ – is a set of a set of acceptable security configurations after the occurrence of a crisis or emergency situation with the number $v \in V$.

F_{CM} is determined at the stage of designing cyberspace so that it provides the desired features or usability properties of cyberspace during its operation.

Conclusions

The main goal of modeling cyberspace and cybersecurity is to enable the construction of an effective cybersecurity management system and the preparation of such steering decisions (directives), operating procedures, which will allow for the optimal management (control) of cybersecurity, in the sense of the adopted security criterion. In practical terms, optimal decisions consist in determining detailed plans and procedures for protecting cyberspace systems in relation to identified cyber threats and possible occurrence of cyber attacks, while meeting the actual system constraints and the current boundary conditions. As a result of forecasting the state of cyber threats and assessing the level of cybersecurity, decisions are made with regard to the course of operational activities based on the established function of the security criterion and a wide spectrum of various conditions and limitations. The physical manifestation of these decisions will be e.g. detailed plans for the protection of domain-specific cyberspace systems which take form of cyberspace protection scenarios.

The views on the essence of cyberspace and cybersecurity presented in this article are the result of certain arbitrary assumptions and subjective choices, hence they are necessarily incomplete in the sense of exhausting the topic of research on cyberspace and cybersecurity models. The most risky question remains open, namely about the future of cyberspace and the information society that is realized in it. Considering the growing dynamics of changes in the sphere of ICT solutions (technosphere), infosphere (explosion of information, but also information smog), as well as in the socio-sphere (creation and development of social media), it should be assumed that the future of cyberspace and cybersecurity will probably be different than we currently imagine. Undoubtedly, phase of development of contemporary civilization, or rather the current and future phase (in the sense of predictable trends or megatrends), can be referred to as a developing information civilization as mentioned by Sienkiewicz (2015). Its development brings with it numerous benefits as well as new unknown threats related to cyberspace. Therefore, it is important to constantly conduct research in the area of cybersecurity and search for answers to emerging questions regarding effective management and ensuring the required level of security. In searching for answers to these questions, models undoubtedly play an important role, allowing for research on large systems, including cyberspace. Models of cyberspace and cybersecurity introduced in this paper refer to them as a complex systems that remain in relations and system dependencies, which enables them to carry out a common mission. Their functioning has been illustrated within models by separate elements (components). The structures of systems create appropriate functional and safety configurations. Which when properly designed can minimize the effects of cyber incidents and reduce the set of risk factors of the nature of cyber threats or cyber attacks.

Effective counteracting of identified cyber threats and cyber attacks requires building an effective cybersecurity management system, the key elements of which are appropriately selected functional and cyberspace security configurations. Generated security configurations should ensure an appropriate level or state of cyberspace security, accepted by all cyberspace entities of action. Experience shows that the cybersecurity management system requires the construction of an adequate cybersecurity model, a clear division of competences of cybersecurity staff and their absolute cooperation. In addition, building an effective cybersecurity management system is a long-term process that requires a lot of work and large financial resources. The models presented in this study may prove useful at the

stage of designing this system and testing its properties (e.g. by simulation), including effectiveness, operating costs, etc.

Abstract

The central link in ensuring economic security in the education system is the economic security of an educational organization. The economic security of an educational organization depends on a large number of factors of a very different nature, duration and scale, which determines its essence. Three groups of factors of economic security of an educational organization have been identified. As indicators of the degree of risk, it is advisable to use risk coefficients showing the likelihood of unfavorable outcomes when the goal of a certain level is achieved by one of the interested parties. Special types of risks for education are presented. The work highlights two aspects of information security: protection from the negative impact of the influencing information environment and the provision of a basis for positive socialization and individualization of the teacher in the context of achieving a high level of education quality.

Keywords: Digital Educational Environment, Economic Security, Information Security, Innovative Economy.

In modern economic literature, much attention is paid to both theoretical and practical security issues. Proceeding from a common understanding of security (at any level) as protection from external and internal threats, relying on the research of Russian economists O.V. Komarov, Yu.Yu. Velichko, N.V. Zhakhov, N.V. Sirotkina, V.Krivoshlykov. FROM. and other economic security of the country means, including the rhythmic functioning of all spheres of public life and national economy (industry, energy, finance, education, health care, etc.) [1-9].

The central link in ensuring economic security in the education system is the economic security of an educational organization. The economic security of an educational organization depends on a large number of factors of a very different nature, duration and scale, which determines its essence.

It should be noted that modern legislation does not contain specific norms aimed at ensuring the security of the digital educational environment. Nevertheless, it should be noted that paragraph 27 of the Doctrine of information security of the Russian Federation, approved by the Decree of the President of the Russian Federation of 05.12.2016 No. 646 [10] (hereinafter the Doctrine), proclaims the main directions of ensuring information security in the field of science, technology and education:

- achieving the competitiveness of Russian information technologies and the development of scientific and technical potential in the field of information security;
- creation and implementation of information technologies, initially resistant to various types of impact;
- conducting scientific research and carrying out experimental developments in order to create promising information technologies and information security means;
- development of human resources in the field of information security and the use of information technology [11];

- ensuring the protection of citizens from information threats, including through the formation of a culture of personal information security.

Thus, within the framework of the implementation of the goals proclaimed in the Doctrine, it is necessary to develop and adopt a separate regulatory legal act that will provide a legal basis for the security of the digital educational environment in order to exclude unauthorized entry into educational information resources of “harmful” information that can have a negative impact on students.

It is advisable to present the system of factors of economic security of an educational organization as follows:

The first group of factors is associated with resource provision: personnel, financial, material. Since all economic resources receive a monetary value, this group of factors is associated with the financial condition of the organization.

The second group of factors is associated with the economic security of the person involved in the educational process. For educational organizations, there is an urgent need to take into account this system of factors, which is due to the large number of individuals participating in educational activities. Information security, legal security, life safety, etc. are intertwined in educational activities.

The third group of factors is associated with the adoption of management decisions in the field of economic security for a given educational organization. This aspect must be introduced due to the fact that, ultimately, both resource provision and the economic security of an individual depend on what management decisions in the field of economic security are made in a given organization.

The level of economic security of an educational organization depends not only on the level of internal factors, but also on the state of the education economy in the country as a whole.

In the course of their educational activities, educational organizations are faced with a set of different types of risk, which differ from each other in the place and time of occurrence, and are interconnected by the fact that a change in one type of risk can cause a change in most of the rest. Therefore, it is important not only to identify the risks of educational activities, but also to systematize, analyze them, determine the interdependence among themselves and the degree of influence on the achievement of the main goal of the educational organization - the provision of high-quality educational services.

As indicators of the degree of risk, it is advisable to use risk ratios showing the probability of unfavorable outcomes when the goal of a certain level of one of the interested parties is achieved. The education sector is characterized by special types of risks (Figure 1).

One of the ways to solve information security problems in modern educational organizations is seen in the formation of a safe personal information space.

The modern information system in the field of education is a complex system consisting of a large number of components of varying degrees of autonomy, which are interconnected and exchange data.

Figure 1: Risks specific to the education sector

Almost every component can be damaged or damaged. It is advisable to divide the components of an automated information system in the field of education into the following groups:

- hardware - computers and their components (processors, monitors, terminals, peripheral devices - disk drives, printers, controllers, cables, communication lines, etc.);
- software - purchased programs, source, object, load modules; operating systems and system programs (compilers, linkers, etc.), utilities, diagnostic programs, etc .;
- data stored temporarily and permanently, on magnetic media, printed, archives, system logs, etc .;
- personnel - service personnel and users.

Dangerous impacts on a computer information system can be divided into accidental and intentional. Information

is exposed to various random influences at all stages of the life cycle of the system.
The reasons for accidental impacts during operation can be:

- emergency situations due to natural disasters and power outages;
- hardware failures and failures;
- bugs in software;
- mistakes in staff work;
- interference in communication lines due to environmental influences.

Intentional actions are deliberate actions of the offender. An employee, visitor, competitor, mercenary can act as an offender. The actions of the offender can be caused by different motives:

- employee's dissatisfaction with his career;
- a bribe;
- curiosity;
- competition;
- the desire to assert itself at any cost.

The most widespread and diverse type of computer violations is unauthorized access (UA). NSD uses any error in the protection system and is possible with an irrational choice of protection means, their incorrect installation and configuration.

The researchers of this issue refer the following to the factors of the information and educational environment that can become dangers of information security of schoolchildren:

- availability and unlimited amount of information coming to the child;
- the presence in the information environment of means of manipulating consciousness, affecting the mental and physiological systems of a person;
- the presence in the information content of specific elements that purposefully change the psychophysiological state of children and adolescents.

Information security in an educational institution in modern science is defined as a system of mandatory contexts of the social situation of development. In order to determine the level of information security, due attention should be paid to fixing the levels of cognitive and personal development of the student, which are a determining factor in assessing the ability to withstand the unfavorable components of the social situation of development in the context of information security.

Thus, two aspects of information security are distinguished: protection from the negative impact of the influencing information environment and the provision of the basis for positive socialization and individualization of the teacher in the context of achieving a high level of education quality (Figure 2).

Figure 2: Information security structure

A safe information educational environment of each institution should be based on the integration of information and

communication technologies into the methodological aspect of pedagogical influence, which determines the need for the formation of new technological and information levels of all processes accompanying this activity. One of the ways is the formation of positive educational content in the educational process, which serves as the basis for a high degree of interest of students, interactivity of teaching, and its differentiation.

Thus, to ensure the safety of the digital educational environment, it is necessary to conduct regular interdisciplinary scientific and scientific-organizational events aimed at identifying the features of the impact of ICT on the physical condition of children and adolescents; to develop methodological approaches to the use of digital technologies in the educational process; create safe conditions for visual work with modern digital equipment (interactive panels, tablets); develop modern hygienic regulations to ensure the hygienic safety of digital education.

Abstract

In this paper we investigated some possible common influences behind the synchronicity of financial cycles in Romania, Hungary, Poland and Czech Republic. We tried to see whether the common movements in these EEMS appear under the influence of the global financial cycle measured in terms of quantities – through capital flows –, risks premiums and global investor risk aversion. The results showed that the high co-movement in yields, equity prices, house prices and credit is highly associated with global capital flows and to a somewhat lesser degree with risk premiums (represented in our analysis by the CDS) and the global investor sentiment or risk aversion (measured by the VIX index) – measure traditionally correlated with the global financial cycle.

Keywords: Financial Cycle; Global Financial Cycle; Capital Flows, Factor Analysis, Comovement.

Introduction

Domestic financial cycles have become increasingly synchronized over the last decades, making way for a stream of literature that investigates the common movement of financial cycles and their connection with the global financial cycle (a notion popularized by Rey, 2015). The literature on the subject considers that the effects of the global financial cycle, more intense and more visible lately, largely impact domestic financial cycles.

In this paper we considered the variables most commonly used for the study of financial cycles (bond yields, equity prices, house prices and credit data) in 4 European emerging markets, Romania, Poland, Czech Republic and Hungary, and we analyzed their common movement with the goal of identifying the importance that the global financial cycle (measured in quantity terms as in Borio, 2019, Habib and Venditti, 2019), investors global risk aversion (measured by the VIX index), and risk premium (measured by the CDS – credit default swap) have in their development. We found very high cross-country synchronization among all variables but especially between equity prices and bond yields. Consequently, we built common cycles for the 4 countries for all our variables. We haven't built one unique measure of the financial cycle in the 4 economies because we wanted to see the manner in which each of the financial indicators responds to the global financial cycle. Our findings suggest that the highest impact in the evolution of the common movement in the domestic financial cycles comes form the capital flow measure of the global financial cycle followed by the risk premium (especially for equity prices) and lastly from the VIX. The conclusion that the VIX influence seems to be somewhat smaller is not surprising, as the economic literature on financial cycles argues that its high correlation with the asset measure of the financial cycle has somewhat weakened recently (Borio, 2019).

Our study comes to enrich the scarce literature on financial cycles for the emerging economies by evaluating the importance of global factors in the common movement of the domestic financial cycles. Studies on synchronicity and co-movement with the global financial cycle cover mainly advanced economies for which the data sample is generous. The short data span available for emerging economies is both a limitation and a challenge as we tried to extract as much information as possible from the available data.

The paper is structured as follows: the first part reviews the literature on the subject, the second part presents the data and methodology and the last part contains the results of our analyses. The paper ends with concluding remarks.

A Case Study on Romania and 3 Other EEMS" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Literature Review

Global financial cycles have recently become the subject of numerous research papers. Starting with Rey (2015) – who described the global cycles in asset prices, capital flows and credit growth and identified the monetary policy of the US as one of the determinants of the global financial cycle – researchers have studied the phenomenon on multiple facets: the asset based cycle and the propagation of US financial conditions to the world economies (Miranda-Agrippino and Rey, 2020a, Miranda-Agrippino and Rey, 2020b; Dées and Gales, 2019), the capital flows – quantity measure – of the global financial cycle (Avdjiev and Hale, 2018; Davis et. al, 2019; Habibm Venditti, 2019), the relation between the global and the domestic cycle (Aldasoro et al., 2020, Borio, 2019).

Synchronicity among cycles was also extensively studied in the dedicated literature in terms of common movement between financial cycles in a cross-country framework or between the economic and the financial sector. Some papers from this category are Rünstler, Vlekke (2016), Breitung and Eickmeier (2016), Comunale (2017), WGEM Team (2018) and Kunovac et al. (2018).

Another problem when investigating financial cycles is how to measure them. We visited earlier papers on financial cycles which develop upon the characteristics and construction options and found that the most frequently used measures are turning point analyses and different types of filters, among which the band pass filter is the most common (Aikamn et al., 2015, Claessens et al., 2011, Claessens et al., 2012, Drehmann et al. 2012, Haavio, 2012). There are also other methods like multi-level factor model (Breitung and Eickmeier, 2016), synchronicity index (Comunale, 2017), multivariate structural model (Rünstler and Vlekke, 2016), principal component analysis, similarity and wavelet coherence (WGEM Team, 2018; Kunovac et al., 2018).

After the global financial crisis, financial cycles became highly important for macroprudential policy, the credit gap (the deviation of Credit/GDP from its long-run trend) being explicitly mentioned in the Basel III regulations (see for example Borio, 2014, Benes et al. 2016, Bruno and Shin, 2015, Drehmann et al., 2011, Gadanecz and Jayaram, 2016).

Data and Methodology

Data and sources

We considered 4 variables characteristic for the financial cycle: 10 year government bond yields, equity prices (we considered the total share price for all shares in the respective countries), house price index (which captures price changes of all residential properties purchased by households and is different from the real estate index, which is a stock market index) total credit to GDP ratio and two measures of the global financial cycle – the global capital flows as share in GDP and the VIX index as measure of global risk aversion. The data had different time spans and was collected for Czech Republic, Hungary, Poland and Romania (as well as world countries for the capital flows), from multiple sources, as can be seen from the table 1 below.

Table 1: Data sources and samples

Variable	Sample	Source
10Y bond yields	2001Q1-2020Q2	FRED database for the Czech Republic, Hungary and Poland and the Romanian National Bank and author calculations for Romania (the data series was extended backwards through regression on long term interest rates for convergence purposes - source ECB, SDW- and ROBOR 12M - source NBR)
Equity prices	1997Q4-2020Q2	FRED database for Czech Republic, Hungary and Poland and the Bucharest Stock Exchange for Romania
House price index	2005Q1-2020Q1	Czech Central Bank and Eurostat for the Czech Republic and Poland, Magyar Nemzeti Bank for Hungary, National Statistical Institute and the Romanian National Bank for Romania
Credit/GDP	2005Q1-2020Q1	BIS for Czech Republic, Hungary and Poland and the Romanian National Bank for Romania
VIX index	2007Q1 – 2020Q2	FRED database
Capital flows/GDP	2007Q1 – 2020Q1	IMF, Balance of Payment data

Methodology

As this study is a continuation of previous research with some common variables, the information presented here can have some minor similarities to that in Muraru (2019), Muraru (2020).

In order to isolate the cyclical components in the series we used the band-pass filter with the filtering bounds of 8 and 60, accounting therefore for a cycle of median length. Even though traditionally financial cycles are considered to be longer (30 years – time span too long for our dataset), the literature on financial cycles considers the median length of a cycle to be 15 years (Drehmann et al., 2010). We further investigated the synchronicity among cycles on each of the selected variables in a cross-country framework by computing the concordance index (developed by Harding and Pagan, 2002) between all 4 countries after identifying the peaks and troughs with the *Bry-Boschan* algorithm for quarterly series. The concordance index is a statistical measure that indicates the proportion of time in which the analysed series move in the same direction, without giving any information about the amplitude of their movements.

We also investigated the common movement of the cycles by applying factor analysis and crosschecking it with the results obtained from principal component analysis. Both methods are multivariate data analysis techniques for data reduction. Factor analysis, identifies the factors that induce the common movement of the dataset and at the same time explain the correlations between the series. Those factors are latent variables and they participate in explaining the initial variables in terms of common influence and unique characteristics.

In the factor model, each variable is written as a linear combination of common and specific factors. The common factors are usually in lower number than the initial variables. In matrix form, the model can be written as:

$$X - \mu = AF + U \tag{1}$$

where:

$X = (x_1\ x_2\ \cdots x_n)'$ is the vector of n initial variables, $\mu = (\mu_1\ \mu_2\ \cdots \mu_n)'$ the mean of the variables, $A =$ matrix of factor coefficients, $F = \left(f_1\ f_2\ \cdots f_p\right)'$ the *p* common factors (p<n) and

$U = (u_1\ u_2\ \cdots u_n)'$ the unique factors for each initial variable.

The assumptions of the factor model are:

(i) common factors have zero mean $E(f_i) = 0,\ i = 1, 2, \dots, p$, unit variance ($var(f_i) = 1$) and are uncorrelated $cov\left(f_i, f_j\right) = 0, i \neq j)$; (ii) unique factors are uncorrelated and of zero mean $E(u_i) = 0,\ i = 1, 2, \dots, n$, but with a different variance ($var(u_i) = \psi_i$); (iii) Common factors are not correlated with unique factors ($cov(f_i, u_i) = 0, \forall i, j$).

Consequently, the variance of a variable x_i can be expressed as: $var(x_i) = \sigma_i^2 = \alpha_{i1}^2 var(f_1) + \alpha_{i2}^2 var(f_2) + \cdots + \alpha_{ip}^2 var\left(f_p\right) + var(u_i)$ z (2)

which can be written as:

$$\sigma_i^2 = h_i^2 + \psi_i \tag{3}$$

where $h_i^2 = \alpha_{i1}^2 + \alpha_{i2}^2 + \cdots + \alpha_{ip}^2$ is the communality, the share of variance explained by common factors and $\psi_i$is the uniqueness, the variance explained by particular factors that influence the evolution of the indicator. These two elements, communality and uniqueness, sum to 1 when the variables are standardised.

Principal components rewrites the information from the initial variables in orthogonal components with decreasing variance therefore allowing for data reduction with a minimum loss of information. Mathematically, principal components are linear combinations of the initial variables. In matrix form:

$$z = A'x, \tag{4}$$

where $Z = (z_1\ z_2\ \cdots z_n)'$ are the principal components, A is the matrix of coefficients

and $X = (x_1\ x_2\ \cdots x_n)'$ is the vector of n initial variables.

The starting point in computing principal components is variance maximization problem. The variance of one component z_i can be written as:

$var(z_i) = var(\alpha^{(i)\prime}x) = \alpha^{(i)\prime}\Sigma\alpha^{(i)}$, where $\alpha^{(i)} = \begin{pmatrix} \alpha_{1i} \\ \vdots \\ \alpha_{ni} \end{pmatrix}$ is the *i*th column vector of *A*.

Consequently, the maximization problem is :

$$\begin{cases} max_{\alpha}\ \alpha^{(i)\prime}\Sigma\alpha^{(i)} \\ \alpha^{(i)\prime}\alpha^{(i)} = 1 \end{cases} \tag{5}$$

where $\alpha^{(i)\prime}\alpha^{(i)} = 1$ is an identification condition.

For studying the common movement of variables, we used the concordance indicator which is a statistical measure that shows the number of times the series are in the same phase of the cycle, and also historical decomposition and wavelet coherence.

The dynamic common movement or coherence among the data series at different frequencies and periods can be investigated by wavelet coherence (see for e.g. Cazelles et al., 2008, Aguiar-Conraria et al., 2008, Aguiar-Conraria and Soares, 2014.). This technique analyses how the different periodic elements in which it decomposes the data series evolve in time. The most commonly used is the Morlet wavelet, which we also used in this application.

Historical decomposition identifies the contribution of shocks in the evolution of the variable. In describing the contribution of shocks, we have to start from the MA representation of the VAR

$$y_t = \sum_{i=0}^{t-1} \varphi_i \vartheta_{t-i} + A_1^t y_0 + \cdots + A_p^t y_{-p+1} \tag{6}$$

from which we can extract the contribution of the kth structural shock to the jth component series of y :

$$y_{jt}^k = \sum_{i=0}^{t-1} \varphi_{jk,i} \vartheta_{k,t-i} + \alpha_{j1}^t y_0 + \cdots + \alpha_{jp}^t y_{-p+1} \tag{7}$$

(Lutkepohl, 2011).

Results

Cycle Synchronicity

The first step in investigating the synchronicity between the domestic financial cycles of the considered countries was to detrend the series by applying a band-pass filter with bounds corresponding to a cycle of median length (we performed this analysis on different time horizons, because data series had different available samples). The following step was to identify the peaks and troughs by applying the Bry-Boschan algorithm (we used the Matlab code provided by Engel, 2019) and to calculate the concordance between the series – the number of times the series shared the same phase of the cycle in all 4 countries.

The results show high concordance for 10Y bond yields and equity prices (Table 2 and Table 3 below), components which had a more rapid increase in synchronicity worldwide on account of the rise in global covariation of equity return premiums and risk premiums (Jordà et al., 2018).

Table 2: Bond yield synchronization

10Y bond	***Factor Analysis***		***PCA***	***Concordance (%)***
	Communality	***Uniquness***	***% variance 1stPC***	
Czech Republic	*0.87*	*0.13*	*91.79*	*62.82*
Hungary	*0.61*	*0.39*		
Poland	*0.86*	*0.14*		
Romania	*0.92*	*0.08*		

Table 3: Equity price synchronization

Equity	*Factor Analysis*		*PCA*	*Concordance (%)*
	Communality	*Uniquness*	*% variance 1stPC*	
Czech Republic	*0.995*	*0.005*	*88.37*	*60.44*
Hungary	*0.71*	*0.29*		
Poland	*0.86*	*0.14*		
Romania	*0.87*	*0.13*		

House prices and total credit/GDP seem to share to a lesser extent the same phase of the cycle, they are concordant about one third of the times (see Table 4 and Table 5). In what concerns credit/GDP, the lower synchronicity comes from credit – we investigated the concordance across countries separately for total credit and GDP and while for GDP the concordance was around 45 percent, for total credit, it was lower than 30 percent. This result suggests that there are national specificities (even policies, changes in legislation) on housing and credit markets which occasionally induce a different pattern (conclusion similar to Breitung and Eickmeier, 2016). Still, factor analysis and principal component analysis give strong support for the existence of a common latent factor that explains the correlation between the evolution of house prices and total credit in the 4 EEMS. In both cases, one common factor is enough to summarise the data with an acceptable loss of information (12 percent in the case of house prices and 22 percent for total credit). In addition, the common factor has high communality both for house prices and credit for all countries, with the exception of Poland, in which case the common factor for total credit had a much higher uniqueness.

Table 4: House prices synchronization

House prices	*Factor Analysis*		*PCA*	*Concordance (%)*
	Communality	*Uniqueness*	*% variance 1stPC*	
Czech Republic	*0.82*	*0.18*	*87.83*	*36.07*
Hungary	*0.61*	*0.39*		
Poland	*0.61*	*0.39*		
Romania	*0.61*	*0.39*		

Table 5: Credit/GDP synchronization

Credit/GDP (%)	*Factor Analysis*		*PCA*	*Concordance (%)*
	Communality	*Uniqueness*	*% variance 1stPC*	
Czech Republic	*0.30*	*0.70*	*77.87*	*25.81*
Hungary	*0.36*	*0.64*		
Poland	*0.995*	*0.005*		
Romania	*0.60*	*0.40*		

The communality accounted by the common factor and the share of variance described by the first principal component are very high in the case of equity prices and 10Y bond yields, therefore one factor proves to be sufficient for explaining their common movement (see Table 2 and Table 3).

Identifying Global Influences

The goal of our paper was to identify to what extent the common evolution of domestic cycles is explained by global evolutions. We considered three measures for global influences: risk premiums (measured by the CDS), global risk aversion (measured by the VIX index) and a measure for global capital flows.

We considered the CDS variables for our sample of countries and then applied principal component analysis to build an aggregate measure for the risk premium. We have used the same methodology for building the global measure of capital flows. In building this measure we used gross inflows/GDP and not the net position because the net position has lower volatility, especially in the latest period, and a lower synchronicity with global risk aversion (Davis et al., 2019). The

global measure of capital flows can be considered a proxy for the global financial cycle as it is strongly connected with other measures of the global cycle. Habib and Venditti (2019) and Avdjiev et al. (2017) show that it is tightly correlated with the Miranda-Agrippino and Rey measure of the global financial cycle, with the VIX index and also with other price measures of the global financial cycle.

After applying principal component analysis on the capital flows data (we used a number of 31 countries which had a balanced data set for the period 2005Q1-2020q1), we obtained a global cycle measure that explains 62 percent of total variance and which is strongly correlated to the inverted form of the VIX index – a correlation coefficient of 0.52.

For the capital flows variable we studied the concordance with the common movement extracted for each of our variables in the cross-country framework and they proved to be highly synchronous with the equity price and credit/GDP variables (Table 6).

Table 6: Concordance between capital flows and domestic financial cycle variables

Variable	10Y bond	Equity	House prices	Credit/GDP
Concordance (%)	*24,59*	*62,30*	*49,18*	*59,02*

Sample period: 2008q1-2020q1

Also, wavelet coherence (we used the Matlab Cross Wavelet and Wavelet Coherence Toolbox provided free of charge by Grinsted, 2004) represented in Fig. 1 below, shows high synchronicity between capital flows and the financial cycle measures, especially at lower frequencies, higher frequency coherence being identified in a persistent manner only with credit to GDP ratio. The graph below shows the coherence between the series at different frequencies, identified by the periods on the y-axis – the lower part of the graph represents higher frequencies while the upper part the lower frequency. The intensity of the correlation is shown by the colour – yellow means a high level of coherence between the series (higher that 0.8) while the dark blue is an indicator of very low correlation between the series. The black continuous lines in the graph are the confidence interval for the measure.

Fig. 1: Wavelet coherence between capital flows and financial cycle measures

We also investigated the historical decomposition (Fig. 2) of each of the financial cycle series in a Bayesian VAR with CDS, VIX and the global capital flow/GDP measure. As can be seen from Fig. 2 below, the highest impact comes from the global capital flows. Regarding the magnitude of the impact, the global capital flows mostly influence the common cycle in house prices (explaining at certain moments even 80 percent of its evolution), but are also significant for equity prices and credit/GDP (explaining about 20-30 percent of their evolution at certain moments). None of the measure is capable of explaining the evolution of the common cyclical measure of 10Y bond yields, their contributions are very low. Risk premium and risk aversion also contribute to explaining the common cycles but to a much lower level.

Fig. 2: Historical decomposition

Conclusions

In this paper we investigated the role of some global factors in explaining the common movement in financial cycle variables (bond yields, equity prices, house prices, credit/GDP) for 4 emerging European countries: Romania, Hungary, Poland and Czech Republic. We have chosen measures of risk premium, global risk aversion and capital flows (the last two being good approximations of the global financial cycle) and reached the conclusion that the common domestic cycles are largely attributable to the global cycle in capital flows. The reason for this is that the global cycle in capital flows is highly correlated to different measures of the global financial cycle as global risks are transferred to capital flows especially through cross-border flows, loans by banks and other financial institutions (Habib and Venditti, 2019). The risk premium is of lower importance when compared to the capital flows, but still has a relatively important contribution in explaining the common cycles of some variables. The importance of risk premiums in explaining financial cycles co-movement has been debated in the related literature and explained especially for equity price synchronisation (Jordà et al. 2018), for which in our dataset is the main contributor in historical decomposition. The historical decomposition shows an even weaker impact from the global risk measure, but this could become higher as financial integration deepens and there is a change in investors' sources of financing. From a practical point of view, the results confirm our hypothesis that domestic financial cycles cannot be interpreted individually, that there is important synchronicity in their evolution, especially in terms of bond yields and equity prices, indicators mostly prone to react to external evolutions. As our results point out, the co-movement of cycles can be associated with the global financial cycle, through the influence of capital flows, risk premium and risk aversion. Still, besides the undoubtedly global influence, there are also national specificities that shape domestic financial cycles. An interesting research subject and a perspective for our future research is to see how the domestic economic cycles are connected to a global measure of capital flows as there is a known and much studied connection between economic growth and capital flows.

Abstract

This study extends the existing research by examining the direct effects of big data analytic capability on business performance, as well as the mediating effects of dynamic capabilities on the relationship between big data analytic capability and business performance. Big data analytic capability can catalyze the ability of firms to improve their business performance, but there is little research to explore the mediating role of technological and managerial capabilities. To address these gaps in the literature and practice a conceptual model was developed to test the hypotheses between these variables. The research methodology was based on quantitative method and a cross-sectional study. We employed a structural equation model (SEM) to test our conceptual model using questionnaire data from a sample of PhD students enrolled in the A-Success project from University POLITEHNICA of Bucharest (UPB), Romania, working in different companies. As expected, we found that management, and technological capabilities mediate the relationship between big data analytic capability and business performance. This finding suggest that firms should look beyond direct effects of big data analytic capability on business performance and to investigate the mediating effects of technological and managerial capabilities to improve the business performance. This study attempts to contribute to the literature through novel findings and recommendations. These findings require further investigation in future research on theories, and practices for academic leadership development. Finally, implications for practice are discussed, and future research directions are proposed considering the limitations of our study.

Keywords: big data, business analytics, business performance, value.

Introduction

McAfee et al. (2012) showed that the value of big data analytics derives from the fact that data is a strategic resource that allows businesses to develop critical insight and gain a competitive advantage. Data can be considered as observation or experience about real world and can be expressed as a set of values of variables. Data has a different format and can be stored in a database in various forms – structured data, semi-structured, or unstructured. The volume of data is growing fast, but the largest share of this growth is represented by unstructured data such as video, images, or social media posts. The key to information and knowledge is data what can be analyzed and processed for value. Zeng et al. (2018) mentioned that having more data, information and knowledge can enable firms to identify and exploit business opportunities.

Baltzan (2017) defined that big data is a collection of large and complex data which cannot be analyzed using traditional methods and tools. That is to say, big data include extremely large volumes of data characterized by high velocity, wide variety, and veracity need advanced analytics to capture insights for decision making. Chen et al. (2012) showed that analytics involves the ability to gain insight from data using simulation, optimization, statistics, and other techniques to a help firms gain a competitive advantage. Gillon et al. (2014) point out that big data

Cite this Article as: Gheorghe MILITARU, Andreea BARBU and Mihaela-Rodica GANCIU "Exploring the Relationship between Big Data Analytic Capability and Business Performance" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

requires sophisticated tools to analyze and visualization data such as correlation analysis, exploratory data analysis, pattern recognition analysis, behavioral analysis, social media analysis, speech analysis, text analysis, or web analysis.

The existing research has focused primarily on relationship between big data analytics and different variables. Chakravarty et al. (2013) point out that big data analytics improve business processes in a way to enable firms to explore new opportunities as well as to exploit those opportunities efficiently. Lu and Ramamurthy (2011) showed that prior studies have identified a positive link between big data analytics and firm outcomes. While empirical studies suggest that big data analytics have a positive impact on the competitive performance, more research is required to investigate the mediating effects of different factors. Mikalef et al. (2020) highlight that big data analytics has an indirect effect on marketing and technological capabilities, which is mediated by dynamic capabilities. Firms need to exploit the full potential of big data analytics to improve innovation, competition, and productivity that can ultimately provide a competitive advantage.

The purpose of this paper is to investigate the direct effects of big data analytic capability on business performance, as well as the mediating effects of technological and managerial capabilities on the relationship between big data analytic capability and business performance. Sharma et al. (2014) argue that big data analytics can create value. Yet, there is scarce research on how firms should proceed to embed the big data analytics into their business processes. Therefore, there is limited understanding on how firms should approach their big data solutions and how they could increase their business performance. To address these gaps in the literature and practice a conceptual model was developed and for testing it a structural equation model (SEM) is applied. This study investigates the mediating effects of technological and managerial capabilities between a firm's big data analytics and business performance. The results have supported the hypothesized direct and mediated relationship. The significance of the theoretical relationship was assessed using structural model. A sample of PhD students was used to test the hypotheses. They worked in the small business that used big data analytics to some extent (Hadoop). The study was based on the analysis of students' perceptions regarding the role of big data in increasing business performance.

We extend big data literature by examining the role of technological and management capabilities on relationship between big data analytics and business performance. Main contribution of this paper to the literature consists in the fact that management, and technological capabilities mediate the relationship between big data analytic capability and business performance. We also provide a way of improving business performance by using big data analytics. Thus, using questionnaire survey data collected from 38 PhD students, we found that there is a significantly effect of technological and management capabilities on relationship between big data analytics and business performance. This finding suggest that firms should look beyond direct effects of big data analytic capability on business performance and to investigate the mediating effects of technological and managerial capabilities to improve the business performance.

The paper is structured as follows. In the next section we provide a theoretical background and develop the hypotheses. Next, we present the research method employed in this study. This is followed by the result analysis and provides the main findings. Finally, managerial implications, limitations, future directions and conclusions are discussed.

Theoretical Background and Hypotheses

According to Gupta and George (2016), big data analytics are defined as the ability of the organization to capture and analyze data toward the generation of insights, and use advanced analytics to make better decisions. Kiron (2017) showed that big data analytics in the organization enable the identification of new business opportunities through the combination of diverse data sources and seek the necessary knowledge and assets to seize those opportunities. Liu (2014) notes that big data analytics make the difference between high-performing and low-performing firms and enable firms to identify new business opportunities and gain a competitive edge. McAfee et al (2012) stress the importance of data because managers base their decisions on insight rather than instinct. Rialti et al. (2019) showed that there is a need for more empirical research explicating because the proper implementation of big data analytics allows firms to effectively exploit it.

Wamba et al. (2017) have found a positive impact of big data analytics on business performance. The gradual decrease in costs for collect and data storage has determined firms to invest in big data analytics. Big data analytics can generate multiple useful effects in different industrial sectors. Companies need to evaluate the potential value that an opportunity can create. For example, service firms can achieve improved customer satisfaction or more efficient use of resources. In the manufacturing sector, the production processes be improved or operations in the

supply chain can be optimized. Nevertheless, the main problem facing companies is the lack of human resources with digital skills. The ability to analyze new sources of data and stay agile and work faster gives companies a competitive edge and possibility to identify new opportunities. Artificial intelligence will learn patterns of human behavior over time. Machine learning offers companies the opportunity to build models that can analyze bigger and more complex data to identify profitable opportunities or avoiding unknown risks. Hagel (2015) mentioned that big data analytics gained more and more attention in the business environment because it has become a vital solution of the decision-making process of agile organizations. Furthermore, Ji-fan Ren et al. (2017) showed that big data analytics has become a catalyst for the improvement of business processes, and the acceleration of business innovation

According to Rialti et al. (2019), big data analytics is an emerging technology and for this reason there is little research on how to effectively use and exploit it. Even though prior studies have shown of adopting big data analytics can lead to competitive preference gains, there is a lack of evidence on how to apply this technology to create value and gain a competitive advantage. Furthermore, Ashrafi and Zare (2018) showed that some managers decided not to invest in big data analytics, especially those who have not successfully adopted business intelligence. These mediation effects occur as a result of increasing the capacity of firms to sense emerging opportunities and threat, size opportunities before competitors, and enhanced operational capabilities. According to Turban et al (2017) there are some obstacles to adoption of business analytics solutions such as lack of talented employees with analytics training, slow technology adoption due to cost or risk aversion associated with security and privacy issues.

Business performance refers to the efficiency and effectiveness of a company measured by the degree of achievement of its objectives in relation to the resources used. The correlation between big data analytic capability and business performance can be expressed as profitability, growth, efficiency, or product differentiation. The insight form the speech analytics is used to develop a deeper understanding of customer preferences and their perception of the offers of competing companies. Wills (2014) showed that “Amazon” generate 35% of sales from personal recommendations to customers based on big data analytics. According to Germann et al (2014) big data analytic capability is positively related to business performance. Moreover, this technology is used to make the difference between high and low performing companies and to sustain to stay current with trends and operate efficiently. Mikalef et al (2020) showed that firms must constantly reconfiguration their capabilities to respond to changes for survival and better fit market needs. Therefore, big data analytics can improve business performance for any company. Hence, this technology can lead to improving business performance.

***H1**. There is a positive relationship between big data analytics and business performance*

According to Ho (2008), a managerial capability refers to an organization’s skills, knowledge and experience, which are used to handle different managerial tasks. Lorenzo et al., (2018) showed that managerial capability has a significant positive influence on business performance. Big data analytics exploit huge amounts of data form different sources to generate new knowledge that along with existing ones help forms to make decisions in the real time. The collected information is used to identify new opportunities through the combination of diverse data sources. Managers need to know customer preferences and future needs or market expectations. Communication also is easy nowadays by using big data analysis. Managerial capabilities enable managers to improve business performance through clear definition of objectives, implementing cost reduction, or product differentiation. Better profitability may provide the firms with greater resources to expend. Therefore, companies must invest in different means to generate new knowledge and improve the skills that can be used to improve business performance. According to McAfee (2012) big data analytics will lead to best prediction and best prediction produce best decisions. Thus an investigation is required to determine whether managerial capability mediate the relationship between big data analytics and business performance. Therefore, the following is hypothesized:

***H2.** There is a positive relationship between big data analytics and managerial capability*

***H3.** There is a positive relationship between managerial capability and business performance*

Technological capability is valuable asset and not easy to replicate by rivals. Technological capabilities are the information and skills, technical, managerial and institutional those allow company to utilize equipment and technology efficiently. They are considered a dynamic capability held a company, skills and knowledge of technology are strategic resources that enable companies to be profitable. Technological capability enables the company to transform inputs into outputs in an efficient way. Technological absorptive capacity can affect the company’s capability for generate new knowledge and improve business performance. Technical knowledge must be transformed into specific product designs that constitute product innovation. However, technology alone is an

insufficient resource unless there is a technological capability which encourages creativity contributes to new product development. Therefore, technological capabilities refer to a company's ability to search, develop and capitalize new innovative products.

According to Coombs and Bierly (2006), technological capability is a very significant source of competitive advantage such as by increasing revenue, reducing costs, and improving the quality of a firm's existing products and processes. Zeng et al. (2018) showed that technological complexity could determine managers to reject big data analytics because they may not understand their potential and how such system work. Big data analytics can provide firms the opportunity to innovate and create more value for their customers. Technological capabilities are important for firms to obtain core competencies and to achieve competitive advantage that leads to an improve business performance. However, there is a lack of empirical studies that investigates the mediating effect of technological capabilities between big data analytics and business performance. For survival companies must be able to identify changes in customer preferences and demand. Thus an investigation is required to determine whether managerial capabilities mediate the relationship between big data analytics and business performance. Based on the above arguments, the following assertion is therefore hypothesized:

H4. *There is a positive relationship between big data analytics and technological capability*

H5. *There is a positive relationship between technological capability and business performance*

Method

Research Design

In order to meet the research objectives and to test the proposed hypotheses, we developed a quantitative empirical study of the mediating effect of management and technological capabilities on the relationships between big data analytics and business performance. As for research, a survey instrument was created using a combination of existing and newly development measures. The constructs and survey items used in this research are based on previously published latent variables that support their validity. This exploratory study used cross-sectional survey data. The proposed model will be empirically examined using the Structural Equation Model (SEM) to analyse data collected by a survey. The data for this study were collected using a questionnaire consisted of four constructs that was administrated to the respondents from sample. The majority of respondents who participated in the survey have good digital skills and have access to information about business performance where they work. The first phase of the research was a pilot study. In this phase, we conducted a discussion with two specialists in computer science with experience in big data analytics. Based on their comments, we designed the questionnaire used in the survey. Therefore, questionnaire was taken as acceptable instruments to be administrated.

Data for the research were collected through over a period from October to November 2019. Data were collected from a sample of PhD students (38 students) enrolled in the A-Success project from University Politehnica of Bucharest (UPB), Romania, working in manufacturing and service companies. This university is the largest and the oldest technical university in Romania. About 60 percent of the respondents worked in manufacturing companies and 40 percent of the respondents worked in service companies. The firm age ranged from 3 to 16 years (SD=2.16 years). The average firm age was 6.3 years. The response rate was 71 percent and resulted in 27 valid questionnaires (N=27). The data were assessed for the extent of missing values. The missing values were completely at random and the means substitution method was used the replace them. All of the items were also measured on a 7- point scale ranging from 1 (strongly disagree) to 7 (strongly agree).

Profile of respondents and their experiences in business are the following. A total of 20 respondents (52.6%, 20 out of 38) had experience between 2 to 3 years; 26.3% (10 out of 38) of them had 1 to 2 years of working experience and followed by 7.9% (8 out of 38) of the respondents had more than 3 years of working experience.

Measures

The scales for the various constructs were adopted from prior literature and have been previously tested in empirical studies. In order to ensure the reliability criterion, the study instrument is based on the existing measures whenever possible, reverse questions and pretesting of the questionnaire. Scales were taken from the existent literature and previous research and adapted to our requirements.

Dependent variable. *Business performance* is a multidimensional construct covering more indicators – financial performance, customer – related outcomes, innovation and internal organizational processes. In this research we used 4 items adapted from Satwinder et al (2016): "Employees are satisfied with the organization – **EO**"; "Sales revenue has increased in the last two years – **SR**"; "Company's profitability has increased in the last year – **PRO**" and "Company innovates to develop new products – **INOV**".

Independent variables. *Technological capabilities* were measured using a version developed by Wilden and Gudergan (2015) and it was measured using 3 items: "The company owns valuable technological assets (equipment, software, information systems) – **TA**"; "The company uses in its operations the external networks of technology – **NET**", and "Technological assets are integrated within the company – **OIT**". *Managerial capabilities* were measured using 3 items developed by Mahoney (1995): "Management team attract and retain talented employees – **TE**"; "Management team make good decision – **GD**" and "Management team perceives opportunities and potential threats – **OT**". *Big data analytics capabilities* were measured using 3 items adapted for this study from Gupta and George (2016): "The company invests in technology systematically – **TECH**"; "The key employees have technical skills – **TEC**"; "Data plays a key role in employees' decisions and business processes – **DAT**".

Control variables. We included three control variables such as industry type, firm size, and firm age that were not of direct interest for testing our hypotheses but could be theoretically related to the business performance and might provide plausible alternative explanations for our findings. We controlled firm size by taking into account the natural log of the number of full-time employees of individual firms in our sample. The natural log was taken in order to normalize the data.

Analysis and Results

Given that the aim of this study is to predict the influence of big data analytics capabilities on the business performance and the mediating effects between big data analytics and business performance of technological and managerial capabilities. We have tested all of the hypotheses using the research model described above. All measurements of the constructs are based upon the respondent's perceptions. Because measures for the dependent and independent variables were taken from the same questionnaire, we performed Harman's one-factor test to see whether one factor accounted for the majority of variance in the data. Therefore, we entered all items used in the questionnaire into an unrotated exploratory factor analysis. The first factor accounted for 23 % of the variance. Since a single factor did not emerge and one-factor did not account for most of the variance, this suggested that common method bias was not a serious concern in our data set.

Table 1 presents the descriptive statistics and correlations for all variables used in this research. We can see that correlation coefficients are within acceptable levels. That is, no bivariate correlation is greater than 0.7, and there is little threat of common methods in our data. The highest correlation coefficient is equal to 0.67. Therefore, no constructs were found to correlate so highly (at .90 or more). The correlation analysis shows that most coefficients are low (well under 0.7), which minimizes concern with multicollinearity issues in our analysis. Many indicators showed a significant positive correlation. Correlation greater than or equal to 0.22 are significant at $p<0.05$. Correlation greater than or equal to 0.42 are significantly at $p<0.01$.

Table 1: Descriptive statistics and scale reliabilities

*Note. N =27, *p <0.05, **p<0.01*

Data was analyzed with SPSS 20.0 software with maximum – likelihood estimation. Cronbach's alpha was used to determine the internal consistency of items in each scale. Statistical procedures were used to establish the reliability and validity of the measures with all items. Reliability of the factors was measured using Cronbach's alpha for each construct and was found to be greater than 0.7 indicating acceptable level of reliability. Hair et al. (2007) have recommended minimum of 0.6 which suggest that the constructs are internally stable and reliable for analysis. Also, the significant Keiser-Meyer-Olkin (0.728) and Bartlett's test of sphericity of 1362.7 confirms the data are valid for the data analysis. Table 2 shows the Cronbach's alpha and factor loadings of each variable. The factor loadings range between 0.765 and 0.847 and they exceed the minimum 0.5, as suggested by Hair et al. (2007).

Table 2: The Cronbach's alpha and factor loadings of each variable

▪ TE	0.788	0.844
▪ GD	0.829	
▪ OT	0.765	
Big data analytics capabilities		
▪ TECH	0.765	0.788
▪ TEC	0.833	
▪ DAT	0.817	

Hypothesis Testing

The hypothesized relationships among variables were examined by means of structural equation modelling (SEM) analyses using LISREL 8.80 program. A path-analytic model was developed and tested. Path analysis allows researchers to test direct and indirect effects of multiple independent variables on multiple dependent variables. In this way, we were able to test all study variables simultaneously. On the predictor side, the structural model included the big data analytic capability variable. Two mediating variables (technological and management capabilities) and one dependent variable (business performance) were included.

The fit indices for this model were as follows: $\chi 2$ = 49.32, df=47, CFI=0.82, RMSEA= 0.034, GFI=0.923, PNFI=0.53, NFI=0.53, AGFI=0.87 and AIC=103.27. The validity of the entire model needs to measure the goodness of fit (GFI), which checks for sample size effects and should be above 0.9. Adjusted goodness-of-fit index (AGFI) is generally accepted so that values of 0.90 or greater indicate well-fitting model. Our results indicate the AGFI=0.87 very close to the cut-off of 0.90. As suggested by Hair et al. (2007), the root mean square error of approximation (RMSEA) measures population discrepancy per degree of freedom. A value of the RMSEA of about 0.05 or less would indicate a close fit of the model in the relation to the degrees of freedom. Our results indicate a good fit, RMSEA=0.034. Thus, the results indicate an acceptable fit of our model.

The results of the hypothesis testing were as follows: Hypothesis 1 states that big data analytic capability will positively affect the business performance. The path coefficient of big data analytic capability to business performance (β=0.356, t=3526, p<0.01) is positive and significant. Thus, the hypothesis H1 was supported. This result is compatible with previous research which shows that big data analytic capability exerts a positive and significant effect on organization performance. The path coefficient of big data analytic capability to managerial capability (β=0.34, t=3392, p<0.01) is significant and this result provide support for hypothesis H2. Managerial capability had a positive impact on the business performance (β = 0.478, t=8691, p<0.001). This suggests that big data analytic capability has an indirect effect on business performance by managerial capability. Therefore, hypothesis H3 was supported. The path coefficient of big data analytic capability to technological capability (β = 0.289, t=2786, p<0.01) is positive and significant, and hypothesis H4 was supported. The path coefficient of technological capability to business performance (β=0.209, t=1896, p<0.01) is positive and significant. This result provides support for hypothesis H5. Finally, we tested for the mediating effects of technological capability. We additionally tasted whether technological capability has an impact on management capability. Contrary to our expectations, no such significant effect was found (β=0.062, t=472, p>0.05). Thus, the hypothesis was rejected. One might think that the effect of technological capability on managerial capability is weaker and difficult to be identified through PhD students' perception measurements. We also examined the influence of control variables on business performance. The relationship with the business performance was found to be nonsignificant in all cases.

Conclusion

The study results imply that the management must understand the business implications of big data analytics and how to use technology as a source for competitive advantage. The key managerial insight provided by this study is that it provides managers some guidelines about how they can use big data analytics to improve business performance. This research tested and found a positive relationship between big data analytic capability and business performance. This result is consistent with prior studies that assessed the relationship between these variables. Our empirical findings indicate that big data analytics alone has direct effect on business performance but also has an indirect effect on business performance through managerial and technological mediating contributions. Thereby, managers need to invest in big data analytics, adopt solutions of business intelligence, and attract employees with analytics skills. Big data technologies can be at the core of the business processes contributing to the decrees of the operational costs and to increase the competitiveness on the market.

The practical implications are very important for managers and practitioners, but these aspects are largely neglected. Although big data analytic capability has been discussed from a variety of perspective, this study highlights big data analytic capability affects a company's performance which, in turn, strengthens both management and technological capabilities. An interesting implication for practice is as big data analytic capability is much more than a simple investment in technology. Companies that have employees with good technical skills and managers who understand how big data analytics can be used to make good decisions which, in turn, result in strengthened business performance. Our findings indicate that technological and managerial capabilities can be used to improve the business performance because they mediate the relationship between big data analytic capability and business performance. Observed in more detail, big data analytics usage contributes to make good decisions and identifying solutions to minimize risk while seeking to maximize opportunities for growth. In other words, big data analytics give companies a competitive edge and possibility to identify new opportunities or avoiding unknown risks, their capabilities have become a vital solution of the decision-making process of agile organizations.

The findings of this study should be interpreted in light of some limitations and these need to take into account in the current study. First, for each firms included in sample was a single PhD student as the source of information. Only the perceptions of PhD students were surveyed in this study. Because the data were collected from a single source (e.g., PhD students) there is possibility of common method bias. Therefore, it would be helpful if future researchers examine perspectives of not only the PhD students but the managers and business specialists (multiple sources of survey data). Second, the present research assumes that relationships between variables are in some kind of statistical equilibrium. Nonetheless, we encourage researchers to engage in longitudinal research on the effects of the relationship between predictors and business performance for big data analytic capability in companies. Researchers using a longitudinal study can provide more specific information about the stability and change of the variables, and thus could complement the present empirical finding. Third, our findings are also limited to the Romanian economic context. Fourth, the sample size provides the minimum number of participants required, the result would be more reliable with additional respondents. As regards the sample, a larger sample would reduce the influence of random variation. Future studies look to refine this variable through further pilot testing with managers, entrepreneurs, and business specialists, or by selecting a different set of items to represent the constructs.

Acknowledgment

This work has been funded with the support of the University POLITEHNICA of Bucharest through the project "Engineer in Europe" in an online system, through the Financial Agreement registered at the Ministry of Education and Research with 457/GP/06.08.2020, which is a found for financing special situations that cannot be integrated into the financing form for higher education state universities.

Abstract

This work is meant to provide a conceptual insight on how properties of fractals could be used into modelling an encryption solution and the way it could complement quantum architectures for data protection, taking into consideration how data safety takes its toll on adapting to and adopting evolving Internet technologies. This need comes from the assumption that, soon, the sheer power of quantum computing will be able to break modern day algorithms and could put at risk the majority of our personal data. Avoiding turning data safety into a social crisis means the Internet can be governed ethically and people's privacy is not undervalued.

Keywords: Cybersecurity Threats, Organic Computing, Cryptographic Algorithms, Ethics.

Introduction

General motivation; shaping the context of our concepts

In our days information is everywhere but behind all of it stands a secure environment assuring that only people that are meant to access sensitive data actually get a hold of it. Thus, data security plays an important role in our daily lives. Technological progress can be considered, on one hand, a well-deserved evolution of mankind but, on the other hand, a threat to the models of data encryption.

The evolution of a frequently used cryptographical algorithm is a recurring pattern of the exploits that we're able to crack it and the temporary solutions that we're found for that specific problem until another inherent breach is found.

Privacy becomes a matter worth looking into as so many details about ourselves are one press away and could potentially be revealed to unauthorized persons or used with malicious intents. This is where the importance of regulatory actions, such as the European GDPR, shines through and demands for future-oriented visions.

The security of data flow on the Internet becomes an important issue of social scale when confidentiality can't be imposed. Major breaches over the years (such as the Yahoo or Uber ones), along with secret national data surfacing through leaks show us that our current cryptographic models and solutions don't always protect us.

A powerful data encryption algorithm used as of today is the RSA. It's incredibly unlikely that any actual supercomputer will crack such an infrastructure in a relevant or reasonable time if correctly implemented. However, quantum computing holds the promise of much greater computing resources that could hypothetically reduce the time needed to brute-force its way into protected areas, thus making current algorithms obsolete.

Fractals and their potential use in cryptography algorithms

Profoundly studying Kant's reflections regarding the „mathematization" of natural sciences that define culture and civilization, we can conclude that there exists a logical structure in scientifical investigation.

We'll further present the Mandelbrot Set as an example of a remarkable fractal having applications in theoretical physics, engineering and how it helps us demonstrate the theoretical aspects of our concept.

Named by James Gleick in his book from 1987, „the most complex object in mathematics", it is obtained beginning from the set of points "c" from the complex plane (starting with zero) on which we recursively apply the $f(z) = z^2+c$ polynomial. The set can't be generated for any set of numbers from the complex plane, though. It's important to mention the fact that the Mandelbrot Set is a bidimensional representation of this complex polynomial and it manifests its self-similarity only for periodic iterations generated into a specific direction and having a special scale factor close to a Feigenbaum constant. Such properties are useful for us describing the utility of fractals in data security.

Introducing the notion of fractals implies the need of characterizing this mathematical object that has some special properties. The concept of a fractal's dimension was brought to light in order to describe how complicated a self-similar figure actually is.

Based on the way they are generated, fractals can be classified as: fractals that are time-independent, being defined by a recurrence relation at each full point (the Mandelbrot set, the Julia set, the Lyapunov fractal), iterating systems that function using a set rule of geometrical manipulation (Sierpinski's triangle, Koch's curve) and random fractals that follow stochastic generating processes instead of deterministic ones (the trajectory of Brownian motion, dendritical fractals).

So, if the fractal is made out of N similar parts with the scale factor L, the formula corresponding to the Hausdorff dimension D is:

$$D = \frac{\log\ (number\ of\ similar\ fragments)}{\log\ (scale\ factor)} = \frac{\log N}{\log L}$$

Fig 1. Formula describing a fractal's Hausdorff

Regarding their self-similarity, fractals possess true self-similarity, quasi-self-similarity and statistical self-similarity (per se being the „weakest kind" of self-similarity).

Our proposal regards the use of dendritical fractals as a model for a concept of graphical cryptography. These are generated randomly and are of biological inspiration. The principles of organic computing can be taken into consideration for creating such fractals. An organic computing principle used for analyzing such graphical structures is the Moran Process. Its formulation that is useful to us is derived below.

$$D = \frac{\log N}{\log L} \leftrightarrow D \log L = \log N \leftrightarrow \log L^D = \log N => L^D = N \leftrightarrow \frac{N}{L^D} = 1 \leftrightarrow$$

$$\frac{1}{L^D} + \frac{1}{L^D} + \cdots + \frac{1}{L^D} = 1$$

Fig 2. Derivation of a formulation of the statistical Moran

Considering the sum of all the individual iterations with a specific scale factor L of an N-dimensional fractal we reach the Moran equation where P is the probability that our scale factor associated to a self-similar structure is actually correct:

$$P\left(\frac{1}{L_1^D}+\frac{1}{L_2^D}+\cdots+\frac{1}{L_N^D}\right)=1$$

Fig 3. The Moran equation

Looking at this equation from a statistical point of view, we can analyze the classification of the fractal in question but there can be hidden possible "traps" for "parasitic" decryption algorithms, given the complex nature of fractals.

We can imagine this process by attributing the concept of a "map" or maze with many branches blocked over the fractal graphical representation of such a security.

Quantum Computing: A Threat or The Future of Cryptography?

The RSA encryption algorithm is efficient because the process of obtaining the prime factors from a key (usually a number between 225 and 232) is time consuming using conventional methods. For example, if we have a 78-digit key (this "key" is usually the result of the product of two or more prime numbers), the prime factors could be extracted in about 10 minutes. For a key consisting of 231 digits, however, it would take 2000 years of calculation for a single computer or, on the other hand, a month for 24000 computers.

A substantially more efficient way (but also impractical in everyday life) involves using Shor's algorithm. Initially, it is made an attempt to guess randomly a prime factor; if the guessed factor does not match then it is converted to another prime number, which is more likely to be correct.

The advantage of quantum computers is due to the fact that the generation of a convenient power takes place almost instantly. Thus, several "consecutive guesses" can be taken in turn until all the prime factors of N are obtained (from 10 guesses we can obtain the prime factors with a probability of 99%).

Given the nature of qubits and the quantum mechanics' properties they possess it is necessary to concentrate our attention towards the processing potential of quantum computers, rather than the processing speed.

The addition of an additional qubit doubles the available "resources", as opposed to the redundant linearity of the additional power conferred by the increase in the number of bits available. The efficiency of quantum computers is relevant only in the context of tasks of considerable complexity where the possibility of performing processing tasks in parallel matters. Meanwhile, a conventional problem could be solved faster with just bits.

Their efficiency consists in the fact that a conventional computer runs the iterations of a task one-by-one at a given time, while a quantum computer runs "all" of the needed operations at the same time, in a probabilistic manner.

Fig. 3: Graph showing how increasing the number of processing units impacts the efficiency

Two scenarios are thus outlined:

1. Quantum computers will pose a threat to usual encryption
2. Quantum computers will be always "one step ahead" the attackers (theoretically unbeatable in the context of data security)

This being said, the RSA algorithm presented earlier succumbs to the power of quantum computing and loses its relevance.

We propose an approach to cryptographic algorithms based on the mathematical model of latices.

Given the fact that, from a topological point of view, fractals have their Hausdorff dimension greater than their inductive one, this irrational "N"-dimensionality shapes a family of random fractal latices. Their random nature creates links between neighboring regions.

In a research study by Kosior and Sacha (2018) a graphical representation of such a fractal was contoured and we can use it to better visualize our concept; it implies its representation in two Gaussian dimensions where its border is composed of these links that end up being called „short" vectors.

Without knowing a basis of these latices (generated on a big number of layers) that can shape their solution it is impossible, as of current knowledge, even for a quantum computer to break this algorithm. Cryptanalysis problems get classified as "worst case hardness" if at least one of their underlying instances is very hard to solve.

Fig. 4: Schematic representation of a quantum-aided system of generating fractal

All of these can be the basis of a dynamic system that uses organic computing techniques to impose self-security (similar to the way immune systems respond to the contact with unwanted organisms). Using a quantum computer for both generating and overseeing the encryption deed will facilitate the real-time recognition of a "brute-force" attack.

The self-similar structure of the algorithm will be broken by introducing a misleading parameter that will lead the source of the attack towards the infinite processing of one of the fractalized lattice's dimensions that doesn't contain the key to the wanted information.

The next logical step in the evolution of cryptographic solutions is the use of quantum units of information along with the implied quantum mechanics properties for implementing encryption algorithms.

We propose the use of neutrinos as quantum bits. Their state is characterized by the superposition of the possible masses for such quanta.

The advantage of choosing neutrinos over photons or electrons lies in their state as they have a very weak interaction with regular matter). Though, we must acknowledge the fact that they are really hard to detect and manipulate using actual techniques.

Any attempt at measuring the states of the entangled neutrinos is, on one hand, infeasibly expensive and, on the other hand, actually useless, as the act of measuring the superposition of the particle will lead to its wave function collapsing.

This is a possibility of simultaneously implementing a quantum key distribution along with using fractal lattices for the main encryption (in this case, the neutrinos performing the task of qubits).

Fig. 5: Model of our conceptual data security infrastructure, combining each aspect previously

We can watch this process step by step: N pairs of entangled neutrinos, having superpositions corresponding to the vectors in the basis of the fractal lattice are generated. Their state is measured after they've been captured by the receiver and has to be equivalent to the initial one.

This leads to finding the basis of the fractal lattice that will be used to encrypt the input text. After communicating the encrypted message to the receiver, it has to be decrypted using that aforementioned basis if it has been correctly deduced. The outcome is the successful transmission of that message as the output.

Overall, this can be compared to a rather common asymmetrical data encryption algorithm.

Overview. Social and Ethical Implications

Even though information security breakthroughs and novel understandings of how our evolving society behaves don't seem that close related, it's safe to assume that relieving pressure on both organizations providing various services on the Internet (e-commerce, e-learning, e-mail etc.) and their users will help transform the tech landscape. A virtually impenetrable data encryption algorithm could transform the Internet into a place that has a stronger bond to ethics.

The classic way that organizations today comply to the EU GDPR is sometimes vulnerable to easy interceptions. For example, a lot of data operators that have a mixed interaction with its clients (a very common approach in the COVID-19 pandemic context), such as banks or public offices, still required physical papers to be completed by hand and later be processed by other employees. Obviously, this is a soon-to-be redundant practice and personal information can easily be mishandled this way. In an era where the Internet of Things is a reality human kind will have to embrace, data encryption becomes even more so important and it represents an area with a huge development potential.

Looking at all of the aforementioned ideas as the components of an abstract data protection system could serve as a basis for imagining a dynamic system utilizing organic computing techniques with self-securing capabilities, much like the way immune systems respond to the contact with unwanted organisms. A quantum computer assigned with both generating and overseeing the process of data securing could identify the occurrence of a brute-force type attack in real time. Brute-forcing the solution, however, would only result in breaking the self-similar structure of the fractal-based algorithm and, consequently, divert the source of the attack towards infinite processing by introducing a misleading parameter.

Practical implementation of our data encryption concept is unlikely, but quantum computers may be used to bring into discussion the 2nd aforementioned scenario, revolving around the existing Quantum Key Distribution proposed encryption algorithm. Though, the generation of complex latices benefits from quantum properties possessed by qubits and neutrino maneuvering.

Conclusion

Considering all the discussed technical concepts, there is enormous potential for exploiting mathematical resources and imagination is only the limit of emerging cryptography concepts. People's trust in the way organizations protect their data is the leading factor that could make or break future practices involving sensitive information. Fractal theory gives us a graphical feedback of the complex domain and while quantum computing is still developing, exciting properties are already discovered and their sheer power prove there can be new encryption solutions being outlined, leading to a safer environment for the people browsing the Internet.

Abstract

The purpose of this article was not to analyze the idea of laying the foundation of new firms; entrepreneurship can happen inside an organization already established. This concept is defined as corporate entrepreneurship. Entrepreneurs usually operate in small businesses, but they have several traits which can refresh the old-fashion bureaucratic way of the healthcare industry. Healthcare looks at the macro level as any industry in the marketplace, but in reality, there are factors in this environment which can discourage entrepreneurship or investors to innovate the market. With these two contradictory goals in place, it takes serious creativity to succeed. In most of the cases, bureaucracy and the public health system can hinder patients to look for a solution of treatment or seek the most qualitative medical service without spending too much money out of their pockets.[1] In order to do proper screening of the current situation of the pandemic, the best tool is a qualitative and quantitative statistical survey, formulated with open questions addressed to both healthcare professionals and citizens or patients. The number of study participants varied depending on the target audience group – for healthcare workers a number of 35 respondents versus 76 respondents on the general audience survey. It was much easier to reach and share the study survey to regular people via multiple channels; instead, healthcare workers were more difficult to reach and attract their eagerness to respond. The results in this research project are presented below in a statistical and interpretational manner, through charts and SWOT analysis. The critical point has been reached in the health systems and now more than ever we need new players, especially leaders, to adopt and propose creativity, innovation, thinking and entrepreneurial behaviour as a major catalyst to achieve positive change in our health care system and delivery of healthcare.

Keywords: COVID-19; Pandemic; Healthcare Crisis; Healthcare Systems; Survey Analysis.

Introduction

On December 31, 2019, Chinese Health officials informed World Health Organization about 41 patients with a different type of pneumonia. The cases are connected to a seafood market in Wuhan city, Hubei province, China. A week later, Chinese authorities identify the virus which caused the pneumonia – a new type of coronavirus. On January 30, 2020, World Health Organization declares a global public-health emergency, then, on March 11, 2020, a pandemic. The 23 million of infected persons mark was surpassed on August 22nd, 2020.

Cite this Article as: Monica DUMITRA, Corina Ionela DUMITRESCU, Vlad Alexandru SANDU, Cătălina Georgiana DÎLBEA and Răzvan Mihai Dobrescu "Healthcare Organizations – Analysis of Systems, Entrepreneurial Approach and Management of the COVID-19 Pandemic" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The official name of the virus which currently affects the Planet is SARS-CoV-2. COVID-19 is the disease it causes, which stands for CORONAVIRUS DISEASE 2019. The disease spreads primarily from human to human through small droplets which are released when a person infected with COVID-19 sneezes, coughs or speaks, and can enter the human body directly through our eyes, nose or mouth.

The entire humanity has to face now with this war against the unexpected and unknown variables in all plans generated by the pandemic. Society must understand that prevention and the contribution of each individual together have a key role.

Healthcare systems are facing high challenges and trying to do their best in order to stop the spreading of the virus and also keep a closer monitoring and treatment for those who were infected and hospitalized in ICU's. [2]

Literature Review

The COVID-19 Crisis and its Management in the Medical/Healthcare Systems

In this pandemic context, healthcare professionals and technical support personnel are unfortunately the first-line fighters of the virus who are also the most exposed to infection. Therefore, many medical units and hospitals have adopted vital and necessary precautions in order to avoid further spread of the virus. Although through the medical world, hit by the pandemic, there were many protesting actions due to the shortage of personal protective equipment. Awareness of that issue have mobilized NGOs and private businesses to raise funds to supplement the hospital workers' needs. Also, it is very important to optimize the usage of the supplies in order to avoid the shortage explained earlier.

Operational Strategies developed in Italy - Radiology department staff measures from Milan, Parma, Bologna, Rome Hospitals

There were introduced operations and measures to facilitate the triage of patients and to make disinfection of the rooms and equipment more efficient:

- Special isolated rooms were established in order to provide CT scans to suspected or confirmed COVID-19 patients, including console and examination room for both X-ray and CT. The equipment in these rooms should be covered with waterproof protective material. The personnel working in these areas should wear personnel protective equipment PPE: waterproof gowns, as well as surgical masks, gloves. Special training regarding the correct way of dressing and undressing the PPE and sanitization of surfaces ought to be performed.
- Patients have to wear surgical masks at all times.
- Patients with diagnosed COVID-19 should not be mixed with those that are suspects during examination
- Items which were not essential were moved to allow simpler sanitization.
- For suspected and confirmed infections, a dedicated pathway to perform radiological examinations to be planned, along with the appropriate sanitization scheduling for the equipment, as all equipment ought to be sanitized after suspected or confirmed patients were in contact with them (e.g. CT or X-Ray equipment).
- Dedicated mobile X-Ray units should be utilized for imaging of the suspected or confirmed COVID-19 cases, especially in the intensive care ward and high isolation therapies ward (COVID Units). [3]

Operational Strategies developed in China - West China Hospital of Sichuan University

- The conductors of the study used WHO guidelines in order to categorize and diagnosing COVID-19 via CT scans and treatment plans elaborate by their National Health Commission NHC.
- Suspected patients with the virus, may undergo chest CT. Isolation and barrier procedures are necessary to protect department staff from other patients in the hospital [4].
- The hospital provide personal protective equipment (medical protective clothing, surgical caps, N95 mask, gloves, face shields, an googles) to all its workers who are in first line. Also, in the parking lot were created medical tents for better screening of symptomatic patients, examine areas for patients suspecting that harboring the virus, and place confirmed patients in isolation ward. They have also established separate means of access in the hospital building and fever tents in order to prevent cross-contamination.
- The emergency management and infection control measures, and the implemented plan in the radiology department during the outbreak, have been approved by the infection control committee of the hospital. These measures are in accordance with relevant laws and regulations to protect patients as well as the staff:
- Radiology Emergency Management and Infection Control Team (EMICT) which include deputy director, chief technologist, head nurse, equipment engineer supervisor, infection control nurse.

- Team responsibilities include:

  - Coordination between the hospital's management and planning of infection control and hospital departments (including radiology).
  - Collection of up-to-date information in order to elaborate material to educate and train department staff.
  - Reallocation of staff according to current and future situations.
  - Establishment of an emergency plan to ensure safety and order in hospital daily operations.

Operational strategies developed in Singapore

Strategy 1—Equipment and Manpower Readiness
Similar to the SARS outbreak in 2003, hospital's EMD (emergency department) have set outdoor extensions of tents ("fever facilities") with portable radiography services effectively triage patients. The immediate priority is to identify patients with symptoms concerning for COVID-19 with or without relevant contact or travel history, which is updated daily by local health authorities according to global situation and manage them separately from low-risk patients to minimize disease transmission.

The hospital also experienced a large nee for manpower due to the following factors:
Increased workload in certain modalities (e.g. Portable CXRs) with necessary quick turn-around times.
Increased time required to perform procedures for case suspects due to additional precautions required.
Limitation of staff cross-coverage due to team segregation strategies

Strategy 2—Strict Infection Control
Strict Adherence to PPE Guidelines - All staff are required to wear surgical masks when on clinical duty. The use of PPE with fluid-resistant characteristics, disposable gloves with coverage over gown cuff, eye protection (including face shields or goggles), and fit-tested N95 or higher face mask is mandatory when handling suspected or confirmed COVID-19 patients. The department also advocates the double glove practice with the outermost layer of gloves changed between every patient. The inner layer of gloves are not removed when cleaning surfaces that had patient contact to minimize the risk of contact transmission [5].

Strategy 3—Team Segregation (Physical and Temporal)
Gaining experience from the SARS outbreak in 2003, local radiology departments have adopted team segregation strategies to: reduce risk of human-to-human transmission with team quarantine in the event of staff infection and (2) maintaining the capabilities to meet the hospital needs. The department is hence split into independent teams, each comprising of selected individuals with different skill sets (i.e., radiologists, radiographers, nurses) to serve the daily hospital needs. In our institution, we adopted a combination of temporal and physical segregation strategies.

Strategy 4—Limitation of Staff Interactions
Although physical segregation of radiology staff serves to limit intra department staff interactions, additional steps can be implemented to limit interdepartmental staff interactions. These interdepartmental interactions may be unscheduled interactions, such as doctors coming to the department for urgent scans request or discussion, or scheduled interactions, such as multidisciplinary meetings. Scheduled interactions, such as multidisciplinary meetings, are performed through third party video-conferencing applications (e.g., Zoom [San Jose, California]) to facilitate complex patient care discussions, while maintaining physical segregation.

On a social level, lunch meetings and after-office-hours social gatherings between colleagues are discouraged during this period, as is attendance at professional conferences and seminars. This is to minimize congregation of health care workers from different institutions or different countries. [6]

COVID-19 Crisis in the Romanian Healthcare System

All health units in the public and private system have the obligation to ensure the provision of medical care to all patients, in accordance with the provisions of the approved plan of measures. The refusal to ensure the provision of medical care according to the specific attributions is sanctioned according to the legal provisions.

As a first step, designated support hospitals are non-emergency medical units that can provide medical care for other medical and surgical emergencies. Included in the network of support hospitals, municipal / city units and hospitals in other counties mainly those with Infectious Diseases departments, as well as hospitals in other networks than the Ministry of Health (Ministry of Transport, Ministry of National Defense, private health units).

In the context of COVID-19, personal protective equipment should be used based on the risk of exposure (e.g. type of activity) and the transmission dynamics of the pathogen (e.g. contact, drops or aerosols).

The type of PPE used when caring for patients with COVID-19 will vary depending on the situation, healthcare staff and work carried out. Medical personnel involved in the direct care of patients should use the following PPE: gowns, gloves, mask and eye protection (goggles or face shield).

Specifically, for aerosol-generating procedures for patients with COVID-19 (e.g. intubation, noninvasive ventilation, tracheostomy, cardiopulmonary resuscitation, manual ventilation before intubation, bronchoscopy, gastroscopy, and COVID PCR testing) medical personnel should use as protection, gloves, gowns, masks FFP2 and FFP3; waterproof aprons will also be used if overalls / gowns are not waterproof.

Evaluation of current situation via open question questionnaire poll

In order to do a proper screening of the current situation of the pandemic, we consider that the best tool to bring a statistical both qualitative and quantitative is to formulate open questions addressed to both healthcare professionals and simple citizens or patients. [7]

Data interpretation from the online launched surveys:

The questions listed below were uploaded on Google Forms and distributed on different channels, most of them online – Facebook and LinkedIn groups in order to reach the target audience (especially healthcare professionals).

The number of study participants varied depending on the target audience group – for healthcare workers we reached a number of 35 respondents vs 76 respondents on the general audience survey. It was much easier to reach and share the study to regular people via multiple channels and my network of people; instead, healthcare workers were more difficult to reach and attract their eagerness to respond.

COVID-19 Survey for the general audience

1. How old are you? (open)

63.2 % of the respondents for the general audience survey were aged between 20 and 30, which is plausible regarding my age reported to my social network. 1.3% are aged between 15-20, so just 1 high-school teen-aged respondent (so not much interest of this age segment), between 30-40, 11.8%, 9 respondents, 40-50 10.5% 8 respondents, over 50, 13.2 % 10 respondents.

2. Please provide your country of origin.

Geographically, it can be observed that social media can be a great tool to create long distances pipelines of feedback. Obviously, the majority of my network is established in Romania, 69 respondents (91%) and the rest of the world which one candidate of each country, except Germany where were two respondents (USA 1, UAE 1, France 1, Spain 1, Turkey 1).

3. The thought of illness scares me. (1-5; 1 – No, 5 - Yes)

The majority of 32 respondents (42.1%) considered that the level of fear (from 1 to 5) is medium scaled.

4. Do you think that you had/have/will have problems at your current job due to the crisis generated by the pandemic? (1-5; 1 – No, 5 - Yes)

The majority (28 respondents - 37%) affirmed that the job loss is less probable to happen, and only 18.4% are seeing the pandemic as a catalyzer for their businesses and jobs.

5. I feel good and safe when I action to prevent COVID-19. (1-5; 1 – No, 5 - Yes)

The majority of 35 respondents (46.1%) chose 3 from 1-5 scale, probably because they sense a slightly discomfort in order to keep themselves safe (wearing mask and disinfect hands, belongings, house, every time) when in the normal non-pandemic times, there were not so many guidelines and sanitation recommendations.

6. Do you believe the citizens have settled in the current situation and follow the rules and regulations? (1-5; 1 – No, 5 - Yes)

There is an interesting fact of the results of this topic, as many people and fellow citizens are not following the recommendations from the authorities and acted irresponsibly, getting fined; more than 50% of the respondents (levels 1 and 2) have noticed the same problems.

7. Are you well informed or do you follow news feeds regarding COVID-19 updates? (1-5; 1 – No, 5 - Yes)

There is no doubt that nowadays people and audience in general get very easy access to information and get in touch with the news feed even if they are voluntarily watching/listening or not. Therefore, most of the respondents are updated with the situation of the pandemic.

8. Which source of information do you use? (multiple choice)

Regarding the sources of information, it depends on the age and level of education of respondents. While the elderly Romanian population consider more accessible to watch TV to gather their information and TV information is not all the time transparent and well researched, the younger segment prefers to search into detail the statistics and details.

In this case, the majority prefer Social Media & TV to get informed regarding the pandemic, while 35 respondents also use scientific papers to enrich their knowledge of COVID-19.

9. Do you consider quarantine a fair measure for a person who contact an infected one? (1-5; 1 – No, 5 - Yes)

Quarantine is considered the right and fair measure by 61.8% of respondents, and few of them considered that is not that necessarily to respect the quarantine. That is the first mistake in managing this pandemic by the population side. It is true that most of the people are feeling constrained by the measures imposed, but in order to eradicate the new blooming cases of infected people, the population must understand the necessity of this measures, imposed for their healthiness.

10. On a scale 1-5, how much do you adopt the behavior and measures to prevent the COVID-19 spread?

A previous question in the survey was centered on how good people feel in acting to prevent the disease from spreading. Here, most of respondents 47.4%, act and take preventive measures against COVID-19, but their actions are most likely based on fear.

11. Do you believe the authorities have adopted the all right measures? (1-5; 1 – No, 5 - Yes)

There is no doubt that most of the governments worldwide have taken care to implement emergency and action plans to fight against the virus, even though in some countries the measures have been implemented much later that in others. Still, the respondents think that the measures adopted have been fair and imperative.

12. Is there place for better measures or lessons to be learnt? (open short 2-3 sentences)

Some of the answers given are focused on science-based approaches for treating COVID-19 patients and preventing the disease from spreading. More tests done on a daily basis, more PPE stocks for the medical personnel and avoiding fake news and panic are also suggested as measures for improvement.

13. Have you reached psychological assistance since the beginning of the outbreak until the present time? (yes, no)

Considering the psychological impact of the pandemic, some of the population have gone into mental breakdown due to economic crisis, business' fall downs, and job losses, but most of the respondents were from Romania, and here the crisis has not such a great impact like in the US for instance, therefore most of the respondents did not appeal to or seek for psychological assistance or therapy.

COVID-19 Survey for the healthcare professionals

1. How old are you?

As far as the age of respondents, the young medical workers aged from 20 to 40 are the majority category who responded to this study.

2. Please provide your country of origin.

As in the previous survey, the majority of healthcare workers who responded are from Romania - 31, and a few spread in Health/Medical Centers Worldwide (2 from Canada, 1 South Africa and 1 from Germany).

3. Please select the appropriate category of the hospital in which you are employed.

As the chart shows, there are many types of centers involved in the healthcare system and patient care in the context of the COVID-19 pandemic. The majority of healthcare workers are hired in private centers (28.6%), where the measures are slightly mild compared public hospitals. On the second place, with 22.9%, are workers from University Hospitals.

4. Is there an emergency protocol adopted for treatment/prevention of medical staff in your hospital? (yes/no)

As shown, most of the Healthcare Units have adopted a plan for prevention for their medical staff in proportion of 88.6%.

5. Do you consider that this protocol helps prevent the spread of disease among yourself and your colleagues? (1-5; 1 – No, 5 - Yes)

The workers consider that the protocol mentioned earlier is efficient in order to protect them in doing their daily shift activities.

6. Did your managers provide PPE for hospital workers? (yes/no)

For this protocol to work, the managers from healthcare units have to provide, as a mandatory task, PPE for their employees; in the majority centers from which the respondents are, this task was performed.

7. Do you consider the PPE provide efficient and qualitative? (1-5; 1 – No, 5 - Yes)

Very important is the quality of the PPE provided to the workers, in order not to get infected. Almost all the participants have received good quality materials.

8. Did your hospital treat COVID-19 patients? (yes/no)

Only 10 respondents (28.6 %) have confronted with COVID-19 cases and plans of treatment for their infected patients.

9. If yes, how many?

Most of respondents' centers (67%) have treated a small number of infected patients, between 1-50 patients, 8% treated between 50 and 100, 17% treated between 100 and 200, and 8% had above 200 cases.

10. Which measures would you add to or remove from the protocol implemented in your hospital?

Many recommendations were made, the most important being:

- Accommodation provided for medical personnel;
- 48h waiting time before surgery, even if the PCR test of the patient is negative;
- Relaxation/break room for the medical personnel;
- Before being admitted to the hospital, patients should be tested;
- Making the removal of the contaminated gear clear in the protocols;
- Clearly specifying the correct disinfection substances;
- Better triage of the medical personnel and the patients.

11. Have you got an option of accommodation in case you do not want to return to your family after finishing the shift?

Here is a debatable topic: not all hospitals have provided accommodation for their workers as it was imposed by the authorities; 42.9% of the participants had to return home to their families, with a high risk of contaminating or infecting them.

12. Do hospital workers have access to psychological assistance?

A very important aspect is for hospital managers is to offer to their workers psychological assistance, because in emergency state, things can go in a very stressful way for worker on a daily basis shift. The ratio is 51 to 49 in favor for those participants who can benefit from this therapy sessions.

Data Interpretation – SWOT Analysis

After reviewing the recommendations and feedback receive from both parties, the inputs were transformed in a SWOT analysis, to have a clearer picture of the actual situation [8][9].

Strengths:

- Fast response of the state officials to the COVID-19 crisis, fast implementations of rules, regulations and lockdown – head start vs Spain, Italy, France, US, Brazil (for states with lower cases of confirmed cases of infected/deaths).
- Well implemented awareness campaigns on social media and TV to respect the measures and adopt proper hygiene and disinfection.

Weaknesses:

- Stocks of certain materials (PPE).
- Misconduct of and lack of leadership in healthcare organizations.
- Not enough tests performed for the general population on a daily basis by healthcare system.
- Late reaction in closing the borders to help prevent the infection
- Fear caused the authorities and law enforcement by applying severe measures against the citizens, and not trying to implement an approach based on education.

- Low mental health for people seriously affected by the crisis (jobs loss, shut down of business', etc.
- Restricting certain rights and freedoms of citizens during the pandemic can provoke certain revolt and dissatisfaction reactions towards the authorities.
- Poor system funding in order to fight the pandemic, especially in emerging and underdeveloped countries.
- Poor adaptability for population and authorities if the wave of infections reaches high peaks.

Opportunity:

- More tests among the population.
- Education and better understanding the measures proposed and implemented by state officials.
- Social distancing by physical outdoor activities in small groups, not for partying and large venue activities.
- Combating fake news and panic spread; more transparency about all pandemic related topics; better flagging on social media.
- Better mobilizing the law enforcement.
- Psychological assistance programs for the citizens in need for discussing their mental issues and give population hope.
- Hygiene products to be offered for free to the population with a lower income by the government.
- Home monitoring for infected patients

Threats:

- Stocks of certain materials (PPE).
- Misconduct of and lack of leadership in healthcare organizations.
- Lack of population perception to the rules and regulations implemented by the authorities
- Fake news propaganda, and lack of transparency in some TV Journal programs.

Conclusions

The critical point has been reached in the health system and now more than ever we need new players, especially leaders, to adopt and propose creativity, innovation, thinking and entrepreneurial behavior as a major catalyst to achieve positive change in our health care system and delivery of healthcare.
Entrepreneurial activities should be used by healthcare organizations to improve organizational growth and profitability and should be promoted as a means to achieve more efficient, flexible and adaptable management in external environments competitive and turbulent.

Different healthcare systems across the globe, encourage corporate entrepreneurship at all levels. Entrepreneurship and healthcare are linked with bonds which propose improved business practices, professionals and resource allocation (price/service, product ratio), in order to deliver the best solutions in patient care. Therefore, entrepreneurship is moving the healthcare industry forward, it has to evolve and keep the trending at higher levels.

The COVID-19 pandemic was and is, beside a catastrophe, a starting point for healthcare organizations and the individuals with entrepreneurial skills and abilities to help improve the system as a whole. Many more challenges will be faced, not only by the healthcare systems around the globe, but by humanity entirely; corporate entrepreneurship will ensure the survival of industries and individuals – improvise, adapt, overcome.

Abstract

State-owned enterprises (SOEs) play a notable role in the economy representing an important part of the whole government activities, performance and financial position. The analysis of the role of state's control over productive property in progressive restructuring of market-based economies figures largely in heterodox economics discourse. That is why research that clarifies what should be categorized as a SOE is of unquestionable importance for scholars researching the subject and working with data on SOEs. In achieving the objective of this research, a qualitative analysis was conducted using organized, transparent, and replicable procedures at each step in the process. By comparing and discussing different academic definitions of SOEs, we identified the key elements that should be used in defining SOEs: ownership, control, activity, objective, legal form. Furthermore, our work has proposed an explicit, neutral, reliable, transparent and rigorous layout for defining SOEs based on the previous literature.

Keywords: State-owned enterprises, governance, performance, accountability.

Introduction

Transferring public service provision to state-owned enterprises (SOEs) raises concerns over accountability deficits (Klausen, Winsvold, 2019). The importance of SOEs on global market, but also on a state economy is crystal clear for economists, politicians, and area researchers. Despite of massive privatization efforts during the past decades, the state often retains a central role in some sectors of the economy, especially utilities and infrastructure (Ennser, 2014). The share of gross domestic product (GDP) contributed by state-owned enterprises (SOEs) still represent an important part for the global markets. More than 10% of the world's largest firms are state-owned coming from 37 different countries and their joint sales represents more than 6% of world GDP (Buge et al., 2013). In Organisation for Economic Co-Operation and Development (OECD) countries, the value of SOEs is more than 2 trillion USD and employ over 6 million people even if they represent only 2.5% of national employment on average. In the majority of economies, the SOEs are highly concentrated in strategic sectors on which large parts of the private economy depend, and half of SOEs by value operate in the network industries (telecoms, electricity and gas, transportation and postal services) (OECD, 2014). There is the belief that SOEs are and will be an important part of economies, especially in developing economies (Papenfus et al. 2019; Ennser-Jedernastik, 2014) and former communist countries.

Previous academic studies have broadly analysed the research patterns on public administration and management (Bruton et al., 2015) focused on the more general stream of literature on privatization and nationalization reform (Murray, 2010), or alternatively, on the SOEs' role in economies (Buge et al., 2013; Papenfuss and Schmidt, 2015). The impact of incentive structures on SOEs performance (Ulf et al, 2020), the theory of SOEs in the market economy or the balance between the quality and the quantity of innovations developed in SOEs (Jia et al., 2019) are also covered topics. Privatization reform is seen as an improvement of SOEs' governance, as a step prior to private sector participation (Murray, 2010), and performance (Aivazian et al., 2005). Contrarily, others consider that privatization is not the sole right solution for restructuring public enterprises. They argue that services could be more efficient if provided by for-

profit entities, rather than subject to ministerial control and government interference (Luke, 2010). The nationalization of some traditional public service activities is another topic of interests for researchers. Several governments' temporary nationalised private companies (banks, manufacturers) to face the economic crisis better (Bernier, 2011). For example, in Italy, SOEs appeared on the strength of financial issues (Antonelli et al., 2014; Rinaldi et al., 2012). In the UK, their origins are related to the problem of merging utility networks (Millward, 2011), while Canada uses SOEs to exploit their natural resources and develop various industries that the private sector was not naturally inclined to create (Bernier, 2011).

Despite the relevant body of literature on SOEs and the wide variety of research findings, surprisingly there has not been any systematization of the knowledge regarding SOEs definitions. The defining concern of the SOEs concept has played only a marginal role in the previous researches. The unquestionable importance for scholars and practitioners researching or working with data on SOEs is endorsed by the progressive restructuring of market-based economies. The state's control over productive property figures largely in heterodox economies discourse. These challenges were the starting point for a literature review intended to examine the understanding of SOEs' concept in various research areas and to offer a definition that includes a multitude of research streams.

The novelty of the study is circumscribed to the idea that SOEs are and will be an important part of economies. Through our proposed layout that comprise the main characteristics of SOEs, we offer support in delineating the boundaries of their sectors. We consider that this research based on a multi-disciplinary approach and a broad range of perspective will be especially used by emerging countries that, as all the other countries, need to have clearly delimited the sectors and, most of the time they do not have the necessary resources as professional bodies, qualified personnel, to fulfil their obligations as regulators. This brings us to the outline of this article. After an introduction which describes the current state-of-art and the importance of the study, we derive for the methodology used to achieve the aim of the paper. Further, section 3, comprises the research results highlighting aspects concerning SOEs definition. Conclusions to the study follow in the final section.

Methodological Approach

The analysis of the role of state's control over productive property in progressive restructuring of market-based economies figures largely in heterodox economics discourse. That is why research that clarifies what should be categorized as a SOE is of unquestionable importance for scholars researching the subject and working with data on state-owned entities. In achieving the objective of this research, a qualitative analysis was conducted. Through a descriptive and thematic investigations, our review provides an interdisciplinary and an international overview of current understanding of the SOEs appellations, definitions/ key elements and characteristics.

A preliminary step was performed aiming to determine what labels were the most used when referring to these types of enterprises. The result of the preliminary step was that the most commonly used terminology is "state-owned enterprises"/"SOE". The methodological approach used in order to analyse the academicians' point of view presumes four steps. First, a selection of papers was performed, based on relevant keywords: "state-owned enterprises" and "SOE". We carried out an electronic search in WOS and screened the studies by scanning the abstracts and titles. In the second step, we screened studies by reading the full abstracts and/or text. We were interested in discovering the different contributions from the research areas: business administrations and public administrations (Mauro et al., 2016), the most relevant disciplines in studies approaching SOEs considering their pattern of activating at the intersection of sectors (Grossi and Steccolini, 2015). Previous studies reveal that governments are directing more attention and spending more resources on the improvement of their system of governance, accountability and performance measurement and management (Broadbent and Guthrie, 2008; Mauro et al., 2016). Consequently, the enthusiasm of previous research should gravitate around governance, performance, and accountability to be included in this analysis. The third step in data-gathering, consisted in reading the full text of the studies included in this investigation in order to eliminate the loosely focused papers. The last step consisted in analysing three types of information: bibliographical, methodological, and manner of defining SOEs.

Findings and discussions concerning SOEs

The variety of terms used in literature

The process of defining the concept of "state-owned enterprises" is quite laborious and exciting, as countries differ with respect to the range of institutions that they consider as state-owned enterprises, and these types of companies are found under various names and several entities are described as SOEs. We looked for related terms and how these terms were defined.

One of the first conclusion of the investigation reveals the fact that depending on the country, different terms are used when referring to SOEs. Although, the enterprises where the state has ownerships are common, the terminology often differs from country to country. For example, European countries such as Greece, Norway, Germany, Ireland, Italy, Austria, Switzerland, UK, Estonia use the terminology "state-owned enterprises" (Burnes, 2004; Ongaro et al., 2008; Tonurist, 2015; Wettenhall, 2005), while non-European countries use the following terms: government-linked companies (GLC) in Malaysia (Roper and Schoenberger-Orgad, 2011), government-owned companies (GOCs) or SOEs in New Zealand, government business enterprises (GBEs) in Australia, crown corporations in Canada, public sector undertaking in India, government-sponsored enterprises in USA (Stan et al., 2014). Research also exposes the use of public organizations (Bolivar, 2007), public enterprises (Millward, 2011; Wettenhall, 2004), state ownership of public utilities (Parker, 1999), public corporations (Atkinson and Paschall, 2011) and hybrid organisation (Argento et al., 2019, Stecker, 2014). Taking into account the fact that SOEs is the most frequently used term among those listed above, we decided to focus our study on discussing the SOE concept, but not before saying a few words about the other widely used terms in the literature: "government business enterprises", "public enterprises" and "hybrid organizations".

Government business enterprises are defined as "public companies limited by shares and organised under corporate law" (Wettenhall, 1998), "involved in international activities" (Wettenhall, 1992) which "had to compete against the private sector" (Coates, 1990). Analysing the definition used by Coates and Wettenhall, it can be observed that government business enterprises are not recognised as a part of the public sector. Due to the changes that arose through public sector reforms, they started to apply and to be organised under private law. In our opinion, even so, government business enterprises are public companies which act at the intersection of public and private sector, because the public ownership requires more than in the private sector. It implies social responsibility for their decisions, trust for their actions and transparency for the use of public money.

Some authors are using the notion of "public enterprises" when referring to SOEs. Thynne and Wetternhall (2001) state that it is inaccurate the use of the term "public enterprises" in referring to a particular organizational category. Public enterprises are "established through regular company formation procedures" (Wettenhall, 2005) and represent a "functional category conducted by government (national, regional or local level) or another non-departmental-organization, with functions such as commercial, executive, regulatory, adjudicative, appellate or advisory" (Wettenhall, 2004). Thynne and Wetternhall and Grossi et al. (2019) highlight through the definition provided the interdisciplinary character of SOEs. Another important aspect endorsed by them, but disapproved by others, refers to the fact that public enterprises are conducted by governments. The first consequence of these contradictory statements leads to important gaps in identification, definition and organisation of these types of companies.

From another point of view, SOEs are considered "hybrid organizations that have elements of state ownership and control on one hand and private participation in ownership and control on the other" (Bauwens et al., 2020; Bruton et al., 2015). Being created by the government (Koppell, 2007) and operating in both the market and public sector (Grossi and Thomasson, 2015), these hybrid organisations are structured and managed according to the private sector but created to address public needs, in an attempt to increase the efficiency of the public sector (Cornforth, 2020; Thomasson, 2009). With a long history in the USA, they were designed to accomplish specific policy objectives, while achieving performance requirements related to the policy objectives (Koppell, 2007). The term used by Bruton, Koppell, Grossi and Thomasson focuses and succeeds highlighting the position of these type of companies into the public and private sector. Moreover, through the term "hybrid" they recognise not only the positioning element, but also the activity (split between market and public sector) and legal form element (created by governments, but organised according to the corporate law).

How are SOEs defined by academicians?

Some authors prefer to define the concept of SOEs using the definitions provided by international organizations (Kloviene and Gimzauskiene, 2014), while others define the concept using key elements as ownership, control, objective, activity, legal form (Avsar et al.,2013; Bajona et al.,2010; Collins et al.,2013; Du et al.,2012; Ho, 2012; Holz, 2011). Even if the definitions provided by authors usually approach the term by combining at least two of the identified key elements, SOEs are non-uniformly understood and defined by researchers.

A broad definition of the concept is given by Bozec et al. (2004, 2007), who indicate the connection between the governments and SOEs by nominating them as arm's length corporate companies. In both articles (2004 and 2007), the authors define SOEs as companies established to pursue public policy and commercial objectives, highlighting their ability to operate in many important sectors, aiming to provide services and goods to the consumer. Considering the fact that Bozec et al (2004, 2007) argue that SOEs are not exposed to pressure from the stock market, we can deduce that even if a SOEs could have commercial activities, they still have a special statute in the public sector and their commercial characteristic definitely doesn't imply the same obligations and rights like in the private sector. Goldeng et al. (2008) also present a rather broad definition, which additionally highlights the non-economic goals followed by governments through these types of entities, such as the need for public control over natural resources, employment or social issues.

Another definition is provided by Lawson (1994) and Lin et al. (2003) who define SOEs from control and ownership perspective. They consider that the ownership characteristic may be insufficient in practice, complementing the definition based on ownership criteria with another one grounded on the control characteristic. In other words, SOEs are defined as enterprises either partially or totally owned by the state, in which control is exercised directly by the government when it comes to major policy changes or delegated to the SOEs board's members (Li et al., 2014; Papenfuss, 2014; Siqueira et al.,2009; Wang, 2013; Wettenhall et al.,2009; Zhu et al.,2007).

Even if researchers provide definitions of the concept using key elements as ownership, objectives, control and legal form, we were able to identify on one hand, important restrictive criteria, and on the other hand several controversial issues. The discussions are presented in the following section in a structured manner depending on the key elements.

(a) Ownership

One of the most studied elements of defining relates to ownership criteria. Based on our analysis we identified three different approaches related to the ownership structure. The first approach recognises as SOEs only those entities that are wholly owned by the government (Bird, 2015). By introducing the restrictive criteria of state ownership (100%), significant enterprises that still meet all other criteria are not recognised as SOEs, and consequently the whole picture of the sector is patently distorted. The second approach focuses on SOEs as companies partially owned by the governments, introducing the hybrid character of SOEs. Hybrid SOEs have elements of state ownership on one hand and private participation in ownership on the other hand (Bruton et al., 2015). Even if, this approach is less used by researchers, scholars should devote additional attention to this organizational form that generates significant revenues and represents some of the world's largest firms (Bruton et al., 2015). A more permissive approach is the third one, being the most widely used from the sampled studies (Belloc, 2014; Chan, 2009; Chiwamit et al.,2014; Ding, 2014; Hertog, 2010; MacCarthaigh, 2011; O'Conner et al.,2004, 2006; Stan et al.,2014; Sun et al.,2005; Wang, 2014). From our point of view is a more reliable approach, considering that it acknowledges both types of state ownership (totally or partially).

(b) Control

For the analysis regarding the control criteria of our pool of papers, we refer to our bibliographic analysis, which shows that the publications focus on two different types of control: direct (Millward, 2011; Sun et al., 2005; Wang, 2014) and indirect (Lawson, 1994). The differences between direct and indirect control is that under the first, government has the power to set the organizational, social and political objective of the SOEs, while under the second, SOEs would not be (anymore) to government control. As subject of indirect control, SOEs are transformed from integral part of state-bureaucracy into legal independent entities, entailing substantial delegation of decision-making rights (Chiwamit et al., 2014; Hauptman et al., 2015). Party-state control of SOEs is a puzzle to many researchers (Chan, 2009; Chiwamit et al.,

2014; Cooke, 2006; Goldeng et al.,2008; Sun et al.,2005). For example, Bird (2015) highlights the influences of party-state control and how it works: governments still have the power to control the long-term policies of the subjected SOE, while the board is responsible for the sort-term strategies. There is a belief that due to economic difficulties, the state often cannot fully support these activities, resulting in a mixture of public and private ownership. However, it is crucial that the state remains in control, being able to intervene when deemed necessary to do so, in order to defend national interests. In other words, using control key element, SOEs can be defined as enterprises either partially or totally owned by the state, in which control is exercised directly by the government when it comes to major policy changes or delegated to the SOEs board's members.

(c) Activity

The activity criterion is another key element used by researchers in defining SOEs. We were able to identify two types of activities used by researchers in defining the concept: commercial activities and non-commercial activities. Although, SOEs were created to pursue goals other than profit maximization (Enderle, 2001), they became much more (yet not completely) market-oriented (Cooke, 2006). A common insight derived from the studies is that researchers have disagreed on the SOE's activity. On one hand, Goldeng et al. (2008) and Sun et al. (2005) reported that SOEs are entities with a large number of social/political roles and obligations, recognising (only) the non-commercial type of activity. Chiwamit et al. (2014), MacCarthaigh (2011), Morsing (2011), O'Conner et al. (2004, 2006) defined SOEs using the commercial type of activity. However, a considerable number of studies recognised both types of activities undertaken by SOEs in practice (Bozec et al., 2004, 2007; Bird, 2015; Chan, 2009; Kankaanpaa et al., 2014; Stan et al.,2014). In our opinion, it is the most reliable approach, because, SOEs are still fundamental enterprises with high strategic importance for national security, and domestic and economic livelihood (Chan, 2009). Even if SOEs were initially created to achieve either non-commercial or commercial objectives, we believe that in order to provide a comprehensive definition of this type of public entities, it is more appropriate to consider both types of activities.

(d) Legal form

Despite the highlighted interest in studying SOE's ownership and control, it is surprising that the legal form characteristic has attracted such limited research attention in the scholarly literature. The practices demonstrate the use of one specific regulation for this kind of enterprises or the use of corporate law. On this matter, Wang (2014) recognises that SOEs are regulated by the corporate legislation, while Morsing (2011) argue that SOEs should comply with a legal framework tailored in accordance to their specific characteristics. Even if, for the purpose of this paper we are considering both types of legal form, we consider that the most appropriate form of regulation is the second one, the specific regulation. SOEs are unique, essential and complex public entities, which ask for, and should embrace a specific regulation.

(e) Objective

By analysing the studies focused on state-owned enterprises, we were able to identify that SOEs could have economic, social, and/or political objectives. There is the belief that SOEs are instruments of their holders to meet their political objectives, promoting social and political unification, securing national defence and related to strategic considerations (Bozec et al.,2004, 2007; Chan, 2009). On the other hand, SOEs are recognised as useful strategies to pursue social goals (Goldeng et al., 2008; Koppell, 2007), while others define SOEs recognising only their economic/commercial objective (MacCarthaigh, 2011). A broader approach that perceives SOEs as entities with mixed objective is endorsed by Bird (2015) -economic and political; Bruton (2015), Millward (2011), Stan et al.(2014) -social, economic, political; Morsing (2011) -social, economic; Sappington et al.(2003) -it should be mainly social objectives; Sun et al.(2005) – mixed objectives only for "partially privatized" SOEs. Even if the authors recognise the mixed objective of SOEs, some of them highlighted one of goals as being principal. For example, Sappington et al (2003) focused on the social objective as essential, while O'Connor et al. (2006) displayed the commercial objective. So, SOEs serve economic, political and socio-economical spheres of society, reflecting the multi-purpose reality on society (Enderle, 2001).

Conclusions

As markets where SOEs operate become increasingly competitive, the role of state's control over productive property in progressive reorganisation of market-based economies figures largely in heterodox economics discourse. Our study aimed to determine what type of entities should be categorized as a state-owned enterprise is of unquestionable

importance for scholars and practitioners focusing the subject and working with data on SOEs. By comparing and discussing different academic definitions of SOEs, we identified the key elements that should be used in defining SOEs: ownership, control, activity, objective, legal form. Furthermore, our work has proposed an explicit, neutral, reliable, transparent and rigorous framework for defining SOEs based on the previous literature.

The brief overview of main features of the SOE may help identify and clarify a number of critical issues, which led to the proposal below (Figure 1). The importance of the layout (Figure 1) could be explained as follows. First, the ups and downs of the reform process of SOEs over the last decades generated a wide range of variants of SOEs. Second, the questionable role of SOEs in providing public policy functions and the extent of government business activities in economy led to important gaps in terms of governance, transparency and accountability. Third, a proper definition for SOEs will positively affect research on SOEs and help countries understand how such organisations can play key economic and development roles (Buge et al.,2013). Forth, the generally and neutrally proposed layout is meant to capture the entire casuistry, useful for future studies approaching the macroeconomic and microeconomic areas, as well as commercial or even public sector studies.

The results of this study show that scientific literature authors prefer to use one of these definitions or they are just describing the term. Although a definition is not provided, they focus in the effects of reforms or events that affected SOEs, on explaining SOEs through their importance in the economy, their role and the way they operate. The terminology used by academicians is state-owned enterprises, government business enterprises and crown corporations.

The imperative achievement of the study is that the main features of SOEs identified through this investigation must be used altogether both by practitioners and academicians in referring to SOEs. The definitions of SOEs provided by academicians have a comprehensive approach linking different key elements, but most of the times, no more than two or three key characteristics. For example, the researchers who address topics as governance and performance in their research provide complex, but not restrictive definitions, while researchers who discuss topics as accounting and accountability treat the concept in a restrictive way, providing simpler definitions, and often using criteria as ownership and control.

The results of the paper are relevant both for scholars and practitioners, as it clarifies aspects regarding the complex topic of SOEs. Besides, acknowledging that there is a shortage of research on SOEs concept, it closes the gap in the literature related to the existence of an article focused on the definition on this term. The studies selected for this review provide insights on the challenges faced by governments in different settings, therefore the results of this investigation might be generalized at international level. Through our proposed layout that comprise the characteristics of SOEs we offer support in delineating the boundaries of the sectors. However, further research in the area of SOEs concept is still needed. There is still limited insight on the appropriate design and influences of interfaces between theory and context. Moreover, the influence of SOEs on consolidated financial statements in the public sector could be further researched.

Abstract

Different systems and processes such as proportional valves, temperature regulators, motors, etc. require certain controllers for optimum performance; compared to common controllers, the fractional PID controller provides the optimal solution for these systems because they have memory, quick answers and few errors. Various evolutionary algorithms can be used to optimize the parameters of the fractional PID controller, such as artificial bee colony irony (ABC), particle swarm optimization (PSO), genetic algorithm (GA), etc. In order to optimize our performance, we will implement these algorithms in different ways and we'll compare to the classic mode of operation of the controllers. These implementations and trials are based on code sequences in different languages such as python, c++, matlab, based on which results we can prove why these algorithms are an optimal solution. Different system components are modified within the PSO algorithm, optimizing some properties such as configuration or location.

Keywords: PID controller, fractional calculus, Swarm particle, PSO algorithm.

Introduction

PID controllers are well known and used in power system control applications, making it simple to do and easy to adjust. These controllers are commonly used to cushion system oscillation, increase stability and reduce errors in a constant state. These controllers are full order controllers because the part of its derivative is integral to these controllers. The fractional pid regulator consists of five parameters kVp, ki, kd, λ and μ. The comparison between the normal PID regulator and controller is complete and the features are studied in detail. Different algorithms such as the PSO algorithm (optimization

Cite this Article as: Dorian Valentin-RĂDUCAN, Cristian Constantin-ROMAN and Mihai REBENCIUC "PID Controller with Fractional Calculus" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

of particle rots) can be used to optimize fractional pid parameters. Figure 1 shows the diagram of a PID controller circuit.

Fig. 1

FRACTIONAL ORDER CONTROLLER PID

The full-differential equation defining the control action of a fractional-order PID is given by:

$$u(t) = K_p\, e(t) + K_i D^{-\lambda} e(t) + K_d D^{\mu} e(t) + \cdots \quad (1)$$

Where:

λ- "in order

μ - differential order

K_p, K_i, K_d - The parameters for the PID Controller

u(t)- control signal

e(t)- error signal

The classic proportional-integrated-derivative controller is the most used controller for industrial applications because of its simplicity in performing and adjusting. Extension of derivative and integration order from full to fractional provides more flexibility in controller design, thereby controlling the wide range of dynamics in a system.

The generalized transfer function of the fractional controller is given as:

$$C(s) = K_p + \frac{K_i}{S^{\lambda}} + K_d .s^{\mu} \quad (2)$$

A fractional integrator of the order k+α, k-based N , 0<α<1 is to perform the error cancellation.

Fractionation effect should be limited when implemented. The fractional integrator must therefore be implemented as:

$$\frac{1}{s^{\alpha}} = \frac{1}{s}\, s^{1-\alpha} \quad (3)$$

Similar to the fractional integrator, the fractional differentiator, s^{u}, the fractional differentiator must be limited when implemented. This ensures fine control effort and high requency noise rejection.

Fig. 2: Circuit regulator PID

PID CONTROLLER COMPONENTS

1. Proportional component

The proportional component (P) gives the control signal proportional to the calculated error. Using a single proportional control always provides a stationary error, unless the control signal is zero and the system process value equals the desired value.

The proportional part is given by equation (4):

$$P_{out} = k_p e(t) \tag{4}$$

2. Integral component

The integral part (I) is a previous error. The error summary will continue until the system process value equals the desired value. The integral part is usually used together with proportional in so-called PI regulators. Using the integral part only gives a slow response and often an oscillating system.

The whole part is given by equation (7):

$$I_{out} = k_i \int_0^t e(\tau) d\tau \tag{5}$$

3. Differential component

Differential component (D) is the rate of change of error. Adding this component improves the response of the system to a sudden change in its status. The differential component D is typically used with P or PI algorithms, such as PD or PID controllers. The high differential component D usually provides an unstable system.

The differential is given by equation (6):

$$D_{out} = k_d \frac{de(t)}{dt} \quad (6)$$

OPTIMIZE PID TEMPERATURE CONTROLLER PARAMETERS

1. Abc (algorithm of artificial bee colonies)

Based on the intelligent feeding behavior of bees , optimization will be done in the ABC algorithm. There are three types of bees in the model of this algorithm: Bees "employees", bees concerning and bees investigated. Colony includes half as employed bees and half of them consists of observant bees. One bee artificially engaged in one feed source. The algorithm contains the following steps:

1. For all engaged bees the initial source of feed will be produced;
2. REPEAT
3. A source will be found when each committed bee goes to the food source in the memory. Increasing it determines the amount of nectar.
4. Observant bees select their source according to the dance of engaged bees. After selecting the neighbor they go to the nectar source.
5. If new sources of feed are found by the research, abandoned food sources shall be evaluated and replacedCea mai bună sursă de hrană este înregistrată

Until the requirements are met, steps are executed.

2. Smart particulate optimization (PSO)

The aim of this optimization is to solve the problems in terms of the calculation, where it is a robust technique of acquisition based on the motion and intelligence of the wheels. It is inspired by nature from bird swarms, fish, etc. the PSO algorithm tries to copy the natural group communication process of individual knowledge, which occurs when such swarms are crowded, migrating, etc., to achieve some optimal properties such as configuration or location.

In the PSO, an roi consists of N particles moving within a dimensional D search space The random speed is assigned to each particle. Each private changes their flight based on their own experience and the attendant at each iteration. Together with ANT Colony Optimization, they form the Swarm Intelligence algorithm class.

Swarm intelligence (SI) is the collective behavior of decentralized, self-organized, natural or artificial systems. The concept is used in working on artificial intelligence. The expression was introduced by Gerardo Beni and Jing Wang in 1989 in the context of cell robotic systems.

The formulae (1) and (2) are the formulae for updating the speed and position of the particulates:

$$v_{id}^{t} = \omega \times v_{id}^{t-1} + c_1 \times r_1 \times (p_{id}^{t-1} - x_{id}^{t-1}) + c_2 \times r_2 \times \left(p_{gd}^{t-1} - x_{vd}^{t-1}\right) \quad (7)$$

$$x_{id}^{t} = x_{id}^{t-1} + v_{id}^{t} \quad (8)$$

The particle i^{th} is noted that $x_i = (x_{i1}, x_{i2} \ldots\ldots x_{id})$, whose best previous solution is as $P_i = (p_{i1}, p_{i2} \ldots\ldots p_{i2})$, the current speed (position change speed) is described as $V_i = (v_{i1}, v_{i2} \ldots\ldots v_{id})$. The best solution achieved so far by the entire roi it is represented as: $P_g\left(p_{i1}, p_{i2} \ldots\ldots\ldots p_{gd}\right)$.

At any of the steps, each private goes to the locations P_{best}, g_{best}. Fitness evaluates the performance of particles to determine if we'll get the best mounting solution.The ω is the inertia factor, c_1 and c_2 are acceleration constants; r_1 and r_2 are random numbers between zero and one; ω can be developed using the following formula:

$$\omega = \omega_{max} - \frac{\omega_{max} - \omega_{min}}{T_{max}} t \quad (9)$$

Where, ω_{max} and ω_{min} is the maximum and minimum values for the inertia factor, and T_{max} is the maximum iteration, t is the current number of iterations.

Algorithm Elements

The method consists of a group of particles moving within the search area, their trajectory being determined by the value of the best fitness found. Each particle is represented by a vector x length n indicating the position in n-dimensional space and has a speed used to update the current position. The vector velocity is calculated taking into account the following rules:

• each particle tends to retain its current direction (inertia);

• each particle is attracted by the best position on that has reached her so far;

• every particle is attracted by the best particle of the population g (or from the neighborhood).

The formulas used to update each individual in the population to iteration t+1 are:

$$v[t+1] = w_1 v[t] + w_2 rand(\,)(p - x) + w_3 rand(\,)(g - x) \quad (10)$$

$$x[t+1] = x[t] + v[t+1] \quad (11)$$

Parameters

w_2 and w_3 - learning factors - is the weight of acceleration terms that attract each particle to particles p and g

- w_2 - cognitive parameter - a tendency to duplicate past actions of its own which they have proved successful
- w_3 - social parameter - the tendency to follow the success of other individuals
- w_1 - Inertia weight - ensures the balance between exploration/exploitation; also used as a decreasing weight over time (as in Simulted Annealg)
- • maximum allowable speed - indirectly affects the ability to scan, reducing the speed value below an allowable limit.

Results

In order to better understand the two algorithms I produced a simulation in MATLAB to optimize the parameters of the fractional PID controller, and used various performance indices to arrive at more concrete answers.

Performance indices used are: ISE, IAE, ITAE, ITSE and have mathematical expressions:

1. Root root square error (ISE):

$$ISE = \int_0^\infty [e(t)]^2 dt \quad (12)$$

2. Full of the absolute value of the error (IAE):

$$IAE = \int_0^\infty e(t) dt \quad (13)$$

3. Time-weighted ITEE:

$$ITAE = \int_0^{\infty} t\big(e(t)\big)dt \tag{14}$$

4. ITSE time-weighted:

$$ITSE = \int_0^{\infty} t[e(t)]^2 dt \tag{15}$$

For simulation, we have used the parameter limits of Table 1 for k_p,k_I and k_d.

Table 1: Controller parameter limits

Limits of wins of the controller	k_p	k_i	k_d
Upper limit	0	0	0
Lower limit	10	10	10

The simulation applications have resulted in optimized parameters that are given in Table 2.

Table 2: Parameters optimized by 2 tests

System	Algorithm	Components	IAE	ISE	ITSE	ITAE
Test system 1	PSO	k_p	9.874	9.342	7.505	9.505
		k_i	8.479	8.614	9.454	5.68
		k_d	9.934	1.793	8.915	2.305
	ABC	k_p	8.602	6.405	8.580	7.331
		k_i	9.510	9.047	9.461	9.214
		k_d	1.225	1.791	7.817	1.821
Test system 2	PSO	k_p	2.093	5.782	2.277	4.591
		k_i	7.341	9.998	1.273	7.141
		k_d	0.545	1.520	1.774	1.149
	ABC	k_p	5.818	4.327	6.358	5.191
		k_i	1.483	3.026	9.998	7.119
		k_d	1.263	1.458	1.547	1.298

Also, to observe the optimization of fractional PID temperature Controller parameters, we used the MATLAB simulation to observe the deviations of that controller. These deviations are shown in the following figures.

Fig. 7: Deviation of the line power in the interconnected thermal reheating system in two zones with particle-optimization

Conclusion

- The PID control algorithm is a robust and simple algorithm that is widely used in the industry.
- PID control algorithms are popular and offer many advantages, such as ease of use, the new development helps implement other PID control and control options for common industrial applications.
- This work examined some PID implementations and how to improve system performance.
- We will then try to impose these algorithms on the "Cruise system control" of a car

Optimization of Test Case Allocation Scheme in Program Partition Testing

Kazimierz WORWA

Institute of Computer and Information Systems, Faculty of Cybernetics,
Military University of Technology, Warsaw, Poland
kazimierz.worwa@wat.edu.pl

Abstract

The issue of random testing of the program in the aspect of comparing the effectiveness of random testing and partitioning testing was considered in this paper. However, unlike other works on this subject, the term partition does not refer directly to a specific subset of the all program testing cases, but to a fragment of the program, which is a specific set of paths, leading from the beginning of the program to its end, where each path belongs to exactly one of the selected subsets of paths. A formal model of the program under the testing is presented. This model is based on the notion of a control flow graph. The relationship between faults and failures is characterizes by means so called the characteristic matrix of the program under testing. The main result of the paper is obtaining formulae for the mean value of the number of faults encountered during the random testing and program partition testing. The formulation of the single-criterion optimization task which allows the determination of a testing strategy that maximizes the expected value of the number of program faults is also formulated. Considerations are illustrated with a simple numerical example.

Keywords: random testing, partition testing, software reliability

Introduction

It is well known that a software development process consists of the following four phases: specification (including user requirements definition and software requirements definition), design (structural design and detailed design), coding and testing. The practice of modern software engineering shows that the testing stage has the largest impact on the error detection process.

The method of generating the test data set, on the basis of which the software testing process will be carried out, depends on the adopted testing method, each of which is based on a specific criterion for the selection of test data set. Depending on the approach to the problem of designing the test data set, the testing methods used in practice can be divided into deterministic methods and random methods.

Deterministic testing methods assume the generation of a test data set in a exclusively deterministic way, i.e. without the participation of a random factor. Individual sets of input data, which are elements of the designed test set, are determined based on the analysis of the requirements specification or analysis of the source code of the tested program.

Unlike deterministic methods in random methods, part of the test data sets (or even all) used in the software testing process is created using a random factor, i.e. by randomly selection, whereby the most commonly used in practice of designing test cases is the sampling without returning. The method of creating a test data set based on a randomly selection is very widely used in testing practice. This is mainly due to its simplicity (it does not require e.g. a very labor-intensive analysis of the logical structure of the tested program), the direct consequence of which is the low cost of the testing process and high susceptibility to its automation. The second, which determines the wide practical use, feature of the random method is its high efficiency, measured by the number of errors detected in the testing process. Research conducted to compare the effectiveness of the most-used testing methods in practice has shown that for a wide class of programs, testing based on random generation of test data is more effective in terms of error detection capability than other methods, see e.g. Duran and Ntafos (1984), Weyuker and Jeng (1991). In practice, random testing is carried out as random testing or partition testing.

Cite this Article as: Kazimierz WORWA "Optimization of Test Case Allocation Scheme in Program Partition Testing" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Random testing consists in using in the testing process a set of test cases, created by randomly selection (usually without returning) its subsequent elements from the entire set of program input domain, i.e. set of all test cases of the tested program. The main problem here is determining the probability distribution with which individual test cases are randomly drawn. In the absence of relevant premises as to the nature of this distribution, a uniform distribution is often assumed over the program domain. Very often used in practice variation of the random testing is a such testing in which the sampling of subsequent test cases is based on the probability distribution specified by the so-called the operational profile of the program, determining the probability of occurrence of individual test cases of the program in the conditions of its actual use.

Partition testing, also called subdomain testing, consists in dividing the set of a program domain into subsets called partitions and then drawing a specific number of tests from each subset. Consequently, the testing process is carried out based on a number of test sets (corresponding to the number of separate partitions), with the sampling of individual data case within the extracted partitions is most often based on an uniform distribution.

The rest of this paper is organized as follows. Section 2 present related works, Section 3 describes the formal model of the program under the testing. Section 4 discusses the use of the expected number of faults detected during the random testing of the program. Section 5 analyzes partition testing using the expected number of faults and compares it with random testing. Section 6 presents formulation of the single-criterion optimization task, which allows the determination of a testing strategy that maximizes the expected value of the number of program faults. Section 7 summarizes and concludes this paper.

Related Works

A comparison analysis of partition testing and random testing has attracted significant attention in the literature. Specific contributions have been made by Boland et al (2003), Duran and Ntafos (1984), Gutjahr (1999), Hamlet and Taylor (1990), Weyuker and Jeng (1991), Chen and Yu (1994, 1996), Chen et al (2004, 2010). Duran and Ntafos (1984) as well as Hamlet and Taylor (1990) performed a series of simulations and experiments to compare the effectiveness of partition testing and random testing. Their results were at first surprising to many people. They found that even when partition testing was better than random testing at finding bugs, the difference in effectiveness was marginal. Thus, when the overhead of partitioning is relatively expensive to random testing, it is likely that random testing will be more cost effective than partition testing in terms of cost per fault found. Weyuker and Jeng (1991) conducted a formal analysis of partition testing strategies and compared the effectiveness of partition testing and random testing. They found that partition testing can be an excellent testing strategy or a poor one, as compared to random testing. Essentially, they found that the effectiveness of a particular partition testing strategy depends on how well that strategy groups together the failure-causing inputs, that is, inputs which produce incorrect outputs. In particular, partition testing is most successful when the subdomain definitions are fault-based. Their findings were very helpful in explaining the seemingly counter-intuitive results in the empirical analysis of partition testing and random testing by Duran and Ntafos (1984). Gutjahr (1999) has compared partition testing and random testing on the assumption that program failure rates are not known with certainty before testing and are, therefore, modeled by random variables. He has shown that under uncertainty, partition testing compares more favorably to random testing than suggested by prior investigations concerning the deterministic case.

Boland et al (2003) have studied how the concepts of majorization and Schur-Convexity can be used in determining conditions under which partition testing is more effective than random testing. They have generalized some of the results of Weyuker and Jeng (1991), Chen and Yu (1994, 1996) and Gutjahr (1999) and established more precise conditions under which partition testing outperforms random testing.

Various reliability metrics have been in use in the analysis of the effectiveness of subdomain testing and random testing, each based on a different intuition. Almost all of these measures are formulated in terms of failures rather than faults. Ideally, we would like to assess the effectiveness of testing in terms of the faults detected. Faults are the software defects caused by programmer errors, while a failure is an observed departure from the specified behavior of the software. Normally, only failures are revealed by testing, and the associated faults are usually identified during debugging. It is worth noting that the above-cited works completely ignore the distinction between terms failures and faults.

In the article, as in the analytical works, see e.g. Boland et al (2003), Chen and Yu (1994, 1996), Gutjahr (1999), Weyuker and Jeng and Worwa (2009), the issue of random testing of the program in the aspect of comparing the effectiveness of random testing and partitioning testing is considered. However, unlike the works cited above, the term partition does not refer directly to a specific subset of the all program testing cases, but to a fragment of the program, which is a specific set of paths, leading from the beginning of the program to its end, where each path

belongs to exactly one of the selected subsets of paths. This means that the division of the program domain into disjoint subsets of test cases is determined by the method of dividing the set of all paths leading from the beginning to the end of the program into subsets of these paths, referred to as program partitions in this article. It is worth emphasizing that such an approach is close to the random path testing proposed by Gotlieb and Petit (2010).

Unlike the software reliability measures used in these works formulated in terms of failures the expected number of faults detected to analyze subdomain and random testing will be used in this paper. A program fault may cause a number of failures, while a program failure may have more than one fault associated with it. There is no simple relationship between faults and failures. This makes it difficult to use faults in measuring the effectiveness of testing. In this paper relationship between faults and failures is characterizes by means so called the characteristic matrix of a program under testing.

Description of the program under the testing

The tested program will be characterized by means of a directed *G* graph, defined as follows:

$$G = (\boldsymbol{I}, \boldsymbol{U}),$$

where:

$\boldsymbol{I}$ - set of graph vertices corresponding to the set of module numbers of the tested program:

$$\boldsymbol{I} = \{1, 2, ..., i, ..., I\},$$

$\boldsymbol{U} \subset \boldsymbol{I} \times \boldsymbol{I}$ - set of ordered pairs $(i, j) \in \boldsymbol{I} \times \boldsymbol{I}$, while a pair $(i, j) \in \boldsymbol{U}$, if after the *i*-th module is executed, the *j*-th module can be executed next.

Without loss of generality it can be assumed that the relevant program has one input module and one output module with numbers i_{IN}, i_{OUT} respectively, $i_{IN}, i_{OUT} \in \boldsymbol{I}$. In literature, the graph *G* is called the control flow graph.

Let $\boldsymbol{D}$ denote the set of numbers of all paths of the tested program, while the term path means the sequence of modules from the input module i_{IN} to the output module i_{OUT} for which there is at least one input data set that activates it:

$$\boldsymbol{D} = \{1, 2, ..., d,..., D\}.$$

It is worth noting that the set $\boldsymbol{D}$ can be very numerous but it is always finished.

Let $\boldsymbol{I}_d$ denote a set of all module numbers of the *d*-th path:

$$\boldsymbol{I}_d = \left\{ i_{d,1},\ i_{d,2},\ ...,\ i_{d,k},\ ...,\ i_{d,I_d} \right\},\ d \in \boldsymbol{D},$$

where:

$i_{d,k}$ – a number of the *k*-th module of the *d*-th path (in the order of execution of the modules included in it), while $i_{d,1} = 1$ and $i_{d,I_d} = I$,

I_d – the number of modules forming the *d*-th program path.

Let us define the reliability of a module as the probability that the module performs its function correctly, i.e., the module produces the correct output and transfers control to the next module correctly. When a set of user input is supplied to the program, a sequence of modules will be executed. The reliability of the output will depend on the sequence of modules executed and the reliability of each individual module. We first assume that the reliabilities of the modules are independent. This means that faults will not compensate each other, i.e., an incorrect output from a module will not be corrected later by subsequent modules. Since errors do not compensate each other, the result of the execution of the program is correct if and only if the proper sequence of modules is executed and in every instance of module execution, the module produces the correct result. The reliability of a module, in general, is a function of many factors, and the study of the reliability function of a module is beyond the scope of this paper. However, if no modification is made on the modules and the user environment does not change, the reliability function of a module should remain invariant. Let r_i stand for the *i*-th module reliability coefficient. The module reliability coefficients form a following vector $\boldsymbol{R}$, called program reliability vector

$$\boldsymbol{R} = (r_1, r_2, ..., r_i, ..., r_I).$$

We next assume that the transfer of control among program modules is a Markov process. This implies that the next module to be executed will depend probabilistically on the present module only and is independent of the past history. It is noteworthy that this assumption may not be valid for all types of programs.

Let us represent the logical structure of the program by a directed graph where every node *i* represents a program module and a directed branch $(i, j) \in \boldsymbol{U}$ represents a possible transfer of control from the *i*-th module to the *j*-th module. To every directed branch $(i, j) \in \boldsymbol{U}$ we will attach a probability p_{ij} as the probability that the transition (*i*, *j*) will be taken when control is at *i*-th node. If $p_{ij} = 0$, the branch (*i*, *j*) does not exist. Without loss of generality, let us assume that the program graph has a single entry node *1* and a single exit node *M*.

Probabilities p_{ij}, $i, j = 1,2,..,I$, form the following square matrix $P = \left[p_{ij} \right]_{I \times I}$, called the transition matrix:

$$P = \begin{bmatrix} p_{11} & p_{12} & \cdots & p_{1i} & \cdots & p_{1I} \\ p_{21} & p_{22} & \cdots & p_{2i} & \cdots & p_{2M} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ p_{i1} & p_{i2} & \cdots & p_{ii} & \cdots & p_{iI} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ p_{I1} & p_{I2} & \cdots & p_{Ii} & \cdots & p_{II} \end{bmatrix} \tag{1}$$

where element p_{ij} means the probability of the event that after execution of the *i*-th module, the *j*-th module will be executed next, $i, j = 1,2,...,i,...,I$. The matrix *P* determines so called the operational profile of the program.

Let $p_q, p_q > 0$, mean probability of an activation by a single test case of the *d*-th path of the tested program, wherein

$$p_q = \prod_{i,j \in \boldsymbol{I}_d} p_{ij}, \; d \in \boldsymbol{D}. \tag{2}$$

The process of program execution for a given test case of program input domain consists in activating a certain sequence of modules corresponding to this case, forming one of the executable paths of the program. It is assumed that the measure of reliability of the considered program is the probability of its correct execution for a single, randomly selected, test case. This probability is equal to the product of the probabilities of the correct execution of the modules included in the path from the input module to the output module, which activates the given test case. Using the introduced assumptions, the program reliability coefficient with the reliability structure $\boldsymbol{R}$ and the transition matrix *P* can be determined as follows:

$$r = \sum_{d \in \boldsymbol{D}} p_d \prod_{i \in \boldsymbol{I}_d} r_i \; . \tag{3}$$

The random testing of the program

Execution of the program under the testing process with one input data set (test case) will be called a run in this paper. The run can be successful, if program execution did not lead to encounter any default or not successful, if program execution was incorrect, i.e. some default were encountered.

It is assumed that the testing process of the considered program consists in carrying out n test cases (tests), drawn from the set of all possible test cases, with the draw being carried out based on the probability distribution, determined by the operational profile of the program, determined by the transition matrix *P*, defined by (1).

According to assumed testing scheme a situation that a number of different test cases of all *n* tests encounter the same program fault is possible. So, according to the note mentioned above, a situation that several runs will lead to encounter the same program fault is possible.

Let q_{nm} define the probability of an event that *n* faults will be encountered as a result of the program testing if there are *m* tests that lead to reveal failures during the program testing process. If we assume that every run of the program

with a single test can lead to reveal at most one program failure, and every failure makes it possible to detect exactly one fault we have

$$0 \le q_{nm} \le 1 \text{ if } n \le m,\ n \ge 0, \tag{4}$$

where in particular

$$\begin{aligned} q_{00} &= q_{11} = 1 \\ q_{nm} &= 0 \quad if\ n > m \end{aligned} \tag{5}$$

Probabilities q_{nm}, $n \in \{0,1,2,...,m\}$, $m \in \{0,1,2,...,\}$, that are defined by (4-5) form an infinite matrix $Q = [q_{nm}]$ that has a following form

$$Q = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & ... \\ 0 & 1 & q_{12} & q_{13} & q_{14} & ... \\ 0 & 0 & q_{22} & q_{23} & q_{24} & ... \\ 0 & 0 & 0 & q_{33} & q_{34} & .. \\ 0 & 0 & 0 & 0 & q_{44} & ... \\ & & ... & & & \end{bmatrix}, \tag{6}$$

while

$$\sum_{n=0}^{\infty} q_{nm} = 1, \quad m \in \{0,1,2,...\}. \tag{7}$$

The matrix Q contains the values 0 below the main diagonal because – in accordance with earlier assumption that every run of the program with a single test can lead to reveal at most one program failure and every failure makes it possible to detect exactly one fault - it is not possible to encounter more different faults than the number of failures. The values of probabilities q_{nm} that form the matrix Q depend on a logical structure of the program under the testing.

In particular, an important impact on these probabilities has: number of paths that have been identified in the program, degree of covering individual paths, that can be measured by number of program instructions that belong to two or more paths and length of individual paths, i.e. measured by number of program instructions that are executed in case of path activation. The matrix Q will be called the characteristic matrix of the program under the testing.

As a result of the program testing process in accordance with the assumed testing scheme a number of failures may be revealed. Because different tests can reveal the same failures, the real number of faults encounter as a result of running n tests may be less. of course, the faults associated with reveal failures are usually identified during debugging.

Let $M(P)$ denote the number of tests that lead to incorrect execution of the program under the testing with the transition matrix P, i.e. to reveal failures, during the program testing process.

Let $N(P,Q)$ mean the total number of faults encountered during the program testing process with the transition matrix P and the characteristic matrix Q. While planning the program testing process it is reasonable to consider the values $M(P,Q)$ and $N(P,Q)$, as random variables, while $N(P,Q) \le M(P)$.

Joint distribution of the random variables ($N(P,Q)$, $M(P)$) can be determined as follows:

$$Pr\{N(P,Q) = n, M(P) = m\} = Pr\{N(P,Q) = n|_{M(P)=m}\} Pr\{M(P) = m\} \tag{8}$$

According to earlier denotations we have

$$q_{nm} = Pr\{N(P,Q) = n|_{M(P)=m}\}, \tag{9}$$

and

$$Pr\{M(P) = m) = \binom{L}{m}(1-r)^m r^{L-m}, \tag{10}$$

where L is the number of tests performed during program testing process.
So,

$$Pr\{N(P,Q) = n, M(P) = m\} = q_{nm}\binom{L}{m}(1-r)^m r^{L-m}. \tag{11}$$

Probability distribution of the random variable $N(P,Q)$ can be determined as a marginal distribution in a distribution of two-dimensional random variable (N, M):

$$Pr\{N(P,Q)=n\}=\sum_{m=0}^{L}Pr\{N(P,Q)=n,M(P)=m\}=$$
$$\sum_{m=0}^{L}Pr\{N(P,Q)=n|_{M(P)=m}\}Pr\{M(P)=m\}=\sum_{m=0}^{L}q_{nm}\binom{L}{m}(1-r)^m r^{L-m}. \quad (12)$$

The knowledge of the probability distribution function (11) makes possible to obtain a formula for the mean value of the number of faults encountered during the program testing process. We have

$$E_r[N(P,Q)] = \sum_{n=0}^{L} n\,Pr\{N(P,Q)=n\}, \quad (13)$$

and then, according to (12):

$$E_r[N(P,Q)] = \sum_{n=0}^{L} n \sum_{m=0}^{L} q_{nm}\binom{L}{m}(1-r)^m r^{L-m}. \quad (14)$$

Let Q^*, Q^{**} denote characteristic matrices that have form:

$$Q^* = \begin{bmatrix} 1 & 0 & 0 & 0 & \dots \\ 0 & 1 & 0 & 0 & \dots \\ 0 & 0 & 1 & 0 & \dots \\ 0 & 0 & 0 & 1 & \dots \\ & & \dots & & \end{bmatrix}, \qquad Q^{**} = \begin{bmatrix} 1 & 0 & 0 & 0 & \dots \\ 0 & 1 & 1 & 1 & \dots \\ 0 & 0 & 0 & 0 & \dots \\ 0 & 0 & 0 & 0 & \dots \\ & & \dots & & \end{bmatrix}. \quad (15)$$

The characteristic matrices Q^*, Q^{**} correspond with some specific, extreme forms of the program testing scheme. The matrix Q^* correspond with a such testing scheme in which different tests can encounter only new faults, i.e. not encounter by tests that were executed earlier. The matrix Q^{**} correspond with a such testing scheme in which all tests can encounter at most one and the same program fault.

The formula (14) will be simplified if the program characteristic matrix Q is of the form (15), i.e.:

$$E_r[N(P,Q^*)] = \sum_{n=0}^{L} n\binom{L}{n}(1-r)^n r^{L-n} = L(1-r) \quad (16)$$

and

$$E_r[N(P,Q^{**})] = \sum_{n=0}^{L} q_{nm}\binom{L}{n}(1-r)^n r^{L-n} = \sum_{m=1}^{L} 1\binom{L}{m}(1-r)^m r^{L-m} = 1-P\{M(P)=0\} = 1-r^L. \quad (17)$$

In practice, the formula (14) for evaluating the mean value of the number of faults encountered during the program testing process can be used if the program characteristic matrix Q is known. If the probabilities q_{nm}, $n,m \in \{0,1,2,...L\}$, , are unknown, it is possible to determine the boundary values of this evaluation.

Let Q^*, Q^{**} denote characteristic matrices of the program under the testing of forms (15). Then, as proved by Worwa (2005), for any characteristic matrix P is:

$$E_r[N(P,Q^{**})] \le E_r[N(P,Q)] \le E_r[N(P,Q^*)], \quad (18)$$

where the quantities $E_r[N(P,Q^*)]$ and $E_r[N(P,Q^{**})]$ are determined by (16) and (17), respectively.

The partition testing of the program

Testing a program with partitions consists in dividing the program into fragments, each of which is a specific set of program paths, leading from the input module i_{IN} to the output module i_{OUT}, with each path belonging to exactly one of the selected subsets of paths. In further considerations, these subsets will be called program partitions.

Let's consider the division of the graph $G = (\boldsymbol{I}, \boldsymbol{U})$ of the tested program into the subgraphs $G_k = (\boldsymbol{I}_k, \boldsymbol{U}_k)$ such that $\boldsymbol{I}_k \subseteq \boldsymbol{I}$, $\boldsymbol{U}_k \subseteq \boldsymbol{U}$, while $i_{IN}, i_{OUT} \in \boldsymbol{I}_k$, $k=1,2 \dots K$, and

$$\bigcup_{k=1}^{K} \boldsymbol{I}_k = \boldsymbol{I}, \quad \bigcup_{k=1}^{K} \boldsymbol{U}_k = \boldsymbol{I}. \quad (19)$$

Let's consider the division of the set of numbers of all paths of the tested program leading from the input module i_{IN} to the output module i_{OUT} into disjoint subsets $\boldsymbol{D}_k \subseteq \boldsymbol{D}$:

$$\boldsymbol{D}_k = \left\{ d_{k,1},\ d_{k,2},\ ...,\ d_{k,l},\ ...,\ d_{k,D_k} \right\},\ k=1,2\ ...K,$$

wherein

$$\bigcup_{k=1}^{K} \boldsymbol{D}_k = \boldsymbol{D} \text{ and } \bigcap_{k=1}^{K} \boldsymbol{D}_k = \boldsymbol{\Phi}\ . \tag{20}$$

Each subgraph $G_k = (\boldsymbol{I}_k, \boldsymbol{U}_k)$ has a fragment of the transition matrix $P_k = \left[p_{ij}^{k} \right]_{I_k \times I_k}$. It takes place

$$\sum_{k=1}^{K} P_k = P\ , \tag{21}$$

where the summation operator is the matrix summation operator.

The division of the set of all program paths leading from the input module i_{IN} to the output module i_{OUT} into disjoint subsets $\boldsymbol{D}_k \subseteq \boldsymbol{D}$ means the division of the set of all possible test cases into disjoint subsets, with each test case activating exactly one path. Therefore, this division can be treated as one of the ways to divide the all program input domain into the partitions referred to in Boland et al (2003), Chen and Yu (1994, 1996), Duran and Ntafos (1984), Gutjahr (1999), Weuyker and Jeng (1991) and Worwa (2009). In the presented considerations, the term "partition" refers, however, not so much to a specific subset of all possible test cases, but to a part of the program being tested, represented by the subgraph $G_k = (\boldsymbol{I}_k, \boldsymbol{U}_k)$, the probability of transitions between modules described by the matrix P_k, $k=1,2,\ldots, K$. In further considerations, the term "partition" will be understood as a part of the program being tested, which is a subset of the set of paths leading from the input module i_{IN} to the output module i_{OUT}.

Similarly to the formulae (3), the reliability coefficient of the k-th partition of the program with the transition matrix P_k, understood as the probability of correct execution of the program for a single test case activating the path with the number from the set $\boldsymbol{D}_k$, can be determined as follows:

$$r_k = \sum_{d \in \boldsymbol{D}_k} p_d \prod_{i \in \boldsymbol{I}_d} r_i\ ,\ k=1,2,\ldots, K. \tag{22}$$

Let n_k be the number of test cases randomly selected from the subset of all test cases that activate the set of paths with the numbers from the set $\boldsymbol{D}_k$, $k=1,2,\ldots, K$.
As an alternative to the testing strategy described in Section 3, the testing strategy consisting in randomly selection from each set $\boldsymbol{D}_k$ $n_k > 0$ test cases, $k = 1,2, \ldots, K$, will be now considered.
Let $\mathcal{L}$ denote the set of vectors as follows

$$\mathcal{L} = \{ \boldsymbol{L} = (L_1, L_2, \ldots L_k, \ldots, L_K):\ \ L_k > 0,\ \sum_{k=1}^{K} L_k = L \} \tag{23}$$

The vector $\boldsymbol{L} \in \mathcal{L}$ will be called a testing strategy with program partitioning. To ensure the proper conditions for comparability of random testing strategy and testing strategy with program partitioning, it is assumed that this occurs

$$\sum_{k=1}^{K} L_k = L \text{ and } \sum_{k=1}^{K} r_k = r\ . \tag{24}$$

Let $M_k(\boldsymbol{L},P)$ denote the number of tests that lead to incorrect execution of the k-th program partition under the testing with the testing strategy $\boldsymbol{L}$ and transition matrix P_k, i.e. to reveal failures, during the program partition testing process. Let $N_k(\boldsymbol{L},P,Q)$ mean the total number of faults encountered during the program partition testing process with the testing strategy $\boldsymbol{L}$ and the transition matrix P and the characteristic matrix Q. While planning the program testing process it is reasonable to consider the values $M_k(\boldsymbol{L},P)$ and $N_k(\boldsymbol{L},P,Q)$, as random variables, while $N_k(\boldsymbol{L},P,Q) \leq M_k(\boldsymbol{L},P)$.
Conducting considerations analogous to those presented in Section 3, it can be shown that the expected value of a number of faults encountered during the testing the k-th partition determines the following relationship:

$$E_k\,[N(\boldsymbol{L}, P_k, Q_k)\,] = \sum_{n=0}^{L_k} n \sum_{m=0}^{L_k} q_{nm} \binom{L_k}{m} (1-r_k)^m r_k^{L_k - m}\ ,\quad k=1,2,\ldots, K. \tag{25}$$

Thus, the mean value of total number of faults encountered during the testing of all K partitions takes the form

$$E_p\,[N(\boldsymbol{L}, P, Q)\,] = \sum_{k=1}^{K} E[N_k(\boldsymbol{L}, P_k, Q_k)\,] = \sum_{k=1}^{K} \sum_{n=0}^{L_k} n \sum_{m=0}^{L_k} q_{nm} \binom{L_k}{m} (1-r_k)^m r_k^{L_k - m}\ , \tag{26}$$

while L_k is the number of tests performed during testing the k-th program partition.

The formula (26) will be simplified if the program characteristic matrix Q is of the form (15), i.e.:

$$E_p[N\left(\boldsymbol{L},P,Q^*\right)] = \sum_{k=1}^{K}\sum_{n=0}^{L_k} n\binom{L_k}{n}(1-r_k)^n r^{L_k-n} = \sum_{k=1}^{K} L_k(1-r_k) = L-\sum_{k=1}^{K} L_k r_k \tag{27}$$

and

$$\begin{aligned} \mathrm{E}_p[\mathrm{N}\left(\boldsymbol{L},P,Q^{**}\right)] &= \sum_{k=1}^{K}\sum_{n=0}^{L_k} q_{nm}\binom{L_k}{n}(1-r_k \sum_{n=0}^{L_k} q_{nm}\binom{L_k}{n}(1-r_k)^n r^{L_k-n})^n r_k^{L_k-n} = \\ &= \sum_{k=1}^{K}\sum_{m=1}^{L_k}\binom{L_k}{m}(1-r_k)^m r_k^{L_k-m} = \sum_{k=1}^{K}(1-P\{M_k(\boldsymbol{L},P_k)=0\}) = \sum_{k=1}^{K}(1-r_k^{L_k}) = K-\sum_{k=1}^{K} r_k^{L_k}. \end{aligned} \tag{28}$$

Taking into account the relationship (28), the following lower and upper estimations of the mean value of total number of faults encountered during the partition testing of the program with a given characteristic matrix Q can be determined in the form:

$$E_p[N\left(\boldsymbol{L},P,Q^{**}\right)] \le E_p[N\left(\boldsymbol{L},P,Q\right)] \le E_p[N\left(\boldsymbol{L},P,Q^*\right)]. \tag{29}$$

Taking into account the relationship (18), the following lower and upper estimations of the mean value of total number of faults encountered during the partition testing of the program with a given characteristic matrix Q can be determined in the form:

$$E_p[N\left(\boldsymbol{L},P,Q^{**}\right)] \le E_p[N\left(\boldsymbol{L},P,Q\right)] \le E_p[N\left(\boldsymbol{L},P,Q^*\right)], \tag{30}$$

and therefore

$$\sum_{k=1}^{K-1}(1-r_k^{L_k})+1-r_K^{L-K+1} \le E_p[\boldsymbol{L},P,N\left(Q\right)] \le L(1-r_k)+Kr_k-r. \tag{31}$$

Optimization of the program partition testing

The basic problem to be solved at the planning and organization stage of the software testing process is to specify a subset of the set of all possible test cases that would maximize the probability of detecting all program faults made in earlier stages of the software development process. This problem arises because, in general, due to the duration and cost of the testing process, it is impossible to test the software based on the entire set of all possible test cases. The problem of defining the mentioned subset is the problem of designing the test cases (tests). Each test is an acceptable combination of values that can take the input variables of the software program being tested, required for its single run, and the input variables are those variables whose values are determined directly based on the input data, e.g. as a result of executing the data loading instructions.

As noted earlier, the partition program testing consists of dividing the program into fragments, each of which is a specific set of paths, leading from the input module i_{IN} to the output module i_{OUT}, with each path belonging to exactly one of the selected subsets of paths. In the process of planning the implementation of the program testing stage, it is necessary to decide how many test cases should be used for testing each of program partitions.

Mentioned problem can be solved based on the formulation and solution of a single-criterion optimization task, allowing the determination of a testing strategy that maximizes the expected value of the number of program faults.

As noted earlier, the program testing process with partitions involves splitting the program into fragments, each of which is a specific set of program paths, leading from the initial vertex i_{IN} to the final vertex i_{OUT}, with each path belonging to exactly one of the selected subsets of paths. In the process of planning the program testing process, we should decide how many test cases should be used for testing each of program partitions.

The aforementioned problem can be solved based on the formulation and solution of the single-criterion optimization task, which allows the determination of a testing strategy that maximizes the expected value of the number of program faults. The optimization problem that was mentioned above can be formulated as follows:

for specific transition matrices P and characteristic matrix Q determine the testing strategy $\overline{\boldsymbol{L}} \in \mathcal{L}$ such that:

$$E_p[N\left(\overline{\boldsymbol{L}},P,Q\right)] = \max_{\boldsymbol{L}\in\mathcal{L}} E_p[N\left(\boldsymbol{L},P,Q\right)], \tag{32}$$

where quantity $E_p[N(\boldsymbol{L},P,Q)]$ is determined by the formula (26) and $\mathcal{L}$ is a set of acceptable strategies defined as follows

$$\mathcal{L} = \{\boldsymbol{L} = (L_1, L_2, \ldots L_k, \ldots, L_K): \ K>1, L_k>0, \sum_{k=1}^{K} L_k = L\}. \tag{33}$$

Numerical Example

The methodology of determination of the program reliability structure that has been presented can be illustrated by the following numerical example. Let Fig. 1 be the directed graph representing the control structure of a program with seven modules, where the module number *1* represents the input module and the module number *7* is the output module.

Let's assume that the control flow graph of the tested program has the form shown in Fig. 1.

Fig. 1. Graph of the sample program

According to the Figure 1 we have:

$\boldsymbol{I} = \{1, 2, 3, 4, 5, 6, 7\}$, $i_{IN}=1$, $i_{OUT}=7$,

$\boldsymbol{U} = \{(1, 2),(1, 3), (1, 4), (1, 5), (1, 6),(2, 3), (5, 6), (2, 7), (3, 7), (4, 7), (5, 7), (6, 7)\}$,

$\boldsymbol{D} = \{1, 2, 3, 4, 5, 6, 7\}$,

$\boldsymbol{I}_1 = \{1, 2, 7\}$, $\boldsymbol{I}_2 = \{1, 2, 3, 7\}$, $\boldsymbol{I}_3 = \{1, 3, 7\}$, $\boldsymbol{I}_4 = \{1, 4, 7\}$, $\boldsymbol{I}_5 = \{1, 5, 7\}$, $\boldsymbol{I}_6 = \{1, 5, 6, 7\}$, $\boldsymbol{I}_7 = \{1, 6, 7\}$.

Let the program transition matrix has the form

$$P = \begin{bmatrix} 0 & 0{,}4 & 0{,}1 & 0{,}3 & 0{,}1 & 0{,}1 & 0 \\ 0 & 0 & 0{,}7 & 0 & 0 & 0 & 0{,}3 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0{,}6 & 0{,}4 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

T

hen, according to (2), the probabilities of activation by a single test case of paths have the following values:

$p_1 = p_{12}p_{27} = 0{,}096$, $p_2 = p_{12}p_{23}p_{37} = 0{,}2016$, $p_3 = p_{13}p_{37} = 0{,}09$, $p_4 = p_{14}p_{47} = 0{,}24$,

$p_5 = p_{15}p_{57} = 0{,}028$, $p_6 = p_{15}p_{56}p_{67} = 0{,}0294$, $p_7 = p_{16}p_{67} = 0{,}07$.

Let the values of the program reliability vector is as in Table 1.

Table 1: module reliability coefficients

i	1	2	3	4	5	6	7
r_i	1	0,8	0,9	0,8	0,7	0,7	1

Then, according to (3), the value of the program reliability coefficient is $r = 0.755$. Let's assume that the testing process of the investigated program consists in executing 10 randomly selected test cases, i.e. $L = 10$. Let the characteristic matrix Q has the form

$$Q = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0,8 & 0,3 & 0,1 & 0,05 & 0,05 & 0,05 & 0,05 & 0,05 \\ 0 & 0 & 0,2 & 0,5 & 0,6 & 0,2 & 0,1 & 0,05 & 0,05 & 0,05 \\ 0 & 0 & 0 & 0,2 & 0,2 & 0,5 & 0,3 & 0,3 & 0,1 & 0,05 \\ 0 & 0 & 0 & 0 & 0,1 & 0,2 & 0,4 & 0,3 & 0,3 & 0,15 \\ 0 & 0 & 0 & 0 & 0 & 0,05 & 0,1 & 0,2 & 0,2 & 0,3 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0,05 & 0,05 & 0,1 & 0,2 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0,05 & 0,1 & 0,05 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0,05 & 0,05 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0,05 \end{bmatrix}$$

According to (16), the value of mean value of the number of faults encountered during the program testing process is $E_r[N(P,Q)] = 1,557$. If the characteristic matrices have the form (15) we have respectively $E[N(P,Q^*)] = 2,45$ and $E[N(P,Q^{**})] = 0,9398$. That means, according to (18), that indeed it happens

$$E_r[N(P,Q^{**})] = 0,9398 \le E_r[N(P,Q)] \le E_r[N(P,Q^*)] = 2,45 .$$

Let $K=3$ and program partitions have the form presented on the Fig. 2.
According to (22) we can calculate the values of the k-th program partition coefficients, $k=1, 2, 3$. The values of these coefficients are summarized in Table 2.

Table 2: values of the program partitions coefficients

k	1	2	3
r_k	0,3876	0,24	0,1274

Fig. 2: Sample program partitions

Of course, according to (24) it occurs $\sum_{k=1}^{3} r_k = r = 0,775$.

Table 3: the mean values of the number of faults encountered during the program testing

31	3	1	6	5,103681	
32	2	2	6	5,090683	
33	1	3	6	5,184819	
34	2	1	7	5,210870	
35	1	2	7	5,196417	
36	1	1	8	5,264051	

The analysis of the data contained in Table 3 shows that for each strategy $\boldsymbol{L} \in \mathcal{L}$ the relationship (30) happens indeed. We can also notice that the best, i.e. the strategy that maximizes the expected value of the number of errors detected is the strategy $\overline{\boldsymbol{L}} = (1,1,8)$ for which $E_p[N(\boldsymbol{L},P,Q)] = 5,264051$. Successively, the worst, i.e. the strategy that minimizes the expected value of the number of errors detected is the strategy $\overline{\overline{\boldsymbol{L}}} = (6,2,2)$ for which $E_p[N(\boldsymbol{L},P,Q)] = 4,403888$. From the calculations carried out in the example under consideration it follows that in the light of the program reliability coefficient, any program testing strategy with partitioning is better than a random testing strategy.

Conclusions

In this paper, as in the analytical works, see e.g. Boland et al (2003), Chen and Yu (1994, 1996), Gutjahr (1999) and Worwa (2009), the issue of random testing of the program in the aspect of comparing the effectiveness of random testing and partitioning testing was considered. However, unlike the works cited above, the term partition does not refer directly to a specific subset of the all program testing cases, but to a fragment of the program, which is a specific set of paths, leading from the beginning of the program to its end, where each path belongs to exactly one of the selected subsets of paths.

A formal model of the program under the testing was presented. This model is based on the notion of a control flow graph. It was assumed that the probabilities of transitions between individual program modules are determined by the transition matrix *P*, the element p_{ij} means the probability of the event that after execution of the *i*-th module, the *j*-

th module will be executed next. The transition matrix defines so called operational profile of the program, determining the probability of occurrence of individual test cases of the program in the conditions of its actual use.

The use of the expected number of faults detected during the random testing of the program was discusses. Unlike the software reliability measures used in these works formulated in terms of the expected number of faults to analyze subdomain and random testing have been used. The relationship between faults and failures is characterizes by means so called the characteristic matrix Q of the program under testing, while the q_{nm} element of that matrix define the probability of an event that n faults will be encountered as a result of the program testing if there are m tests that lead to reveal failures during the program testing process. The values of probabilities q_{nm} that form the matrix Q depend on a logical structure of the program under the testing. The main result of this section is obtaining a formula for the mean value of the number of faults encountered during the program testing process. In practice, the formula for evaluating the mean value of the number of faults encountered during the program testing process can be used if the program characteristic matrix Q is known. In this section shown that if this matrix is unknown, it is possible to determine the both sides boundary values of the mean value of the number of faults encountered during the program testing.

Using the expected number of faults partition testing was analyzed and compares with random testing. The main result of this section is obtaining a formula for the total mean value of the number of faults encountered during the testing of all partitions.

A formulation of the single-criterion optimization task, which allows the determination of a testing strategy that maximizes the expected value of the number of program faults.

Presented considerations have been illustrated by a simple numerical example.

Abstract

Artificial intelligence (AI) has become an important component of the digital economy due to the increase in the efficiency of digital systems and the expansion of their scope. The analysis showed that the pandemic really acted as a driver for the introduction of AI into technological, production and economic processes and has already led to irreversible processes of digital transformation of the economy. In the context of the COVID-19 pandemic, the importance of AI has clearly increased; it has shown itself to be unusually effective in solving emergency problems and outlined promising areas for the development of technologies in the coming years. Using the case method, significant changes in technological and economic processes in China were analyzed. The areas of application of artificial intelligence technologies were identified, in which, due to the pandemic, the use of AI was the fastest: 1) providing remote work for business (2) tracking systems, (3) smart city technologies, (4) big data, (5) medicine and (6) unmanned vehicles. The main directions of state support for the development of AI in China are considered.

Keywords: Artificial Intelligence, COVID-19 pandemic, China, technological and economic processes

Introduction

The Chinese economy is facing new challenges due to a slowdown in economic growth and higher wages, which leads to the transfer of industry from China to other countries, and this, in turn, leads to an outflow of capital from the country. In the context of increasing global competition, the People's Republic of China (PRC) is looking for new drivers of economic growth based on the digitalization of the economy and capable of providing a technological breakthrough and increasing the efficiency of the economy. Artificial intelligence has become an important component of the digital economy due to the increase in the efficiency of digital systems and the expansion of their scope. Research and projects in the field of AI are currently receiving priority development in the world. Experts agree that the development of AI will lead to the next technological revolution, which will change human daily life and production.

The existing forecasts for the development of AI are based on its application in traditional areas, taking into account their growth. The COVID-19 pandemic led to the transition of many production processes to remote mode, made it possible to make sure of the effectiveness of using artificial intelligence to solve various new problems in new areas of the economy. It is becoming clear that the pandemic will accelerate the development of technology, as well as change the composition of those industries where artificial intelligence will be most actively implemented.

China has a huge progress towards the development and application of AI. At the same time, the experience of recent years has shown tremendous opportunities and great prospects for using AI, which requires deep study. This paper examines positive experiences and evaluates opportunities for the development of artificial intelligence in the PRC.

Review of relevant studies and problem statement

The concepts of digital economy development originate in the papers of D. Bell (1999) and E. Toffler (1980) in the

Cite this Article as: Anton Andreevich KAZANTSEV and Natalia Anatolyevna NAVROTSKAIA“ Does the pandemic drive the use of Artificial Intelligence? Evidence of China” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

1960s. Later, in the paper of D. Tapscott (1997), the definition of “digital economy” was first used. These concepts laid the foundation for research into the digital transformation of the economy, which is entering a new stage of development.

The changing importance of the digital economy and artificial intelligence for the development of China's economy is discussed in various papers, analytical materials and studies. Thus T.H. Davenport and R. Ronanki (2018) write that a number of areas such as health care, financial services and education can become less costly for society, but at the same time improve their quality and efficiency. First of all, according to the authors, this will happen due to the automation of routine work, as well as through the use of cognitive technologies. A number of authors note the threats and risks associated with the development of AI. So, M. Buiten (2019) writes that AI is non-transparent and complex from the point of view of legal regulation. The authors propose to develop an approach to working with AI with completely transparent algorithms in order to reduce risks, control them and regulate them by law.

Many papers on AI are exploring its technological features. At the same time, since the inception of this technology, scientists have sought to make AI as similar as possible to the human mind. Jeste, D., Graham, S. et al., (2020) offer their point of view on this issue. They believe that artificial intelligence should be based on human neurobiology. In their opinion, this will allow AI to self-learn and correct mistakes, comply with ethical norms, recognize human emotions and help people make decisions. K. W. Church (2018) discusses the general issues of the development of artificial intelligence in China, the prospects for speech recognition technologies and the activities of Baidu.

In studies of the development of the European market for AI and technological leadership in this area, it is noted that China is a serious competitor and challenge. J. Straus (2020) also mentions the impact of coronavirus on the development of the AI sector and draws attention to the need for government support for large IT companies and startups.

At the same time, the coronavirus pandemic has brought medical technologies and artificial intelligence technologies in medicine to the fore. S. E. Davies (2019) writes about the high potential of AI in vaccine development and cancer treatment. More importantly, in the context of the COVID-19 epidemic, AI can predict the spread of disease and the emergence of disease outbreaks.

It should be emphasized that the use of AI in medicine is prohibited in most countries of the world, which proves the existence of many problems in the field of regulation of its application and the importance of the problem under study.

Thus, we came to the conclusion, that existing research affects certain areas of application of artificial intelligence, the prospects for its development and risks. At the same time, the new challenges and opportunities for the use of AI caused by the pandemic have not yet been sufficiently reflected in science and practice. It is especially interesting to study the development of these processes in China, in which the digitalization of the economy and the development of AI technologies are proceeding most rapidly.

Research Methodology

Our conclusions and proposals are based on the results of the analysis and interpretation of the main concepts that are associated with the analysis of the digital economy, Industry 4.0 and AI. We also pay special attention to the study of the Chinese experience in the development of artificial intelligence, because this sector is developing rapidly. Market volumes and investment dynamics are significant on a global scale, which is especially associated with a sharp change in technological processes in the economy.

Our hypothesis is the assumption that the pandemic acts as a catalyst for the introduction of AI and in the future will lead to significant irreversible changes in technologies and, as a result, in the organization of production and economic processes.

From a methodological point of view, we use new methods and their combinations to get an idea of the changes that the coronavirus has brought to the world economy and in particular to the Chinese economy. Using the method of system analysis, we consider the relationship of problems caused by coronavirus with the prospects for the development of AI. In addition, we use the case study method to analyze the successful application of AI technologies in China, to identify main areas of AI development in the coming years in key areas and industries. We do an analysis of specific successful projects, while the existing research mostly considers only individual industries without taking into account Chinese characteristics, or studies Chinese industries rather superficially, focusing mainly on investment and government support.

The data used for the analysis represents information from companies and the evidence of leading companies in China on the implementation of artificial intelligence, official information from government websites, analytical firms and news publications, as well as information from current scientific research.

Results

Case study analysis of the use of AI in China

AI is an important part of modern technological and business processes. Its importance is due to the automation of production and the rapid digitalization of the global economy. It is widely used in a number of industries such as medicine, finance, education, autonomous driving technology, language recognition, and so on. Currently, more and more companies are starting to implement AI, which is due to the fact that artificial intelligence reduces costs and increases efficiency, it allows you to automate routine work and make it even faster.

In a pandemic, there is an active search for new and expansion of existing areas of application of AI technologies in connection with changes in production processes.

It is possible to identify a number of sectors of the economy in which AI has received the greatest development in the epidemic COVID-19 is: (1) providing remote work for business (2) tracking system, (3) technology (4) "smart cities", (5) big data, (6) medicine and (7) unmanned vehicles.

One of the main features of 2020 is self-isolation, which implies a remote work format. As well as throughout the world, China has sharply increased the popularity of working at home after COVID-19 crisis, when the company ordered its employees to stay home. About 200 million people were working remotely by the end of the Chinese New Year (Bick, R. et al., 2020).

Amid the protracted global fight against the COVID-19 pandemic, China is experimenting with remote work on collaboration platforms. Companies have started buying online work platforms with various features such as DingTalk (Alibaba), Feishu (ByteDance) and Wechat Work (Tencent). All of these platforms offer the same services as Google Drive, Dropbox, Zoom and Doodle Survey, and more. Firms are so eager to keep doing business as usual that their demand is generating a huge market for online tools to work with. This experience has changed the perceptions of many businessmen about how their companies should be organized. Most likely, the trend for remote work will continue after the coronavirus. Artificial intelligence in this case will be able to help those that provide the necessary technological capabilities to employees who work from home. In addition, some of the business processes will strive for automation, this is a good prospect for the development of various robots, chat bots, and so on. We can say that this is more likely not only Chinese, but also a global trend. Thus, the first area where AI will develop is the technological support of the remote work mode for business.

The next area, which is also related to self-isolation in a pandemic, is tracking the movement of people. For these purposes, artificial intelligence is extremely useful. The results of China's fight against the spread of COVID-19 were the best in the world. The coronavirus pandemic has shown how closely and effectively Chinese IT giants and Chinese authorities can interact. On February 10, 2020, at a press conference of the State Council of the PRC, the authorities announced the need to create an application that could help control the spread of the virus by analyzing the movement of people. Aliyun has released a free smart mini-app for community prevention and control of the epidemic. The application registered the entrances and exits of company employees, tracked the health status of employees. At the same time, Tencent almost simultaneously released the Tencent electronic pass, which detects people's movements, records body temperature, identifies a high-risk group and encourages people to report information about their health (Yueliang (李月亮), 2020). It seems possible that even after the coronavirus pandemic, such applications will be in demand to control the spread of seasonal diseases.

We can also show the experience of other Chinese companies that have successfully worked in the field of tracking the movements of citizens. The “Health QR code” system, which tracked the movements and contacts of the Chinese, was integrated with the Wechat and Alipay applications, which increased the reach of users. In this case, the “Health QR Code” receives user data from the National Online Government Service Platform. Telecommunications companies such as China Mobile, China Unicom and China Telecom monitored the movements of citizens using cellular communications and passed this information to government agencies. All of the above applications, together with the consciousness of the Chinese population, have brought good results and helped to localize the epidemic foci, reduce isolation times and minimize economic damage to business.

Xi Jinping said in April 2020 that the experience of controlling the epidemiological situation in the country is a "historic chance" for China to turn the crisis into an opportunity. It is the coronavirus pandemic that can become a driver for a faster change in China's economic model, and will increase the share of exported goods with high added value precisely thanks to high technologies, one of which is artificial intelligence (Shevko, 2020).

The idea of tracking the movements of citizens is not new for China, especially when you think about the social responsibility system. Cameras on the streets of cities, which can identify a person in a few seconds, have already become commonplace in Chinese cities. But in addition to surveillance, AI technologies in China can be used to develop smart cities. The Hangzhou City Brain is a good example of such a smart city - a smart city where AI processes huge amounts of data on the movement of people, traffic and safety in the city. Xi Jinping, during his visit to this city (March, 2020), praised the experience of City Brain. It is very likely that such a smart city system will be extended to other cities in the PRC. In addition, the development of smart cities is included in the so-called “Digital Silk Road” plan.

Delving deeper into the technologies that will be in demand after the pandemic in the context of smart cities, it is worth noting the Chinese system for regulating passenger traffic SensCrowd Analytics Server. It helps regulate passenger traffic so that there is no overcrowding in transport. This system can be actively used in crowded places: in parks or at stadiums. The system analyzes crowd behavior and can notify administrators about possible dangers so that measures can be taken to eliminate them. This technology is especially useful during riots and protests. The system allows you to track and analyze the actions of more than 100 people using one camera (SenceTime company, 2019b).

Such systems that help to recognize faces are in demand not only in China. At the moment, about 18 countries use intelligent monitoring systems that were produced in China. For example, the monitoring system for Ecuador (ECU-911) was developed by two Chinese companies - C.E.I.E.C. and Huawei (Mozur et al., 2019).

Continuing the theme of change during a pandemic, it should be noted the trend in contactless delivery of goods. Self-driving cars can ensure the delivery of goods as safely as possible for the buyer. Grubhub, Uber Eats, DoorDash, and others have introduced contactless food delivery to minimize contact between couriers and users (Cai, 2020).

This trend could be an excellent opportunity for China, as the self-driving car sector is actively developing in the country. According to experts, in 2018 the market for self-driving cars was estimated at more than 89 trillion. yuan, by the end of 2020, there may be more than 15 million self-driving cars in the country. Deloitte predicts that by 2030, annual sales of new self-driving cars in China will exceed 500 thousand units, which will account for 24% of annual sales in the world (Hecker, et al., 2018).

The self-driving car market includes many car companies and IT companies. The IT sphere is represented by most of Baidu and Alibaba. So Alibaba is developing the AutoNavi project, which provides the creation of accurate maps of highways in the PRC. In addition, startups such as “Pony.ai” are active players in this market and are already partnering with major car companies. For example, Toyota invested $ 400 million in this company in 2020 (Pony.ai company, 2020). The Pony.ai startup uses machine learning and deep learning to practice driving situations in a variety of conditions. James Feng (head of Pony.ai) believes that self-driving transportation can become not only safer, but also truly contactless. However, the most important thing in this area is that Chinese companies can now build complete production chains without the help of foreign companies. In turn, this will allow China to produce more goods with high added value, which the country has been striving for in recent years. The centers of this industry are expected to be Beijing, Shanghai and Shenzhen.

During the pandemic, AI was most widespread in medicine. The main challenge in the fight against the virus has become the development of a vaccine. The process of searching for a cure is complex and long, the mass vaccination of the country is expected to begin only in 2021. The long term is always due to the need for clinical trials. TwoXAR CEO Andrew Radin is confident that AI technology can accelerate this process, primarily through patient group matching and forecasting (Cai, 2020).

Tom Siebel, owner of C3.ai, has decided to use AI to fight the coronavirus. Within a few weeks, a “data lake” was created, where information about the pandemic was collected. Using this app, healthcare providers could access valuable data for free, which was then shared with the World Health Organization, the Institute for Health Metrics and Evaluation, and other organizations that collected data from COVID-19 patients. About 2000 researchers are already using the C3.ai database (Feldman, 2020). Thus, AI can be developed in the processing and systematization

of medical data.

It is also worth noting the development of Chinese specialists for intelligent diagnosis and treatment. So the SenceTime startup created the SenseCare platform, which, using AI and Big Data technologies, makes it possible to more effectively diagnose, treat and rehabilitate patients. The platform provides technical support to medical personnel with a minimum investment of time. The system automates some processes for scientific and clinical trials and has a high degree of information security (SenceTime company, 2019a).

In addition, the Chinese startup Megvii Technology Limited has developed intelligent temperature measurement systems based on artificial intelligence, the system is called MingJi. This system has been widely used in China in places with large numbers of people. This technology has also been used in other countries, which also confirms the demand for Chinese AI systems (Megvii Technology Limited, 2020).

For China, the interaction of local authorities and large companies is quite typical. During the pandemic, the National Health Commission of China decided to include computed tomography as the standard for clinical diagnosis of COVID-19 in the Hubei Province. At that time, hospitals did not have the necessary equipment to automate diagnostics. Therefore, doctors had to analyze a huge number of images, double-check them and make their diagnosis. Doctors manually reviewed up to 300 images a day. A large amount of information not only reduced the speed of obtaining a diagnosis, but also reduced its quality, since there is always a fact of human error, especially when we talk about such a load on doctors.

HUAWEI CLOUD with the cooperation of Huazhong University of Science & Technology and Lanwon Technology have created and launched an AI-assisted quantitative medical image analysis service for COVID-19. With HUAWEI CLOUD's leading AI technologies such as computer vision and medical image analysis, the service can automatically, quickly, and correctly output CT quantification results to imaging and clinical doctors, alleviating the shortage of imaging doctors who can accurately diagnose COVID-19, relieving the pressures of quarantines, and reducing the heavy workloads of doctors. "AI + doctor review" is dozens of times faster than manual quantitative image evaluation, which greatly improves the diagnosis efficiency.

The AI-Assistance system can analyze the image in a short time and draw conclusions for doctors. This facilitates the work of medical personnel, increases efficiency, since the image analysis process is performed by a computer. By analyzing the condition of patients' lungs based on clinical and laboratory data, the system assists doctors in determining the stage of coronavirus disease, which helps in prescribing the correct treatment. AI technology has the potential not only to diagnose diseases, but also to treat them. It is worth noting that this system can analyze 4D dynamic data that tracks the patient's lung condition. This helps doctors monitor the patient's condition and see the results of the prescribed treatment or drug (Huawei Cloud, 2020c).

The Chinese company HY Medical, which developed an algorithm based on the actions of doctors and machine learning technologies showed another positive experience, which was able to analyze images and make a diagnosis. The HY Medical AI system automatically adapts to medical images that come from different sources and are created on different equipment. The detection of the disease and the accuracy of the diagnosis were 96%. But the most important thing is the efficient use of doctors' time and the automation of this routine operation. The processing of 500 images with the HY Medical system takes only 2-3 seconds (Bloomberg Business, 2020). An analysis of the experience of using AI in medicine showed that the automation of the process of analyzing images greatly helped medical personnel, allowing them to do things that cannot yet be done using a computer.

Artificial intelligence can even automate the imaging process. This will eliminate physical contact with infected patients, which significantly reduces the risk of illness for doctors. In addition, the hospital saves on personal protective equipment. If the AI diagnoses a coronavirus in a patient, then the image is transferred to the doctor to confirm the diagnosis; the doctor excludes work with cases when the disease is absent. At the same time, AI can distinguish between types of infection, give recommendations suitable for a specific situation (Liu, 2020).

Thus, the pandemic has become an opportunity to adapt the use of AI technologies in medicine. A number of Chinese companies, including Huawei Cloud, have established a free trial period for some AI technologies with the prospect of further cooperation in the future (Huawei Cloud, 2020a). In March 2020, Ecuador began using the coronavirus screening system developed by Huawei Cloud and HY Medical. This screening system using AI technologies was able to determine the affected areas of the human body, and the diagnosis fully corresponded to the actual infection (Huawei Cloud, 2020b).

Such a system significantly speeds up the diagnosis of patients, it has great potential for development in the entire

medical field. It can be noted that there is a demand for such technologies, primarily in developing countries, and China will count on these markets. There he will be forced to compete with the United States and European countries. However, there is no doubt that such technologies will develop and improve, thanks to them it will be possible to reduce the damage from possible epidemics in the future.

Thus, we can say that due to the pandemic, AI technologies in medicine will be introduced much more actively than before, since they have successfully proven themselves.

Development of AI Support System in China

To better understand the experience of China, it is worth paying attention to the conditions that exist for the development of artificial intelligence technologies. The basis for supporting the development of AI in China is made up of government programs and development strategies, investment programs and research centers.

Thus in 2018, the volume of Chinese investments in artificial intelligence reached 131.1 billion yuan, which is 60% of global investment in this sector. According to rough estimates, the number of companies that are engaged in the development of AI technologies in China is already more than 400 thousand. In March 2020, the Chinese authorities announced a new development program, which was called "New infrastructure," the need for it arose, including due to the coronavirus pandemic. This strategy is designed to mitigate the economic damage from the epidemic, as well as to contribute to the sustainable development not only of the economy, but also of the whole country. Li Keqiang in May formulated the main building blocks of this new infrastructure: 5G, AI, industrial Internet, big data, smart energy and transportation (Xinhua, 2020). According to Chinese experts, the volume of investments in the "new infrastructure" industry by 2025 could amount to 17.5 trillion yuan. Taking into account the fact that the idea of a new infrastructure resonates with the "Made in China-2025" plan, such a volume of investments seems to be quite acceptable, especially since these programs will be implemented in parallel. Artificial intelligence in the new infrastructure, in our opinion, is the most important, since its development and active implementation will ensure growth in other industries as well. The plan for AI development in China can be seen in the "Notice of the State Council Issuing the New Generation of Artificial Intelligence Development Plan".

According to the report, in 2022, the scale of the AI industry in China is expected to approach $30 billion. It is likely that after 2022, investments in artificial intelligence will grow, this assumption can be confirmed with the help of the state plan, which was put forward back in 2017, it states that by 2030 China will become a center for AI development (Shevko, 2020).

One of the most important conditions for the development of AI in China is the active assistance of the country's authorities at all levels. The Internet of Things (IoT) is also developing in China, and here is an example of the active participation of local authorities. In 2019, a large number of enterprises in the field of the IoT appeared in Jiangxi Province. Since October 2018, local authorities began to provide comprehensive support to companies working in the field of the IoT. As a result, 828 IoT companies were registered in Jiangxi Province, which is 57.7% more than in 2018. (Official website of the People's Government of Jiangxi Province (People’s Government of Jiangxi Province, 2019). More than half of the companies are engaged in software development, information transfer and information technology services. With the development of the IoT, Jiangxi Province wants to become the center of this industry in China. This is a really good example of how the interest of the authorities helps businesses and at the same time increases the level of digitalization of the economy.

To find new unique solutions in the field of AI, Chinese companies work closely with Chinese universities: as a rule, joint research centers and laboratories are created. For example, the Law and Artificial Intelligence Laboratory (Peking University) and the Shenzhen Institute of Artificial Intelligence and Big Data. Thus, artificial intelligence makes business processes more efficient, reduces costs and creates completely new jobs globally. These places are created mainly in the developed eastern provinces and in traditional innovation centers: Beijing, Shanghai and Shenzhen, but at the same time, as part of the program to reduce the imbalances in development between regions, western regions, such as Sichuan, can also become AI centers. There is also a conditional specialization of regions: Beijing is a scientific center where new solutions are being sought, while Shenzhen is more focused on practical applications, since a huge number of IT companies are concentrated there, including Huawei, Tencent and ZTE.

At the present time, the demand for AI specialists exceeds their supply. According to Chinese experts, China lacks 30,000 AI specialists. The greatest demand is for specialists in the development of AI chips, machine learning technologies, natural language processing, sound recognition, and computer vision (Liqin (力琴), 2020).

In the short term, the demand can be satisfied by foreign specialists, however, this does not meet the interests of China. China needs its own specialists. According to the AI Innovation Action Plan for College and Universities, by 2020, China should create a favorable technological and scientific environment for the development of AI. There are already concrete results: 32 Chinese universities have opened colleges specializing in the training of AI specialists by 2019, and 19 universities have created separate research institutes. In addition, Chinese IT companies have collaborated with universities to create AI colleges. The training of new specialists has just begun, but in the long term, China will provide itself with highly qualified personnel. Mutual cooperation between universities and business to improve the quality of education looks very successful. Students can receive not only theoretical education, but also apply it in practice in order to gain the necessary experience (Synced Review, 2018).

Conclusions

The analysis showed that the pandemic really acted as a driver for the introduction of AI into technological, industrial and economic processes and has already led to irreversible processes of digital transformation of the economy.

Based on the reviewed cases of the use of AI in China, we can conclude that the COVID-19 epidemic has changed many business processes, opened up new directions for the use of AI. We have identified the following areas in which AI has developed most rapidly in the context of the pandemic: providing a remote work mode for business, tracking systems, smart city technologies, big data, medicine and unmanned vehicles. In these areas, AI has shown itself to be very effective in eliminating damage from the coronavirus or in adapting to new business conditions.

China has shown an unusually high rate of AI adoption in technological processes. China's experience is based primarily on government development programs and investments. At the same time, an important component of the successful development of AI is an established mechanism of interaction between authorities and business. China is making significant efforts to address the challenges that hinder the development of AI. The government is taking measures to eliminate the shortage of qualified specialists in this area. Here the most effective is the format of interaction between business and universities, as well as the system of clusters. In addition to training future specialists, the state, together with companies, promotes scientific research in the field of AI.

Many scientists and businessmen believe that the economy in a post-pandemic world will never be the same again. AI turned out to be one of the most demanded drivers for transformation and adaptation of technological processes to new challenges. For China, the pandemic has become an opportunity for a more rapid development of AI, which may allow China to become the world leader in this field. When asked, "Can China do it?" the future will answer.

Introduction

The topic of leader and leadership is popular and frequently visited, and not just these days too. From the definitions and opinions on who actually a leader is, through various style and approaches to leadership all the way to competences or characteristics which should be found in a leader. Ability to improvise, development of professional intuition, creativity and openness to change are necessary attributes of a good leader. However, these require specific ways and methods which we discuss in this work. The point being the development and cultivation of both analytical and intuitive thinking, creative and critical approach, since both of these qualities are complementary to each other and their use alternates depending on the ongoing process. In this article we discuss selected aspects of thinking of people in general and leaders in particular, with the focus on cultivation and potential development of thinking which leads, through the leader, to achieving the goals of the group, company, or organization.

Our goal was to introduce unconventional approaches to development of leaders' way of thinking. These are not entirely usual but they allow for much deeper and vaster experiences, or open ways towards new, so far unexplored directions, which may be crucial for future leaders and may influence their future success.

A Leader in The Digital Age

The human created environment and the way of life we are forming in various societies is changing and developing more dynamically, than the natural environment. In relations to these changes and transformations there are also changes in needs for quality, potential and abilities of professionals and leaders. These are people who hold specific roles and perform activities related to organizing environments of human systems and their governing. Through the process of human society development and thanks to various changes and transformations (modern information technology, globalization, etc.), the characteristics of our environment are approaching characteristics of an unstable environment.

In the industry 4.0 environment, considering natural potentials of human resources, there is a tendency to discuss the problematics of information digitalization, artificial intelligence, virtual reality and vicarious communication. Aside from undeniable direct and obvious advantages and positive effects of these aspects, there are also secondary and asymmetrical, hidden or obscure, complex and non-linear influences and effects on psyche, mind and thinking of particular people or human societies. We perceive the shadowy effect of digitalization and vicarious communication in two modalities. The first suggests, that by overusing them, the quality of consciousness, of self-consciousness, in the literal meaning of the term, is changing. The second effect related to the growth of digitalization, algorithmization

and artificial intelligence, is lessening of the part the intuition and analogy on the cognitive processes and on building of knowledge used for decision making and behavior in a concrete situation. It also lessens the spontaneous adaptability to the change of conditions and the circumstances of the roles situations. (Ullrich, Pokorny, Sladek, 2018)

The Threat To The Divergent Way Of Thinking

The mental mobility skill, openness towards changes and selected subtle skills directly influence the flexibility of paradigm. We think, that clairvoyance is a necessary part of thinking of a leader. There is an emergence of many programs focusing on NGL – next generation leadership. The essence is to focus not only on what leaders need for their work today, but more importantly, what they'll need in the future; and to focus on how to prepare them for future challenges. The question is, how to measure and develop the ability to "foresee"? Logically, the ability to predict influences the level of useful creativity of the given individual.

There is a whole range of threats to the creative, divergent way of thinking. We may point out the paradigm effect[1], or the selective point of view, blocking of the "clairvoyance", rigid adherence to paradigm, paradigm paralysis, or blindness of success of the old paradigm and of our investment into it, personality type, fear and impatience, dependency and many others.

Mental Mobility And Critical Thinking

Systemic (ecological) and situational mobility

a) Systemic (ecological) mobility relates to the environment and is recognized by the mobility in environments with largely artificial characteristics and in environments with largely natural characteristics. Also in professional environment and in environments of cooperation and collaboration.
b) Situational mobility is formed as the proactivity in the adaptability to the change of conditions and circumstances.

Relationship mobility

This includes social and organizational mobility. It manifests in the social continuum (self vs team member), organizational continuum (hierarchical vs organization network structures) as well as in managerial continuum (control/management/leadership).

Mental Mobility

Thinking in terms of ability to build up knowledge fro decision making and acting in the process of fulfilling a task in the most energetically effective and the least demanding way.

The mobility in the cognitive, ecological, situational, social and organizational continuum requires in the end a change in the inner attitude of every member (human individual). This change needs to go towards the self-development and self-actualization, individual development and cultivation of natural potentials in a professional role and work position (Ambrozova, et al. 2016). This fact applies equally to professional moral and value orientation. An example is the results of value orientation research on military leaders, which has shown that, that „the value orientation of CAF members changes depending on their military rank" (Mikulka, et al. 2020). The above mentioned trends of changes and the quality of potentials requirements of people and human systems demand an innovation in the perception of the terms of control, management and leadership. At the same time these trends require new approaches to identification and development of resources and potentials and qualities of the leaders operating in today's environments.

The following is one possible way of operationalization of the critical thinking as a quality, or ability, which should be found in every individual who takes for himself the right to lead other people and other human systems: "*Critical thinking is an individual ability to create optimal conditions for correct discernment in a situation or a role. This ability is shown in the mental mobility. Mental mobility satisfies the following measurable parameters:*

a) Cognitive variability and mobility between analysis and intuition[2].

[1] Paradox being, that people who don't know the old paradigm, have the potential to advance them, since they're not limited by them

[2] Includes both the ability of overview of the whole and the insight in a sense of subtle and accurate detail discernment; concrete (positivist) and abstract thinking; work with the similarity, difference and also relationship. The cognitive variability relates to professional quality, not the expert appearance, and is seen in the ability to

b) *Skeptical[3] curiosity and courage[4], openness and spontaneity of learning*
c) *Psychophysical condition, stability of quality and quantity of output of psychological functions in time (attention and memory). (Ambrozova, et al. 2016).*

From the point of view of situational and systemic leadership, the critical thinking plays a dominant role and manifests as a mobility in the cognitive continuum. The central aspect of the cognitive continuum is the quasi-rationality (Kostron, 1997, Hammond, 2000), which represents an adequate substitute for intuition and analysis, as modalities of ways of learning for particular situation and task.

Hidden Qualities Of Consciousness And Their Potential Development[5]

President Masaryk spoke frequently about hidden human qualities and spiritual nature of our own self: *"…. It is not to be doubted, that more and further, blind forces drive a human more, than functional autonomy of the reason. … We are driven to work by urges material as well as spiritual."* (Tvrdy, 1930, s. 36). He speaks about the inner truth, which shapes the character, with the state of society and democracy is a reflection of the character of the democrats. *"We must love the truth, we must bravely be the whole humans, in short – we must find our soul and have faith in that soul and all will be taken care of. We need ideas, living and grand ideas, and so we won't be little. Our ideas need to be world encompassing, ideas not for ourselves, but for all. One who wants to persevere and stay strong, needs to think, feel and work for all others, not just for himself. We need ourselves grand and living ideas. Those will redeem us because they will redeem the others."* (Belobradek, Slama, 2012).

A stay in altered or expanded states of consciousness helps to internalize individual parts of our self and, therefore enables their development, integration and reflection. In the case of fear and pain it helps us to understand its source and eliminate its influence. By these stays, it is possible to experience of a very specific state of being, existence, which burdens are in the least possible way, energetically speaking. We could call this stay the optimal state of mind, body and spirit, all connected in harmony. Thoughts, emotions and acts are not opposing one another, but are in synergy. Remaining in such a state is regenerative and healing. By applying the experiences from the inner work in the altered states of consciousness, we reach certain lessening of the effect of the pendulum of life, emotions, assumptions and we cease to be slaves of blaming ourselves and everything in our surroundings. The effect is priceless and has an enormous potential for a making of a leader.

Jakobi (1967, s. 130) states that only in the very center, it is possible to be a full human being. Have we forgotten? It is the return to our center, to our own source, balance, health and power, that is the central theme connecting the cognitive management, altered states of consciousness and sweat lodge rituals. Already, in 17th century Komensky spoke of staying in the center, where we can obtain the power to live in truth and to live in harmonic relationships. He also stressed the importance of not dwelling on unimportant matters and put the importance on strictly own experience: *"We acquire knowledge from our own experiences, while ascending a spiral."* (Lectorium Rosicrucianum, 2002, s. 45) We search and search; we are fascinated by new trends and we don't notice the wealth, leaders, personalities and ancestors, who in so many ways prepared our path. During sweat lodge ceremonies and specific ex ante and ex post programs, it is possible to gain experience of all mentioned above.

Altered states of consciousness are perceived as a significant subgroup of extraordinary states of mind, having a curious therapeutic and transformational potential. "In the practice of modern psychiatry, its significance is far-reaching." Grof states that in these states we are able to "transcend narrow boundaries, limitations of our body and ego. We may reach the full understanding of our true and real identity." (2014, s. 19 – 20) Epstejn (2008) explains them as the return to the infancy, when we experienced undifferentiated bliss and oneness with mother. Walsch

---

pragmatically, situationally create "meta-method" for learning in the actual role (either from the known elements and method principles (innovation), or to create "discover" a new one). There exists a continuous relationship between intuition and analysis (continuum, gradual transition). This is whence the theory of cognitive continuum takes its name from. A transition in a sense of adequate way of cognition when it comes to a situational task, can be understood as "common sense", or, as per K. R. Hammond, as quasi-rationality.

[3] Skeptical, in the sense of inquisitive, discerning thinking, containing detachment, neutrality and impartiality. It enables to formulate well-based doubts and to make justified arguments which separate simple meaning from an opinion.

[4] In a sense of going beyond boundaries of the task, context in time, space, conditions; to think "the unthinkable" (Taleb, 2011).

[5] Subchapter was processed as a citation of a part of an article; authors: SLADEK, Pavel, ULLRICH David. The potentials of Methods Working with Altered States of Consciousness for the Development of Selected Managerial Competencies. Scientia et Societas, 2018, vol. XIV, no. 3, p. 85-92. ISSN 1801-6057.

describes that he was very taken aback by the experience and that he was stricken by an exceptional paradox. In a common state of consciousness, he advocates the requirements for one field of science for all states of consciousness, which would study both common states of mind and extraordinary experiences. (2011, s. 269). Maslow (1967) thinks about these mystical experiences as rebirth, "little death", coming from various sources and being brought up by various means. The content is similar, though. Individual contents, meticulously studied and categorized. Grof adds that he was repeatedly a witness to other people using this direct experience to open themselves to an alternative perception of reality and the whole world. They wake up form, so called "Newton's sleep". (Laszlo, Grof, Russel, 2013)

Cultures all-around the world work with the potentials of these states of mind for thousands of years; see Zeleny (2007), Eliade (1997), Harner (2010), Van Gennep (1997) and others. They use them not only to survive, but also for self-actualization, self-cultivation, understanding, healing, psychological and physiological resources activation, education and shaping and cultivation of personalities of chiefs of given societies, those we call leaders.

Sweat Lodge Method And Its Use[6]

To be able to speak of sweat lodge as a method affecting multiple levels (physical, mental, spiritual), it is necessary to add exact elements bringing about the altered state of consciousness and also psychophysical preparation. Only then the ritual has the capacity to purify and harmonize the body, mind and soul, all together. We can call this method a multi-dimensional one. This phenomenon and its use all over the world, was studied by Aaland (1978) who states that the ritual was in the past extensively used by the native Americans and, after some time, also by the colonists. It was used for both healing and harmonization of the body, mind, emotions and spirit. Smith (2005) uses sweat lodge as a form of psychotherapy. The sweat lodge ceremonies were also compared to group therapies (Colmant & Merta, 1999; Smith, 2005) and were described as holistic experiences, improving the quality of emotional, physical, cognitive and spiritual life (Wilson, 2003). Colmant and Merta (1999) found that many native Americans speak about the importance of strengthening of socialization and friendship due to the healing nature of the ceremony, which comes about with group laughter and positive mood in the sweat lodge.

Altered States of Consciousness Through The Eyes of Psychologists

Maslow (1976) perceives these mystical experiences as rebirth, "little death". He stems from various sources, although their content is similar. Maslow meticulously studied these contents and divided them into 25 points:

1. At the peak of the experience, the individual perceives the whole universe as an integrated and united whole.
2. The attention is solely on the experience, there comes a change of cognition, it becomes non-judgmental, non-comparative and non-evaluating.
3. The world, outside objects and individual human beings are being perceived separately from human interests – there comes an ability to perceive world from within a distance, like it was independent on human beings. We are able to grow and are becoming bigger.
4. The perception may become ego-transcendental, a person reaches a state of being without needs and requirements. A person is able to forgive oneself and to be selfless.
5. Mystical state is self-asserting. It proves its own truth and inner value.
6. Mystical state is more the desired end, rather than means to an end.
7. Typical is time and space disorientation or non-perception of time and space.
8. The world is perceived and accepted as beautiful, attractive, valuable, etc. Bad things on the other hand are perceived more holistically.
9. The positive perception of the world is closely related to the all-encompassing understanding.
10. The content are inner values of existence, infinite truths, or spiritual, highest religious values.
11. A human is more ready to listen and is capable of deeper listening.
12. The state is characterized by emotions such are wonder, awe, respect, humility, surrender and reconciliation.
13. Dichotomies of life, polarities and conflicts are being dissolved.
14. Fear, anxiety, reservations, awkwardness and defense mechanisms disappear temporarily.
15. The experience has sometimes immediate, or gradual effect on the individual. It is often a very profound and powerful effect which can transform the individual forever.
16. Using a metaphor, the mystical states can be compared to a visit in personally defined heaven.
17. A person grows closer to perfection

[6] Subchapter was processed as a citation of a part of an article; authors: SLADEK, Pavel, ULLRICH David. The potentials of Methods Working with Altered States of Consciousness for the Development of Selected Managerial Competencies. Scientia et Societas, 2018, vol. XIV, no. 3, p. 85-92. ISSN 1801-6057.

18. A person feels greater responsibility to him/herself and has more "free will".
19. Liberation from self and transcending ego is directly related to the strength and purity of identity of each individual.
20. Thanks to increased ability to love and accept, a person becomes more spontaneous, honest and free.
21. A person is governed more by the psychological laws, particularly the laws of a "higher life", rather than laws of physics.
22. Other typical characteristics of the state are selflessness and decreasing of motivation which leads to the person not having wants, needs or wishes.
23. Typical for the state is the feeling of gratitude and all-encompassing love for all and everything.
24. The polarity between humility and pride disappears.
25. Very common is a feeling of sacred, "unified consciousness" (1976, s. 65-74).

Below, we present some of the principals and techniques which can be used to reach the altered state of consciousness. Modified, based on Grof (2014):

- Work with mind and attention (meditation, prayer, contemplation, self-hypnosis, visualization),
- Direct and indirect work with breath (pranayama, throat singing, nada yoga, holotropic breath work),
- Sound techniques (drumming, rattling, recitation, rhythmic sounds),
- Dancing (whirling dance, trance dance),
- Social isolation and sensory deprivation (isolated stay in remote places, often with more difficult living conditions, deprivation of one or more senses, sudden change of environment),
- Sensory overload (combination of acoustic, visual and other sensory inputs, pain),
- Physiological means (fasting, sleep deprivation, dehydration),
- Specific body work and stretching (yoga, qi-gong),
- Zero gravity simulation (floating tank),
- Consumption of plants or animal secrets.

With the help of these techniques, the practitioner enters the stet of trance, thanks to which there is the possibility for quantitative transformation of personality, individual's life quality enhancement, finding new sources of creativity, inspiration, strengthening of particular ways of thinking and reasoning.

Psilocybin and Its Effect on Creativity of Thinking and Wellbeing

Contemporary neurological studies prove effective methods for <u>*increasing the neuroplasticity of brain and the growth of new neurons.*</u> *"Psilocybin is a certain biological key, which we use to open and enable a psychological material, such are suppressed emotions for psychotherapy."* (Tyls, 2018)

The newest study proved a very intense neuroplasticity effect of members of main chemical groups of serotonergic psychedelics *in vitro* and *in vivo*. (Ly et al., 2018) LSD, DMT, DOI increased the complexity of dendritic tree (neuritogenesis), stimulated the growth of dendritic spines (spinogenesis) and stimulated formation of synapses (synaptogenesis). (Tyls, 2018)

Fig. 2: Neuron growth after administration of various psychedelic substances[7]

[7] Figure 2. Psychedelics Promote Spinogenesis, Synaptogenesis, and Functional Plasticity (Ly et al. 2018)

Source: Ly et al. 2018

Psilocybin effect in healthy volunteers (Tyls, 2018)

- Long term wellbeing enhancement. (PEQ) (Griffiths, 2008)
- Trend for decrease in utilitarian / deontological solution ratio in moral dilemmas. (Pokorny, 2017)

Apparent potential use is seen in personal and personality development, stress reduction, creative process enhancement, mental activities, psychological dysfunctions prevention, solution to complex dilemmas and problems.

Conclusion

Today's modern age, although it wields newest technological innovations, is still not able to fully substitute role of human as the principal agent, being with the ability to think and to lead. As written by Horak, Kutej (2016, s. 8): *"Only human mind can give meaning to data, or added value to information."*

Modern technological innovations are in many areas a substitute for human work. But they are not able to penetrate into human minds, discover human habits, way of thinking and behavior. In the end it is again a human being, who can discern the true essence of things, predict future development and to lead a team to a successful task fulfillment. There is no doubt, the role of leader is a difficult one not only due to complex ways of thinking. A leader must be capable of good mental flexibility, critical thinking and continuous reflection. Fulfillment of these attributes leads to the leader's ability to adapt to the environment, to act quickly, creatively and effectively (Kompan, 2019), in the military environment is used the term "mindset" for it (Hrnčiar, 2018).

To fall for the paradigm paralysis may mean a threat to accuracy or correctness of a decision. There are many factors influencing the quality of decision. These factors are dependent on history, values, availability of information and personality. It is very important to cultivate inner potentials and metal work of leaders, to prevent erroneous decisions and illnesses that may come from the great psychological stress, dependency and fear. For the greater mobility in cognitive continuum, a person can learn better utilization of analytic and intuitive way of thinking which are complementary to each other. Many of the qualities which could enrich the work and life of not only leaders are hidden and can, over time, be discovered, trained and enhanced by appropriate methods, presented in this text. Since the science already knows the ways of enabling brain plasticity and neuron growth, it would be interesting to perform further testing in the context of a leader's work competencies.

The complex regeneration of organism and mind using the sweat lodge may be suitable especially in the phases of incubation and illumination, when a people change their regular environment they are used to, which can be limiting for their relationship with creativity and foreseeing of future events. Individual methods would have to be set up, tailored to attitude and leaders' personality type. They hide a great potential which is so far not recorded or explored in a scientific literature.

Analysis Motivation to Start A Start-Up Business Start-Up To the Youth of Romania

David-Florin CIOCODEICA

Bucharest University of Economic Studies, Bucharest, Romania
david.ciocodeica@mk.ase.ro

Abstract

One of the main aims of European policies in the new knowledge-based society is to make the economy in the European space the most competitive and dynamic, capable of sustainable growth, with more and better jobs, with greater social cohesion. In order to achieve this objective, the competitiveness of the organizations must continuously improve, in the conditions of a labour market that will adapt quickly to the changes in the economic, social and informational environment and to the modernization of the work process based on higher qualifications, efficiently capitalizing on the well-prepared human resources from a professional point of view. The purpose of this paper is to bring a surplus of value by presenting the most important information about entrepreneurship in Romania, starting with the conceptual delimitations of entrepreneurship and entrepreneur, and continuing with the sector of small and medium-sized enterprises, management, managerial functions, creation and development of the start-up sector and specific strategies for start-ups. It also brings to mind the motivation of young people to start their own business and to have the most efficient and accurate information when they decide to set up an organization / enterprise, as well as how the entrepreneurial principles can be applied in any area and area, in every action carried out in daily activities.

Keywords: Entrepreneurship, Entrepreneurial Marketing, Start-Ups, Campaign, Economic.

Introduction

The concept of entrepreneurship is not just about the economic environment. Antonoaie, Antonoaie and Antonoaie (2013, p. 40) highlight this concept by suggesting about entrepreneurship that “it is not just about economic activities; being possible to encounter entrepreneurial behaviour at any time in most of our fields and actions”.

Entrepreneurship is that "process by which individuals have the opportunity to become aware of the viable option that represents the development of a business, formulate new business ideas, acquire the skills necessary for a true entrepreneur and take the necessary steps to start and develop the business" (Chigunta, 2002)

The entrepreneurial spirit at the youth level is sensitive to a variety of factors, such as entrepreneurial education, institutional and business environment, access to various sources of financing, etc. (Schoof, 2006)

Peter Drucker (1985) says about entrepreneurship that it is the process of creating a new organization, without considering the organization's ability to maintain itself. Thus, Drucker considers it sufficient for an individual to open a new business, for later to be listed as an entrepreneur. This exposure to risk and uncertainty is the element that differentiates entrepreneurship from the routine tasks of management regarding the allocation of resources in an organization that is already developed.

Entrepreneurs are those innovative individuals, with a proactive orientation, who take many calculated risks (Carree, Thurik, 2005, p. 8). They are the ones who create or develop the economic activities, identifying new opportunities, with the purpose of generating value, depending on the temporal and spatial context.

In a context of globalization and technological changes, much faster that have managed to fundamentally change the importance of the innovation process, all entrepreneurial firms that fall into the category of small and medium enterprises are the engine of the whole innovative activity (Ács, Audretsch, 2003), representing the growth factor.

Entrepreneurial Marketing

Marketing, although present for a long time in the economic environment, has begun to be customized in the fields of activity: marketing and business communication, direct marketing, political marketing, international marketing, tourism marketing, event marketing. It was also implemented in entrepreneurship, although "marketing and entrepreneurship were traditionally considered two distinct fields of study. Awareness of the increasing importance of entrepreneurship and innovation, as well as of marketing for a successful entrepreneurship, has led to attempts to combine the two disciplines at present, thus forming entrepreneurial marketing" (Stokes, 2000)

"Entrepreneurial marketing is the way in which the individual and / or the organization that applies a philosophy of challenging existing conventions in the market in the process of developing new solutions behaves" (Chaston, 2000)

"The ability of entrepreneurs and small firms to manage the scale and complexity of regulations depends on entrepreneurial ability, which is an important concern of members of small business associations and representatives of entrepreneurs worldwide" (Deakins, Bensemann and Battisti, 2016).

Through entrepreneurial marketing we can capitalize on the opportunities on the market and the realization through human resources, material resources and information resources of products that consumers will love.

"Entrepreneurial marketing is based on identifying opportunities on the market and transforming the resources - knowledge, money and technology - acquired, both internally and externally (networks and alliances of the organization), in order to make products that consumers perceive. as being valuable" (Shaw, 2004).

The activities characteristic of this type of marketing involve attracting and coordinating resources necessary for the realization of innovative dreams and ideas that represent opportunities on the business market.

Entrepreneurial Process

The entrepreneurial process, according to the literature, comprises a series of five distinct stages. These are: identifying and analysing opportunities; obtaining the necessary resources; elaboration of a business plan; setting up the organization; ensuring its management. The stages of entrepreneurship can be represented graphically, using the structure that Hisrich and Peters have performed, as follows:

1. The identification and analysis of the opportunities can be realized intuitively or in a scientific way, by researching the types known by the opportunities, some of them being accessible to the entrepreneur who starts an entrepreneurial process.
2. Obtaining the necessary resources can be achieved by combining the resources that come from own sources, attracted or borrowed, taking care of the costs of each source.
3. Developing a business plan is one of the most used entrepreneurial tools.
4. The establishment of the company depends on the factors that influence the pace of this phenomenon (national economy, macroeconomic fluctuations, unemployment cost, etc.).
5. Management assurance is the entrepreneurial leadership that is absolutely necessary in any field. The knowledge of the entrepreneurial practices is not only used by those companies that face some more complex situations, generating many changes, but also in the interest of the company (Neguţ, 2010, p. 3).

The conceptual model regarding the entrepreneurial process in Romania

This conceptual model that was proposed, regarding the Romanian entrepreneurial process, starts from the GEM (Global Entrepreneurship Monitor) model published in 2008, which was revised minor (European Commission, Innovation Union Scoreboard, 2011, p. 6).

The GEM model we refer to highlights the different stages of economic development that can be experienced by a country and also claims that the activity of large companies can be modified according to the general conditions of the national economy, and the entrepreneurial activity according to the conditions within entrepreneurship.

The proposed model does not represent a gap, and within it has neglected the entrepreneurial behaviour manifested in large companies, both internally and internationally. Consequently, this model refers exclusively to the entrepreneur's representative of Schumpeter's model and the SME managers. (Wennekers, Thurik, 1999, p. 442).

The former is represented by entrepreneurs in training. After achieving their goals, entrepreneurs in training usually become owner-managers for companies (Reynolds et al., 2005, p. 209).
Taking into consideration the definition of entrepreneurship presented, the proposed model considered a similarity between entrepreneurship and entrepreneurial behaviour respectively. Behaviour that is based on the specific entrepreneurial perceptions and attitudes, namely the entrepreneurial activity.

Starting from those stages of major importance of the economic development of many countries, economies based on the factors of production, efficiency and innovation (Porter, Schwab, 2008, p. 7), focus on the conditions of the entrepreneurial framework that appear only in the last two stages of development. In Romania, the conditions of the entrepreneurial framework are focused on increasing efficiency and innovation, reflecting animated major characteristics of the economy and society (Györfy et al., 2007, p. 8).

The evolution of the Start-ups sector in Romania

Peter Drucker said that "small business is the main catalyst for growth." These businesses contribute intensely to achieving those fundamental objectives of the national economy, becoming "driving forces" for economic and social progress. (Drucker, 1999)

In connection with these two economic manifestations, prior to 1989, D. Voiculescu (Voiculescu, 1999) stated that privatization refers, in fact, to an operation to divide the national wealth, carried out while encouraging the establishment of new enterprises, which is a function of construction, which should be assumed by the authorities much more determined, as it causes the increase of the national wealth.

In the Romanian economy at present, start-ups are those that hold the first place as a share of their number: 99.44% of the total number of companies that have been registered in recent years, in Romania.

Defining the decision problem

Currently, in Romania, an increasing number of young people would like to access European public funding, so it is very important for them to have access to all the information regarding the modalities of obtaining these funds. For most young people, the most important problem they encounter when they want to access non-reimbursable funds is the lack of entrepreneurial education and information about funding opportunities, and this research aims to provide information that can help young people who want to access non-reimbursable funds and then start a start-up business.

The purpose of the research

The main purpose of this research is to study the perception of young people regarding entrepreneurship programs financed by non-reimbursable funds.

The research objectives

O1. Identifying the degree of development of start-up businesses on the market.
O2. Determining the advantages and risks associated with launching start-up businesses and highlighting the difficulties encountered when setting up the business.
O3. Identifying the entrepreneurial and managerial skills needed for a successful entrepreneur.
O4. Identify the advantages and disadvantages encountered in the success of an entrepreneur.
O5. Identification of the facilities that an entrepreneur will have from a start-up business.

Design of the questionnaire

The questionnaire was made according to the funnel principle, the questions being addressed from general to specific and it had a number of 22 questions, of which 2 filter questions, 5 closed, 4 questions measured on a Likert scale, 4 questions of a semantic differential scale type. The questionnaire comprises 7 socio-demographic identification questions.

The questionnaire contains open, closed, dichotomous and multiphotonic closed questions.

The questionnaire was designed in electronic format on the platform http://www.esurveyspro.com/. It was sent to the individuals who set up a start-up with financing European for the last 2 years within the entrepreneurship projects carried out in the Academy of Economic Studies in Bucharest, this being distributed to other groups of entrepreneurships in Romania.

In the research presented, a non-probability sample of 72 respondents was used, the technique of selecting the respondents was "snowball". The questionnaire was distributed to 107 respondents, out of 72 respondents completed the questionnaire, and 35 respondents were eliminated through the 2 filter questions.

Univariate analysis and interpretation of research results

Most of the respondents (70%) set up a start-up business with European non-reimbursable funds, while the remaining 30% did not set up the first start-up business with European non-reimbursable funds.

37.70% of the respondents agree that accessing the non-reimbursable funds was a difficult process and only 9.84% fully agree. 34, 43% are indifferent to this statement. 34.43% and 3.28% disagree, respectively total disagreement.

45.90% of the respondents disagree with the fact that the opening of the start-up was a costly and difficult task and 14.75% are in total disagreement. 21.31% of the people surveyed are indifferent to this statement. In contrast, a percentage of 14.75% and 3.28% agree, respectively, in total agreement that the opening of the company (start-up) was a costly and difficult action.

Most of the respondents (50.82%) agree with the statement "The eligibility conditions regarding the accomplishment of the business plan were easy to fulfil" and 9.84% totally agree with this statement. 26.23% of the surveyed persons are indifferent about the eligibility conditions. 9.84% and 3.28% disagree, respectively totally disagree with this statement.

37.70% and 16.39% agree, respectively completely agree with the statement "The knowledge necessary to achieve a business plan I have acquired them through ANC accredited entrepreneurship courses". 22.95% and 3.28% of those surveyed disagree, respectively completely disagree with the statement and 19.67% are indifferent.

A percentage of 45.90% and 9.84% agree, respectively in total agreement with the fact that the provisions regarding the financing required a considerable effort to fulfil the conditions for setting up the start-up, as well as obtaining the subsidies. 24.59% of the people questioned are indifferent to this statement. 16.39% and 3.28% disagree, respectively totally disagree with this statement.

A percentage of 31.15% and 11.48% of the respondents agree, respectively in total agreement with the statement "We have easily solved the administrative aspects regarding obtaining the financing". 28.51% and 9.84% disagree, respectively total disagreement with the fact that they easily solved the administrative issues regarding obtaining the financing and 18.03% are indifferent.

Over half of the respondents had problems with launching the start-up regarding high administrative costs (54% of cases), lack of information on tax law (54%), delay of financing (88% of cases), lack of entrepreneurial education (56%), lack of organization development location (57%) and competitive barriers (66%).

The small number of people interested in a start-up business was not a hindrance, nor was the lack of knowledge regarding the steps to be taken when launching a start-up.

30% of young people with start-ups agree that entrepreneurial and managerial education is the main facility that an entrepreneur can benefit from financing and only 27% consider that reducing taxes is the main facility. Another 18% consider that this main facility is the qualification and training of the personnel, 16% sports legislation, and 9% consider that the access »within the associations of entrepreneurs is the main facility of the given list.

Conclusion

Entrepreneurship cannot be done by anyone, it involves initiative and ideas, a high degree of creativity, competence, knowledge and skills that allow you to move quickly in any field of activity. It involves attracting and using in an effective way some categories of resources for solving certain requirements in our society, regardless of the activity we carry out.

Consumer behaviour differs because people's needs and perceptions are different, influence factors differ. In addition, the cultures are different, and this is one of the essential factors of the consumption decision. In other words, producers who want to operate in a different market must model themselves according to its specificity and culture if they want to meet their needs.

The main conclusions from the research are:

• 47.54% of the respondents agreed that accessing some non-reimbursable funds was a difficult process while 37.71% considered that the funds could be easily accessed.

• Opening the company (start-up) is not a costly and difficult task, as stated by 60.65% of the respondents, while only 18.08 do not agree with this.

• Most of the respondents (50.82%) agree with the statement "The eligibility conditions regarding the realization of a business plan were easy to fulfil" while 13.12% reject this statement

• 54% of the respondents stated that they have entrepreneurial knowledge acquired through ANC accredited entrepreneurship courses".

• A percentage of 45.90% and 9.84% agree, respectively in total agreement that the provisions regarding the financing required a considerable effort to fulfil the conditions for setting up the start-up, as well as obtaining the subsidies. 24.59% of the people questioned are indifferent to this statement. 16.39% and 3.28% disagree, respectively totally disagree with this statement.

• A percentage of 42.63% of the respondents stated that it was easy to solve the administrative aspects regarding obtaining the financing". 28.51% and 9.84% say the opposite.

• A total of 88% of the respondents consider that the implementation of their own business idea is an advantage of opening a start-up, 74% that the operational management is the sought advantage, and 85% that obtaining non-refundable funds is the advantage of opening such a project. The risks perceived by young people when initiating start-ups from non-reimbursable funds are represented by the existence of an laborious process of accessing the sources of financing of the business (69%), the implementation of an inappropriate idea that can have an unfavourable result (69%) , long start-up time (67%), high costs for financing a start-up (63%), lack of information on European regulations targeting various development areas (60%), fierce competitive environment (58%) .

• Over half of the respondents had problems with launching the start-up regarding high administrative costs (54% of cases), lack of information on tax law (54%), delay of financing (88% of cases), lack of education entrepreneurial (56%), lack of an organization development location (57%) and competitive barriers (66%).

• The small number of people interested in a start-up business was not a hindrance, nor was the lack of knowledge regarding the steps to be taken when launching a start-up.

• The respondents consider that the most important competences for a successful entrepreneur are: prioritizing tasks (91%), successfully completing activities (90%), analytical (89%), proactivity (86%), sociable (70%), efficient communication (66%).

• 30% of young people with start-ups consider that entrepreneurial and managerial education is the main facility that an entrepreneur can benefit from in the financing and only 27% consider that reducing taxes is the main facility.

Abstract

The use of celebrities to alert people about social causes is currently a popular marketing technique used by non-profit organizations, and philanthropy becoming a trend for the younger generation gave the spotlight for non-profit organizations to do social campaigns, especially campaigns using celebrities. Therefore, this research intent is to know how effective communication using celebrities in the non-profit sector. This research discusses Celebrity Credibility, Entity Credibility, Attitude Towards Ad, Behavioural Intentions, Perceived Fit, General Fit, Motivation Attribution, Attitude Towards Celebrity being used in communication using celebrities. Structural Equation Modelling using Lisrel 8.8 was used to analyze communication effectiveness using a celebrity in the non-profit sector. The research result shows that Attitude Towards Ad and Entity Credibility influences Behavioural Intentions, Entity Credibility, and Celebrity Credibility influences Attitude Towards Ad, Motivation Attribution along with Perceived Fit influences Celebrity Credibility, Perceived Fit influences Motivation Attribution, and Perceived Fit is being influenced by Attitude Towards Celebrity and General Fit.

Keywords: Attitude Towards Ad, Motivation Attribution, Attitude Towards Celebrity, Non-Profit Sector

Introductions

An advertisement spending survey conducted by Nielsen in 2017 reports about Indonesia's advertisement income growth of 8%, surpassing more than 10 million dollars. The growth can be explained with the growth of digital advertising itself in Indonesia. Another survey by PubMatic 2019 Digital Ad Trends Report predicts Indonesian digital advertising will increase by 26% in the future. Advertising using celebrities is a form of brand advertising used by companies to form a long mutual bond with consumers. Generally, using celebrity endorsement is a well-established marketing strategy. Multinational companies like Nike and Adidas have long used this strategy, and it's always a success. For instance, Badenhausen from Forbes (2018) reported that Lionel Messi alone yields a massive 111 million dollar for Nike, and Cristiano Ronaldo yields around 216 million dollars for Adidas. Not only massive multinational companies use this strategy, big regional companies such as E-Commerce company Shopee is also known to have Cristiano Ronaldo and famous K-Pop girl group Blackpink as their ambassador. Shopee is also known for its viral catchy campaign video song with Blackpink. In Indonesia, local E-Commerce company Tokopedia hauls K-Pop superstar BTS as their brand ambassador. A local cosmetic company called Wardah also has a lot of celebrity spokespersons for their cosmetic campaigns. The usage of celebrities in advertising is a part of the persuasive advertising technique. Other than celebrities, companies can use emotional appeal, bandwagon advertising, or patriotic advertisements to use persuasive advertising (Romanova & Smirnova, 2019). Celebrity endorsement itself is defined as 'every person who gains popularity from the public and use it for advertising products or services' (Osei-Frimpong et al., 2019).

Cite this Article as: Nadifa Nur Aliza SHAFIRA and N.I.S PUTRI "Communication Using Celebrities in The Non-Profit Sector: Case Study of BAZNAS" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

There is growing interest in the non-profit sector to use a different marketing strategy, and using celebrities to convey messages about social causes become a popular marketing technique (Kotler & Andreasen, 2003). Many celebrities are supporting non-profit organizations and campaigns about social cause actively. Even though a celebrity's popularity is deemed extremely useful for the non-profit organization, the public may question the celebrity true motives during social campaigns (Samman et al., 2009). Amidst the popularity of using celebrity amongst non-profit organizations, a celebrity's association with a non-profit organization can either improve or worsen public perspective towards non-profit organizations. A relationship between celebrity endorser and a non-profit organization can be strengthened if the celebrity fits the non-profit organization's image. The public's response towards messages conveyed by celebrity endorsers about a social cause can be perceived differently depending on the public who accepts the message (Hajjat, 2003).

For instance, Leonardo DiCaprio is a well-known activist and is listed as WWF's leaders, where his campaigns about climate change have gathered 65 million dollars so far for WWF. In Asia, actor and idol Choi Siwon has donated 1.4 million won to UNICEF and encourages his fans to do the same, resulting in many donations made by his fans under his name. In Indonesia, it's a trend for Indonesian youth to be a social entrepreneur. With the founding of new philanthropic movements for youth such as Pekan Donasi Online Indonesia (PEDOELI) and the Filantrop Muda Festival, the competition between one non-profit organization and another tightens using celebrities to endorse their social cause became a popular marketing strategy. For example, UNICEF is naming Nicholas Saputra as their national ambassador for Indonesia and using him for campaigns about the lack of sanitation in isolated areas for children. The campaign eventually gains interest from the public because Nicholas Saputra is endorsing it. Another example is the young singer Maudy Ayunda who created a famous youth philanthropic movement called 'Kejar Mimpi' to help young children fulfil their dreams.

Not every celebrity or public figure can be an eligible endorser for non-profit organizations. Mostly, non-profit organizations chose public figures who have been an activist for quite a while, since non-profit organizations need a fit between their social cause and celebrities representing them (de los Salmones et al., 2013). A celebrity itself is a famous figure who enjoys public recognition by a group of people (Schlecht, 2003). A celebrity can be a comedian, athlete, actor or actresses, singer, or anyone known to the public by their merits. According to Legg, (2009), televangelism or religious public figure is popular in America during the 1980s, and famous pastors on the television are equivalent to a celebrity. Besides preaching, famous television pastors raise funds for their church through the television. Raising funds through television is proven effective because famous pastors on television have a cult following who will do as what the pastor said, therefore making religious public figures raising funds a known strategy.

In this research, the research's focus will be on a non-profit organization called Badan Amil Zakat Nasional, known as BAZNAS. BAZNAS is a non-profit organization established by the government to raise and allocate Zakat, Infaq, and Sedekah in Indonesia. The youth philanthropy trend could be a breakthrough for BAZNAS to raise awareness of the youth to pay zakat once they fall to the Zakat-able category dutifully. On July 11 of 2018, Ustadz Abdul somad, a famous Indonesian preacher and well-known religious public figure from Asahan, North Sumatera, is named as Indonesian Zakat Ambassador by BAZNAS. Indonesian Zakat Ambassador is hoped to inspire Indonesian people, especially its youth, to dutifully pay their zakat through BAZNAS and perform BAZNAS' motto, "Strong because of BAZNAS," symbolizes that Indonesia will be stronger because of zakat. Ustadz Abdul Somad is a popular religious public figure amongst the youth, making him the perfect influence for the younger generation to pay zakat later in life. According to BAZNAS, Indonesia has a 233,8 billion untouched Zakat potential that has been failed to be optimized, making BAZNAS resorts to creative marketing strategies to optimize said potentials.

This research aim is to see the impact of communication using celebrities for the non-profit sector. Using celebrities in the non-profit sector differ from the profit sector; therefore, this research also evaluates credibility attributes that can change public perception towards the celebrity's social cause. This research also aims to identify the role of a non-profit organization towards celebrity endorsing them, research the influence of altruistic motivation attribution of a celebrity towards its effectiveness of conveying social cause, and research the fit between celebrity and social cause. Therefore the research title is "Communication Using Celebrities In The Non-Profit Sector: Case Study of BAZNAS" to achieve those aims.

Theoretical Review

Celebrity Credibility

A celebrity is a famous figure who enjoys public recognition by a group of people (Schlecht, 2003). A celebrity can be a comedian, athlete, actor or actresses, singer, or anyone known to the public by their merits. Celebrity credibility is one factor considered for choosing a celebrity to endorse a brand (Terrence, 2000). Celebrity credibility can be explained by the source credibility model and source attractivity model. This model explains that the effectiveness of a message conveyed by a celebrity depends on their expertise, attractiveness, and trustworthiness, which also the factors affecting advertising effectiveness using celebrities (Clarke, 2002).

Entity Credibility

A non-profit organization can be defined as an organization in which profit is used for an organizational social purpose. A non-profit organization's key factors are accountability, trustworthiness, honesty, and openness to each stakeholder who has invested money, time, and trust in the organization. A non-profit organization is responsible for its donors, funders, volunteers, program recipients, and the public. The more focused a non-profit organization with their missions, the more credible they are to the public, and the more people will donate to their organization (Ciconte, Barbara L.; Jacob, 2011).

Attitude Towards Ad

Attitude towards ad can also be defined as a tendency to respond positively or unfavorably to a particular advertising stimulus during a particular situation (Ahmed Sallam & Ali Algammash, 2016). According to Ahmed Sallam & Ali Algammash, (2016), attitude toward advertisement is already presumed with any consumer. Since the consumer is already exposed to the advertisement, the advertisement's influence can be observed from the consumer's reaction. Brand beliefs and feelings also thought to be affecting attitudes towards ad. (Kaushal & Kumar, 2016)

Fit

Generally, the fit is defined by the strategic fit between a celebrity and a non-profit organization's social cause, audience target, and values (Becker-Olsen et al., 2006). The more compatible a non-profit organization with a celebrity who endorsed them, the higher consumer's cognitive consistency, and the higher the positive response is (Speed & Thompson, 2000). If the fit between a non-profit organization and the celebrity-endorsed them is low, the consumer will undergo a cognitive inconsistency that affects their response negatively (Porter & Kramer, 2002). One of the factors of successful communication advertising using celebrities is fit, which refers to similarity and suitability between a social cause and a celebrity. Generally, a good fit increases celebrity credibility and eventually increases communication effectiveness.

Motivation Attribution

The relationship between a non-profit organization or a celebrity with altruistic motivation can result in higher credibility of both if there is a high fit between a non-profit organization or celebrity with social motivations (Klein & Dawar, 2004); Ellen et al., 2006). According to Forehand & Grier, (2003), it's shown that consumer responds negatively towards a non-profit organization social campaign if they have egoistic motives, the consumer would feel cheated and deceived. Consumer's perception towards altruistic motivation needs the similarity between social messages conveyed with the organization's real motives; if not, the consumer will feel deceived and manipulated (Enrique Bigné et al., 2009).

Behavioral Intentions

Specific behavior marks a consumer's relationship with a non-profit organization. When the consumer exhibits a positive attitude towards a non-profit organization, it proves a positive relationship between the consumer and the non-profit, and has the consumer will have a positive tendency to donate (Ranganathan & Henley, 2008). According to Zeithaml et al. (1996), consumers' satisfaction and positive quality perception positively affect behavioral intentions. There is a positive relationship between the quality perception of service and the consumer's desire to recommend a service company (Parasuraman & Berry, 2004). A consumer can be concluded to have positive

behavioral intentions towards a company if they have a favorable opinion towards the said company, recommending the company to other people, paid extra to the company, and is loyal to the company (Parasuraman & Berry, 2004).

Ustadz Abdul Somad and Badan Zakat Nasional

Ustadz Abdul Somad Batubara is a preacher and religious public figure from Asahan, North Sumatera. He was a lecturer in Universitas Islam Negeri Sultan Syarif Kasim, is a bachelor graduate of Al-Azhar Egypt, and a master graduate of Dar al-Hadith al-Hassania Marocco. BAZNAS or Badan Zakat Nasional is the only official organization that is entrusted to allocate zakat. BAZNAS is an independent organization that is responsible to the Ministry of Religious Affairs of Indonesia.

Methodology

The study population comprises Indonesian people who are Muslim and aged 18 to 24 years old, a university student and are familiar with both Ustadz Abdul Somad and Badan Zakat Nasional. Before completing the questionnaire, the respondent was asked whether they are familiar with Ustadz Abdul Somad or not, and only those who are familiar can continue the survey. Respondents were also given a reading passage about Ustadz Abdul Somad and BAZNAS. The sampling method used is non-probability sampling, with a purposive sampling technique. The questionnaire is given using google form. This research was able to gather 283 respondents, but only 170 are eligible for the research. One hundred thirteen of the collected response wasn't eligible because of incomplete responses and did not fit the criteria needed in this study. The respondents are mostly female, boasting an 84.5% or 142 out of 170, and the rest was male, 28 out of 170, or 16.50%. This research is also adapted from de los Salmones et al. (2013) for a non-profit organization context, without changing any variables. However, the criteria of respondents are changed to match the non-profit organization used in this research.

There are nine hypotheses on this research, which is;

Figure 1: Research Model

H1: Celebrity credibility is directly and positively related to the attitude towards the advertisement.
H2: Entity credibility is directly and positively related to attitude towards the advertisement.
H3: A good image fit between the celebrity and the social cause is directly and positively related to celebrity credibility.
H4: Attribution of altruistic motivations to the celebrity is directly and positively related to their credibility**.**
H5: A good image fit between celebrity and the social cause is directly and positively related to the attribution of the altruistic motivation of the celebrity
H6: The attitude towards celebrity is positively related to the perceived fit between the celebrity and social cause.

H7: The positive attitude towards the involvement of celebrities in social causes is directly related to the perceived fit between the celebrity and the social cause
H8: The attitude towards advertisement is directly and positively related to behavioral intentions
H9: Entity credibility is directly and positively related to behavioral intentions.

This research is causal analysis research using Structural Equation Modelling or SEM. The SEM method is used because this method can analyze relationship patterns between the latent variable and its indicator, one latent variable to another, and can find measurement mistakes directly (Hair et al., 2010). Primary data that has been gathered is analyzed using SPSS 25 and LISREL 8.80. SEM method begins with a validity and reliability test for the measurement model, followed by a model compatibility test using the goodness of fit test. Model compatibility is also tested within the structural model, also using the goodness of fit test. The structural model test is run using a causality relationship analysis to see significance and value between hypotheses variables by evaluating the t-value, SLF, and determination coefficiency in the research model.

Results

Descriptive Statistics

The result obtained from the main test showed 283 respondents, but only 170 is eligible for the research. This sample size is adequate as there are only 35 items in the questionnaire. Hair (2010) stated that 10 times the maximum number of inner or outer model links pointing at any latent variable in the model (Goodhue et al., 2012), which is 175 from 35 multiplied by 5 because 10 divided with two for the inner and outer model links equals 5. This research's criteria are specific, which only those whose age is between 18 to 24 years old, is currently a university student, and a Muslim is eligible for the research. Based on said criteria, 19 of the initial respondents do not fit the criteria under the age of 18, and 94 of the respondents are not familiar with BAZNAS nor Ustadz Abdul Somad. Therefore, only 170 of the remaining respondents are eligible for the research and free of central tendency.

Table 1: Respondents

No.	Profile		Amount	Percentage
1	Gender	Female	142	83.50%
		Male	28	16.50%

On the above table, most of the respondent is female, 83.50% of the majority and the rest is male, around 16.50% percent.

Validity and Reliability Analysis

Measurement model analysis starts with a validity test and reliability test; in which the test is conducted using Composite Reliability measure (CR) value and Variance Extracted measure or VE value from all of the variables used in this research. CR value must be above 0.70 to be deemed reliable, and the VE value must be above 0.5 to be deemed valid. All the variable of this research is valid because all the VE value exceeded 0.5, and t-value exceeded 1.645. All variables also concluded as reliable because the CR value exceeded 0.7.

Table 2: Reliability Analysis

GOF Measures	Value	Fit Indicator
Absolute Fit Measures		
Chi Square	1062.40 (P = 0.0	
Value NCP	413.96	
Value GFI	0.76	Poor Fit
Value RMR	0.038	Good Fit
Value RMSEA	0.066	Good Fit
Incremental Fit Measures		
TLI/Non-Normed Fit Index	0.98	Good Fit
Value NFI	0.96	Good Fit
Value Adjusted Goodness of Fit Index	0.71	Poor Fit
Value RFI	0.95	Good Fit
Value IFI	0.98	Good Fit
Value CFI	0.98	Good Fit
Parsimonious Fit Measures		
Value PGFI	0.64	-
Value PNFI	0.86	-
Value Akaike Information Criterion	1179.96	Good Fit
Value Saturated AIC	1332	
Value Independence AIC	23869.89	
Value Consistent Akaike Information Criterion (CAIC)	1593.54	Good Fit
Value Saturated CAIC	4086.44	
Value Independence CAIC	24018.78	
Other GOFI		
Value Critical N	103.95	-

Followed by the compatibility of the model test using the goodness of fit test. The goodness of fit is used to evaluate the fit between data and model (Wijanto, 2008). There are three measures of GOF, absolute fit measures, incremental fit measures, and parsimonious fit measures (Hair et al., 2010). For a model to be called fit, there have to be three indices that can be deduced as a good fit, one from absolute fit measures, one from incremental fit measures, and one from parsimonious fit measures. The chi-square value and degree of freedom value are also considered. For this research, the model is concluded as a good fit because the RMSEA value is 0.066, CFI, and IFI value is 0.97. The AIC and CAIC value is also concluded as a good fit because both values approached the saturated value more than its independence value. Therefore, the model can be concluded as a good fit.

Structural Model Analysis

The next step is to analyze the structural model, starting with a goodness of fit test conducted to the structural model. The goodness of fit of the overall structural model is concluded with a good fit; the RMSEA value is 0.08, the CFI and IFI value is 0.97. The AIC and CAIC value is also concluded as a good fit because both values approached the saturated value more than its independence value. Therefore, the model can be concluded as a good fit.

Structural analysis is conducted by analyzing the relationship between latent variables by evaluating t-value and standardized loading factor or SLF value. T-value is used to analyze the influence on the latent variable of the model. T-value used in this research is T-value≥ 1.645 since this research is one-tailed. The criteria for the SLF value of the observed variable is above 0.5.

Table 2: Causal Model Analysis

Hypotheses	Path	*t-value*	Explanation
H1	CC → AAD	**8,26**	Significant and positively influent
H2	EC → AAD	**2,25**	Significant and positively influent
H3	FIT → CC	**4,07**	Significant and positively influent
H4	MA → CC	**3,85**	Significant and positively influent
H5	FIT → MA	**8,8**	Significant and positively influent
H6	AAD → FIT	**7,58**	Significant and positively influent
H7	GFIT → FIT	**4,24**	Significant and positively influent
H8	AAD → BI	**3,31**	Significant and positively influent
H9	EC → BI	**5,50**	Significant and positively influent

This research also showed the determination coefficiency or R^2 to see the dependent variable's influence towards the independent variable. R^2 is seen from a reduced form equation (Wijanto, 2008).

Table 3: Determination Coefficiency

No.	Variable	R^2 Value
1	Celebrity Credibility	0.75
2	Attitude Towards Ad	0.66
3	Perceived Fit	0.60
4	Motivation Attribution	0.67
5	Behavioral Intentions	0.41

a. Celebrity Credibility R^2 is 0.75, which means 75% of the celebrity credibility variable is explained by perceived fit and motivation attribution, and other variables explain the rest.
b. Attitude towards ad R^2 is 0.66, which means 66% of the ad variable's attitude is explained by entity credibility and celebrity credibility, and other variables explain the rest.
c. Perceived Fit R^2 is 0.60, which means 60% of the perceived fit variable is explained by the attitude towards celebrity and celebrity credibility, and other variables explain the rest.
d. Motivation attribution R^2 is 0.67, which means 67% of the motivation attribution variable is explained by perceived fit, and other variables explain the rest.
e. Behavioral intentions R^2 is 0.41, which means 41% of the behavioral intentions variable is explained by the attitude towards ad and entity credibility, and other variables explain the rest.

Mediation Analysis

In the model used for this research, some variables have a mediation effect, the hypothesis which tests the relationship between entity credibility and behavioral intentions. The relationship between both variables happens directly and indirectly through the attitude towards the ad variable.

Table 4: Mediation Analysis

Relationship	Indirect Effect Coefficient	T-value Indirect Effect	Direct Effect Coefficient	T-value Direct Effect	Mediation
ECRED→ AAD→BEHINT	0.04	1.89	0.52	6.04	*Complementary mediation*

From the direct effect and indirect effect test conducted above, the results show that both effects have significant t-values. It can be concluded that the entity credibility variable significantly and positively influenced behavioral intentions, both directly and indirectly. The indirect effect coefficient of entity credibility towards behavioral intentions is 0.04; meanwhile, the direct effect coefficient of entity credibility towards behavioral intentions is 0.52; therefore, it can be concluded that the direct effect is greater than the indirect effect. The result corresponds with de los Salmones et al., (2013) research, which also concluded that behavioral intentions are mostly explained with entity credibility. The same research also explains that attitude towards ad is also influencing behavioral intentions, so behavioral intentions are not entirely only explained by entity credibility.

Explanations

Based on the result of this research, this research accepted all the hypotheses available.

H1: Celebrity credibility is directly and positively related to the attitude towards the advertisement.

H1 shown that celebrity credibility is directly and positively related to the attitude towards the advertisement. The relationship between the two variables shown a T-value of 8.26, therefore accepting the hypothesis. Results correspond with de los Salmones et al. (2013), which also shown celebrity credibility is directly and positively related to the attitude towards advertisement and corresponds with Eisend & Langner, (2010) research, which explains that credible celebrities increase advertisement effect.

H2: Entity credibility is directly and positively related to attitude towards the advertisement.

H2 shown that entity credibility is directly and positively related to attitude towards the advertisement. The relationships between said variables have a T-value of 2.25, therefore accepting the hypothesis. Results correspond with (de los Salmones et al., 2013) and with (Newell & Goldsmith, 2001), which explains that the more credible a company is, the more positive results can be gained.

H3: A good image fit between the celebrity and the social cause is directly and positively related to celebrity credibility.

H3 results in good image fit between celebrity and the social cause are directly and positively related to celebrity credibility. The relationships between both variables have a T-value of 4.07, therefore accepting the hypothesis. Results correspond with (de los Salmones et al., 2013). Another research also corresponds with the result (Enrique Bigné et al., 2009), which explains how consumers would assess a celebrity if the celebrity fits the social cause.

H4: Attribution of altruistic motivations to the celebrity is directly and positively related to their credibility.

H4 results in attribution of altruistic motivations to the celebrity are directly and positively related to their credibility. The relationship between the two variables has a T-value of 3.87, therefore accepting the hypothesis. Results correspond with (de los Salmones et al., 2013), which explains the egoistic motive of a celebrity can decrease the credibility of a celebrity, therefore making an altruistic celebrity more credible.

H5: A good image fit between celebrity and the social cause is directly and positively related to the attribution of the altruistic motivation of the celebrity

H5 shown that a good image fit between celebrity and the social cause is directly and positively related to the attribution of the celebrity's altruistic motivation. The relationship between both variables has a T-value of 8.80, therefore accepting the hypothesis. It can be concluded that this research corresponds with (de los Salmones et al., 2013), and (Rohini & Zeynep, 2000), which explains that if there is a good fit between celebrity and social cause, the consumer will assume that said celebrity’s motivation is altruistic.

H6: The attitude towards celebrity is positively related to the perceived fit between the celebrity and social cause.

H6 shown that attitude towards celebrity is positively related to the perceived fit between the celebrity and social cause. The relationship between both variables has a T-value of 7.58, therefore accepting the hypothesis. Results correspond with (de los Salmones et al., 2013), Choi & Rifon (2007), which explain that consumers' perceptions towards celebrity can affect consumers' perceptions of fit between celebrity and social cause.

H7: The positive attitude towards the involvement of celebrities in social causes is directly related to the perceived fit between the celebrity and the social cause

H7 shown that a positive attitude towards celebrities' involvement in social causes is directly related to the perceived fit between the celebrity and the social cause. The relationship between the two variables has a T-value of 4.24, therefore accepting the hypothesis. This also corresponds with (de los Salmones et al., 2013) and Van den Bulck et al. (2016), which explains that generally, consumer supports the use of celebrity to convey messages; therefore they will have a more positive attitude towards other celebrities who represent social causes.

H8: The attitude towards advertisement is directly and positively related to behavioral intentions

H8 results in attitude towards advertisement are directly and positively related to behavioral intentions. The relationship between the two variables has a T-value of 3.31, therefore accepting the hypothesis. This corresponds with (de los Salmones et al., 2013) and Ranganathan & Henley (2008), which explains that a positive attitude towards advertisement leads to a positive attitude towards donating to non-profit organizations.

H9: Entity credibility is directly and positively related to behavioral intentions.

H9 results in entity credibility are directly and positively related to behavioral intentions. The relationship between the two variables has a T-value of 5.50, therefore accepting the hypothesis. This corresponds with (de los Salmones et al., 2013) and Ranganathan & Henley (2008), which explains that non-profit organizations' credibility affects consumers' behavioral intentions.

Results and Discussions

According to Zahaf & Anderson (2008), the celebrity factor might not have any real effect on consumers even though consumers' willingness to buy can be complemented by a celebrity endorser. Therefore, in some cases, celebrity endorsers would not have any impact on the consumer. The effectiveness of celebrity endorsers can also decrease when the celebrity overexposes themself to the public (Osei-Frimpong et al., 2019). From these results, it can be concluded that using celebrities is not always effective, whether the celebrity is used for the profit sector or the non-profit sector. Even so, celebrities are still considered very effective fundraisers. De los Salmones et al. (2013) have proven that even though celebrity activism is criticized, many people realize that using celebrities for promoting non-profit organizations is beneficial. Therefore, non-profit organizations using celebrities as their marketing strategy won't be questioned anymore, making the strategy even more effective.

This research aims to know the effectiveness of communication using celebrities in the non-profit sector. Based on previous explanations, it can be concluded that this research generally has the same results as de los Salmones et al. (2013). The results show that attitude towards ad and BAZNAS' entity credibility directly and positively affect consumer's behavioral intentions. BAZNAS' entity credibility and Ustadz Abdul Somad's celebrity credibility directly and positively affect attitude towards the ad. Motivation attribution and perceived fit between Ustadz Abdul Somad and BAZNAS directly and positively affect Ustadz Abdul Somad's celebrity credibility. The perceived fit between Ustadz Abdul Somad and BAZNAS also positively and directly affect consumer's perception of their attribution of motivation. Also, attitude towards celebrity and general fit directly and positively affect perceived fit between BAZNAS and Ustadz Abdul Somad.

Suggestions and Future Research

This research can conclude that attitude towards ad and entity credibility affects consumers' behavioral intentions towards non-profit organizations. Explained with mediation analysis, it is known that the indirect effect of entity credibility towards behavioral intentions is less influential compared with the direct effect of entity credibility towards behavioral intentions. It can be concluded that it's more effective for the non-profit organization to directly increase entity credibility to affect consumers' behavioral intentions positively. Entity credibility is also greatly affected by the effectivity of conveying social messages to the public; therefore, a credible entity is an entity that is honest with their claims.

To effectively convey messages using celebrities, one must pay attention to said celebrities' credibility, since a celebrity's credibility significantly affects the effectivity of conveying social causes. The more credible a celebrity, the more effective the communication is. To convey a social cause, a celebrity needs to have a vast knowledge of social causes to be perceived as credible to represent the public's social cause.

For future research, there is a need to further study the effectivity of communication using celebrities. This research has researched only the non-profit sector. To see a different result, a comparison could be made with a study of communication using a celebrity in the profit sector. Future research can use broader occupation criteria for respondents and a broader age limit for the respondents as well.

Abstract

Women entrepreneurship is an inclusive entrepreneurial activity of women who initiates businesses with potential for innovation and competitiveness. Women contribution both in domestic and international trade is significantly essential to the overall economy and for improved national GDP. The assumption is that women entrepreneurs' contribution to export is critical to achieving SDG plans 1 -5, 10 and 12- zero hunger, good health and wellbeing, gender equality, quality education, poverty reduction and responsible consumption and production. However, women entrepreneurs face limitations ranging from the initial start-up fund, socio-cultural, political, legal and environmental problems, governmental inconsistencies, operational infrastructure constraints. These evolved low intensity of entrepreneurial involvement, and many women are establishing their businesses in the low-growth informal sector, thereby hindering sustainable growth in the nation. Hence the focus of the study is to measure the relationship between women entrepreneurial inclusiveness and the inherent constraints in the non-oil export sector and the performance implication. The study adopted a descriptive approach using SPSS version 24 via both correlational and regression data analyses. The study employed one hundred and thirty-four (134) women entrepreneurs in Spice and Food processing, Apparel/Fashion, and Information Technology services as sample population for the survey. The findings indicated governmental policy inconsistent and support constraint have an inverse relationship with women entrepreneurs' performance, explaining it as a critical issue, while procedural, and environmental have a moderate effect, marketing constraint has no significant effect. Hence, women entrepreneurs need improved government support, favourable policies, and entrepreneurial training required for sustainable higher innovative performance in the export market.

Keywords: Women entrepreneurial inclusiveness, Entrepreneurial Constrains, Non-Oil Export, Performance.

Introduction

Women involvement in international trade is recognised as equally important to the overall economy and improved GDP of nations. Conversely, existing literature uncovered that women are under-represented due to the socio-cultural perception of being incapable of accomplishing entrepreneurial feats and unfit to participate in emerging business opportunities. Yet, their contribution to society and poverty reduction cannot be overemphasised (Misango & Ongiti, 2013; Sajuyigbe & Fadeyibi, 2017). Women entrepreneurs own close to 10 million of the world's small and medium-sized enterprises (SMEs); and account for almost 80% of jobs around the world, as well as generate 50% of global GDP (OECD, 2018). Nigeria pursues a more diversified economy that allows more inclusive opportunities for women entrepreneurs to participate actively and complementarily, and benefit from entrepreneurship incentives. However, there exists a significant number of constraints facing women entrepreneurs in their efforts to participate in emerging business opportunities competitively. The inequity in resource allocation is a clog in the growth of entrepreneurship, as well as widened the gender gap in the contribution towards sustainable development (Bako & Seyd, 2018). Women entrepreneurs face limitations ranging from the initial start-up fund, skill gaps, socio-cultural, and environmental problems, governmental inconsistencies, operational infrastructure constraints. These constraints evolved low intensity of entrepreneurial involvement, and many women establish their businesses in the low-growth informal sector, thereby hindering sustainable growth in the nation (Ekwochi, 2020; Kolawole & Adeigbe, 2016). Still, McKinsey report (2015) posited that women could grow Nigeria's GDP by 23% ($229 Billion) by 2025, based on achieving gender parity in the distribution of resources.

In the non-oil export sector, the Nigeria Export Promotion Council report (NEPC, 2016) alluded that women entrepreneurs face a harsh struggle in Nigeria. They have challenges regarding creating and managing high-performance ventures premised on inadequate financing, low education, weak social networks, insufficient information, as well as deficient quality standards measures. Exporting women entrepreneurs also face the dilemma of choosing and making decisions on how to grow and sustain their businesses in the face of rapid changes in foreign market environments. These reasons, among others, make few women own or manage firms engaged in foreign markets to operate sustainably (International Trade Centre (ITC, 2019). The assumption is that women inclusiveness and growth in export sector (international business) is critical to achieving SDG goals 1 -5 (People- no poverty, zero hunger, good health /wellbeing, gender equality, quality education); goals 8-10 (Prosperity- decent work/ economic growth, Industry/innovation/infrastructure, reduced inequalities); and goal 12 (Planet- responsible consumption/production). Trade flows stimulate productive capacity, efficient markets, transforming economies, reducing vulnerabilities and building resilience (Osakwe & Kilolo, 2018; UNCTAD, 2020). Hence the study investigates the relationship between the women entrepreneurial inclusiveness and related constraints in the non-oil export sector and performance.

Literature Review

Women Entrepreneurial Inclusiveness

Women entrepreneurship is an inclusive entrepreneurial activity of women who initiates businesses with potential for innovation and competitiveness (Ariffin, Baqutayan, & Mahdzir, 2018; ITC,2018). Women entrepreneurs intentionally scan their environment for opportunity identified, take risks to combine resources uniquely and manage the production of goods/services innovatively, which could alter the norm in the industry of choice. Several studies concluded that economic development is closely related to advancing women participation in the economy to enable consistent growth; otherwise, women restriction may slow the economy (Bako & Syed, 2018; Sajuyigbe, & Fadeyibi, 2017). Women entrepreneurship has a power drive for employment generation, poverty alleviation and economic expansion (Etim & Iwu, 2019; Moses, Olokundun, Falola, Ibidunni, Amaihian, & Inelo, 2016; Nsengimana, Tengeh, & Iwu, 2017b).

Entrepreneurship, according to Perez-Perez and Aviles-Hernandez (2016), exposed from a gender perspective, the difference in orientation, motives, level of participation, and strive for opportunity identification between women and men. Women entrepreneurial activities are linked to push (necessity-driven) factor necessitated by unemployment and economic downturn. However, this may be common to both gender, particularly in the art of putting family obligations over business activities, but it is weightier for women than for men (Mahadeo, Dusoye, & Aujayeb-Rogbeer, 2015). Many women start businesses based on the push factors like economic necessities, inflexible working

hour/condition, wage differences between sexes, workplace segregation and discrimination, lack of child care facilities, dissatisfaction with employ/employer relationships, glass ceilings. Conversely, some other women engaged for pull factor (opportunity-driven) reasons, like autonomy, self-fulfilment, personal growth, financial independence, flexible working hours, market opportunities identified, social networking (Chhbra, Raghnathan, & Rao, 2020; Ekwochi, 2020; Hardiani, Hastuti, Junaidi, 2019). However, factors like socio-economic demographics like age, education, related experience, income, and institutional influence the underlying motive for entrepreneurship (Adom, Asare-Yeboa, Quaye, & Ampomah, 2018; Devece, Peris-Ortiz, & Rueda-Armengot, 2016; Wu, Li, & Zhang, 2019). Women in their dual roles are found in family enterprises because it is a way to manage their business activities and at the same time, perform their motherly tasks (Sodipo, 2017). They concentrate more on personal fulfilment than economic values, so they situate their businesses in low capital required and retail sector. This view made entrepreneurship perception a masculine-oriented pursuit and remained dominated by men (Cesaroni, & Paoloni, 2016; Dileo & Pereiro 2018).

In recent times, however, women entrepreneurial activities have grown globally, contributing significantly to the wellbeing and national economic growth (GEM 2015/2016; Kelley *et al*. 2017). The changes in entrepreneurial activities are explained by the influence of globalisation and urbanisation, improved level of education, increased autonomy, crave for financial independence, delayed marriage, family planning, increased support from relevant institutions, agencies, and government (GEM, 2015/2016). Women entrepreneurs drive the world economy and enhance entrepreneurial diversity, especially in developing nations where women start businesses at a double rate than their men counterparts (GEM, 2015/2016). In Nigeria, the level of women entrepreneurial activities has increased in comparison with men in Nigeria (GEM, 2012). Women entrepreneurial success points to their achievement drive, motivation, foresight, pre-business start-up training, and being members of cooperatives, as well as essential factors of entrepreneurial success. However, most Nigerian female entrepreneurs examined had no employment before the establishment of their businesses (Ekpe, 2011). Women entrepreneurs, in Nigeria, comprised of 40% to 50%, own or manage a micro, small or medium scale enterprises (MSMEs) in the private sector, most of which are in the informal segment. Still, they generate over 70% of employment and contributes 60% to the GDP of the nation (Imhonopi, Urim, Kasumu, & Onwumah, 2016; Shmiln, 2017). Despite the growth of women entrepreneurs, a range of constraints constrained their activities and limited the growth of their firms (Asongu & Odhiambo, 2019; Jamali, 2009; Makama, 2013; Naidu & Chand 2017; Amadi & Adim, 2020). Women entrepreneurs are marginalised in every sector because their productivities are rarely acknowledged (Aladejebi, 2020).

Nigerian Non-Oil Export and Women Inclusiveness

The non-oil sector is any chain of economic activities, outside crude oil and natural gas (Ude & Agodi, 2014). With a focus on non-oil export, Nigeria is in control of her commodities prices, and quantities as guided by the law of demand and supply, as against the oil price that is exogenously determined and thus limit the potential of the economy (Olayungbo & Olayemi, 2018). For instance, NEPC (2016) reported that 13per cent of GDP is from information and communication Sector; 40per cent from agricultural products; 23per cent from agriculture, and 60per cent from service export. Other sectors that have the potential for significant growth are consumer goods, retail industry, including E-shopping; and real estate due to a rising middle class and urban migration, the manufacture, as well as, infrastructure, especially transportation and power (PWC, 2015; Uwajumogu, Nwokoye, & Ogbonna, 2019). Nigeria's endowment of over ninety per cent (90per cent) arable land size, besides her large workforce with seventy-two per cent (72per cent) under the age of 30 is strategically positioned within the ECOWAS region to cover a market of three hundred (300) million people. She also has comparative advantages in forty-four (44) solid minerals in commercial quantities, among which Iron-ore is the twelve (12th) largest reserves in the world (NEPC, 2016).

This positive contribution propels Nigeria to look inward to her vast natural resources deposits and an extensive service sector to support the oil and gas value chain, which has significant market potential via exploration and exploitation opportunities. Onwualu (2012), and Olayungbo and Olayemi (2018) stated that the agriculture value chain has enormous potential for enhancing industrialisation, thereby creating massive employment that will lead to economic growth and poverty alleviation. For instance, the Economic Recovery Growth Plan (ERGP 2017- 2020) program launched as a medium-term economic growth plan, was founded on direct or indirect diversification of the export sector and non-oil export development. By progressive implementation, it spurred a positive signal at the close of 2017 when the economy grew to 1.92 per cent, from the contracted -1.73 per cent recorded in 2016. Therefore, the huge opportunity in the comparative economic advantage of the nation, women now spur entrepreneurship more inclusively both domestically and internationally.

Many women are productively engaged in export activities, but are situated in the informal segment and are mostly for survival. With improved effort in the education and training of women entrepreneurs recently engaged in by Nigeria Export Promotion Council in collaboration with the SheTrade initiative anchored by Internation Trade Centre (ITC), some women entrepreneurs own or manage small businesses with few employees' in agribusiness, manufacturing, textile, service, and other real sector value chains with a sustainability perspective. Nigerian spice market, an area where women entrepreneurs are actively involved is, for instance, valued at USD 15.11 billion with a future growth plan of USD 20.99 billion by 2024 (Daily Trust, August 18, 2019).

Women Entrepreneurial Constraints

Studies have shown that women entrepreneurs often face more challenges than their male entrepreneurs, and have attributed the constraints to socio-cultural, political, legal and environmental problems (Agbionu *et al*., 2015; Moses *et al.,* 2015; Sodipo, 2017; Vossenberg, 2013). Specifically, Aliyu, (2013), and Amadi and Adim, (2020) summarised the problems as motherhood, socio-cultural, finance, weak social networks, inadequate information, educational and institutional constraints (Iyiola & Azuh, 2014; Moses *et al.,* 2016; Uchegbulam, Akinyele, & lbidunni, 2015). These reasons, among others, make few women own or manage firms engaged in foreign markets to operate sustainably (International Trade Centre (ITC), 2018).

Women entrepreneurs in non-oil export, however, are constrained by inadequate resources to access broader foreign markets. Unavailability of innovation infrastructure to perform their tasks inhibits compliance of sanitary and phyto-sanitary requirements, problems of quality packaging and labelling, product-specific standard conformity, and inability to meet up with supply-side quantity and price competitiveness (Nigeria Export Promotion Council (NEPC), 2016). They have little knowledge of internal functioning- (strategic and marketing capabilities), and external business environment influences (policies and regulations, and institutional support) making their performance low in terms of sales, revenue, customer base, and profitability (Ibidunni, Olokundun, Falola, & Ogunnaike, 2018). These reasons, among others, make few women own or manage firms engaged in foreign markets to operate sustainably (Adedeji, Uchenna, & Oluyemisi, 2020; ITC, 2018). The commitment to removing these constraints to innovation and growth might be critical to women entrepreneurs' higher performance. The objective of the study, therefore, set to investigate the relationship between women entrepreneurial inclusiveness and the inherent constraints to their output in the non-oil export sector in Lagos State, Nigeria.

The constraints are succinctly categorised into the following four factors:

i. Procedural Constraints

Procedural limitations are hurdles from processing exports to international markets. The export procedure includes documentation of firms' processes, licencing, export clearance and certifications. However, the inherent complexities often result in poor management of export price negotiation, transaction language, supply invoice and receipt of payment delay (Chandra, Paul, & Chavan, 2020). These may be uncontrollable in the short-run, but manageable in the long run as experience in internationalisation increases; yet, there are some beyond the firms' control (Chandra, Paul, & Chavan, 2020). However, issues related to procedure difficulties could be mitigated by engaging commercial experts in export logistics (Ramaswami & Yang, 1990; Madu, 2012).

ii. Governmental constraints

Governmental constraints refer to government constructive or unconstructive outlook to exporting through supportive disposition to aiding policies or impeding framework of regulations on export practices (Han & Park, 2019). Studies have shown the positive correlation between government incentives, promotional policies with export operations success (Nakku, Agbola, Miles, & Mahmood, 2020). However, in developing economy like Nigeria, struggles with export promotion activities due to the inhibitive governmental bureaucracies, corruption in policies implementation processes, inadequate quality information, lack of strong visionary leadership resulting into unsatisfactory support, and expansion in export. The Dutch disease- being monolithic and import dependent-, created constraints to giving adequate constructive aids to non-oil trade, especially, in the manufacture (Oghenerobo, 2019; Zoramawa, Ezekiel, & Umar, 2020).

iii. Market constraints

Women entrepreneurs in non-oil export are constrained with different consumers' behaviours, preferences and competition in the foreign market (Leonedou, 2004). Consumers have different products demand specifications due to differing natural and economic climates, socio-cultural inclinations, which makes firms to incur varying more transaction costs, products differentiation. Of importance is the reduction in the product life due to global competition

and the foreign government protection policies and legal frameworks making strategic management decision to foster competitiveness, a challenge (Narayanan, 2015; Samudro, Sumarwan, Yusuf, & Simanjuntak, 2018; Wach & Wojciechowski, 2014).

iv. External Environmental Constraints

Exogenous constraints are associated with the exterior environments consisting of the economic, socio-cultural, political and legal context of the global markets in which the firms operate (Leonidou, 2004; Wach, 2015). Women entrepreneurs battle with comprehending the interplay of the environment. They have to analyse their external operational situation for possible opportunities and threats that may foster or hinder the growth of the firms via the paradigm of PESTLE (Political/ Economic/ Social/ Technological/ Legal/ Ecological environment) classifications (Narayanan, 2015).

Theoretical Link

The liberal feminist theory underpinned this study. It attributes gender-based differences to the variations in power and opportunity accorded men and women in society, that is, the structural positions women and men occupy in society (Beasley, 1999). The differences in the achievements of men and women are ascribed to the inability of women to realise their full potential because they have limited access to opportunities, resources and involvement in the labour markets than their male counterparts. This limitation, in turn, hindered women from acquiring the knowledge, skills and capabilities necessary for development. The development of a nation, however, premised on gender inclusiveness, particularly the rating and positioning of women in society. According to Aliyu (2020) and Bako and Seyd (2018), neglecting women create a typical colossal human capital waste otherwise pivotal to all-inclusiveness growth in the political, social, and economic developments of the nation.

Liberal feminism consciousness propagated improved women entrepreneurial activities formally. It has improved the policy framework for gender blind access to resources, but patriarchy philosophy empowered by cultural systems reduces the full integrating of women entrepreneurship in the national socio-economic strata (Ayimoro, 2020; Jaiyeola & Isaac, 2020). This inequality and constraints hindered the expansion and growth of women in entrepreneurial activities. It is consistent with the unwritten gender disparity in the allocation of resources in Nigeria (Nkama, 2019; Urim, Imhonopi, & Ahmadu, 2014). Women entrepreneurs, in Nigeria for instance, have 20% access to resource allocation (Awolowo, 2018), and constrained access to financial support, among others, based on their inadequate exposure to financial literacy, lack of owned property rights required as collateral, and technical skills and support (Moses et al., 2015; Taiwo, Agwu, Adetiloye, & Afolabi, 2016).

Although liberal feminism works within the conventional social structure to integrate and influence more responsive women's rights, still, it does not directly challenge the system itself or the ideology behind women's oppression. It focuses on women's ability to maintain their equality through individual actions and choices (Lorber, 1997). However, when resources are accessed equally, gender differences in performance seemingly disappear (Henry& Marlow, 2014). Women entrepreneurs in non-oil export are not different in underlying psychology but are more resolute in overcoming these challenges due to their exposure to entrepreneurial orientation propensity. They make a crucial contribution to equating women's status with control of economic resources and cognitive development for sustainable growth in entrepreneurial activities and growth (Hechavarria, Bullough, Brush, & Edelman, 2019; Owoseni, Wakunuma, Tolani, & Twinomurinzi, 2020).

Hence the study investigates the following Hypotheses:

i. H_O There is no significant effect on non-oil export women entrepreneurs' procedural constraints and their performance.
ii. H_O There is no significant effect between non-oil export women entrepreneurs' governmental constraints and their performance
iii. H_O There is no significant effect between non-oil export women entrepreneurs' market constraints and their performance.
iv. HO There is no significant effect between non-oil export women entrepreneurs' environmental constraints and their performance.

Methodology

This study adopted a descriptive research design via the structured survey instrument- questionnaire. The population for this study comprises of five hundred and twenty-nine (529) enterprises with Nigerian Export Promotion Council, Women Desk (NEPC Conserve list, 2019). The researcher, however, limited the population to sample frame of 320 women entrepreneurs that are listed both on the NEPC registered list and are accessible through associations (NASME/ OWIT/ NASSI) located in Lagos State. The choice of Lagos State because it remains the foremost commercial hub in sub- Sahara Africa and in Nigeria, thus can adequately represent the nation Nigeria. Lagos State hosts the major seaports and national borders to other African countries and the world where most of the export activities take place. Hence, it is a significant contributor to the financial revenue of the Federal Government of Nigeria. It hosts significantly about 60% of women exporters in Nigeria based on the number of registered enterprises in the NEPC Women Desk Directory (NEPC Conserve list, 2019). In estimating the sample size, a five per cent (5%) margin of error (confidence interval) and 95% confidence level were used, making one hundred and seventy-five respondents.

Reliability of the research instrument, which contained ten items, was ascertained and tested using the Cronbach's Alpha with a value of 0.739. The researcher administered one hundred and seventy-five (SS 175) questionnaires to randomly selected respondents from the prior determined population (SF 320) based on Krejcie and Morgan (1970). One hundred and thirty-four (134) copies of the questionnaire were retrieved, which showed a 77% response rate used for the analysis. The researcher tested the hypothesis with the aid of the Statistical Package for Social Sciences (SPSS version 23) using regression analysis.

Analysis of Data and Result

Specifically, the study raises the question on the effect of the constraints on the performance of women entrepreneurs in non-oil export.

Table 1: Response to Procedural Constraints

RESEARCH ITEM	SA %	A %	U %	D %	SD %	Total	Mean	SD∂
Documentation requirements	36 26.9	50 37.3	6 4.5	12 9.0	30 22.4	134 100	3.37	1.52
Fees and charges	28 20.9	56 41.8	4 3.0	14 10.4	32 23.9	134 100	3.25	1.50
Customs valuation	42 31.3	44 32.8	2 1.5	12 9.0	34 25.4	134 100	3.37	1.52
Inspections and controls during clearance	46 34.3	34 25.4	8 6.0	22 16.4	24 17.9	134 100	3.42	1.53

The survey table above revealed the hassles in the exporting women entrepreneurs' business system. The response on the documentation requirements and procedures depicted that 36(26.9%) of the respondents strongly agreed, 50(37.3%) agreed, 6(4.5%) are undecided, 12(9.0%) disagreed and 30(22.4%) strongly disagreed with the difficulties experienced. It also explained that 28(20.9%) strongly agreed, 56(41.8%) agreed, 4(3.0%) are undecided, 14(10.4%) disagreed and 32(23.9%) strongly disagreed with the vast entrant and process fees required. Furthermore, the customs valuation protocol and indiscriminate charges made 42(31.3%) of the respondent to strongly agreed to the irregularities inherent, 44(32.8%) agreed to it, 2(1.5%) were undecided, 12(9.0%) disagreed and 34(25.4%) strongly disagreed. For the inspections and controls during clearance, 46(34.3%) of the respondents strongly agreed to the porous system and time-wasting process, 34(25.4%) concurred, 8(6.0%) were undecided, 22(16.4%) disagreed and 24(17.9%) strongly disagreed with the assertion. The mean values of above 3.0 revealed that the typical (average) responses of agreeing with the questions asked. By the statistics, standard deviation depicted the variability level of cluster around the mean without the outlier. The small value of the difference between the highest standard deviation and the lowest standard deviation that is far less than one or two further validate the level of clustering around the construct been measured (Julius, 2005).

Table 2: Response to Market Constraints

RESEARCH ITEM	SA %	A %	U %	D %	SD %	Total	Mean	SD∂
My product capability competes positively with the competitor's in the overseas markets	24 17.9	50 37.3	14 10.4	18 13.4	28 20.9	134 100	2.82	1.42
My exported products are of quality compared to that of competitors in the overseas market.	22 16.4	52 38.8	22 16.4	12 9.0	26 19.4	134 100	2.76	1.37

The table explained the interconnectivity in the business environment. The heterogeneity of Nigerian non-oil basket created the platform for the complementary domestic market, and that informed the drive for improved productivity vis-a-vis the foreign market. The study showed 24(17.9%) of the respondents strongly validated the competitiveness in the market environment, 50(37.3%) agreed, 14(10.4%) are undecided, 18(13.4%) disagreed and 28(20.9%) strongly disagreed with the fact that their product capability competes positively with the competitors in the overseas markets. Women entrepreneurs' exported products are of quality compared to the competitors' in the overseas market as 22(16.4%) of the respondents strongly agreed, 52(38.8%) agreed, 22(16.4%) are undecided, 12(9.0%) disagreed and 26(19.4%) strongly disagreed with the claim. The mean values of above 3.0 revealed that the typical (average) responses tend toward agreeing with the research items. The results of the standard indicated level of variability can be said to cluster around the mean and that no outlier is discovered. The small value of the difference between the highest standard deviation and the lowest standard deviation that is far less than one or two further validate the level of clustering around the construct been measured. (Julius, 2005).

Table 3: Response to Governmental Constraints

RESEARCH ITEM	SA %	A %	U %	D %	SD %	Total	Mean	SD∂
Export incentives are effective in boosting export market	32 23.9	52 38.8	8 6.0	18 13.4	24 17.9	134 100	2.82	1.42
Government export financing is realistic	24 17.9	46 34.3	24 17.9	20 14.9	20 14.9	134 100	2.76	1.37

The table above clarified that 32(23.9%) of the respondents strongly agreed that government export financing is realistic. 52(38.8%) agreed to the fact, 8(6.0%) are undecided, 18(13.4%) disagreed, and 24(17.9%) strongly disagreed. Also, 24(17.9%) of the respondents strongly agreed, 46(34.3%) agreed, 24(17.9%) are undecided, 20(14.9%) disagreed and 20(14.9%) strongly disagreed with the fact that export incentives are effective in boosting the export market. The mean values of above 3.0 revealed that the standard (average) responses tend toward agreeing with the research items. The results of standard deviation showed that the level of variability can be said to cluster around the mean and that no outlier is discovered. The small value of the difference between the highest standard deviation and the lowest standard deviation that is far less than one or two further validate the level of clustering around the construct been measured. (Julius, 2005).

Table 4: Response to External Environment Constraints

RESEARCH ITEM	SA %	A %	U %	D %	SD %	Total	Mean	SD∂
I encounter cultural/ethical/language constraints	40 29.9	32 23.9	20 14.9	14 10.4	28 20.9	134 100	3.31	1.51
The image rating of women exporters by my customers is positive	50 37.3	44 32.8	18 13.4	8 6.0	14 10.4	134 100	2.19	1.29

The table above showed that when respondents were asked if they encounter cultural/ethical/language constraints, 40(29.9%) of the respondents strongly agree, 32(23.9%) agree, 20(14.9%) are undecided, 14(9.0%) disagree and 28(20.9%) strongly disagree with the claim. Also, the table explains that 50(37.3%) of the respondents strongly agree, 44(32.8%) agree, 18(13.4%) are undecided, 8(6.0%) disagree and 14(10.4%) strongly disagree with the claim that the image rating of Nigeria exporters by their customers is positive. The mean values of above 3.0 revealed that the common (average) responses tend toward agreeing with the research items. The results of the standard deviation also showed the level of variability clustered around the mean and that no outlier is discovered. The small value of the difference between the highest standard deviation and the lowest standard deviation that is far less than one or two further validate the level of clustering around the construct been measured. (Julius, 2005).

Test of Hypotheses

The tables below revealed the results of the five hypotheses tested as measures of the relationships and effects of the variables proposed.

Ho: There is no significant effect between non-oil export women entrepreneurs' constraints and their performance

Table 5: Regression Analysis of the Effects of the Non-Oil Export Women Entrepreneurs' Constraints and their Performance

Model		Unstandardised Coefficients	Standardised Coefficients	t	R2	F	Sig.	Remark
		B	Beta					
PC→ P	(Constant)	.205	.185	2.158	.034	4.656	.033	Rejected
GC→ P		-.371	-.213	.186	.045	6.272	.013	Rejected
MC→ P		.063	.016	.186	.000	.034	.853	Accepted
ENVC→P		-.312	-.243	-2.878	.059	8.284	.005	Rejected

The decision rule states r-value of less than 0.5 has a weak relationship; the r-value within the range of 0.5 is moderate while r- values above 0.05 is said to be high. The associated sign (+/-) with the r-value determines either a positive or negative relationship between the variables. Also, the p-value must be less than 0.05 to be considered significant at 95% confidence level.

R is the correlation coefficient, and R2 is the coefficient of determination. R measures the linear association between the explained and explanatory (dependent and independent) variable, while R2 measures how the independent variable explained the total variability in the dependent variable. Table 5 above shows the regression analysis of the four hypotheses tested in this study.

The regression result in hypothesis one indicated that procedural constraint explained 3.4% of the variance (R2 = .0.034, F = 4.656 @ P<.05). It can be concluded that procedural constraints significantly influence the export performance even though with a limited contribution (3.4%). The result implies that the rejection of the null hypothesis while the alternate is accepted.

The second model tested the effect of governmental constraints on export performance. The result concluded that the null hypothesis should be rejected based on the overall significance level of the model. The alternate hypothesis accepted This is because the governmental constraints explained 4.5% of the variance in export performance variance (R2 = 0.045, F = 6.272 P < .05). of note is the significant inverse relationship between governmental constraints and export performance.

Meanwhile, the regression model showed that no contribution from market constraints to the variance in export performance. (R2 = 0.000, F = 0.034 @ P > .05) further indicated that the market constraints make no significant contribution to export performance. In other words, the null hypothesis is accepted while the alternate is rejected. Therefore, there is no significant effect of non-oil export women entrepreneurs' governmental constraints on performance.

The fourth model tested the effect of environmental constraints on export performance, and it was found that the null hypothesis should be rejected. The alternate hypothesis accepted based on the overall significance level of the model. This is because the environmental constraints explained 5.9% of the variance in export performance variance ($R2 = 0.059$, $F = 8.284$ $P < .05$). It implied that environmental constraints have significant effects on export performance

Discussion of Finding

The findings indicated that governmental policy inconsistencies and inadequate support have an inverse relationship with women entrepreneurs' performance, explaining it as a critical issue. Still, women entrepreneurs' inclusiveness has expanded the non-oil sector, in terms of job creation, increased revenue, improved networks, education and training. Procedural and environmental have a moderate effect, and marketing constraint has no significant impact. The result showed the variance in the level impact of the limitations on women entrepreneurs could be traced to opportunity perception and motivation. Other reasons could be context-specific decisions and actions, use of digital technology, visionary leadership which alter these constraints for high- growth-oriented women entrepreneurs, but limit low-growth women entrepreneurs (Hechavarria et al., 2019). The result explained the reason many women situate their businesses in the informal, low- growth areas. It caused international business operations to be unpredictable and immensely challenging. The study is in line with the works of Aliyu, 2020; Amadi and Adim, 2020, and Narayanan, 2015.

Conclusion/ Recommendations

This study attempted to investigate the relationship and effect of constraints inhibiting the performance of women entrepreneurs' inclusiveness in Nigeria non-oil export sector. The dependency on the oil sector export boom caused the imbalance in the economic structure of the nation and the consequent under-representation of women. Women inclusiveness is critical to driving export diversification and significant industrial GDP growth, especially in the non-oil sector of the economy. The outcome of this study recommends, therefore, intense and prompt attention to resolving the constraints- facing women inclusiveness to enhance increased productivity and contribution to the GDP of the economy. Export women entrepreneurs/ managers should take the measures to alleviate the perceived inhibiting impact of constraints on exporting firms through improved knowledge acquisition and knowledge sharing within the eco-system via exposure to education and training, to reform the practices in the non-oil export sector.

By policy implication, the government should promote quality export practices by instituting real-time and practicable policies and regulations. The government should control the instability of Nigeria macroeconomic policies like high inflation rate, over-evaluation of currency, unstable exchange rate which has been the clogs in the wheel of non-oil export practice for effective export planning and engagement.

Abstract

Weightlifting exercises are not easy to get the hang of, especially for beginners. Weightlifters need to be well informed and ready before they start working out with dumbbells, or otherwise, they might end up with very problematic injuries. This paper builds a model that allows the detection of wrong movements during the workout so that users can quickly check it and correct their mistakes using machine learning and deep learning techniques. It presents the possibility of having a model that can guide people throughout their weightlifting process. This model will help reduce injuries by tracking body motion with no requirements needed other than the Kinect camera. The results of testing showed the difference in performance by three different algorithms k-nearest neighbors algorithm (KNN), the support vector machine (SVM), and the FAST Dynamic time warping (FAST-DTW) dynamic time warping, concluding that the FAST-DTW was the most efficient one with higher accuracy and faster processing time.

Keywords: Machine learning, Gym injures, and IR Camera.

Introduction

Gym exercises are more complicated than they might seem; many factors play an important role, like the technique (Mayo Clinic, 2020) and its angle of motion. Those factors need to be considered to achieve the target of working the muscles correctly and healthy. Another essential factor in weightlifting exercises precisely is ensuring that the weight being lifted is the right one at the specific stage of exercising. Weightlifting exercises using dumbbells must be accurately executed in every way, or they will almost definitely result in injuries. In some cases, it can be very severe and may lead to permanent damages. Most of the Gym related injuries occur due to dumbbells' inappropriate use, so the workout technique must be on point. Moreover, the solution to this problem is to get a personal training expert to help master the workout technique and guide you all the way, but this will cost much money and not an option for every gym-goer out there.

Another research scope was the weightlifting injuries, specifically the back and leg injuries, and avoiding them by using sensors to track body motion (Ebert et al., 2017). Alternative projects used the normal camera for the same objective, but the Kinect camera is the optimal solution for a sensor-less tracking of body motion (Zhang et al., 2012; Yun & Lee, 2014) because it accurately detects body joints and saves it as numerical data so it is less time consuming than a regular camera. Shoulder injuries are the most common dumbbell-related injury. This project focuses on detecting and correcting every movement using the kinect camera to track the upper body joints. Additionally data collection is essential in optimizing the accuracy of the overall system. The dataset should be divided into right and wrong moves to train and test the classifier.

Cite this Article as: Diaa SALAMA ABD ELMINAAM, Hager SOBEAH, Ahmed MOHAMED MORABEA, Abd El-Rahman TAREK KHASHABA, Ahmed NAGY ABE EL LATIF and Poula MOHEB "Workout Assistant Using Kinect Camera to Prevent Dumbbell Related Injuries" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The video will be taken by a Kinect camera that analyses and extracts the upper-body joints in the video frames in x, y, and z dimensions. The system will be trained at first on five different subjects to optimize the system's accuracy and then test it on various topics. The classifier's training and testing phases were done by using three different algorithms, the SVM, which achieved 83 % accuracy, KNN achieved 86 % accuracy, and Fast-DTW achieved 90 % accuracy. Based on that, we used the Fast-DTW algorithm and started to classify each rep recorded, whether it is right or wrong, by dividing the whole testing file into a set of frames containing each rep.

The paper's remainder is organized as follows; section 3 recognizes the previously published work related to the system. Section 4 **presents** the methodology of the project containing the pre-processing and the processing phases in detail. Afterward, the experimental results of both right and wrong movements will be shown in section 5. Moreover, section 6 summarizes our work and gives a conclusion to the overall system. Lastly, in section 7, we recognize everyone who helped to make this research possible.

Related Works

Many papers and researches used similar algorithms and equipment for the same idea of automating a trainer and to get different accuracy and results as: In (Ebert et al., 2017) proposed: in SensX using the sensors to and sports equipment to take the demand of the work out without a trainer or a supervisor, a sensor-based architecture for monitoring, recording, and analyzing complex and multi-dimensional motion chains, using the **HMM** with 90 % accuracy, NBC 85 %, SVM, 96 %. , In (Yun & Lee, 2014) proposed: a wearable device used to monitor muscle movement, heart rate, and other bio-signals an affordable tool The sensor is made by infusing graphene nano-flakes (GNF) into a rubber-like adhesive pad, using GNF to monitor the muscle movement, In (Wiehr et al., 2017) An EMS-based Assistance System for Real-Time Running Style Correction Today, by using an FSR force-sensing resistor to

collect the data and analyses it. In (Chatzitofis et al., 2013), Anargyros Chatzitofis created a weight lifting assistance program using the IR of the Kinect camera to calculate the angle and the velocity of the weight and the angle of the knee position, In (Zhang et al., 2012) Lichao Zhang et al., presented using the Kinect camera in detecting the golf player swings. The used the SVM for classifying and GMM for clustering, In (Wiehr et al., 2016) Frederik With et used IR in kinect2 camera to detect the skeleton of a climber, In (Gaddam et al., 2015) Sai Prakash Reddy Gaddam et used the kinect2 and vicon and the force plates to calculate the force of a jump.

Many other researchers who are recognized in the literature on Optimization and Metaheuristics algorithms and applications such as [Abd Elminaam, D.S.(2020)], [Elminaam, D.S.A.(2018)], [Elminaam, D.S.A . (2018)], [El-Ashmawi, W.H.(2019)] ,[Abd Elminaam, D.S.(2019)], and [El-Ashmawi, W.H.(2020)] studied the predictions problems and its solutions. As a result of the collected information, we decided to combine all the features that the previous attempts worked on to enhance the expected results' efficiency.

Methodology

'Firstly, the proposed model will detect the body and track its motion. After that, the pre-processing and joints extraction by static analysis. Lastly, the classifier will predict the output and specifies how to correct the wrong movements if it occurred to prevent the injury from happening, as shown in Fig. 3 & Fig.4.

Fig. 3: Activity Diagram

Fig. 4: The architecture diagram

Our proposed model aims to massively reduce weightlifting-related injuries shown in Fig. 5. by having **every day** the easily usable application that guides the way to mastering the workout techniques. The app will also help choose the dumbbell weight by calculating the one rep maximum weight of the user (Men's Health, 2019; Lauren Bebosky, 2018) and then recommending his suitable weight and providing instruction before attempting the exercise. Additionally, it will inform the user of the maximum load ever to be lifted based on his/her body weight (Strengthlevel.com, 2020). That way, the user can entirely depend on the system and start exercising without worrying about getting injured.

Fig. 5: Charts of Injuries That Could Happen Due to the Wrong Weightlifting.

Video Extracting

Extract all upper-body joints from the whole video to **reduce** the processing time of the classier.

Pre-Processing

After the **extraction** using the Moving Average Smoothing technique to clean the noise from the data to improve the accuracy as in fig.6 and fig.7

Fig. 6 Before smoothing

Fig. 7 After smoothing

Processing

After Pre-processing, we will start to work on the dataset by using KNN and get the Euclidean distance between a test sample and the specified training samples, and also the k-Nearest-Neighbors (Trstenjak et al., 2014; Zhang et al., 2017; Cai et al., 2010; Peterson, 2009)

d(xi,xl)=SQRT((xi1xl1)2+(xi2xl2)2++(xipxlp))

SVM The problem of learning a binary classifier can be expressed as that of learning the function \textbf f <R^n → ± 1 (Kim & Choi, 2014; Tong & Koller, 2001)

The dynamic time warping (FAST-DTW) is used to find the shortest distance between two-time series (Salvador & Chan, 2007), the range will be in arbitrary lengths (Al-Naymat et al, 2012), and by using the Euclidean distance between the two waves the ratio will be calculated (Choi & Kim, 2018). It is a lot faster than the previous algorithm as its worst complexity is O(N*N), so it will be perfect for the short time series (Strle, 2009).

Experimental Results

The video will be taken by Kinect the camera, which will analyze and extract the joints in the video frames. This system aims to detect the movement that will be recorded by the Kinect camera, which will be analyzed to get the dimensions of x y z (see Fig. 1) of the specific joints. The system will be trained at first on five different subjects to make the data set more accurate, and the testing subjects will be different from the training subjects to test the system's accuracy. Moreover, The training and testing phases of the classifier with algorithms for the detected movements were done by using the SVM which achieved 83 accuracy, KNN achieved 86 accuracy and Fast-DTW which made 90 accuracy algorithms, for more achievement of the perspective of the project we used the Fast-DTW due to its high efficiency, and started to classify the movements one by one not the whole video , by dividing the progress of the testing dataset and training the training data set has more then 2400 rep of shoulder press movement to be classified.

Table 1: Accuracy %age of the classifiers

SVM	KNN	Fast-DTW
83%	86%	90%

Detecting Right Movement

The workout was executed correctly, with the arms going up and down in just the right range.

Fig. 8: Right Movement

Detecting the Wrong Movement

The workout is wrong because the elbows went below the shoulders, resulting in damaging the rotator cuff, which is the primary shoulder joint.

Fig. 9: Wrong movement

Conclusion and Future Work

The prosed model introduces an efficient approach to recognize and correct the motion in workout movements using machine learning and AI. The proposed method consists of three main phases the input of signals as video, extract frames, classification, and movement correction. Using sensors to detect body motion could be efficient but not usable for everyone, so this system is the best alternative to achieving high accuracy. Our future work will enhance the

system's efficiency even more and add different types of workouts that will need the tracking of more body joints motion.

Acknowledgment

Many thanks to Coach Ahmed El Kaissony, the Egyptian Bodybuilders national team's previous coach, and Coach Ahmed Nashaat. Great thanks also for the Muscle Land Gym's association and for allowing us to use their facility and assisting us with recording the dataset used in the system.

Abstract

With the Covid-19 (Corona Virus) spread worldwide, people are using this propaganda, and the citizens' desperate need to know the news about this mysterious virus by spreading fake news. Moreover, since Social Media has become a significant news source, it is profoundly needed to detect this fake news. This research aims to develop a web-based model using machine learning algorithms to detect fake news. The proposed model includes an advanced framework to identify tweets with fake news using Context Analysis. We suggest that Natural Language Processing (NLP) would not be enough alone to make context analysis. Tweets are usually short and do not follow even the most straightforward syntactic rules, so we used Tweets Features as several retweets, several likes, and tweet-length. We also added statistical credibility analysis for Twitter users. The proposed algorithms are tested on four different benchmark datasets. To achieve the best accuracy, we combined two of the best algorithms used: SVM (widely accepted as a baseline classifier, especially with binary classification problems) and Naive Base for comparison.

Keywords : Fake News, SVM, NLP.

Introduction

Nowadays, Social Media has been taking a considerable part in people's lives. It has become one of the most common places for fake news as it has no restrictions on people's posts since anyone can edit their posts whenever they want. However, that did not stop people from using Social Media as their source. The extensive use of social media has an enormous impact on many aspects of our life. Considering the harmful outcome of spreading fake news, it has an enormous social impact. It can mislead citizens into believing misinformation about a specific product/ person or situation. The spread of economic and political fake News can directly affect the stock market government economics in general. For example, publishing politically fake news significantly affects society, security, tourism, economics, and many more things. Also, during the 2016 US presidential election on Twitter, it was found that it was responsible for the early promotion of misinformation. They targeted influential users through replies and mentions. The sharing of fact-checking articles nearly disappears in the core of the network, while social bots proliferate.

Figure 1: statistics show how the stock market was affected by the fake news.

This fake news spread several times, and the last one was on the 12th of December, the rumor also spread vigorously through the social networking site" Twitter" to top the hashtags" Mubarak Matt," the list of the most frequently used tags on" Twitter," and ranked first in the list of the most traded in Egypt. Also, Tourism income can be affected by fake news, as spreading fake news in countries can make tourists not interested in visiting certain places, which costs losing much revenue. This targets social media users that rely on social as their source of information.

This study aims to build a robust intelligent model for detecting fake news using machine learning algorithms. The rest of the paper is described as follows: the paper's related work can be found In Section 2. The methodology is presented in Section 3. Section 4 shows a comparison between proposed algorithms and the experimental results. Finally, Section 5 shows the conclusions and future work.

Related Work

Various researchers have worked on the analysis of fake news in different social media venues. Some of the work performed focused on identifying the text's linguistic properties and identifying the context [Atodiresei, C.S (2018)]. They have utilized a news dataset represented on Kaggle and performed the analysis using multiple classifiers, including deep neural networks.

In [Jang, Y.(2019)] this research, the proposed research is Identifying fake news and fake users on Twitter . in this paper, the authors have credibility models to calculate the score for each of the tweets and the users and uses TWITTER CRAWLER for gathering data to use it as a dataset to train.

Another paper mentioned in the survey [Ajao, O.(2018)] was a publication discussing sentiment analysis based on SVM, which also focused on the linguistic approach. Lukas Povoda, Radim Burget, and Malay Kishore Dutta discussed that Support Vector Machine(SVM) is mainly used in text analysis. It can be trained by the massive amount of data and can deal with tricky combined words and deal with different languages. At the same time, they were working with big data (SVM) improved accuracy. The best accuracy obtained was 95.31 % for recognition of the rate of positivity and negativity.

In a similar paper [Gilda, S.(2017)], Gilda, Shlok used two different datasets: signal media, which gets news from local news, blogs, articles, and the outgoing list of fake and real News from OpenSource.co. They used SVM, Bounded decision tree, Random Forests, and Gradient Boosting as classifiers to increase accuracy and to get the difference between them. SVM happened to get the highest accuracy (77.2 %).

In another publication [Girgis, S. (2018)], Eslam Amer has talked first about social media and how it is the right place for fake news; he also mentioned that Facebook has a 50% percentage of fake news traffic. He said that 62% of US adults get their news from social media. He also discussed the impact of fake news and its usefulness, and

how it will help people overcome this problem. The paper also mentioned that NLP is used to reach optimum results. The utilized algorithms are RNN and LSTM, and he used the Liar dataset.

In the closest research to our intended work [Jain, A.(2018)] the authors aim to Identify relevant features associated with fake news stories without previous knowledge of the domain; they used a variety of dataset like CharlieHebdo • SydneySiege • Ottawa Shooting • Germanwings-Crash • Ferguson Shooting, and classifiers like LSTM-CNN, LSTMdrop.

Another publication [Krishnan, S.(2018)] identified tweets with fake news: by making user analysis and context analysis by using NLP using only one classifier, which is SVM, and the result accuracy was 62%.

Other work [Povoda, L.(2016)] focused on the tweet features only, the authors choose tweets features to work on and select LSVM and KNN as a classifier to test the best accuracy and also worked on the Effect of increasing character N-grams on the efficiency of LSVM classifier to finally choose the best approach. Identifying fake news and fake users on Twitter:

Another feature used to analyze the creditability was the users' score [Ajao, O. (2019)] and TWITTER CRAWLER for gathering data to use it as a dataset to train. This paper used machine learning and deep learning classification and the sentiment analysis feature to detect the news's effect on people's emotions by using an equation. The authors train their classifier by using PHEME labeled twitter dataset.

Many other researchers who are recognized in the literature on Optimization and Metaheuristics algorithms and applications such as [Abd Elminaam, D.S.(2020)], [Elminaam, D.S.A.(2018)], [Elminaam, D.S.A . (2018)], [El-Ashmawi, W.H.(2019)] ,[Abd Elminaam, D.S.(2019)], and [El-Ashmawi, W.H.(2020)] studied the predictions problems and its solutions. As a result of the collected information, we decided to combine all the features that the previous attempts worked on to enhance the expected results' efficiency.

Methodology

Our Proposed model aims to detect fake news by using machine learning and a combination of algorithms. The proposed diagram uses the MVC model (Model View Controller). The user views a web-based application, entering a topic to search on, passing tweets related to this topic to the controller. These tweets need pre-processing to be well-defined data to work on like (stemming, stop words, tokenizer, n-grams). After that, the controller will send organized tweets to work on additional features.

Fig. 1: Architectural Diagram

Architectural Design

*A-**Model**:* The model part is responsible for the functionality of the system, which is first doing pre-processing on data to make it in the form that is suitable for the functions to use (Tokenizer, stop words, Stemming, N-Gram) and then extracting tweet features like Retweet count, Favourite count and Tweet length, sentiment analysis, and phrase credibility, the final step is entering those features is a hybrid classifier between SVM, Decision Tree and Neural networks those are the algorithms we will use and sends it to the controller to save it in the database.

a) Algorithms:

- **SVM:**

SVM plot each data item as a point in n-dimensional space where n is the number of classes we have, which is fake and real. Then we perform classification by finding the hyperplane that differentiates the classes very well.

- **Decision Tree:**

The decision tree uses the tree representation to solve the problem in which each leaf node corresponds to a class label, and attributes are represented on the tree's internal node.

- **Neural networks:**

Set of algorithms, modeled loosely after the human brain, that is designed to recognize patterns. They interpret sensory data through a kind of machine perception, labeling, or raw clustering input.

b) Libraries:

Twitter API: its REST API allows you to read and write Twitter data; in other words, it can be used to create new tweets, read user-profiles and the data of followers (among other data from each profile), since it identifies the various Twitter applications and the users who register.

Fig. 2: Twitter API Diagram

NLTK:
the Natural Language Toolkit (NLTK) is a platform for building Python programs that work with human language data to apply in statistical natural language processing (NLP). It contains text processing libraries for tokenization, parsing, classification, stemming, tagging, and semantic reasoning.

Fig. 3: NLTK

Sci-kit Learn:
Scikit-learn is a free machine learning library for Python. It features various algorithms like support vector machines, random forests, and decision trees, and it also supports Python numerical and scientific libraries like NumPy.
Numpy: This library is responsible for handling arrays.

B- ***View:*** It is responsible for the presentation of data and representing the User Interface(UI). We have two different interfaces. One is responsible for retrieving the data from the user. The second one is responsible for displaying the user's output data and the data analysis.

C- ***Controller:*** It is responsible for binding the view and model. The interactions and requests made within the view are taken and sent to the database to fetch data using models, then it forwards data to the view again to be shown. The controller we have is the user controller that deals with the user input stored in the database. Applying our functionality to it then sends data to the view model to display the user's result.

Fig. 4: Features diagram

After that, the controller sends the organized tweets; they have to work on additional features, which are :

- The first feature is gathering information about each tweet and actions made upon them like the retweet count, length of the tweet, and the favorite count to determine the tweet's credibility and generate a prediction.
- The second feature is the user graph, which is gathering information about each user and actions made by them like the friend's count
- , screen name and the favorite count and representing it using a graph structure helping us determining the credibility of the person is he trusted or not
- The second feature is the phrase credibility; we check whether this tweet is credible or generates a prediction.
- The Final feature is the API check; we check if this piece of news does exist in a credible source of news like BBC or not and generating a prediction.

Those features differentiate between real and fake accounts and tweets on Twitter

Dataset Description

In our work, we utilize different types of the dataset; the first type is datasets of documents and string to compare the tweets' linguistic features to, we focused on the politics and celebrity fields as domains. Below are the details of these datasets.
The first dataset we utilized was politics-data. The data set is composed of 2 columns. The first one is Text (The tweet or the news), and label (0 means false, and one means true. This dataset was extracted from kaggele.com. Below is a screenshot of the extracted dataset.

gossipdata

Fig. 7: Celebrity dataset

The second type of datasets used is a dataset representing the authoring users of tweets. This dataset includes details about the user like the number of tweets published, friends count and followers count. We use this dataset as one of the scores to determine the credibility of the user himself.

Results and Discussions

In this section, we review the results of the experiments we performed to determine the best possible feature and classifier to be used in any future work. In the first experiment, we used various weights to determine how changing the features would affect the classification result.

Analysis of Weight variation of features on the results

Test2

Tweet: Taylor Swift cancels all appearances

Type: True

Number of tweets: 9

API check	Phrase	Tweet-Features	Sentiment	TP	FN	FP	TN
1 .5	1	0.5	0.5	6	3	0	0
0	0.5	1	0.5	0	9	0	0
1.5	1	0.5	0	9	0	0	0

Conclusion and Future Works

In recent years, detecting fake news on social media plays a huge role, especially this year as a pandemic and a disease is spreading worldwide; most people take this as a chance to spread fake news and mislead people, causing them to panic. This paper explains our web-based system that aims to detect fake news by using machine learning. The training of a system with many datasets is categorized to help achieve the best accuracy. They also combined features with experiments finding the best of them working together and with a combination of algorithms like SVM, decision tree, and neural network. Our future work includes the use of different pre-trained models, followed by deep-learning systems. In this paper, the content features are used in the binary classification. In the future, we intend to use a combination of content, temporal, and context features to be used in multi-class classification. Capsule networks can be included in plans to detect their effect on the performance.

Abstract

The construction sector is highly prone to non-value additional activities and uncertainty regarding a disturbance in labor and material on site. These factors make projects prone to overruns and humongous costs. Being the hub of massive construction projects, UAE is a popular tourist attraction and an investor's eye candy. However, the construction firms have been keen on making their projects defect-free to provide minimum variability and maximum customer satisfaction. In this regard, the SCM principles, especially Lean Six Sigma (LSS) principles, have served as a beacon to improvise the UAE's construction sector. The paper thoroughly evaluates the LSS techniques and tools to study the SCM impact on the UAE's quality of the construction sector. Under the analysis in this report, the company's Arabtec Holding incurred losses of 774.5 million dirhams in 2019 from a profit of 256.3 million dirhams in 2018 (Gulf News Reporter, 2020).

Keywords: Quality Improvement, Quality in service, Lean Six Sigma, JITT, TQM.

Introduction

Today, manufacturing businesses are more inclined towards reducing product defects. They are focused on product optimization, improvement of quality day in and day out while streamlining the production line. Construction businesses are no far behind in this regard. The companies are using multiple quality management systems such as TQM (total quality management), JIT (just in time), DFM (design for manufacturability), and LSS (lean six sigma), among many others for waste reduction and quality improvement by eliminating defects in production (Ricardo Antunes, Vicente Gonzalez, 2015). Being the hub of massive construction in the twenty-first century, Middle Eastern construction companies that venture on mega construction projects of building skyrocketing towers and robust stadium share the same concern about quality management.

Delivering residential and commercial construction projects throughout the Middle East, Arabtec has gained expertise in building the most complex yet flawless infrastructures. The Arabtec Construction, established in 1975 as the largest subsidiary of Arabtec Holding PJSC, aims at providing maximum value to the customer while maintaining the quality of construction projects. The three-phase strategic roadmap of Arabtec envisages maintaining a leaner organization at the target benchmark level (Nahyan, 2017). Experience of more than 40 years combined with a highly skilled team let Arabtec Construction completed more than 240 projects, including the world's tallest building, Burj Khalifa, in Dubai, and the inspirational Louvre at Abu Dhabi (Arabtec UAE Team, 2020).

After having a profitable ending of the year 2018, Arabtecncurred a huge loss of $210 million by the end of the year 2019 that resulted in the resignation of its group CFO (Dadlani, 2020). The company has handed over six big projects since the third quarter of 2019 and is expected to complete nine more legacy projects by the end of 2020. It

shows that the economy did not get slow, but the issues arose inside the company. Therefore, this report will thoroughly evaluate the Lean Six Sigma tools and techniques for identifying Arabtec's relevant issue.

Literature Review

The construction sector tends to be the most important sector for the economic development of a country. The construction activities are gradually becoming complicated, and traditional management methods have failed to manage over the years (Shaharudin et al. 2018). The complexity of designs is the major problem that needs different goods and services from different suppliers. It has become an issue with selecting experienced and specialized suppliers in any project. In the projects' design, suppliers handle each fragment at their specialized end, which helps to complete the whole project on time. Here, Supply chain management plays the most important role to efficiently manage all the complexities of the whole project (Peter et al. 2020).

So, Supply Chain Management plays a very important role in the construction industry for the following reasons:

1. Decentralization lessens the time which is needed to attain efficient control.
2. Management of contractual agreements become very difficult to manage as many different suppliers are involved.
3. The intersection of different suppliers/ contractors could lead to conflicts.
4. Technological advancements have moderated timings for project completion, so there is very little time to concentrate on the clients (Lekan et al. 2019).

Regardless of these challenges, Supply Chain Management helps the construction industry around the globe. Construction projects consist of many types and complexities. Supply Chain Management has improved the construction industry's performance in this competitive world by minimizing costs (Okagbue et al. 2018).

"Procurement": Procurement is the most important component in the construction sector. Supply Chain Management is the system of interrelated people including suppliers, manufacturers, and logistics required to complete the procurement process. With the use of technology, there is a modification in the procurement process and traditional methods are fading away (Tansakul et al. 2018). The implementation of technological advancements ensures continuous Supply Chain management in the construction industry procurement, which helps increase profits and reduce costs (Vardhana & Venugopal, 2019). Research about the originality of suppliers (Wang et al. 2017) and efficient supply quality at different phases of projects reduces the stress of delays, time, and resource wastage (Thunberg & Fredriksson, 2018). It also helps to make sure that rules are not invaded (Morrison & Trushell, 2016). Management of materials also requires strategy, so the quality is maintained and procured throughout the supply chain (Caldas et al. 2015). Despite all these strategies, there are still some challenges present. The complexities of the supply chain evaluate quality complicated (AlMaian et al. 2016). The partitioned nature of projects by different parts helps the tasks be completed in some restricted time and makes the supplies quality-oriented. This affects the quality at the pre-construction stage (Seng et al. 2018).

Supply Chain Management Models

Models are designed and practically applied when there are some gaps in managing the supplying chain. The complexities, timings, and size in the construction industry can be managed through supply chain models. The models can help to lessen the rework changes, cost reduction, time management, helps logistics, and information flow management (Nuss et al. 2016). The construction industry can improve logistics by applying models that help assess the propinquity of suppliers (Dallasega et al. 2018). Cost models for the supply chain can help to manage the total cost of the project. This can be managed by assessing each fragment's impacts as the total construction cost is related to it (Kim et al. 2016). Different suppliers have different decisions and objectives which end in creating conflicts among them and it becomes very difficult to achieve similar goals and intrusts for the project (Peter et al. 2020). Models designed for the partnership with suppliers and managing the life cycle of the product help improve the effectiveness of supply chain management in the construction sector (Ju et al. 2017). Furthermore, collective risk can be excluded from the construction projects by determining the risk models (Liu et al. 2017). If the risks are ignored, the construction projects can be exposed to supply chain troubles (Peter et al. 2020).

Improvement in Construction Supply Chain Management

The construction sector consists of huge industries and needs to have the best and efficient supply chain management for the construction chain. Construction companies need structured approaches to achieve the best relationships with suppliers and the best results for the whole supply chain. Strategic planning is the first and important step in the Supply Chain Management process. All the other steps are based on the planning stage. The working of contractors affects the whole project. Construction companies should develop initiatives to improve the performance of suppliers. These initiatives should include training, providing feedback, and consultation of suppliers. Effective training also positively affects managerial and employee performance and commitment. It reduces the obstructions and enhances the supply chain performance (Papadopoulos et al. 2016).

Measurement of Performance: Measuring performance has become a competition for all the construction companies. In this competitive era, construction companies provide their managers with the guidelines so they can evaluate the performance of suppliers. Firstly, the managers need to set some benchmarks for the suppliers to measure their performances. Secondly, the usage of the information after measuring the performance to improve it (Acquaye et al. 2018).

Benchmarking: The development of benchmarking is still in the initial phase. Benchmarking is based on comparing the performance of metrics to determine objectives to attain in a specific period. So, it would be very beneficial for the construction sector if they upgrade benchmarking for their projects. However, setting benchmarks for the construction project becomes very difficult without supply chain management (Kärnä & Junnonen, 2016).

Information Management: During the supply chain management process, suppliers and contractors get the chance to get information about the whole supply chain, which helps implement the knowledge to improve the performance during the whole construction project (Pucihar et al. 2017).

Waste Identification and Exclusion: it is very important to identify the non-value-added services and activities present in the supply chain process to eliminate the costs, wastage of energy, and material. It can be done at the operational level during purchasing, managing, stocking, etc (Papadopoulos et al. 2016).

Application of Information Technology in Supply Chain Management: In this technological era, it is very important to know about the developed technology. The construction industry should apply technological advancements throughout the supply chain management process to achieve the best and effective results (Kaushik, 2018).

The construction projects are quite dynamic with myriad participants involved and many processes, making it difficult to implement the supply chain management principles. However, the same reason becomes the basis of implying SCM principles (Johnson & Babu, 2020). Thus, the Lean construction model has significantly helped to generate active coordination among highly fragmented sectors of the construction project (Algan Tezel, Yasemin Nielsen, 2013). As reported by the Khaleej Times, the value of ongoing construction work in UAEs estimated to be $3 trillion (Abbas, 2019). The construction projects are expected to continue until 2030, making UAE the second-largest hub of construction. Such issues affect the cost of labor and material and thus affect supply chain management.

Arabtec construction firm is facing challenges with the start of the current year, swinging to a third-quarter loss in revenue of about Dh774 m in 2019 (John, 2020). In a former statement, the company has attributed the loss to its construction industry. It poses a high time for the firm to realize a lean model for its projects (Gulf News Reporter, 2020). One such model is Lean Six Sigma that is the blend of Lean Manufacturing and Six Sigma. It is developed to create a comprehensive system that removes waste and reduces process variation for efficient manufacturing and optimum product yield (Saad Sarhan, Andrew Fox, 2013).

Lean Six Sigma principally uses Six Sigma processes and methods, including DMAIC and the belt system as the mainstay of the system to drive dedicated improvements in manufacturing while incorporating many techniques and tools from Lean to reduce wasteful steps and processes (Dear Systems Staff, 2018). Some of the renowned methods of six sigma used by Lean Six Sigma are DMAIC (that stands for Define, Measure, Analyze, Improve and Control) and DMADV (that stands for Define, Measure, Analyze, Design and Verify). While DMAIC is for the existing projects, six sigma uses DMADV for new projects and designs (Algan Tezel, Yasemin Nielsen, 2013).

Figure 1: Six Sigma Methodologies

In construction projects, the key issue is having an increased non-value, adding actions regarding the flow of material and labor on-site (Hasim et al. 2020). This waste can be related to material like excessive material stock, vandalism, or mass production or it can be labor efficiency-related such as delays in work in process, laziness, poor working status, etc. (Ricardo Antunes, Vicente Gonzalez, 2015). In brief, there are eight key concerns for construction projects that are identified by different researchers namely; the flow of on-site material challenges such as inventory-related challenges, overproduction, over-processing, transportation (freight costs), and flow of labor on-site such as skills mismatch (Saad Sarhan, Andrew Fox, 2013). Issues related to Arabtec can be regarding the flow of labor and material on the construction site.

Research Methodology

This study's primary objective is to analyze the impact on quality in the supply chain in the construction sector in UAE (concerning analyzing the Arabtec project). The methodology envisages a thorough review of the literature to identify that if the flow of material and labor on site is a major issue in the United Arab Emirates or not. To analyze that either flow of labor and material on site does affect the satisfaction of the customer or the services provided by the construction company, a survey was conducted based upon ten questions. There were a total of 30 responses for each question.

Data Analysis & Results

From the survey, the following data were analyzed:

Figure 2 shows that 80% strongly agreed that the flow of material and labor on-site is a main and continuous worry within the construction industry, 10% partially agreed while 10% disagreed.

Figure 2: Flow of Material

Figure 3 shows that 53.33% strongly agreed that SCM in the United Arab Emirate's construction industry needs to modify the flow of material and labor on-site, 20% partially agreed, while 23.33% partially disagreed and 3.33% strongly disagreed.

Figure 3: SCM in UAE

Figure 4 shows that 76.67% faced difficulty with the construction industry's construction process due to the flow of material and labor on-site, and 23.33% didn't.

Figure 4: Construction Industry Process

Figure 5 shows that 43.33% strongly agreed that the flow of material and labor on-site strategies and ways should be modified, 23.33% partially agreed, 6.67% were neutral, 6.67% disagreed, and 20.00% strongly disagreed.

Figure 5: Labor on-site strategies

Figure 6 shows that 73.33% agreed that the modified flow of material and labor on-site within the supply chain management overcame the issues between the supplier and client, 20.00% disagreed, and 6.67% weren't sure about it.

Figure 6: Final Product Change

Figure 7 shows that 36.67% agreed that the final product's quality changed due to the material and labor movement on construction sites, 43.33% disagreed, 13.33% said sometimes, and 6.67% didn't know about such stuff.

Figure 7: Companies Relationships

Figure 8 shows that 70% agreed that the relationships between companies and their client could be fruitful with a sustainable flow of material and labor on-site, 3.33% were partial, 6.67% disagreed, and 20.00% strongly disagreed.

Figure 8: SCM principles

Figure 9 shows that 80% said a need to change the supply chain management's principles and rules regarding the flow of material and labor on-site, 16.67% disagreed, and 3.33% wasn't aware of such issues.

Figure 9: Lean Construction

Figure 10 shows that 43.33% were aware of the lean construction models regarding the United Arab Emirates construction industry, 33.33% weren't, 20.00% knew a little bit, and 3.33% were experts in it.

Figure 10: Construction Industry Transparency

Figure 11 shows that 60% strongly agreed that the construction industry still needs a transparent and decentralized approach regarding the flow of material and labor on-site, 16.67% partially agreed, 6.67% disagreed and 16.67% strongly disagreed.

Figure 11: Construction Industry Decentralized Approach

Discussion

The data analysis identified two key factors that hamper the performance of Arabtec Construction in the UAE. These key factors are the disturbance in the flow of labor and material on site. The above data analysis showed that disturbance in labor and material on site causes a lot of trouble in Supply chain management. Because of this, customers and clients don't seem much satisfied with the services and final products. Following is the fish map showing the issues and possible challenges in the Supply chain management regarding material and labor issues:

Figure 12: Cause and Effect Diagram

Any project in the construction industry can be successful if accurate labor has relatable skillfulness and material is delivered at the right time with reasonable finances. The project will be unsuccessful if the flow of material and labor on-site goes wrong or disturbed due to the wrong material in the wrong location at the wrong time. To obtain the labor and material on time, it's necessary to have the capital and cash flow without which this all is impossible.

There are multiple tools and techniques of lean six sigma that can be used in this situation at Arabtec to better labor and material flow. Some of the tools and techniques of Lean Six Sigma that can be useful in this situation are as follows:

- A one-piece flow model enables the manufacturer to focus on flow efficiency.
- JIT – Just in Time: Reducing production time, supplier, and customer response time.
- Kanban: This is a technique to eliminate MUDA (waste) by ensuring continuous workflow.
- Kaizen: A methodology to incorporate small, ongoing changes in the system to ensure regular improvements.
- 5S (Sort, Set Order, Shine, Standardize, and Sustain)
- Value Stream Mapping: It shows the flow of materials and information in one of the processes and developed to improve and optimize flow throughout the organization.
- Six sigma conversion table: It identifies the main issues in the disturbance of material and labor on-site by studying the project's weekly activities.

Recommendation

Following is the figure of the Lean construction model, which can assist in overcoming the challenges faced regarding the flow of labor and material on site:

Figure 13: Lean Construction Cycle

Also, there is a need to have skilled planning regarding the material and labor on-site flow for the projects, a thorough analysis of the projects to curtail indicators mentioned in the fish map. To minimize disturbance of the flow of material and labor on-site in high-rise construction, Arabtec Construction must use multiple lean six sigma tools and techniques from the ones mentioned in the report's discussion, including JIT, Kanban, 5S, and standard six sigma conversion tables.

The data gathered through six sigma conversion tables will help to construct control charts, thereby mitigating the uncontrollable uncertainty to a certain extent. The sigma level could be improvised after a thorough analysis of data. Another important consideration for this project is classifying and identifying sustainability factors based on risk management standards. The company should also consider it imperative to improve productivity through a special focus on utilizing the Value Stream Mapping tool.

Conclusion

Lean Six Sigma is a well-regulated and data-based method for the improvement of quality. The tools and approaches adopted in Lean Six Sigma are similar to other quality improvement techniques, but the structured methods used for improvement procedures give it a recognized value. However, Lean Six Sigma in the construction sector is a novel idea in developing nations like India, China, etc, and is being adopted in developed countries. Because of non-standardized procedures and insufficiency in advanced quality capabilities in the construction sector, it falls behind the other important industries like services and manufacturing. The recent challenge to satisfy customers' demand for enhanced quality and good products at reduced costs needs sustainable tools and structured methods for quality improvement.

Leans Sig Sigma confirms that there are no issues and decreased variations in a procedure and concentrates on consumer satisfaction. It also supports reducing energy, waste, and pollution during construction and presents the concepts and key plans for sustainable development. Lean Six Sigma is a prominent solution for all the issues related to quality in construction. It supports the improvement procedures, which result in the reduction of cost and waste. Lean Six Sigma can also introduce a culture that guarantees uninterrupted improvement and perform appropriate re-evaluation of procedures, which supports sustaining a competitive position in the international market environment.

. Additionally, SS can develop a culture that ensures continuous improvement and conduct a timely and purposeful reassessment of processes, which will help maintain a competitive edge in the global business environment.

The impact of Supply chain management on the UAE construction industry has been noticeable. However, there is still room for a more transparent and decentralized project management approach. Incorporating Lean Six Sigma (LSS) tools and techniques, customized as per project needs, is imperative for a rise in customer satisfaction and revival of monetary gains, especially for Arabtec Construction and other construction companies in general.

The UAE's construction industry will grow with project timelines as long as the year 2030. Such timelines need to have more synergized processes, with each process well integrated with the final output to retain customer

satisfaction. Among the many tools for such projects, LSS is the most advisable option for UAE construction firms' managers. The models have a proven impact on the quality of the product ranging from manufacturing, software, IT firms to the infrastructure industry.

Abstract

Supporting the sector of small and medium-sized enterprises (SMEs) by public sector institutions takes place through a variety of instruments such as: ranging from advisory and educational programs to financial support through various loan funds, subsidies, including grants in EU funds in the case of European Union countries. The purpose of the article is to present partial research as a part of a research project carried out by the Kujawsko-Pomorskie Voivodeship, the Warsaw School of Economics and the Nicolaus Copernicus University in Toruń. These institutions are as a part of the Gospostrateg - Regiogmina project: "Location of support instruments for SMEs at the level of local governments, operating on the basis for a model of multi-level regional governance". Examples of such support in several analysed countries out of 16 respondents and assumptions of such support for the Kuyavian-Pomeranian Voivodeship are presented. The main purpose was to focus on financial instruments, including the developed of "Local Economic Development Fund (LFRG)", which may be one of the instrument supporting small and medium-sized enterprises in a given local or regional area. The concept is based on a combination of the initiative of representatives of the regional and local public sector and private entities, mainly entrepreneurs with SMEs.

Keywords: SMEs, Public sector, enterprise support.

Introduction

Initiatives and activities aiming to support entrepreneurship with an outlook to increase competitiveness and wealth of our economies have become part of our everyday lives. Supporting the sector of small and medium-sized enterprises (SMEs) by public sector institutions takes place through a variety of instruments such as: ranging from advisory and educational programs to financial support through various loan funds, subsidies, including grants in EU funds in the case of European Union countries.

The purpose of the article is to present partial research as a part of a research project carried out by the Kujawsko-Pomorskie Voivodeship, the Warsaw School of Economics and the Nicolaus Copernicus University in Toruń. These institutions are as a part of the Gospostrateg - Regiogmina project: "Location of support instruments for SMEs at the level of local governments, operating on the basis for a model of multi-level regional governance". Examples of such support in several analysed countries out of 16 respondents and assumptions of such support for the Kuyavian-Pomeranian Voivodeship are presented. The main purpose was to focus on financial instruments, including the developed of "Local Economic Development Fund (LFRG)", which may be one of the instrument supporting small and medium-sized enterprises in a given local or regional area. The concept is based on a combination of the initiative of representatives of the regional and local public sector and private entities, mainly entrepreneurs with SMEs

Basic SME Support Instruments

The instruments of SME support on the part of public sector institutions include: direct and indirect financial and non-material aid as well as all activities aimed at creating a climate conducive to the activity of economic entities. The basic instruments for such support include (Cowling & 2018, Foreman-Peck & 2014, Jarosiński & 2015):

- information instruments,
- promotional and organizational instruments,
- training and advisory instruments,
- financial instruments,
- fiscal instruments,
- infrastructure instruments.

Information instruments may be, for example: informing entrepreneurs about subsidies from EU funds or other aid programs, information e.g. about changes in the local spatial development plan indicating business zones, also communal real estate databases, etc. (Maśloch 2012). Information instruments are complemented by promotional and organizational instruments, such as local economic organizations, local economic development plans, programs supporting the promotion of local products, promotion of the commune itself, its infrastructural potential, development strategy, relatively lower taxes and local fees, etc.

These instruments also include the establishment of a unit for the promotion of entrepreneurship, the organization of competitions for the best product and enterprise by the commune, organizing foreign trips by the commune for entrepreneurs, frequent meetings with presidents of local companies and exchange of experiences, mutual support in the field of advertising and promotion, joint activities promotional activities outside the commune, integration of entrepreneurs from a given commune, development of special aid programs for small businesses by the commune, creation of fast paths for investment projects in the commune, economic cooperation of the commune with local entities in the implementation of investment projects, frequent meetings with presidents of local companies and exchange of experiences.

Among the training and advisory instruments, we can distinguish: active participation of the commune in training for entrepreneurs and the unemployed, providing consulting and training centres in the commune, The financial instruments include: local and regional economic development funds, loan guarantees for entrepreneurs, establishment of business incubators or technology parks in the commune, involvement of the commune in venture-capital projects, contributing property to companies by the commune, communal guarantee fund, purchase of services from local companies by the commune, purchase of land by the commune for the purpose of consolidation, reinforcement and division. Sale of communal land for economic purposes (Maśloch 2020).

Fiscal instruments that complement or even overlap with financial instruments may be: forest tax rates lower than the maximum, the application of maximum reductions for newly established plants that create new jobs in the commune, real estate tax rates lower than the maximum, further tax cuts on real estate or means of transport, forest tax reliefs and exemptions, agricultural tax rates lower than the maximum ones, agricultural tax reliefs and exemptions, stability of the commune's tax policy (Boonvut 2017).

The infrastructural instruments include, among others: land development for economic activity, infrastructure investments, such as road, water and sewage, heating, gas, telecommunication, and educational investments (Bhattacharya & 2015, Studart & 2018).

SME support funds and organizations in selected countries

In many European countries, support for the development of SMEs is provided under the Small Business Act (SBA). For example in Denmark. In 2007, five regional business development institutions (in Aalborg, Aarhus, Odense, Vordingborg and Copenhagen) were established to improve the quality of specialist advice to entrepreneurs. These institutions, called Houses of Growth (Væksthuse), were established by the municipalities as foundations. They had a uniform structure, and their activity encompassed both regional and national initiatives. Houses of Growth provided

entrepreneurs with access to various types of experts, they also helped SMEs in preparing market analyses, allowed them to exchange experiences and connect on the web. They were also responsible for the 'second chance' system, providing free, impartial and confidential advice to SMEs in financial distress. If it was too late for changes, the Houses of Growth strived to make the bankruptcy process as efficient as possible (Dilger 2016, Giebe & 2006, Honore & 2014).

In line with the assumptions of the 2007 local government reform, Business Forums (Virksomhedsforum) were also established at the regional level. There were six of them - they operated in each of the regions and on Bornholm. Business Forums consisted of representatives of local and regional authorities, entrepreneurs, educational institutions, employees and managers. They were responsible for preparing regional business development strategies, as well as for monitoring development conditions. They were also assigned to recommending the government to co-finance activities for business development (including from the European Union funds). The Danish Growth Fund, which is a state-owned investment fund, is the most important source of financing for Danish entrepreneurs. The fund is not only an equity investor; it also provides loans and guarantees to small and medium-sized enterprises in cooperation with private partners and Danish financial institutions. The Growth Fund offers loans and guarantees to companies from all sectors and all stages of development, both start-up loans and loans suitable for more mature companies intending to invest in further development. The Fund's offer includes, among others start-up loans for young entrepreneurs. They are granted in the amount of 0.4-1.5 million DKK, for a period of up to six years, require co-financing by private investors in a 1: 1 ratio (Malinowska-Misiąg 2020).

In Finland, despite broad autonomy, central and regional institutions are designated to promote entrepreneurship. Such institutions include ELY Centres (Economic Development, Transport and Environment) playing a significant role in promoting regional business policy. An effective regional business policy is the result of cooperation with other regional entities. ELY Centres aim to provide a balanced regional structure that provides a solid foundation for competence, entrepreneurship and growth and to promote employment opportunities. ELY centres support the establishment, development and development of small and medium-sized enterprises by providing consulting, training and expert services as well as financing investment and development projects.

One of the development ideas for SMEs in Finland is the so-called "Business Finland" - Sustainable Production program in Finland. It aims to strengthen the innovation and production volumes of companies in a sustainable manner. Targeted at companies aiming for international growth, particularly small and medium-sized companies. Funding is available for start-up companies, SME's, large companies, and research organizations. In some cases, a company may apply to organizations such as Finnvera for funding for projects financed by Business Finland. Finnvera is a specialized financing company owned by the State of Finland. It provides risk financing to enterprises with a sound business idea and preconditions for profitability when a company has insufficient collateral to raise funds for investments and development projects (Business).

In Finland, there are self-government entities whose permanent and main goal is economic promotion, e.g. Lahti Region Development, Turku Science Park (under the Turku Business Region brand. The governmental institution operating at the national level is the mentioned Business Finland. Local government institutions are e.g. Lahti Region Development, Turku Science Park, Business Tampere, Cursor Oy (Kotka-Hamina region), Helsinki Business Hub. Institutions created by entrepreneurs are, for example, Turku Chamber of Commerce, Oulu Chamber of Commerce. Government institutions are financed by the government, while self-government institutions are financed by the local government and possible Government grants EU funds are an important source of external financing, but depending on the organization, for example, the statute may include provisions on the obligatory membership of entrepreneurs in its bodies, such as the Advisor Board, but this is not a legal requirement, but the will of the owners. One of the largest entities on the market of credit institutions is the company MuniFin dealing with providing financing for local governments, local government companies and housing companies. It is 100% owned by the Finnish public sector. Such companies may be established jointly with other communes (André & 2018, Meyer 2005, Väänänen 2003).

One of the instruments for supporting SMEs are business incubators. The creation of business incubators and technology parks are activities of local governments or, more often, local government institutions / companies promoting economic development. The created entities most often have legal personality. In France, on the other hand, local entrepreneurship is supported by regions and local governments. Regions are responsible for carrying out an annual quantitative and qualitative evaluation of the aid and support programs implemented in their territory. The region is also responsible for organizing local consultations and convening a regional council in case the economic

balance of the region or part of it is disturbed. The region may also decide to adopt a regional economic development plan. In its coordinating role, the region is responsible for carrying out an annual, quantitative and qualitative evaluation of the aid and support programs implemented in its territory. One of the tools for local development in France at the local level is the so-called financial engineering, i.e. the possibility of granting subsidies by local governments and / or their grouping to organisms whose sole task is to provide financial support for the implementation of investments by SMEs, or to non-profit organizations. The purpose of this support is not to ensure full project financing, but to facilitate the intervention of the traditional banking system through technical and financial assistance. Another tool is the protection of the economic and social interests of the population, consisting in the intervention of the commune to ensure economic development or to correct irregularities resulting from a private initiative by supporting:

- establishing or maintaining services in rural areas,
- companies in difficulty,
- the field of cinema and audio-visual services,
- the implementation of cultural projects of common interest at the local level,
- the cinema room operators,
- companies in the field of cinematographic and audio-visual production,
- the field of health in rural areas,
- conventional for healthcare professionals,
- tax,
- local government interventions.

Another instrument are entrepreneurship centres (pépinière d'entreprises / hôtel d'entreprises), which are established by local government units interested in creating jobs in their territory. The centres most often offer office space, warehouses, logistic services such as joint printing, meeting rooms and consulting services. Thanks to public support, the centres offer the above-mentioned services at preferential rates for a period of 5 years. Incubators of innovative enterprises are a similar instrument. These incubators in France (around 30) were established by higher education and research institutions (universities, colleges, research institutes) following a project competition announced by the Research Minister in March 1999 under the so-called the Allègre Act on Innovation and Research. Their main goal is to support the development of enterprises commercializing the research results of research institutions, although they may also be innovative projects from the business world.

In Spain, support for SMEs takes place through the Directorate General for Industry and SMEs of the Ministry of Industry, Trade and Tourism. There is a platform with a database of support programs and incentives addressed to enterprises by the public administration and its subordinate institutions aimed at supporting, maintaining and developing economic activity and entrepreneurship. Additionally, on the websites of city offices you can find offers aimed at local business. City halls are responsible for developing projects for local entrepreneurship. Economic planning and development of the region is carried out in agreement between the regional government and the central government. The exceptions are the Basque Country and Galicia, which have exclusive competence in this regard. Equity instruments for local SMEs are formulated at the level of the 17 regional governments of the Autonomous Communities and city halls. There is no uniform basis for such instruments. In Slovakia, support is practiced for small and medium-sized enterprises in the form of abandoning the collection of rental fees or their reduction, especially in the current pandemic situation. These decisions depend on the decisions of local governments and are related to their economic situation. To support business in Slovakia, the Slovak Trade and Investment Agency was established, which, however, focuses primarily on supporting strategic or large investments, especially direct foreign investments. In Slovakia, the Economic and Social Development Program of the PHSR commune was introduced, which is a planning document of local self-government in the field of local economic development. There are other institutions, including Slovak Business Agency (SBA).In Slovakia, there are no financial institutions supporting entrepreneurs at the local level, but local governments can participate in PPP projects or issue municipal bonds. Communes organize industrial parks and business incubators. If they are the property of the commune, the commune has the right to determine the amount of the rent (Romero-Jordán & 2014).

In Italy, according to the Constitution of the Italian Republic (Art. 117), the tasks of local government units also include the promotion and coordination of economic development and the provision of support for economic activities

in line with the territorial strategic plan. The following instruments are examples of forms of support for entrepreneurs by the local government:

- Grants to support innovative investments by SMEs aimed at introducing new products and / or production processes into the company, which will contribute to increasing production efficiency and employment;
- Tax credits for SMEs operating in industrial crisis areas to promote entrepreneurial initiatives that will help to strengthen local production structures and attract new investments;
- Contribution to the development of the production activities of SMEs from the tourism and cultural sector located in the Aquilia seismic crater;
- Funding for projects that produce socially desirable outcomes: SMEs can obtain funding for social innovation projects in areas related to citizens' well-being and territory development;
- Lending at low interest rates to SMEs operating in the agricultural production, processing and marketing sectors to finance investments in projects to increase productivity or employment;
- Facilitate the transition of SMEs to a low carbon economy: incentives to reduce energy consumption and gas emissions from businesses and production areas, including the installation of renewable energy production systems for own use, with priority to high-efficiency technologies (Costa 2017, Jędrzejewski & 2020, Xu & 2016).

A popular formula for capital support for SMEs in Italy, both at the commune and provincial levels, is the mobilization of liquidity potential and the popularization of confide (mutual credit guarantee syndicates). Examples of initiatives include:

- TrevisoFund - an instrument created by the commune as part of the response to the economic crisis in connection with COVID-19, assuming the transfer of a total of 200,000 to those involved in the confidi initiative EUR - for each EUR 1 received from the city, the consortia undertake to provide a guarantee of EUR 6 for local SMEs. An agreement was reached with the banks on the launch of a credit line of up to EUR 2.5 million with an interest rate of 0.70%. Under the initiative, SMEs can apply for loans in the amount of PLN 10-35 thousand. EUR with max. 72 months the repayment period,
- Provincial Microcredit Fund for Women - a system of counter-guarantees (up to 50% of the loan value) granted by the province of Reggio Emilia Confidi supporting access to credit for entrepreneurs from the SME sector. Under the facility, it is possible to obtain a loan of up to 25,000 EUR from 60 months the repayment period,
- Agreements concluded by the autonomous provinces involving much greater means,
- Reaching EUR 250 million and involving various partners, including confidi, the Trento Economic Recovery Fund established in order to combat the economic effects of COVID-19 (entrepreneurs using the Confidi guarantee may apply for a loan of up to PLN 300,000. EUR with a two-year repayment period and an interest rate of 0.40%),
- Alto Adige's € 1 billion recovery program provides for the active involvement of Confidi in a guarantee (90% of value) of interest-free two-year loans (assuming that the bank will waive interest in the first year and pay it by the province in the second) of 35 thousand EUR. In addition, loans of up to 800 thousand. EUR interest free for the first 6 months (Jędrzejewski & 2020).

Financial support instruments in Poland for SMEs

In Poland, at the central level, the SME sector is supported, among others, by the Polish Development Fund, which co-finances selected investments carried out by Polish entrepreneurs. Other forms of support are national programs and programs with the participation of EU funds addressed to entrepreneurs from various industries. At the commune level, forms of support include, for example, tax breaks, economic zones or regional loan funds. As part of the Regiogmina project implemented by the Kujawsko-Pomorskie Voivodeship, the Warsaw School of Economics and the Nicolaus Copernicus University, a proposal for a financial support instrument for SMEs was developed - the local economic development fund (LFRG).The intention of the Local Economic Development Fund is to provide joint resources for financing SMEs, which both banks and existing investment and loan funds do not provide. The formula of operation Local Economic Development Fund is therefore to create a local financial cluster. Through the implementation of investment projects involving the local capital of entrepreneurs and small investors, it creates a local capital market to support projects within the powiat (s) in which it operates.

The consequence of the measures taken is to build the investment attractiveness of the local economy and increase productivity and stabilize the economic development of enterprises from the SME sector in the area of influence of individual LFRGs. The LFRG should ensure access to financing that can be allocated to working capital and investments.

Proposed organization and operating principles of the LFRG (see Chart 1):

- The fund will be established as an Alternative Investment Company in the form of a limited joint-stock partnership,
- The company will be managed and represented by a general partner - a limited liability company as an internal managing body of the LFRG,
- The size of the fund is PLN 120-150 million, gradually paid over 4 years for projects selected and not questioned by the investment committee. LFRG's share in a particular project is PLN 2-5 million.
- LFRG will complete approximately 30 transactions (6-7 annually). Investment process: investment analysis (project analysis, due diligence and negotiations) - 6 months; 2 investment rounds (1 per year). After 4-6 years, the fund resells the shares to business owners or the stock exchange, or to other companies or funds.

Chart. 1: Proposed Organizational Chart

Source: (Own research)

The scope of financing offered by the fund:

- Loans for private companies (grants loans for projects to natural persons running a business by converting them into shares by converting them into commercial companies),
- Capital involvement for local companies (it will finance the company's development with capital (business scaling, new products, entering new markets) and will make available funds in the early stages of operations in the form of equity financing for companies as commercial companies),
- Buyout of shares in companies resigning from activity (it will finance the buyout of shares, their takeover and stabilization of management in the event that the original owner and creator, for random reasons, can no longer run his business and there are no successors),

- Supporting companies in the period of recovery from the crisis after the coronavirus epidemic (it will provide loans to companies of natural persons operating with conversion into shares and transforming them into commercial companies, and will finance commercial law companies to strengthen their liquidity and development opportunities after the crisis).

The Fund is expected to start operating in the second half of 2021. It is assumed that the LFRG will start investing after the first half of the year, and the investment period will run from 2022 to 2027 (Table 1).

Table 1: The Fund's financial flows over a period of 10 years

Data in PLN milion	2021	2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	Sum

Source: Own research

Private shareholders - limited partners, are entrepreneurs or natural persons from one or two powiats, cities, participate as shareholders in SKA / ASI in which they always have equal shares, together with 51% of shares they co-finance management costs, grant loans in the form of bonds for projects proposed by the company managing. The rate of return on investment may differ between public and private investors. Based on the current bond offers, it has been assumed that the interest rate for the issued bonds will be set at 7-8% per annum. Public shareholders - limited partners are the Kujawsko-Pomorski Development Fund 22%, the Polish Development Fund and / or the European Investment Bank 22%, municipalities and powiats in the LFRG area of operation 5%, as SKA / ASI shareholders.

Conclusion

Many countries support the development of the SME sector at various levels of public administration. They use various support instruments for this. In most European countries, financial instruments are proposed by central and regional levels of government and business environment institutions. At the level of communes, support is based on building technical infrastructure by communes and fiscal instruments such as tax breaks. In most cases, loans and credits for SMEs are offered by national and regional entities providing this type of service, such as banks or loan funds. A local fund for economic development, being prepared in Poland, is a new proposal.

Résumé

L'objectif de cet article est d'évaluer l'incidence de la couleur comme composante atmosphérique inhérente aux sites web commerciaux, sur les réactions à la fois affectives (l'état d'humeur) et cognitives (la mémorisation et l'intention d'achat) du e-consommateur marocain.
En se basant sur une revue de littérature approfondie et une étude exploratoire menée auprès des webmasters marocains, la présente étude expose les fondements méthodologiques menant à la proposition d'un modèle conceptuel qui traite de la question.
La collecte des données s'est effectuée via un questionnaire administré auprès de 384 personnes interrogées. La modélisation par équations structurelles et plus particulièrement LISREL est l'approche d'analyse mobilisée.
L'analyse réalisée n'a révélé aucun effet de la couleur sur les états humoraux de l'internaute marocain. Toutefois, l'humeur impacte la mémorisation et l'intention d'achat de ce dernier.
Les apports de cette étude sont synthétisés en trois pôles : théoriques, méthodologiques et managériaux.

Mots clés : Couleur, Site Web, Commerce Electronique, Humeur, Mémorisation, Intention D'achat.

Abstract

This article aims to assess the impact of color as an atmospheric component inherent to commercial websites, on both affective (mood state) and cognitive (memorization and purchase intention) reactions of the Moroccan e-consumer. Based on an extensive literature review and an exploratory study conducted among Moroccan webmasters, this study outlines the methodological foundations leading to the proposal of a conceptual model that addresses the issue.

The questionnaire is the privileged tool for collecting data from 384 respondents. Structural equations modeling and more particularly, LISREL is the used analysis approach.

The analysis carried out doesn't reveal any effect of color on the humoral states of the Moroccan web user. However, mood does impact the memorization and purchase intention of the Moroccan web user.

The contributions of this study are synthesized in three poles: theoretical, methodological and managerial.

Keywords: Color, website, e-commerce, mood, memorization, purchase intention.

Introduction

À la lumière du développement révolutionnaire d'Internet, le panorama de l'achat virtuel et de la vente en ligne a été aussi modifié. Ainsi, la conquête d'un consommateur en ligne reste tributaire de l'utilisation propice des facteurs atmosphériques dont la couleur joue un rôle communicationnel et affectif clé.

Dotée d'une ubiquité multidisciplinaire, la couleur se veut présente avec force dans les environnements commerciaux. Plus particulièrement, cette dernière figure à côté de la musique et des senteurs, parmi les outils les plus probants du marketing sensoriel qui semblent affecter notablement les différentes offres mercatiques.

Parmi les composantes clés du marketing visuel, nous retrouvons la couleur ; une composante quoique élémentaire joue un rôle important.

L'intérêt porté à la couleur peut être expliqué par deux raisons :

- La première, c'est que le marketing visuel est considéré comme un levier du Marketing Sensoriel, puisque la vue est le sens le plus sollicité chez le consommateur (Lahmidi, 2015).
En effet, l'atmosphère des sites web marchands se base tout d'abord sur l'apparence de l'interface. De ce fait, la vue capte non seulement 80% des informations environnantes, mais exerce aussi une influence sur d'autres aspects perceptuels (Mattelart, 1996).
- La seconde, c'est que l'élément atmosphérique « couleur » reste un élément très étudié (Divard & Urien, 2001) que ce soit dans le lieu de vente, au niveau du packaging ou en publicité.
Mais, jusqu'à présent, très peu d'études s'y sont intéressées dans le contexte du commerce électronique.
Il nous semble ainsi judicieux de comprendre l'impact de la couleur sur les réactions du consommateur, dans le contexte des sites web de commerce électronique. Soit un terrain fertile et d'actualité au Maroc (Lahmidi et Aomari, 2019).

Dans cette optique, la couleur en tant que composante de l'interface d'un site web commercial est susceptible d'être manipulée comme une variable explicative du comportement de l'internaute.

Nous pouvons avancer la problématique suivante : **Dans quelle mesure la couleur de l'interface virtuelle des sites web e-commerce, pourrait-elle impacter la mémorisation et l'intention d'achat de l'internaute marocain tout en influençant son état humoral ?**

Le présent article fournit une revue de littérature présentant le fondement conceptuel de l'étude, étale le protocole méthodologique mis en place, expose l'analyse statistique des données recueillies et souligne les principaux résultats dégagés en les confrontant avec les études ayant précédé.

Soubassement Théorique

Avec le progrès croissant du World Wide Web, la question de l'efficacité des efforts commerciaux appliqués aux sites Internet nécessite d'être reconsidérée (Moss, Gunn, et Heller, 2006).

Dès lors, bon nombre de travaux comme ceux de Lemoine (2008a ; 2008b) ont mis en relief un certain rapprochement entre les atmosphères physiques (points de vente classiques) et les atmosphères virtuelles (sites web marchands).

Si dans un magasin traditionnel, le consommateur parcourt des espaces, des rayons, des produits, des publicités, tous, disposés de façon à attirer son attention et ainsi à le stimuler pour passer à l'acte d'achat. Nous retrouvons parallèlement sur un site web, des pages dont l'objectif est de mettre en exergue tout un mécanisme d'attraction en recourant à des stimuli autour de la couleur, de la musique, des animations…etc., Tous, faisant partie de l'atmosphère virtuelle des sites web.

Ainsi, en transposant la définition proposée par Kotler (1973- 1974) relative au concept de l'atmosphère, Dailey (2000) y voit : « *la conception volontaire de l'environnement Internet visant à créer des effets positifs (par exemple un affect ou des cognitions positifs) chez l'internaute, afin d'accroître ses réponses favorables de fréquentation (revisites, butinage etc.)* ».

C'est via cette vision que Dailey (2000) propose une définition de l'indice environnemental virtuel qui désigne « *tout élément d'interface web contenu dans le champ perceptuel de l'individu et susceptible de stimuler ses sens, comme l'ont suggéré Milliman & Fugate (1993)*».

De ce fait, la couleur dans le contexte des sites web est considérée comme un indice environnemental virtuel qui joue un rôle crucial dans l'apparence de l'interface du site web (environ 80% des informations recueillies proviennent de la vue (Mattelart, 1996)) et ainsi contribue à la création d'un climat virtuel favorable et propice, susceptible d'influencer les comportements des internautes.

À partir du postulat selon lequel les facteurs atmosphériques affectent les états internes du consommateur (Pelet, 2008), nous modélisons de quelle manière les composantes atmosphériques d'un site web e-commerce et plus justement le stimulus chromatique « couleur », pourrait agir sur l'état affectif de l'internaute.

Par définition la notion de couleur est tridimensionnelle. Elle comporte trois paramètres : la teinte, la luminosité et la saturation (Munsell, 1966). Dans la présente étude nous nous sommes intéressés à la teinte chromatique, étant la dimension la plus marquante selon Pelet (2008) dans le contexte des sites web e-commerce.
Au sein du point de vente, l'étude de l'impact qu'exerce la couleur s'étale sur un niveau à la fois physiologique et psychologique.
Psychologiquement, les couleurs influencent l'affect dans sa globalité.
Sur le plan physiologique, la couleur a le pouvoir d'attirer l'attention et donc d'activer le système émotionnel chez le consommateur (Pelet, 2008).

En plus des états affectifs, le stimulus couleur influe sur les perceptions sensorielles et les mécanismes cognitifs (Elbachir et Chenini, 2016).
Le paradigme Stimulus- Organisme- Réponse (S.O.R) de Mehrabian et Russell (1974) constitue le fondement du modèle conceptuel étudié. Ce dernier considère trois composantes clefs : Stimulus (S), Organisme (O), Réponse (R) (Bitner, 1992 ; Eroglu, Machleit et Davis, 2001 ; Turley et Milliman, 2000).
Dans notre cas :

- Le stimulus S désigne la couleur de l'interface virtuelle des sites web e-commerce ;
- L'organisme O correspond aux états affectifs ressentis par les internautes ; et
- La réponse R concerne le comportement d'approche (passer plus de temps sur le site, revenir sur le site à nouveau, recommander le site à son entourage) ou encore d'évitement (quitter le site, déconseiller le site, ne pas recommander l'achat du site).

Dans la présente étude, nous nous sommes focalisés sur les volets affectifs et cognitifs de l'internaute, sans pour autant se pencher vers le pilier conatif.

Nous considérons ainsi que le stimulus atmosphérique « couleur des sites web e-commerce » est susceptible d'influencer et de conditionner l'état affectif de l'e-consommateur, en prenant en considération l'humeur plus distinctement.

L'objectif est d'appréhender le comportement d'approche ou d'évitement adopté par le e-consommateur, et ce, en fonction de la couleur du site web e-commerce, susceptible d'occasionner à la fois la mémorisation de ce dernier et l'intention d'en acheter également.

Impact direct de la couleur sur l'organisme (O) de l'internaute : Lien « Couleur- Affect »

Considéré comme concept prêtant à confusion (Derbaix et Pham, 1989), l'affect, l'état affectif ou encore les réactions affectives se présentent sous sept catégories (Lichtlé et Plichon, 2005) : l'émotion choc, le sentiment, l'humeur, le tempérament, la préférence, l'attitude et l'appréciation.

Derbaix et Poncin (2005) qualifient les réactions affectives éprouvées par le consommateur, après l'exposition à un stimulus atmosphérique, de l'affectif intégral. Bien entendu, la perception du stimulus (la couleur pour notre cas) est déterminante de l'affectif intégral (sentir de la joie par exemple).

Ainsi, nous tentons de mesurer l'influence de la couleur des sites web e-commerce sur l'état d'humeur éprouvé par l'internaute.

Lien : Couleur - Humeur

Qualifiée de longue durée mais de faible intensité, l'humeur est un état affectif explicatif des réponses comportementales (Zhang, 1999). D'où, l'importance de l'intégrer parmi les états affectifs à évaluer.

En effet, plusieurs recherches ont montré les liaisons pouvant exister entre la couleur et les états d'humeur (Wexner, 1954). Tout comme les associations reliant les couleurs aux émotions, et au regard des expériences vécues par l'individu modifiant ses propres perceptions émotionnelles de couleurs, la combinaison des couleurs avec l'état d'humeur se voit également altérée.

À titre illustratif, Odom et Sholtz (2004) constatent qu'en fonction des couleurs, certains états d'humeur sont les plus récurrents par rapport à d'autres. Le jaune est lié tantôt à la gaieté tantôt à l'excitation, tandis que le bleu se voit plutôt rattaché à la tranquillité.

Pourtant, face à la même atmosphère commerciale colorée, un consommateur avec un état d'humeur positif ne sera pas influencé de la même façon qu'un consommateur ayant une humeur plutôt négative (Elbachir, 2016).

Selon Chebat et Morrin (2006), dans un contexte d'achat traditionnel, la perception du consommateur est souvent affectée par les couleurs utilisées. Ce constat est transposable au contexte des sites web e-commerce. Car, si la couleur est susceptible d'occasionner la stimulation émotionnelle du consommateur, il est également envisageable de le rendre en bonne humeur.

En vue d'évaluer concrètement le lien entre la couleur et l'humeur, nous émettons l'hypothèse suivante :

H1 : La couleur de l'atmosphère virtuelle des sites e-commerce influence positivement l'humeur.

Impact indirect de la couleur sur les réponses cognitives (R) de l'internaute

Après que l'internaute ait développé un ressenti interne, de type affectif notamment, quant à la couleur du site web commercial. La réaction affective est susceptible d'influencer son comportement. Dans cette optique, le comportement d'approche n'est pas souvent couronné par l'acte d'achat, mais peut se manifester par l'intention d'achat (Donovan et Rossiter, 1982).

Ceci, rejoint l'idée stipulant que le comportement d'approche inclut tout type de comportement revêtant un caractère positif (Vinitzky et Mazursky 2011), le cas échéant la mémorisation et l'intention d'achat pour notre cas.

Les travaux d'Hall et Hanna (2003) précisent que les effets des couleurs à la fois dominantes et dynamiques sur les perceptions de lisibilité, par rapport à la dimension esthétique éprouvée, quant à la rétention des informations et à l'égard de l'intention d'achat ne sont nullement insignifiants.

Lien : Affect – Mémorisation

Il est évident que la rétention de l'information n'est pas directement liée à la couleur de la charte graphique du site web. C'est plutôt la lisibilité et la visibilité de l'information permise par le contraste des couleurs, qui affectent la mémorisation (Hill et Scharff, 1997, 1999).

Le mécanisme de mémorisation prend ainsi place selon la réceptivité de ladite couleur par l'internaute (Biers et Richard, 2002).

En effet, le ressenti émotionnel contribue considérablement à l'optimisation de la mémorisation. Ainsi, les souvenirs scrupuleusement gravés en mémoire sont à l'origine d'un ressenti affectif assez intense (Roullet, 2004).

La présence de l'affect est évidente que ce soit au niveau perceptif, cognitif ou encore décisionnel (Damasio, 1999 ; 2003).

Ainsi, la composante affective et le processus cognitif majeur « la mémorisation » semblent indissociablement rattachés.

Selon Davidson (1994), si l'émotion modère les actions, l'humeur impacte plus les cognitions.

Ainsi, nous émettons l'hypothèse suivante :

H2 : L'humeur positive de l'internaute lors de sa visite d'un site web e-commerce influence positivement sa mémorisation.

Lien : Affect - Intention d'achat

Suite aux recherches en psychologie environnementale, les réactions internes du consommateur à savoir ses réactions affectives, influencent son comportement (Bitner, 1992). Ces états affectifs sont susceptibles d'augmenter l'éventualité d'achat et se voient désormais modifiés, lorsque l'environnement et plus justement les composantes atmosphériques sont considérées (Kotler, 1973).

En effet, étant une variable atmosphérique, la couleur d'un site web de commerce électronique par analogie aux points de vente traditionnels est perçue comme étant un facteur situationnel spécifique aidant à convertir les intentions cognitives en comportements d'achats.

Ainsi, la couleur des sites web de commerce électronique est certes liée au processus de traitement cognitif et est susceptible d'influencer la prise de décision et par conséquent l'intention d'achat.

Dans un environnement virtuel par exemple, les sites web commerciaux recourant aux couleurs sont plus appréciés sur le plan esthétique. Ainsi, l'appréciation esthétique est liée à de grandes intentions d'achat (Hall et Hanna, 2003). Dans cette lignée, Percy et Rossiter (1983) précisent l'effet marquant qu'exerce la couleur en tant que composante esthétique sur l'intention d'achat. Hamilton et Luo (1999), rajoutent plus tard que le degré de complexité de l'interface virtuelle du site web e-commerce affecte l'intention d'achat des utilisateurs.

Notons à ce niveau que l'appréciation esthétique du site web est généralement rattachée à l'intention d'achat (Hall et Hanna, 2003). Quoique, les associations de couleurs n'ont pas d'impact marquant sur l'intention d'achat du consommateur (Hall et Hanna, 2003).

Ainsi, l'humeur générée d'une atmosphère plaisante ; l'atmosphère d'un site web commercial en l'occurrence, est susceptible de susciter l'intention d'achat (Park, Lennon et Stoel, 2005).

Nous énonçons l'hypothèse suivante :

H3 : L'humeur positive éprouvée par l'internaute lors de sa visite d'un site web e-commerce influence positivement son intention d'achat.

Notons que sur la base de la logique paradigmatique du Stimulus- Organisme- Réponse de Mehrabian et Russell (1974), l'humeur faisant partie de l'affect et intégrant la composante « organisme » joue le rôle d'intermédiation sur le plan théorique.
Pour plus de lucidité, cette relation d'intermédiation est à vérifier via le test de significativité statistique.

Le modèle conceptuel de l'étude se présente comme suit :

Figure 1 : Modèle conceptuel de l'étude fondé sur le paradigme S.O.R de Mehrabian et Russell (1974)

Protocole Méthodologique

La réalisation de l'étude quantitative auprès de 384 internautes marocains, vient à la suite d'une étude exploratoire élaborée en tant que prélude.

L'objectif de cette étude consiste à vérifier la validité du modèle conceptuel, en faisant preuve de beaucoup de lucidité. Pour ce faire, nous présentons d'abord le cadre d'échantillonnage, pour exposer ensuite les échelles de mesure manipulées pour l'évaluation des construits théoriques.

Cadre D'échantillonnage

Pour déterminer l'échantillon étudié, nous préconisons l'utilisation de la méthode probabiliste, à trois degrés. En effet, le nombre important de notre population mère et la rigueur scientifique que confère la démarche probabiliste sont les deux principales raisons qui justifient notre choix.

Dès lors, la population retenue est extraite du dernier rapport « Maroc en chiffres » de 2018 établi par le Haut-Commissariat au Plan [1].

La population concernée par cette étude comporte les individus ayant plus de 10 ans et résidant dans le milieu urbain. Selon le rapport de l'Agence Nationale de Réglementation des Télécommunications (ANRT), intitulé « Usages des TIC dans les ménages et par les individus » [2], l'éducation des enfants à l'usage d'Internet doit commencer avant l'âge de 15ans. Nous avons ainsi considéré la tranche d'âge (10- 14ans).

Pour ce faire, nous avons déterminé tout d'abord, les unités d'échantillonnage primaires en passant par l'échantillonnage stratifié non proportionnel, calculé sur la base de la population observée.

En effet, notre population observée a fait l'objet d'une segmentation en fonction de la tranche d'âge, afin de déterminer la proportion que représente chaque segment d'âge. Ce premier degré d'échantillonnage nous a permis de déterminer l'échantillon à sélectionner de chaque catégorie d'âge.

Sur la base des unités d'échantillonnages primaires, les unités d'échantillonnages secondaires sont construites. Nous obtenons ainsi un échantillon à un seul degré comportant 1.491.371 individus. Toutefois, ce nombre reste important et fera l'objet d'un deuxième échantillonnage.

Comme deuxième degré, nous optons pour l'échantillonnage aléatoire de type simple.
Cette deuxième étape est concrétisée via la formule de Steven K. Thompson (2012).
La formule de calcul de l'échantillon, se présente ainsi :

$$n = \frac{N \times p\,(1-p)}{[N-1(d^2/z^2)] + p\,(1-p)}$$

En admettant que :

n : Représente la taille de l'échantillon ;

z : Constitue le coefficient de marge de 1,96 et correspondant au niveau de confiance le plus élevé (95%) ;
N : Corresponde à la taille de la population observée ;
p : Soit la proportion estimée de la population. p est fixée à 0,5 (l'intervalle de confiance le plus petit) ;
d : Constitue la marge d'erreur acceptable ou estimée e est fixée à 5%.
Après l'application de la formule :

$$n = \frac{17.899.990 * 0,5*(1-0,5)}{[17.899.990 - 1(0,05^2/1,96^2)] + 0,5*(1-0,5)}$$

Nous obtenons un échantillon de **384 personnes**.

L'échantillon Statistique De L'étude

Au final, nous avons abouti à un total de 384 questionnaires, soit 384 observations.
Nous présentons ci-après les principales caractéristiques de l'échantillon étudié.

- ***Caractéristiques De L'échantillon***

Nous présentons plus particulièrement la répartition de l'échantillon selon la tranche d'âge d'une part et selon le sexe d'autre part.

Tableau 1 : Répartition de l'échantillon selon l'âge

	Effectif	Pourcentage	Pourcentage cumulé
De 10 à 24 ans	114	29,7	29,7
De 25 à 34 ans	79	20,6	50,3
De 35 à 44 ans	67	17,4	67,7
De 45 à 59 ans	77	20,1	87,8
De 60 ans et plus	47	12,2	100,0
Total	384	100,0	

Nous remarquons d'après le tableau, une prépondérance au niveau des tranches d'âge [10- 24 ans], [25- 34 ans], [45- 59 ans], [35- 44 ans] et [60 ans et plus], ce qui correspond respectivement à : 29,7%, 20,6%, 20,1%, 17,4% et 12,2%. Nous constatons également que les femmes ayant contribué à l'étude représentent 67,7%, contre 32,29% pour les hommes.

- ***Fréquence de consultation des sites web e-commerce***

Il nous est important de savoir le niveau de fréquentation des sites web de commerce électronique de notre échantillon étudié.

Tableau 2 : Fréquence de consultation des sites web e-commerce

	Effectif	Pourcentage	Pourcentage cumulé
Jamais	7	1,8	1,8
Parfois	155	40,4	42,2
Rarement	55	14,3	56,8
Souvent	109	28,4	84,9
Toujours	58	15,1	100,0
Total	384	100,0	

Suite au tableau, nous pouvons dire que : 40% des répondants fréquentent parfois les sites e-commerce, 28,4% les consultent souvent, 15% visitent les sites web marchands toujours et 14,3% le font rarement.

- ***Déficience de la vision des couleurs***

Par la déficience de la vision des couleurs, nous entendons les personnes daltoniennes. Le tableau ci-dessous présente la proportion des répondants daltoniens et non daltoniens.

Tableau 3 : Nombre des répondants daltoniens et non daltoniens

	Effectif	Pourcentage	Pourcentage cumulé
Non	308	80,2	80,2
Oui	41	10,7	90,9
Peut-être	35	9,1	100,0
Total	384	100,0	

D'après le tableau : 10,7% des individus interrogés sont atteints de daltonisme, 9,1% doutent qu'ils sont daltoniens, alors que la majorité soit 80% des répondants ne sont pas daltoniens.

Échelles de mesure des variables de l'étude

Selon Argot et Milano (2007) : *« assurer le lien entre les concepts théoriques et les données empiriques est l'étape cruciale de tout travail de recherche »*.

Pour une conception fiable du questionnaire, il est important de présenter les items utilisés, nécessaires à l'évaluation de chaque concept faisant partie de notre modèle conceptuel de recherche.

Items de la variable « couleur de l'atmosphère virtuelle des sites e-commerce »

Nous avons jugé propice de puiser les items relatifs à la « couleur », à partir de l'étude exploratoire préalablement menée (Lahmidi et Aomari, 2019).

Étant donné la nature descriptive et générale de notre étude, nous avons mesuré la variable couleur globalement, sans pour autant considérer ses trois paramètres.

Certes, nous ne nions guère l'importance de la teinte, la luminosité et la saturation. Mais compte tenu de la nature préliminaire de notre étude au Maroc, il serait judicieux d'évaluer d'abord la couleur dans sa dimension générale, pour pouvoir mesurer ensuite, dans des études ultérieures ses trois dimensions sous-jacentes.
Les items considérés pour l'évaluation de la variable « couleur » sont ainsi issus d'une confrontation entre la théorie et l'étude exploratoire.

Tableau 4 : L'échelle de mesure de la couleur sur la base de la confrontation théorie-exploratoire (Lahmidi et Aomari, 2019)

Dans un site e-commerce, le sens de la couleur est dépendant de mon goût et de ma préférence personnelle.
Dans un site e-commerce, la signification d'une couleur est construite sur la base de mes expériences virtuelles vécues.
Une couleur de site e-commerce relaxante, me permet de naviguer plus longtemps.
La première opinion constituée d'un site e-commerce est fondée sur les couleurs employées seulement.
Face à un site e-commerce dont la couleur est claire, je risque de ne pas faire attention à toutes les rubriques.
Tout comme le lieu de vente classique, la couleur est la première composante permettant la visibilité d'un site e-commerce.
Dans l'interface des sites e-commerce, la couleur joue un rôle purement esthétique.

Items de la variable de « humeur »

Pour mesurer l'humeur, nous avons utilisé l'échelle « Brief Mood Introspection Scale », connue par BMIS, de Mayer et Gaschke (1988), notée de 1 à 5 et composés de 16 items dont 8 sont des états d'humeur positifs et 8 sont des états d'humeur négatifs.

Tableau 5 : Items de l'humeur de Mayer et Gaschke (1988)

Heureux (se)
Excédé (e)
Paisible
Mélancolique
Nerveux (se)
Satisfait (e)
Plein (e) d'entrain
Affectueux (se)
Triste
Énergique
Bienveillant (e)
Somnolent (e)
Agité (e)
Maussade
Fatigué (e)
Actif (ive)

Items de la variable « mémorisation »

En ce qui concerne l'évaluation de la mémorisation, nous proposons une échelle de mesure qui prend en considération le contexte marocain. Pour la construction de notre instrument de mesure, nous avons aussi puisé des constats déduits de notre étude exploratoire (Lahmidi et Aomari, 2019).

Pour s'assurer de sa fiabilité, cette échelle de mesure fera l'objet d'une épuration via l'analyse en composantes principales.

De ce fait, la mesure de la variable mémorisation se fera à travers 8 items.

Tableau 6 : L'échelle de mesure de la mémorisation proposée par l'auteur sur la base de l'étude exploratoire menée (Lahmidi et Aomari, 2019)

Il m'arrive de mémoriser les informations commerciales *(comme le prix, certaines caractéristiques du produit souhaité…)* **d'un site e-commerce grâce à la couleur utilisée seulement.**
Plus je passe du temps sur un site e-commerce, plus je retiens ce qu'il y a dedans.
Face à une couleur donnée, plus je navigue plus longtemps sur un site e-commerce, plus je mémorise les informations qui s'y trouvent.
La couleur sombre d'un site e-commerce me rappelle instantanément le type de site visité.
En me rappelant d'un site e-commerce déjà visité, je m'aperçois que c'est la couleur qui m'a facilité ce rappel.
Ma première expérience infructueuse dans un site e-commerce, m'a permis de me rappeler très bien de ce dernier.
Une expérience de navigation réussie sur un site e-commerce, favorise le rappel de la couleur de ce dernier.
Parmi plusieurs sites e-commerce, j'ai pu reconnaître un site qui m'a beaucoup marqué, grâce à sa couleur uniquement.

L'intention D'achat

Pour évaluer l'intention d'achat, nous jugeons propice d'utiliser une échelle adaptée au contexte des sites web e-commerce. Les items de la variable intention d'achat sont également déduits de l'étude exploratoire réalisée (Lahmidi et Aomari, 2019). Il s'agit de 6 items, adaptés au champ du commerce électronique.

Tableau 7 : Items de l'intention d'achat proposés par l'auteur sur la base de l'étude exploratoire menée (Lahmidi et Aomari, 2019)

Auriez-vous l'intention d'acheter d'un site e-commerce, si sa couleur inspire confiance ?
Penserez-vous à acheter d'un site e-commerce dont la couleur est sombre ?
Quand je suis satisfait (e) de la couleur du site e-commerce, je suis prédisposé (e) à acheter de ce dernier.
Plus je passe du temps à naviguer sur le site e-commerce, à explorer ses produits et à regarder/ sa couleur plus la probabilité d'en acheter est élevée.
Me rappeler d'un site e-commerce qui m'a marqué (positivement ou négativement) pourrait susciter mon intérêt afin d'en acheter.
Lors de mes consultations de sites e-commerce, il m'est arrivé de visiter un site e-commerce que j'ai déjà consulté auparavant. **Le fait que je le reconnaisse parmi d'autres m'a permis de penser à en acheter.**

Analyse Des Résultats

Pour mesurer efficacement les construits latents de notre étude et après s'être assuré de la faisabilité de l'analyse factorielle, nous présentons d'abord, une analyse factorielle avec rotation Varimax. Pour tester ensuite la validité du modèle structurel à travers l'étude de la significativité des liens causaux.

L'ISREL (LInear Structural RELations), fondée sur l'analyse des covariances est l'approche poursuivie dans la modélisation par équations structurelles. Celle-ci s'oriente vers l'estimation des paramètres et privilégie l'analyse des constructions causales.

Analyse factorielle avec rotation Varimax

Pour la validation des items des variables de l'étude, nous élaborons une analyse factorielle avec rotation Varimax sous SPSS.

Validation des items de la « Couleur »

Concernant la variable « couleur », sur sept items deux ont été retenus : « La première opinion constituée d'un site e-commerce est fondée sur les couleurs employées seulement » et « Tout comme le lieu de vente classique, la couleur est la première composante permettant la visibilité d'un site e-commerce ».

Tableau 8 : Analyse factorielle avec rotation Varimax pour la « Couleur »

Axes	Variables	Contribution relative	Valeurs propres	Variance totale expliquée	Alpha de Cronbach
Couleur	La première opinion constituée d'un site e-commerce est fondée sur les couleurs employées seulement.	,835	1,395	69,730	,566
	Tout comme le lieu de vente classique, la couleur est la première composante permettant la visibilité d'un site e-commerce.	,835			

Validation des items de l' « Humeur »

Concernant l'humeur, quatre items ont été retenus : « Plein (e) d'entrain », « Affectueux (se) », « Énergique » et « Bienveillant (e) ». Ces derniers sont les plus explicatifs de l'humeur.

Tableau 9 : Analyse factorielle avec rotation Varimax pour l'« Humeur»

Axes	Variables	Contribution relative	Valeurs propres	Variance totale expliquée	Alpha de Cronbach
Humeur	Plein (e) d'entrain	,766	2,335	58,371	,761
	Affectueux (se)	,792			
	Énergique	,745			
	Bienveillant (e)	,752			

Par rapport à la variable « Humeur », nous pouvons dire que l'information sauvegardée est de 58,371%. Chacun des quatre items conservés, comporte une contribution relative dépassant 0,7, ce qui traduit un très bon résultat.

Aussi, le coefficient Alpha de Cronbach est satisfaisant, il est supérieur à la norme minimale recommandée par la littérature, et il est de 0,761.

Validation des items de la « Mémorisation »

Comme il figure dans le tableau ci-dessous, l'analyse avec rotation Varimax a constaté trois items.

Tableau 10 : Analyse factorielle avec rotation Varimax pour la « Mémorisation »

Axes	Variables	Contribution relative	Valeurs propres	Variance totale expliquée	Alpha de Cronbach
Mémorisation	Face à une couleur donnée, plus je navigue plus longtemps sur un site e-commerce, plus je mémorise les informations qui s'y trouvent.	,785	1,886	62,855	,704
	En me rappelant d'un site e-commerce déjà visité, je m'aperçois que c'est la couleur qui m'a facilité ce rappel.	,808			
	Une expérience de navigation réussie sur un site e-commerce, favorise le rappel de la couleur de ce dernier.	,785			

En effet, pour la variable « Mémorisation », l'information retenue suite à la rotation Varimax est de 62,855%. De ce fait, chacun des trois items maintenus, a une contribution relative qui dépasse 0,7, ce qui reflète un très bon résultat.

Le coefficient Alpha de Cronbach est satisfaisant, il est supérieur à la norme minimale recommandée par la littérature. Ce dernier est de 0,704.

Validation des items de l'« Intention d'achat »

Au niveau de l'intention d'achat, trois items ont été exclus :

- *« Auriez-vous l'intention d'acheter d'un site e-commerce, si sa couleur inspire confiance ? »*
- *« Penserez-vous à acheter d'un site e-commerce dont la couleur est sombre ? »*
- *« Quand je suis satisfait (e) de la couleur du site e-commerce, je suis prédisposé (e) à acheter de ce dernier. »*

Lesdits items ne sont pas explicatifs de l'axe « intention d'achat ».

Tableau 11 : Analyse factorielle avec rotation Varimax pour l' « Intention d'achat »

Axes	Variables	Contribution relative	Valeurs propres	Variance totale expliquée	Alpha de Cronbach
Intention d'achat	Plus je passe du temps à naviguer sur le site e-commerce, à explorer ses produits et à regarder/ sa couleur plus la probabilité d'en acheter est élevée.	,727	1,719	57,286	,624
	Me rappeler d'un site e-commerce qui m'a marqué (positivement ou négativement) pourrait susciter mon intérêt afin d'en acheter.	,797			
	Lors de mes consultations de sites e-commerce, il m'est arrivé de visiter un site e-commerce que j'ai déjà consulté auparavant. Le fait que je le reconnaisse parmi d'autres m'a permis de penser à en acheter.	,745			

Ainsi, l'information maintenue après l'élaboration de la rotation Varimax est de 69,156%. Chacun des trois items conservés, a une contribution relative excédant 0,7, ce qui reflète un très bon résultat.

Le coefficient Alpha de Cronbach reste satisfaisant, il est supérieur à la norme minimale recommandée par la littérature. Il est de 0,624.

Pour l'ensemble des axes créés, la variance totale expliquée est satisfaisante, elle est nettement supérieure à 50% (le seuil minimal admis par la littérature).

De ce fait, nous jugeons que l'information conservée après avoir rassemblé les items dans des variables latentes, est supérieure à 50% de l'information initiale.

Étant donné que le coefficient Alpha de Cronbach est sensible à la taille de l'échantillon et au nombre d'items, nous pouvons dire que les résultats sont très satisfaisants à l'exception de la variable couleur.

Test de la validité du modèle structurel

À travers l'étude empirique, nous avons mis en relation les différents facteurs à savoir : *Couleur, Humeur, Intention d'achat, Mémorisation,* dans un test de corrélation s'appuyant sur le test de Corrélation de Pearson.

De ce fait, nous mettons en relation les différentes variables par le test de corrélation. Les résultats se présentent ainsi :

Tableau 12 : Test de corrélation entre variables sous SPSS

		Couleur	Humeur	Mémorisation	Intention d'achat
Couleur	Corrélation de Pearson	1	,033	,002	,028
	Sig. (bilatérale)		,514	,969	,581
	N	383	383	383	383
Humeur	Corrélation de Pearson	,033	1	,366**	,204**
	Sig. (bilatérale)	,514		,000	,000
	N	383	384	384	384
Mémorisation	Corrélation de Pearson	,002	,366**	1	,319**
	Sig. (bilatérale)	,969	,000		,000
	N	383	384	384	384
Intention d'achat	Corrélation de Pearson	,028	,204**	,319**	1
	Sig. (bilatérale)	,581	,000	,000	
	N	383	384	384	384

D'après les résultats du tableau nous remarquons :

- Une corrélation positive et non significative entre la variable « couleur » et les variables : humeur (R= 0,033 ; P-value= 0,514), mémorisation (R= 0,002 ; P-value= 0,969) et intention d'achat (R= 0,028 ; P-value= 0,581). C'est-à-dire que lorsque la couleur augmente, les variables : humeur, mémorisation et intention d'achat augmentent aussi.
- Une forte corrélation entre l'humeur et les variables : mémorisation, intention d'achat. Soit des corrélations respectives aux valeurs : (R= 0,366 ; P-value= 0,000), (R= 0,204 ; P-value= 0,000). Ce résultat sous-entend que lorsque l'humeur augmente, la mémorisation, l'intention d'achat, augmentent aussi.
- Une corrélation à la fois positive et significative entre la mémorisation et l'intention d'achat (R= 0,319 ; P-value= 0,000). En effet, quand la mémorisation augmente, la variable : intention d'achat augmente aussi.

L'analyse de la nature des corrélations liant entre les différentes variables ne peut pas à elle seule confirmer ou infirmer les hypothèses de la recherche.

En vue de confirmer la nature du lien entre les différentes variables de l'étude, nous analysons les résultats de la modélisation par équations structurelles.

Analyse des estimations des paramètres

Pour étudier la significativité des liens causaux, nous analysons les estimations des paramètres de notre modèle causal.
Le tableau suivant présente les résultats du test T de Student et de la signification.

Tableau 13 : Résultats des liens de causalité et validation des hypothèses de recherche

			Estimate	S.E.	C.R.	P	Label
Humeur	<---	**Couleur**	6,082	5,481	1,11	0,267	**Non Validé**
Intention d'achat	<---	**Humeur**	0,336	0,11	3,048	0,002	**Validé**
Mémorisation	<---	**Humeur**	0,646	0,122	5,295	0,000	**Validé**

La variable " Couleur " a un impact positif mais non significatif sur la variable " Humeur " (R= 6,082 ; T de Student= 1,11 ; p-value= 0,267). ***(Impact rejeté).***
La variable " Humeur " a un impact positif et significatif sur la variable " Intention d'achat " (R= 0,336 ; T de Student= 3,048 ; p-value= 0,002). ***(Impact accepté).***
La variable " Humeur " a un impact positif et significatif sur la variable " Mémorisation " (R= 0,646 ; T de Student= 5,295 ; p-value= 0,000). ***(Impact accepté).***

L'humeur : test d'une variable médiatrice

En voulant vérifier le lien de médiation de la variable « humeur », nous sommes contraints de passer par trois étapes, conformément à la démarche d'analyse des effets médiateurs de Baron et Kenny (1986). Il s'agit de :

1)- Vérifier la significativité du lien entre la variable indépendante (couleur) sur les variables dépendantes (mémorisation et intention d'achat), en vue de montrer l'existence d'un effet à médiatiser ;
2)- Vérifier l'impact significatif qu'exerce la variable indépendante (couleur) sur la variable médiatrice considérée (humeur) ;
3)- Vérifier l'effet significatif de la variable médiatrice sur les variables dépendantes (mémorisation et intention d'achat).
Ce n'est qu'en validant les trois étapes précitées, que la variable « humeur » est bel et bien considérée en tant que médiatrice.

Rien qu'en évaluant l'incidence directe de la variable explicative (couleur) sur les variables à expliquer (mémorisation et intention d'achat) ; soit la première étape, il s'avère que la validité du lien causal entre la couleur et les deux variables cognitives à expliquer n'est pas vérifiée.

Du moment que cette première phase n'est pas validée, il nous est impossible de poursuivre l'analyse. Nous ne pouvons donc considérer la médiation au sein de notre modèle conceptuel.

Discussion des Résultats

Lors de la phase de validation des hypothèses de recherche, les résultats obtenus énoncent que l'atmosphère colorée des sites web e-commerce n'affecte pas les états humoraux de l'internaute marocain.

Cette constatation est en opposition avec les travaux de recherche qui ont précédé.

En effet, une imposante littérature révèle que la couleur en tant que composante situationnelle inhérente à l'environnement commercial est susceptible de modifier positivement ou encore d'altérer les états affectifs du consommateur (Roullet, 2004).

Par ailleurs, nous avons constaté que l'état d'humeur éprouvé par l'internaute n'est pas influencé par l'atmosphère virtuelle colorée du site commercial. Sachant que les items ayant reflété l'humeur sont tous positifs, ce qui est à l'encontre des apports théoriques stipulant que l'état d'humeur positif n'est pas influencé de la même façon pour un consommateur ayant une humeur plutôt négative (Elbachir, 2016).

Dans le contexte considéré : celui des sites web de commerce électronique et au sein du terrain marocain, nous avons rejeté l'hypothèse de la relation d'impact de la couleur sur les états humoraux de l'internaute.

Ce résultat peut être expliqué par la différence du contexte d'application : les points de vente classiques versus les sites web e-commerce, car les comportements du consommateur au sein de l'espace de vente classique peuvent clairement différer de ceux des internautes face à l'interface commerciale virtuelle (Hoffman et Novak, 1996).

Cependant, nous soulignons avoir relevé une relation positivement significative entre l'humeur et la mémorisation. Ce qui confirme les dires de Davidson (1994) témoignant de l'impact exercé par l'humeur sur les cognitions à l'instar du processus mémoriel en l'occurrence.

Pour ce qui est de la relation : humeur- mémorisation, celle-ci a été bel et bien approuvée dans la mesure où une bonne humeur suscitera une meilleure mémorisation.

De ce fait, l'hypothèse énonçant que l'humeur positive de l'internaute lors de sa visite d'un site web e-commerce influence positivement sa mémorisation est confirmée.

De même, l'humeur générée d'une atmosphère plaisante, celle d'un site web commercial en l'occurrence, semblerait susciter l'intention d'achat (Park, Lennon et Stoel, 2005). Constat théorique qui concorde avec notre résultat empirique.

En effet, suite à notre test d'hypothèse, nous avons relevé un effet significatif de l'humeur sur l'intention d'achat. Notre hypothèse annonçant que l'humeur positive éprouvée par l'internaute lors de sa visite d'un site web e-commerce influence positivement son intention d'achat est ainsi confirmée.

À vrai-dire, dans un contexte d'achat classique les états affectifs sont susceptibles d'influencer les processus d'évaluation, d'appréciation ou encore de prise de décision (Mehrabian, 1996) et implicitement l'intention d'achat. Ce constat est validé dans le contexte d'achat virtuel, sur notre terrain d'enquête, avec comme états affectifs : l'humeur.

Nous pouvons dire que les réponses cognitives considérées sont affectées par les réactions internes de l'internaute, à l'instar de l'humeur.

Conclusion

Cette étude souligne que l'état d'humeur positif du visiteur des sites web e-commerce est susceptible d'entraîner aussi bien la mémorisation que l'intention d'achat de ce dernier.

Nous pouvons dire que les réponses comportementales cognitives considérées sont affectées par les réactions internes de l'internaute, à l'instar de l'humeur.

Cependant, l'atmosphère colorée des sites web e-commerce est loin d'affecter l'état d'humeur de l'internaute marocain.

Ainsi, l'infirmation de la première hypothèse, reste attachée à plusieurs facteurs. Nous citons :

- Le contexte d'application (le point de vente classique versus le site web de e-commerce),
- Le biais de désirabilité sociale (Crowne et Marlowe, 1960), étant donné qu'une bonne partie des questionnaires recueillis était administrée aux répondants en présentiel et en présence de l'enquêteur ;
- L'étude de l'impact engendré par la teinte chromatique comme dimension unique de la couleur. Ceci, au détriment des deux autres paramètres cités dans la littérature à savoir : la luminosité et l'intention d'achat.

Ainsi, lors des recherches à venir, une manipulation tridimensionnelle de la notion « couleur » est vivement recommandée avec la potentialité de reprendre l'enquête, en envisageant de passer par l'immersion ou encore par l'expérimentation.

La principale contribution de cette étude se rapporte au cadre conceptuel de recherche qui apparaît dans la continuité du principe : affect-cognition (Derbaix et Pham, 1989) et du fondement de la psychologie environnementale (Mehrabian et Russel, 1974), portant sur le paradigme Stimulus- Organisme- Réponse (SOR) initié par Mehrabian et Russell (1974) et développé par Eroglu et alii (2001).

Le principe de ce modèle consiste à montrer l'impact de l'environnement physique sur le comportement d'approche ou d'évitement de l'individu, en passant par ses ressentis affectifs. Dans la présente étude, nous avons transposé le même modèle en l'adaptant au contexte d'Internet.

Méthodologiquement, pour une analyse efficace des données, nous avons privilégié la modélisation par équations structurelles, largement manipulée en sciences sociales (Hair et al., 2010) et couramment adoptée par les travaux empiriques (Valette Florence, 1988 ; Evrard et al, 2003). Celle-ci, intégrant l'analyse factorielle confirmatoire nous a permis de tester les relations causales multiples afin de vérifier la validité des construits latents (El Akremi, 2005).
Sur le plan managérial, le stimulus chromatique ne semble pas affecter à lui seul les réponses aussi bien affectives que cognitives des internautes marocains. Pour ce, les webmasters peuvent éventuellement orienter leurs facultés de création- web vers les facteurs d'apparence, les facteurs de navigabilité et les facteurs sociaux, tous combinés.

Multivariate Item Response Theory Models in Measurement of Social Attitudes

Justyna BRZEZIŃSKA

University of Economics in Katowice, Katowice, Poland
justyna.brzezinska@ue.katowice.pl

Abstract

Item Response Theory (ITR) is an extension of Classical Test Theory (CTT). The mathematical foundation of IRT is a function that relates the probability of a person responding to an item in a specific manner to the standing of that person on the trait that the item is measuring. It means that the function describes, in probabilistic terms, how a person with a higher standing on a trait is likely to provide a response in a different category to a person with a low standing on the trait. In this paper we present multivariate IRT models as an extension of classical and unidimensional IRT models. Multidiensional models explain the probability of a correct response to a given item as a function of a vector of latent traits, instead of a single latent trait. In this paper we present the background, theory, and application of MIRT models for the measurement of social attitudes based on own studies. All calculations will be conducted in R from CRAN.

Keywords: Multivariate Item Response Model, Test Item, Measurement Theory, R Software.

Introduction

The classical test theory (CTT) and the item response theory (IRT) are two commonly used psychometric theories in conducting item selection and reduction for measures. These two theories work based on different assumptions and statistical approaches, and both have shortcomings. Although CTT was the dominant statistical test model in the first half of the 20th century (Guilford, 1936, Gulliksen, 1950), other developments were also taking place. In England, Walker (1931) set the stage for what later was to become known as Guttman (1944, 1950) scaling, by introducing the idea that if a respondent can answer a harder question correctly then he or she should be able to answer easier questions on the same topic correctly as well. Walker also introduced the idea of an quantitative index measuring deviation from this deterministic model in real data (Loevinger, 1948). This was a deterministic approach without a random error component to the analysis of data collected by a set of items that are assumed to measure one psychological property in common. A little earlier, in the 1920s, Thurstone (1928) developed his statistical measurement method of comparative judgment. Thurstone's work may be viewed as the most important probabilistic predecessor of item response theory (IRT).

According to Bartholomew (1987) there are different types of latent variable models, depending on the type of manifest (observed) variable and latent variable.

Table 1: Classification of latent variable models

Manifest variable	Latentvariable	
	Continous	**Discrete**
Continous	Factoranalysis	Latent profile analysis
Discrete	Item response theory models Latent trait analysis	Latent class analysis

Source: Bartholomew (1987).

The main advantage of IRT models is the fact that the item location parameter (b) and the person trait level (θ) are indexed on the same metric. Therefore, when a person`s trait level is higher than the item location on the trait continuum, that person is more likely than not to provide a trait-indicating (positive or true) response. The converse is true when a person`s trait level is below the item location. IRT models are well suited to cope with dichotomous and polytomous responses, where the response categories may be unordered as well as ordered. The incorporation

Cite this Article as: Justyna BRZEZIŃSKA " Multivariate Item Response Theory Models in Measurement of Social Attitudes" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

of linear structures allows for modeling the effects of covariates and enables the analysis of repeated categorical measurements.

In the literature the most common IRT models are models that are dichotomously scored. Test items have a polytomous format when the responses are scored in more than two categories. Such models have a reponse function for each different category. Although the response categories of dichotomous items typically have a fixed order (e.g., correct–incorrect; true–false), this does not necessarily hold for polytomous items. Polytomous items have a nominal response format if their response categories can be classified but an a priori order between them does not exist. The nominal response model below is appropriate for items with this format. If an a priori ordering of the categories does exist, a graded response model or partial-credit model should be chosen. The two models differ in the problem-solving process that is assumed to lead to the responses. Models for a graded-response format are more generally known as cumulative models in ordinal categorical data analysis. The partial-credit models below are known as adjacent-category models. These two options do not exhaust all possibilities, a more comprehensive review of different polytomous response formats and IRT models is given in Mellenbergh (1994).

Multivariate IRT Models

Unidimensional IRT models are appropriate for analyzing examinees' responses to items measuring a single latent trait or ability. However, for complex items that measure multiple latent traits simultaneously, item responses should not be modeled using a unidimensional IRT model because the probability of a correct response would not be a function of a single latent trait anymore. When item response data do not satisfy the unidimensionality assumption, multidimensional item response theory (MIRT) should be used to model the item-examinee interaction. MIRT enables one to model the interaction of items that are capable of discriminating between levels of several different abilities and examinees that vary in their proficiencies on these abilities. In this article graphical MIRT analyses designed to provide better insight into what individual items are measuring as well as what the test as a whole is assessing are presented and discussed.

Multidimensional item response theory (MIRT) provides an ideal foundation for modeling performance in complex domains, taking into account multiple basic abilities simultaneously, and representing different mixtures of the abilities required for different test items. MIRT models explain the probability of a correct response to a given item as a function of a vector of latent traits, instead of a single latent trait. Although MIRT can be used for various purposes, this modeling framework is particularly useful for modeling the item response data when one or more items measure multiple latent traits simultaneously (Reckase, 2009), and for improving measurement precision when there are individual tests or subtests measuring correlated latent traits (Wang, Chen, & Cheng, 2004). MIRT models can be categorized into two groups based on the test structure. These are between-item models and within-item MIRT models (Adams et al., 1997; Wang et al., 2004). In a between-item MIRT model, each latent trait is measured by a unique set of items. In other words, each item is associated with only one of the latent traits measured by the test. This type of test structure is also known as simple structure, as with a factor analytic solution where items load onto a single factor. Between-item MIRT models are typically used for estimating subscores from subtests measuring correlated latent traits (e.g., Bulut, Davison, & Rodriguez, 2017; de la Torre, Song, & Hong, 2011; Wang et al., 2004). In a within-item MIRT model, each item can be associated with two or more latent traits measured by the test. This type of test structure is known as a nonsimple or complex structure. A good example of within-item multidimensionality is the bi-factor test structure from cognitive ability assessments, where all items are associated with a general latent trait (i.e., general intelligence) and each item is associated with a secondary latent trait (i.e., specific cognitive abilities).

Multivariate Item Response Theory models are mostly used for complex items for measuring complex items that involve multiple latent traits. Such models explain the probability of a correct response to a given response item as a function of a vector of latent traits, instead of a single latent trait. Multivariate IRT models are mostly used for various purposes:

- for modeling the item response data when one or more items measure multiple latent traits simultaneously (Reckase, 2009),
- for improving measurement precision when there are individual test or subtests measuring correlated latent traits (Wang, Chen, Chen 2004).

Multidimensional IRT models can be categorized based on whether the weakness or deficit in one dimension.

First, we present the two-parameter multidimensional model (M2PL), which is an extension of the unidimensional Birnbaum model. This M2PL model is a compensatory MIRT model including item difficulty and item discrimination parameter from a multidimensional test. The M2PL model is defined as:

$$P\left(u_{ij}=1\middle|\boldsymbol{\theta}_{\mathbf{j}},\mathbf{a}_{\mathbf{i}},d_i\right)=\frac{\exp(\mathbf{a}_{\mathbf{i}}\boldsymbol{\theta}_{\mathbf{j}}^{`}-d_i)}{1+\exp(\mathbf{a}_{\mathbf{i}}\boldsymbol{\theta}_{\mathbf{j}}^{`}-d_i)}, \qquad ()$$

where: $\boldsymbol{\theta}_{\mathbf{j}}$ is a $1\times M$ vector of latent traits for examinee j $\left(\boldsymbol{\theta}_{\mathbf{j}}=\left(\theta_{j1},\theta_{j2},\ldots,\theta_{jM}\right)\right)$, $\mathbf{a}_{\mathbf{i}}$ is a $1\times M$ vector of slope (i.e., item discrimination) parameters for item i $\left(\mathbf{a}_{\mathbf{i}}=\left(a_{i1},a_{i2},\ldots,a_{iM}\right)\right)$, and d_i is the intercept term for item i. The intercept in M2PL model is not similar to the difficulty parameter in 2PL model, because it cannot be considered a unique indicator of the difficulty of the item (Reckase, 2009). To obtain a multidimensional difficulty parameter for item i we can use a transformation formula:

$$B_i=\frac{-d_i}{\sqrt{\sum_{m=1}^{M}a_{im}^2}}. \qquad ()$$

The higher the value of B_i gets, the more difficult the item becomes. Similarly, we can obtain the discrimination parameter using the transformation presented below:

$$A_i=\sqrt{\sum_{m=1}^{M}a_{im}^2}, \qquad ()$$

where A_i is the multidimensional discrimination parameter representing the overall discrimination power of a multidimensional item. For unidimensional IRT models with a single latent trait the difficulty parameter would contain only one non-zero element.

Multidimensional Rasch model was introduced by Adams (1997). This model can be used for estimating item parameters from a test measuring multiple latent traits. The general form of the Rasch model is (Adams 1997):

$$P\left(u_{ij}=1\middle|\boldsymbol{\xi},\boldsymbol{\theta}_{\mathbf{j}}\right)=\frac{\exp(\mathbf{b}_{\mathbf{ik}}^{`}\boldsymbol{\theta}_{\mathbf{j}}^{`}+\mathbf{a}_{\mathbf{ik}}^{`}\boldsymbol{\xi})}{\sum_{k=0}^{K}\exp(\mathbf{b}_{\mathbf{ik}}^{`}\boldsymbol{\theta}_{\mathbf{j}}^{`}+\mathbf{a}_{\mathbf{ik}}^{`}\boldsymbol{\xi})}, \qquad ()$$

where $\mathbf{b}_{\mathbf{ik}}$ is a score vector for category k of item i across the M dimensions, $\mathbf{a}_{\mathbf{ik}}$ is a design vector for score category k of item i across that defines the relationship between the item difficulty parameters, $\boldsymbol{\theta}_{\mathbf{j}}$ is a vector of latent traits $\left(\boldsymbol{\theta}_{\mathbf{j}}=\left(\theta_{j1},\theta_{j2},\ldots,\theta_{jM}\right)\right)$, and $\boldsymbol{\xi}$ is a vector of item difficulty parameters for item i. In multidimensional Rasch model presented above $\mathbf{a}_{\mathbf{ik}}$ and $\mathbf{b}_{\mathbf{ik}}$ do not refer to item discrimination and item difficulty parameters. In multidimensional case of Rasch model they refer to weights derived from the test structure based on the researcher`s hypothesis. Parameters that are estimated under multidimensional Rasch model are $\boldsymbol{\xi}$ and $\boldsymbol{\theta}_{\mathbf{j}}$.

Now we present multidimensional IRT model that is used for polytomously scored items. This model is an extension of unidimensional Graded Response Model (GRM) and presents the probability of examinee j selecting response category k in item i:

$$P\left(u_{ij}=k\middle|\boldsymbol{\theta}_{\mathbf{j}},\mathbf{a}_{\mathbf{i}},\delta_{ik}\right)=\frac{1}{1+\exp\left[-\sum_{m=1}^{M}-\left[a_{im}\left(\theta_{jm}-\delta_{ik}\right)\right]\right]}, \qquad ()$$

where $\boldsymbol{\theta}_{\mathbf{j}}$ is a $1\times M$ vector of latent traits examinee j $\left(\boldsymbol{\theta}_{\mathbf{j}}=\left(\theta_{j1},\theta_{j2},\ldots,\theta_{jM}\right)\right)$, a_i is a $1\times M$ vector of slope (i.e., item discrimination) parameter for item i $\left(\mathbf{a}_{\mathbf{i}}=\left(a_{i1},a_{i2},\ldots,a_{iM}\right)\right)$, and δ_{ik} is the category boundary location for the response category k of item i. As we compute the probability of responding on the k th category of item i, $P\left(u_{ij}=0\middle|\boldsymbol{\theta}_{\mathbf{j}},\mathbf{a}_{\mathbf{i}},\delta_{ik}\right)=1$ and $P\left(u_{ij}=K+1\middle|\boldsymbol{\theta}_{\mathbf{j}},\mathbf{a}_{\mathbf{i}},\delta_{ik}\right)=0$.

In the further part of this paper we present the application on multidimensional item response models using R software.

Applications in R

In this paragraph we present results of our studies based on a test measuring social attitudes toward university students. We conducted research at the University among group of students asking them 26 questions. First 16 questions are not connected with the social attitude so we skip them and we choose only 10 questions from 17 to 26. The answers were binary with categories: 1 (yes) and 0 (no). Now we conduct IRT analysis, first classical (unidimensional), and multidimensional comparing several IRT models. The data set contains the responses from 242 examinees to 26 items.

We stard from unidimensional IRT models. We use eRm package of R. We build one, two and three IRT model using rasch and ltm function. The results of the analysis and goodness-of-fit statistics are presented in Table 2.

Table 2: Goodness of fit statistics for IRT Models

IRT Model	AIC	BIC	LogLik
Rasch model	2111.301	2149.679	-1044.65
Birnbaum two parameter	2096.752	2166.53	-1028.376
Birnbaum three parameter	2107.227	2180.495	-1032.614

Source: own calculations in R.

The analysis of information criteria shows that the smallest value of AIC is obtained for two parameter Birnbaum IRT model with AIC=2096.752.

The analysis of model coefficients shows that the most difficult question in the test was those with difficulty parameter greater than 0 (only question 22). Questions with negative values of difficulty parameter indicate easy items (question 17, 18, 19, 20, 21, 23, 24, 25 and 26). The discrimination coefficient for most of the questions is high and very high (discrimination coefficient greater than 1.35); only questions 20 and 22 present low discrimination level.

Now, for the chosen two-parameter Birnbaum IRT model, we apply graphical presentation of the model using Item Characteristic Curve and Item Information Curve (Fig. 1).

Fig. 1: Item Characteristic Curves and Item Information Curve for two-parameter Birnbaum model. Source: own calculations using R.

On the Item Characteristic Curve there is a relationship between ability (latent unidimensional trait) and probability of answering correctly for a particular item. The curves are mostly S-shaped, however there are two more linear for item 20 and 22. Those items had low discrimination level.

The other part of Fig. 1 is Item Information Curve presenting the relationship between ability (latent characteristic) and information level. From the analysis of those curves we can see that there are two lines lying very low having very low information level on all levels of ability. Those are items 20 and 22. The rest is bell-shaped differing with the level of kurtosis.

In this part of the paper we focus on multidimensional IRT models (MIRT). We use mirt package of R and we build several types of MIRT models. The test structure and unidimensional IRT analysis allows to structure multidimensionality, where item 20 and 22 are associated with the first latent trait, while items 17-19, 23 and 23-26 are associated with the second latent trait. Due to the characteristic of dataset, we define two latent traits: θ_1 and θ_2. To fit multidimensional Rasch IRT model we use mirt function in the mirt package with mrasch model setting, for Birnbaum two-parameter model we set 2PL setting.

Table 3: Goodness of fit statistics for IRT Models

Multidimensional IRT Model	AIC	BIC	LogLik
Rasch model	2265.656	2307.523	-1120.828
Birnbaum two parameter	2096.831	2170.099	-1027.416
Birnbaum three parameter	215.332	2223.489	-10266.666

Source: own calculations in R.

From table 3 we can see that using AIC information criteria for model selection we can choose Birnbaum multidimensional two parameter IRT model as fitting best with AIC=2096.831.

For Graphical presentation of multidimensional IRT models we present Test Standard Errors and Test Information Functions for Rasch (Fig. 2), two- (Fig. 3) and three-parameter (Fig. 4) Birnbaum multidimensional IRT model as a surface in three dimensional space.

Fig. 2: Test Standard Errors and Test Information Function for multidimensional Rasch model.

Source: own calculations using R.

Fig. 3: Test Standard Errors and Test Information Function for two-parameter Birnbaum model

Source: own calculations using R.

Fig. 4: Test Standard Errors and Test Information Function for two-parameter Birnbaum model.

Source: own calculations using R.

As information criteria from the analysis of multidimensional IRT models are very close for two- and three-parameter Birnbaum models, plots of Test Standard Errors and Expected Total Scores are also very similar.

Summary

Item response theory (IRT) is widely used in assessment and evaluation research to explain how participants respond to item level stimuli. This method is widely used in educational and psychological research to model how participants respond to test items in isolation and in bundles (Thissen and Wainer 2001).It is a general framework for specifying the functional relationship between a respondent's underlying latent trait level.

In this paper we introduce multidimensional Item Response Theory models (MIRT) that are suitable statistical method for the analysis of multivariate test structures where two or more latent traits are intended to be measured. MIRT models can be characterized as either compensatory or noncompensatory based on the presence of a compensatory relationship between the latent traits. To demonstrate how to estimate MIRT model we applied mirt

package of R and we presented results from own study on social ability among students. We compared uni- and multidimensional IRT models and we provided graphical presentation of IIC and ICC in two and three dimensional space. We applied information criteria for model selection.

In this paper we discussed theoretical and practical aspects of item analysis in the measurement theory. We presented Multidimensional IRT models as an extension for classical unidiemnsional IRT models providing more information about the latent trait under analysis. The variety of statistical packages and computer software that enable the analysis of latent characteristics give a great opportunity for applying IRT models in the analysis in different backgrounds.

Abstract

The complexity in production has increased with each phase of industrialization. This complexity must be managed by appropriate methods and tools. The fast and dynamic development of globalization processes would be impossible without the logistics supply chains support. The present demarche is to emphasize the challenges managers have to face towards Industry 4.0 period.

Keywords: Industry 4.0, complexity, resilience

Introduction

The changes that have taken place within the theoretical and practical approach regarding the physical flow of raw materials, products and people have led to the emergence of new terms, including physical distribution, logistics, materials management, logistics management, supply chain management or supply-delivery. Often, these terms are considered synonymous, being used to describe the same field called logistics. Some experts believe that these terms are interchangeable, others give a different meaning to each concept and believe that there is no single definition that can be applied to any product or company. (Badea, D. and Petrisor, S.M.. 2012)

Thoben, D.K. et al, 2017 stated that the industrial transformation associated with the smart manufacturing revolution and the introduction of CPS (cyber-physical systems) creates numerous challenges for organizations, technologies, and employees. The complexity in production has increased with each industrial revolution. Complexity is now a ubiquitous part of our lives. The "complex" view of reality is perceived as increasingly fundamental to understanding strategies at all levels, from the international consensus to domestic realm, and from governmental to private entities everywhere. Therefore, the inclusion of complexity into management discourse is a natural consequence, and many researchers, strategists, or managers have attempted to find the right approach to managing complexity.

Complexity in a system is a hard thing to measure and can be approached from numerous different ways. We can measure complexity based off the number of complex systems needed to accomplish the solution, from the degree of difficulty in describing the system, the amount of outcomes that are produced from the system or even the amount of inputs and monitoring of the system needed and numerous other ways that we can create to measure complexity.

STANCIU, Andreia Elena DINACHE (SIMIOANA) and Marius Eugen OPRAN "Supply Chain Management Challenges Facing Industry 4.0" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Dynamic socio-technical systems have emerged, consisting of many tangibles, intangible, as well as human elements. This complexity must be managed by appropriate methods and tools.

Phases of industrialization

According to Encyclopaedia Britannica, the Industrial Revolution describes “the process of change from an agrarian and handicraft economy to one dominated by industry and machine manufacturing”.

Furthermore, Kagermann et al., 2013 argued that “industrialisation began with the introduction of mechanical manufacturing equipment at the end of the 18th century, when machines like the mechanical loom revolutionised the way goods were made. This first industrial revolution was followed by a second one that began around the turn of the 20th century and involved electrically powered mass production of goods based on the division of labour. This was in turn superseded by the third industrial revolution that started during the early 1970s and has continued right up to the present day. This third revolution employed electronics and information technology (IT) to achieve increased automation of manufacturing processes”.

Industrial wave	Characteristics
Industry 1.0	Mechanization, waterpower, steam power
Industry 2.0	Mass production, assembly line, electricity
Industry 3.0	Computer and automation
Industry 4.0	Cyber physical systems

Fig.1: Phases of industrialization [source: Cadcam-group.eu]

According to Cadcam Group, "Industry 4.0" represents the integration of modern information systems and technologies with physical production and processes, which enables the development of new markets and models.

According to infopulse.com the new digital systems, emerging as part of Industry 4.0, gauge data from both physical and digital sources including:

- Industrial IoT devices;
- Robotics tools and autonomous robots;
- Big Data analytics systems;
- AI and Cognitive systems;
- Augmented Reality.

Economic Context

Simultaneously with the globalization of the markets, the products become more and more "globalized", resulting from the combination of inputs coming from several countries.

The old framework of production in one country and sale in another country have given way to international manufacturing operations. Technological progress has made it possible to decompose and disaggregate the production of goods in various phases, which take place in different countries. The lower costs of transport and communication and the liberalization of foreign trade have created economic incentives to locate the different phases of production in various countries. Firms choose for each production phase or component of a good country that meets the optimal production conditions, allowing yarns to capitalize on the comparative advantage offered by production locations in different countries, including differences in labour costs between different locations.

Within the functional fields of the international enterprise, the production management occupies a very important position. The proper governance of risks becomes a must (Pulfer R et al. 2015). It should be mentioned that the economic discussions on the theory of a company's location analyse, mainly, the location of the productive entity. According to the classic usage of choosing the location of the enterprise, priority has importance for production, only then following the other functions. Another reason why production management has such great significance is that the internationalization of production in the industrial sector is related to the substantial use of resources than in the case of other functions. Criteria such as product quality, logistics costs, supply prices, wages and hours of work, the percentage of employee participation in the company's profit are just a few examples of decision-making variables of enterprise policy, which decisively influence the location of the production unit. To these are added the effects of hiring staff often influenced by the social policy of the host country (an example is the privatizations in the former communist countries which stipulate that the new buyer of the factory must keep the same number of employees for a certain period of time)

The increase of the internationalization of the enterprise's activities has a considerable importance for the central function of the enterprise, the production. We can talk about the company's activities as being international from two points of view:

- On one hand, in the case of deliveries of goods across national borders to reach the customer (export-based strategy)

- On the other hand, in the case of increasing investments of companies in manufacturing units abroad (policy based on investments abroad)

The term "national competitiveness" is important from the point of view of international production management for 2 reasons:

- On one hand, the relocation of production units abroad is discussed as a key word of "national competitiveness", being not infrequently the subject of numerous political influences. The reason is the unilateral approach to production, which focuses heavily on job competitiveness. Topics such as marketing

competence or infrastructure do not remain out of the discussion even if fundamental topics such as wages, working time, manufacturing costs are in the forefront.

- On the other hand, besides the microeconomic effects, it is necessary to analyse to what extent these effects also have on the employment and the well-being of the nation, so important for the economic policy of the country. Production figures are therefore at the heart of the competitiveness debate. Relocation of production abroad, respectively foreign direct investment in the country, these can be the key variables of political success, which often means the re-election of the government to power. In order to ensure the long-term well-being of the nation, the state acts through interventionist measures, especially before the elections, when in no case should there be problems of employment or lowering of living standards.

It follows that in industrial policy the term "competitiveness" has meanwhile become the key word, not least and due to the example offered by the Japanese economy in the 80s and early 90s. Especially in the case of large multinational enterprises governments to try to influence the relocation of production abroad through subsidies, tax relief, favourable ways of amortization.

An organization might outsource certain activities in the value chain where there may be a specific comparative advantage. Production based on labour-intensive use can be relocated, for example, to countries with cheap labour, while capital-intensive processes require the employment of highly skilled personnel. Therefore, production will always be oriented towards external locations that have a supply of adequate labour and the necessary infrastructure. Regarding the optimal allocation of the production process from a geographical-spatial point of view, each production level must be examined with its cost structure (determined by the intensity of use of labour and capital production factors) in order to evaluate the efficiency of relocating that level. On the other hand, in this case, the costs of production logistics must be considered, first of all, those with transport and storage.

In general, the distribution of production levels in different countries can be established according to the needs and characteristics of each location, considering logistics and transfer costs. Such a production configuration is often meaningful when transportation costs for components and finished products are relatively.

Discussions

Essential for the international relocation of production is that, in principle, an optimal degree of concentration can be chosen for each level of production. This allows, on the one hand, to use the advantages of location-specific production factors and, at the same time, to achieve economies of scale.

In case of a high degree of concentration each stage of production can be achieved / concentrated only in one country, while the other levels are in at least 2 different countries. In an opposite case, the raw materials and the finished product are obtained in several production units dispersed spatially in more than 2 countries while the intermediate production is realized concentrated from a geographical point of view. Knuppell shown that the related international production can be achieved in a great variety of forms

This is how, for example, the first level of supply can be achieved in different countries, while the next 2 levels - intermediate and final production - are concentrated in one country. Conversely, the last level is oriented on the sale of several products, while the first 2 levels operate centrally.

Thus, in case of dispersion of the last level of the related international production, several variations can be found at the level of the finished product, without these implying disadvantages for the production efficiency. Based on the unique levels of supply and intermediate production, the same finished product can be made in different countries (product A), there can be slight variations of the finished product (product A and product A ') or different products can be manufactured, at least partially - starting from the same intermediate product on the principle of modular construction of the product. (product A and

product B) A relevant example in this sense is provided by Renault, which created the Megane and Logan models based on the same structure (intermediate product), differentiated modulated for each model. These are standardized components and intermediate products, which are then assembled in their own assembly units located near the sales markets. Such an adaptation is possible in the case of the short distance between the place of manufacture of the finished product and the buyer for communication reasons and it is preferred to concentrate all levels of production in a country, from where to then export to markets.

An essential advantage in terms of coordinating all partial processes in a given location is to minimize transportation costs and risks for raw and prefabricated materials. This is primarily explained by shorter transport distances. This results in a reduction of risks, as on short distances quantitative shortages or qualitative deteriorations are less likely than on cross-border transport over longer distances, as will be necessary in the case of decentralization of production levels. Spatial dislocation of production levels leads in addition to high transport costs and risks and the need to establish costly buffer deposits at each level, to avoid interruptions in the transport chain and thus a fall in production of production levels that follow in the cycle of production.

Delloite cited by infopulse.com proposes the following 3 solutions in order to use Industry 4.0 as organizational advantage: process optimization, process flow and quality monitoring and new business models implementation. All elements shall follow the initial connectivity stage as described in fig.2.

Fig. 2: Implementing Industry 4.0 [source: infopulse.com]

Process optimization implies increasing networking and digitalization, improving current process, and optimizing use of assets. Moreover, this means increasing automation and upgrading other standards to reduce costs and maximizing collected data and leveraging data with advanced algorithms

Process flow and quality implies creating digital threads throughout the entire process, from sourcing of raw materials to post sales and implementing new cybersecurity measures to address risks of increased connectivity

Within the present approach the new business models step embeds using collected data and insights to create new revenue streams and value for customers and building new products based on insight digitally gathered from clients

Furthermore, we should also emphasize the challenges of new technologies, as for example Artificial Inteligence, Quantum Computing or Blockchain.

The incorporation of artificial intelligence into defense strategies is already beginning to act as a trigger for the major transformation in terms of data assimilation and processing to effectively identify strategies. Scientific and technological advances contribute to shaping both the requirements and solutions for new approaches to meet the EU's defense capability needs.

The subject of recent discussions on Big Data and AI for military decision-making has been to highlight where that technology is heading and what opportunities it allows to improve military decision-making. Emphasis was placed on the impact on the OODA loop (Observe, Orient, Decide, Act). We can see major consequences from AI , Machine Learning and Big Data in terms of observation in terms of the ability to collect and assimilate large amounts of data streams generated and then process them efficiently.

When scientists refer to the way in which the principles of quantum computing are formulated using the most fundamental ideas of quantum mechanics, in fact the embodiment of which can be contemplated in virtually every branch of quantum physics. Efforts are now fully dedicated to producing operational devices using a profoundly new form of information processing resulting from specialties in atomic physics, quantum optics, nuclear and electronic magnetic resonance spectroscopy, superconducting device physics, electron physics and mesoscopic research, and with quantum dots.

Due to the scientific attractiveness of the new product, including its huge commercial potential, we are actually witnessing a global race that has as competitors Google, Microsoft, Intel, IBM, etc. to build the world's first operational QC, the perfect hardware scientists to develop new materials, accurately predict the evolution of weather globally and communicate through impenetrable encrypted messages.

In terms of blockchain technology, we are talking about an IT protocol dating back to the 1990s. However, its widespread use and success are related to the spread of cryptocurrencies and virtual currencies, the best known of which is Bitcoin. However, it would be a mistake to think that blockchain and cryptocurrencies are one and the same thing . Indeed, as a result of capitalizing on the blockchain to increase the computing power and capacity of IT systems for data analysis and given the strengthening of connectivity in Europe and the continued development of artificial intelligence systems, the potential to use distributed registry technology to a number of purposes unrelated to cryptocurrencies are growing exponentially. (Bucovetchi et al., 2018)

Blockchain is both a code, ie a communication protocol, and a public register, in which all transactions between network participants are recorded one after the other, with a high degree of transparency and in a way that cannot be changed. This order of records comprises a set of "blocks" (parts of code) that are cryptographically linked, making each part of the block that forms the chain traceable and unchangeable. These "linked blocks" are registered simultaneously on each of the devices through which blockchain participants connect. Each participant is a link in the chain, helping to validate and store the data that is exchanged. In this way, transactions always take place horizontally and are validated by a number of participants, which makes it impossible for a single operator to modify or destroy records.

Conclusions

Contemporary supply chain entities must realize that they function in the changing environment. Unfamiliarity with business partners, the establishment of economic organizations, e.g. global chains, on an ad hoc basis, sometimes

merely for the sake of fulfilling one single task, together with a lack of adequate legal regulations are the common challenges facing organizations while managing their business processes, to mention only a few. The fast and dynamic development of globalization processes would be impossible without the logistics supply chains support.

However, at the same time, globalization itself poses many challenges to logistics. Globalization is accelerating and this in turn leads to huge structural changes in the supply chains and to new challenges as regards effective supply chain performance management. The priority for businesses should be to develop new products and technologies. For companies to be competitive on the market and monitor further development flows, full digitization of the process is one of the primary goals and general principles on which Industry 4.0 is based. Furthermore, people should prepare for Industry 5.0 as the fifth-generation industry will bring a higher level of personalization to the final products, making the end customer feel more satisfactory.

Abstract

Implementing ERP systems in an enterprise requires taking a number of actions to ensure full success of this process. It is particularly difficult to implement an ERP system in a small or medium-size enterprise due to their limited resources. The existing body of literature provides a great number of publications on launching ERP systems and instances of good and bad practices involving ERP. The aim of this article is to point to an additional aspect of launching ERP systems, i.e. the role of IT consulting in this type of projects. What was an inspiration to study this subject was the involvement of multiple authors in seeking critical elements for the successful implementation of enterprise resource planning. In order to achieve the goal of the article, we undertook the analysis of the literature on the subject and conduct surveys amongst those managers who decided to implement an ERP system in their organisation. This research is of a preliminary nature and its major limitation is the modest amount of collected feedback and the limited time scope and geographical range of the research. The results presented can be of useful reference to managers facing the implementation of IT projects with the assistance of external consultants.

Keywords: ERP system, IT consulting, implementation of IT system.

IT systems for supporting management and the methods of implementing them in organisations

Integrated IT management systems are construed as information systems for providing support in managing business enterprises, and which are implemented using specialist software. They could emerge thanks to the development of science and technology; in particular, in such fields as computer-aided product design, process design, quality assurance, and manufacturing (Muscatello, Small, Chen, 2003). Integrated IT management systems combine the application of IT in assisting technical production preparation and control over production processes with the management issues of running the whole organisation (Trana, 2014).

An integrated IT system in an enterprise is broadly defined as modularly organised software embracing such areas of running a company as marketing, planning, purchasing, technical preparation and production control, distribution of ready goods, sales, servicing, financial-accountancy work, or human resources (Ehie, Madsen, 2005, p. 546; Ömür, 2009). In effect, what happens is the combination of the assistance in enterprise management processes with comprehensive systems of computerised manufacturing. In order to achieve full efficiency, it is necessary to develop IT resources for the whole organisation along with the rules of collecting, processing and sending them, as well as uniform rules for applying the tools and procedures of the system development (Ferreira, Kuniyoshi, 2015; Parthasarathy, Sharma, 2016; Umar et al., 2016; Maditinos et al., 2012; Wang et al, 2007; Ranjan et al., 2016).

Contemporary computer systems emerged through the development and refinement of such systems as CAD (Computer Aided Design), CAM (Computer-Aided Manufacturing, Computer-Assisted Manufacturing), CIM (Computer Integrated Manufacturing), or CAE (Computer Aided Engineering). Attempts were made to combine demand for goods with demand for the resources required to manufacture them (Chung, Snyder, 2000). In this way, the MRP (Material Requirements Planning) system was developed. Following its further development, the system was enriched with the following modules: business planning, sales, production capacities, and production

scheduling, HR-payroll scheduling and financial accounting scheduling. The MRP II concept is already an integrated multi-access IT system. Apart from production and purchasing, planning the MRP II also involves sales and resources planning, balancing production capacities and finance (Klaus et al., 2000; Ranjan et al., 2016; Koh et al.; 2009).
Another stage in the development of integrated systems was the emergence of two-sided mechanisms for the optimisation of planning processes and allowing integration with external entities under the supply and sales chain. Consequently, another integrated system emerged, i.e. ERP (Enterprise Resource Planning) (Botta-Genoulaz V., Millet, 2006). The growing popularity and access to the Internet allowed a) extending ERP systems with access to the base through an Internet browser for the benefit of both organisation members, clients and suppliers, b) integrating ERP systems with other systems via the Internet, interfaces for analytic systems, and tools for modelling economic processes (Koh, Gunasekaran, Rajkumar, 2008).

The effect of yet another stage of the development of the systems accessible on the market is ERP III. Under this solution, it is possible to plan the enterprise's resources with particular attention and emphasis on mobility. Additionally, data integration and data exchange were improved, not only between the organisation and its business partners, but also between such institutions as banks, the Social Security Office, or public administration. Those enterprises which take advantage of this solution can fulfil the concept of conducting their activity in real time. Under this concept, enterprises gain competitive advantage through eliminating lags in taking decisions by the management and being able to maintain operational continuity in implementing key processes (Øverseth, 2017, pp. 28-29; Das, Dayal, 2016, pp. 11-13). However, what is the most important thing is the possibility to use mobile devices such as smartphones or tablets. Access to the system from personal devices means quick access to the organisation's data and, possibly, a quick response.

The process of the implementation of IT systems with a view to giving assistance to the enterprise's management can take multiple forms. Depending on the approach and strategy selected, the implementation process will involve different types of risk. None of strategies can become the ultimate solution due to the varied features of enterprises, processes and environments in which they operate (Mahmood, Lloyd, 2017).

When the management are expecting immediate effects, achieved at a small cost, the strategy that is applied is the 'breakneck speed' strategy. It is relatively popular as it does not take as much time as other implementation strategies. This, however, means eliminating a number of key activities normally performed as the pre-implementation analysis. A rarely used method of implementation is the 'star strategy'. That it is rarely applied results from the fact that it requires a lot of involvement on the part of top managers. On the one hand, this strategy means obtaining immediate acceptance for the implemented solutions, which reduces the risk of failure and shortens the implementation time, but, on the other hand, it consumes the time the management might otherwise spend on other issues concerning the running of the enterprise. Then, the 'turnkey strategy' does not take much of the employees' time. All of the work is done by the provider of the product. This model most often uses standard solutions to which the ways of doing work by staff are adjusted. The staff's not having influence on the implemented solutions and new ways of working reduces the probability of their active use of the new software. Then, the strategy of 'own' implementation means relying on the company's own cadres in the process of implementation. However, the expertise and skills of the staff delegated to conduct the implementation are often not good enough to effectively complete the given task. Giving up external consulting services results in elongating the implementation time due to the lack of experience in performing this type of tasks by the organisation's own cadres. The 'budget' strategy entails similar threats as it relies on keeping costs down by purchasing relatively inexpensive software and delegating own staff to perform the implementation. In such an event, the company runs the risk of mismatching the selected IT system to the actual needs of the company and having the implementation conducted by incompetent staff. Then, the 'partner' strategy significantly reduces the risk of having incompetent staff to perform the implementation as it means the cooperation of the company's own staff with the experts of an external implementation company. The drawback is that long and numerous talks on optimally adjusting the new software to the needs of the buyer might considerably elongate the implementation process. In such a case, the dispersed responsibility of both the buyer's and provider's staff may lead to conflicts the resolving of which only extends the implementation time. Next, the 'low risk' strategy means that work is carefully planned and achieving each subsequent task proceeds according to detailed measures of performance. Moving to the next stage is only possible after completing the previous stage, while the completion time is not determined. In case of failing to complete a task, its implementation is withheld and work on the troublesome issues is continued until the problems are finally solved. Projects implemented with the application of this strategy entail considerable financial and human resources with little complexity of tasks and no time pressure. A side effect of this solution are high costs against potentially limited benefits and the risk of having the solutions run out-of-date before the project is even completed.

Most of the above presented strategies of implementing IT systems in enterprises involve cooperation with an external IT provider or consultant. This may take the form of consulting, which also involves particular types of risk.

Consulting in the implementation of IT systems

Implementing new systems in an organisation is a strategically important project which, on the one hand, opens up new opportunities for the business, but, on the other hand, generates huge risks and challenges. Choosing a wrong IT system or implementing it incorrectly can translate into lost opportunities in the organisation's further development or, worse still, generate significant losses (Ranjan et al., 2016). The implementation of an IT system is a time and money-consuming process. As many research findings show (Khaparde, 2012; Ömür, 2009; Loh, Koh, 2004), the implementation of ERP systems is not always successful. One way to avoid such a failure is to use the expertise of consultants (Wang et al., 2007). Even though hiring consultants itself is not a guarantee of success, their work often allows having a new look at the issues concerning system implementation and, in effect, achieving better results.

An overview of the literature on the assistance provided by consultants in ERP systems implementation reveals that it is an issue which still requires further in-depth analyses. In the literature, the assistance is mostly reduced to transferring knowledge between consultants and enterprises (Wang et al., 2007). However, a mere transfer of knowledge is not the only type of support that an organisation aiming to implement ERP is after. Managers expect consultants to show such skills as technical skills, human interaction skills, business context skills and consulting framework skills. In particular, consultants should be experienced and familiar with the issues in the implementation; they should have the ability to determine the organization's needs and expectations and assign personnel to meet those needs and expectations; and have expertise in systems implementations (Metrejean, Stocks, 2011). Furthermore, it is very often emphasised that with this type of projects the cultural context and industry practices are also of key significance.

The process of IT consulting most often involves the following actions (Wang et al., 2007):

- process analysis – current state and target state,
- selection of relevant solutions tailored to the specifics of the organisation,
- setting optimum implementation scope and its schedule,
- proper preparation of the organisation to project launch.

The selection of IT solutions by the organisation itself may prove to be suboptimal, mainly due to information provision shortcomings. IT systems are often chosen on the basis of the first good impression, general presentations, and partial and oversimplified lists of requirements. Such an approach fails to ensure the reliable verification of solutions and the optimum composition of implementation teams. Managers sometimes forget about it or they lack in the competence to enter into a secure contract with providers. In effect, they only focus on simple issues, such as contractual penalty for delays or extending the deadline of receiving the product, rather than focus on critical issues (Bakari et al., 2013). In such an event, external consultants should step in as early as the stage of agreeing the requirements the new system should meet and finding a capable provider. This requires relevant expertise and experience gained while working with previous clients (Chen et al., 2008). A consultant with high competences can provide support to the organisation at every single stage of the system implementation process.

Research Methodology

The recognised need for further analyses into the issues of the implementation of ERP systems concerns the research gap relating to the advantages and threats of using consulting companies in IT systems implementation projects.

The basis for the launch of this research was a survey conducted on a group of 66 enterprises, that were clients of a consulting company in the field of implementing IT solutions. The findings showed that companies do appreciate the services of IT consulting. As a consequence, we wanted to check the advantages and threats of such consulting. In the research process, two methods were applied – a literature overview and case study – which allowed the triangulation of the study (Saunders et al., 2003). The literature overview in accessible databases involved the following concepts: "ERP system implementation", "success factors in ERP implementation", "IT consulting". The case study method was chosen due to the type of the research question, the scope of the researcher's control over behavioural facts going on in reality and the level of interest in contemporary facts (Yin, 2014).

The research question asked was: "how does IT consulting impacts the process of selection and implementation of the ERP IT system?" In the study, it was assumed that IT consulting would be analysed in the context of the process approach to the implementation of an ERP system as presented by, among others, (Loh, Koh, 2004; Mahmood, Lloyd, 2017), and that IT consulting provides tangible benefits during ERP systems implementation. The subject of the analysis is enterprises which implemented the ERP system using the assistance of an IT consulting company. Combining the results of the literature overview with the cases under analysis, a table was drawn up featuring the dependencies between the implementation subprocess and the potential assistance provided by consulting companies. The analysis method used was patterns matching (Yin, 2014).

Results

An overview of the literature

Economic practice and the publications available show that ERP systems implementations are still not a very common practice in Poland. According to data by the Main Statistical Office, in 2019, only 28.5% enterprises used an ERP system. In industrial processing, heading towards industry 4.0, the figure was only 32.5%. According to Eurostat data, Poland takes the 6th last place across the European Union in terms of utilising ERP systems (https://portalprzemyslowy.pl/wyroznione/raport-erp/).

In the implementation of ERP systems, a number of steps must be taken. Being a process project, it requires going through the following stages: pre-implementation analysis, solution selection, project management (system implementation), post-implementation issues (Al-Mashari et al., 2003; Mahmood, Lloyd, 2017; Stojkić et al. 2015; Loh, Koh, 2004). Figure 1 presents the subsequent stages of the implementation of ERP systems.

Fig. 1: The stages of ERP systems implementation. Source: (Loh, Koh, 2004)

The implementation of ERP systems usually entails a change in the whole organisation, including changes in the approach to management from functional to process. Implementing IT systems improperly can lead to conflicts and failure of the whole project (Loh, Koh, 2004; Maguire et al., 2010). Success is achieved when the enterprise can run its business processes more efficiently owing to the implemented ERP system (Wei et al., 2008). The indicators of implementation success include: costs reduction, lower stocks, shorter order processing time, etc. (Umble et al. 2003).

Many authors have attempted to define the key success factors of the implementation of ERP systems. Most often they point to: support provided by top managers, a well-knit project team and effective communication. Furthermore, equally important are: a well-devised plan and a vision of future changes, a project manager with high and adequate qualifications, well prepared processes of managing the organisational change, a well identified current and target state of the processes within the organisation, properly devised approval tests, monitoring and control of implementation advances, organisational culture focused on change, and consultants' support (Loh, Koh, 2004; Mahmood, Lloyd, 2017; Markus and Tanis, 2000; Bingi et al. 1999; Duchessi et al. 1988; Nah et al. 2001; Ehie and Madsen 2005; Sarkar and Lee 2003; Umble et al. 2003; Kim et al. 2005; Nah and Delgado 2006; Maguire et al. 2010; Umar et al., 2016).

An analysis of scientific publications on ERP systems shows that it is also important to identify and point to the causes of failures in this type of IT projects (Calisir and Calisir, 2004). The literature identifies the following threats: the excessive alignment of IT system with the organisation's actual needs, lack of involvement on the part of top managers, improper project team composition, inefficient communication, lack of trainings, lack of change leaders, conflicts, combining old (already implemented) and new IT systems, erroneous needs analyses, mis-identified processes in the organisation (Nah et al. 2001, Huang et al. 2004; Mahmood, Lloyd, 2017).

Analysis and discussion

An analysis of the Polish market of the implementation of ERP systems reveals that most projects are conducted in the large enterprise sector (https://portalprzemyslowy.pl/wyroznione/raport-erp/). Meanwhile, the ERP system also allows streamlining the operations of small and medium-sized enterprises. The major obstacles for the widespread implementation of ERP systems in this sector are the lack of expertise and insufficient resources (Vijay, 2012).

As evidenced by the results of the preliminary inquiries, the 66 surveyed enterprises pointed to the helpful role of IT consultants in implementing ERP systems. Most of the respondents (company or project managers) admitted they had used the services of a consulting company in the process of ERP implementation for the following reasons:

- they lacked in expertise on IT systems – 40 responses,
- they lacked in the knowledge on the IT market and its standards (costs, implementation scope, agreements) – 34 responses,
- they lacked in the time needed to draw up the documentation on the company's expectations – 31 responses.

The respondents also said that in the area of "the specification of functional and non-functional requirements", the assistance of a consulting company was most important – 24 responses. The other activities, such as assistance in preparing tender procedure for the system delivery, propositions on processes streamlining, and business processes mapping and analysis, scored fewer responses (13 each).

The subject of the discussion is an attempt to find the answer to the research question of "how does IT consulting impact the process of selection and implementation of ERP IT systems?" The first element to be analysed was the selection of ERP systems implementation success factors. Based on a literature overview, a set of factors believed to play the most important role was selected. They include as follows: project management, ERP teamwork and composition, effective communication, top management support, business plan and vision, project champion, Business Process Reengineering and minimum customisation, change management program and culture, Software development, testing and troubleshooting, monitoring and evaluation of performance.

The second aspect under discussion was the position of the consulting company and its positive or negative influence on the implementation of ERP systems. Table 1 provides data obtained through a literature overview and a case study – an enterprise having implemented an ERP system with the assistance from a consulting company.

Table 1:The benefits and threats of using IT consulting in the implementation of an ERP system

Process phases	Critical Success Factors (CSFs)	The benefits of consulting	The threats of consulting
Chartering Phase	Project management	- matching the implementation scope to the specific conditions of the organisation - expertise in projects methodology	- using ready schemes - reluctance to understand how the organisation works and conducts processes
	ERP teamwork and composition	- access to consultants' expertise - matching team members' competence with tasks more effectively	- not enough competence of the consultants - inability to motivate the team - reluctance to point to software benefits
	Effective communication	- allows revealing the clients' subconscious know-how - applying tools and standards of communication – helpful in the organisation's future operations - talking staff into the implemented changes	- lack of rapport in terms of consulting scope - lack of rapport in terms of the client's expectations about software - excessive amount of communication tools and channels - mis-matched information recipient - reluctance of personnel to share knowledge with external consultants - lack of consistency in maintaining effective communication
	Top management support	- sharing expertise in the area of available ERP systems and their functionality - support to top management in managing the change - knowledge on implementation costs and system maintenance	- wrong identification of problem leading to recommendation of impossible solutions - passing the implementation responsibility on consultants (lack of management's support)
	Business plan and vision	- knowledge of planning tools and technology - ability of sharing the vision with personnel - setting strategic targets and ERP implementation targets compatibility	- reluctance of staff to share knowledge with external consultants - reluctance of staff to adopt the vision imposed from outside the organisation - failing to include the organisation's basic activity in the plan
	Project champion	- expertise transfer	- consultants' reluctance to get fully involved due to their already won reputation

Project Phase	BPR and minimum customization	- adequate expertise and experience allow minimising the technical problems of implementation - adequate conflicts management allows improving the implemented software - evaluation of organisation's processes and data allows determining the scope of integration and pointing to useful solutions for data analysis and reporting, including those based on AI technology	- lack of expertise and due experience leads to introducing improper solutions in terms of software and the quality of its implementation - conflicts resulting from different approaches to problem solving during system implementation
Shakedown Phase	Change management program and culture	- support to staff in understanding the validity of the changes - finding change leaders - support in building organisational culture favourable to the changes	- reluctance of staff to share knowledge with external consultants - treating consultants as strangers and reluctance to the changes they propose
Shakedown Phase	Software development, testing and troubleshooting	- awareness of system functionality and dependencies between modules - ability to devise approval tests - consulting and training on system exploitation	- lack of knowledge about other systems in the organisation and thus problems with systems integration - consultants' conviction of knowing better if the system is working properly - improperly devised and conducted training scheme
Onward & upward Phase	Monitoring and evaluation of performance	- analysis into the ERP system implementation effectiveness - recommendations for system streamlining	- lack of post-implementation servicing

Source: Author's own work on the basis of a case study and Muscatello, Small, Chen, 2003; Loh i Koh, 2004; Wang, Chen, 2005; Wei, Chien, Wang, 2005; Soja, 2006; Wang et al., 2007; Woo, 2007; Ömür, 2009; Maditinos et al., 2012; Bakari et al., 2013

Having an ERP system implemented with the assistance of consultants requires paying attention to the aspects of the quality of such cooperation. Referring to the research done amongst Taiwanese companies by (Wang, Chen, 2005), the successful cooperation of the client with IT consulting companies depends on the effectiveness of communication and conflict resolution. Effective communication is the prerequisite for successful client-consultant cooperation. The lack of it can result in the misconceived expectations and needs of the client (Qurashi et al., 2013). Furthermore, effective communication ensures grasping well the business needs of the client and the scope and possibilities of the implemented and sought-after changes following the implementation of ERP systems (Bloomfield, Danieli, 1995). The complexity of projects involving ERP systems implementation calls for long-lasting cooperation within the project team. Similarly, the assistance provided by consultants must evolve into a long-lasting relationship, which might result in conflicts, given different approaches to the issues and different organisational cultures (King, 2005; Koh et al.; 2009). Resolving those conflicts for the benefit of all the parties concerned enables the project team to learn and develop (Robey et al., 1993) and determines the success of ERP systems implementation. Swift and effective communication between the organisation and the consultant helps build mutual trust and resolve conflicts (Janka et al., 2019). The prime task of a consulting company is to provide expertise for the proper selection of ERP system and its smooth implementation. This is exactly the area in which companies recognise their major shortcomings. The lack of own staff's expertise is the main reason why consultants are approached to provide their assistance (Al-Mashari et al., 2003; Bingi et al. 1999; McLachlin, 1999; Wang et al, 2007).

Conclusions and Further Research

One of the major trends of development globally is the 4.0 industry. A successfully implemented ERP system is a key element for the company's success in using IT solutions (Stojkić et al. 2015; Stachowiak et al. 2019). The ERP system, in particular its latest versions which allow working in real time, allows achieving higher efficiency of running the enterprise on condition that is it properly implemented. Companies try to minimise the difficulties of the implementation of systems by using the assistance of external experts in the area of using expertise and good practice offered by IT consulting companies. If those companies are truly professional and can embrace the area of the organisation's operations, their services become invaluable. However, it happens that services are provided by companies lacking in expertise and experience, which results in doing more harm than good. In such an event, the selected ERP system will not match the needs and expectations of the organisation, and the organisation's staff will be reluctant to use it. It is also important that technical consultants have extensive knowledge about the system's implementation aspects allowing pre-implementation development of relevant IT infrastructure. They should also have enough knowledge and skills to be able to calculate and present the benefits derived from the implementation of ERP system in the organisation.

The basic limitation for the effective involvement of consultants in the ERP systems implementation process is their lack of competence – expertise and experience. When this potentially negative aspect of consulting is non-existent, their role is mostly positive (Maditinos et al., 2012). Organisations which decide to have ERP systems implemented

with the assistance of consultants can rely on their help in matching targets with the system's capabilities, support given to staff in achieving essential competences and a sense of the newly implemented solutions being meaningful. Well prepared consultants can adjust the organisation's software to the needs of specialist analyses required for the smooth running of the enterprise.

The analysis of the literature and the case study conducted allow me to draw only preliminary conclusions, presented in a tabular form. The identified advantages of consulting and the threats involved require further analysis, primarily, conducting more case studies supported by questionnaires. This will allow giving them due significance and, in effect, pointing to the extent of available advantages and risks involved.

The Efficient Performance of a Caravanning Microenterprise – Case Study

Daria MOTAŁA

Abstract

The Covid-19 crisis has led to a significant rise of interest in renting and purchasing recreational vehicles. It is not the only determinant of the efficient performance of companies in this field of tourism industry. The aim of the study was to identify other factors that may affect economic operations in this sector. The conclusions were based on the analysis of an exemplary micro-enterprise which has operated and has been constantly developing in the field of the rent, sale and service of campervans for years.

Keywords: Micro-Enterprise, Motorhomes, Determinants of The Efficient Performance.

The Industry Origin and Current Interest

Caravanning is perceived as a form of car tourism, travelling by recreational vehicles for sightseeing and leisure (Cudny, 2018). A recreational vehicle refers both to caravans (camper trailers) and campervans or motorhomes. They may be used to travel, i.e. go caravanning, or to go camping, i.e. use them as a form of stationary tourism and camping (www.encyclopedia.com). This kind of leisure is suitable for people who appreciate independence and high mobility, at the same time accepting conditions which are far from luxury.

The world's first leisure trailer was built by the Bristol Wagon & Carriage Works in Great Britain. In the 1890s, the first trailer appeared in the US. In 1912, Bill Riley's team of the UK developed the first professional camper trailer. In the 1950s and 1960s, the first campervans were built (Greenwood, 2011; Hogue, 2011; Fenton, 2013; Østby, 2013; Prideaux, 2018).

There are approximately 140 manufacturers of recreational vehicles (cars and trailers) in Europe. The four largest producers, whose share accounts for 75% of the European market are (Motorhome Market Outlook, 2020): Erwin Hymer Group, Trigano VDL, Knaus Tabbert and Hobby.

As far as the resources and registrations of new camping vehicles are concerned, the regions of the world with the biggest potential of the caravanning industry are: the US and Canada (64.8%), Europe (25.5%) and Australia (6.7%). In Europe, in turn, the sales of campervans are growing more quickly (about 60% of the caravanning market) (Recreational Vehicle Market Report, 2020).

In the years 2009 – 2010 in Europe, we observed the crisis in the caravanning market. The number of registered campervans and motorhomes fell in the three leading countries – by 10.6% in Germany, by 31.5% in France, and by 13.8% in the Netherlands. The recession hit the top European manufacturers with their sales dropping by as much as 30%. The owners of companies dealing with the sales of campervans and caravans had to reduce the size of their fleets by 50% on average. As a result of the crisis, a number of European companies reported losses, and, consequently, had to go bust. In 2014, the sales started to increase and have continued to rise ever since (see: https://www.civd.de/en/artikel/european-market).

The Polish caravanning market is far less developed in comparison to Western countries. This is probably due to citizens' lower income, inadequate infrastructure, the shortage of proper camping sites and the lack of service facilities. Another reason seems to be increased interest in the offer of cheap airlines, which make it possible to travel easily to many parts of the world. The statistics show, however, that, year by year, the Polish caravanning market is growing (https://www.motorhome.pl/rynek-kamperow-w-polsce). This is shown in the diagram which presents the number of recreational vehicles registered in Poland in consecutive years.

In April and May 2020, we observed a significant rise in the interest in recreational vehicle in Poland, which was a direct effect of the Covid-19 pandemic (Łukaszeiwcz, 2020). This form of leisure seems to be the safest and was one of the first to be allowed after the period of compulsory isolation. When people travel in a recreational vehicle, they stay with their closest family and use personal lavatories and kitchen, just like at home, which considerably reduces the risk of infection (COVID – 19 https://www.civd.de/en/artikel/effects-on-caravanning-tourism).

The determinants of the development of tourism services

The development of the tourism market depends on complex rules and processes. It is difficult to consider these factors in a uniform way, because they may be discussed from a number of perspectives, including aspects of economy, demography, geography, law and politics, and mass-media (Middleton, 1992; Prideaux, Carson, 2011).

What is the most important economic factor affecting tourism demand is the income of a potential customer. Tourism is a luxury good, so the demand for services arises after the basic needs have been fulfilled. Due to the differences in customers' expectations and forms of travel, it is impossible to define the level of income determining interest in tourism services (Cheng-Fei, 2020; Camilleri, 2018).

Demographic determinants are connected with economic factors. They include population, the size of household, its structure, the age of household members, their level of education, the place of living, and profession. As people gain education, they often express the need for personal development, reflected in their desire to learn about new places and cultures. This is achieved a lot more easily by travelling on one's own in a campervan rather than by all-inclusive holiday (Prideaux, 2019).

Legal and political factors regulate tourism demand. The pandemic blocked the freedom of movement for a few months, which significantly affected tourism. The later easing regulations restored the possibility of moving within the country and abroad relatively freely.

The importance of the impact of mass-media is a very broad topic. The media play the key role in informing the mass recipient. It is them, which create people's opinions and choices in the 21st century. Thus, they indirectly influence consumers' decisions (Patluang, 2017).

Psychosocial factors constitute a very complicated and diverse group. Each trip can thus be motivated by different factors and will be different for each social group. Holidays spent driving a motorhome have been in fashion for a few years and are preferred by specific groups of people. Moreover, they are now perceived as one of the safest forms of leisure, allowing people to be isolated from others.

The efficiency of Microenterprises

A microenterprise is defined according to the number of employed people and the maximum balance sheet total or revenue. The European Commission defines an enterprise as any business entity, irrespective of its legal form. A microenterprise is an entity which employs no more than nine people and the annual balance sheet total or turnover of which does not exceed EUR two million (European Commission Recommendation 2003/361/EC).

The efficiency of enterprises is usually assessed in the context of financial results, which enable the development of a company (Baumast, 2017). However, this type of approach does not always reflect how micro-entrepreneurs perceive success and effective operations (Ioniță, 2013). For many of them, it is enough to stay in the market for a long time to find their companies successful. They often define their objectives as job satisfaction, making a

reasonable living, need for autonomy, creativity and community respect (Toledo-López i in., 2012; Bhattacharyaa S., Londhe B.R. 2014; Henrekson M., Sananda T., 2014).

Regardless of the detailed assumptions concerning the goals of business operations, it is customers and information that are the most important elements in the long-term functioning of a company. Customers' interest depends on the scope of information and the way in which it is communicated. Well prepared and properly conducted marketing activities are thus important here (Porto et al., 2017). This factor and the abovementioned aspects of the perception of success are also found in the findings of studies carried out in the company. Like other microenterprises, also the one under study does not aim to expand its range of operations, focusing on improving its existing activities (Gherhes et al., 2016).

Characteristics of the Enterprise

The company under analysis, which meets the above criteria, deals with the sales, rent and service of campervans. It was established in 2006, which makes it one of the longest operating caravanning enterprises in Poland. It is owned by a natural person conducting a business activity and is located in Poznań.

The company operates in seasonal business. Vehicles are rented from March to November, with the highest demand between May and September. As regards sales and maintenance, these activities are conducted throughout the whole year. In the periods of lessened demand, the company focuses on the preparation for the next season. This involves drawing up new price offers, marketing activity, seeking cooperation opportunities, preparing vehicles for rent and sale, or industry training. The enterprise cooperates mainly with Italian and French partners, currently among the largest recreational vehicles in Europe.

Fig. 2. Average annual gross revenue from the rent of recreational vehicles and the number of rented vehicles in the years 2006-2018

Source: authors' own study

The figure shows the average annual gross revenue from the rent of RVs and the number of vehicles rented in the period from 2006 to 2018. The average annual gross revenue from renting one vehicle is 43,864.08 PLN, which accounts for approximately 5% of the total turnover of the company, including sales and maintenance. In the initial years of operation, the enterprise put more emphasis on rent; thus, it had more vehicles available in the years 2008-2011. The value of revenue from the rent of recreational vehicles led to a change in the corporate strategy and shifting focus to sales.

Research Methodology and Results

Research on the functioning of enterprises related to the car tourism industry is rarely conducted (Cudny, Jolliffe, 2019). The aim of our study was to identify the determinants of the efficient performance of the company under analysis in the specific business conditions (Middleton, 1992).

We assumed that there are specific external factors and features of an enterprise which help it operate in the market efficiently. The findings below concern one company, which stems from the relatively small size of this sector. Our

aim is to identify those elements which can serve as the starting point for further study and obtaining more general results.

The SWOT analysis (Gürel E., Tat M., 2017) and Porter's Five Forces Framework (Grundy, 2006) were used here because of their highly complex character, which allows us to identify both the inetrnal and external factors affecting the company. This made it possible to distinguish the most imporant determinants of the efficient performance of the microenterprise.

In order to obtain necessary information, we interviewed the owner of the company and its employees (SWOT analysis and Porter's five forces analysis) (Middleton, 1992; Prideaux, Carson, 2011). On this basis, we attempted to identify the factors which are key for maintaining the competitiveness of a caravanning enterprise (see: Lee, 2020). Due to the key role of marketing in the functioning of the company, we asked its customers to fill in a questionnaire.

As a consequence the results of our analysis of the functioning of the microenterprise and its competitive environment were additionally verified by a survey carried out among its customers. It was done online and its findings were summed up at the end of 2019.

SWOT analysis of the functioning of an enterprise

What has been the prevailing external factor in the last few months is the Covid-19 pandemic, the influence of which has two aspects. As a consequence of isolation introduced in order to prevent the spread of the disease, many people's wages have been reduced, which may be temporary or may pose a problem connected with the loss of job. At the same time, the fear of becoming infected makes Poles less willing to travel abroad, even despite the loosening of restrictions and opening borders. Poles have shifted their attention to home holiday destinations. They also seek a solution which would allow them to stay isolated from other people and spend their free time relatively freely and comfortably. A camping trailer or a campervan are often the result of their search.

From the long-term perspective, the increasing wealth of the society plays a role. Year by year, the company under analysis improves its financial performance, especially in two fields of activity: the sales and rent of recreational vehicles. The growing interest of potential customers, manifested by the number of e-mails asking for an offer and the rising number of visitors at industry fairs, may reflect the improvement of their financial condition.

The brands that the company under study cooperates with have been present in the market since the 1960s. The strong tradition and experience of car manufacturers, who constantly improve their vehicles and extend maintenance offer, make the potential customer trustful and loyal to them. Regular cooperation helps to retain customers – people interested in using recreational vehicles – by offering cars of well-known makes to them. In turn, selling vehicles made by the same manufacturers boosts their sales. Thus, the relation between RV manufacturers and salesmen is very strong.

What is an opportunity for the development of the caravanning industry is the extension of the infrastructure of national expressways, which enable customers to access the company swiftly and move easily in campervans. Expressways ensure fast and comfortable connections within the whole country. Moreover, the location of the microenterprise in the vicinity of the motorway is another asset as it is a starting point for trips to Western Europe countries, which have been the most popular tourist destinations so far.

As exchange rates tend to fluctuate these days, changes in the Euro to PLN rate are a factor that impedes the further development of the company. All vehicles it buys come from French or Italian manufacturers, who use Euro as the basic currency. Even the slightest change of the rate automatically increases the car's value in zlotys, which discourages customers from purchasing vehicles.

Banks' decisions, especially those concerning loans, may affect the condition of a company. The development of an enterprise requires financial outlays. Difficulties in obtaining bank loans or adverse interest rate movements pose a direct threat to the company, which purchases new vehicles every year. Customers are also dependent on banks because, without sufficient credit rating, they will not buy a car, which, consequently, reduces the company's revenue.

Another industry-specific threat is the possibility that cars with the engine capacity of more than two litres will cease to be produced. Campervans with such engines are mainly manufactured for the Polish market. Poles' interest in 2.0l engines stems from the significantly lower excise duty. If the production of such vehicles was reduced, a given manufacturer would probably sell a lot fewer of them, which would make cooperation with the Polish sales office unprofitable and could lead to the termination of the contract.

Problems with the fulfilment of customers' individual requirements and long delivery time may discourage people from purchasing a new recreational vehicle. Cars have fixed specifications and the choice is limited to what is

offered in the catalogue. If a customer has any individual needs that cannot be met, they will seek models that would suit them better at the dealers of other brands.

Delivery time may be as long as six months. This is due to a number of reasons, usually on the manufacturer's part. The production capacity is one of them. The production of a recreational vehicle is not a fully automated process and is additionally dependent on the fulfilment of orders from subcontractors (e.g. chassis, heaters, fridges). What is more, all car models offered by the company under analysis are made in Italy, where there is a three-month shutdown of production in the summer period. As a result, customers may not wish to wait so long for a new car and often decide to buy a second-hand vehicle.

What is a significant advantage of the company is its location in a place well visible and easily accessible from the main road leading from a big city, in the vicinity of the motorway. Customers are also attracted by an interesting design of the building. Visitors often come with a view to learning more about the caravanning industry and its products, but, in the end, they often rent or buy a recreational vehicle.

As the company has operated in the Polish market for a long time – more than ten years – its employees have a lot of experience in customer service. On a regular basis, they participate in different training courses concerning both technical areas connected with caravanning vehicles and fields such as customer care and corporate management.

Customer loyalty is also increased by the complexity of services offered: the rent, sales and maintenance of vehicles. A potential customer, who is not yet convinced of the caravanning industry products, usually starts from renting a vehicle. Having experienced this form of spending leisure time, customers seek to purchase their own, customized vehicle. After the purchase, they can also rely on the company to service their car. Customers' individual expectations can be met to a certain extent thanks to cooperation with a few suppliers, who deliver diverse cars in terms of size, finish and accessories. Manufacturers offer a wide range of models and specifications. The above factors make the company highly rated by customers, who return every year to rent or service a vehicle and encourage other people to visit the company, too.

What some customers may find a problem is the fact that the company does not deliver vehicles to their door. This is difficult for logistics reasons and because the company cannot afford to delegate workers to this task. In high season, in the period of customers' increased interest in renting vehicles, the headquarters must be fully staffed.

Another barrier to the rent of a vehicle is the amount of deposit claimed. It is necessary, however, because it is the only guarantee for the company in case of damage caused by a customer. This does not obviously refer to collisions or road accidents, which are covered by an insurance policy.

The company has also decided to introduce a daily mileage limit for short-term rents. This was the implication of numerous rents in which the daily mileage highly exceeded the average, which significantly affected the appreciation of a vehicle. For those customers who are more interested in travelling by a campervan than in leisure, this may be the factor that will turn them to other renting companies.

Vehicle appreciation is also affected by its use in winter season. The company has to provide additional accessories then: winter tyres, extra isolation of containers to prevent water from freezing, etc. These costs and risks related to worse road conditions made winter rents unprofitable and the company gave them up.

Prospective buyers often pay attention to the insufficient number of demonstration cars. Manufacturers' offer is very wide and the middleman is not able to ensure that each model will be on display on site. Consequently, a person seeking a car to buy has to rely on catalogue visualizations and similar vehicle models of the same manufacturer that are available in the company.

The company owners also decided not to hold cars on consignment. Their experience and preliminary calculations showed that this type of activity is not profitable. The condition of cars left on consignment is often far below the standards accepted by buyers and they are more difficult to sell that new vehicles.

The analysis of the competitive environment based on Porter's Five Forces Framework

Depending on the examined field of activity, competition for the company under analysis differs. There are relatively fewer companies offering recreational vehicles for sale than those which deal with rent or sell used cars. It requires a lot more capital and effort to become the dealer of new cars as it involves establishing relations with manufacturers and signing contracts with them. The same applies to opening car service points, for which the manufacturer's authorization is needed. As a result, there are not many rivals in the new recreational vehicles market, but their competition is quite tough as customers are more interested in second-hand cars. This is mainly due to their lower price.

There is a lot bigger competition in the sector of car rent, with a number of microenterprises and large companies dealing with hiring caravanning vehicles. Actually, it is enough to be the owner of just one car and offer it for rent

when one does not need it and, thus, become a competitor in the market. Large-scale competition, however, requires investing more capital, which is seen as a barrier to entry for new entities.

The need for raising large initial capital and low profit are obstacles to purchasing the sufficient number of cars for rent and demonstration to meet the expectations of prospective buyers. Another expense is the purchase or lease of location. The premises have to be large enough to accommodate an office, a place for campervans, a car service hall and free space for moving vehicles easily. What is more, a company and its brand have to be promoted. This involves launching a website, search engine positioning, placing information banners, permanent social media administration, radio and press advertising, as well as hiring and training the sufficient number of employees.

What may be another barrier to entry, which reduces a threat of competition in the sector, is the limited access to RV manufacturers. Some of them have already signed exclusive contracts with brokers in Poland, which decreases chances of establishing new cooperation. Moreover, car makers demand the specific organization and design of the company headquarters to represent the products of their prestigious brand in a proper way. New entrants lack sufficient knowledge of the sector, which is usually acquired through learning and gaining experience. This usually concerns the regulations in Poland, the technical solutions applied, logistics skills and broadly defined "know-how".

Depending on the expectations of campervan users, different substitutes can be distinguished. When it comes to the freedom of travelling and the possibility of sleeping in any chosen place, it is a towed trailer that can be considered a substitute product. After reaching a specific destination, it is almost as comfortable to use as a campervan or a motorhome. The main difference is that it is a bit more complicated to drive a car with a trailer. It is an obvious disadvantage, but, on the other hand, one can park a caravan and then go sightseeing by car. Sleeping in tents also guarantees relative freedom as one can put them up at camping grounds and wild campsites. Comfort is significantly lower, though. If a campervan user only wants to reach a given destination and spend some time there, it will probably be cheaper and more comfortable to rent a cottage or a holiday apartment. In such a case, the trip will also be shorter as passenger cars move faster than caravanning vehicles.

It should be noted, however, that those who took to travelling by RV rarely give it up. If they have bought a campervan, they somehow want to compensate for the high cost of purchase and use the car intensively. Another kind of barrier would be cheap airline flights, which allow people travel freely. On the other hand, they have become less accessible due to the risk caused by Covid-19. A campervan or a caravan seem the safest way of spending holiday nowadays.

What is the strongest bargaining power of suppliers is the arbitrary mark-up on a vehicle, where the buyer has little influence on its amount. Discounts are only available to those entrepreneurs who order a large number of cars. Unfortunately, the caravanning industry in Poland is at the developing stage, so it is highly unlikely for any company to purchase cars in bulk. An enterprise would have to invest a lot without any guarantee that it would resell all cars, thus, risking insolvency. Manufacturers have an advantage of choosing the company that will represent them in a given region. It is first of all the market position of a car seller that is taken into account, with special consideration given to the guarantee of car sale. There are relatively few RV producers, especially as compared to buyers, including intermediaries and end consumers. This makes them feel safe and lets them dictate price conditions.

Buyers do have some influence on the type of vehicles manufactured. In Poland, campervans with 2.0l engines account for a large share of the market. This is due to a lot lower excise duty (by 15.5%), which constitutes 3.1% of the car's market value based on Eurotax system. If cars with such engine capacity ceased to be produced, the contract with the manufacturer could be terminated.

Porter's Five Forces Analysis we conducted shows that access to the sector is hindered mainly by necessary financial resources and by the knowledge and experience of incumbent businesses in the market. Substitute competition has some influence on the attractiveness of the caravanning industry, but it is hardly likely that recreational vehicles will be supplanted. RV manufacturers cooperate closely with representatives in individual countries. They do not deal with the direct sales of cars to customers, but do it through dealers. The lack of mutual cooperation between producers and buyers would lead to the fall of sales. There is tough competition between companies in Poland because not many customers have been interested in buying or renting a campervan so far. Moreover, there are only a few enterprises offering new RVs for sale because the demand for them has only begun to rise. That is why more attention is paid to customer satisfaction and efficient marketing activity.

Customers' feedback on the microenterprise's activity

74 respondents were asked to indicate the source of information about the company (press, social media, radio, website, motor show, personal recommendation), state whether they were satisfied with the service received and what factors determined their satisfaction or dissatisfaction. The vast majority of the survey participants found out

about the company from their acquaintances (43%) or at a motor show (26%). Most of them (66 people – 89%) expressed their satisfaction with the service, with only eight (11%) people dissatisfied.

Fig. 3. Factors influencing rental car satisfaction

Source: authors' own study

Depending on whether they had expressed satisfaction or dissatisfaction with the services of the company, the respondents were directed to the next question in which they were asked to tick the three most important elements (out of ten) which had influenced their opinion. The results were presented in the diagrams. The most common reasons for customer satisfaction included the high quality of customer service (19.6%) and of the vehicle (16.5%), trust in the company (14.4%), the possibility of leaving their private car free of charge for the rental period (12.9%) and additional accessories in a campervan (11.9%). Much less frequently did they indicate discounts at partner camping sites in Europe (6.7%), extra insurance package included in the rental price (6.2%), the wide selection of vehicles for rent (5.2%), promotions for customers (4.1%), and the rental price (2.6%).

Fig. 4. Factors influencing rental car dissatisfaction

Source: authors' own study

The main factors influencing customers' dissatisfaction included the insufficient range of vehicles for rent (29.2%), too high rental price (25%), mileage limit for short-term rent (16.7%) and too high deposit (12.5%). The least frequently given reasons were the lack of possibility of delivering a car to the place indicated by the customer and short opening hours (both answers – 8.3%).

In the end, the survey participants were asked whether they would be willing to use the company's services again. The results correspond to the findings of the car rental satisfaction study. The overwhelming majority of the respondents expressed their willingness to rent the car from the company again (66 people – 89%), while only eight people (11%) gave the opposite answer.

Factors influencing the efficient performance of a caravanning microenterprise in Poland

Following our analysis, we identified the factors which significantly influence the performance of the company. The aim of the study was to single out those which have the strongest impact. It was done by comparing factors resulting from the SWOT analysis with the conclusions drawn from the analysis of the company based on Porter's Five Forces Framework and the findings of the customer survey.

Tab. 1: The factors influence the performance of the company

SWOT		Porter
Opportunities	A campervan is a safe choice in the context of the ongoing pandemic	Only a towed trailer and a holiday cottage or apartment can be substitutes for a campervan
	Increase of household income in recent years	
	Customers' loyalty to companies offering RVs due to their experience	
	Difficulty in the entry to the market of potential customers because of high financial outlays	Little competition in the area of the sales and maintenance of new cars because of the necessity of authorizing sale and service points by manufacturers
	Little competition in the local market as far as sales and service are concerned	Limited access of new companies to RV manufacturers
	Development of road infrastructure	
Threats	Covid-19 related travel restrictions	Limitations concerning the use of budget airlines to travel abroad
	Decrease of household income due to isolation during the pandemic	
	Exchange rate fluctuations	Manufacturers' mark-up on cars without a chance to negotiate
	Dependence on banks and their credit decisions	Difficulties in ensuring the sufficient number of demonstration cars and exhibition space for the owner, and in promoting the company
	Little possibility of customers' contribution to the specification of the car in production	The range of new vehicles offered includes models available in the European market without the possibility of introducing any changes to their specification
	Long waiting time for the delivery of the car ordered	
	Cessation of the production of vehicles with 2.0 l engine capacity	Potential loss of interest in new vehicles caused by the withdrawal of 2.0 l engines because of high excise duty
SWOT		**Questionnaire survey**
Strengths	Convenient location of a company	Free guarded car park for the private cars of customers who rent vehicles
	Long experience in running an enterprise	Extra car accessories to suit customers' expectations
	Cooperation with a few manufacturers	
	Comprehensive range of services – rent, sales and maintenance	High quality of recreational vehicles offered
	High customer rating	Trust in the company
	Systematic development of a company and its employees	High quality of customer service
Weaknesses	No possibility of holding cars on consignment	
	No possibility of delivering the vehicle to the customer	
	Insufficient number of demonstration cars	Limited choice of vehicles both as regards rented and demonstration cars
	High deposit	Too high deposit
	Mileage limit for short-term rent	Mileage limit for short-term rent
	Rent offered from spring to autumn, without the winter season	

Source: authors' own study

The above table shows that both the incumbent business and potential entrants to the market do not pose a great threat. This is due to the fact that manufacturers have signed exclusive contracts with representatives in Poland and that significant amount of capital is required to start and develop a business. The reason for which prospective customers may lose interest in recreational vehicles is that they are difficult to customize and that there is a limited choice of cars, mileage limit for short-term rents and a high deposit. Demand may also fall if RV manufacturers cease to produce cars with 2.0l engines because this would entail an increase in the price, which is already high enough to position campervans and motorhomes in the category of luxury vehicles.

The time for summing up the findings of our study coincided with the Covid-19 pandemic and school holiday. It showed how much popularity the option of spending leisure time in relatively safe conditions enjoyed – people appreciate the fact that only members of the same group of holidaymakers have access to sanitary facilities and the so-called shared space. Most RV rentals fully booked all their cars for the holiday period weeks ago. Thus, the pandemic opened a great opportunity for this market, particularly with limits imposed on budget flights to popular destinations.

The examined enterprise has gained a competitive advantage owing to customers' trust based on its constant attention paid to the high quality of services offered. Not only are the vehicles well-maintained and additionally equipped to suit customers' current expectations, but also the employees regularly improve qualifications to serve them better. People renting campervans are offered the possibility of leaving their private cars on a guarded car park for the rent period. This solution makes up for the lack of delivery option. The above factors have an impact on

positive customer rating. Customers express their satisfaction and declare willingness to use the company's services again.

The study of a single micro-enterprise does not allow for drawing general conclusions, however, it points to specific factors that require analysis on a larger group of caravanning companies. The final results of our analyses show that the information given by the company management is consistent with what its customers say. This allows us to view the obtained results as a well-established set of factors that enable achieving efficiency perceived by the company's owners and employees. These factors should thus be considered the proper set on which to base the further study of the efficiency of companies in the sector of sale and rent of recreational vehicles.

Market Volatility and Asset Pricing in The Conventional And Downside Risk Frameworks

Leslaw Markowski

University of Warmia and Mazury in Olsztyn, Poland

E-mail: leszekm@uwm.edu.pl

Abstract

The purpose of this paper is to investigate risk-return relationships for assets quoted on the Polish capital market. Besides unconditional relations, the study proposes the conditional relationships, considering different market volatility regimes and different market condition. The unconditional relations and conditional relations on market volatility are estimated in the downside risk approach as well. The unconditional cross-sectional regressions demonstrate that the downside beta outperform the classical one in asset pricing. While the market condition is incorporated as the conditioning variable the asset pricing is insignificant and independent on market volatility in conventional risk approach. When the downside systematic risk was arranged the positive and significant risk premiums were observed in two volatility regimes under third quartile threshold. The CAPM holds when models are tested based on both in high and low market volatility and market condition. Beta coefficients generate positive premiums in the up market and high and low volatility periods and negative premiums in the down market and high and low volatility periods.

Keywords: CAPM, downside risk, market volatility, conditional relations

Introduction

Rational decisions of investors allow achieving the equilibrium of the capital market, presented in the theory of finance in the form of the Capital Asset Pricing Model (CAPM). According to it, the adjustment of prices, and thus rates of return to the level of market balance, results from the linear relation of the expected return on assets to the level of systematic risk, expressed as beta (Sharpe, 1964; Lintner, 1965; Mossin, 1966). CAPM is widely used to determine, among others cost of capital, therefore, verification of this model on a given capital market is a desirable task. Many studies on capital markets indicate CAPM as proper to determine the price of financial instruments (Chan et al, 1991; Hawawini, 1991). Others studies, however, show discrepancy of the capital assets pricing with its postulates (Östermark, 1991; Cheung and Wong, 1992) or propose extended version of the model with risk factors, such as: company size, price-to-profit ratio or book value per share (Banz, 1981; Fama and French, 1992; Dimson and Musavian, 1999).

It is worth noting that the previous research assumed that risk-return relationship is independent of market conditions or market volatility and moreover beta coefficient is the only relevant systematic risk measure that investors should consider in decisions making. This statement enables other approaches to CAPM testing. In this paper some research theses are formulated. Firstly, the downside beta coefficient is appropriate measure of assets' risk on the Polish capital market. Secondly, conventional CAPM is plausible in different market volatility periods and thirdly the model describes inverse risk-return relations in the bear market periods.

Given the fact that only the pricing of assets in the light of the CAPM can be tested however, it should be noted that the verification of the risk-return relationship in the context of that model is associated with a number of assumptions regarding this model. Is it possible to verify the CAPM when the market portfolio is not exactly known. Another problem is the Error In Variables phenomenon. Certainly, the solution to avoid the deviations caused by this phenomenon would be to use equity portfolios. The single-stock biases in risk measures estimates would cancel out by portfolios constructions. However, Markowski (2020) indicated that estimates both for individual assets and portfolios do not differ significantly in terms of sign and value of risk premium.

The main objective of this study is to investigate risk-return relationships for assets quoted on the Polish capital market. Besides unconditional relations, the study proposes the conditional relationships, considering different market

volatility regimes and different market condition. The unconditional relations and conditional relations on market volatility are estimated in the downside risk approach as well.

This study is organized as follows: Section 2 shortly reviews the literature on testing of CAPM. Section 3 describes the methodology with hypotheses of conditional and unconditional cross-sectional regression. Section 4 introduces a dataset and research findings and discussion is on Section 5. The last section offers conclusion.

Literature Review

Many past CAPM tests based on conventional beta coefficient poorly explained returns of assets. The reason for criticism may be a different understanding of risk. Rational investors differently perceive deviations below and above the threshold, e.g. risk-free rate. Deviations above the accepted rate are treated as a profit, but below that rate as a potential loss. Under this approach, we have a new concept of risk called downside risk. Numerous studies in developed capital markets provide convincing findings for downside risk measures (Ang et al, 2006; Post and Vliet, 2006). Furthermore, the downside asset pricing models achieve higher level of explanatory power of returns than conventional CAPM (Chen et al, 2009). Tsai et al (2014) demonstrate that downside betas outperform classical ones in explaining volatility of expected returns of assets. In the emerging markets, Estrada (2002; 2007) and Momcilovic et al (2017) proposed new measures of the downside risk and showed that investors are rewarded with a market premium for these measures.

One of the key issues that decided to reject CAPM was the proper use of realized returns. While in up market periods the theory of asset pricing is valid but in down market periods assets with high beta reach much lower returns than assets with low beta (Kurach, 2013). This suggests the use of conditional risk-return regressions in contrast to the unconditional procedure proposed by Fama and MacBeth (1973). Pettengill, Sundaram and Mathur (1995) prove that relations between the realized rates of return and the beta coefficients are positively correlated with the sign of the difference between the realized market return and the risk-free rate. Isakov (1999) based on assets listed on the Swiss stock market found a statistically significant positive (negative) relationship between betas and realized returns in the up and down markets, respectively. The approach of conditional relationships is also supported in many studies which illuminate often pessimistic conclusions regarding the CAPM tests (Kim and Zumwald, 1979; Jagannathan and Wang, 1996; Tang and Shum, 2003; Bilgin and Basti, 2014; Markowski, 2019).

The third crucial aspect closely related to the topic of the work is whether changes in market movement has an impact on risk-return relationships. In the other words an important aspect of cross-sectional regressions is to examine the impact of market volatility on the market risk premiums, especially for high frequency data. Galagedera and Faff (2005) defining conditional market volatility by ARCH-type models, found that the beta risk premium under three market volatility regimes is priced but only when market conditions are applied contemporaneously. Nurjannah et al (2012) confirmed previous research and provided further insights in conditional beta-return relation giving an evidence from Indonesian stock market. Abdymomunov and Morley (2011) using Markov-switching process found time variation in betas across volatility and rejected the unconditional CAPM.

Methodology

Unconditional Relationships of Conventional and Downside Risk Pricing

The conditional and unconditional relationships is fulfilled in two-stage procedure. In the first stage, based on an estimation period the systematic risk measures were approximated. In the second stage, in cross-sectional regression the realized excess returns of securities were determined by risk measures of these securities estimated in the first stage of the procedure.

The conventional beta coefficients of individual securities were estimated as follows:

$$R_{it} = \alpha_i + \beta_i R_{Mt} + \xi_{it} \quad (t = 1, \dots, T_e;\ i = 1, \dots, N) \tag{1}$$

where R_{it}, R_{Mt} – rates of return for the *i*-th security and the rate of return of the market portfolio, respectively; α_i – constant term; β_i – beta coefficient of *i*-th security; ξ_{it} – random error term of *i*-th equation; T_e – length of estimation period; N – number of assets in sample.

In addition to estimate from Equation (1) only one value of the beta coefficient (constant beta), the moving regression with rolling window was applicated to determine rolling beta for each testing period.

The verification of pricing relationships in the downside framework is based on the data generating process given as:

$$R_{it} = \alpha_i^d + \beta_i^d \min(R_{Mt}, 0) + \xi_{it} \quad (t = 1, \dots, T_e;\ i = 1, \dots, N) \tag{2}$$

where α_i^d – constant term; β_i^d – downside beta coefficient of *i*-th security. This equation examines the sensitivity of securities' returns to negative returns of market portfolio. The slope coefficient in Equation (2) can be taken as a measure of downside risk due to the fact that

$$\beta_i^d = \beta_i^{BL} - \alpha_i^d E(\min(R_{Mt}, 0))/E(\min(R_{Mt}, 0))^2 \tag{3}$$

where β_i^{BL} is the special case of downside beta coefficient of Bawa and Lindenberg with zero return as the threshold and is given as follows:

$$\beta_i^{BL}(\tau = 0) = \frac{E(R_{it},\ \min(R_{Mt}, 0))}{E(\min(R_{Mt}, 0))^2}. \tag{4}$$

Therefore β_i^d can be used in this research to study the risk-return relationships in the downside approach.

The beta coefficients obtained in Equations (1-2) were used to estimated market risk premiums from unconditional relations in testing period. The cross-sectional models for each observation t from testing period ($t = T_e + 1, \dots, T$) are as follows:

$$R_{it} - R_{ft} = \lambda_{0t} + \lambda_{1t}\hat{\beta}_i + \eta_{it} \quad (i = 1, \dots, N) \tag{5}$$

$$R_{it} - R_{ft} = \lambda_{0t} + \lambda_{1t}\hat{\beta}_i^d + \eta_{it} \quad (i = 1, \dots, N) \tag{6}$$

where R_{ft} denotes risk-free rate; $\lambda_{0t}, \lambda_{1t}$ – parameters of t-th equation; η_{it} – random error term of t-th equation; T – the whole period length.

The relationships (5-6) implicate the testable hypotheses regarding asset pricing theory. The average values of parameter λ_1 should correspond to the market risk premium for conventional and downside risk and these premiums are expected to be positive. The relevant statistical hypotheses are as follows:

$$H_0: E(\lambda_1) = 0 \qquad H_1: E(\lambda_1) > 0\,. \tag{7}$$

In addition, since the asset uncorrelated with the market portfolio has the expected rate of return equal to the risk-free rate, the average value of parameter λ_0 should be statistically insignificant which means that:

$$H_0: E(\lambda_0) = 0 \qquad H_1: E(\lambda_0) \neq 0\,. \tag{8}$$

The hypotheses in (7-8) were tested using *t* test for average value with a one-sided or two-sided critical area.

Conditional on Market Volatility Relationships of Risk Pricing

Conditional pricing relationships involve separate testing of individual versions of this model in the situation of high and low conditional market volatility regimes. Conditional, due to the market volatility, the standard testing equations are given as follows:

$$R_{it} - R_{ft} = \nu\lambda_{0t}^H + (1-\nu)\lambda_{0t}^L + \nu\lambda_{1t}^H\hat{\beta}_i + (1-\nu)\lambda_{1t}^L\hat{\beta}_i + \eta_{it} \tag{9}$$

$$R_{it} - R_{ft} = \nu\lambda_{0t}^H + (1-\nu)\lambda_{0t}^L + \nu\lambda_{1t}^H\hat{\beta}_i^d + (1-\nu)\lambda_{1t}^L\hat{\beta}_i^d + \eta_{it} \tag{10}$$

where ν is a dichotomous variable used to determine the observation day with high market volatility ($\nu = 1$ if $\sigma_t^2 > \sigma_{0.5}^2$ or $\sigma_t^2 > \sigma_{0.75}^2$) and the observation day with low market volatility ($\nu = 0$) in otherwise, where σ_t^2 is the conditional variance of market returns and $\sigma_{0.5}^2, \sigma_{0.75}^2$ are the median and the third quartile of conditional market series; $\lambda_{0t,}^H \lambda_{0t}^L, \lambda_{1t}^H, \lambda_{1t}^L$ – parameters of t-th equation; η_{it}– random error term of t-th equation.

Hypotheses regarding parameters λ_{1t}^H and λ_{1t}^L are the same as the hypotheses written for unconditional relationships in (7-8). Rejection of null hypotheses in both cases (high and low market volatility) indicate the occurrence of systematic, conditional relations between the risk measures and realized rates of returns.

Finally, the conditional relationships based on market volatility and market condition were estimated during the testing period in each observation interval as follows:

$$R_{it} - R_{ft} = \nu\delta\lambda_{0t}^{HU} + (1-\nu)\delta\lambda_{0t}^{LU} + \nu(1-\delta)\lambda_{0t}^{HD} + (1-\nu)(1-\delta)\lambda_{0t}^{LD} +$$

$$\nu\delta\lambda_{1t}^{HU}\hat{\beta}_i + (1-\nu)\delta\lambda_{1t}^{LU}\hat{\beta}_i + \nu(1-\delta)\lambda_{1t}^{HD}\hat{\beta}_i + (1-\nu)(1-\delta)\lambda_{1t}^{LD}\hat{\beta}_i + \eta_{it} \quad (11)$$

where δ is a dichotomous variable used to determine the positive and negative market excess return, then $\delta = 1$ if $R_{Mt} - R_{ft} > 0$ (up market) and $\delta = 0$ if $R_{Mt} - R_{ft} < 0$ (down market); $\lambda_{0t,}^{HU} \lambda_{0t}^{LU}, \lambda_{0t}^{HD}, \lambda_{0t}^{LD}, \lambda_{1t}^{HU}, \lambda_{1t}^{LU}, \lambda_{1t}^{HD}, \lambda_{1t}^{LD}$ – parameters of t-th equation; η_{it}– random error term of t-th equation.

Regardless of the market volatility an inverse relationship between the beta coefficient and realized returns should be expected when the market excess return is negative. In periods with positive market excess return this relationship should obviously be positive. This approach for average parameters λ_1^U, λ_1^D in the case of beta coefficient and co-kurtosis is result in hypotheses as follows:

$$H_0: E(\lambda_1^{HD}) = 0;\ H_1: E(\lambda_1^{HD}) < 0 \ \text{ and } \ H_0: E(\lambda_1^{LD}) = 0;\ H_1: E(\lambda_1^{LD}) < 0 \quad (12)$$

$$H_0: E(\lambda_1^{HU}) = 0;\ H_1: E(\lambda_1^{HU}) > 0 \ \text{ and } \ H_0: E(\lambda_1^{LU}) = 0;\ H_1: E(\lambda_1^{LU}) > 0\,. \quad (13)$$

Rejection of null hypotheses in both cases indicates the occurrence of systematic relations between beta coefficient and the realized returns of securities.

Data

A dataset includes a full-time series of daily log returns of 16 securities quoted on the Warsaw Stock Exchange and belonging to the index WIG20. The time period is from January 3, 2011 to December 30, 2019 what spans 2244 observations. The WIG index is used as the market portfolio approximation and the proxy for the risk-free rate was the Warsaw Interbank Offer Rate (WIBOR 3M) for a three-month investment. All data were obtained from the EMIS database. According to the adopted methodology, the period sample was divided into two sub-periods. The first of them (2011) was the period of estimation, while the second one (2012-2019) was the period of CAPM testing. The above division does not apply to the use of moving regressions for which the rolling window comprise 252 observations, that is about one year. The number of the observations in individual parts of testing period are presented in Table 1.

Table 1: The number of observations for testing period of conditional CAPM relationships

Market volatility	Market condition	Median	Third Quartile
High volatility	Up market	542	279
	Down market	454	219
Low volatility	Up market	491	754
	Down market	505	740

Source: own study.

For modelling conditional volatility of WIG returns was used GARCH(1, 1) process with mean equation $R_{Mt} = \mu + \varepsilon_t$ and conditional variance equation $\sigma_t^2 = \alpha_0 + \alpha_1 \varepsilon_{t-1}^2 + \alpha_2 \sigma_{t-1}^2$. The estimates were: $\mu = 0.000220$, $\alpha_0 = 0.000003$, $\alpha_1 = 0.045088$, $\alpha_2 = 0.919455$ and statistically significant at the 1 per cent level. Based on the value of conditional variance and its median and third quartile, observations with low and high market volatility were distinguished. The up and down market condition are an observation with positive $(R_{Mt} - R_{ft}) > 0$ and negative $(R_{Mt} - R_{ft}) < 0$ market excess returns.

Results and Discussion

In the first step, unconditional risk-return relations in both conventional and downside risk are discussed (Tab. 2-3). Estimates of models (5-6) reveal that there are statistically significant positive relations at the 5 per cent level between systematic risk and returns only in the downside framework and using constant beta approach. Downside risk results refer to the study of Ang et al (2006) and Lee et al (2008). The contradiction between these results and CAPM theory arise from overlapping risk premiums estimated in periods with positive and negative market excess returns. These results are partly consistent with Nurjannah et al (2012) where the significance of the premium for both types of risk were not confirmed.

The support for downside risk was obtained using average returns of portfolios based on six companies with the highest and lowest conventional and downside beta coefficients. Mean returns for sorted securities are presented in Fig. 1 and the Table 4 shows results for composed portfolios.

Fig. 1: Average returns of securities sorted by beta and downside beta coefficient

Source: own study.

Table 4: Return and risk level in the conventional and downside framework

Risk level	Securities	Average beta	Average return
Securities sorted by conventional beta			
Low risk	Orange Polska, Cyfrowy Polsat, CCC, PGNiG, LPP, Tauron Polska Energia	0.911	0.000088
High risk	Grupa Lotos, Bank Pekao, PKN Orlen, PKO BP, mBank, KGHM	1.293	0.000188
Spread		0.382	0.000100
Average return per unit of risk		0.00026	
Securities sorted by downside beta			
Low risk	Orange Polska, Cyfrowy Polsat, CCC, PGNiG, PZU, Tauron Polska Energia	1.239	-0.000014
High risk	CD Projekt, Grupa Lotos, PKO BP, mBank, PKN Orlen, KGHM	1.764	0.000549
Spread		0.525	0.000563
Average return per unit of risk		0.00107	

Source: own study.

Using the downside beta, the composition of high and low risk portfolios changes and differ from one asset. As a result, the difference in spread of risk is relatively lower than the difference in return. In the consequence the return per unit of downside risk (0.00107) is several times higher than the ratio for conventional beta coefficient (0.00026) and thus portfolio based on downside risk is more effective than portfolio based on conventional risk.

The conditional cross-sectional regressions are further continuation of the research where the market movement as measured of conditional volatility were considered. The estimates of risk premiums in high and low market volatility regime (median and third quartile thresholds) are presented in Tables 5-6. The premiums for CAPM beta risk are positive and statistically significant but only for periods with high volatility determined by third quartile. Therefore, the results cannot support the relationship between conventional systematic risk and realised returns conditional on market volatility. For downside risk the results are more convincing. The premium associated with downside risk is statistically

significantly different from zero (at the level of 10%) both two market volatility of third quartile regime and under assumption of using of constant beta. The obtained results are partly consistent with estimates of conditional relationships with respect to the market volatility in Indonesian Stock Exchange (Nurjannah et al., 2012).

Source: own study

The final part of the analyses were cross-sectional regressions considering both market volatility and market condition according to the relation (11). These analyses provide important practical implication on the relationship between the realised returns and the CAPM beta and they are presented in Table 7. The beta risk premiums are statistically significant at the 1 per cent level. In the high and low volatility regimes, these premiums are positive (negative) in the up (down) market, that is, what was expected. It should be noted that the absolute values of the market risk premium based on rolling betas were higher than the premiums estimated in constant beta approach.

Fig. 2: Average returns of securities sorted by beta coefficient in different volatility regimes and other market conditions

Source: own study.

Empirical correspondence of the results with capital asset pricing model in the context of expected values is presented in Fig. 2. The study finds the positive relationship between beta coefficients and expected rates of return in periods of positive market excess return and negative relation in periods of negative market excess return, under the two volatility thresholds. The results give the strong evidence that the higher the beta values, the higher the absolute average returns. This means that on the Polish capital market the market risk is dependent on the market volatility and market condition.

Conclusion

The paper presents research verifying the pricing of the biggest securities listed on the Warsaw Stock Exchange in the context of the CAPM model. In this study, the unconditional risk-return relationships were estimated using classical and downside measures and conditional relations not only in terms of market volatility and additionally, the market condition.

This research provided some important findings. The unconditional relations reveal that the downside beta is a more appropriate risk measure than their classical counterpart. The downside risk premiums in using constant beta approaches are significantly positive which means, that the downside risk is priced in Polish stock market. The conditional cross-sectional regressions demonstrate that the asset pricing is insignificant and independent on market volatility in conventional risk approach. When the downside systematic risk was arranged the positive and significant risk premiums were observed in two volatility regimes under third quartile threshold. While the market condition is incorporated as the conditioning variable the beta factor acquire significance. Beta coefficients generate positive premiums in the up market and high and low volatility periods and negative premiums in the down market and high and low volatility periods.

Conditional relationships confirmed the validity of assets pricing in accordance with the CAPM postulates, which was often rejected in many tests of this theory. The study proves that the measures of systematic risk such as the beta coefficient in conventional and downside approach are appropriate risk factors of asset pricing. Additionally, the pricing model is much more sensitive to market condition than market volatility.

Endnotes

The Bawa and Lindenberg (1977) coefficient based on the lower partial moments (Rutkowska-Ziarko et al, 2019) assume risk-free rate as the threshold: $\beta_i^{BL}(\tau = R_f) = \frac{E[(R_{it}-(R_f))\min(R_{Mt}-(R_f);0)]}{E[\min(R_{Mt}-(R_f);0)]^2}$. Other downside beta coefficient with the mean return as the threshold was proposed by Harlow and Rao (1989) and it is given by: $\beta_i^{HR} = \frac{E[(R_{it}-E(R_i))\min(R_{Mt}-E(R_M);0)]}{E[\min(R_{Mt}-E(R_M);0)]^2}$.

Abstract

The article is an attempt to answer the question about the correctness of the organisational structure. The dominant literature view on structural solution correctness is based on the situational approach, standing that the structure is appropriate when it is adjusted to both external and internal circumstances. In the article, the shortcomings of situational appropriateness of the structure are discussed: the adjustment of the structure and context to each other is considered statically, conflicting demands on the shaping of different features of the structure and limited rationality of decision makers. Based on principle of the simplicity of the structural solution, the attempt to correctness of the structural solution, taking into account the time factor and – to a greater extent – the realities of management decisions, is developed.

Keywords: Organisational Structure, Simplicity, Management.

Introduction

The organisational structure is an element of every organisation – a fundamental instrument of the management process. This process, in turn, influences the executive process, thus determining the efficiency of functioning and the development of the organisation.

It is assumed that the organisational structure (i.e. a structural solution) is a set of rules organising the behaviours of the organisation members, which are, to some extent, are of a formal nature, i.e. they are introduced officially. Sometimes, however, they arise spontaneously and turn out to be appropriate in everyday work. Such informal rules are as if they were behind the scenes and are an additional source of orientation patterns and expectations that usually correspond to formal rules (Steinmann and Schreyögg, 2001).

The structured organisational rules set out the ways in which members operate, making their activities more predictable. This limits the freedom of action. Moreover, the more rules there are, the more work and management is devoid of the stigma of individuality (Steinmann and Schreyögg, 2001).

Many literature reports assume that the structure is correct or, as the representatives of the situational approach to management science would put it, appropriate when it is adjusted to both external and internal circumstances (Pugh *et al*, 1968; Kieser and Kubicek, 1983; Donaldson, 2006). It means that:

- Such an organisational structure is adapted to the organisation's environment and its other elements, which, according to Leavitt (1965) are people, goals and technology. More specifically, its features are adapted to the characteristics of the environment and the other elements of the organisation that form the context of the structure.

- There is a kind of mapping relationship between the organisational structure and its context at some "t" point. The structure and context are then entirely appropriate for each other since the adjustment value is maximum.

Such an understanding of correctness (appropriateness) is treated as a point of departure for research on organisational structures within the framework of the already mentioned situational approach – one of the main strands of research projects concerning structural solutions. Such undertakings focus on looking for the answers to the question of what factors shape the structure. Scholars working within this strand aim at detecting general regularities of structural solutions as a certain whole or particular dimensions depending on situational conditions (Nalepka and Kozina, 2007).

However, the situational appropriateness of the structure is not free from certain doubts and shortcomings. It pertains to the following points:

- The adjustment of the structure and context to each other is considered statically. However, what we deal with it is the entanglement of structure in time. In any of its states, references can be found not only to the present structure-forming pressures but also to the past because the development of a structural solution is characterised by interactive continuity (Mreła, 1983). Moreover, there are also references to the future when the forecast of its conditions is taken into account when making changes.

- The full (total) appropriateness of the structure is also a theoretical construct, abstracted from reality since its contextual features may place conflicting demands on the shaping of the features of the structure. In such a situation, adapting the structure and context to each other requires the use of simplified models of both sets, which consequently leads to the fact that a given state of context is accompanied not by one state but by a set of permissible structure states.

- Obviously, it is underestimated that it is people – not its context – who shape and modify structural solutions. According to the theory of limited rationality, it is, therefore, unrealistic to demand the optimisation of decisions concerning the function of organising activities.

This calls for a new look at the correctness of the organisational structure, at least partially devoid of the shortcomings that have been signalled. More specifically, it seems necessary to answer the question concerning the correctness of the structural solution, which should take into account the time factor and – to a greater extent – the realities of management decisions. Thus, the purpose of this article is to attempt to answer this question. This attempt is based on the principle of the simplicity of the structural solution, which will be presented in the first part of the study. The second part of this paper is dedicated to the presentation of the concept of the simplification of the structure and its suitability.

The principle of a Simple Organisational Structure

It is assumed that simplicity is "(...) a feature of a complex object being an element, and in the case of a complex object having a (relatively) small number of elements or relations between them which do not differ in terms of their characteristics" (Pszczołowski, 1978, p. 190). Simplicity understood in this way is a relative concept. Thus, what is simple for one person is not necessarily so for another person.

Therefore, if the structure is made up of organisational rules, in a simple solution, there are few of them. The image of the simple solution is quite similar in many literary reports (Table 1) – it is based on the model of a simple structure developed by Mintzberg (1979). The so-called strategic apex (no middle management), with broad decision-making powers, is of crucial importance and the main instrument of coordination is direct supervision. The activities performed are characterised by low specialisation, standardisation and formalisation. Most often, such a solution can be found in small and young organisations operating in a dynamic environment. Over time, it tends to bureaucratise its solutions.

Table 1: simple organisational structure according to some authors

Author(s)	Simple organisational structure
Hopej-Kamińska *et al* (2015, p. 265)	A flat structural solution, characterized by small number of hierarchical levels and a large span of control, low degree of centralization, formalization, specialization and standardization
Pawlak and Smoleń (2008, p. 109)	A small number of positions, organisational units, organisational ties
Robbins and DeCenzo (2002, p. 245)	Low degree of specialisation, formalisation, flattened hierarchy,

	significant centralisation
Sobczak (2006, pp. 277-278)	Low degree of internal differentiation, high degree of centralisation
Zakrzewska-Bielawska (2012, p. 295)	Small number of management levels, low degree of specialisation, variable centralisation

Source: based on the literature reports cited

If one person sets the rules and everyone else has to obey them, there is little room for manoeuvre under these conditions. It is undoubtedly greater when coordinating activities not through direct supervision but through the mechanism of mutual adjustment, consisting of direct arrangements among participants in the organisation during their work. The calculations carried out using the fatal calculus indicate that the structural solution is simpler because along with the decrease in the intensity of direct supervision, simplicity increases and it decreases (complexity increases) when intensity increases (Hopej-Kamińska *et al*, 2015). A simple structure is, therefore, not a centralised solution but a decentralised one, expediting the decision-making processes.

A structure similar to the simple one is the solution that Silbiger (2014) described as amorphous. It gives the members of the organisation a great deal of freedom in decision-making and action, allowing them to establish and terminate organisational relations depending on the current requirements related to their tasks. When Facebook started, it was organised in this way. The opposite is the complex structure, characterised by an extensive and complex hierarchy, a high degree of specialisation, centralisation, formalisation and standardisation. An example is a multi-line, bureaucratic tensor solution.

Simple and complex structural solutions are the extremes of the continuum of organisational structures presented in Figure 1.

Fig. 1: A continuum of organisational structures

Source: the author's own study

Moving it towards the S-point means an increase in simplicity while moving it away from the S-point stands for an increase in the complexity of the structural solution. Some of its symptoms are listed in Table 2.

Table 2: some symptoms of the increased complexity of the organisational structure

Increase in complexity	Symptoms
Increase in the degree of specialisation, centralisation, formalisation and standardisation and the expansion of the organisational hierarchy	• Increase in the inertia, friction and sluggishness of the organisation
	• Generating "noise" in information channels, distorting information
	• Focusing members' attention on irrelevant problems
	• The decreased rationality of decisions taken
	• The decreased motivation for work
	• Monotony, physical and mental fatigue
	• The reduction of members' commitment to common goals
	• Lowered ability to respond to new problems
	• Learned incapability
	• The vicious circle of bureaucracy
	• Many meetings with many people
	• The need for employing specialists and coordinators
	• More discussion than action

Source: based on Hopej and Kandora, 2019.

Thus, one question can be asked: what should the organisational structure be in terms of simplicity? It should be emphasized that although there is a growing amount of research on the relationship between the simplicity of structural solutions and contextual factors, there is still little of it. To paraphrase the words attributed to Einstein

("everything should be made as simple as possible, but no simpler"), one can assume that the structure should be as simple as possible but not simpler. Thus, it should be:

- an element of the set of structural solutions allowed by its context;
- the simplest solution of this set, i.e. located on the continuum closest to the P point (characterised by the least developed hierarchy and the lowest degree of specialisation, centralisation, standardisation and formalisation).

This raises another question: what does the simplicity of the organisational structure depend on? The research carried out on a sample of 100 companies assumed that it depends on 11 factors, distinguished mainly on the basis of the four-element organisation model devised by Leavitt (1965). The research covered business organizations operating in Poland, employing at least 10 people. One survey was filled in by each organization. Higher-level managers or other people who have a broad view of the entire enterprise were the respondents (it was assumed that such a person, in addition to the president and his/her deputy, could be, for instance, an organizational specialist, a business process management specialist, a quality specialist, *etc.*). Due to the purpose of the study, the sample was not representative. First of all, the aim was to obtain numerically similar groups as far as their sizes and significant diversification in terms of their activity type.

The regression analysis performed for particular structural characteristics (the step-by-step regression method was applied) revealed the following phenomena:

- The hierarchy is explained in 47% (adjusted R2=0.473) by four variables (factors), i.e. employment size, income level, the degree of the diversification of activities and the management's desire to simplify the organisation. This means that the hierarchy is, therefore, less developed, the smaller the organisation (due to the number of its members and revenues)is, the less diversified the business activity is and the stronger the management's drive to simplify the organisation.
- The degree of centralisation is explained in 19% (adjusted R2=0.191) by manufacturing technology, employment size, organisational culture and the period of the operation of the enterprise (the more non-routine the technology, the bigger and younger the enterprise and the more open the organisational culture is, the lower the degree of centralisation is).
- The degree of specialisation is explained in 65% (adjusted R2=0.649) by manufacturing technology. Thus, the more non-routine the technology is used, the simpler the structure is in terms of the specialisation of activities.
- The degree of formalisation is explained in 43% (adjusted R2=0.433) by employment size, the organisation's dependence on its environment and the management's desire to simplify the organisation.
- The degree of standardisation is explained in 20% (adjusted R2=0.203) by manufacturing technology and employment size, i.e. the more non-routine the technology and the smaller the organisation, the simpler the organisational structure is in terms of standardisation.

What would, therefore, result from this is that the simplicity of the organisational structure is linked to such factors as the size of the organisation, the manufacturing technology used, the diversification of activities, organisational culture, the involvement of management in simplifying the organisation or its dependence on its environment. However, in the light of the research, no factor is the predictor of all dimensions (characteristics) of the structure (Kaminska-Hopej *et al*, 2015).

Research by Davis *et al* (2009) prove, by means of simulation methods, that it is necessary to adjust between the simplicity of the organizational structure, the organizational strategy and the dynamics of the environment in the context of coping with the tension between flexibility and organizational performance.

In turn, e Cunha and Rego (2010) postulate a match between the simplicity of a structural solution, the complexity of the workforce and the complexity of the environment. Empirical research by Tworek *et al* (2019) confirmed the match between the degree of simplicity of the structure, the complexity of the workforce and the features of the environment, however, only in a complex, dynamic and uncertain environment such a fit led to high organizational results, in other conditions the relationship between this fit and the results was ambiguous.

Simplifying the Organisational Structure

The changing external and internal conditions of organisational structures are the reason why organisations often change them. However, their management receives conflicting signals as to when and how to do it. It also, and perhaps even more importantly, pertains to whether a new structural solution is necessary or whether a modification of the existing one is sufficient.

One of the most interesting answers to this question that has been recently formulated is the concept developed by Girod and Karim (2017). They distinguished two types of reorganisation – restructuring and reconfiguration. Restructuring entails changing the structural archetype of the organisation, i.e. adopting a new type of structural solution while reconfiguration is an evolutionary change, not affecting the foundations of the organisational structure.

Both types of such a change aim to increase the organisation's innovation. The authors referred to above write that "(...) success in this field almost always depends on circumstances. Organisations need to shake up their structures from time to time to get rid of the organisational cholesterol – that is, inertia, cumbersome procedures and arrangements that gradually weaken the pace of growth – to change the strategic direction in the face of a profound transformation of the industry. Besides, in the era of the unsustainable competitive advantage, companies must constantly adapt to market changes through small-scale reconfigurations. The leaders of organisations should not choose between revolution and evolution. They must subject their businesses to both processes in the right way and at the right time" (Girod and Karim, 2017, p. 78).

Due to the tensions and uncertainties that accompany any revolutionary change, Girod and Karim are of the opinion that it is vital to keep subsequent restructurings separate for at least five years because if too many structural solutions are tried out in too short a period, chaos creeps into the organisation. It should also be remembered that after restructuring, a new organisational culture is often necessary. It also refers to new processes and operating systems.

In addition, the right rhythm of reconfiguration needs to be found as too few reconfigurations lead to the risk of not gaining sufficient experience and thus, to making those reconfigurations irrational. At the same time, however, too frequent reconfigurations can cause overload with changes. There is also a danger that they will take the form of a snowball, unintentional restructuring (Girod and Karim, 2017).

However, it should be stressed that the concept of balancing between evolutionary and revolutionary changes in the organisational structure is consistent with the principle of simplicity understood in the following manner:

- all changes involve adapting structural solutions to their external and internal conditions;
- the need to get rid of "the organisational cholesterol" from time to time, manifesting itself as a hindrance to innovative activities, is emphasised;
- the postulate of a proper rhythm of reorganisation is formulated; it manifests itself in the abandonment of the strategy of continuous change.

However, the principle of simplicity may also be the basis for certain complementation of the concept developed by Girod and Karim. It is linked to the following aspects:

- Both restructuring and reconfiguration should result in the most flexible structural solution, which is possible in a given context. However, when making a decision, one may encounter barriers that limit its rationality. Overcoming them requires, above all, that the bureaucracy be treated as an enemy which must be fought absolutely. It is well understood, among others, by J. Welch, who once asked by a college student about what he should do when encountering bureaucracy in a large organisation, advised him to throw a grenade there. He believed that releasing people's potential is inextricably linked to removing harmful bureaucracy by giving people the freedom to decide and act (Krames, 2005).
- Although people can adapt to change and do it better and better, they also need peace and stability to be able to act effectively. Therefore, it seems that limiting the number of structure changes should be as far-reaching as possible. Good surgeons know that if an operation is not necessary, it should not be performed. Managers do the same thing, simplifying their work and lives. They do not want

"everything to be in motion all the time". Instead, they change structural solutions only when they have to do so, after best planning the change and employing the protective measures (Malik, 2015). This point of view is supported by the results obtained by McKinsey's analysts, which show that changes should only be made if there is clear evidence that the current structural solution is inappropriate and if it is not possible to overcome specific inadequacies with less intrusive actions (Fraser and Strickland, 2006).

- The actions to simplify the organisational structure may be carried out not only by the organisation's management but also by other participants, within the limits of their powers. They should, however, be preceded by the process of agreeing on the amendment with all those concerned as well as with those who have some expertise in this field. Naturally, the more important the change, the wider the network of arrangements should be imposed, including, if necessary, the supervisor.

Although the idea of removing the structural burden within self-organisation is not complicated, its implementation is not easy. It can take the form of a permanent routine, based on an appropriate level of the so-called productive organisational energy. It can be mobilised both by communicating the risks associated with complexity and by making people aware of the opportunities associated with simplicity. In each case, it is desirable to evoke the desired emotions and link them to the simplicity (complexity) of the structure so that those emotions can be spontaneously become activated by people when coming in contact with it. The concept of the prevention and removal of the structural burden is discussed in the literature (Hopej and Kandora, 2019).

In the light of the above, the following statement can be formulated: in making (both evolutionary and revolutionary) structural changes which is in line with the principle of simplicity, what seems more important is the very process of simplifying and not describing the solutions adopted in detail. The innovative potential of the organisation members which is inextricably connected with this principle may result in various solutions characterised by the least developed hierarchy in the given conditions and the lowest degree of specialisation, centralisation, formalisation and standardisation.

For this reason, the following question can be posed: what is the correct organisational structure? What follows from the above considerations is that its subsequent states must be adapted to the present and future conditions and, at the same time, they need to have the most far-reaching flexibility under these conditions, giving people the possibility of self-organisation. It should be added that as far as it is possible, evolutionary changes should be characterised by continuity, building an organisational identity as an essential factor of its success (Linke *et al*, 2018).

Generally speaking, a structural solution at any "t" time is correct when it is the result of the process of its simplification, which is consistent with the concept outlined above. Moreover, it should be emphasised that this process ought to be based – so to speak – on dedicated organisational staff who maintain a kind of organisation's civic community (Drucker, 1994). Not only does it promote innovative organisational behaviours but it also lowers management costs. Furthermore, this happens when the correlations between structural and contextual characteristics are not particularly high.

Concluding Remarks

The article has been an attempt to answer the question about the correctness of the organisational structure. More precisely, its purpose was to answer the question concerning what structure is correct. The answer can be formulated in the following way: it is correct when its subsequent states are the result of the rational process of simplifying the organisational rules which constitute it. Above all, it manifests itself in the following areas:

- adopting further structural solutions with the greatest possible flexibility which – at the same time – are the least expensive. On the one hand, they should be adapted to the current and future conditions (i.e. context). On the other hand, however, due to the need to take care of the organisation's identity, they should be continuous;

- making both evolutionary and revolutionary changes, the number of which should be limited to the necessary minimum, because who reorganises all the time for the changes themselves causes chaos and risks chronic disorganisation (Kotarbinski, 1973).

There is also one more point which needs a brief remark. The ability to organise, and thus to create and modify the organisational structure, is (or at least it should be) one of the necessary managerial skills. Next to the ability to stimulate the energy of the organisation members by motivating them, the ability to organise efficiently is

increasingly appreciated. Some scholars go even further and view it as a permanent source of competitive advantage in times of a fleeting environment whose complexity and dynamics are the norm (Nadler and Tushman, 1997; Hopej and Kandora, 2019).

It is essential to underline that the research presented above has some limitations. First of all, the research sample was not representative, the research is therefore rather pilot than conclusive. Secondly, the verification is based only on the sample of organizations operating in Poland. The concept requires further verification in different business contexts. Additionally, there are different factors influencing an the simplicity of organisational structure solution. However, it would be advisable to consider in the future the time as an variable. Further research could attempt to test continuity to see changes in organizational structure together while the sets of conditions are changing. Finally, also the features of decision makers would be incorporated in the model to consider the issue of the optimization of decisions concerning the function of organizing activities.

The Crisis Management but the Civil Protection in Poland

Grzegorz PIETREK

WSB Banking University in Gdansk
Poland, gpietrek@wsb.gda.pl

Abstract

The system of the civil protection in Poland has numerous challenges ahead of it and changes which are necessary. He seems to be essential, in order to execution of tasks associated with the civil protection she was consistent with tasks performed in frames of the act on the crisis management, this way, so that the system of the crisis management harmonized and supplemented taken action in favor of the civil protection. In contingencies they are endangered different values. Mainly for exchange oneself life and human health, possessions in great sizes or also natural environment. The research purpose of the article is to present the essence of crisis management in Poland and the related civil protection issues. On this basis, differences, and similarities in both conceptual and functional layers will be indicated. This will form the basis for conclusions and proposals on the functioning of these security areas in Poland.

In order to achieve the intended research objective, the author in his article first carried out a critical analysis of the literature of the subject, mainly Polish - speaking, since this area concerns the text. The two systems (crisis management and civil protection) were analyzed and compared. Through the use of other research methods, including induction, deduction and synthesis and abstraction, a number of generalizations have been made, allowing for the formulation of final conclusions which synthetically indicate further prospects for system development, integration and evolution.

Keywords: Crisis Management, Civil Protection, Government.

Crisis Management

In the European Union, the emphasis has been laid in a different way. Crisis management is more focused on the political dimension of security than on undertakings which immediately satisfy civilians' needs. Such an approach suggests that the European Union is focused on the limitation of threats, preparation for response and recovery after a particular event to the normal state of affairs. Hence, response has been left to the countries.

"Crisis management" as a term entered the vocabulary for good after the end of the Cold War. This term appeared in place of another, replacing (in many countries) the concept of civil defense, which in its Cold War dimension was exhausted at the end of the twentieth century. For the record, "civil defence" at the end of the Cold War was defined as an undertaking that could significantly reduce the impact of all forms of military action on civilians, including conventional, nuclear, chemical and biological attacks. These projects were generally passive, unrelated to defence activities within the remit of the armed forces.

Considering implementation of humanitarian tasks, civil defence used to perform an important role in civil protection when a threat of the use of mass destruction weapon was real. At that time, considering its basic assumptions, the structures of civil defence were usually located at the ministries of defence. However, in new conditions related to security, it required some changes, because until then civil defence tasks had mainly referred to two or three stages:

- preparation to the global war;
-response to the outbreak of the global war;
-general reconstruction after total destruction (the use of nuclear weapon).

Cite this Article as: Grzegorz PIETREK" The Crisis Management but the Civil Protection in Poland" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Hence, preparations were made with regard to the war, with a possibility to use the structures of civil defence during the time of peace. Considering new conditions, there was a number of notions which required redefinition, a number of better solutions to be found and new concepts to be defined. A new integrated system had to be developed, which was supposed to include all the entities and the whole society.
New solutions mainly considered recognition and elimination of risk factors, risk modeling, prevention of threats and recovery after disasters that would be adjusted to the relevant requirements. Such an approach emphasized the universal character of the systemic solutions, integration of the systems in terms of their capabilities to face any dangers and their civil (non-military) character.

The first specified concept refers to the suggestion presented by FEMA (the Federal Emergency Management Agency) in the USA. The concept presents a closed cycle of crisis activities consisting of four stages:

- mitigation;
- preparedness;
- response;
- recovery.

Each of the stages has been assigned with 12 to 15 undertakings which provide them with the required efficiency. Crisis management has already gone through numerous modifications. In 2007 in the USA, under the supervision of FEMA, a group of specialists and scientists developed general principles which since then have been adapted in various countries. These are namely:

1. universality – it refers to all threats, all stages, all entities responsible (threat addressees) and those exposed to risk;
2. development capabilities – undertaken activities optimise readiness. A society is developed which is resistant to catastrophes and which can face difficult situations;
3. risk – endurance – the use of risk management achievements for the development of priority rankings and for the securing of resources;
4. integrity – making all the levels of authority, all the elements and links of a society concentrate their efforts on the priority aims;
5. cooperation – development and implementation of broad, transparent relations which are based on honesty, including team work performed by individuals, communities, teams and organisations which are based on trust and understanding;
6. coordination – it consists in synchronisation of activities performed by all the threat addressees in order to achieve a common aim;
7. flexibility – it results from creativity and innovativeness in the approach towards solving problems connected with catastrophes;
8. consequence – it results from the rationality of the activities performed in the field of security – there is no room for negligence and abandonment in the field of crisis management;
9. harmony – it consists in the development, implementation and permanent verification of standards and crisis law;
10. professionalism – it refers to the superiority of science and knowledge based on education, training, exercises, practice, ethics, values, efficiency and permanent improvement.

Considering the point of view presented in this article, it should be advisable to notice that during the recent years the perception of crisis management has changed. It has been perceived in systemic categories, that means a pursuit of integration but not of centralisation of various elements, links, micro-systems and sub-systems into one integrated system which shall include all the actors in the field of security. It shall refer to all the levels (government, self-government, non-government), sectors (public, private, cooperative, communal) in all the stages and in the reference to all threats, with the use of all the available resources (civil emergency planning).

Having emerged and strengthened among practitioners and theoreticians, a modern concept of crisis management has also been recognised by international organisations. Let us mention the International Association of Emergency Managers (IAEM) as an example. It is a non-profit organisation which has been established to promote protection of life and property during disasters. Similar great merits in the development of crisis management standards are assigned to the World Bank, which in 2006 established the Global Facility for Disaster Reduction and Recovery (GFDRR). It turned out to be of great significance for the long-term partnership in the field of loss reduction during disasters through the channeling, modification and reduction of disaster risk. Such activities of the World Bank forced rational use of financial means in the field of security, because states and international organisations, who

wanted to acquire funds for the implementation of some undertakings, were forced to follow systemic reinforcement of their crisis readiness through formalisation and legitimisation of the recovery stage.

Also in the European Union some positive tendencies could be observed. However, it was only in 2001 when the Community Mechanism in the field of civil defence was accepted and implemented (a counterpart of crisis management in the EU terminology). It was a significant fact for the unitary character of such activities, because the main aim was to systematise cooperation in civil defence and support provided to the EU members in that respect. It referred to major disasters, because minor disasters were left in the national competences of the states. A novelty was the fact that there appeared activities which preceded a disaster (prevention and preparedness).

Generic Crisis Handbook also cites an interesting definition of crisis management according to NATO's concept. In line with this concept, crisis management should be seen broadly, taking into account the procedures and actions aimed at taking control of the crisis situation by crisis managers, enabling them to shape the course of the crisis through preparatory action.

Western states also made their attempts at some legislation efforts in the field of the systematisation of crisis law. Most legal acts from that period came from the years 2001-2005, that is namely: after the attack on the WTC on 11th September 2001.

The acquired knowledge, experience and disasters which had been faced, forced the EU states and NATO to make general changes in their security systems. At that time, the structures of civil defence were still under their liquidation, because they had been considered as non-adjustable to the conditions of a decentralised society. However, practicism suggested that some of their elements should be used in the redevelopment of the new systems. The new situation required verification of axioms and solutions, performance of research and implementation of research results, training provided to services, new law and adaptation to the surrounding reality.

The crisis management system is aimed at a decrease in risk related to the possibility of threats and at the development of activities that would provide security to people, protection of critical infrastructure and natural environment. Hence, it is one of the most important systems which affects the functioning of the state and the sense of security in its citizens. Therefore, it can be assumed that the priority objective of the operation of that system is the implementation of the tasks which provide proper civil protection, which should be nowadays understood as *a set of activities undertaken by the relevant public authorities, rescue units and humanitarian organisations, as well as by individual citizens, which are to provide security to the whole society*.

Civil Protection

Civil protection is defined in a different, broad sense by Waldemar Kitler, who identifies it as one of the fundamental missions implemented for national security by state administration authorities, other state bodies and state institutions, entrepreneurs and other organisational units, non-government organisations and citizens themselves, and in some justified cases by the armed forces. Such a mission involves the implementation of numerous preventive, preparatory, interventional and recovering tasks in order to protect life and health of people, to protect their property, objects of cultural legacy and natural environment to the extent indispensable for survival. The mission also involves any humanitarian and legal aid provided during catastrophes, natural disasters, armed conflicts and occupation and directly after such events.

Expert literature provides another interesting opinion on the discussed problem. Aleksandra Skrabacz defines civil protection as a set of interdisciplinary undertakings implemented by joint efforts made by all entities of the state law who act in order to protect life, health, property and natural environment against any potential danger caused by the forces of nature or by people, to overcome their consequences and to provide conditions indispensable for survival.
So far, civil protection has not been defined in any currently binding legal act. It is, however, possible to fall back on a draft act on civil protection of 31st August 2009, article 2 which states that civil protection comes as integrated operation of state administration authorities and entities which implement tasks of civil protection in order to provide security to citizens, public order, protection of life and health of people who reside in the territory of Poland, protection of property, natural environment and cultural legacy in any cases of potential threats.

The above-mentioned draft act defines the principles referring to the organisation and functioning of the civil protection system, relevant authorities responsible for civil protection and their tasks, entities responsible for the implementation of these tasks. The draft act also defines the principles of alarming and warning, education of people, citizens' rights and obligations. Additionally, the document states the main assumptions of the practical implementation of civil protection, viewed through the prism of the following:

- providing conditions indispensable to protect human life and health, to provide people with basic conditions necessary to survive in emergency situations;
- providing cooperation of all the rescue systems, monitoring, warning, alarming, informing about potential threats, also units, services and other entities which implement tasks for civil protection;
- providing substantive, organisational, material and financial support to the operations implemented by non-government organisations which perform tasks for civil protection, particularly to social rescue and humanitarian organisations and voluntary service;
- organisation and coordination of humanitarian aid;
- maintaining resources which may be used to implement tasks for civil protection;
-providing education to society to increase awareness of potential threats and to teach proper behaviour in case such threats should take place.

It seems indispensable to accept and implement a new regulation on civil protection into life. In fact, there is such a project, however since 2009 the related legislation work has not been finished yet. While analysing that document, it is possible to find a number of very significant elements there, the implementation of which would be favourable for its assumed aim, that is namely: the development of relevant legal framework in order to provide conditions indispensable for protection of human life and health, basic conditions for the survival of people in emergency situations, cooperation of rescue systems, authorities, services and other entities which implement tasks in the field of civil protection, improvement in coordination, receiving and providing humanitarian aid, providing proper resources used in rescue operations and civil protection. The contents of the draft act allows us to draw a rightful conclusion that it should also strongly emphasize the development of the awareness in the society and promotion of proper behaviour in the face of threats in order to increase security and to decrease any direct consequences resulting from threats. The act should pay particular attention to the processes of prevention and preparedness which are undertaken in order to minimise natural or man-made threats. An important point in the implementation of the act is the development of a mechanism which enable people who work in social, rescue and humanitarian organisations to acquire indispensable knowledge and skills, along with protection of their legal interests. The protection of interests of employers who employ the above-mentioned people comes as another important aspect which makes the whole mechanism work properly.

Based on the above-mentioned range of tasks and a pragmatic approach towards the question of civil protection, it is advisable to pay some attention to the institutional context of their implementation, that is namely: specification of entities which are competent to perform such tasks.

There is another important opinion worth noticing. It has been provided by Romuald Kalinowski who sees civil protection as an institution (in this case: a formation) that is: Civil Protection. For Kalinowski, civil protection – considered in a systemic approach as well as in an individual one – is significant because of the legal and humanitarian approach of various entities towards that question. He indicates that it is important to provide civil protection to the whole population of the country in the time of peace as well as in the time of war.

Considering the semantic approach, the above-mentioned W. Kitler states that the term *civil defence* may refer to: civilians' resistance or civil fighting, non-military protection, civil (non-military) protection, facing threats by civilians, aid and self-aid in the society, social self-defense, civil power used in defensive fight. It can also describe non-military power and means applied for fight, defence, protection and self-defense; it can refer to the method of fighting with the use of non-military tools, the character, the type and the set of defensive or protective operations performed with the use of non-military tools and activities undertaken by civilians in the face of military and non-military threats.

Leaving aside the changes which have taken place in the way of understanding the term *civil defence*, it is possible to assume that it comes as one of the most important components in the national defence system which functions within the framework of so called non-military defence system. In the world, civil defence operates on the basis provided by the regulations of the Geneva Convention of 12th August 1949, with Amendment Protocols ratified by Poland in 1991. In our country, legal regulations referring to civil defence can be found, first of all, in the Act on General Obligation to Defend the Republic of Poland, of 1967. According to the author, one of the most important concepts which result from the analysis of that document is an indication that organisations (structures) of civil defence in the time of peace may be applied for cooperation in fighting against natural disasters, threats to natural environment, in removing their results, organised and led by other authorities.

Therefore, it is possible to assume that civil defence is aimed at protection of people, places of employment, public facilities, objects of cultural legacy, rescue operations and support provided to victims in the time of war and at

cooperation in fighting against natural disasters, threats to natural environment and removing their results. It is also possible to conclude clearly that the time range of the functioning of civil defence has not been confined only to the time of war (as it is commonly thought).

Considering the aspect of time of peace and time of war, some theoreticians state that a division into civil protection during the time of peace and civil defence during the time of war is irrelevant. They claim that regardless of the time, the right notion is civil defence, which in turn should be divided into civil protection, general rescue services, and other tasks. Considering the systemic approach, the above-mentioned author, R. Kalinowski sees a great role performed by Civil Defence as one of the leading entities of the national defence system of Poland, that is namely: an organisation based on the structures of state administration which implements humanitarian tasks in order to protect people. Hence, civil defence can be perceived in a very broad sense, and it can be defined as a system of civil protection in Poland which consists of an operational sub-system of Civil Defence, a sub-system of local support, a sub-system of national support and a sub-system of international support.

Following the thought of the cited author, it is possible to assume that in general understanding civil defence refers to structures, tasks, operational principles and forces which provide services to people. Considering modern character of civil defence, it should be emphasized that it is based on coordinated operation of forces and resources of all the departments, regional authorities of state administration and self-governments, other units, entities and organisations along with widespread involvement of the whole society. The implementation of tasks takes place in accordance with the principle of territorial primacy, with the consideration of three-level division of the country, in consistency with the current legal regulations. This is the most proper procedure, considering the aspects of economy and efficiency of operations and responsibility for decisions made in the field of civil protection.

The above-presented considerations may lead to a well-grounded conclusion that in our national system, the tasks referring to civil protection against various threats are entrusted to numerous centres, administration structures and self-governments. The efficiency of operation is ensured by collective cooperation coordinating rescue actions undertaken by particular entities.

Considering a number of tasks implemented in that field, A. Skrabacz presents their systematisation, divided into three main modes:

a. *permanent standing-by and ad hoc response* – performance of routine activities oriented towards rescue of people, property and natural environment; elimination of direct results of sudden emergency situations; prevention and counteraction undertaken against any potential threats;
b. *crisis* – response to situations in which any direct threats may lead to a crisis and response during an ongoing crisis;
c. *armed conflict (war)* – civil protection in accordance with the regulations of international law.

Considering the high level of the implementation of undertakings which are aimed at civil protection, the same author also suggests some principles which should systemise such implementation, that is namely:

- primacy of a territorial system; it means that the foundation of the whole model of civil protection is a horizontal system of authorities formed on the basis of a three-level division of the country, in which the department system performs only an auxiliary function;
- one-person leadership and responsibility for the standing-by mode to provide civil protection; it does not mean any resignation from teams who provide opinion and advice, but it implies resignation from making decisions by a collective body;
- the adequacy of the character and scale of a threat and of the level of the state administration authority which should response to such a threat; it means that all activities should be performed by the lowest level of competences in a particular situation;
- the common character of the civil protection system means that it refers to all the citizens, and it imposes particular tasks and obligations on them, depending on a situation in which the stand-by system is functioning at a particular moment;
- management and responsibility held by one-person authorities of general administration: a village head, a starost as the self-government authorities of a borough and a district, and a provincial governor (voivode) who represents government authorities at the level of the province.

Hence, the area in which the tasks of civil protection are implemented is very broad. It is advisable to provide a systematisation of the problem, as I.T. Dziubek suggests. The discussed undertakings are divided by the category of tasks implemented for:

- collective protection – it comes as systemic activity run by relevant institutions; it involves: recognition of threats and alarming, providing proper shelter, evacuation and blackout;
- individual protection – various activities undertaken by citizens who are prepared to behave adequately to particular situations.

In reference to the above-presented considerations, it is possible to conclude that further development of civil protection structures is inseparably connected with the development of the crisis management system. In accordance with the legal act, the latter system has been developed in order to carry out preventive and rescue operations and to reconstruct the critical infrastructure in the case of any potential threat. The system of civil protection in Poland faces numerous challenges, and it has to undergo some inevitable changes. It seems necessary to make the implementation of civil protection tasks cohesive with tasks implemented within the framework of the Act on Crisis Management in such a way that the crisis management system should cooperate and complete activities performed for civil protection. Considering civil defence, it is possible to observe that solutions and structures applied for the tasks are dispersed in various legal regulations, and sometimes they are not covered by any of them. Therefore, it is possible to suggest some regulations in that field, for example:

- definition and introduction of a term of civil protection into legal regulations – so far it has not been done, hence there is some terminological chaos in that respect;
- explicit indication and identification of tasks assigned to state administration authorities in the field of civil protection, and consequently, indication of authorities responsible for the implementation of such tasks at the level of a borough, a district, a province and the country;
- new definition of the way in which the state should implement civil defence tasks referring to the protection of victims of international armed conflicts – it should be considered whether particular entities who perform civil protection tasks should be granted a status of entities performing civil defense tasks in the time of armed conflict (war) in an automatic, statutory way.

It also seems necessary to provide statutory regulations referring to tasks performed to rescue life, health, property and natural environment, to provide aid to those who need ad hoc humanitarian support in the time of peace and in the time of emergency. It can be specified in a single legal act which would indicate such elements as: principles of providing humanitarian aid, citizens' obligations in the field of civil protection, programmes of civil protection, methods and principles of informing, warning and alarming, tasks and entities responsible for education and training provided to citizens, shelters provided to people, protection of property in emergency situations, methods and principles of creating resource reserves, definition of the functioning of civil protection during the "W" period; the funding of tasks, penal regulations.

Such a solution does not come down to the development of new structures. It should be considered whether these are the structures responsible for that question are the structures of the crisis management system or the structures of the civil defence system, all the more that some of the above-mentioned tasks are implemented based on some other legal acts. In order to introduce new solutions, it is first necessary to identify entities of civil protection, because it is possible to assume that they shall be activated during the state of emergency, and in the state of mobilisation they could be transformed in National Defence in the time of an armed conflict or war.

It seems advisable to place tasks of civil protection and civil defence in the current system of national security as well as in the latest solutions which refer to crisis management and general defence obligation (e.g.: the conscription of Territorial Defence Forces), in order to properly and clearly define competences of territorial self-government authorities. Consequently, it would be possible to implement civil protection tasks and to adjust legal regulations to current threats and to improve ways of response to such threats.

There is one more conclusion: the perception of the implementation of civil protection tasks takes place through the prism of civil defence. It is not surprising though, considering the stages of civil defence development[1].

Integration of the Systems

The crisis management system and the civil defence system have a lot in common. Let us have planning for example. At each of their operational levels bodies and institutions involved into civil defence must follow their plans, as well as it takes place at each level of crisis management. The detailed content of civil defence plans and the content of crisis management plans is similar. However, despite the fact that there are some consistencies, it

should be emphasized that the civil defence plan is to be applied during a situation of external threats to national security and during the time of war, whereas the crisis management plan is to be applied during the time of peace. It can be an indication referring to the necessity and tendency to maintain the structures of civil defence in Poland. Although at present civil protection is perceived through the prism of crisis management, and as a result, civil defence is pushed into operation exclusively during the time of war, it does not mean it cannot be used during a crisis.

A decision made by the government on the Programme of Rescue Services and Civil Protection in 2014-2020 seems to be very promising. It is actually the first document which – in a holistic and complete way - describes the problems referring to the organisation of rescue operations undertaken to protect life, health, property and natural environment by all public and social entities which perform such tasks. The resolution No. 59/2014 of the Council of Ministers of 29th April 2014 on the acceptance of the Programme of Rescue Services and Civil Protection in 2014-2020. The programme is to define objectives which must be achieved in the field of rescue services and civil protection in the years 2014-2020, conditions which must be met to achieve such objectives, with all the basic but indispensable legal, financial and organisational instruments. The suggested solutions shall be applied to provide comprehensive support and development of the potential of national security within which an executive sub-system is operated, that is namely: protective capabilities formed by services and organisations which implement rescue and civil protection tasks, along with entities of the crisis management system.

An important element which improves the crisis management system is incorporation of the problems of civil protection into the field of crisis management and integration of the current systems through new legal regulations, including integration of tasks and structures. New legal regulations should provide a framework for conditions indispensable for protection of human life and health, basic conditions for survival, cooperation of systems, authorities, services and other entities which perform civil protection tasks, for improvement in coordination of humanitarian aid and, additionally, for securing proper resources.

Another element is incorporation of a range of tasks referring to the field of civil protection, which come as a particular form of civil protection implemented by the same authorities and executive entities during the time of war. It is related to international obligations of Poland and a possibility to integrate already prepared organisational and legal solutions which function during the time of peace, with the rescue elements, and during the time of war. Considering the anachronistic character of the solutions applied in currently functioning civil defence, it is necessary to implement new legal regulations which enable the state authorities to meet their obligations in the field of broadly understood security provided to citizens in the time of war and peace.

Summary

The civil protection system in Poland is multi-element. It can be concluded that specialists in this field have a considerable problem with determining the components of this system. According to the authors, it can be pointed out that the civil protection system operates a crisis management subsystem (together with some of the implementing elements – and here the State Fire Service – which is important for the rest of the process). In addition, it can be included in the system of rescue subsystem (among others, the National Rescue and Fire-Fighting System - headed by the Commander-in-Chief of the State Fire Brigade), including the Armed Forces of the Republic of Poland or the State Medical Rescue. In addition, it is complemented by an element related to Civil Defence, which is now more of a theoretical subsystem than a practical one. Civil defence is based on the General Obligation to Defend the Republic of Poland Act 1967 and is generally adapted to the conditions of military conflict or crisis with such elements. Very often, the rescue, civil defence and crisis management systems are confused and conceptually mixed.

Considering the functioning of the civil protection systems and their integration, it seems necessary to provide statutory regulations referring to tasks performed in the field of rescuing human life and health, property and natural environment, providing ad hoc humanitarian aid to the people in need in the time of peace and in emergency situations. It would be possible through a specification confined in one, relevant legal act that would integrate all the dispersed elements. However, it would not be advisable to develop new structures and the tasks should be entirely entrusted to the units of the crisis management system or civil defence, even more that some tasks have been already implemented on the basis of some other legal acts. In order to implement new solutions, prior identification of civil protection entities shall be necessary, because it can be assumed that they shall be activated during natural disasters, and in a situation when mobilisation is announced such entities could be transformed into Civil Defence during the time or war or a military conflict.

The civil protection and crisis management system in Poland must be universal and interdisciplinary. It should reach the lowest levels of local government and a large number of companies, workplaces, museums and cultural institutions. The new generation of threats, including hybrid threats and those below the threshold of war, but also those we are currently facing, mean that the state must have instruments that support and complement the work of specialised services, but above all relieve them when necessary.

The civil protection system in Poland faces numerous challenges and changes which are unavoidable. It seems necessary to make the implementation of civil protection tasks consistent with tasks implemented within the framework of the act of crisis management, in such a way that the crisis management system should cooperate and complete operations undertaken for civil protection.

Smart Cities Governance: Lessons Learnt from Amsterdam

Rasha ALABDALI

Ministry of Transport, Communication, and Information Technology,
Muscat, Sultanate of Oman
rasha.alabdali@mtc.gov.om

Abstract

The adoption of the Smart City (SC) concept has been evolving with the growing need to utilize the technological advancements for serving communities and people and provide better services and solutions for their daily needs and problems. Many implementations of this concept, SC, have been taking place around the world, yet handling such a multi-disciplinary domain which requires huge engagement of stakeholders from various areas with different needs and expectations is not an easy job, as we are looking at it from a city level. ***Ruhlant*** mentions in his study that "city governance is enormously complex with the multi-faceted and multi-level ecosystem of various agencies and stakeholder groups (e.g. local governments, citizens, urban planners) that are often driven by conflicting interests" **(*Ruhlant*, 2018).** Thus, the need to have a model or an approach to govern the interactions and engagement of all stakeholders within this context becomes very essential. The purpose of this paper is to look at the governance mechanisms used by the city of Amsterdam to draw a better understanding of how a successful smart city governs its projects.

Keywords: Smart Cities, Governance, Model, Amsterdam.

Introduction

The concept of smart city has been defined as city that is making an effective use of information and technology communication as platforms to elevate the quality of human life, while improving the city`s operations and services that allow for competitiveness (Tanaka et al, 2018).

Smart city has been described by Ruhlandt as "a multi-dimensional mixture of: human, infrastructural , social open network and entrepreneurial capital, that are merged, coordinated and integrated into the fabrics of the city using new technologies to address social, economic and environmental problems, involving multi-actor, multi-sector and multi-level perspectives" (Ruhlandt, 2018). This complexity urges a fresh governance perspective that would facilitate human interactions with all these elements, using ICT to enhance the outcomes of the governance process with more openness (Meijer et. al, 2016).

In the context of Smart City, governance primarily refers to citizen participation and the collaboration among all stakeholders (Castelnovo et. al, 2016). Pereira et al define Smart City Governance as: "the smartness of a city refers to its ability to attract human capital and to mobilize this human capital in collaborations between the various (organized and individual) actors through the use of information and communication technologies" (Pereira et. al, 2016). Understanding smart city governance is vital to learn how to accommodate the complex government needs of SC and support any changes that will be required to handle the transformation of a city`s vision (Dameri and Benevolo, 2016).

The next section discusses the key aspects of smart city governance based on previous work conducted by other researchers.

Literature Review

Challenges in governing smart cities

1. Technology-driven:

Previous research has focused on the current status of the adoption of smart cities and the underlying challenges that require new venues of governance. One of the remarkable views that characterizes smart cities projects is the fact that they are mostly driven by ICT-oriented governments in order to provide better services to their residents. Despite those benefits however, aside from technological problems, there is a whole other set of social and organizational issues significantly linked to various stakeholders, competing values, social and political complexity, and interdependence (Pereira et al, 2016). Almeida et al also support that view by stating: "This peculiar view led to a certain bias, assuming smart cities' implementation as mostly a technological issue, which results in a set of outcomes that are not alien to other related environments such as the tendency to see technology as the primary means to solve problems or the increasing power of platforms that may be able to offer viable solutions for cities' problems". Thus, a holistic approach is required to govern Smart Cities, which examines the needs and issues of a city from all dimensions first, then utilizes technology as an enabler to overcome them.

2. Market driven:

The concept of smart cities was originated by the traditional ICT industry aiming to discover new opportunities in the market. According to Alfamicro and Alfamicro (2015), "The technology "pushed" solutions failed to engage the citizens and the public authorities who didn't take ownership of the "smart" services". Corporate interests along with the technological agenda in the background have been shaping the direction of smart cities. Key players in the ICT market such as IBM claimed to be the originators of the smart cities concept back in 2008, as Joss mentioned in his study, leaving no surprise that government applications of SC has generally been led by corporates and innovation agencies (Joss, 2018). Yet, smart city initiatives require a neutral approach and guidance that focuses more on the particular city's agenda and priorities to achieve public value while acquiring market offerings.

3. Emerging technologies and impact on society:

Technological advances along with city growth have had a huge impact on societies, which has resulted in a new wave of urban issues. Emerging trends in technology such as big data, open data, and global communication are all moving societies into a digital era with a new way of life and sharing knowledge. Despite all the improvements in communication that arose out of this technological evolution, the "social cohesiveness of small groups" according to Alfamicro and Alfamicro (2015), has not been satisfied. It is still at its inadequate levels as interactions among people in cities have become unnecessary, whereas in the past they used to play a central role in connecting people with each other.

Context

The word "smart" has different connotations depending on various conditions under different contexts, such as: political system, geographical situation, and technology status (Ruhlandt, 2018). Meijer et.al state in their study that "Smart solutions cannot be simply copied but need to be assessed on their value for different contexts and translated to fit other conditions" (Meijer et. al, 2016). For instance, European smart cities have adopted various patterns, roles and relations of their actors, implementation approaches, and policy instruments (European Parliament, 2014). Hence, It becomes very crucial to understand the main elements in any given context before applying governance practices imported from another city`s implementations of the smart city concept.

A good example for understanding contextual differences in applying smart cities governance is a case study conducted by Lin. Y (2008) where he makes a comparison between selected Western countries and China. The key finding of his study was that various political systems and institutions have significantly affected the strategies of smart governance, the arrangements, and the outcomes. According to Lin, the Western model of smart city initiatives focuses on e-democracy and e-governance, while in China the focus is directed towards smart management and services. Such a difference led to selecting opposite governance approaches as discussed in his case study. Western countries went with a bottom-up approach that encourages participation in decision making to satisfy democracy

needs. Conversely, China is using a top-down approach to support "the integration, openness, and use of datasets for governmental management and services" (Lin, 2018).

Key Actors

Previous literatures classify key actors within smart cities into four main categories: public, private, academic, and civic; at which these categories represent the wider range of stakeholders who could relate to city issues under the governance umbrella (Ruhlandt, 2018). Some authors highlight that dedicated non-governmental organizations (i.e. associations, foundations, etc.) could play an effective role in empowering participation, collaboration, and partnership (Dameri and Benevolo, 2016). Whereas Kourtit et al. (2017) and Bolívar (2016) both point out that city governments should play a bigger role in smart cities, the latter suggested three potential roles for governments: as a coordinator, as a funder, and as a regulator. In contrast, Taylor Buck and While (2017) emphasize on the importance of public-private partnerships and how their cooperation and exchange could build a strong network that enriches smart cities governance. Chourabi et al. (2012) agree with that as well by highlighting such partnerships as essential characteristics of smart governance and smart cities.

ICT Role in SCG

Misuraca defines ICT-enabled governance as "the use of ICT to comprehensively simplify and improve the internal administrative operations of government; facilitate public service interaction among government, citizens, and other stakeholders, enable citizen participation, and ensure inclusiveness and equal opportunity for all" (Misuraca, 2010).

Although many smart cities have claimed to be ICT-enabled cities in the race of digitizing everything, city governance has been left behind (Castelnovo et al, 2016). New technologies can now contribute to building effective governance (Marek et al., 2017) through creating communication platforms among different stakeholders where government and citizen participation can be more enhanced, and public-private collaboration can be strengthened (Cano et al., 2014). Examples of such technologies have been highlighted in some previous studies, such as: "geo-science tools and big data" (Kourtit et al, 2017), "data warehousing and monitoring tools" (Meijer, 2016), "sensors, virtualizations, geographic information technologies, social media applications" (Gil-Garcia, 2012).

Research Question

Many research studies have determined key aspects for governing smart cities. These studies however were either conceptual or discuss smart governance from a different perspective. The purpose of conducting a case study on Amsterdam is to learn about how the city has managed to run a successful governance program on its smart cities initiative.

Amsterdam was chosen as a case study for the following reasons:

1) Amsterdam is generally considered a leading European SC example (Manville et. al., 2014).
2) The Amsterdam Smart City Association (ASCA) proved to settle within the early stages of the smart program`s establishments (Dameri, and Benevolo, 2016). At European levels it is considered as a model for allowing bottom-up projects within different fields (Papa et al, 2013).
3) It has a unique partnership among businesses, authorities, research institutions and the people of Amsterdam with the objective of developing the Amsterdam Metropolitan Area into a smart city with a focus on the themes living, working, mobility, public facilities and open data (Meijer and Bolivar, 2018).
4) The city presents itself as an 'urban living lab' that allows businesses to both test and demonstrate innovative products and services. This partnership creates an infrastructure for knowledge exchange and learning among all these actors and results in concrete projects focusing on sustainable energy, innovative health solutions, better transport and more (digital) citizen participation (Almeida et al, 2018).

The case study aims to capture answers for the following questions:

Q1: What governance structures are being used?
Q2: What stakeholders are involved and how do they participate?

Q3: Why has this approach been effective for Amsterdam?

The results of this study will aid in setting policy recommendations for Smart Cities Governance.

Methodology

The author collected literature from registered online libraries such as Web-Science, ResearchGate, and Springer. In addition, many articles were found using google scholars engine. More than 40 papers were collected using key words such as "smart city" and "smart governance" to narrow the search parameters and identify relevant publications that would assist the author throughout the study. Moreover, the author used NVevo software for the literature review that enabled generating specific nodes to aid in the analysis of the literatures. The total number of references that were used for collecting data after review was **32**.

Figure 1: Research Methodology

Table 1: Nodes generated by NVevo while conducting literatures reviews to aid with the analysis and the related references

Literature reviews assisted the author in exploring the main components of SCG and drafting the key questions for the case study. Due to the limitation of resources and time, the author utilized existing online platforms to collect data and articles for building the case study about Amsterdam, such as: Amsterdam Smart City portal, SmartBee website, and other published case studies.

Case Study: Amsterdam

Amsterdam Smart City Journey

The Amsterdam Smart City (ASC) program was initiated in 2009 as a collaboration between Amsterdam Innovation Motor (AIM, now merged into the Amsterdam Economic Board) and grid operator "Liander". The program received support from the municipality of Amsterdam, City Government, and Amsterdam Climate Program. For this reason, the first smart city project was focused on energy efficiency. The first phase of ASC program ran from 2009 until 2011 where 16 pilot projects were developed with the main goal of testing both new technical solutions and new forms of collaboration. The second phase of the ASC program was between 2012 and 2014: in this phase the focus was shifted towards the creation of scalable models, with the objective of allowing end-users to take action. In 2011, KPN Telecom joined as co-founder and invested in the city telecommunications infrastructure, allowing ASC to enter a new range of implementation other than energy (i.e. internet-related applications.). In August 2014, the program consisted of 54 projects, involving 143 partners, an increase from the initial phase which involved only 16 projects and 71 partners in end of 2011 (Capra, 2016).

ASC Governance Model

Amsterdam has adopted a holistic approach in governing smart cities in which multiple actors have been involved to contribute effectively to creating a real smart city. Those key actors consist of government, business, academia and research, and citizens. The city has adopted a hybrid approach, making use of both bottom-up and top-down approaches. The bottom-up approach has been used to facilitate the city projects that focus more on enhancing the quality of life, boosting economic growth and start-ups, as well as enriching social inclusion (European Commission, 2016). For that, the city uses citizen-centric and stakeholder-centric methods for promoting participation, transparency, openness, and broad mind-sets to work on bringing excellent solutions with added value for all. Likewise, the top-down approach was used to implement ensure proper governance, especially with regard to connecting the city government with the private sector under one vision to achieve the program objectives.

Amsterdam has covered key verticals that were considered indicators for its smart city program. Those verticals are: smart economy, smart environment, smart government, smart living, smart mobility and smart people (Smith, 2017). There are number of projects that fall under each one of these indicators and managed at a "program level" along with the key sponsoring partners. Those partners are responsible for funding and managing the smart city projects, where each founding partner handles each indicator and works on developing the underlying projects with relevant stakeholders and with the collaboration of the other partners (Capra, 2014).

Figure 2: Smart City Governance Structure (adapted from Capra 2016)

Citizens` Participation

Meeting citizens' needs and goals is the main priority for Amsterdam. In order to achieve that, a co-creation model has been used by the municipality to engage its citizens in developing smart cities initiatives. This cooperation is considered to be one of the key reasons that the city won an innovation award (Putra, 2018).

Although there are official governance settings for Amsterdam Smart City at the program level, various governance models co-exist at the projects level. Some of them take formal and legal forms while others are more informal, and governance is practiced based on a given trust among different stakeholders. The government institutions act as a partner, rather than a decision maker with the other stakeholders when it comes to developing smart initiatives (Project level). This empowerment has encouraged experimenting organizational set ups, supported partnerships, and cooperation among various stakeholders. Amsterdam has defined different topologies of citizen` participation in the development of smart cities projects which vary based on the complexity of these projects. Citizen participation ranges from being informed and consulted to being a close partner in projects related to social innovation (Capra, 2016).

Furthermore, many venues have been offered as platforms for citizen participation. Two good examples are the WAAG Society and FABLAB Amsterdam:

- *Waag Society:* Waag Society was established back in 1994 and is considered as one of the world-renowned institutes for research, built to be a hub for artists, scientists and technology innovators. This hub works as a think tank for people coming from various disciplines (such as artists scientists, hackers, designers, academics, entrepreneurs, government officials, or any curious citizens) to learn about the recent technological solutions and think together about how to capitalize on knowledge, expertise and skills to create creative solutions that benefit their city (Henriquez, 2018).
- *FABLAB Amsterdam:* FABLAB was built by WAAG in 2007 and the name is an acronym for "Fabrication Laboratory." The concept was founded by MIT student Neil Gershenfeld and was subsequently led to a

global network of standardised open hardware setups, where people can play, try, learn, experiment and implement ideas, as well as mentor others (Henriquez, 2018).

ICT Platform and Governance

In the Amsterdam case, technology has been considered as an enabler even though the overall concept is not tied exclusively to technological solutions (Gorynski, 2017). The following are key initiatives by the city to enable the SC program using ICT platforms and establish good governance.

Ecosystem of smart city solutions

The city has established an ecosystem that combines fresh collaborative mindsets with governmental regulations that are favourable. That encouraged the rise of the entrepreneurship and attracted big number of various stakeholders from within and outside the city, which resulted in creating a big network for testing and experimenting new ideas and innovative projects, which is the core that has shaped city to become "smart" and a leader in this domain. Amsterdam was able to showcase forty-seven completed projects at least because of that with the other projects that are active in the Amsterdam Smart City Platform (Gorynski, 2017).

Amsterdam's City Data

Amsterdam launched a project called "Amsterdam's City Data", an open database, after consolidating data sets and records from more than thirty individual city departments. The database contained topographical and address data, land value and ownership information, healthcare data, traffic data and more. However, data on its own would not be useful without establishing a dynamic interaction and cooperation among all stakeholders from public sector, private organizations, and the citizens` input, which is considered to be a key success factor. Thus, Amsterdam has established an online platform as "a primary cross-sector actor" for that and appointed a Chief Technology Officer for the city as a project leader, to push the smart city program forward (Smith, 2017).

Internet of Things (IoT) Living Lab

This lab is mostly a network that was built with the collaboration of several companies to connect end users to data over the cloud using Bluetooth-enabled devices in order to create smart city applications. The network is located in the city and it consists of iBeacons that uses machine-to-machine standard protocol, which made it possible to achieve such an integrative and smooth process (Gorynski, 2017).

Case Study Summary

The below table provides a summary of the case study results.

Table 2: Case Study Results

Research Question	Finding
Q1: What governance structures are being used?	Bottom-up + Top-Down Approaches
Q2: What stakeholders are involved and how do they participate?	• *Government:* Set the needed regulations to set the program direction and enable smart city agenda. Establish a collaborative ecosystem by collaborating with the private sector and inviting all stakeholders to participate and contribute to smart cities initiatives. • *Businesses:* as co-founders of the city program, key investors, and subject-matter experts in the technical and knowledge related projects. Academia and research: serve as innovation think-tank and development hubs • *Citizens:* their participation vary based on the complexity of the projects from being informed and consulted to being a

	close partner in leading social innovation projects.
Q3: Why has this approach been effective for Amsterdam?	• Amsterdam has empowered all stakeholders to contribute in driving the smart city initiatives within an organized framework that created a balance of control and innovation, which led to building trust among the different stakeholders to take ownership. • Amsterdam partnership with the private sector ensured continues support and funding for its SC initiatives • Amsterdam provided open platforms for the citizen to participate in the SC projects at various degrees • Amsterdam utilized ICT to integrate city data for providing timely services, and established accessible infrastructure to allow for innovation. • At the same time, it focused on creating an ecosystem for with talents from inside and outside the city for developing innovative solutions.

Conclusion and Policy Recommendations

The study highlighted many challenges that are facing the governance of smart cities programs, such as having initiatives that are mostly technology focused and are led in many cases by the market more than municipalities. In addition, other challenges were discussed related to the digital divide and its impact on societies and it`s connection with its citizens. Moreover, several key aspects of smart cities governance have been addressed by the author in this study to understand the essential elements of governing smart cities, such as: context, key actors, and the role of ICT.

The study focused on Amsterdam as a case study as the city has proven to adopt one of the successful models in governing its smart cities initiatives. The focus on the big picture and allowing all actors to contribute to its smart initiatives within an organized framework are key factors to its success. Empowering citizen participation platforms where the city can gain access to talent and capitalize on it has also strengthened the collaboration and its impact. Moreover, partnership with the private sector has led to increased investment and support that has enabled financing the city's smart initiatives. Finally, ICT has played a key role in enabling smart cities initiatives and facilitated the governance processes.

Several recommendations can be drawn from this study and after benchmarking Amsterdam as a leading city in this domain:

- ***Recommendation No.1:*** When building a Smart City Governance Model, policymakers need to consider all stakeholders from all domains via establishing an active ecosystem and open platforms. The involvement of the stakeholders should not be limited to technology organizations alone. Government representatives from all fields covered under smart city indicators, academic institutions (including researchers, students, etc.), private sector (including CNI organizations) and citizens should be part of that model.
- ***Recommendation No.2:*** Policymakers need to follow a balanced approach on their governance practices for leading smart cities initiatives, in which a mixture of top-down and bottom-up styles can be adopted depending on the specific context (European Parliament, 2014).
- ***Recommendation No.3:*** Municipalities need to take a leadership role in the governance of smart cities and be part of policy-making to support smart cities initiatives.
- ***Recommendation No.4****:* Citizens are the main beneficiaries of smart cities initiatives; therefore, their direct engagement and empowerment can subsequently lead to creating services that match the actual needs and enhance the quality of their life. Policymakers need to create powerful platforms for effective citizen participation in addressing their needs and be part of smart city projects.
- ***Recommendation No.5****:* Government partnership with the private sector as co-founders of smart cities initiatives can result in enriching the experience, opening more opportunities, and increasing the investments.
- ***Recommendation No.6:*** ICT should be used as an enabler to build collaborative platforms that establishes effective interactions among all stakeholders to be able to interact, innovate, and share ideas.

Acknowledgments

I would like to thank Judy Blackhouse for her direct supervision and feedback while conducting this research at the United Nation Institute UNU-eGov in Portugal, and to thank the Institute for sponsoring my residency during that time.

Abstract

Cardiovascular diseases (CVDs) are "the leading cause of death" according to WHO (2017) and the Organization for Economic Cooperation and Development (OECD), which points out that the "rate of obesity and diabetes is on the rise", and that by 2030, 180 million people will be at risk of CVDs (2015). For this reason, the demand for cardiac diagnostics in health care facilities has increased significantly. Hospitals have improved diagnostic processes owing to their influence on the time, cost, and efficiency of medical care. In this study, a systematic review of the literature was carried out on the subject of machine learning in cardiac diagnostics. Articles related to the research topic were consulted to answer questions raised as the first step of the systematic review method. The review has shown the relevant trends in medical precision and revealed the most appropriate and effective machine learning techniques in cardiac diagnosis.

Keywords: Machine Learning, Diagnosis, Heart Disease, Systematic Literature Review, Method.

Introduction

Diagnosis of diseases is the most important activity in cardiology. Inaccurate results can be dangerous for hospitals because they lead to significant losses, such as time and labor costs, which directly affect the hospital's budget and patient care. Therefore, effective prediction plays an important role in the cardiac diagnostic process. Many predictive estimates are based on measurements, models, and algorithms that are aimed at increasing diagnostic accuracy for cardiologists.

Owing to the complexity inherent in accurate estimation in diagnoses, machine learning techniques can be applied to cardiac diagnostic procedures. This review focuses on highlighting the relevant and prevalent trends in the use of machine learning to diagnose heart disease.

A detailed review of the existing techniques was performed to identify research gaps in the literature. This article is organized as follows. Section II contains the background and work related to the investigation. Section III details the review methodology. Section IV showcases the results of the systematic review, section V presents the discussions on the work, and Section VI provides the conclusions and suggested future investigation.

Background and Related Work

Research conducted in Colombia by Saldarriaga-Giraldo (2020) on a cardiovascular syndrome called heart failure

Cite this Article as: Brandon GRADOS-ALVAREZ, Javier GAMBOA-CRUZADO, Norma GÁLVEZ-DÍAZ, Carlos GUILLERMO PAUCAR, Carlos ALMIDÓN ORTIZ and Renzo CAÑOTE FLORES "Machine Learning for Diagnosis of Heart Disease: A Systematic Review" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

with preserved ejection fraction (HFpEF) demonstrates the complexity of diagnosis, since this variable tends to increase in prevalence and involves factors such as genetics, lifestyle, and a high burden of chronic conditions. In their research, Ayon et al. (2020) state that cardiac diagnostics encounter more cases like the previous one, making it a demanding task for doctors and physicians. For this reason, many organizations opt for several methods to improve their diagnoses. Relevant statements by different authors have been summarized below.

In their web-based CVD detection system article, Alshraideh et al. (2015) propose cross-validation for the decision tree classification algorithm, which provides an accuracy of 98.29% to verify the patient's health status at all times. These types of complementary techniques significantly improve the precision of the algorithm.

Gupta et al. (2017) propose an intelligent model to support the decisions of physicians in predicting heart disease based on historical patient data. Naïve Bayes is the most efficient model, providing an accuracy of 86.42%.

In their study on the identification of heart diseases from patient publications, Ahmed et al. (2020) compared four types of algorithms, applying hyperparameter adjustment and cross-validation. The Random Forest algorithm garnered the greatest precision with an accuracy of 94.9%.

Diagnostic or prediction results are not perfect owing to errors in misclassification. To reduce misclassification, bagging techniques are proposed. The classification algorithm used in the study is Random Forest, in accordance with Saifudin et al. (2020).

It can be concluded that the most prominent studies applied complementary methods to improve accuracy and reduce error in cardiac medical diagnosis. Although it is true that these studies are from different authors in different domains, they have the same purpose—that of achieving the highest precision in diagnosis prediction.

Review Method

Marshall, Kitchenham, and Brereton (2018) defined the systematic review process to help mitigate the drawbacks of conventional literature reviews. According to Salinas (2020), literature reviews are becoming increasingly frequent, whether they are narrative, systematic reviews, or meta-analyses.

Narrative reviews in many cases included a simple quantification of the results, limiting itself to counting the number of studies with positive and negative results (Guirao, 2015).

Systematic reviews can identify the reasons for discrepancies or contradictions between the results of the various investigations, encouraging the redesign of studies with the aim of improving research (Beltrán, 2005).

In this article, a systematic review of the literature was chosen; a study with this type of detail requires many criteria and a series of steps in order to propose an improvement to the research. Following the steps of the systematic review proposed by Marshall, Kitchenham, and Brereton, eight steps were performed: research questions, search equations, search, exclusion criteria, selection of studies, quality of studies, classification of studies and, finally, the review of studies.

Research Questions

The first step of the review is to choose the research questions that will serve as guidance for the review process. In this step, our goal is to map the research on machine learning for heart disease diagnosis and be able to answer the following questions.

RQ1: What methods are used for applying machine learning to the diagnosis of heart disease?

RQ2: What complementary methods are the most relevant for applying machine learning to the diagnosis of heart disease?

RQ3: What variables are most related to machine learning for the diagnosis of heart disease?

RQ4: Who are the most active authors in the domain?

RQ5: Which are the preferred publications in the research domain?

Search Equations

In this step of the procedure, search equations were proposed. Before applying the equation, the following variables were used (Table 1).

Table 1: Search Descriptors

Name	Variable Type
Mobile app	Independent Variable
Machine learning	Intervening Variable
Method/Methodology/Model	
Diagnosis of heart disease	Dependent Variable
Heart disease	

These words were key to the framing of the equation, since they perfectly describe the research topic. The dependent variable "Mobile app" is undoubtedly the most used by the population. Machine Learning encompasses the entire topic of methods, methodology, and model, which has also been defined as an intervening variable. The final dependent variable is "Diagnosis of heart disease". Once the variables were established, the following equations were obtained according to the search source.

As a fundamental equation based on the search terms, the following was obtained.

[All: mobile app] AND [All: machine learning] AND [All: diagnosis of heart disease] AND [All: method or methodology or model]

Table 2: Sources and Equation

Source	Generic Search Equation
Taylor & Francis	[All: mobile app] AND [All: machine learning] AND [All: diagnosis of heart disease] AND [All: method or methodology or model]
ProQuest	(Mobile app) AND (Machine Learning) AND (diagnosis of heart disease) AND ((method OR methodology OR model))
EBSCOhost	TX mobile app AND TX machine learning AND TX diagnosis of heart disease AND TX (Method OR TX Methodology OR TX Model)
IEEE Xplore	((("Full Text & Metadata": mobile app) AND "Full Text & Metadata": machine learning) AND "Full Text & Metadata": diagnosis of heart disease) AND "Full Text & Metadata": method or methodology or model)
ScienceDirect	("mobile app" and "machine learning" and "heart disease" and ("method" or "methodology" or "model"))
Scopus	ALL ('app AND mobile' AND machine AND learning AND diagnosis AND of AND heart AND disease AND (method OR methodology OR model))
Microsoft Academic	mobile app AND machine Learning AND diagnosis of heart disease AND (method OR methodology OR model)
Wiley Online Library	"mobile app" anywhere and "machine learning" anywhere and "diagnosis of heart disease" anywhere and "method or methodology or model" anywhere
IOP	machine learning AND diagnosis of heart disease AND (mobile app OR method OR methodology OR model)
ERIC	machine learning AND (diagnosis of heart disease OR mobile app) AND (method OR methodology OR model)
ARDI	(machine learning) AND (diagnosis of heart disease) AND (mobile app or method or methodology or model)
ACM Digital Library	[All: mobile app] AND [All: diagnosis of heart disease] AND [All: machine learning] AND [All: method or methodology or model]
ETHzurich	All fields containing app mobile AND All fields containing diagnosis of heart disease OR All fields containing heart disease AND All fields containing machine learning AND All fields containing (method OR All fields contains methodology OR All fields containing model)
Google Scholar	Mobile app AND heart disease AND machine learning AND (method OR methodology OR model)

Search

In this step of the research, searches were performed in the 14 selected sources. When performing the searches a large amount of information was obtained and processed. The quantities of articles found were as follows the Fig 1.

Fig. 1: Search Results

It can be seen that the total amount of searches was considerable, with a total of 21,505,055 articles related to machine learning in cardiac diagnosis, with ETHzurich being the search engine providing the highest amount of results.

Exclusion Criteria

In this step, ten exclusion criteria were formulated and applied to the articles. Given that this topic is constantly being updated, it was decided to exclude articles that were more than five years old. Furthermore, owing to the variety of techniques that can be applied in this domain, the most relevant studies were referenced and those that do not apply machine learning, neural networks, artificial intelligence, and internet of things (IoT) were excluded.

Therefore, non-experimental articles were excluded as the purpose of the study is to propose prediction techniques. In addition, it was decided to exclude articles that did not use predictive algorithms or models. Therefore, articles with qualitative data were also excluded.

The most relevant research has considerable sample size, and for this reason articles with a sample size of less than 30 were not considered. Investigations in the field of machine learning are complex, and there are different ways of using the techniques. Therefore, image processing was excluded, since it is a topic that deserves separate research. For similar reasons, studies on children were excluded given that they present different indicators.

Finally, articles that did not answer the research questions posed above and those that did not adequately describe data collection methods, were also excluded.

Study Selection

This corresponds to the articles obtained after the criteria proposed above were applied. In sections 3 and 4, the automatic search was applied, and 329 articles were obtained, of which the last section was manually processed. Furthermore, the quality studies were applied to the exclusion criteria, of which the number of results was maintained, given that the information met the quality requirements established by the automatic search. Based on these criteria, we started filtering the articles. The Fig 1. shows this process.

Fig. 2: Stages of the Study Selection Process

Based on the previous selection criteria, a total of 78 articles were obtained for the study. Table III shows the final number of articles obtained by source, with ARDI and ETHzurich accounting for the largest number of studies.

Quality Criteria

In this step of the review, the following quality criteria were established.

QA1: The results of experiments are identified and reported.
QA2: The investigation describes how the sample was extracted.
QA3: Appropriate methods are used to analyze the results.
QA4: The context in which the research was carried out is explained.
QA5: The purpose of the research is explained.
QA6: The research findings are explained.

These criteria were applied to all selected articles (n=78). They were all retained because they all met the quality criteria.

Classification of studies

Before proceeding to the review, the final studies were organized using Zotero, which classifies articles and provides tools for research analysis (Fig 3.).

Fig. 3: Zotero Reports of Classified Studies

Study Review

In this stage, a detailed review of the articles was carried out. RQ4 was answered with the purpose of obtaining the number of articles per year on this research topic. Responses to RQ5 revealed the most active authors in the domain of research. The dates of publications of the articles were also obtained to respond to RQ6. Finally, the country of origin of each study was determined with the purpose of establishing a global vision of machine learning around the world.

For providing information relevant to research questions RQ1, RQ2, and RQ3, word processing was used with Power BI, which optimized the search for relevant ideas.

Results

This section contains the results of the systematic review analysis with respect to the five research questions set out in section III.

RQ1: What methods are used for applying machine learning to the diagnosis of heart disease?

The following table shows the number of machine learning methods and the percentage of these used in the articles, to answer the research questions.

Table 3: Machine Learning Method Estimation Approaches

Machine Learning Method	No. Articles	Percentage
Neuronal Network	40	49%
Decision Tree	46	57%
Random Forest	37	46%
Clustering	29	36%
Logistic Regression	35	43%
Support Vector Machine	61	75%
Deep Neural Network	26	32%
Naïve Bayes	19	23%
K-Nearest Neighbor	22	27%

Table 3 indicates that currently the most commonly used method is Support Vector Machine, accounting for 75% of the 78 articles reviewed (see Appendix A). This result is expected, since in recent years there have been many regression and classification problems in supervised learning for medical data, and this method is tailor-made, so it should be taken into account when highlighting this type of project. Decision Tree is second with 57%, owing to

the popularity and feasibility of the method when correct estimates are required for diagnostic data reliability.

RQ2: What complementary methods are the most relevant for applying machine learning to the diagnosis of heart disease?

To answer this question, four fundamental methods for data validation were analyzed. Table 4 shows that cross-validation, apart from being the best known, has good documentation for researchers, and is the most used. Many of the studies that applied this method were able to significantly improve machine learning.

Table 4: Machine Learning Complementary Method Estimation Approaches

Complementary Method	No. Articles	Percentage
Cross-validation	57	69%
hyperparameter	8	9%
hyper parameter adjustment	4	4%
K-Fold Cross validation	14	16%

RQ3: What variables are most related to machine learning for the diagnosis of heart disease?

The performance of the algorithm depends on this fundamental question, so it is important to determine which variables are related to CVDs (Table 5).

Table 5: Machine Learning Attribute Estimation Approaches

Machine Learning Attribute	No. Articles	Percentage
Thal	17	21%
Main vessels	15	19%
ST segment	37	46%
Old Peak	26	32%
Angina	20	25%
Heart rate	80	99%
Resting electrocardiographic	6	7%
Fasting blood sugar	14	17%
Serum cholesterol	8	10%
Blood pressure	46	57%
Chest pain	20	25%

Eleven machine learning attributes were analyzed for the data validation. It can be observed that the heart rate data is widely used for cardiac diagnosis, and the least used is Resting electrocardiographic; this is closely related, since performing an analysis on this type of patient implies a high cost and therefore, other variables that serve equally well for the diagnosis tend to be used without harming the budget of the organizations. In general, most of these variables do not fall below 7% and are used frequently, because they are key to the diagnosis of the disease.

RQ4: Who are the most active authors in the domain?

Similar to RQ3, this question is fundamental, because of this depends the performance of the algorithm, thus, it is important to determine which variables are related to CVDs.

Autores	2015	2016	2017	2018	2019	2020	Total

Fig. 4: Number of citations by author per year

To determine the most active authors in the domain, article citations were processed to obtain the authors with the highest mentions. Fig 4 shows that Weng et al. (2017) are the most renowned authors with 341 citations, which give them a significant advantage over the other authors, followed by Arabasadi et al. (2017) with 121 and Goldstein et al. (2017) with 120.

RQ5: Which are the preferred publications in the research domain?

Fig 5 shows the number of articles per publication over the last 5 years. This will help identify the main publications in this research domain.

Fig. 5: Number of articles by publication

For publications in the research domain, articles were analyzed to determine the one with the most mentions. Physiological Measurement is the most popular publication on the subject of cardiovascular diagnosis using machine learning, with 14 relevant articles in recent years.

Discussion

Implications for Research and Practice

The findings revealed a significant number of relevant articles on the diagnosis of CVDs using machine learning. The results achieved were achieved following the systematic review of literature methods.

For professional use, the study results need to be applied in a relevant manner. The results suggest that the field of research is not mature, and that directly applying the methods and instruments used in the studies may not produce the desired effects. In view of this, we believe that a detailed analysis of the context in which the research was carried out is necessary in order to assess the possibility of generalizing the results to other fields.

Limitations of this Review

The limitations of this work are common among this type of research. By following the guidelines established by Marshall, Kitchenham and Brereton (2018), the automatic search was used to obtain relevant publications for the selection process, reducing the biases. A multi-stage selection process was applied and the exclusion criteria were recorded at each stage. The issues in the selection process were specifically solved through virtual meetings.

Conclusion and Future Work

In this review, 21 505055 studies processed using the automatic search were analyzed. Of them, 78 studies provided answers to the six research questions. These studies encompass the topic of the use of machine learning in diagnosing heart diseases, and address issues such as methods and variables that are used to develop this field.

It is concluded that the articles respond effectively to the research questions, with the Support Vector Machine method being the most used and the cross-validation method being the relevant complementary method. Regarding the variables, it is not possible to determine in a general way which would be the most accurate, since it depends on the field of research and other factors involved in a diagnosis.

For future work the research variables should be considered as they are unknown in the diagnosis process. Therefore, the intention is to identify variables with more correlation that do not imply high costs.

Taxonomic Analysis of Spatial Differentiation in The Transport Development Level in Poland

Agnieszka WANIEWSKA

Faculty of Management, General Tadeusz Kościuszko Military University of Land Forces,
51-147 Wroclaw, Czajkowskiego Street 109, Poland, agnieszka.waniewska@awl.edu.pl

Abstract

The article attempts to use taxonomic methods to analyze Polish regions' diversity in terms of transport development. The article aims to answer the question of what is the degree of diversification of transport development in Poland by voivodeships. The research object was sixteen voivodeships in Poland. The analysis was carried out only for the data from 2018 from the quantitative data available in the sources of the Central Statistical Office (GUS). The linear ordering method was used based on the taxonomic measure of development (TMR) according to Hellwig's concept, which allowed distinguishing the ranking of the development transportation level. A modern state functions properly when transport is developed at a high level. The analysis result is the presentation of the spatial differentiation of transport development in individual voivodeships in terms of the adopted measures.

Keywords: Linear Ordering, Hellwig's Method, Transport.

Introduction

Transport is one of the world's most important service sectors. Most frequently the term is understood as the deliberate movement of people and loads. The transport development depends mainly on technical progress, innovation, and entrepreneurship, which change as economies and societies develop. The dynamic development of transport (mainly cars) is at the same time a significant source of problems. The unfavorable effects of transport are felt both by the society (mainly related to the consequences of accidents and collisions) and the environment. In the face of contemporary social and economic changes, the development of transport is one of the effective and modern factors of competitiveness and development of regions in the conditions of a knowledge-based economy. Therefore, in recent years, significant efforts to develop transport in Poland have been made. The article aims to use taxonomic methods to analyze the spatial differentiation of transport development in individual voivodeships in Poland.

The concept and determinants of transport development

Two approaches to defining transport are noticeable in the literature. The first one indicates that transport and communication are "hierarchically subordinated concepts, according to which transport is the broadest term encompassing all activities of moving people, cargo and, messages (communication deals with the movement of messages). While communication is a special form of organizing the transport of persons, cargo, or messages, which ensures the permanent possibility of using the transport facilities of a given route" (Małek, 1997). The second approach treats transport and communication as "partially overlapping concepts, where transport is the activity of deliberately moving people and cargo, and communication is the process of exchanging information between people, which consists of communication (transporting messages) and enabling communication by means of transport. Thus, the concept of transport overlaps with the concept of communication" (Piskozub, 1975).

Transport should be considered in terms of a system. The transport system is "an ordered whole of all modes of transport operating with the use of infrastructure (Skorobogatova, Kuzmina-Merlino, 2017) in a specific area, with the size and structure of the human factor, inter-branch connections within this whole, and the connections of the entire transport system with the environment" (Gołembska, 2009).
The elements of the transport system are infrastructure and supra-structural objects (Skorobogatova, Kuzmina-Merlino, 2017).

The transport system development depends on two types of conditions.
Internal conditions are related to the functioning of the transport market and the quantitative and qualitative changes taking place there. External determinants concern those factors and phenomena that are somewhat outside the sphere of transport (Merkisz-Guranowska, Merkisz, Kozak, Jacyna, 2013). They are determined by the changes occurring in the social and economic life, which include (Koźlak , 2008):

- the ongoing process of globalization and the development of world trade,
- creating a network of connections to rationalize economic processes,
- development of information and communication technologies,
- implementing the concept of sustainable development.

Linear Ordering – Hellwig's Method

Multidimensional comparative analysis enables the assessment of complex objects and phenomena, i.e., those whose state and behavior are simultaneously influenced by many features (variables) and factors (Surówka, 2019). The concise definition given by Hellwig says that (...) *the methods and technique of comparing multi-feature objects are called multidimensional comparative analysis* (...) (Hellwig, 1981). The main goal of a multidimensional comparative analysis is the construction of a synthetic measure that allows for comparing the elements of a set (of objects) described by means of many variables (features). To achieve that, linear ordering methods are often applied.

These methods assume that the result obtained following the application of an appropriate algorithm will be such an arrangement of a set of objects in which (Bąk, 2018):

- each object has at least one neighbor and no more than two neighbors,
- if the object *a* is a neighbor of object *b*, then the object *b* is a neighbor of the object *a*,
- there are only two objects with one neighbor.

It should be emphasized that the concept of a taxonomic measure of development is a useful tool that allows universal application in economic research. The great advantage of Hellwig's concept lies in its cognitive qualities in the process of explaining economic reality and the usage flexibility (Pietrzak, 2014).
The construction of Hellwig's synthetic measure is as follows:
a) normalization of variables (standardization):

$$z_{ij} = \left(\frac{x_{ij} - \overline{x_j}}{s_j} \right) \tag{1}$$

where:

x_{ij}- observation of the *j*-th variable for the object *i*,
$\overline{x_j}$— arithmetic mean of observations of the *j*-th variable,
s_j— standard deviation of the observation of the *j*-th variable,
b) pattern coordinates:

$$z_{oj} = \begin{cases} \max\limits_i \{z_{ij}\} \text{dla zmiennych o charakterze stymulat;} \\ \min\limits_i \{z_{ij}\} \text{dla zmiennych o charakterzedestymulat;} \end{cases} \tag{2}$$

c) distances of objects from the pattern: $$d_{i0} = \left[\sum_{j=1}^{m} \left(z_{ij} - z_{0j} \right)^2 \right]^{\frac{1}{2}} \tag{3}$$

d) aggregate variable values:

$$q_i = 1 - \frac{d_{io}}{d_o} \tag{4}$$

where:
$q_i \in [0; 1]$, $\max\limits_i \{q_i\}$ — the best object, $\min\limits_i \{q_i\}$— the worst object,

wherein:

$$d_0 = \bar{d}_0 + 2S(d_0) \tag{5}$$

$$\bar{d}_0 = \frac{1}{n}\sum_{i=1}^{n} d_{i0} \tag{6}$$

$$S(d_0) = \left[\frac{1}{n}\sum_{i=1}^{n}\left(d_{i0} - \bar{d}_0\right)^2\right]^{\frac{1}{2}} \tag{7}$$

The measure d_i usually takes values from the interval [0; 1]. These values are the higher, the closer the object is to the pattern.

Selection and statistical verification of variables

Following the above remarks and previous experience, as well as the availability of statistical data (the Central Statistical Office was an important source of the numerical information), to measure the degree of diversification of transport development in Polish voivodship, it was assumed that the potential variables proposed for the research cover the following set of diagnostic features:

X_1 – expressways and highways per 1000 km^2 (stimulant)
X_2 – passenger cars per 1000 population (stimulant)
X_3 – trucks per 1000 population (stimulant)
X_4 – fatal accidents (destimulant)
X_5 – injured in accidents (destimulant)
X_6 – railway lines in operation
X_7 – passenger transport per capita (stimulant)
X_8 – commune and poviat hard surface roads per 100 km^2 (stimulant)
X_9 – commune and district roads with unsurfaced surface per 100 km^2 (stimulant)
X_{10} – suburban railway lines in km (stimulant)
X_{11} – regional railway lines in km (stimulant)
X_{12} – long-distance railway lines in km (stimulant)
X_{13} – average mileage of 1 car (bus) during the year (stimulant)
X_{14} – the number of parking lots in the Park & Ride system (stimulant)
X_{15} – passenger transport per capita (stimulant)
X_{16} – the public transport fleet adapted to the transport of disabled people (buses).

Table 1: Statistical characteristics of diagnostic variables

Voivodeship	X_4	X_5	X_7	X_8	X_9	X_{10}	X_{15}

Source: Own study based on data from the Regional Data Bank.

The verified set of variables included in the analysis, basic information about them and the results of statistical verification are summarized in Table 1. Next, the data was statistically verified for the coefficient of variation. Only those features were selected for the analysis where the coefficient of variation V(x) was within 10% - 30%, which indicates that the selected variables can be considered diagnostic. The following one were excluded from the taxonomic analysis are: X_1 - expressways and highways per 1,000 km^2, X_2 - passenger cars per 1,000 population, X_3 - trucks per 1,000 population, X_6 - railway lines in operation, X_{11} - regional railway lines in km, X_{12} - long-distance railway lines in km, X_{13} - average mileage of 1 car (bus) per year, X_{14} – the number of car parks in the Park & Ride system. Among the proposed variables, those that were destimulants[1] were reduced to stimulants[2].

Table 2: Organizing Polish voivodeships according to the TMR value

Position	Voivodeship	TMR Hellwig	Position	Voivodeship	TMR Hellwig
1	Mazowieckie	0,47	9	Lubelskie	0,15
2	Wielkopolskie	0,42	10	Zachodniopomorskie	0,13
3	Opolskie	0,36	11	Podkarpackie	0,11
4	Dolnośląskie	0,32	12	Śląskie	0,10
5	Kujawsko-Pomorskie	0,27	13	Łódzkie	0,08
6	Warmińsko-Mazurskie	0,26	14	Lubuskie	0,06
7	Podlaskie	0,21	15	Pomorskie	0,05
8	Świętokrzyskie	0,19	16	Małopolskie	0,03

Source: own study.

The results of organizing the voivodships using the Hellwig's method are presented in Table 2. The Mazowieckie and Wielkopolskie voivodeships are in the leading positions in terms of transport development. In the Mazowieckie voivodeship, the maximum values were reached by the variable X_7 (passenger transport per 1 inhabitant) and X_8 (commune and poviat roads with hard surface per 100 km^2), while in the Wielkopolskie voivodeship the variables X_4 X_7, and X_8 were predominantly shaped, at least at the level of 75% of the values of the reference object's corresponding variables. The last positions (in different order) are taken by the following voivodeships: Lubuskie, Pomorskie, and Małopolskie (positions 14 to 16). The low position in the ranking of these voivodeships is due to low values of variables.

Conclusions

The article presents the possibilities of assessing the road infrastructure in Polish voivodeships based on statistical data using the Hellwig's linear ordering method. In the case of the method applied, the Mazowieckie voivodeship was ranked first in the study. Furthermore, based on the analysis, it can be concluded that Polish voivodeships are characterized by a diversified level of road infrastructure. There is no clear division into Eastern Poland and the rest of the country in the spatial diversity of road infrastructure in Poland.

[1] destimulant - a feature for which lower values are desirable (e.g., unemployment rate - the lower the better)
[2] stimulant - a feature for which higher values are desired (e.g. GDP - the higher the GDP, the better the economy develops),

Abstract

CBMA is one of the preferred external growth strategies by many firms worldwide. Similar trend is also observed for firms from ASEAN member countries. Nevertheless, it is reported that there is high rate of non-value creation involving CBMAs transactions due to higher risk as compared to domestic M&As. Exchange rate is one of the sources of risk related to CBMAs transaction. This study aims at examining the role of exchange rate in ASEAN firms' CBMA success. This is due to the active involvement of ASEAN firms in CBMA and high exchange rate volatility in ASEAN countries. This study used CBMA involving 348 ASEAN bidding firms and 246 ASEAN target firms from the year 2002 to 2013 from Thomson One Banker Database. The results from multiple regression analysis indicate that exchange rate strength is disadvantageous for ASEAN target firms as it would decrease the possibility of CBMA success. The results contradict to cost of capital view which argue that stronger bidder's currency resulted high premium payment and increase the possibility of CBMA success. Hence ASEAN target firms should be more cautious in due diligence process prior to accepting CBMA offer from country with stronger currency.

Keywords: Cross-border mergers and acquisitions (CBMAs), Exchange rate, CBMA Success, ASEAN.

Introduction

Cross-border mergers and acquisitions (CBMAs) have been widely used as an external growth strategy for firms worldwide. This is corroborated by the statistic from the World Investment Report 2016 (UNCTAD, 2016), which reported a large increase (66.8%) in worldwide CBMA value in the year 2015. World Investment Report 2015 indicated that the firms from countries of Association Southeast Asian Nation (ASEAN) actively involved in CBMAs, consistent with the worldwide CBMA trends. Among the contributing factors is the establishment of ASEAN Economic Community (AEC) (UNCTAD, 2015; ASEAN Secretariat, 2019). Despite the popularity of CBMAs, a study by Froese (2010) revealed that 50% of CBMA failed to create value. The reason for this is because CBMA is riskier than domestic M&A. One of the sources of CBMA risks originated from the difference in currency between target and bidding country.

However, the debates persist whether exchange rate could affect the firm's performance and hence, a CBMA success or it leaves no effect at all on CBMA success. While Froot and Stein (1991) argued that exchange rate could affect the firm's performance based on the cost of capital argument, Kish and Vasconcellos (1993) proposed an opposite view by arguing based on profit remittance following CBMA. A later study by Blonigen (1997) is consistent with Froot and Stein (1991) where exchange rate could affect a firm's performance, but Blonigen (1997) used the firm-specific asset as the basis to support the argument.

Cite this Article as: Nurhazrina MAT RAHIM, Ruhani ALI and Ei Yet CHU "The Effect of Exchange Rate on Cross-Border Mergers and Acquisitions (CBMAs) Success: Evidence from ASEAN CBMA" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The effect of exchange rate on CBMA success is more prevalent for ASEAN firms. This is due to the fact that ASEAN countries have a volatile exchange rate (Rahutami, 2013) and they are actively involved in CBMA. The World Investment Report 2016 (UNCTAD, 2016) reported an increase in both ASEAN CBMA purchase (33.8%) and CBMA sales (15%) in the year 2015. In addition, Rahutami (2013) reported that ASEAN countries have volatile exchange rate where Malaysia and Philippines recorded the highest exchange rate volatility in the year 2002 to 2003 while Indonesia in the year 2011. Thus, there is a high possibility that the currency movement of ASEAN countries would be detrimental to the success of CBMA deals. Therefore, this fact indicates that the exchange rate could decidedly affect the success of CBMA deals involving ASEAN firms. Thus, this study aims to examine the exchange rate effect on ASEAN firms' CBMA success.

This study provides an opportunity to advance our knowledge on the impact of exchange rate on ASEAN firms' CBMA success. Even though the study on exchange rate by Jongwanich, Brooks, and Kohpaiboon (2013) involving emerging ASEAN economies, their focused was on the exchange rate effect on CBMA intensity, not the firm's performance and CBMA success. Thus, the uncertainness of the role of exchange rate for CBMA success in ASEAN firms still exists.

The results indicated that there is a significant negative impact of exchange rate on ASEAN target firm's CBMA success. This study highlight that the inferior governance standard of ASEAN target countries has resulted in low premium paid to ASEAN target firm, contrary with cost of capital argument. Hence, there is deterioration in performance which led to low possibility of CBMAs success. The remaining part of the paper proceeds as follows: Section 2 discusses the literature and hypothesis development, Section 3 describes the research methodology, Section 4 presents the results and discussions, and the last section concludes the paper.

Literature Review

The studies on the impact of exchange rate on CBMA outcome (intensity and firm's performance) had commenced since the 1990s. However, debates are still ongoing not only with regards to the underlying views but also the mechanism (exchange rate strength or exchange rate volatility) on how exchange rate affects CBMA outcome. There are three main views, which are widely discussed in the previous CBMA literature and they are; cost of capital view, (2) profit remittance view, and firm-specific asset view.

Cost of capital view

First, an early study by Froot and Stein (1991) asserted that informational imperfection and asymmetries in the capital market could explain the influence of exchange rate on the intensity of foreign company acquisition in a country. They claimed that information asymmetry, which resulted from imperfection in the capital market makes internal financing cheaper as compared to external financing. Thus, the bidder will utilise their net wealth to finance the CBMA transaction. The bidder's net wealth will appreciate if the bidding country's currency strengthens relative to the target country's currency, hence reducing the bidder's cost of capital to acquire the target. Consequently, the intensity of foreign acquisition in the target country will also increase. The Froot and Stein (1991) cost of capital view has been supported by later studies (Uddin and Boateng, 2011; Erel, Liao and Weisbach, 2012; Boateng *et al.*, 2014) where the bidding country's currency appreciation relative to the target positively affects the CBMA intensity in the target countries.

Other than increasing CBMA intensity, Harris and Ravenscraft (1991) argued that the relative change in bidder's currency as compared to the target will also affect the firm's performance during CBMA. This study also used Froot and Stein (1991) cost of capital view and claimed that the cost of capital advantage resulted in lower acquisition price and enabled bidding firms to pay a higher premium to the target firms (Kiymaz, 2004; Starks and Wei, 2013). This would positively affect the wealth gains for the target firms during CBMA, hence improving the firm's performance. Later studies by Kang (1993), Danbolt and Maciver (2012), and Gregory and O'Donohoe (2014) also put forth the Froot and Stein (1991) cost of capital view where they asserted that informational imperfection and asymmetries in capital market resulted in decreasing cost of capital and thus, explain the variation in bidding firm's return during CBMA. Therefore, the low cost of capital would positively affect both target and bidding firms' performance following CBMAs. However, a later study by Shetty et al. (2019) indicated no relationship between change in bidders' currency and bidding firm's return.

Profit Remittance View

Even though numerous studies found support for Froot and Stein (1991) cost of capital view, there are also studies that found no significant impact of bidding country's currency strength on neither CBMA intensity (Kish and Vasconcellos, 1993; Rajan, 2008; Brooks and Jongwanich, 2011; Jongwanich, Brooks and Kohpaiboon, 2013) nor a firm's performance (Cakici, Hessel and Tandon, 1996; Kiymaz, 2004; Bhagat, Malhotra and Zhu, 2011; Steigner and Sutton, 2011; Danbolt and Maciver, 2012; Chang, Choi and Huang, 2015). Kish and Vasconcellos (1993) argued that the absence of exchange rate impact on both CBMA intensity and the firm's performance was due to the remittance of profit to bidding country at a higher exchange rate. Thus, it will result in less amount of profit repatriated, setting off the advantage of earlier lower acquisition cost.

Kish and Vasconcellos (1993) profit remittance view was supported by a later study by Kiymaz (2004) who stated that currency strength not only affects the acquisition cost but also the value of profits repatriated to the bidding firms. Therefore, according to Kiymaz (2004), bidding firms would benefit if their country's currency is strong during acquisition and weak during profit remittance. As a result, Kiymaz (2004) claimed that it is the exchange rate volatility (variation in the exchange rate of the home country of bidding and target firms), not the bidder currency strength, which could affect the firm's performance during CBMA. The study hypothesised that high exchange rate volatility will negatively affect a firm's performance during CBMA because it represents a high uncertainty of profit remittance. The results indicated that the exchange rate volatility only gives a significant negative impact on bidding firm's performance and not for target firm, though the coefficient is also negative.

Chakrabarti, Gupta-mukherjee, and Jayaraman (2009) also reported a negative impact of exchange rate volatility on bidding firm's performance during CBMA, though it is not significant. Anomalous results were reported in later studies by Morresi and Pezzi (2014) and Ahern, Daminelli, and Fracassi (2015). They found that the exchange rate volatility gives a significant positive impact on a firm's performance creation during CBMA. There are also studies (Filobok, 2006; Rajan, 2008; Lim, Makhija and Shenkar, 2016) that examined the impact of exchange rate volatility on CBMA intensity. However, their results indicated an insignificant negative effect of exchange rate volatility on CBMA intensity.

Firm-Specific Asset View

Even though Kish and Vasconcellos (1993) claimed that exchange rate leaves no significant impact on CBMA intensity and the firm's performance, there is another view that recognised the significance of exchange rate on CBMA intensity, which is Blonigen (1997) firm-specific asset view. Blonigen (1997) claimed that exchange rate could affect CBMA intensity when the acquisition involved purchases of firm-specific assets, which are able to generate profit in currencies other than that were used to acquire the asset. Therefore, there is no issue of profit remittance that could offset the low acquisition cost. This study reported an increase in U.S. CBMAs by Japanese firms in industries with the firm-specific asset when the real U.S. dollar depreciates. The Blonigen (1997) firm-specific asset view was supported by Georgopoulos (2008) who reported that depreciation of home country currency resulted in an increase of CBMAs in industries with firm-specific asset (high R&D intensity). Therefore, according to this view, exchange rate is relevant in explaining the variation in CBMA intensity and possibly the firm's performance.

Hypothesis Development

As stated in the previous section, exchange rate (exchange rate strength or exchange rate volatility) could explain the variation of CBMA outcome (intensity and firm's performance). Since there are numerous arguments regarding the impact of exchange rate on post-CBMAs firm's performance, it is interesting to examine the impact of exchange rate on a firm's performance, and hence, a CBMA success. This is due to the fact that CBMA success is represented by the improvement in the firm's performance following CBMA as compared to before CBMA.

This is more crucial for ASEAN firms as they are highly involved in CBMA and one of the unique and diverse characteristics of ASEAN countries is the exchange rate volatility (Rahutami, 2013). Therefore, CBMA involving firms from ASEAN countries would serve as a perfect backdrop to examine the exchange rate impact on ASEAN firms' CBMA success. Furthermore, it would provide an insight as to whether the volatility of the ASEAN countries exchange rate is advantageous in the context of CBMA success.

Contrary to Kish and Vasconcellos (1993), this study hypothesised that exchange rate will have a significant positive impact on CBMA success for both target and bidding firms. The reason is related to the high information asmmetry in emerging market such as ASEAN countries. According to Yokotaki and Kashijuku (2015), the difficulty percentage of getting reliable information from ASEAN countries is the highest (27%), surpassing India (17%) or China (14%). Hence, ASEAN bidder would utilise internal financing to finance CBMA transaction as per Froot & Stein (1991) view.

The strength of the bidding country's currency relative to the target's would result in purchasing advantage to the bidding firm (Harris and Ravenscraft, 1991; Danbolt and Maciver, 2012). This was supported by latter studies which claimed that a strong bidder's currency would result in lower price to be paid to acquire the target firm (Boateng *et al.*, 2014). Consequently, the lower acquisition price would reduce the cost of financing the acquisition (Gregory and O'Donohoe, 2014). Thus, the transaction cost involved in CBMA could be minimized, hence advantageous especially for the bidding firm performance.

Additionally, a strong bidder's currency relative to the ASEAN target country would also be advantagoeus to the ASEAN target firm. This is caused by the changes in the relative wealth of the bidder against the target, which induced the bidder to pay a higher premium (Starks and Wei, 2013). Hence, this study posits that both reduction in bidding firm's transaction cost and target firm's gain through receiving high premium would result in improvement in both ASEAN target and bidding firm's performance following CBMAs. This could ultimately Therefore, the hypotheses are:

H1: There is a significant positive relationship between exchange rate and CBMA success for ASEAN bidding firms.

H2: There is a significant positive relationship between exchange rate and CBMA success for ASEAN target firms.

Methodology

Research Design

This study intends to examine the effect of exchange rate on the CBMAs success for both ASEAN target and bidding firms. The focus of this study are CBMAs involved firms from ASEAN member countries as either target or bidding firms. The exchange rate data for the countries related to the target or bidding were collected to examine the relative changes in exchange rate. The Tobin's Q is used as a proxy for CBMAs success. The following section will discuss the data source, sample selection and the data analysis.

Data Source

CBMAs were extracted from the Thomson One Banker Database. This database has been widely used in many studies (Danbolt & Maciver, 2012; Hogholm & Knif, 2015; Song et al., 2010b, 2010a; Thenmozhi & Narayanan, 2016; Uddin & Boateng, 2011) as a source of mergers and acquisitions data. The financial data were obtained from Thomson Reuters DataStream.

Sample

The CBMA sample involving ASEAN member countries as bidding or target firms was extracted from the population of all CBMAs involving ASEAN firms in Thomson One Banker Database. This study focused on bidding and target firms from six ASEAN member countries (Indonesia, Malaysia, Philippines, Singapore, Thailand, and Vietnam) because they are the most active CBMA players in the region. The selected CBMAs involving ASEAN firms as the bidder and target were announced and completed between the years 2002 and 2013. The selection of sample ended in the year 2013 to enable the computation of long-term (three years) performance following CBMA as the proxy for CBMA success.

In addition, the CBMA deal is completed by the end of the sample period. The ASEAN bidding and target firms are public-listed companies and are not classified under financial industries. This study also excludes the CBMA in which the target completed more than one transaction in the same financial year. Lastly, the financial data in Thomson Reuters DataStream for one year prior to the completion year and three years following completion

year must be available. The total number of CBMA transactions that satisfied the sample selection criteria was 594. They comprised of 348 CBMAs involving ASEAN firms as bidder and 246 CBMAs involving ASEAN firms as target firms.

Definition of Operational Variable

CBMA Success

CBMA success is the dependent variable of this study. A CBMA is considered a success not only when it is completed, but also when it created value to ASEAN firms through an improvement in the firms' performance following CBMA as compared to before CBMA. The study by Chakrabarti et al. (2009) also used long-term performance as a proxy for CBMA success. Therefore, in this study, the changes in the ASEAN bidding and target firms' performance after CBMA are the proxy for the CBMA success.

This study utilised Tobin's Q to measure the firm's performance. Following Chung and Pruitt (1994), Tobin's Q is calculated by deflating the sum of market capitalisation, preferred stock, and total liabilities by the total asset. The change in the ASEAN bidding and target firms' Tobin's Q was calculated by deducting Tobin's Q in the financial year prior to the completion of the CBMA transaction from the average Tobin's Q of the bidding and target firms three years following CBMA completion (Wang and Xie, 2009; Jory and Ngo, 2011).

Exchange rate (EXR_{BT})

Following Ahern et al. (2015), and Danbolt and Maciver (2012), the exchange rate is the relative change in exchange rate between the bidding and target country currencies over the period of 12 months before the date of the bid completion.

Control variables

This study incorporated a few control variables (firm-specific factors and deal characteristic factors) because they are important determinants of CBMA success. These factors are firm's size (SIZE) (Martynova and Renneboog, 2008; Song *et al.*, 2010; Basuil, 2011; Du and Boateng, 2015; Sharma and Raat, 2016; Wu *et al.*, 2016), firm's leverage (LEVERAGE) (Thao Ngo, Durand and Laing, 2014), firm's financial advantage (pre-acquisition performance: ROA_{-1}) (Changqi and Ningling, 2010; Song *et al.*, 2010; Du and Boateng, 2015), transaction size (TRVLUE) (Aybar and Ficici, 2009; Bhagat, Malhotra and Zhu, 2011; Aybar and Thanakijsombat, 2015), advisor (ADVISOR) (Lowinski, Schiereck and Thomas, 2004), and relatedness (RELATED) (Corhay and Rad, 2000; Aybar and Ficici, 2009; Song *et al.*, 2010; Jory and Ngo, 2011).

Data Analysis

Model specification

To examine the effect of exchange rate on ASEAN bidder and target CBMA success, this study regresses the bidders' or target performance change (Tobin's Q) on:

$$Performance\ \ change = \alpha + EXR_{BT} + \Sigma\beta kControlsk + \varepsilon$$

Where EXR_{BT} is the relative change in exchange rate between the bidding and target country currencies over the period of 12 months before the date of the bid completion and *Controls* is the control variables.

Results and Discussion

This section presents the result of the study, beginning with descriptive statistics and inferential statistics for both target and bidding firms. The multiple regression will then be presented followed by the discussion of the results.

Descriptive Statistics

*Notes: Unstandardized coefficients are shown with standard errors in parentheses. ***, ** and * stand for statistical significance at the 1%, 5% and 10% level, respectively.*				

The regression models are reported in Table 5 (Panel A). Model 1.1 is the regression model for ASEAN bidding firms while Model 1.2 is the regression model for ASEAN target firms. Both regression models reported a

Durbin-Watson statistic of close to 2.0 and hence, there is no autocorrelation issue in the regression analysis. The heteroscedasticity issue in the estimation of the regression model is addressed using White's adjustment procedure.

Model 1.1 indicated that the coefficient for the exchange rate is negative but not significant. Therefore, this result is contrary to hypothesis H1. This is because exchange rate leaves no significant impact on bidding firms' performance, aligned with Kish and Vasconcellos (1993). However, the negative sign means that the stronger the ASEAN bidding country's currency relative to target country's currency, the lower the bidding firms' Tobin's Q change, and the lower possibility of CBMA success. This negative relationship contradicts to Froot and Stein (1991) cost of capital view.

Discussion

The negative impact of exchange rate on ASEAN Bidder CBMA success might be due to the features of ASEAN countries as emerging countries which has poor corporate governance standard (Yen, Chou and André, 2013; Lebedev *et al.*, 2015). Hence, this indicated that ASEAN bidder might pursue CBMA because of hubris. Therefore, instead of benefiting from the low cost of capital when ASEAN bidding country's currency strengthens, they might have utilised the cost of capital advantage to overpay the target firms during CBMA due to hubris. As a result, high acquisition cost negatively affects the firms' performance and CBMA success. Thus, Hypothesis 1 is not supported.

Similarly, for ASEAN target firms, Model 1.2 also reported a negative coefficient for the exchange rate, significant at 5% level. This indicates that the stronger the bidding country's currency relative to ASEAN target country's currency, the lower the ASEAN target firms' Tobin's Q change, and the lower the possibility of CBMA success. The result is also contradicted to Froot and Stein (1991) cost of capital view because according to this view, target firms are also expected to benefit from the strengthening of bidding country's currency due to a high premium paid. However, similar to the above argument for ASEAN bidder, the bidding firms might have paid a minimum premium due to the risk of exposure to inferior corporate governance standard of ASEAN target country (Starks and Wei, 2013). Therefore, Hypothesis 2 is also not supported. Table 6 summarize the hypothesis testing.

Table 6: Summary of Hypothesis testing

Hypothesis		Results	
H1	There is a significant positive relationship between exchange rate and CBMA success for ASEAN bidding firms	Not significant (Negative)	Not supported
H2	There is a significant positive relationship between exchange rate and CBMA success for ASEAN target firms	Significantly negative	Not supported

Robustness Test

Table 3 (Panel B) presents the robustness test for both ASEAN bidding and target firms, using binary logistic regression analysis as per previous M&A literature (Aybar and Ficici, 2009; Zhu and Jog, 2012; Popli and Sinha, 2014). For this analysis, the dependent variable, which is Tobin's Q change is modified to the dichotomous variable. Instead of a continuous scale dependent variable, a dummy variable of one (1) is assigned when there is positive Tobin's Q change and zero (0) when there is negative Tobin's Q change.

Model 2.1 is the regression model for ASEAN bidding firms while Model 2.2 is the regression model for ASEAN target firms. The result is consistent with the earlier regression model. In fact, the coefficient of the exchange rate for ASEAN bidding firms is significantly negative, as shown in Model 2.1. This indicates that the exchange rate is disadvantageous in influencing both ASEAN bidding and target firm's CBMA success because it has a significant negative effect on the firm's performance.

Conclusion

The popularity of CBMA as external growth strategies by firms worldwide does not preclude it from the fact that CBMA is unable to create value for the firms and thus jeopardise the CBMA success. This is due to the fact that CBMA is more challenging than domestic M&A because of the difference in target and bidding firms' country of origin. One of the main differences risks CBMA success is the exchange rate. The features of ASEAN countries with high exchange rate volatility and high involvement of ASEAN firms in CBMA raise a question if the exchange rate could have an adverse impact on the CBMA success of ASEAN firms. The results indicated that there is a negative effect of exchange rate on CBMA success for both ASEAN bidding and target firms. Both hypotheses are not supported. Nevertheless, this study provides an insight that the change in ASEAN bidding country currency relative to target country currency neither benefit nor jeopardise the CMBAs success. Additionally, the stronger the bidding country currency relative to ASEAN target country, the lower the possibility of CBMAs success. This result contradicts with cost of capital view where ASEAN target firms might have received low premium due to inferior governance standard of ASEAN countries. Hence, a more vigilant due diligence process must be executed by ASEAN firms when the bidder is from country with stronger currency. This study is limited to the impact of one factor only (exchange rate) on the CBMA success. There are more factors related to country differences, which could affect CBMA success such as geographic distance and cultural differences. Further research should be undertaken to provide an additional insight into the limited CBMA literature on the role of other country-related factors in the CBMA success.

Abstract

The diet and regularity of physical activity are two areas that determine a person's lifestyle and components of all health determinants. In turn, maintaining an individual's health at an appropriate level determines the effectiveness of his or her activities in both the private and professional sphere. The professional function of a manager is a profession characterized by high pressure of the environment, high professional mobility, high levels of stress and "non-standard" working time. The research concerned a socio-professional group of middle-level managers in hierarchical organizational systems of hospitality and sport. As a result of the sampling methodology adopted, the final sample size (GB) reached N = 107 observations. Two subgroups were identified in the study group: P1 n = 43 (sport managers/trainers) and P2 n = 67 (hotel managers/managers of four-star hotels). The selection of the sample was deliberate. Along with the increase in the assessment of the impact of diet, an increase in self-esteem of eating habits was noted (rtt = 0.391) and vice versa, the assessment of the impact of physical fitness on the effectiveness of work performed also increased (rtt = 0, 356); a strong and positive correlation was observed between opinions on eating habits and physical fitness of the subjects (rtt = 0.393); in the strong, positive and transitive correlationship relationship are also the physical fitness of the subjects and assessment of their impact on work efficiency (rtt = 0.380); the number of hours of professional work escalates the intensity of stress resulting from work (rtt = 0.359). nAs a result of our research, we can observe, in particular, that managers assess their eating habits as average. The study also showed that in the opinion of the analyzed group of respondents, the diet is determined by the effectiveness of their professional work.

Keywords: Lifestyle, Manager, Management, Sport, Tourism, Eating Habits.

Introduction

The currently growing social awareness of the importance of healthy eating and physical activity both in the private and professional life of each individual is not always connected with the realities of everyday existence. It is particularly difficult to meet these requirements for persons with high professional activity, whose specificity of work makes it impossible to maintain regularity in the way of satisfying basic physiological needs, which undoubtedly include: the need to satisfy hunger and physical activity (Maslow, 2009; Sekuła 2008). This group undoubtedly includes the managerial profession. To apply for a managerial position, a candidate must meet many requirements included in a multi-stage, often stressful recruitment process. In addition to the desired hard competences in today's managerial staff, which is reflected in appropriate education, the importance of a wide range of soft skills is increasingly emphasized, such as: charisma, diligence, availability, interpersonal skills, resistance to stress, intelligence, self-control skills, loyalty, the ability to organize both own work and the work of the subordinates, flexibility, high manners, eloquence, holistic thinking skills, entrepreneurship. Due to the complexity of all the requirements posed by the professional sphere, the managers often forget about leading a hygienic lifestyle while focusing on the perfect fulfillment of their roles on the organizational level. The physical activity and proper eating habits are considered to be one of the positive measures of human health (Drabik, 1997). The higher its level, the

Cite this Article as: Agnieszka Gorka-CHOWANIEC, Kazimierz NAGODY-MROZOWICZ And Slawomir PATERAK“ Eating Habits and Lifestyle of The Executive Managers in Hierarchized Organizational Systems of Sport and Tourism” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

better health, which is undoubtedly an important determinant of the development of efficiency and intellectual capacity, so required for the effective operation of modern managerial staff.

The issue of the influence of diet and the frequency of physical activity on the effectiveness of the work of the executives (managers) in the Polish scientific reality has only recently been recognized, which means that we cannot find many studies on this subject, therefore the authors took up the challenge of filling the gap in this area, which may become a contribution to further research in this field. In Europe, however, the issue of the diet of this professional group and its impact on the effectiveness of managers' work has been the subject of research by many scientists for many years (Hutchin, 1966; Klarreich, 1987; Lalonde, 1974).

Undoubtedly, it is worth analyzing the lifestyle of people occupying managerial positions, it is worth diagnosing health behaviors in order to be able to limit their negative effects, which may also affect the effectiveness of their goals fulfilment in the professional space.

Taking into account the above premises, the aim of this study was to identify and evaluate eating habits with particular emphasis on physical activity as a pro-health behavior in the attitudes of middle-level managers in the hospitality and tourism sector. Making use of empirical research, the authors decided to answer the following study questions: **P1** What are the eating habits of modern middle-level managers in the hospitality and tourism sector and what are they characterized by? **P2** What is the awareness of the needs and importance of rational nutrition of middle-level hospitality and tourism managers for effective managerial work? **P3** What are the attitudes of middle-level management in the hospitality and tourism sector towards physical activity? **P4** How do the surveyed managers assess the quality of their lives?

In the spectrum of the presented research issues, the following hypotheses were put forward: **H1** Taking into account the highly stressful work environment of the surveyed managerial staff and the high time absorption during the performed managerial duties, it can be concluded that work conditions significantly translate into de-escalation of pro-health behaviors, i.e. irregular meals, low quality of consumed food and a low frequency of eating. **H2** Middle-level hospitality and tourism managers are aware of the needs and importance of rational nutrition for maintaining the effectiveness of their managerial work. **H3** Contemporary managers in the analyzed sector are characterized by positive attitude towards physical recreation, although its behavioral component is not shared by the majority of the surveyed executives. **H4** The level of the quality of life in the opinion of the respondents is not satisfactory. This state of affairs should be seen mainly in the nature of their professional work, its high mobility, which does not create favorable circumstances for undertaking pro-health physical activity and regular eating.

Material and Methods

The research covered the socio-professional group of executive managers (middle-level) in hierarchical organizational systems of hospitality and sport. In managerial practice, they fulfill their socio-professional roles based on their knowledge and education, managing hotel companies or sports teams.

Employee or sports teams are directly subordinated to managers who fulfil the executive function in the organizational system in relation to hierarchically higher-placed management positions. The middle line of managers in the organizational structures of hotels and sports centers simultaneously plays managerial and executive roles, which entails duplication of roles and antagonisms of their regulations, causing work overload, psychophysical stress, or potentially even occupational burnout. An important role for psychophysical health is played by a healthy lifestyle, physical activity and nutrition, which have a secondary impact on the effectiveness of leading employee teams.

As a result of the adopted methodology of sample selection, the final size of the study group (GB) reached N = 107 observations. Two subgroups (samples) were distinguished in the study group: P1 n = 43 (sports managers/coaches) and P2 n = 67 (hotel managers/hotel executives). The process of collecting the study sample was carried out in several stages and in three channels in order to provide the test group with the appropriate level of representativeness (size and structure). The common feature that connects both subgroups (conjunction factor) (P1 and P2) is the fact that their members have education (related to sports or recreation and hotel industry) or have learned and performed a socio-professional role. It was also assumed that both these factors related to the learning process distinguish the studied group of GB from other social and professional groups. This research is therefore a contribution to planning and carrying out a comparative analysis of different professional groups in terms of eating habits and lifestyle. Due to the asymmetrical size of the P1 and P2 subgroups and their small size, no comparative analyzes were performed regarding the significance of differences in the shaping of the studied variables in both P1 and P2 subgroups.

The sample was collected purposefully using the traditional method and indirectly using the Internet. In order to select the study group, recommendations and connections in the research community were used, as well as social networks: LinkedIn, Goldenline, Tweeter and Facebook social groups: Mission Hotel, Association of AWF Kraków students, Psyche Zone of SWPS University, AWF Katowice Students + Graduates, AWF Wrocław - Academy of Physical Education in Wrocław, Personal Trainer - Katowice, AWF Warsaw, Physical Education and Sport, AWF Katowice, AWF Warsaw, AWF Kraków, Fitness Instructors - replacements/work in Silesia, Fitness Instructors' and personal trainers' work, Human capital management - mgr 2016- 2018 and Hotels.

Direct routes were taken to the following facilities: Hotel Mariacki - Katowice, Hotel Imperial Resort&MediSpa Sianożęty, "Ambassador" gastronomic service - Zabrze, Focus Hotels- Bydgoszcz, Hotel Diament S.A. Gliwice, Hotel Diament Bella Notte - Chorzów/Katowice, Hotel Krynica - Krynica Zdrój, Hotel Gołębiewski - Karpacz, Hotel Arłamów, Hotel Grand Lubicz - Uzdrowisko Ustka and Hotel Gołębiewski Mikołajki.

The e-mail channel allowed sampling from the following hotels: Hotel Amadeus - Wodzisław Śląski, Hotel Angelo - Katowice, Hotel BEST WESTERN - Katowice, Hotel Gołębiewski - Wisła, Hotel Gorczowski - Chorzów Batory, Hotel HOLIDAY INN - Dąbrowa Górnicza, Hotel Jawor - Jaworze, Hotel Klimczok - Szczyrk, Hotel Meta - Szczyrk, Hotel na Podzamczu - Tarnowskie Góry, Hotel Noma Residence - Tychy, Hotel Pałac Czarny Las - Woźniki, Hotel Pałac Kotulińskich - Dziedzice, Hotel Hotel Paruga - Bielsko-Biała, Hotel Park - Hotel - Diament - Katowice, Hotel Poziom 511 Design Hotel Spa - Podzamcze, Hotel President - Bielsko-Biała, Hotel Qubus Hotel - Bielsko-Biała, Hotel Rezydencja - Piekary Śląskie, Hotel Sahara - Bielsko-Biała, Hotel Spa & Wellness Hotel Diament - Ustroń, Hotel Stok - Wisła, Hotel Szafran - Czeladź, Hotel Zawiercie - Zawiercie and Hotel Zimnik Luksus Natury - Lipowa.

Participation in the survey was voluntary and resulted from the respondents' willingness to share their professional knowledge as well as issues related to their positions and social functions. This was thanks to the social nature of specific forums used by their participants to share their experiences and professional knowledge. Thus, the selection of the subjects was on their own accord, spontaneous and natural, which objectifies the motivation to participate in the studies and gives them credibility.

In the structure of the GB study group, there was a share of 68% of women and 32% of men aged 25-45 [98%] with higher [82%] and secondary [15%] education.

The diagnostic survey was carried out in the period from 1 June to 31 July 2018 using the questionnaire: *Dietary habits in the attitudes of managers,* which was composed of 15 mixed-type questions, from which for six were chosen for statistical verification, measured with scales: *1) assessment of eating habits, 2) assessment of the influence of eating habits on work efficiency, 3) assessment of physical fitness, 4) assessment of the average amount of sleep on working days, 5) assessment of the level of experienced stress, 6) assessment of the time-consuming work during the working day*. The questions were constructed on the basis of metric scales, which allowed for their statistical verification and further operationalization. The numerical values of the scales are as follows: for questions numbered 1,2,3,5: 0-1 - definitely wrong; 2: rather bad; 3 - wrong; 4 - rather good; 5 - good; 6 - definitely good. Numeric values for questions 4 and 6 in accordance with the content of the numerical value (e.g. 6 hours of sleep, 10 hours of work). Statistical analyzes were performed using the STATISTICA software.

Results

As a result of the research, it was possible to note several facts.

The executive managers in the surveyed organizations assess their eating habits on average at a rather good level (x = 3.9) and almost 30% of the respondents describe them as bad (see Table 1, Figure 1). They estimate that the diet influences the effectiveness of their work on average at a rather good level (Table 1). The members of the study group did not satisfactorily assess their physical fitness, describing its average level as rather bad (x = 3.3, Table 1). It should be added that the respondents showed clearly unanimous opinions in their assessments (SD does not reach the level of statistical significance in any case, cf. Table 1).

Table 1: Assessment of the eating habits and lifestyle of middle-level managers in chain hotels and sports clubs

Measuring scales	Controlled variables	Descriptive statistics of the development of the studied variables				
Question number		Not important	Average	Minimum	Maximum	Standard deviation
1.	Assessment of eating habits	107	3,981308	1,000000	6,00000	1,220743
2.	Impact of the assessment of eating habits on work efficiency	107	4,093458	2,000000	5,00000	0,852662
3.	Assessment of physical fitness	107	3,327103	1,000000	5,00000	0,798297
4.	Assessment of the average length of sleep on working days	107	6,579439	4,000000	9,00000	0,971649
5.	Assessment of the level of experienced stress	107	3,897196	1,000000	6,00000	1,106879
6.	Assessment of the number of working hours on a business day	107	7,906542	3,000000	12,00000	2,204338

Source: own study based on the conducted research

In the case of the assessment of experienced stress (question No. 5, Table 1), the situation looks a bit better, because, according to the study group, this variable reaches a rather good level.

With regard to the assessment of the length of sleep on working days, the respondents unanimously indicated its average duration as 6.5 hours and the time of managerial work as 8 hours, i.e. the numbers that are generally considered standard and not causing any surprise (Table 1).

Histogram: assessments of eating habits

Fig. 1: Distribution of assessments of eating habits

Source: own study based on the conducted research

The analysis of the interdependence of the studied variables showed the existence of a number of interesting and, most importantly, statistically significant, correlation relationships between the assessments of the test group, which

will be listed for order and clarity in points (Table 2). Due to the limited amount of space, the following conclusions will be presented that best illuminate the research issues of the conducted analysis:

- *as the assessment of the influence of eating habits increased, the self-assessment of eating habits increased* (rtt = 0.391) and vice versa, *the assessment of the influence of physical fitness on the effectiveness of work performed* (rtt = 0.356) also increased,
- strong and positive correlation was observed between the opinions on *eating habits and physical fitness of the respondents* (rtt = 0.393),
- *physical fitness of the respondents and the assessment of their impact on work efficiency* is also in strong, positive and transitive relationship of interdependencies (rtt = 0.380),
- *the number of working hours escalates the intensity of stress resulting from work* (rtt = 0.359),
- *the intensity of occupational stress and the assessment of eating habits* (rtt = -0.292) as well as the amount of work during the working day (rtt = -0.299) were found in a statistically significant and negative correlation, which means that involvement in work limits the possibility of working out healthy eating habits,
- in the respondents' opinions, no statistically significant correlation was found between *the level of stress intensity and the time devoted to sleep* (rtt = -0.113) as well as between *the duration of sleep of the respondents and the development of eating habits* (rtt = 0.052).

Table 2: Spearman rtt rank test results in the study of eating habits and lifestyle of the studied group

Source: own study based on the conducted research

The test of means against a fixed reference value showed that the values of the analyzed variables: 1) assessment of eating habits, 2) assessment of the influence of eating habits on work efficiency, 3) assessment of physical fitness, 4) assessment of the average amount of sleep on working days, 5) assessment of the level of experienced stress, 6) assessments of the time-consuming work during the working day *reached statistically significantly higher values than the fixed reference value.*

Summary

Nutritional awareness is the sum of knowledge about the principles of healthy eating, appropriate technological processing of food products and the method of storing food products, which will ensure the consumer the least possible loss of valuable nutrients in a balanced daily diet.

In the literature on the subject, there are no unequivocal reports on research that would give real recommendations for determining the level of nutritional awareness of consumers, taking into account their professional roles (at the managerial level), which is an indicator of the quality of their professional life (with particular emphasis on the effectiveness of their work), which at present is undertaken not only in the philosophical, psychological, sociological and economic context, but also in the field of medical sciences and health sciences (Kowalska, Szemik, 2016).

In view of the above arguments, it is worth emphasizing that the results of other authors quoted below will refer to the holistic dimension, however, according to the authors, they give the opportunity to make comparisons in the analyzed area and to draw constructive conclusions.

The results obtained by the authors in the course of the conducted research fill the gap in scientific reflection in the area of the discussed issues while finding confirmation of the trends obtained in other national and international studies. The results of the health survey conducted by the National Institute of Public Health - National Institute of Hygiene indicate that no voluntary forms of physical activity for at least 30 minutes continuously) are undertaken by as many as 59.2% of Poles (57.2% of men and 61.0% of women) (Wojtyniak, Goryński, 2018). Additionally, there is a strong correlation between the level of physical activity and the level of education. For example, people with secondary or lower educational level (80.8% of respondents) have little physical activity, while as for the higher educational level this percentage is much lower (only 36.1% of respondents declare lack of physical activity)

(Wojtyniak, Goryński, 2018). In addition, the results of the 2017 Eurobarometer survey show that only 7% of EU residents aged 15 and over regularly (5 times a week or more) play sports or engage in other physical activity (TNS Opinion & Social, 2017). Taking into account the above research results, the authors expected that the surveyed managers with undoubtedly higher education would declare a higher level of their physical fitness. Meanwhile, members of the surveyed group of managers did not satisfactorily assess their physical fitness, additionally defining its average level as "rather bad" (x = 3.3). When analyzing the obtained results, a clear unanimity of the respondents in this respect is also visible (the SP does not reach the level of statistical significance in any case). The obtained result is undoubtedly not very optimistic, taking into account e.g. the fact that, according to the latest Global Disease Burden Study (GBD Study 2017), low levels of physical activity in Poland are responsible for the loss of 1.7% of health years (DALY) (Institute for Health Metrics and Evaluation, 2020). With regard to the surveyed population of managers, characterized by high professional activity and responsibility not only for themselves, but also for their subordinates, high absenteeism at the workplace may significantly affect the effectiveness of the work of an individual, team and the effectiveness of the entire entity they manage.

When analyzing the variable that takes into account the level of experienced stress declared by the respondents, the reader may notice that, in the opinion of the respondents, this variable reached a rather good level (x = 3.9). This state of affairs should be considered very favorable, but it may be somewhat surprising, given the prevalence of the stress epidemic (Marino, 1997). This state of affairs may result from the specificity of the professional role played, the content of which is related to tourism and sport. Perhaps managers in sports and hospitality would like to be seen through the prism of their role as physically fit, healthy and stress-resistant. The results of the research indicate, however, that 88% of managers declare that they achieve high levels of stress at work (Tillson, 1997). How is it possible that the stress level of the respondents was assessed as relatively good. The rational explanation of the obtained research result may be related to the aforementioned self-assessment mechanism. The research entitled "Stress at work", conducted by Pentor Research International in 2007, showed that as many as 85% of professionally active Poles experience stress at work, therefore, the obtained results cannot be clearly interpreted in terms of the assessment of the experienced stress. On the other hand, however, it should be taken into account that the members of the study group are graduates of a field of study that requires increased physical fitness and teaches how to care for health.

The results concerning the length of sleep of the respondents on the days of their professional activity (from Monday to Friday) show that the average duration of sleep varies at the level of 6.5 hours, while the managerial work time is at the level of 8 hours.

According to Carl Hunt, director of the National Center for the Study of Sleep Disorders, sleep is one of the main factors, along with exercise and diet, in maintaining good health. The sleep disorders are the third reported complaint, after headaches and symptoms of colds. They become more common as you get older due to many factors. With age, the organism becomes more sensitive to hormonal changes, physiological functions, many environmental factors (light, noise, temperature) (Bizan, 2011).

The research conducted in the USA showed that approximately 20% of respondents sleep 6 hours or less, 33% - 7 hours, 38% - 8 hours, and 9% - 9 or more hours (Cieślik-Guerra, 2009).

Based on Polish studies, it can be concluded that the average number of hours of sleep in adults in the country is 7 hours and 22 minutes, which is more or less the same as in the study group (Sykut et al., 2017).

The results concerning the eating habits of the respondents turned out to be slightly more optimistic. The surveyed managers assess their eating habits at a rather good level (x = 3.9), which allows the authors to classify this result to the average level of accuracy of the results. Additionally, it is worth emphasizing that almost 30% of the respondents describe their eating habits as bad (Table 1). Taking into account the second result, according to the authors, in order to increase the nutritional awareness of the surveyed group of respondents, their knowledge should be expanded in terms of:

- the content of nutrients in the daily food ration consumed (e.g. proteins, fats, carbohydrates, vitamins, minerals).
- the number of meals recommended in daily food rations and the time horizon in which they should be eaten.
- pro-health value (e.g. the presence of functional products in the diet or dietary supplements in the case of diagnosed deficiencies).
- principles and awareness of the use of diets appropriate to the physiological state of a given organism.
- recommendations on how to store food products at home,
- rules for preparing meals (with particular emphasis on hygiene),

- awareness of the existence of organic, low-processed and low-calorie food,
- the essence of exercise as the most important element in addition to a balanced diet in our daily life.

The knowledge of the essence of a healthy lifestyle, including the principles of rational eating, is essential in the process of shaping correct eating habits (Chlebna-Sokół, Zbęk, Sobczak, 2007). The report of the Public Opinion Research Center (CBOS) (Health and pro-health behavior of the Poles, 2016) of 2016 on the knowledge of Poles about health shows that the awareness of the need to take care of health is systematically and significantly growing among the public. The percentage of respondents who notice the increased interest of Poles in taking care of their own health has more than tripled compared to 1993 (from 19% to 64%). The percentage of persons who declare that they care for their own health is also systematically growing (it has increased by 27% since 1993).

On the other hand, when asked about the types of activities that, in their opinion, determine the health level of an individual to the greatest extent, they most often mentioned: healthy eating, which, in the opinion of the respondents, is associated with the consumption of large amounts of vegetables and fruit and limitation in the daily diet of animal fats (48% of respondents), regular visits to the doctor (30% of respondents), avoiding nervous and stressful situations (30% of respondents) and spending free time on active leisure activities (27% of respondents)[1].

Reflections in the area of theoretical and empirical considerations related to the area of eating habits can be conducted on many levels. The most important ones mentioned by the authors are: consumer behavior, an element of culture, hierarchies of values passed down from generation to generation, adherence to norms and rules as an important area of pro-health behavior conditioning longevity. An improper nutritional attitude of an individual may contribute to the emergence of a number of factors that increase the risk of diet-related diseases, in particular cancer. As indicated by the authors: M. Wiszniewska et al., the most important were those related to the inappropriate lifestyle, incl. improper diet, obesity, lack of physical activity, smoking or alcohol abuse (Wiszniewska et al., 2018). The results are confirmed by the list of three risk factors responsible for the loss of the largest number of years lived in health presented by the Institute for Health Metrics and Evaluation, namely (Institute for Health Metrics and Evaluation, 2020):

- diseases arising from improper nutrition,
- food of inadequate health quality,
- negligible physical activity.

Incorrect eating habits, high professional mobility, work under constant stress undoubtedly have an impact on the health condition of modern managerial staff, and determine their tendency to absenteeism and at the same time reduced efficiency of the entire enterprise. This thesis is confirmed by the results of the study obtained by the authors, in which the respondents indicated that the diet may significantly correlate with the effectiveness of their work and thus affect the quantitative and qualitative dimension of their goals ($x = 4.09$). Although it may seem that employers do not have a direct influence on the shaping of the diet of their subordinates, they can organize the work space of individual members of the organization in such a way as to enable the appropriate shaping of eating habits. J. Kwiecień points to three factors, the simultaneous occurrence of which may become allies in shaping pro-health attitudes of an individual, namely: (Kwiecień, 1019):

1. Awareness of the need for change (training, dietary consultations, educational leaflets).
2. Availability of healthy products.
3. Regularity (both in the educational process of employees and the availability of healthy products in the company).

In addition, the results of research conducted by the Health Enhancement Research Organization clearly indicate that the employees who have healthy eating habits (i.e. regularly eat healthy meals) are characterized by 25% higher productivity at work compared to persons who do not exhibit these habits. (www1).

At this point, the reader is asked the question: what steps in the field of promoting health, healthy eating and increasing physical activity can be taken in contemporary organizational spaces? According to the authors, an effective solution in this regard may be Entrepreneurial Programs for the Promotion of Healthy Eating and Physical Activation of modern managerial staff, the initiation of which should include several stages:

[1] The study was conducted using the method of computer-assisted face-to-face interviews on 8-15 September 2016 on a surveyed sample of 981 adult Polish residents (Health and pro-health behaviors of the Poles, 2016).

STAGE 1 Appointing a team and developing a strategy for the Program of Promotion of Healthy Eating and Physical Activation of the managerial staff.

STAGE 2 Integrate the program strategy into the overall corporate strategy and treat it in the long term.

STAGE 3 Implementation of activities under the program, taking into account a number of initiatives (including *in the area of shaping correct eating habits*: dietary platforms, health week/healthy day, scientific articles on nutrition published on the company's website, dietitians' advice, 24/7 medical care, generally available water dispensers, regularity of meals during employee duties performance, time to eat breakfast, employee canteens with healthy food; *in the area of physical activation:* multisport cards, initiating enterprising sports teams, e.g. football, running, cycling teams, etc.), mobile bicycle service or a calendar of preventive activities.

STAGE 4 Efficient and effective communication process in the area of initiatives undertaken within the program with the use of internal mail, e.g. Intranet.

STAGE 5 Development of mechanisms motivating management staff to participate effectively in the program.

STAGE 6 Continuous improvement of the quality of pro-health activities of the company with the use of ongoing control and implementation of possible corrective programs.

As we can see in the presented analytical materials on the economic effects of health-promoting activities of those companies that have already implemented similar programs, the benefits that the employer obtains on this account entail a return on investments made in this area (Goetzel, 2014; O'Donnell, 2014) .

The research results presented in the article are not without limitations. The authors of the study are aware that the analyzed group was relatively small (n = 107) and the presented results are selective.

Conclusions

As a result of the research, it was observed that the managers assessed their eating habits as normal, not deviating from the average social trends. The research has also shown that, according to the sports and hospitality managers, the diet influences the effectiveness of their professional work. However, the members of the study group did not assess their physical fitness as satisfactory, describing its level as low. They indicated that the number of hours devoted to professional activity during the day increases the intensity of stress resulting from work.

The conclusion that the employers of the management cadre of the studied socio-professional group should put more emphasis on the issue of developing healthy eating habits may sound somewhat truistic.

Despite the observed interest in the above-mentioned issues, unfortunately, there are still no current results of the research analyzing the eating habits and lifestyle of sports and tourism sector managers (at least the authors of this study did not find any), and thus there are no specific recommendations on how to increase awareness of nutrition in organizational structures among middle-level managers and how to activate them to greater physical activity, with particular emphasis on the inter-organizational space.

Managing the human capital of an organization is mainly based on shaping the right and desired employee attitudes, among which there should be room for aspects of a hygienic lifestyle. One of the important areas of the management is the development and improvement of employees through properly planned training methods and techniques.

Summarizing the above considerations, the growing social awareness of the importance of proper nutrition is not always confirmed in the sphere of its professional activity. Therefore, the challenge is to build a strategy for the development of enterprises in the sports and tourism sector in such a way that its important pillar, the pro-health aspect of the individual is taken into account, bearing in mind that the shaping of the correct eating habits is influenced by three dimensions of the environment, including the working environment (Figure 2).

Abstract

This paper examines gender-based perception and lifestyle of megamall patrons in Ibadan metropolis of Nigeria. Gender is viewed as a socially constructed ideas about the role of an individual in the society. Megamall shopping has been regarded has a female activity due to their insatiable characteristics of placing wants above need. Women have the tendencies to patronize megamall for groceries and personal treat because they are hedonic in nature. While men are specializing in utilitarian valued items. However, this world views are getting phased out as societal activities and roles are not restricted to only one gender. Two hundred and sixteen respondents were purposively selected from five different megamalls and responses in the questionnaire were analyzed using descriptive statistics and independent sample t-test to show the differences based on gender. The result shows that men visit malls but solely for recreations purposes, while women perceive megamalls as a place to shop, relate, sight-see, talk, relax, beautify and emotionally-lean on women driven life values. It has clearly shown that megamall patrons have average level of perception of megamall. Also, there is significant difference between male and female shoppers in megamall. It was also discovered that megamalls, among others provide a platform for social interaction where people enjoy their leisure activities. It was therefore recommended that there should be a public enlightenment campaign programme to negate the notion that male folks hardly frequent megamall and make purchases. They should be treated as viable customers like their female counterparts.

Keywords: Gender, Perception, Lifestyle, Megamall, Patrons, Nigeria

Introduction

It has been historically documented in the nineteenth century that urban life for male was separated from their female counterpart. This opened a line of thought on gender perception of viewing mall centres. The split in between male and female world led to mental and emotional representations of gender world and activities. Due to

Cite this Article as: Olawale Y. OLONADE, Dauda A. BUSARI, David IMHONOPI, Tayo GEORGE and Christiana O. ADETUNDE "Gender-Based Perception and Lifestyle of Megamall Patrons in Ibadan, Nigeria" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

this purchasing and shopping power which shifted from one male directional route to a 'female thing' due to their insatiable characteristics of placing wants above need (Vijaya, Niharika, and Lahari, 2017). Female folks began to build activities, formulate identity and demonstration of shopping behaviour which gave birth to modern interest to the establishment of malls in nooks and crannies of the society (Olonade, Busari, Iruonagbe & George, 2020). Mega mall is growing at a rapid and significant pace in Nigeria but still evolving in some parts of the country. The essence of megamalls originated from the variable choices that people make. People love to live a serene, urbanized, safe and secured environment which depicts oneness and totality (Busari, Olonade & Asamu, 2019).

Megamalls provide utopian world with comfort which embodies experiential values. They accommodate social meanings and create social values and image. The advent of mega shopping malls tends to show a high dichotomous divide between gender- male and female folks. Shopping is an everyday commercial activity which allows for social dimension, practices, interest, perceptions and consumptions (Busari, Olonade & Asamu, 2019). It is a reflection of lifestyle which offers social relations. According to Miller (1998), purchasers assemble around items which characterize their personality and move toward becoming highlights of specific schedules of amiability. Hence, mega malls proffer plausible leverage for identity, needs of people and social space. In this vein, literatures have shown that megamalls, recreational and film centres are enmeshed with the presence of female folks more than their counterpart – males (Dholakial and Uusitalo 2002; Osibanjo, Ibidunni, Jevwegaga, Olokundun, Obaoye, and Adebanji, 2019).

Authors and scholars have opened a line of thought on gendered perceptions about the concept of shopping and megamalls. Some schools of thoughts believe there are separate worlds for male and females with peculiarities to needs, wants and recreations ascribed to them according to the society. The importance of gender-factor in mall shopping cannot be over-emphasized. As noted by Vijaya *et al.,* (2017), differences in socialization and upbringing of men and women will ultimately influence their shopping behavior. The quest to get, retain and serve customers to the fullest is increasing, so goes for patrons and shoppers. There is a shortage of literature that shows significant differences in shopping behavior between gender. Shopping has been viewed as women's activities from different quarters. They are more likely to be shopping for food and personal treat while their male counterparts are likely to be shopping for valued and productive. However, these is gradually phasing out as their role is gradually connecting and overlapping. It became an issue for reference to understand the impact the development of mega shopping has on people, male and female as well as the decisions they have formed over time.

Thanaraj (2011) affirmed that mega mall styles have many added features to attract shoppers. Mega malls are putting up measures to assessing consumers' behaviours, loyalty, interest and services so that they can easily be lured from small street stores. Gender difference on its part, is an external influence on consumers' behaviour. In the works of Alreck and Settle (2002), Dholakia and Uusitalo (2002), there has been dossier of information on gender differences such as in message processing, price promotions, impulse purchases, advertising and responses towards the different shopping forms.

Sohail (2015) attests that way of life grasps social association, economic wellbeing, family foundation, identity, inspiration, discernment, and advertising upgrade, which can be recognized by a wide scope of exercises, interests, and sentiments. The shopping courses of action and examples of exercises in which customers invest their energy and cash delineates their way of life just as structure their discernment. Shopping orientations extended to incorporate individual, financial, social and recreational attributes of customers (Visser and Du Preez, 2001). Gem (2001) and Mattew, Osabohien, Olawande and Urhie (2019) sees that megamall turn into an advantageous direction for living that concentrates alluring components of utilization inside a solitary defensive and clear condition. Megamall portrays and offers itself as an option in contrast to the downtown area with offices and feeling to make customer exercises thrilling ones where relationship, unwinding and shopping interlaced in a verified domain (Olonade et al., 2020).

Megamall experience depicts knowledge of, or skills that relate to megamall shopping events which one gains through involvement with those particular events. As far as gender and mega mall are concerned, studies have examined shopping mall patronage and its effects on gender in developed countries, but there is a dearth of study in Nigeria and especially in Ibadan. The way things are, the theme's understanding has remained setting explicitly restricting shopping center support information in creating nations like Nigeria dependent on sexual orientation. And it is apparently important to look at it in relation to some other variables in order to have a rooted understanding of the correlation between gender and megamall shopping. Here, the study added perception and

lifestyle and report the differences. It is against this backdrop that the study tries to look into gender-based perception and lifestyle of patrons in some selected megamalls in Ibadan metropolis.

Study Objectives

i. To examines patrons' perception of megamalls and shopping activities
ii. To ascertain gender differences in megamalls and shopping lifestyle

Conceptual Review

The Concept of Gender

Gender depicts an attribute which constitute masculine or feminine in the society. a persons' gender symbolizes his or her sex whether female or male as biological evidences outlines in many society characterizes sexual orientation as the consequence of socially built thoughts regarding the conduct, activities and jobs a specific sex performs (World Health Organization, 2010). These convictions, qualities, and frame of mind display demonstrate the general public's pleasant and satisfying standards and the individual's genuine beliefs. They are learned from various intersecting sources such as parental influences, a child's socialization in school, and what is depicted in the media is of paramount importance to gender awareness growth, the role to be played, and world view. To fully understand the assignment of gender, the physiological and biological attributes assigned by nature must be taken into account, followed by socially constructed behaviour. Gender obviously involves a wide range of characteristics related to and distinguishing between masculinity and femininity on the basis of these characteristics; biological sex (variation of male or female or intersex), gender- and gender - based social structures.

Gender and Megamall

Among various demographic characteristics, gender is one of the sorts after variable when assessing difference in shopping behaviour. It was seen and perceived that shopping was mainly a gendered activity or directly a "female type" task. In today's big societies, gender roles have changed, studies have shown differences in gender shopping behavior (Otnes and McGrath, 2001; Kuruvilla and Ranjan, 2007). There is vested interest to attract and retain customers and this is increasingly alarming among mega malls. There is dearth of literature that shows staunch difference in shopping behaviors of both gender. Even when shopping is misconstrued to be female activities, men go shopping as well. Women shop more for items such as food and clothing, while men are driven by utilitarian values (Chebat et al, 2005). Nevertheless, as the roles of men and women in society begin to intertwine, these trends are fenced out. Gender peculiarities are a consumer behavior external influence.

According to Klein (1998), 67% of women enjoy shopping compared to 37% of men. Yin (2003) found that women are more likely than women to buy in-store gifts. It was also found that women go shopping to see and browse shopping as a pleasant adventure while men go shopping in Durakbaşa and Cindoğlu, 2002, just to meet their needs. Kuruvilla et al. (2009) and Hawkins et al. (2009) classify buyers and employers as functional, recreational and browser buyers in three broad categories. Functional shoppers are those who mainly visit malls to make purchases with utilitarian shopping motives. Browsers and leisure activities visit the malls without proper plans, but only in the window shop. When interest or appetites are whetted, recreational buyers come to the mall for leisure and browser shops. This paradigm is used because gender-based shopping perceptions are clearly distinguished.

Gender-Based Perception of Megamalls Shopping

There are many factors that can influences the interest in megamall shopping, one of it is gender. In addition, countless studies have been performed on the patronage of shopping malls and the associated enjoyment of customers ' shopping experience. Shopping activities is usually approach by men and women with diverse intentions, perceptions, reasons and contemplations. Literature has shown noticeable differences in men's and women's behaviour, shows attitude and perceives megamalls and shopping. It is apparently clear that men and women think differently about their interest and worldview of megamall patronage. Hence gaining understanding and full knowledge of these gender-based tendencies and perceptions is sacrosanct to the mall owners and the growth of economy in the business world.

Kotze, North, Venter and Stols (2012) carried out a study on gender differences in source of shopping enjoyment. Research has identified different sources of shopping pleasure as socializing shopping, shopping, gratification, entertainment, shopping for others, browsing, exercising, and sensory stimulation. The study's main objective was to investigate gender differences in shopping enjoyment experiences. For the study, self-administered questionnaire was used and findings show gender differences in all shopping enjoyment except for entertainment shopping.

Also, research has shown that perception, purchase, interest and lifestyle of patrons and shoppers are all in the brain. Men are seen to be on a mission, while women are seen to be on a journey (Alreck and Settle, 2002). That is men visit or make purchase in shopping megamalls for specific reasons and not a generic mission like the women folks. A research-based platform, Scientific American, argues that there are numerous physical and noticeable differences between men and women. It was collected through the World Health Organization that women have a thicker callus corpus, the nerve tissue bridge that connects the brain's left and right side. It enables women to use both sides of the brain to solve problems faster, whereas men mainly use the left side of the brain. The left hemisphere carries out logical calculations and processing facts, while the right hemisphere dominates visual imagery and context interpretation. They also use more organized cerebral cortex to perform tasks, whereas men on the left brain use more gray matter. The different brain structure in the shopping language leads to men who tend to be mission-oriented and task-oriented buyers, whereas women are more likely to be discoverer-oriented buyers who readily adjust their goals if a more satisfactory result is achieved by the world. A study conducted by the Mediterranean Journal of Science (2017) indicates that men have an ulterior motive for shopping for utilitarian, whereas women are hedonic. The study shows that customers have different ranges of fundamental drives that activate their shopping behaviors and attitude. It is utilitarian when a intended consequence is consciously pursued. To get some things done, that's shopping. Men tend to follow a more logical, utilitarian approach. They need consumer education that is sufficiently convincing as to why in the megamall they should visit or buy an item. When it is associated with intrinsic and extrinsic responses, it is hedonic. Women, because they love it, shop or visit megamalls. Most of them are hedonic shoppers. They want to know more about a product, the brand, the lifestyle being sold, and how it will make them feel about the product or their presence in the mall. Zappos.com summed up that men focus on clear product category (megamall) navigation while women are emotionally driven.

A study on the perceived quality of online shopping was conducted by Sebastianelli, Tamimi and Rajan (2018). In their perceptions of factors affecting the perceived quality of online retailers on gender differences, data from a sample of U.S. consumers are examined. Factor analysis is statistically derived from seven electronic retailers (e-tailing), dimensions of quality (reliability, accessibility, service ordering, convenience, product content, assurance and credibility). Insurance has been found to be far more important to women than to men. It was also found that there are no gender-based differences in the frequency of online browsing or purchasing, but there are differences in product types that women and men prefer to buy online and at mega malls.

Shopping centers have grown as a result of rapid developments in the food retail industry, particularly in large cities in Saudi Arabia. Sohail (2015) looked at mall shopping's gender difference; a study of an emerging nation's shopping behavior. The aim of the study was to compare men and women for mall shopping differences. The study uses empirical research to examine differences between genders related to mall patronage. Based on a survey of 513 shoppers across Saudi Arabia, the study found significant differences in shopping behaviors.

Theoretical Framework

This study hinges on two theories; William Glasser’s Choice theory and Henri Tajfel and John Turner’s Social identity theory in 1979.

William Glasser’s Choice theory

Choice theory posits behaviour that one chooses are central to his/her existence. Five cardinal needs drive one’s behaviour: love and belonging, freedom, fun and power. While survival needs include food, clothing, shelter, respiration, personal safety, safety, and sex, children. Glasser has four fundamental and psychological needs: power / significance / competence; freedom / autonomy; and fun / learning. The theory of choice suggests that an individual's existence depends on a conscious comfort zone and role models of a perfect world of parents, relationships, possessions, beliefs, etc.

Social Identity Theory

Social identity theory submits that a personality largely depends on the group they belong. The theory was postulated by the two British social psychology Henri Tajfei anf John Turner in the year 1979. It depicts that individual self-concept, belief, persuasion is derived from membership of an organization. It relates the study of the interplay between personal and social identities. It promotes a common identification with a collective or social category that creates a common culture among the participants involved. Tajfel (1979) submits that group serves as one of the important pointer to source of pride and self-esteem.

Theories application to the study

Gender has connection with specific social roles and expectations. The concept of being a woman has a great deal to do with their system of choices, values and beliefs. The group one belongs to tends to influence the life and perception of one's own. This group of individuals belongs to give them a definition of who they are and how in the social sphere they should behave. The classification of male and female into social roles therefore creates problems because people feel they must be at one end of the spectrum and identify themselves as men or women. Overall, communities interpret biological differences between men and women to create a set of social expectations that define men and women's appropriate behaviors and determine the different access to women's and men's rights, power, resources, social power, shopping and lifestyle. The social roles of men and women in relation to each other are based on societal cultural standards that lead to the creation of a gender system. In many societies, the gender system is the basis of social patterns that include gender separation and the primacy of male standards. But in terms of mega mall patronage, females are likely to still lead because of their insatiable desire motive, which does not necessarily mean need.

Methodology

Data were obtained through questionnaire administration and secondary sources (different reviews of related studies from various published and unpublished records, reports, books, journals, and magazines). The questionnaire consisted of questions related shoppers' demographic characteristics, frequency in megamalls and perception of users about shopping. Five (5) different malls in Ibadan with two hundred and sixteen respondents (male and female) were employed for the study. Independent sample t-test, Percentage, Mean and Standard deviation was used for the study.

Table1: Demographic representation of respondents in the study

Age	**Frequency**	**Percentage**
15-24	83	38.4
25-34	101	46.8
35-44	18	8.3
45-54	8	3.7
55 and above	6	2.8
Total	**216**	**100**
Gender	**Frequency**	**Percentage**
Male	120	55.6
Female	96	44.4
Total	216	100
Level of Education	**Frequency**	**Percentage**
Primary	3	1.4
Secondary	16	7.4
Tertiary	173	80.1
Others	24	11.1
Total	216	100
Monthly Income	**Frequency**	**Percentage**
Less than #20,000	42	19.4

#20,000-40,000	70	32.4
#40,000-60,000	33	15.3
#60,000-#80,000	21	9.7
80,000 and above	50	23.2
Total	**216**	**100**
Type of residence	**Frequency**	**Percentage**
Single room	51	23.6
Self-contain	45	20.8
Two bedroom	99	45.8
Three bedroom	19	8.8
Others (please specify)	2	0.9
Total	**216**	**100**

Authors' survey, 2019

Table 1 shows the demographic distribution of respondents. Based on age; 46.8% respondents fall between 25-34 age intervals which has the highest frequency while 2.8% falls between 55years and above. On gender, 120 of the respondents were male and 96 of the respondents were female. This implies that majority of the respondents are male. On level of education, 80.1% falls in the category of tertiary level of education and ranked the highest while, 1.4% only had primary education. This implies that virtually all of the respondents are highly education and knows the important of a mall. On monthly income, 32.4% respondents earn between #20,000--#40,000 which serves as the highest frequency while 9.7% respondents earn between #60,000-#80,000. This ranked the least among monthly earners in the study. On the type of residence, 45.8% respondents live in at least two bedrooms flat while only 0.9% lives in other forms of accommodations. They both ranked highest and least in the distribution. By implication, respondents can afford a decent accommodation to live it which could translate their status to buying from mall.

Research Questions

RQ1: How do megamall patrons and shoppers perceive megamall?

Table 2: Shows perception of megamall patrons

Items	SA	A	D	SD	M	SD	P
I like megamalls	142 65.7	45 20.8	21 9.7	8 3.7	2.89	1.038	Ist
I see it as an avenue to un-mind and mingle	118 54.6	69 31.9	11 5.1	18 8.3	2.48	.993	7th
Hardly can one have access to needed items	10 4.6	51 23.6	49 22.7	106 49.1	2.77	1.061	2nd
It is meant for rich families most especially women	12 5.6	17 7.9	91 42.1	96 44.4	2.56	.985	6th
Megamall does not provide a serene and secured atmosphere	39 18.1	47 21.8	98 45.4	32 14.8	2.67	.989	4th
Customer service relations is second to none	121 56	15 6.9	58 26.9	24 11.1	2.77	1.031	3rd
Megamall exhibits efficient service delivery which is better than street vendors	65 30.1	57 26.4	45 20.8	49 22.7	2.67	.954	5th
There is price reduction service which is better than street vendors	76 35.2	91 42.1	33 15.3	19 8.8	2.48	.979	8th
					Grand mean: 2.67		

Source: Author's survey, 2019

Table 2 shows that majority of respondents indicated that 'I like megamalls' (χ = 2.89) and 'Customer service relations is second to none' (χ =2.77). These were ranked first and second respectively among students. Conversely, 'I see it as an avenue to un-mind and mingle (χ=2.48) and 'There is price reduction service which is better than street vendors' (χ=2.48) were ranked least. It has a grand mean 2.61.

Test of norm conducted was conducted on the perception of patrons in megamalls. The maximum scores for a respondent on 8 items scale above is 32 (8 x 4), that is, the number of items on perception scale multiplied by number of possible response. The level thereof is three which are high, average and low level of perception. Therefore, to establish an interval score the maximum score was to be divided by the number of levels which is (32/3) = 10.7. Therefore, an interval score of 11 was used to chart the norm table.

Table 4.1. Test norm table on patrons' perception of megamall

Interval	Total mean score	Remark (Perception level)
1 – 11		Low
12 – 22	21.29	Average
23 –33		High

Thus, the overall mean score of the patrons' perception of megamalls is 21.29 which fall within the interval distribution of 12-22. It has clearly shown that megamall patrons have average level of perception of megamall and shopping lifestyle.

RQ2: Is there is any significant difference between patrons' perception of megamall shopping based on gender (male and female)?

Table 3: Independent sample t-test analysis of difference in the perception of male and female to megamall shopping

Variable (patrons' perception of megamall shopping)	N	Mean	Standard Deviation	Df	t	Remarks
Female	120	24.20	5.029	223	12.164	.000
Male	96	23.70	5-054	222.808		

Source: Authors' survey, 2019

There is significant difference in the perception of male and female shoppers in megamall.

Summary and Conclusion

Over the years, shopping has been seen as gendered activity. Majority of shoppers today are women and their numbers are increasing so goes for their taste. They tend to shop more than men for items like for items like groceries, beauty cares and clothing materials, men on the other hand shop for automobiles, shirt and house appliances especially electronics. This belief is getting out of place and there has been role reversal. Even choices are becoming global and the narrative is changing. In this present world, personalization is the key which makes businesses and institutions like burgeoning megamalls in Ibadan are keeping abreast of the fact that gender has a role to play in patronage**.** Megamalls' effective operation lies with customer engagement, conversion and loyalty which is devoid of separation or bipolarization in consumerism.

Recommendations

The following recommendations are made to guide gender related research as well as serve as template to changing the narrative of non-empirical views of

i. There should be a public enlightenment campaign programme to negate the notion that male folks hardly frequent megamall and should not be treated as viable customers. The only difference between male and female shoppers is the time used in the mall and what was used for.
ii. Megamall should provide itself with opportunities for all and sundry. Dividing sections and structure for patrons may likely cause gender discrimination and division in thinking patterns as per shopping.
iii. Since megamalls provide avenue for relationship building and interaction among people of different background characteristics irrespective of age, gender and tribe. It is of paramount importance to
iv. Though ostentatious life of patrons most especially women propelled the perception that is making the round, hence there is need for more megamalls as it provides irrespective gender with choice of materials and products, business, relations and pleasures.

The Impact of Information Technologies on Reducing Poverty in The Context of COVID-19

Agnieszka SZEWCZYK

University of Szczecin, Szczecin, Poland
agnieszka.szewczyk@usz.edu.pl

Abstract

Poverty is one of the most disturbing issues in the world. This problem touches virtually everyone since poverty has many faces and it has particularly intensified now, amid the COVID-19 pandemic. Preventing its causes and minimizing its effects is a great task for each of us. Appropriately selected information technologies may be helpful, because they can be fine-tuned to answer the needs of the poor. This article defines poverty very broadly, as various shortages or an inability to fulfil one's needs – not only the "traditional" ones, such as hunger, thirst, cold but also loneliness, that is the absence of another human, ill health, unemployment, or lack of education, proper living conditions, information…

This article is an answer to this challenge. It presents an overview of various types of poverty, their causes and results, and a wide range of information technologies. This data was then used to procure, with the use of an innovative C-E-T (cause – effect – technology) method – based on Gittman-Levine's algorithm and with the use of a method of similarity matrix construction – groups of information technology offers (applications, Internet services, software systems, etc.) which address the needs of the poor who experience the effects of poverty in various areas of life and for various reasons.

Keywords: Poverty, Causes, Effects, Information Technologies, COVID-19.

Introduction

The creation of information society – even though we can all glorify the technological development and all-embracing improvement – is also plagued with a number of disturbing issues. One of the most significant ones is poverty (see Weber, 2007, pp. 437-445; Ringold, 2007, pp. 10-15; The Social, 2008; Tilak, 2007, pp. 430-435).

„How can it be that even today there are still people dying of hunger? Condemned to illiteracy? Lacking the most basic medical care? Without a roof over their heads? The scenario of poverty can extend indefinitely, if in addition to its traditional forms we think of its newer patterns. These latter often affect financially affluent sectors and groups which are nevertheless threatened by despair at the lack of meaning in their lives, by drug addiction, by fear of abandonment in old age or sickness, by marginalization or social discrimination (…).

At the beginning of the new millennium, the poverty of billions of men and women is a problem that more than anything else challenges our human and Christian conscience" (John Paul II, 2001, p. 2).

This article is an answer to this challenge. It presents an overview of various types of poverty – starting with "traditional" financial poverty, through information poverty (also known as digital exclusion), ending with moral poverty – and it also offers certain solutions to these issues. Information society is characterised by the merging of various types of poverty that are qualitatively different and are generated by different determinants, which eventually leads to the need to redefine this notion.

This distribution of poverty has its roots partly in the development of information technologies, which expressly affect this phenomenon. On the one hand they may participate in fighting poverty, but on the other – they contribute to creating deep divisions between people rich and poor in various goods, therefore increasing the disbelief in improving the situation and causing multiple repercussions.

Thus, traditional typologies of poverty are no longer functional in the information society. It has become necessary to create a new approach that would take into account new influence profiles and generating the notion of "new poverty" as well as looking into ways to minimise it.

Cite this Article as: Agnieszka SZEWCZYK" The Impact of Information Technologies on Reducing Poverty in The Context of COVID-19" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

This „new poverty" is clearly connected with broadly understood notion of information. A person who is "informationally" poor is both an individual who does not have full and easy access to information (and that puts him/her at a disadvantage in comparison with others) and an individual who has plenty of information but it does not meet his/her expectations and is largely disqualified.

People marked with this „new poverty" are also those who enjoy dummy luxury, i.e. moral confusion caused by the mass media that do not respect moral principles and the so-called infoholics, people addicted to information which they get from the Internet, computer games, smartphones, etc. They are hungry for truth, free will, time and… freedom.

The „old" and „new" poverty should be battled against with various methods, both traditional and modern ones, adapted to the needs of the 21st century – the age of information, knowledge and wisdom. The weapons in this battle may be information itself and technological inventions, or – to be more specific – people who create and disseminate it, by taking care of its quality and the just distribution of information (Szewczyk, 2006, pp. 9-10).

Faces of Poverty in The Information Society – Theoretical Background

When analysing the essence of information technology and admiring technological achievements that carry the promise of improving life quality, we should, however, ask this question: why are there so many poor people around us?

"They" – the beggars, alcoholics, homeless, drug addicts, prostitutes, mentally handicapped, those with a criminal record. They make us afraid and disgusted; they annoy us with their looks, provocations and their life "style". Who were they before and who could they have been, if…? Those who arouse pity get from us a little money – just to soother our conscience. But it seems this is not enough, because just round the corner there are yet other poor people, so it is simply easier not to notice them.

The poor are also behind walls and fences – more hidden, embarrassed by their condition, but also hungry, cold, helpless, lonely in their poverty…

This is the reality of today! It is also disturbing that poverty came in second when predicting the threats of information society (Maziarz, 1999). The first place was occupied by unemployment, which is one of the main causes of poverty.

Theses formulated by many futurologists clearly show that the issue of poverty requires extensive diagnosis – also in the context of information society – and not burying our heads in the sand and pretending that this is but a marginal issue and we should concentrate on the positives.

Poverty is part of our world history. It is experienced by all societies to a lesser or greater extent. Not only developing/undeveloped countries deal with poverty, but also ones that are higher (or even very high) on the world ladder of economic development. However, each type of poverty is distinct – since its range, scope and depth and factors determining it are different (Szewczyk, 2005, pp. 25-35).

Although we intuitively understand what poverty is, it is difficult to come up with a common definition. There is no definition of poverty that has been unanimously adapted by all governments (politicians). Every group defines poverty in a different way, pointing to a specific criterion which is the centre of their definition.

Respondents to a questionnaire (Szewczyk, 2020, pp. 9-11) understood a poor person as someone hungry, dishevelled or wearing clearly unfashionable clothes, homeless or living in poor conditions, without basic appliances – washing machine, fridge, vacuum cleaner, without bathroom or toilet. They are also people who cannot afford heating their homes, buying new furniture, going on holiday, going to the theatre or cinema or buying even a used car.

More and more respondents see poverty as the lack of radio, home cinema, computer, phone, Internet access…, no money to buy medicine and good healthy food or fruit. Poor people are the ones who barely make ends meet!

Out of many definitions of poverty, the following one can be adapted: „ the situation of a relatively permanent and involuntary low level of satisfaction of one, some or all universal and basic human needs" (Szarfenberg, 2017, p. 121).

And each human has many various needs and is deeply affected by situations, when a lack, shortage or insufficiency of… something or someone prevents him/her from satisfying those needs. In this way, which is very important to our considerations, a poor person is not only someone lacking money, hungry, naked or homeless, without certain material goods, but also a person who is lonely, childless, unhealthy, who has no time or work, a prisoner or an addicted person, that is one who experiences a deficit of freedom, right authorities, or someone who is digitally excluded or has no fresh water or clean air…

We can therefore state that there are people who are poor in the "traditional" sense and who are poor in a different way! Both of these groups need our help, our gift that would allow them to eliminate their specific type of poverty.

They need bread and water, clothes and work, roof over their heads, medicine, access to education and information, someone's presence, family warmth, someone's time, smile and question: how can I help you? And even if the offer to help is not accepted or used, it is important that it is given. Because we all are – or can be – poor!

Experience has taught us that we must engage both heart and brains in the battle against poverty and social exclusion. The causes and effects of various types of poverty are therefore worth exploring objectively so that we can offer help.

Considering poverty through its causes and effects, we encounter a number of problems with identifying what is an effect and what is a cause. For instance a disease may be an effect of poverty if one lacks the funds for treatment, appropriate diet, healthy lifestyle, etc. But it may also be a cause: a person is not able to work or undertake additional activities, earn enough and therefore their living conditions begin to worsen. Similarly alcoholism causes poverty of many families, but it may also be its effect, when poverty drives people to despair. There are many such examples. Hence an innovative approach to research methodology is necessary.

Another problem when considering the issue of poverty is the on-going novel coronavirus (COVID-19) pandemic. This, as we may call it, macrodisease, has changed many areas of life practically all over the world. The notion of poverty is, unfortunately, no exception. The extent of this problem constantly calls for new methods of fighting poverty. There is a chance that a combination of new and traditional methods will give the desired effect, reducing the scale of various types of poverty. It is worth noting that COVID-19 has generated a grand boom of needs, arising from a new situation. "Typical" material poverty, threatening many employers and employees (galloping unemployment!) was joined by a lack of health (risk of death!), lack of contact with other people (dying alone!), no freedom (quarantine!)…

These problems are still relatively new and are growing dynamically. Therefore, this is the reason for the lack of appropriate scientific, theoretical studies, as well as proven practical actions.

Governments of many states propose different methods – anti-crisis shields, subsidies, increased emergency social assistance. Which is good, but in order to help we should also use diverse information and telecommunications technologies, available mainly in the forms of applications or Internet services since we live in a developing information society.

Information Technologies in The Battle Against Poverty in A Situation of the COVID-19 Pandemic

Of course we should not defy ready and proven methods of fighting poverty and we must remember that various types of poverty exist in our society "despite" – and not "due to" – techno-economic development and the development of information technologies. Moreover, information technologies may be a great tool facilitating meeting people's needs (Szewczyk, 2006, pp. 135-148). And according to the adopted definition of poverty (see point 1), which covers its different aspects, a wide spectrum of needs must be taken into consideration.

Studies done in July 2020 (Ericsson, 2020) have shown that information technologies to a large extent help people cope with COVID-19 crisis. It has been demonstrated that 74% of the people studied have increased their use of the Internet (46% - fixed Internet connection, 16% - mobile Internet connection and 12% - both). The increase in the average (declared) time of use is also significant: FBB – an increase of 2,5 hours/day and MBB – 1 hour/day, compared to the time before COVID-19 (Base group were smartphone users aged 15-69 who claimed they have experienced the effects of lockdown and restrictions – from Brazil, China, France, Spain, India, South Korea, Germany, Sweden, the USA, the UK and Italy.) (Majchrzyk, 2020a).

A study conducted during the coronavirus pandemic by the research company Ipsos on behalf of PayPal has shown that during the quarantine as much as 47% of Polish people were paying their bills via web or mobile applications. Furthermore, 75% of respondents have declared that they will continue to do so even after the pandemic has ended. 51% of the respondents over the age of 65 would like to live cashless (Technosenior, 2020).

A ranking of mobile applications in May 2020 in Poland showed an increase in using the Allegro service by 17.4%, OLX.pl – by 15.2% and other services – by 1.6% to 3%. The number of users of the two leading applications is around 4.8 million. And according to the latest data from the analytical company App Annie, the use of mobile applications in the world increased by 40% in the second quarter of 2020, hitting a record high of over 200 billion hours in April. And curiously – the biggest increase was noted in India, Brazil, Italy and Spain. There is therefore a direct correlation with the pandemic (Majchrzyk, 2020c).

The analysis of the use of video messaging in Europe during the pandemic is also interesting. WhapsApp is the most popular application in 22 countries, including Portugal (36% of all video messaging applications users), Spain (20%), Switzerland (43%), Italy (49%) and Germany (33%). Zoom was the most popular in 14 countries (mostly in northern Europe – Sweden 44%, Norway – 34%, and in some Baltic states – Lithuania 26%). The leader of this category in Poland is technological veteran Skype (37%) (Majchrzyk, 2020b).

The presented sample numerical data on the most common behaviours related to COVID-19, according to the report (Digital, 2020) for Q1 2020, indicate:

- huge increase in digital activity, especially in countries with the harshest restrictions,
- a significant increase in the use of social media, with an emphasis on making video calls,
- accelerated growth of e-commerce, especially in the case of grocery shopping,
- more time spent playing video games and watching e-sports,
- new opportunities for digital advertisers.

The process of express interest in information technologies has been going on for a long time but in recent months it has clearly sped up. New friendly applications have been literally mushrooming the market.

Due to the rapidly increasing number of them, it seems necessary to assess and classify as well as to demonstrate what human needs can be satisfied by them – the lack of information about work, COVID-19 and mobility, no possibility to leave home and run errands, no possibility to meet other people… The list could continue infinitely. And we can safely say that information technologies give us such possibilities even now. But we should point to solutions which would allow us to eradicate the groups of similar causes and similar results of various forms of poverty.

The C-E-T method of classifying the causes and effects of poverty and their translation into information technologies

In order to comprehensively cover the three issues discussed (the causes and effects of poverty and the means to help), three stages of bounding, i.e. classification of elements, should be performed. These terms are used interchangeably in the literature. Bounding occurs especially when choosing a method for combining objects. There is, for example, multi-aspect bounding, i.e. according to many criteria, and a single-aspect bounding.

The so-called royalty, i.e. the measure of closeness centrality (similarity) of elements, is usually accepted as the basis for classification; the selection of the similarity function does not significantly affect the result of bounding. The measure of closeness centrality is successfully used by many authors. Some of them require determining *a priori* target number of classes, e.g. the method of factor analysis. Other methods, for instance Rocchio algorithm or Hill method, allow to regulate the number of classes. The Vaswani method uses indirect connections between the elements of future classes and the method developed by Datolii assumes that the set is divided *a priori* into so-called starting classes. Some methods are based on single-aspect classification and others use more criteria, for example the Gitman-Levine method. This is the approach adopted in this article (Pawlak, 1981. pp. 25-27; Salton, 1974. p. 12; Nowak, 1990, pp. 50-65; Ho, Hull, Srihari, 1994; Gitman, Levine, 2000, pp. 30-40).

The analysis of classification methods leads to the conclusion that the method closest to the premises of this article is a bounding method derived from the designer, two-aspect and automatic approach. This is the approach that the Gitman-Levine method favors, which positively distinguishes it from many other methods - both traditional and

those of the newer generations. Moreover, there is no need to set a priori the number of classes or to limit their number.

The designer aspect creates the possibility to bound elements omitting the limitations resulting from the actual state of the tested system. The two-aspect feature allows to include two key criteria of bounding elements, i.e. closeness and validity (weight). It is worth mentioning that the author has successfully applied this approach to classification in economic applications.

The essence of this classification algorithm can be summarised in the following stages:

1. Establishing input data, i.e. the causes and effects of various forms of poverty. The systematization and weighting of these elements is the result of analysing the results of screening tests (in the form of a diagnostic survey) obtained from the Central Statistical Office (Główny Urząd Statystyczny) in Poland and Eurostat, weights of social economy experts and analysis of source literature. These data are then collected in tables. In the side of the first table causes of poverty are listed, sorted by decreasing weights, and in the head – the effects of poverty. Their order is irrelevant. If a certain cause results in a certain effect or effects, then an "x" sign is placed at the intersection of their coordinates in the table. Its location is determined on the basis of an analysis of source literature. The relationship of causes and effects (C-E) is presented in the form of a matrix:

$$C\text{-}E=\{\begin{matrix} C_{11} & C_{12} & \dots & C_{1j} \\ C_{21} & C_{22} & \dots & C_{2j} \\ \dots & \dots & \dots & \dots \\ C_{i1} & C_{i2} & \dots & C_{ij} \end{matrix}\}$$

   where probability:

   p_{ij} = {1 – if the cause causes the effect, 0 – otherwise}
2. This matrix is then transformed into the area of the closeness of causes using the closeness function, e.g.:

   $$b(p_i, p_j) = \frac{p_i \cap p_j}{p_i \cup p_j} \quad \text{where: } b \in \langle 0,1 \rangle$$

   Based on this function, the pairs of causes are compared and closeness factors are defined. It is worth emphasizing that the presented procedure does not convert these coefficients into binary values, like some researchers do, because this conversion, based on adapting a certain, subjective threshold value, would reduce the accuracy of the results.
3. Constructing chains of causes, ordered by decreasing values of function b (decreasing similarities). This process continues until all the elements in the chain are exhausted. As a result, classes of similar causes are obtained, the so-called pmacros. For example – from three different rows of the C-E matrix, only one (i.e. one class of causes similar to each other) arises because they cause the same or similar effects.
4. Check that the following situations apply:

   a. The cause is a candidate for more than one pmacro class; if so, it will be included only in one, i.e. in the one in which there is the closest, in terms of function b, cause with a higher weight,
   b. The cause is not a candidate for any of the previously created pmacro classes, then it becomes the creator of a new class; the remaining single-element classes are then appended to it, resulting in the so-called atypical pmacro class,
5. As mentioned above, in some cases it is difficult to decide what are the causes and the effects of different forms of poverty. Therefore, it is advisable to perform steps 1-4 on the basis of data from the table, constructed according to similar principles as in step 1, and then on the input matrix but in an "inverted" manner, i.e. classifying the effects. The order of causes is irrelevant. This way a matrix showing the relationship of effects and causes (E-C) is constructed, and, as before, situations a) and b) in stage 4 are eliminated. As a result of this classes of similar effects, the so-called syndromes, are created. For example, from four different rows of the E-C matrix, one row will be created, that is one class of effects, similar to each other, because they are caused by the same or similar causes.

6. Specifying a sample offer of information technologies and assigning them weights and classifying them in the same way as above, examining similar offers in terms of satisfying the needs resulting from the pmacros classes and syndromes (excluding possible repetitions). In this situation the table shows offers of information technologies in the side, sorted by decreasing weights, and pmacros and syndromes in the head. Offer classes created in the same way, so-called otis, may be helpful to users when completing: applications, Internet services or other mobile phone offers. They may also be an indication for the creators of various IT solutions, when designing, for example: applications for the "new poor", or macro applications fulfilling many tasks – so-called "n" – at the same time. With the multitude of individual proposals, such a personalized solution will certainly be an attractive offer.

It is also important that people who are "traditionally" poor will also find it easier to, for example, make purchases with application discounts. It may facilitate helping them, directing them in the right way if they cannot afford all modern IT tools.

Application aspects of the C-E-T method – data and results

The practical evaluation of the presented algorithm was carried out on selected model data. It should be emphasized that these data are not complete by definition, because they have been prepared taking into account various forms of poverty during the on-going coronavirus pandemic, i.e. since January 2020. The input data for the model - causes and effects of poverty were obtained from Eurostat and Central Statistical Office in Poland as well as from the literature cited in the beginning part of the article (point 1.). They have not been discussed in detail due to the text size limitations of the article. The choice of information technologies has been limited to those most willingly used by users in the COVID-19 pandemic (point 2.).

First, they were subjected to the process of bounding – causes of poverty, and as a result, classes of similar causes (pmacros) were obtained in view of the effects they cause. Thus, 8 pmacros was obtained:

pmacro 1 = {unemployment, low labour productivity, ruthless market rules, bad income distribution system},

pmacro 2 = {excessive welfare state, inappropriate social policy of the state, decline in the level of economic activity of the country, lack of propensity to risk, refraining from making any effort to get out of poverty, difficulty in accessing basic social institutions, choosing this way of life},

pmacro 3 = {no aspirations, submission to fate, laziness, no hope, no authority, no information},

pmacro 4 = {racial discrimination, discrimination against certain categories of people, gender discrimination, lack of education, weak family and interpersonal structures, social isolation, concentration of the poor, various types of social ills},

pmacro 5 = {sudden unexpected expenditure, debt spiral, not receiving child support, theft of property},

pmacro 6 = {hereditary tendencies and patterns, bad upbringing, unstable family life, absence of one parent},

pmacro 7 = {diseases, disability, accidents},

pmacro 8 = {loneliness, no love, no children, no healthy living conditions, no freedom}.

Then, in accordance with the justification given in step 5, the effects of poverty were subjected to the bounding process, as a result of which classes of similar effects (syndromes) were obtained according to their causes. This way 6 syndromes were obtained:

syndrome 1 = {inappropriate social, economic and educational patterns, restriction of access to rest, homelessness, withdrawal from education, life in the ghetto, digital illiteracy, entering into hooligan groups, withdrawal from participation in social and cultural life},

syndrome 2 = {alcoholism, drugs, designer drugs, crime, demanding attitudes},

syndrome 3 = {diseases, inability to take medication, inability to follow the recommended diet},

syndrome 4 = {loneliness, depression, lowered self-esteem, lack of self-confidence, suicide attempts, unrealistic ideas and expectations, lack of rules or life patterns, feeling of being trapped, feeling of injustice, conviction that you have no influence on your own life},

syndrome 5 = {increased fear for one's own health and life, early motherhood, complexes, distrust of others, passivity, helplessness},

syndrome 6 = {lack of communication between parents and children, unequal start in life, conflicts, domestic violence, debt spiral, indebtedness, arrears in payments}.

And finally, in stage 6, information technology offers were subjected to bounding. They were grouped in terms of the possibility of their use, especially in difficult, specific conditions of a pandemic, i.e. illness, isolation, loneliness, quarantine, joblessness and getting relatively low income, that is when it can be said that there is widespread poverty, and therefore a lot of shortages: lack of health, freedom, trust in others, lack of hope, authority, financial resources, contacts with other people, lack of information ... when the number of family conflicts and suicide attempts increase, people feel they are being trapped and education fails.

As a result of the bounding process, 12 classes of similar offers were obtained:

oti 1 = {text and video communicators, overview of articles and news, systems of reminders and motivational texts, remembering passwords, logins or card numbers, “contact” application – COVID threat, social networks, “where are you” application},

oti 2 = { selection and delivery of products, food, medicines, ready meals, virtual shopping list, e-shopping of a wide range of goods, healthy shopping, remote opening of a parcel locker, e-health, "discount" application},

oti 3 = {software for remote work, distance learning software, creating a list of tasks to be performed (work and home), systems monitoring learning progress, control of working time and the number of breaks},

oti 4 = {fitness applications, building diets, controlling caloric intake, controlling the physical parameters of the body},

oti 5 = {mobile banking applications, virtual wallet, systems controlling expenses and receipts, "lowest prices" application},

oti 6 = {applications for communication in teamwork, planning, description of tasks and deadlines, websites for people looking for employees, websites for people looking for a job},

oti 7 = {charity applications and services},

oti 8 = {scanning old photos, reference books about works of art},

oti 9 = {game collections},

oti 10 = {venture risk management systems, e-psychologists, "faith every day" portals},

oti 11 = {real estate services},

oti 12 = {e-office application for everyone}.

Conclusions from the implementation of the C-E-T algorithm

- Collection of input model data, i.e. the causes and effects of poverty and the desired IT offers, especially for the duration of the pandemic, and assigning weights to them, enabled the C-E-T algorithm to be implemented. Thus, its applicability was found.
- All three types of input data, i.e. the causes and effects of poverty, and information technology offers are bound into groups (classes) that are mostly multi-element, i.e. they are directly related to each other. The few occurring repetitions do not affect the final classification results.

- A thorough analysis of twelve otis (information technology offers) can provide a basis for their correction, development of detailed solutions, and then to link individual applications and build their macro versions so that they respond to the needs of poor people in various areas and for various reasons.

Emerging of the Idea of Criminalization of Corporate Misconduct in the Russian Federation

Anna V. SHASHKOVA

Full Professor MGIMO-University, Moscow, Russia
a.shashkova@inno.mgimo.ru

Ekaterina Kudryashova

Researcher the Institute of legislation and comparative law under the Government of Russian Federation (Moscow, Russia)

Abstract

The present article is dedicated to the problem of interaction between the state and corporations at the industrial period of society, establishment of corporations and their liability. The present article analyses positive and negative examples of participation of corporations in social problems' solution. The author researches corporate crimes and analyses those who have particular importance nowadays. The article focuses on different theoretical approaches towards ideas of establishing corporate criminal liability in the national legislation of the Russian Federation. The article analyses such symbolic court precedents as those elaborated in the UK in cases 'Santa Clara County v. Southern Pacific Railroad Co.' in the USA and 'Salomon v. Salomon & Co. Ltd'. The article states that at the stage of industrial society emerged the current concept of the corporation as a separate subject of the civil turnover with the necessary scope of rights and liabilities. The methodological ground of the present Article represents the dialectic scientific method of the socio-political, legal and organizational processes with the principles of development, integrity, consistency, etc. The consistency analysis method is used while researching the object of the analysis. Some public-private research methods are also used: formally-logical or comparative legal method are used to compare legislation of the United States of America, the United Kingdom and the Russian Federation in the area of corporate liability for bribery. The aim of the present article is to find the root of the problem of interaction between the state and corporations, to show political will behind introduction criminalization of corporate liability. The core part of the research is dedicated to the analysis of emerging of the corporate liability. The question on emerging of corporate liability is analysed from a political point of view concluding that at present the Russian Federation political conditions are not set in for the matter.

Keywords: Industrial Society, Corporate Liability, Criminal Liability, Corporate Crime

Introduction

Introduction of criminal liability for corporate misconduct is a question, which is being discussed in the Russian Federation since 2015, when a draft law 'On Introduction of Amendments to Legislative Acts of the Russian Federation in the Light of Introduction of the Institute of Criminal Liability for Corporations' was submitted by the Investigation Committee of the Russian Federation to the State Duma. Most developed countries criminalised corporate misconduct and there are arguments that Russia shall follow the route of such countries [Bytko, 2015]. At the same time here are strong opponents to the criminalization of corporate crime. For example, the Russian Federal Chamber of Lawyers is in strong opposition to this idea. The arguments here concern mostly the subjective side of a crime, the principle of a personal culpability: actus reus non facit reum nisi mens sit rea (the act is not punishable if there is no perception of guilt), as well as the purpose of criminal liability.

The problem of criminalization of some act is a question of public order, a political question. Criminal action must violate public order, not just rights of particular individuals. An act shall be of great political or social importance, to deserve the stigma to be called a 'crime'. And the problem has mostly political and not legal routs of emergence and evolution [Schumpeter, 1934].

Arising of a Concept of 'Corporation'

A corporation is normally considered as a structure, which acts independently in commercial turnover. It acts independently in its relations with the state as well [Yin, Wang, 2018]. A corporation represents a veil for owners as such corporation hiding it from other counteragents and shareholders of corporation. The court precedent of the House of Lords of the United Kingdom elaborated such concept in 1896. Of course, the idea of a limited liability is much older, than XIX century. Some vestiges are found it in the medieval era in monasteries and religious institutions. Later in XVI century large corporations exploited the trade with the East Indians (e.g. the Vereenigde Oostindische Compagnie) [Grimes, 2013].

The case is recorded under the name of 'Salomon v. Salomon & Co. Ltd'. The concept of this case is of particular interest notwithstanding the decision of the United States court 'Santa Clara County v. Southern Pacific Railroad Co.' adopted 10 years before the UK decision, in 1886 [Bloch, 2013]. The American court applied Amendment Four to the US Constitution to a corporation. It was for the first time in history when the notion 'person' was applied to a legal entity and not to a physical person.

"The right of the people to be secure in their persons, houses, papers and effects, against unreasonable searches and seizures, shall not be violated, and no Warrants shall issue, but upon probable cause, supported by Oath or affirmation, and particularly describing the place to be searched, and the persons or things to be seized"[i].

The concept delivered in the judgment is of current importance: those who gave loans to the company have priority over general creditors [Pulbrook, 1865].

Lifting a 'Corporate Veil'

Such concept of lifting a 'corporate veil' is applied in case there are reasons to look inside the company in order to claim liability of the persons standing behind the company [Goulding, 1999]. In case of breach of law persons in charge will not enjoy limited liability of the corporation and its 'separate personality' [Croal, 2013]. They will be answerable on their fraudulent actions. Thus, the concept of lifting a 'corporate veil' is the integral part of the concept of corporate personality and independence of the company [Dignam, 2011].

Not only English law uses the concept. In German law such concept is called 'Durchgriff hinter den gesellschaftsrechtlichen Schleier', which means penetrating liability, in the American law it is know as 'Piercing the Corporate Veil' [Shashkova, 2015]. In the case Kinney Shoe Corp. v. Polan the court stated that the concept of a separate liability of a corporation may be ignored in case of "use of a corporation as a mere shell or conduit to operate a single venture or some particular aspect of the business of an individual or another corporation»[ii]. Implementation of such concept by courts leads to another concept – 'corporate crime' [Bequali, 1978].

The Interaction between Governments and Corporations

Thus, basing on the analysis of the precedent in the case 'Salomon v. Salomon & Co. Ltd' and the precedent in the case 'Santa Clara County v. Southern Pacific Railroad Co.' the author can conclude that a 'corporation' as a separate person, which can execute self-committing legal actions, meet its obligation, act as a plaintiff or as a defendant in court, as a self-governing legal entity, whose rights and duties are distinct from those of its members, appears only at the end of the nineteenth century.

At this particular stage of industrial society, when private property becomes sacred, the current understanding of a 'corporation' is created [Galbraith, 2007]. Such concept of 'corporativity' of a company means that the company can make transactions on their own behalf, may act as a plaintiff and a defendant in court, can sell, buy, rent, lease, and mortgage property in its own name. The corporation's property is inviolable [Mankoff, 1972]. However, it does not give the individuals that are standing behind a corporation complete indulgence. The legislation and judicial practice clearly show that in case of violation of the law, it is possible to transfer liability to persons actually committed their actions, even if they are covered by the corporation. Thus, the concept of 'lifting a corporate veil' is also a part of the concept of corporativity [Grantham, 1998]. Such concept of 'lifting a corporate veil' is as well an integral part of the concept of the autonomy of the company, an integral part of the corporation as an independent entity. At the same time if the state becomes weak corporations shall assume some functions of the state [Fedorov, 2017].

In early industrial society monopolies acted as land owners in the Roman Empire, collecting tribute for the passage of goods via the river. American railroad tycoons wiped out of business competitors in the same way at the end of XIX century. The mass media adds to the political rhetoric the idea of the antagonistic relationship between the state and corporations in the post-industrial society. The right-wing forces claim that the state intervention in the process of making money is too strong. Therefore, the state rather prevents than helps trading activity and activity of corporations. The left-wing forces draw an image of a corporation as a predator, exploiting workers and consumers and evading taxes. They claim tighter control of corporations from part of the state.

Such contradictions between the state and corporations lead to ineffective operational response to the banking crisis of 2007 - 2008. The Russian government responded to such crisis by passing new acts, more strictly regulating the financial and especially the banking sector, attempted to crack down on corporations using tax havensiii. Was it effective? Some countries such as the United Kingdom did the opposite. They reduced corporate taxes to attract more investment to the economy of the country. The French President François Hollande did the same. He came to power in 2012 on a wave of anti-capitalist rhetoric and in January 2014 announced the reduction of corporate taxes of 30 million euros to resuscitate the stagnating French economy. Though after increase up to 75% of the luxury tax such action of the French President was not noticediv.

It should be noted that notwithstanding all existing controversies between the state and corporations each other is sine qua non. Only because of corporations the economic growth of the state happens, jobs are created, export of goods is realised [Marx, 1844]. All these lead to increase a position of the country in the global economy. Transnational corporations (TNCs) are of specific importance. Such corporations generally pay higher salary, export more goods and pay higher attention to research and development (R&D) of new products and technologies. The state is forced to compromise at this point. An interesting example of the particular case is an advertising and marketing group WPP, which moved its head office from London to Dublin due to tax claims in the area of revenue earned abroad. Later after changes in tax regulations WPP returned its head office back to Londonv.

Corporations cannot exist without the state either. The state legalizes corporations, trains employees of such corporations, creates infrastructure (roads, air control) [Kosolapov, 2011]. All these actions of the state allow corporations to manage business, to deliver their goods in a specific place [Duff, Farmer, Marshall, Renzo, Tadros, 2014]. It is the state that carries out research and development, requiring significant capital investment [Etudaiyae-Muhtar, Ahmad, Matemilda, 2017]. Subsequently corporations commercialize such R&D products: from satellite systems to medical devices.

In certain business sectors, the state is a major client for corporations itself: defence systems, pharmaceutical products. The development of the construction industry also very much depends on public policies [Curti, Mihov, 2018].

Public policy affects corporate structure of business as well. In the USA, for example, high corporate taxes and an increasingly strict legislative regulation of public corporations led to a reduction in the number of public corporations and the establishment instead of limited liability partnerships. Tax regulation according to which the taxation of interest from investments in securities is different in the case of stocks and bonds (for taxation of bonds applies tax deductible, while dividends are paid from net profit) has led to the increase in the number of debt instruments and to the decrease the investment in stocks.

Progress development in the technological area provided the state with the opportunity of total control over citizens through telephony or email. In this field also, the government and corporations can both confront and interact [Ramirez, Ramirez, 2017]. There are almost no areas of business with secrecy and anonymity, especially when the issue at stake is cash money. Will corporations protect their customers from the control of the government, risking accusations of violation of legislative acts?

Social problems' regulation drives the state and corporations into a conflict as well. The Patient Protection and Affordable Care Actvi, which entered into force in the USA in 2010, imposed significant bureaucratic burden on small businesses. Formalities that small businesses had to comply when providing maternity leave for the mother, or even worse for the father, forced small businesses to allocate additional funds and people to comply with the law. In fighting for voters opposing tax increases, the state shifted the burden of social problems onto the shoulders of corporations. That is one of the reasons why the Patient Protection and Affordable Care Act was abolished and substituted with the American Health Care Act (AHCA)vii: to make businesses do business.

Big business corporations clearly understand the dependence of their success on the relations with the state: lobbying rather than brilliant business ideas can put business into effect. Tax regulation can be favourable or can simply swallow the corporation as a whole [Whelan, 2014].

While opening the boundaries and globalization of major types business and social activities the state identified areas of business that must be protected from foreign invasion [Berezko, 2016]. The state decided to determine the maximum share participation of foreign persons in such strategic corporations. In each country these areas may vary depending on the strategic goal of the state: in France it is agriculture, in the UK – financial services, in Russia - gas industry. The state also creates special state corporations dealing in such strategic areas [Alekseeva, Lebedeva, 2016].

It should be noted that the tools of interaction between state and corporations in the rich world and poor world differ. In the rich world, it is the government that dictates the rules, which corporations shall comply. Corporations have to structure their business and corporate organization in accordance with these rules. The role of taxes, government regulations of competition, the understanding of strategic development of technology, the impact of lobbying is of great importance here. In the poor world, everything is easier and more complicated at the same time: corporations of big business feel free to determine the best financial and fiscal conditions for themselves with the help of corrupt schemes. They cover nearly all areas, including the area of security, which traditionally has to be under the regulation of the state. The creation of non-governmental organizations (NGOs) does not allow distinguishing any more between the competence of the corporations and the state as such competence is mixed. The scope of activities of the state and corporations is also mixed: the state begins to do business, and corporations and NGOs start dealing with peoples' security.

The Idea of Criminalization of Corporate Misconduct

Such a notion as 'corporate crime' comes to life. Russian dictionaries define a 'corporate crime' as a 'white collar' crimeviii. At the same time European dictionaries give to a doctrine of 'corporate crime' a broader interpretation.

Criminology refers to a corporate crime as to a crime committed either by a corporation (i.e., a business entity, which is a separate legal entity and not dependent on natural persons that manage its activities), or persons acting on behalf of a corporation or other entity [Fisch, 2007].

The concept of corporation being a separate person means equality in application of liability to such separate person. The starting point for such interpretation was the above-named decision of the US court 'Santa Clara County v. Southern Pacific Railroad Co.'. It applied the notion 'person' to a company.

"The Court does not wish to hear argument on the question whether the provision in the Fourteenth Amendment to the Constitution which forbids a state to deny to any person within its jurisdiction the equal protection of the laws applies to these corporations. We are all of opinion that it does[ix]".

Regulation of corporate crimes arises to the political level. After a large number of fatal accidents on the rail network and at sea a term 'corporate manslaughter' was elaborated in the UK. This was done to attract more attention to technological hazards associated with corporations. In 2007 such offence was criminalized with the adoption of the Corporate Manslaughter and Corporate Homicide Actx. The Corporate Manslaughter and Corporate Homicide Act 2007 is a landmark in law. For the first time, companies and organisations can be found guilty of corporate manslaughter as a result of serious management failures resulting in a gross breach of a duty of care.

The Law Reform Commission of New South Wales states that a corporate crime may create a big threat to the prosperity of the community. The reason is that in case of a corporate crime a group of people to be affected is wider than in case of an individual action. And economic harm potentially caused is much higher as well.

On the one hand these are corporations that develop new technologies and economies of scale. These may serve the economic interests of mass consumers by introducing new products and most efficient methods of mass production [Hagan, 2010]. On the other hand, given the absence of political control today, corporations serve to destroy the foundations of the civic community and the lives of people who reside in them.

The case of the decision of the US court 'Santa Clara County v. Southern Pacific Railroad Co.' and its further construction by the Supreme Court of the US provide an understanding of possibility and reasonability of criminal responsibility of corporations.

"Congress can impute to a corporation the commission of certain criminal offenses and subject it to criminal prosecution thereforxi".

It was held that a corporation should be responsible for the acts of its representative or agent, whom can be a management body or other empowered employee or another person. It shall be stressed that a corporation shall be held liable even if such agent had acted against the express order of the corporation being a principal. A corporation is liable for tort within the agent's authorized powers, not only powers strictly construed. That means that even in case there is no direct contract between the corporation and the agent, the agent is considered to be a legal representative of the corporation.

There are of course certain court decisions against such construction, e.g. Connecticut General Life Insurance Company v. Johnson.

"I do not believe the word "person" in the Fourteenth Amendment includes corporations. The doctrine of stare decisis, however appropriate and even necessary at times, has only a limited application in the field of constitutional law.[xii]"

Decision on the case 'Burnet v. Colorado Oil & Gas Co.', dated 11 April 1932, claims that the court is constantly changing its interpretations of the Constitution of the United States, thus reaching improper construction in the case 'Santa Clara County v. Southern Pacific Railroad Co.'[xiii].

Notwithstanding such decisions the baseline of the American courts' construction of the problem is clear - criminalization of corporate misconduct of a separate legal person.

The Corporate Manslaughter and Corporate Homicide Act of the UK states that it is applicable to particular cases, which are cases of a corporation, a department, a police force, a partnership.[xiv]" The Act also states that a corporation is guilty of an offence only if the way in which its activities are managed or organised by its senior management is a substantial element in the breach. Thus, the Corporate Manslaughter and Corporate Homicide Act stipulates the necessity of the guilt of a corporation. The Act establishes no guilt or liability of an individual of aiding, abetting, counselling or procuring the commission of an offence of corporate manslaughter. It is very important because to make a corporation accountable for the guilty act, such guilty act of a corporation must be accompanied by a mental understanding of the guiltiness of the act. The corporation shall be aware of the guiltiness, which is hardly to believe in case of an artificial person.

In determining a crime and prospective responsibility for the crime the due level of care shall be considered. A 'relevant duty of care' of a corporation that must take place in particular circumstances is provided for in the Corporate Manslaughter and Corporate Homicide Act[xv].

Similar as in case of money laundering crime the liability under the Corporate Manslaughter and Corporate Homicide Act shall be incurred only in case of some predicate crime. That means that the liability under the Act does not arise as is. It arises only after some other crime that is considered to be a crime under the general criminal law has been proved[xvi]". The procedure for incurring liability by a corporation starts from a remedial order. In case a remedial order is not executed with a specified period liability under the Corporate Manslaughter and Corporate Homicide Act shall arise.

"An organisation that fails to comply with a remedial order is guilty of an offence, and liable on conviction on indictment to a fine[xvii]".

Thus, the responsibilities of a corporation as of the Corporate Manslaughter and Corporate Homicide Act shall be: compensation of losses, the publication of information on the crime of the corporation in mass media or unlimited fine.

Analysing the practice of application of the Act the author realizes that in case initiation of criminal prosecution on the murder under the Corporate Manslaughter and Corporate Homicide Act such criminal case is initiated simultaneously against the specific officials of the corporation and against the corporation itself. In contrast to the civil procedure, cases of independent corporate liability of a corporation have not yet happened[xviii].

A Northern Irish company and two other companies JMW Farms Ltd and Lion Steel Ltd were convicted under the Corporate Manslaughter and Corporate Homicide Act under the guilty plea. Another company Cotswold

Geotechnical Holdings Ltd got conviction after a trial. The patterns that emerge after the analysis of the above case and taking in consideration other cases of are these:

- Prosecutions tend to be of small, owner-managed companies, not companies of big business.
- Convictions by guilty plea seem likely to continue if the alternative is the risk to one of the owners of personal conviction and imprisonment.
- Fines remain below the lower threshold of £500,000 suggested by the Sentencing Guidelines Council.

Conclusion

Looking through the Corporate Manslaughter and Corporate Homicide Act the author can state turning backwards in the responsibility system. In case of court decisions of the XIX century lifting of corporate veil was the leading idea of corporate responsibility and inevitability of responsibility of a particular guilty person [Nicholson, 2007]. Nowadays a corporation is the primary responsible person. At the same time application of corporate criminal liability e.g. under the FCPA and the UK Bribery Act demonstrates clear trend to punish both legal entities and natural persons [McGrath, 2017]. Neither punishment of a corporation in accordance with criminal court's decision nor plea bargaining exclude individual criminal liability. The risk of individual liability also increased significantly after the release of the Yates Memorandum in the United States in 2015.

Coming back to introduction of criminal liability for corporate misconduct, the author concludes that under the concept of lifting a corporate veil, liability for corporations is already introduced. However, most Governments introduced civil or administrative liability for companies. Criminal liability for corporations is introduced in many countries as well, e.g. in the majority of the developed countries. Though in the Russian Federation the issue is still pending. Nowadays the absence of criminal liability for corporations in the Russian Federation does not release officials of the corporation from criminal liability – officials are recognized culpable for corporate crimes. Such officials are in fact the persons committed a crime; they signed the documents and made real deeds. According to the Tables given below the number of economic crimes in the Russian Federation drastically decreased from year 2013. The same sign can be traced comparing the first semester of the year 2019 to the first semester of the year 2018. That is a sign that criminal liability is being replaced in particular cases with administrative or civil liability. There is no legal obstacle to introduce criminal liability for corporations, which means that the routs of the problem of criminal liability of corporations are purely political. Thus, a decision to introduce or not such liability shall be considered from political point of view and not a legal one. At present political conditions in the Russian Federation have not come to the point of criminalization of corporate misconduct. From both political and legal concepts of view the author understands that currently there is no necessity in criminalizing corporate misconduct in the Russian Federation.

Abstract

The bibliographic analysis process in the world today faces a critical problem because of the fact that people lack reading habits. This happens because the bibliographies do not capture the attention of readers and in addition to having content that is too extensive, do not motivate their reading. This systematic literature review (SLR) was oriented to bibliographical analysis using machine learning with Python and natural language processing (NLP), and the collection and analysis of articles from different search engines, which helped to meet the determined objectives. Additionally, the information was used in the plotting of the statistical graphs. The research considers studies published between 2015 and 2020 obtained from various sources, making a total of 80 articles selected for publication and review; these contained the information necessary to answer the research questions. The obtained results were satisfactory thanks to the research conducted.

Keywords: Machine Learning, NLP, Python, Systematic Literature Review, Bibliographic Analysis.

Introduction

The situation in the world regarding bibliographic analysis is in a critical state. This is because of the absence of a reading and text analysis culture. Most people simply enjoy seeing the large number of pages in articles, books, work, etc., but do not find them attractive or worth reading.

In Latin American countries, reading rates in the general population have decreased dramatically in recent years. According to Gutiérrez Valencia & Montes de Oca Garcia, 1996, for example, the number of readers in Peru is below average in Latin America, because they do not practice the habit of reading.

Studies have shown that a large percentage of readers does not contribute to bibliographic analysis research, creating a big gap within this area. However, other research works demonstrate the use of tools and techniques that could

address this problem and their efficient optimization. From the SLR process, it is deduced that machine learning technology with Python and NLP has the potential for solving the problem of bibliographic analysis. Studies were found with results that solve or improve the problem posed by the same technology. This work presents information on creating a solution for the need to improve bibliographic analysis. We collected and analyzed articles from different search engines, which helped to meet the objectives determined and plot the statistical graphs.

This research, based on the systematic review of literature, is organized as follows: Section I presents the Introduction, the Background and Related Works are in section II, and section III presents the Methodology used. The results of the SLR are presented in section IV, the conclusions are in section V, and the Discussion of the research is presented in section VI.

Background and Related Work

In recent years, research has been conducted on the potential of machine learning technology, Python language, and natural language processing (NLP) techniques, which have been used in different fields including tourism, fauna, social networks, etc. from which significant results have been obtained, for example:

Tao [1] conducted research based on machine learning supported by Python and NLP, in which he demonstrated the importance of sentiment analysis in the tourism industry, achieving remarkable results.

However, many issues such as bibliographic analysis have been left unresolved within the field of education.

Bibliographic analysis includes several parts of the bibliography to be analyzed and are grouped in two: external and internal analyses. To facilitate different actions such as consultation, recovery or generation of a product that benefits the reader we must go through the process of understanding the content and form of a document.

In today's world, the literature analyses do not capture the core information in the document, which creates numerous adversities for the readers by not complying with their objectives and are also limited to other actions, such as analysis reports, concept maps or a simple extraction of information from the bibliography.

Consequently, machine learning, which is supported by other technologies and techniques such as Python and NLP, offers remarkable benefits that could contribute to current research.

According to Sharma [2], using machine learning algorithms on computer programs allows you to learn from the input data and obtain the desired output within the specific range by analyzing statistics.

Ferrario [3], defines NLP as a discipline that combines linguistics, computer science and artificial intelligence, which studies the interactions between systems and natural human language.

According to Rasool (2020), using Python for analysis statistics on the impact of heart disease helped in determining the best machine learning models to predict and diagnose heart diseases.

The authors conclude the review with recommendations for participants to enhance their understanding on the subject, which can also be used to carry out tests and interpretations of the results.

This review aims to present a systematic review approach to documents to evaluate their approach to bibliographic analysis using machine learning with Python and NLP. The SLR is used to achieve this.

Review Method

Letelier et. al [4] state that systematic reviews are clear summaries and structured information available to answer certain questions in a specific field. Because they consist of multiple articles and information sources, they represent the highest level of evidence within the hierarchy of evidence. In this research, the reviews of two different types of publications are identified as the systematic and non-systematic or narrative review, according to Beltrán, G., & Óscar, A. [5].

- The systematic review is an integrative, observational, retrospective, secondary study, in which studies evaluating the same question are combined. Statistical methods are used to enable the combination and quantitative analysis of the results obtained in each study, according to Beltrán, G., & Óscar, A. [5].
- The narrative review is a less comprehensive study compared to the systematic review. It is elaborated by experts on a topic and developed without an explicit methodology or protocol and does not specify the search strategies for the included studies, according to D. González-Bravo [6].

The present review was conducted on bibliographic analysis with machine learning, Python and NLP. We chose the systematic literature review, following the steps proposed by Letelier et. al [4], to propose an improvement for the research that is being carried out. To conduct this review, the following steps were followed: questions were posed based on the research, equations were formulated, a search was carried out on various selected search engines, exclusion criteria were applied, questions were raised on the quality of the studies, the studies were selected and classified, and finally the review and data extraction were carried out.

Research Questions

This review begins with a number of research questions that will serve as a guide for the review process. This step is useful for mapping the research on autonomous learning with machine learning, Python and NLP in the bibliographic analysis and answering the following questions:

RQ1: What are the criteria for measuring the effectiveness of machine learning with Python and NLP?
RQ2: In which areas has machine learning with Python been applied?
RQ3: In which areas have the techniques of the NLP been applied?
RQ4: What tools and libraries are used for the application of machine learning with Python and NLP?

Search Equations

The next step in the systematic review is to propose search equations according to the search terms grouped by variables (Table 1).

Table 1: Search terms grouped by variables

Search Terms	Variable
Machine Learning Solution AND Python AND Natural Language Processing	Independent Variable
CRISP-DM	Intervening Variable
Methodology/Method/Model	
Bibliographic Analysis	Dependent variable
Bibliography	

The words listed in the table above are fundamental for performing the search equation, because they accurately describe the research topic such as machine learning, Python and NLP, which encompasses a number of techniques and tools that are used in their application. The intervening variable was the CRISP-DM methodology because a methodology that includes following an order and procedures that achieve good results will be needed to carry out this research work. The dependent variable was matched with the bibliographic analysis. Table 2 shows the search equations as a result of the inclusion of these variables:

Table 2: Search equations

Source	Generic Search Equation
Springer Link	Machine learning and python and natural language processing and Bibliographic analysis
ERIC	Machine Learning AND Python AND natural language processing (AND CRISP-DM OR Methodology) AND Bibliographic Analysis
IEEE Xplore	((((("All Metadata": Machine Learning) AND "Full Text & Metadata": Python) AND "Full Text & Metadata": natural language processing) AND "Full Text & Metadata": CRISP-DM) OR "Full Text & Metadata": Methodology) AND "Full Text & Metadata": Bibliographic Analysis)
1findr	Machine Learning AND Python AND natural language (processing OR Methodology AND Bibliographic Analysis)
Science Research	Machine Learning AND Python AND natural language processing AND CRISP-DM OR Methodology AND Bibliographic Analysis
Taylor&Francis	[All: machine learning (python)] AND [All: and natural language processing] AND [All: bibliographic analysis]
Microsoft Academic	Machine Learning AND Python AND natural language processing AND CRISP-DM OR Methodology AND Bibliographic analysis
UNED	Machine Learning AND Python AND natural language processing AND CRISP-DM OR Methodology AND Bibliographic analysis
Science Direct	Machine Learning AND Python AND natural language processing AND CRISP-DM OR Methodology AND Bibliographic analysis
ACM	[All: machine learning] AND [All: python] AND [All: natural language processing] AND [All: crisp-dm] AND [All: bibliographic analysis]
ProQuest	Machine Learning AND Python AND natural language processing AND CRISP-DM OR Methodology AND Bibliographic Analysis

A. Search for documents

The search was carried out using the following equations by an extensive research, the most relevant being the direct science search source. Fig 1 shows the quantities according to each source.

Fig. 1: Number of studies per search engine

B. *Exclusion Criteria*

The number of studies collected for this research was large; however, because there are advancements in the technological field every day, we decided to include some criteria for selecting the suitable articles. The first exclusion criterion was that the articles should not be older than six years; because a wide variety of research studies was included, the second criterion was that the results should not be articles.

Given that some search engines only allow you to review research articles by subscriptions and/or payment, the next criterion that was selected was that the articles found should not be accessible. Most of the results showed a wide variety of publication languages; for the present evaluation we chose articles in the English or Spanish.

Finally, the research that would be most helpful for this review includes the articles that deal with machine learning, Python and NLP. These applied criteria will help select research that is more oriented to the subject and thus, obtain results with evidence of the use of these techniques in bibliographic analysis (Fig 2).

Fig. 2: Application of the exclusion criteria

C. *Study Selection*

The selection process of the studies was carried out according to the titles, which were automatically displayed using the different search engines. Those that clearly did not have anything to do with the subject (N=292 272) were excluded. Finally, the researchers applied the exclusion criteria (Fig 2) in the set of relevant studies, obtaining 80 articles, which were potentially vital for the research.

D. *Quality Assessment*

This section reviews the quality of the resulting or selected studies, which can be used to create a filter that facilitates the selection of suitable articles to answer the research questions; these reviews were conducted after applying the exclusion criteria. The selected quality criteria are presented below:

QA1: Is the purpose of the investigation clearly explained?
QA2: Does the topic belong to the fields of computer science, information systems or management?
QA3: Are the research objectives clearly presented in the document?
QA4: Can you clearly identify the results of the experiments that were carried out?
QA5: Does it adequately describe the analysis of data used in the study?
QA6: Are the results of the study clearly established and supported by the results?

It should be noted that each of the quality criteria was applied to the 80 selected articles, and each one of them complied with the above-mentioned criteria. Therefore, these 80 articles were used for the review.

E. *Data Extraction*

Data extraction was performed on the 80 selected articles, where each study was assigned a unique reference. The following information was extracted from each article: study title, source or search engine where it was found, year of publication, country, number of pages, language used in the article, type of publication, scientific article or SLR, name of publication, research methodology, author or authors, affiliation of the author (university), number of quotations, summary of the article, keywords, and sample size. All these data were used to plot graphs and create a better understanding of the studies.

Results

This section presents the results of the present SLR according to the established RQs.

RQ1: What are the criteria for measuring the effectiveness of machine learning with Python and NLP?

RQ1 aims to determine the most frequently used criteria within the selected articles and measure the effectiveness of machine learning with Python and NLP. We identified the criteria used in the studies to measure the effectiveness, which are presented in Table 3.

Table 3: Effectiveness criteria

Criteria	Amount	Percentage
Accuracy	54	53,47
Precision	35	34,65
Sensitivity	7	6,93
Specificity	5	4,95

As shown in the table, we obtained four criteria, which measure the effectiveness and precision of the models used in the articles based on machine learning to solve the problems presented in them. Additionally, many of the authors mention more than one criterion in their solutions, which is why they appear repeatedly in the articles.

As shown in Fig 3, the most common criterion is accuracy, which measures the precision and effectiveness of the classification models, that is, the fraction of prediction that the model in the article is accurate.

This criterion covers 53,47% of the selected articles. Therefore, it can be inferred that accuracy is a significant criterion that should be taken into account when working with machine learning because it indicates that your solution can certainly be effective in solving a problem. Moreover, the rest of the criteria presented are quite significant because they also present valuable information about the models.

Fig. 3: Criteria efficiency

RQ2: In which areas has machine learning been applied with Python?

To answer this question, Fig 4 was used to elaborate the areas of greatest interest, which have applied machine learning with Python. These technologies are capable of solving problems in many areas, but for the present research,

the five most common fields of study were identified within the selected studies. It can be observed that the studies that are carried out with the highest frequency are in the area of literature. This field is closely related to the present research because it includes bibliographic analysis.

Fig. 3: Machine learning areas of application

A manual analysis was performed on the articles to determine the number of articles found within these areas and calculate their percentage relative to all the selected items.

As shown in the Table 4, Literature included a total of 15 articles (32,61%), indicating that it is one of the areas where these technologies are most applied. Thanks to these data, we can obtain information that significantly contributes to the present SLR.

Table 4: Application areas of machine learning

Area	Amount	Percentage
Computing	9	19,57
Education	5	10,87
Environment	3	6,52
Literature	15	32,61
Medicine	14	30,43

RQ3: In which areas have the techniques of the NLP been applied?

As shown in Table 5, NLP techniques are more widely used in the literature (38,24%) and computer science (26,47%) fields, because the use of these techniques has made it possible for computers to interact with the human language, resulting in computationally effective communication. It is also widely used in the field of medicine (23,53%) because the application of these techniques achieves beneficial results in identifying and discarding diseases that a mere human can not predict.

NLP is also used in the field of education because of the various techniques it incorporates. Therefore, it provides a new approach for improving learning through interactions with models that can predict and teach things that are out of the ordinary.

The present research takes into account 80 articles, which were rigorously selected to obtain results that show that this technique is widely used to solve various problems that currently demand time and money.

Table 5: NLP application areas

Area	Amount	Percentage
Computing	9	26,47
Education	3	8,82
Environment	1	2,94
Literature	13	38,24
Medicine	8	23,53

RQ4: What tools and libraries are used for the application of Machine Learning with Python and NLP?

Table 6 clearly answers the above question; the obtained results indicate that the most used tools are NLTK (31,91%) and TensorFlow (23,40%). Because they are open source, the use of these tools allows the creation and/or training of models that can be used to solve various types of uncommon and difficult problems that could only previously be solved by a human. The other tools were not widely used in this research; however, they are equally important because they are used in other fields and achieve positive results. The selected tools are vital and each one offers different functionalities, making their application significantly effective in the results obtained; they are easily accessible for use in various areas and types of research.

Table 6: Most used tools and libraries

Tools	Amount	Percentage
NLTK	15	31,91
Numpy	5	10,64
OpenNLP	2	4,26
PyTorch	5	10,64
SciPy	4	8,51
Spacy	5	10,64
TensorFlow	11	23,40

Discussion

To the best of our knowledge, this is one of the first attempts to review bibliographic analysis using machine learning with Python and NLP. In the findings, a considerable amount of empirical research on the study of the application of machine learning, Python and NLP in areas such as medicine, wildlife, tourism, education, etc. was found. Considerable attention was given to the studies that were applied in education, based on the same fact that bibliographic analysis is within this area. Additionally, few studies found replications; one of the consequences or implications caused by this research is that it gave a glimpse of the potential of these technologies and their contribution to society in different areas, more so in bibliographic analysis as well as the benefits that will be obtained.

For professionals or students who would like to take this SLR as an example, they should look for more information on the subject, because the evidence shows that the application of machine learning with Python and NLP for bibliographic analysis is not mature and that the direct application of the methods and instruments used in the studies may produce unwanted results. According to Park, D. and other authors [19], human efforts determine the quality of the results, whereas automated approaches can significantly increase the efficiency of the research efforts.

Conclusion

Presently, machine learning, Python and NLP are used by a large number of researchers from different areas, enabling the optimization of their resources in the execution of tasks. It is of utmost importance to know the benefits, results and importance of using the techniques and tools provided by Machine Learning, Python and NLP.

The present review aims to raise awareness on the use of machine learning tools and techniques, Python and NLP in bibliographic analysis, as well as make it known that these are currently the most used for solving various problems, because of their effectiveness in the results obtained in the different areas where they have been applied.

The 80 selected and reviewed articles for this review indicate that the research topic is of great interest because it is used and applied by many researchers in different studies. It should be noted that there is still a lot more to explore and discover in this field of technology.

The present review has obtained a considerable number of publications in scientific databases. However, it should be noted that it is used in different areas for the purpose of optimization and application. Currently, access to this type of information is possible owing to the variety of sources and/or existing databases.

In the literature area, publications stand out for the variety of techniques and tools applied for the development of various problems. This implies that the research is within the scientific community of informatics. In the analysis of the publications by years, it is demonstrated that the articles in which machine Learning, Python and NLP are used are current because of the advancement of technology over the years. This advancement has led to the discovery of new entities, and the tools and techniques have become more efficient and effective when providing solutions.

The use of machine learning, Python and NLP have made technology more attractive and useful because of the various solutions that they offer by incorporating automated tools and techniques.

This research concludes that it is possible to conduct bibliographical analysis with the help of these tools and techniques, because there is a lot of research on this subject that has presented satisfactory results.

Managerial Premises for The Implementation of The Industry 4.0 Concept on The Car Assembly Technology Line

Leszek PACHOLSKI

Poznan University of Technology, Faculty of Engineering Management
Poznan, Poland
leszek.pacholski@put.poznan.pl

Abstract

The publication addresses a decision-making management problem related to the implementation of the INDUSTRY 4.0 concept in an automotive industry company. The object of research, determining their theoretical and implementation scope, is a practical case of the car assembly technology line. The subject of the research are the managerial relational premises linking the attributes of the above-mentioned implementation with the macro-environmental strategic conditions of its implementation. The methodology of the expert studies presented in this publication uses three tools: PEST analysis, brainstorming, Delphi method and the fuzzy formula of inference. The scientific purpose is quasi-taxonomic and consists in discovering (research question) the hierarchical structure of the relationship strength of the analyzed managerial premises. The research conclusions highlight the technological and organizational problems of cyber-attacks and excessive investment costs as well as the issue of reliability and stability of cyber-physical systems and processes of the INDUSTRY 4.0 concept, as well as the socio-cultural aspects of supervision over the autonomy of these systems and processes, the dangers of both privacy violations and depriving employees of employment.

Keywords: Industry 4.0, attributes of Industry 4.0, PEST analysis.

Introduction: the purpose, type, object and scope of the research

The concept of INDUSTRY 4.0 is the fourth stage of managerial technological and organizational innovations in the field of industrial production of technical products. The foundation of each of these stages are successive basic innovations constituting the technological and organizational response of production engineering and management sciences to the socio-cultural and economic-economic imperative of need. It should be noted that the above-mentioned three areas (technological-organizational, economic and socio-cultural) together with the political and legal aspect (Pacholski L., Piotrowski K., 2008) define the basic spheres of the macro-environment which has a key impact on the functioning of the manufacturing enterprise. Referred to as general segmentation of the environment (in the form of PEST analyzes) these areas also determine (through an in-depth analysis such as: BCG Matrix, ADL Matrix, McKinsey Matrix, GE Matrix) the portfolio strategy of this enterprise.

The relationships linking the attributes of the implementation of the INDUSTRY 4.0 concept with the macro-environmental conditions for its implementation, which constitute the basic expert research question and the purpose of the research presented further in this publication, can be considered the key decision-making premises of the operating strategy of a manufacturing company. The object of the expert research, determining their theoretical and implementation scope, is a practical case of a technological line of car assembly. Contemporary cars are characterized by considerable design complexity and the use of various assembly technologies. Car production is a complex process consisting of many phases and stages. This process includes: construction of the so-called sheet metal structure, technologies for sealing, painting and anti-corrosion protection of this structure, and assembly of the complete vehicle. In terms of the research type, it can be considered that this publication is a case study.

Research subject: Industry 4.0 concept

Returning to the issue of the four basic innovations constituting the foundations of the four so-called industrial revolutions the following should be listed:

- the concept of mechanical industrialization based on the implementation of the steam engine invented by James Watt into manufacturing processes,
- the concept of production lines based on machines and electric generators, thanks to the invention of a generator by Warner Siemens (a device that converts mechanical energy into electricity),
- the concept of digitization of manufacturing processes, initiated by the creation of the first electronic, programmable computer and the continued development of software-controlled computers and the creation of the first microcontroller,
- the concept of unifying the real world of production machines with the virtual world of the Internet and information technology.

The above-mentioned four industrial revolutions appeared (as mentioned above) as a result of articulating successive socio-cultural and economic imperatives of need. The contemporary imperative of this type is a consequence of the situation in which the producer operates in the conditions of surprising and increasing turbulence and unpredictability of changes in the enterprises' environment, in various dimensions of this variability (Trzcielinski S., 2011; Kalkowska J., 2018; Pacholski L., Kalkowska J., 2019). Organizational structures for managing industrial manufacturing processes have flattened and teamwork has become the dominant form of organization (Mc Cormack K.P., Johnson W.C., 2001; Trzcieliński S., 2011; Kałkowska J., Pacholski L., 2017). In response, the industrial producer receives a whole range of concepts including: Toyota Production System, Lean Production, Flow Manufacturing, World Class Manufacturing (Schonberger R.J., 1986; Todd J.,1995; Digalwar A.K., Sangwan K.S., 2007; Murino T., et el., 2012), Agile Manufacturing (Goldman S.L., Nagel R.N. 1993; Trzcieliński S. 2011; Yauch C.A. 2011).

The integration of these concepts in the conditions of the real (automated and robotic) world of manufacturing systems requires the use of information technologies that goes beyond the organizational and technological possibilities of the first three industrial revolutions.

INDUSTRY 4.0 is a concept for the production and operation (use and operation) of technical devices based on the standards of the virtual world of Internet networks and information technologies, which combines the real world of intelligent production and operating machines with intelligent information flow systems. This concept covers the entire value chain of the above-mentioned technical devices (products) from ordering and delivering components for ongoing production to their shipment to customers and after-sales maintenance services. It is the integration of intelligent machines and systems as well as the introduction of flexible changes in production and operational processes aimed at improving the quality and efficiency of these processes. INDUSTRY 4.0 applies not only to the technologies of these processes but also to new ways of organizing and managing work as well as new roles of people in the industrial production and exploitation of technical products. The INDUSTRY 4.0 concept, on the other hand, means connecting the real world of people and production machines with the virtual world of the Internet with cyber-physical information technologies. As this concept evolves, computers are connected and communicate with each other to ultimately make decisions even without human intervention. INDUSTRY 4.0 covers the entire logistics value chain: from ordering and delivering components for ongoing production and operation to the shipment of finished products and consumable components to customers and related after-sales services. Products and components can always be identified. They even have the ability to communicate independently. The flow of production and operational information is carried out vertically: from individual products and components to the company's IT department and from the IT department to these products and components. The second direction of information flow is carried out horizontally: between the machines involved in the production process and the product operation system and the production and operation systems of the enterprise. INDUSTRY 4.0 today is not just "data digitization" but a whole technological revolution including the following eight tool concepts: System Integration, Additive Manufacturing, Big Data, Internet of Things, Autonomous Robots, Cloud Computing, Augumented Reality, Cybersecurity. The aim of this revolution is to create new (organizational and technological, economic and socio-cultural and even political) opportunities and benefits that would simply not be available without this type of cyber-IT solutions. The concept of INDUSTRY 4.0 (as assumed

by its authors) opens a new era of high automation in production. Manufacturing processes are a part of the Internet of Things where communication and collaboration between machines and humans occurs in real time.

Summing up, the following cost and efficiency benefits of the concept of INDUSTRY 4.0 should be mentioned:

- flexible and tailored to customer expectations modular production concepts,
- systemic, comprehensive and optimized real-time planning (collaboration horizontal with the use of platforms located in the cloud for production planning),
- real-time production planning (vertical integration) in order to better use production machines and increase their efficiency,
- digitization and automation of processes in order to optimize the use of resources (human and hardware) and faster operational activity
- controlling the flow of products (horizontal integration) in order to better manage inventory and optimize logistics management,
- real-time quality control based on data analysis,
- obtaining current information on deviations in the production process.

Research Method and Results

An expert study of managerial relational premises linking the attributes of the implementation of the INDUSTRY 4.0 concept with its macro-environmental conditions was carried out with the use of the following four analytical tools: PEST analysis, Brainstorming techniques, Delphi approach and Fuzzy Inference formula. The diagram of the author's method of this research is shown in Fig. 1.

The individual symbols appearing in this figure mean:

MGRS - managerial roles,
PEST - PEST analysis,
TITC - INDUSTRY 4.0 tool concepts,
SISL - systems of implementation solutions,
MECI - macro-environmental conditions of implementation,
IMAT - implementation attributes,
B - brainstorming technique,
D - Delphic approach,
F - fuzzy inference formula,
AMRP - analyzed managerial relational premises,
QTAX - quasi-taxonomic indicator

Fig. 1: Scheme of the method of researching managerial relational premises linking attributes implementation of the INDUSTRY 4.0 concept with its macro-environmental conditions (source: own study)

The aim of the research is quasi-taxonomic and consists in discovering (the research question) the hierarchical structure of the relationship strength of premises (AMRP) linking individual attributes (IMAT) of the implementation of the INDUSTRY 4.0 concept with its macro-environmental conditions (MECI).

The resulting relational premises linking the implementation attributes of the INDUSTRY 4.0 concept with its macro-environmental premises were developed based on the opinion of a team of twelve experts. The seven experts are mainly industrial practitioners employed in the surveyed car manufacturing company and familiar with the INDUSTRY 4.0 concept. These experts represented the following managerial specialties: enterprise management, production engineering, logistics, marketing, human resources management, automation and robotics, IT and telecommunications. Five other experts represented the university knowledge in the field of INDUSTRY 4.0 in the following specialties: management engineering, economics, social sciences, automation and robotics, as well as IT and telecommunications.

The classic brainstorming technique was used in the research, the purpose of which was to determine the connections between nine industrial managerial roles (9MGRS – see fig.1) and four macro-environmental categories of determinants for the implementation of the INDUSTRY 4.0 concept (4PEST – see fig.1). Managerial roles were formulated as follows: leader - representative, coordinator (liaison) of activities, counteracting disturbances (conflicts), observer following news, promoter of changes and news, explaining spokesman, entrepreneur - innovator, resource administrator, negotiator towards suppliers and customers. The distinguished categories of macro-environmental conditions included (in accordance with the PEST analysis) the following premises: economic, socio-cultural, technological and organizational, and political and legal.

The same classic brainstorming technique was used to investigate the connections between eight tool concepts of INDUSTRY 4.0 implementation (8TITC – see fig.1) with three technological and organizational variants of the industrial implementation of this concept (3 SISL – see fig. 1).

The eight tool concepts are: System Integration, Additive Manufacturing, Big Data, Internet of Things, Autonomous Robots, Cloud Computing, Augumented Reality, Cybersecurity.

On the other hand, three variants of industrial implementation are described as follows (Pacholski L., Kalkowska J., 2019):

- Implementation of high volumes of car production (with a cost level lower than the competition) by fully robotic, dedicated production lines with common picking modules, using digital tool technologies of the INDUSTRY 4.0 concept,
- Implementation of short, personalized series of manufactured cars (the so-called "mass individualization" of production processes), through highly individualized, robotic, universal production cells (having the value of frequent changeovers), using digital tool technologies of the INDUSTRY 4.0 concept,
- Implementation of the process of manual production of cars with the highest unit value, manufactured on the individual order of the client, by top-class specialists using digital tool technologies of the INDUSTRY 4.0 concept in order to improve the organization of production processes and increase the "ergonomics" of human work.

The results of the research for the first of the above-mentioned applications of the brainstorming technique are shown in a matrix form in Fig. 2.

Nine industrial managerial roles	Four categories of macro-environmental determinants of implementation			
	Economic	Socio-cultural	Technological and organizational	Political and legal
Leader - Representative		X	X	X
Coordinator (liaison) of activities,	X		X	
Counteracting disturbances (conflicts),		X	X	
Observer following news	X		X	X
Promoter of changes and news		X	X	X
Explaining Spokesman		X		X
Entrepreneur - Innovator	X		X	X
Resource Administrator	X		X	
Negotiator towards suppliers and customers	X	X	X	

Fig. 2: The results of the research: Matrix of connections between nine managerial roles and four categories macro-environmental conditions for the implementation of the INDUSTRY 4.0 concept (source: own study)

Using the same technique to test the connections between eight tool concepts of the INDUSTRY 4.0 implementation with three technological and organizational varieties of the industrial implementation of this concept has been signaled, regardless of the business conditions of the selected production variant cars (Shrama M., Kodali R., 2008) similar to the matrix presented in Fig. 2, the dominance of organizational and technological premises.

In the next stage of the research, the experts were required to distinguish (based on the results of the previous stage) ten managerial premises for the implementation of the INDUSTRY 4.0 concept and five attributes of this implementation. These premises and attributes were determined using the brainstorming technique. The results of the research were ten managerial premises (10MECI – see fig.1) for the implementation of the INDUSTRY 4.0 concept (Table 1) and five attributes (5IMAT – see fig. 1) of this implementation (table 2).

Table 1: The results of the research: Ten managerial premises for the implementation of the INDUSTRY 4.0 concept

The managerial premises for the implementation of the INDUSTRY 4.0 concept	
1	The excessive investment costs of the implementation of the INDUSTRY 4.0 concept
2	The difficult adaptation of the company's current business model to the requirements of the INDUSTRY 4.0 concept
3	The social distrust in cyber-computer supervision over the threats of violating privacy, freedom and cultural identity
4	The social problem of threats, in the context of the implementation of the INDUSTRY 4.0 concept, loss of jobs by people who previously performed work and coordination activities
5	The functional and competence redundancy of the corporate IT department in connection with the implementation of the INDUSTRY 4.0 concept
6	The threat of cyber-attacks and the protection of the company's knowledge resources
7	The difficulty of obtaining the reliability and stability of cyber-systems necessary for time-critical computer processing
8	The need to constantly maintain the integrity of cyber-systems and processes of product manufacturing and operation
9	The political determinants of professional legislation with regard to the implementation

	of the INDUSTRY 4.0 concept
10	The legislative and implementation complexity of standards and certification of the implementation requirements of the INDUSTRY 4.0 concept

(source: own study)

Table 2: The results of the research: Five attributes of the implementation of the INDUSTRY 4.0 concept

The attributes of the implementation of the INDUSTRY 4.0 concept	
1	The cyber-computerization of product manufacturing and operation processes, information and decision-making interoperability and autonomy of the mentioned processes, functionality and reliability of these processes and their integration and logistic flexibility
2	The information and decision-making inter-operability and autonomy of product manufacturing and operation processes, functionality and reliability of these processes
3	The functionality and reliability of the processes of production and exploitation of products
4	The integrity and logistic flexibility of the processes of production and exploitation of products
5	The marketing personalization of the processes of production and exploitation of products

(source: own study)

For the purposes of the research on managerial relational premises (50AMRP – see fig. 1) linking ten managerial conditions of the implementation (10MECI – see fig.1) of the INDUSTRY 4.0 concept with five attributes (5IMAT – see fig. 1) of this implementation, four degrees of Delphi expert assessment of the strength of relations (five-level numerical scale from 1 to 5) were adopted for fifty of their potential variants (Trocki M., 1997).

Taking into account each of the twelve expert's opinion, it was assumed that in the next three rounds the experts narrowed the number strength of the relation. If the interquartile range and the new expert opinion was outside this new relation, its justification was expected. In this way, it was forced to move experts undecided and without adequate arguments to the majority group, i.e. to the group whose opinions are in the interquartile ranges.

As part of the fuzzy (F – see fig.1) formula of inference (Zadeh L.,1999; Pacholski L., 2007) concerned the research on managerial relational premises (50AMRP- see fig.1), it was assumed that the probability of high, medium and low strength of the relationship will be tagged (Kalkowska J., 2018):

$$p_{ai}^{h}\ ,\ p_{ai}^{m}\ \mathrm{i}\ p_{ai}^{l}$$

The determination of the above probabilities was entrusted to the aforementioned twelve experts. The probability boundary conditions were defined as follows:

$$pa_i^h + pa_i^m + pa_i^l = 1$$
$$pa_i^h \geq 0;\ pa_i^m \geq 0;\ pa_i^l \geq 0\ , \qquad i \in 1, n;$$

A five-level linguistic scale of expert assessments was then proposed.
Moreover, the linguistic variable z was introduced to describe the strength of the analyzed relations and the fuzzy scale (table 3).

Table 3: Recommended fuzzy scale for the linguistic variable z.

#	Rating of 12 experts	Scale
1	no relation	0<z<0,333
2	relationship strength slight	0,167≤z<0,5
3	indirect relation	0,333≤z<0,667
4	strength of the relation significant	0,5≤z<0,833
5	dominant relation	0,667≤z≤1

(source: own study)

The designation d_j was further introduced as the result of the j-th expert's assessment,
where: ($d_j \in 1, 2, 3, 4, 5$).
According to the fuzzy set theory, the membership of the set N was expressed by the membership function for the interval [0,1] of the form: $\mu_N(x)$
Each result of the d_j expert assessment was assigned to the following five fuzzy sets:

$N_1 = \{(\beta_1, \mu_N(\beta_1)), (\beta_2, \mu_N(\beta_2)), (\beta_3, \mu_N(\beta_3))\}$, if $d_j = 1$;
.
.
.
$N_5 = \{(\beta_5, \mu_N(\beta_5)), (\beta_6, \mu_N(\beta_6)), (\beta_7, \mu_N(\beta_7))\}$, if $d_j = 5$;

for j = 1, 2, 3, .., E; where: E = 12 is the number of experts assessing the relationship.

Then, the following distribution (normalized fuzzy set - table 4) of the scale of relational premises (AMRP – see fig. 1), linking ten managerial conditions of the implementation (MECI – see fig.1) of the INDUSTRY 4.0 concept with five attributes (IMAT – see fig. 1) of this implementation, was taken into account:
• (0, 0.333) - insignificant relational premise,
• (0.333, 0.667) - relatively significant relational premise,
• (0.667, 1.0) - a very important relational premise.

Table 4: Normalized fuzzy set for three variants of relational premises (low, medium and very significant) linking ten managerial conditions for the implementation of the INDUSTRY 4.0 concept with five attributes of this implementation

Type of relational premises	Fuzzy set				
	N_1	**N_2**	**N_3**	**N_4**	**N_5**
Premise insignificant	*0; 0,5*	*0; 0,0*	*0; 0,0*	*0; 0,0*	*0; 0,0*
	0,167; 1,0	*0,167; 0,5*	*0,167; 0,0*	*0,167; 0,0*	*0,167; 0,0*
	0,333; 0,5	*0,333; 1,0*	*0,333; 0,5*	*0,333; 0,0*	*0,333; 0,0*
Premise medium significant	*0,333; 0,5*	*0,333; 1,0*	*0,333; 0,5*	*0,333; 0,0*	*0,333; 0,0*
	0,5; 0,0	0,5; 0,5	0,5; 1,0	0,5; 0,5	0,5; 0,0
	0,333; 0,0	0,333; 0,0	0,333; 0,5	0,333; 1,0	0,333; 0,5
Premise very significant	0,333; 0,0	0,333; 0,0	0,333; 0,5	0,333; 1,0	0,333; 0,5
	0,167; 0,0	0,167; 0,0	0,167; 0,0	0,167; 0,5	0,167; 1,0
	1,0; 0,0	1,0; 0,0	1,0; 0,0	1,0; 0,0	1,0; 0,5

(source: own study based on: Kalkowska J., 2018)

Then, f_{sf} was introduced as an element of the fuzzy set s and m_{sf} as a membership function for the corresponding element of fuzzy sets presented in table 4 and the probabilities of the generalized evaluation of twelve experts were calculated (in two steps) as follows:

• Calculation of the average P_i probability score (where: i = 1, 2, 3) reflecting the frequency of selection made by the experts:

$$P_1 = \sum_{f=1}^{3} f_{1f} m_{1f} \quad P_2 = \sum_{f=3}^{5} f_{2f} m_{2f} \quad P_3 = \sum_{f=5}^{7} f_{3f} m_{3f}$$
