Research-intensive universities are increasingly challenged by the globalisation of research, international competition on innovation and the impact of international ranking mostly based on scientific performance (Hazellkorn, 2008). They have consistently placed research at the very core of their activities. They have hired high-level lecturers and offered a wide range of scholarship activities and lab research opportunities, thereby minimising the teaching process. The purpose of the teaching delivered is scarcely an issue and remains on the margins of academics" thoughts. Yet new pressures are challenging these universities, forcing them to take a closer look at the concept of quality teaching and to contemplate institutional support to step up the quality of the faculty and curricula (Fabrice, 2010).

Meeting Research Requirement

Academic staff have the primary duties of teaching, learning, research and community service (Altbach & Knight, 2007). They are required to show evidence of publication output for their appointment, promotions and career development. This is a major distinguishing characteristic for academic staff (Perkmann & Walsh, 2007). Publication is a vital and indispensable activity for all academic staff and the institution. They are efforts geared at extending the frontiers of knowledge and breaking new ground (Sarah, 2015). Producing regular publications is a requirement and essential component of an academic career. The core of any University's charitable mission is the creation of new knowledge and understanding for public benefit (Marginson, 2011). As stated by Danielson (2011) academia is part of a broad public conversation and individuals have a responsibility to effectively communicate the results of their enquiries as a way of advancing their subject areas and enhancing society and the economy. The reputation and prestige of the individual academic and their institution relies on publications.

Conceptual Linkages

Work Routine Management and Teaching Effectiveness

Lecturers are considered one of the major key elements in higher institution of learning. They are saddled with the responsibility of ensuring teaching effectiveness, publication, mentoring, leadership and maintaining a positive learning environment in the classroom. Although the ability of academic staff to create a positive classroom climate may not eliminate behaviour problems, but it establishes the environmental context that is vital for the attainment of

emotional, social and cognitive developmental outcomes. Studies have indicated that classroom organisation and management skills have significant impact on positive educational outcomes (Ingersoll & Smith, 2003).

However, in Nigeria context, lecturers, particularly in government universities work in a very harsh condition (Archibong, et al., 2010). This implied that most lecturers in Nigeria struggle on regular basis to teach in classrooms that are overcrowded, use obsolete facilities which affect rigorous research activities, terrible working condition just to mention a few. In addition, the slogan 'publish or perish syndrome' is considered a major stressor. There is enormous pressure put on lecturers particularly those at the lower cadre to write and publish many articles in order to meet up with promotion requirements (Akinmayowa & Kadiri, 2016). However, having a positive mindset and the effective daily management of time and tasks is expected to enable academic staff to be able to cope with stressors and experience a positive stress as aganst the negative consequences of stress.

Meeting Research Requirement and Research Output

Meeting research requirements empowers academia in many ways. It raises profiles amongst peers, exposes arguments to critique which sharpen ideas, and puts findings into the public realm where potential users and beneficiaries will notice them and qualifies them for promotion and appointments amongst others (Attama, 2013). Publication productivity is expressed by the number of papers published by a selected unit in a given time (Sudhier & Abhila, 2011). In a study carried out on librarians' publication output, Ogbomo (2010) found that too much demand of daily work routine, rating of journal titles, weak/poor research orientation, unavailability of resources, lack of academic freedom and lack of interest contributes to the pressure of meeting publication requirement. However, adopting coping strategies such as being positive, having a locus of control, seeking for social support, anticipating a positive event when working at meeting up publication demand may foster eustress experience by academic staff.

Conceptual Framework

Figure 1: A Conceptual Model on the Relationship between Eustress and Performance of Academic Staff

Source: Adapted from Lambert and Henly (2010), Archibong (2010), Fabrice (2010) and Georgiou, Sharma and Ling (2017)

The conceptual model of this study proposed in Fig. 1 above shows the relationship between eustress and academic staff performance. The model has components comprising eustress (work routine management and meeting research requirement) and academic staff performance (teaching effectiveness and research output). Therefore, two relationships as regards eustress and performance of academic staff was developed based on the conceptual model. They are stated as follows:

i) Work routine management motivates the teaching effectiveness of academic staff in tertiary institutions.
ii) Meeting research requirements enhances the research output of academic staff in tertiary institutions.

In this conceptual model, work routine management is said to motivate the teaching effectiveness of academic staff in tertiary institutions. Academic staff scheduling their practices, engaging in time and classroom management, having a to do list, delegating overwhelming task when necessary, preparing and scheduling classes well in advance will foster effective work routine management among all the highly demanding daily work schedule. The development of internal locus of control and increase in skills to match the daily work demand especially when there are impromptu tasks will enhance the teaching effectiveness of academic staff in tertiary institutions.

From the model proposed above, meeting research requirement enhances the research output of academic staff in tertiary institutions. Maintaining a positive mindset, having locus of control, seeking social support and being optimistic while working hard to meet publication requirement will help to regulate their feelings when experiencing stress and enhance their research output. When academic staff anticipate for positive events such as promotions, research grants, scholarship, international recognition, collaborations that results from meeting publication requirements, they will be able to boost their coping strategy and enable them experience eustress. This will bring about increase in research output of academic staff in tertiary institutions.

Discussion

Organisations as well as institutions cannot afford anything lesser than a high performance organisation to survive in these competitive times. Enhancing performance in an institution requires understanding what factors influence performance. To this end, this study proposed that the effective management of the numerous work routine required of an academic staff as well as developing a positive emotional state will enhance their ability to make more novel connections and associations between ideas, this is one of the foundational skills for insight and creativity that will improve teaching effectiveness. This aligns with the work of Finelli, Richardson and Daly (2013) supported by Granito and Santana (2016) which showed that factors such as mentor guide, curriculum flexibility, physical classroom management, access to information about effective teaching practices, passion and confidence for teaching, university culture amongst others motivate the adoption of effective teaching among academic staff in tertiary institutions.

Research output is very important not only to academic staff but to institutions in general. Contemporarily, there has been much emphasis on publications and research output by institutions that yearns for high performance rating. Research output is the primary unit by which educational programmes are judged and it is one of the major determinants of academic staff productivity as it is tied to promotion and other academic rewards. This study therefore proposed from the foregoing that developing a positive perception and meeting publication requirement will boost research output of academic staff in tertiary institutions. This validates the work of Attama (2013) supported by Parameshwar and Patil (2009) and Agaba (2010) who examined the effect of academic staff engagement of library resources and their publication output. This implies that meeting publication requirement through utilization of library resources, research cluster activities, conferences etc has a significant positive influence on the research output of academic staff in higher institutions.

Policy Implications

It is important for the management of Nigerian institutions to set-up policies and programs that encourage academic staff to develop an internal locus of control, a high level of self-control and increase their skill level to match new challenges in managing their daily work routine. This will foster effective teaching among academic staff in tertiary institutions.

The policymakers in Nigerian Universities should situate policies and develop programs that enlightened academic staff to anticipate positive events (such as promotion, grants, recognition etc) while working to meet publication

requirements. This will help them develop a positive emotional state that will facilitate a more adaptive cognitive response towards any given assignment

Mindset is a significant factor in determining distress versus eustress. To help academic staff develop a positive perception towards all that is required towards a robust research output, the management of Nigerian Universities should form policies that encourage academic staff to be optimistic and have a positive mindset. This will increase their chances of experiencing eustress and positively respond to stressors.

Policymakers of Nigerian Institutions should set up an advisory service to urge academic staff to develop positive emotions which will help faculty regulate their feelings when experiencing stress. Positive emotions boost friendships, improve coping strategies, and boost psychological resilience, all of which can buffer against the negative mental and physical consequences of stress.

Conclusions and Implications for the Study

The goal of this study was to propose a conceptual model showing the relationship between eustress and academic staff performance in tertiary institutions. It is important to note that eustress has become a crucial point of emphasis because of its dynamic influeuce on an individual's job performance and their wellbeing including that of the organization as a whole. Researchers have proven eustress as another type of stress which is good stress that motivates individuals to perform well and work with interest. Hence, this study proposed a conceptual model to show that eustress has a positive relationship with the performance of lecturers at the tertiary level.

Based on the conceptual model proposed, this study suggests that effective management of work routine, maintaining a positive mindset towards all of the numerous work demands, anticipating a positive event such as research output, promotion, recognition, international collaborations, grants/scholarships, which are mostly the outcome of meeting publication requirements will enhance performance among academic staff in tertiary institutions. Also, being optimistic and improving their skill level to match new challenges will help improve their coping strategies and increase their chances of experiencing eustress and positively responding to stressors as against the negative mental and physical consequences of stress.

Abstract

In article, we describe the development results of educational digital technologies (EDT) adapted to Covid-19 pandemic conditions. In studies, we used methods of data bases constructing within digital educational platforms, web-technologies and virtual reality tools. While Covid-19 pandemic, we have to work on digital transformation of university education, including creation of new concepts for obtaining and presenting didactical materials. We propose to use digital educational platforms, which integrate heterogeneous hardware and software resources with the use of web-technologies in distributed networks and wide application of cloud services. We propose to use Google Classroom, as essential digital educational platform. Recently, we use remote sensing databases for educational purposes within geo-information management disciplines. We consider the issues of digital content creation within university education, essentially in practical training. We present the enlarged groups of didactical works in this area. For data exchange and preliminary discussion while research, was used platform https://www.researchgate.net/profile/Valery_Abramov2/.

Keywords: Educational Technologies, Digital Transformation, Covid-19 Pandemic, Environmental Economics

Introduction

Last year, the Covid-19 pandemic shocks the global economy, including education at university level (UL). Note, this pandemic shock matched the time with Industry 4.0 period, during which a lot of enterprises plan and implement wide spectrum of information technologies (Drabenko, 2019), (Grobitski, 2016), (Frolova, 2019),

ESTRIN "Educational Digital Technologies Development while Covid-19 pandemic" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

(Lukyanov, 2019), (Sikarev, 2020), (Trunin, 2019). Industry 4.0 leads to serious technological changes in natural risk management (Berboushi, 2014), (Ershova, 2018), (Garcia, 2018), (Isaev, 2015), (Istomin, 2018), (Shilin, 2019), which requires the development of new educational technologies, especially for UL (Averkiev, 2020), (Estrin, 2020), (Popov, 2019), (Tatarenko, 2020).

In the article, the authors describe the development results of educational digital technologies (EDT) at UL while Covid-19 pandemic in geo-information management area (Burlov, 2018), (Gomazov, 2018), (Fokicheva, 2016), (Lednova, 2014), (Malakhova, 2014), (Yaily 2019), (Zavgorodniy, 2020), in large environmental projects (Burlov, 2018), (Gomazov, 2018), (Fokicheva, 2016), (Lednova, 2014), (Malakhova, 2014), (Yaily 2019), (Zavgorodniy, 2020), within environmental economics (Bidenko, 2019), (Golosovskaya, 2014), (Karlin, 2014), (Karlin, 2009), (Kolbina, 2020), (Popov, 2016). Significant attention in the implementation of such industrial projects should be paid to geo-information support systems (GISS) of natural risk management (NRM) in the context of climate change (Bidenko, 2019), (Golosovskaya, 2014), (Karlin, 2014), (Karlin, 2009), (Kolbina, 2020), (Popov, 2016), including the issues of information collection and processing (Fokicheva, 2019), (Khaimina, 2014), (Popova, 2019), (Tatarnikova, 2019), (Ya, 2019). The educational technologies, discussed in this article, take all above mentioned factors into account.

Methods and Data

In research, we used Foresight technologies, theory of decision making under uncertainties, risk management approach, methods of data bases constructing, web-technologies and virtual reality tools. Also, we used big data technologies (Popova, 2019), (Yaily, 2019) From the point of view of geo-information management, geo-space is structured to allocate the interconnected components of the solution space (Bidenko, 2019). While study, we used data bases and tools of geo-information digital online platforms (GIDOPs) Earth (Sanina, 2020), (Vekshina, 2020) and EOS, including its Land Viewer (LV) product (Bolshakov, 2020), (Prostakevich, 2020).

Results

In research, we developed educational digital technologies (EDT) adapted to Covid-19 pandemic conditions. We gave preference to the use of digital educational platforms (DEP) that integrate heterogeneous hardware and software resources with the use of web-technologies in distributed networks and wide application of cloud services (Popov, 2019). As DEP in our work, we used Google Classroom. Its main advantages are ease of use, universal access, flexible feedback system and its free of charge. This DEP usage eliminates a system administrator because of Google servers implementing, and also a content Manager because each teacher is responsible for the content of his course (Popov, 2019).

While development of digital content, we used the decomposition as a technique in the preparation of the methodological basis. In figure 1, we present the enlarged groups of didactic works, oriented on practical purposes

1) problem statement;
2) field works on data collection;
3) processing and analysis of the data;
4) preparation of geographical information system (GIS) layers and creating digital geo-information products within geo-information support and decision aids;
decision-making.

Figure1: Enlarged groups of didactic works, oriented on practical purposes

While our work, we developed digital content of practical works within UL in the field of geo-information management disciplines while Covid-19 pandemic for all above-mentioned groups (figure1), using freely distributed recording program CamStudio, a microphone and a camera to record the lecturer's explaining the individual sections.

As essential DEP in the field of geo-information management disciplines while Covid-19 pandemic, we propose to use DOP EOS eos.com, including its product LandViewer (LV) https://eos.com/lv/, that provides efficient tools for searching, processing, and analyzing large amounts of satellite data from the Landsat-8 and Sentinel-2 satellite systems. Usage of DOP EOS allows to find and use satellite images of chosen areas with for training purposes, to determine the location of these areas and to assess their main spatial characteristics (linear and area dimensions), which are the main initial parameters for creation decision aids while geo-information support for environmental economics.

Let's go to examples. In figures 2-4, we show the sequential training operations performed by student in online educational regime for the port of Pevek, the largest Russian port in East Siberian Sea. In figure 2, there is space image on 5th June 2020 (general view by DOP EOS LandViewer) visualized with Natural Colors Application of LandViewer. In figure 3, there is the same as in figure 1, space image, visualized with Atmospheric Removal Application of LandViewer.

Figure 2: Port of Pevek space image (Natural Colors Application) on 5th June 2020 (general view by DOP EOS LandViewer)

Figure 3: Port of Pevek space image (Atmospheric Removal Application) on 5th June 2020

In figure 4 and 5 are Port of Pevek space images on 16th August 2020.

Figure 4. Port of Pevek space image (Natural Colors Application) on 16th August 2020

Figure 5: Port of Pevek space image (Scene Classification Application) on 16th August 2020

Figure 4 and 5 can be used for town Pevek and surrounding territory space characterization for geo-information management purposes. Note, that decoding of above mentioned images was not goal of this article. As essential result, we propose the usage of DOP EOS tools as EDT at UL for geo-information management disciplines while Covid-19 pandemic.

Discussion

The essential task of EDT at UL for geo-information management disciplines while Covid-19 pandemic is to teach students the practical aspects of work with DOP EOS tools, which requires a developed learning base in special geo-information systems (GIS). In Covid-19 pandemic conditions, real practical work in special GIS laboratory can be undergoes with virtual reality (VR) technologies (Popov, 2019), that can reduce total cost of learning process. Results of study can be useful for goals of geo-information management to large space-distributed projects, including emergency management, within the environmental economy while climate change.

Conclusion

In article, we describe the development results of educational digital technologies (EDT) adapted to Covid-19 pandemic conditions. In studies, we used methods of data bases constructing within digital educational platforms, web-technologies and virtual reality tools. While Covid-19 pandemic, we have to work on digital transformation of university education, including creation of new concepts for obtaining and presenting didactical materials. We propose to use digital educational platforms (DEPs), which integrate heterogeneous hardware and software resources with the use of web-technologies in distributed networks and wide application of cloud services. We propose to use Google Classroom, as essential DEP. We consider the issues of digital content creation within university education, essentially in practical training. We present the enlarged groups of didactical works in this area. As essential result, we propose the usage of DOP EOS tools as EDT at UL for geo-information management disciplines while Covid-19 pandemic. The research results presented in this article has significant scientific novelty and can be useful for private investors, public environmental organizations of the civil sector and state environmental control bodies.

Implications for Global Financial System from Big Tech Companies

Tomasz DZIAWGO

SGH Warsaw School of Economics – Banking Institute, Warsaw, Poland
tdziaw@sgh.waw.pl

Abstract

For years, the largest Big Tech companies such as: Amazon, Apple, Facebook or Google have been trying to get a foothold in the financial sector. The main reasons behind entering this sector are: revenue diversification, access to vast amount of customer data, increasing customer loyalty and volume as well as complementing their core services. Younger generation, which is very familiar with digital solutions, shows significant interest for the potential switch to Big Tech companies in order to use particular financial services. Big Tech companies have already started to enter the financial sector, most notably in payments and asset management. Long-term trends could also be beneficial for Big Tech, since financial sector has been undergoing through digital transformation and bank online usage significantly increased, which were only accelerated by COVID-19 outbreak. Moreover, Big Tech companies outperform banks in terms of financial performance after COVID-19. The research paper aims to test two hypotheses, which are as follows:

- Big Tech companies have significant potential to dominate global financial system.
- COVID-19 strengthened Big Tech global position and weakened biggest players in the banking industry financially

For the purpose of the paper, the following methods have been applied: critical analysis of literature and research papers, descriptive method and comparative analysis of presented data.

Keywords: Big Tech, Payments, Banking, Digital
JEL: E42, G21, O14

Introduction

In July 2020 in The United States Congress, testimonies from Chief Executive Officers of the biggest technology companies: Amazon, Apple, Google and Facebook were given. During the opening speech, Mr. David Cicilline – Commercial and Administrative Law Subcommittee Chair, stated that "Any single action by any one of these companies can affect hundreds of millions of us in profound and lasting ways" (Kang C., McCabe D., 2020). In spite of the fact that the hearing concerned mainly tech antitrust and consumer data usage, there are concerns whether massive customer base, significant financial resources and brand recognition, could enable Big Tech companies to become significant players on financial services market overnight. Big Tech companies are among the most influential and the largest business entities in the world. They have been rapidly growing since their establishment (only since Jan 2010 to Dec 2019 the average growth for these 5 companies was ~22% CAGR) (Richter F., A, 2019). However, after COVID-19 outbreak, both global impact and financial results of Big Tech companies significantly increased. According to Fortune 500 list, Microsoft, Apple, Amazon, Alphabet (Google parent company) and Facebook occupy top 5 places in the global ranking in terms of market value (Fortune 500, 2020). With such powerful position and large financial resources, they seek other business opportunities to dominate other markets and one of which is financial sector. Because of heavy digitization process, cultural shift and changing customer expectations, banks often partner with smaller Fin Tech players to help them address these challenges. Only in 2016 over 40% of banks were engaged in join partnership with Fin Tech companies (PwC, 2016). Since Big Tech companies have both financial resources and high degree of innovation, they could enter banking sector right away without collaborating with any other players.

Research Methodology, Process and Hypothesis

The research paper aims to test two hypotheses, which are as follows:

- Big Tech companies have significant potential to dominate global financial system.

Cite this Article as: Tomasz DZIAWGO "Implications for Global Financial System from Big Tech Companies" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

- COVID-19 strengthened Big Tech global position and weakened biggest players in the banking industry financially

For the purpose of the paper, the following methods have been applied: critical analysis of literature and research papers as well as descriptive method and comparative analysis of presented data. Content analysis was aimed at defining Big Tech and presenting largest Big Tech companies, afterwards, Big Tech activity in financial market was depicted and analyzed. Later on, COVID-19 impact on both banking sector and key Big Tech players was presented. Lastly, conclusions regarding tested hypotheses were made.

Big Tech – Definition and Significance

According to Capgemini, Big Tech companies are technology giants dominating their respective markets due to: market understanding, wide customer data access, ability to deliver "delight-inducing" products and services etc.(Capgemini, 2020). Big Tech mainly benefits from obtaining and analysing vast customer data, which they use to enter additional business lines, including financial services. However Big Tech offering in financial services differs with regard to country economy development. In advanced economies, offering is rather narrow and complementing services offered by key players from the banking sector, while in developing countries Big Tech provide much more services (lending, asset management, insurance). This difference occurs not only due to financial development differences, but also due to differences in regulations (Financial Stability Board, 2019). The key difference between Fin Tech and Big Tech is that Fin Tech company specializes in financial services, while Big Tech company offers financial services among other services – therefore financial services is not its' core activity (Ślązak E., 2019). As of 2019, among key Big Tech players, revenue from financial services amounted to ~11% of total revenue.

Chart 1: Total Big Tech revenue breakdown

Source: BIS, Big Tech in finance: Opportunities and risks, 2019.

Key Big Tech players worldwide are often classified as "GAFA" (Google, Amazon, Facebook, Apple), "FAANG" (Facebook, Amazon, Apple, Netflix, Google) or "GAFAM" (Google, Amazon, Facebook, Apple, Microsoft) (Wigglesworth R., 2020). Performance and dominance of the largest Big Tech players on their respective markets have been staggering. Amazon currently has ~38% of e-commerce market share in USA (second player being Walmart with 6% of market share) (Semuels A., 2020). COVID-19 outbreak further helped Amazon, when consumer spending increased by ~60% only between May and July. Facebook's applications (Facebook, Instagram, Messenger, WhatsApp) are being used by ~3 billion users and Facebook itself is the leading social media platform with ~60% internet users (Ghaffary S, 2020, Mohsin M., 2020). Apple has ~32% share of global smartphone revenue and ~66% share of global smartphone profit, in spite of selling only ~15% of global smartphones (Lovehoy B., 2020). It also became the first US-based company valued at USD 1 trillion in August 2018 and also the first US-based company valued at USD 2 trillion in August 2020 (Reinicke C., 2020).

Big Tech Activity in Financial Services Market

Big Tech are particularly interested in financial services market due to the following reasons:

1) Revenue diversification – Big Tech can add or develop significant segment of the overall revenue (Tencent revenue from payments, already accounts for ~28% of total revenue) (Axon S., 2020).
2) Access to vast amount of customer data – since data is often called as "new currency", possibility of obtaining data that previously was available exclusively for banks, might be particularly attractive. Due to large financial resources of Big Tech, they could offer several financial services even at a loss, only to extract more data from clients regarding eg. purchase value, time of purchase, personal preferences on additional services etc. Big Tech opportunities from already existing customer base are significant (Global Business Intelligence, 2020; Kunz P., 2019).
3) Complementing core services – integration of financial services with already existing services could enhance overall customer experience, thus increasing overall revenue (Financial Stability Board, 2019).
4) Increasing customer loyalty and volume – with increased convenience and possibility of having all necessary features in one platform/ app, client retention, loyalty and volume would significantly increase. WeChat is named "the super app" or "app for everything", since apart from messaging and calling, clients can buy goods and services, transfer money, pay bills, access public services, book flight tickets and many more (OPSoftware, 2020).

In order to make a presence on the banking sector, Big Tech companies not only need to have large client base and significant digital experience, but also high level of trust by potential customers. According to the study conducted by Bain & Company - PayPal and Amazon have similar trust level as banks in general in USA (Chart 2). In this study, respondents had to classify depicted banks and Big Tech from 1 to 9 on the basis of trust - 1 indicates the highest trust, while 9 indicates the lowest trust.

Chart 2: Customers trust in Big Tech and banks in USA

Source: Burns M., du Toit G., Evolving the Customer Experience in Banking, Bain & Company, 2017.

Moreover, Big Tech are likely to attract younger clients to purchase financial products from them. In USA - 73% potential clients aged from 18 to 34, are willing to purchase financial products from tech companies, followed by 61% interested in purchasing that are aged 35-54 and 42% interested in purchasing that are aged 55 or older (Marous J., 2017). With increased familiarity with digital, the demand for financial products offered by tech companies is expected to grow. What is more, after COVID-19 global outbreak, in USA there has been significant rise in giving away personal data. Over 53% Americans feel comfortable in making personal data available if it is for the good of society and not sharing is often considered as "selfish" (EY, 2020).

What is more, younger generations have higher likelihood to switch financial services provider from bank to Big Tech, as presented in table 1. From selected Big Tech companies, Amazon poses the biggest threat to traditional banks, since 25% of millennials are willing to switch to this company for financial services. This high level of

likelihood to switch for Big Tech companies occurs in spite of the fact that they are involved in large investigations concerning privacy, security and anti-competitive practices. Therefore, financial security of capital flow in Big Tech companies may not be fully safe as well (Feiner L., Graham M., Levy A., Palmer A., Rodriguez S., Rosoff M., 2020).

Table 1: Likelihood to switch to Big Tech if offered financial services

Company name	Millennials (1981-1996)	Generation X (1965-1980)	Baby boomers (1946-1964)
Amazon	25%	15%	5%
PayPal	21%	15%	4%
Apple	21%	12%	4%
Google	20%	12%	2%
Facebook	10%	6%	1%

Source: Cocheo S., Biggest Threats to Banking in 2019: Fees, Lousy Tech and Digital Disruption, The Financial Brand, 2019.

Furthermore, customers are increasingly likely to adopt banking services from non-traditional players (Non-traditional players referring to Big Tech and challenger banks). The main reasons for potential switch are presented in Table 2.

Table 2: Reasons behind choosing non-traditional player in banking sector

Reason	*% respondents*
Low-cost offering	70%
Ease of use	68%
Faster service	54%
Better features	39%
Personalized products	39%

Source: BIS, Big Tech in finance: Opportunities and risks, 2019.

Customers much prefer to conduct basic transactions via digital, therefore the most promising financial channels for Big Tech to enter, are routine products/ services such as deposits and payments (Chart 3) (Burns M., du Toit G, 2017).

Chart 3: Products/ services preference to perform either via digital channel or human channel

Source: Burns M., du Toit G., Evolving the Customer Experience in Banking, Bain & Company, 2017.

Apart from payments and deposits, Big Tech companies increased their activity in asset management, insurance and granting loans. Particularly, asset management is considered as a great opportunity for Big Tech companies, due to following reasons:

- steady industry growth (~14% YoY within 5 years),
- high average operating margins (~37%),
- lower regulatory requirements than in banking sector,
- favourable socio-demographic trends (growing middle class, increased life expectancy) (RBC Capital Markets 2020; Wittrock C., 2019).

The biggest Big Tech companies disrupting the banking sector are either US-based or China-based and are entering financial industry by following actions:

1) Amazon – allowing clients to deposit cash without a fee in Amazon Cash, grants credits to Small and Medium Enterprises (SMEs) and provided over USD 5 billion between 2011 to 2019 (CB Insights, 2020). Its' payment service Amazon Pay reached 33 million clients in 170 countries and transaction volume doubled from 2015 to 2017.
2) Apple – Apple Pay was launched in 2014 and it was used in ~10 billion transactions by ~400 million customers within 2014-2019. It also announced partnership with Goldman Sachs to launch credit card.
3) Google – launched Android Pay (later Google Pay) in 2015 and expanded to 17 countries in 2019.
4) Facebook – planning to launch Libra – global cryptocurrency and payment infrastructure and established payment platform Facebook Pay. Facebook is also launching Facebook Financial in 2020 – group that will be in charge of future payments and e-commerce projects (Levy S., Barber G., 2019; PYMNTS, 2020).
5) Ant Financial - launched Alipay, which became the largest mobile payments platform in 2014 (Anjulu S., 2020). Established Yu'e Bao money market fund became the biggest money market fund in the world, having USD ~168 billion Asset Under Management in 2018. Also set up Ant Marketplace platform with 180 million users in 2019.
6) Tencent – WeChat Pay established first QR code and app wallet payment in 2013 and accounted for ~40% of mobile payment market in China in 2018 (Capgemini, 2020).

COVID-19 impact on Big Tech and Banking Sector

According to Accenture, after COVID-19 outbreak, the banking sector experienced significant changes, such as: large decrease in cash usage (~60% drop in ATM cash withdrawal and ~75% interviewed clients planning to use less cash after pandemic), e-commerce adoption (~25% of interviewed clients made first online grocery purchase during pandemic), heavy online banking usage (~73% interviewed clients have been regularly doing transactions online with ~21% of them being first-time online users), contactless usage (~66% transactions in Mastercard have been contactless), significant technology adoption (large increase in digital tools usage and group-collaboration programs), urge to pursue contactless payments (38% respondents of the opinion that contactless payments are the future of payments) as well as social distancing (Finextra, 2020; Mercury, 2020; Kekevi S, 2020).

However, such trends were occurring before the pandemic as well. According to Deloitte, using banking services online was varying from ~40% to ~60% of total usage, while pandemic due to pandemic numbers increased from ~50% to ~70% (Deloitte, 2020). The usage of complex digital banking services, such as robo-advisory, has been on the rise as well (Dziawgo T., 2018). Moreover, number of non-cash transactions as well as their value have been increasing ~10% CAGR globally between 2013-17 (Capgemini, 2019). Therefore, it may be concluded that COVID-19 pandemic further fastens trends that have been already ongoing in the banking industry. What is more, banks experienced increase in market capitalization between Q1 2020 and Q2 2020. Considering one quarter period, combined market capitalization for top 25 banks worldwide increased from USD 2.601 trillion to USD 2.71 trillion. However banks lost significantly in market capitalization between Q2 2019 and Q2 2020. Considering one year period, combined market capitalization for top 25 banks worldwide dropped from USD ~3.5 trillion to USD 2.71 trillion. It accounted for ~23% loss in market capitalization (GlobalData, 2019). What is more, not only COVID-19 had significant impact on the financial situation of the banking sector, but banks also need to take into account numerous global and national regulations, while performing operations (Koleśnik J., 2018; Koleśnik J., Zaleska M., 2018). In case of failing to comply to such regulations, banks could take reputational damage (Niedziółka P., 2020).

Meanwhile during COVID-19, GAFA companies have been having great financial performance. GAFA earned over USD 28 billion in Q2 2020, crossed USD 5 trillion in market capitalization and constitute for over 20% of S&P 500 index (Owen C., 2020.). Amazon's quarterly revenue amounted to USD 88.9 billion, which is ~40% increase in comparison to previous year, Apple's sales revenue increased by ~11%.

To further emphasize COVID-19 impact on both markets, the analysis of key players in both sectors in US market was conducted. Top 5 banks as well as top 5 Big Tech companies in North America by the ranks of market

capitalization in Q2 2020 were considered, which are: JP Morgan, Citigroup, Wells Fargo, Royal Bank of Canada and Bank of America (banks) as well as Microsoft, Google, Apple, Amazon, Facebook (Big Tech companies). The analysis aims at depicting performance of Big Tech and Banking sector in: market capitalization, revenue and net income. The outcome of the analysis was shown in Chart 4, Chart 5 and Chart 6.

Chart 4: Market capitalization analysis between banks and Big Tech companies (USD trillion)

Source: Own elaboration based on Macrotrends and GlobalData (accessed: 12th September 2020).

Top 5 banks' market capitalization decreased from USD ~1.13 trillion to USD ~0.8 trillion, which accounted for ~29% drop. On the other hand, Big Tech companies' market capitalization increased from USD ~4.2 trillion to USD ~6.2 trillion, accounting for ~46% growth.

Chart 5: Revenue analysis between banks and Big Tech companies (USD billion)

Source: Own elaboration based on Macrotrends (accessed: 12th September 2020).

Top 5 banks' revenue decreased from USD ~130 billion to USD ~113 billion, which accounted for ~13% drop. On the other hand, Big Tech companies' revenue increased from USD ~206 billion to USD ~244 billion, accounting for ~18% growth.

Chart 6: Net income analysis between banks and Big Tech companies (USD billion)
Source: Own elaboration based on Macrotrends (accessed: 12th September 2020).

Top 5 banks' net income decreased from USD ~29 billion to USD ~8.2 billion, which accounted for ~72% drop. On the other hand, Big Tech companies' net income increased from USD ~38 billion to USD ~40 billion, accounting for ~4% growth.

Future Outcomes and Conclusions

The research paper aimed to test two hypotheses, which are as follows:

- Big Tech companies have significant potential to dominate global financial system.
- COVID-19 strengthened Big Tech global position and weakened biggest players in the banking industry financially

After using the following methods: critical analysis of literature and research papers, descriptive method and comparative analysis of presented data, both of the hypotheses can be proven positively. Big Tech companies are more than capable in disrupting global financial system in order to diversify their revenue, get access to large volumes of customer data, increase customer volume and loyalty as well as complementing core services. They have large financial resources, astonishing market valuation and great financial performance even during COVID-19 outbreak. Because of those, it may have negative implication on society and economy, in a sense that it could pose a significant threat to national economies. Big Tech dominant position could negatively impact growth of domestic market players and therefore market competition. What is more, increasingly more potential clients are willing to trust these companies with their financials, with PayPal and Amazon having similar trust levels as banks in general. That is especially visible in younger generation, which has higher likelihood to switch to Big Tech due to: low-cost offering, ease of use, faster service, better features or personalized products. Although Big Tech companies have already started to enter financial sector – payments and asset management particularly – likelihood to increase their presence during and after COVID-19 could be higher. Long term trends in the financial sector could be beneficial for Big Tech, since it has been significant drop in cash usage, increase in digital transactions, lesser withdrawals from ATM machines or urge to pursue contactless payments. Big Tech companies outperform banks in market capitalization, revenue and net income, showing that they are not only not affected by COVID-19, but they can benefit from it by leveraging their digital presence and customer data. What is more they do not have to be concerned about heavy global and national regulations that banks have to comply with? On the basis of presented data as well as methods applied in the article, the further presence of Big Tech in financial sector is to be expected.

Abstract

Today's information systems have become one of the most vital resources for organizations in the hotel sector, especially with the COVID-19 situation, which limits the functionality of these organizations. Harnessing information systems allows the continuous modernization of strategies, operations, and service levels, to meet the high competitiveness of the market, improve productivity, and increase customer satisfaction. Because the managers of these organizations are aware of the benefits of controlling information, which include achieving better results and attracting the attention of clients, we carried out a case study for companies in the hotel sector that are seeking to improve their reservation management system. An exhaustive systematic review of the literature from studies published between 2016 and 2020 was carried out. These studies were extracted from several reliable academic sources, and a total of 81 articles were selected. This study has led to the identification of suggestive results that demonstrate the competitive advantage of using agile methodologies for mobile applications in different companies of the hotel sector.

Keywords: Booking Management; Hotel; Mobile Applications; SCRUM; Agile Methodology; Systematic Review.

Introduction

Owing to the increase in tourists, the hotel sector has become a typically engaged business sector with most hotel companies receiving a massive influx of customers, which poses the challenge of developing a management system for room reservations. However, if properly harnessed, the study of reservation management systems via mobile applications can help guests and travelers because it will facilitate and reduce the time it takes to find a place to spend the night while considering their needs and preferences. Consequently, the study of reservation management systems helps to avoid setbacks or events that could make it difficult for customers to scout a proper resting place.

Cite this Article as: Miguel QUIROZ-CERVERA, Daniel YAÑEZ-AGURTO, Javier GAMBOA-CRUZADO, Alfonso ROMERO BAYLÓN, Waldy GRANDEZ PIZARRO and Roger CHANDUVÍ CALDERÓN "A Systematic Review on Hotel Reservation Management using Mobile Applications" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Despite the results obtained from years of research efforts, several relevant studies reveal that comprehensive and systematic review of studies on reservation management systems using mobile applications do not exist. Given the specialty of this research topic and the diversity of theoretical conventions related to the study of reservation management using mobile applications, it is important to map out published studies, summarize, and integrate their results, as well as identify opportunities for future research.

In this article, we report the results of a systematic review of studies published between 2016 and 2020, which addressed the challenges related to stockpile management using mobile applications based on different methodologies. We identify and summarize the major topics investigated in these studies, including the research method. In addition, we tried to integrate the results obtained by mobile phone and other applications, although this integration was not always possible owing to the differences between studies.

This study not only added an empirical analysis to study on reservation management using mobile applications, but it also expanded existing literature by validating a research model that integrates the evaluation of journals that publish articles, which earmarks the value of commitment. Instead of serving as a middleman, the mobile application is seen as one of the indispensable actors involved in creating value by respecting the services it offers. Therefore, it is important that companies in the hotel sector begin to take more advantage of new emerging technologies, as this would define their success in the face of a more competitive world, where competition is steadily increasing.

Therefore, it is clear that the use and development of mobile applications plays an important role in stock management in various areas. Most methodologies are based on the development of a mobile application with these methods pointing to optimal performances, which address different challenges related to one or several processes. Owing to the increasing demand for more efficient and accurate techniques compatible with a work environment, there is a scope for these requirements.

This paper is organized as follows: Section I presents an introduction to the research. In Section II, we discuss the background and important concepts related to the topic. In Section III, we present the methodology used for the research, such as the formulation of questions, objectives, statistical analysis plan, search equations, studies identified, exclusion criteria, classification, and detailed review of the study. In Section IV, we demonstrate the results by answering research questions according to the methodology using statistical analysis and interpreting the studies. In Section V, we discuss the research implications of our findings and the limitations of this systematic review. Finally, in Section VI, we present the conclusions of this research and the direction for future work.

Background and Related Works

According to Langelund (2018), mobile phones have become a requirement for any travel experience, and Wang adds that it provides functionality throughout the entire travel life cycle. This is similar in the context of business travel, although the use of these applications by travelers will often depend on the specifications of their company's mobile phone. Approximately 24% of the companies that manage travel tools stated that they plan to implement and manage the use of mobile tools. The increased use of mobile tools means that more travelers can utilize them.

Talantis et al (2020) suggested that such applications are used in almost all commercial contexts, including the hospitality industry. As the global trend tends towards an "all-mobile" society, modern consumers use mobile applications to make hotel and restaurant reservations, read reviews, and participate in corporate point-of-sale systems. Mobile applications for hotels are becoming increasingly user-friendly, offering desirable features that enhance customer experience in terms of convenience. A study by Phocus Wright (2014) examined the evolution of mobile applications from simple information providers to a more value-added model, which includes context awareness, personalization, and supports individual behavior. Regarding travel and tourism, the results of a study conducted in 2015 by Cornell University show that consumers utilize or are willing to utilize mobile devices at all stages of their travel. The study also suggests that most users are willing to download travel-specific applications.

Chuang et al. (2019) mentioned that consumers are willing to spend the most time on 'travel' applications; mobile guidance services provided in these applications have become increasingly important. Mobile guidance applications allow travelers to preview and experience itineraries before they reach their destination; travelers can use their smartphones to complete this action irrespective of their location. A mobile guidance system that integrates travel information and mapping would provide users with route planning for famous places, latest news, event information, including comprehensive data on food, accommodation, transportation, and recreation.

In a research study by Chuang et al. (2019), it was noted that with all the recent research and startling statistics surrounding the adoption and use of mobile applications, organizations in all industries employed mobile applications and other technological innovations to maintain their competitive advantage. Wu et al. (2018) suggests that mobile business solutions transformed the values of tourism and customer relationship management in e-tourism. Regarding the characteristics of mobile technologies that provide location-based services and more dynamic interactions between customers and providers, 'Satisfaction gained from computers may differ from that gained from books'. However, previous e-tourism literature identify functionality, usability, and perceived value as important dimensions for booking a hotel online. In addition, studies rarely agree on the direct or indirect influence of service quality variables (functionality and usability) on online booking satisfaction.

Mobile software development faces exceptional limitations and requirements. R. Altabeb et al. (2018) mentioned that conventional software development methodologies are not suitable for developing mobile applications. Therefore, there is a need to apply appropriate methods to address the challenges faced during the development of mobile applications. One of these challenges is the challenge posed by multiple platforms. Developers are always planning and concerned about the compatibility of their application with mobile operating systems, such as IOS, Android, Windows Mobile, and BlackBerry. Additional challenges include the time to market, limited user interface, power consumption, processor efficiency, memory performance, and intermittent network connection.

Methods and Materials

In this study, a systematic investigation was carried out on reservation management systems using mobile applications. Kitchenham et al. (2004) defined the objective of collecting evidence that can be used to guide research and practice. Therefore, this review is considered part of the evidence-based software engineering effort.

Fig.1: Systematic literature review methodology

Screening Questions

Research Questions

The systematic review used to assess the effectiveness of mobile applications is described as a means to improve room reservation management. The problems to be answered by this research are presented in Table 1.

Table 1: Research Questions

Questions	Motivation
RQ1: What are the criteria for measuring the overall effectiveness of a mobile application?	Determine the criteria for measuring the overall effectiveness of a mobile application.
RQ2: Who are the most active authors in the area?	Define the most active authors in the area.
RQ3: What means of publication represent the main objectives of research production in the area?	To understand the publication means that represent the main objectives of research production in the area.
RQ4: In what areas have mobile systems been applied?	Describe the areas in which mobile systems have been applied.
RQ5: What methodologies are being used to develop mobile applications?	Determine what methodologies are being used to develop mobile applications.

Search Equation

Search Sources

For the systematic review of the literature, we obtained information from 10 search sources, applied the search terms, and formulated the following search equations:

- Google Academic
- IEEE Xplore
- Springer Link
- Science Direct
- Microsoft Academic
- AMC Digital Library
- Taylor & Francis
- Scopus
- EBSCOhost
- ProQuest

Search Terms

To establish the logical relationships that will be given, the word terms or exact set of words that we will use to perform our search equations are established in a clear and precise way, by taking into account our variables: independent, dependent, and intervening.

Table 2: Search Terms

English	English	Description
Applications/Mobile	Applications/Mobile	Independent
Management/Booking	Reservation/Management	Dependent
SCRUM (Methodology/Method/Model)	SCRUM (Methodology/Method/ Model)	Speaker

Search Equations

The search equations, which were used in this research when applying the terms and conditions for each of the sources are presented in Table 3.

Table 3: Search Equations

Identified Studies

Consolidated Number of Results by Source

As can be observed in Fig. 2, "N" represents the total number of articles discovered through the search equations provided by 10 sources, in which a total result was given, where (N = 20 814) articles were published in 10 sources.

Fig.2: Consolidated Number of Results by Source

Deferral Criteria

Exclusion Criteria

A list of exclusion criteria was drawn up to avoid selection bias and to apply the criteria rigorously. These criteria depend on the objectives of the research for which 6 exclusion criteria were defined.

Table 4: Exclusion Criteria

N°	Description	Does it work?
EC1	The items are not older than 4 years OR	✓
EC2	The articles are not Articles OR	✓
EC3	Articles are not written in English OR Spanish OR	✓
EC4	The articles do not have a title or keywords related to our criteria OR	✓
EC5	Articles do not have an Abstract related to our criteria OR	✓
EC6	The articles do not propose a solution compatible with the OR	✓

Consolidated Number of Results when Applying Exclusionary Criteria

As can be observed in Fig. 3, the articles discovered via the search equations and their logical relationships with 10 sources provided a result, where N was equal to 20 814 articles, however, not all of these articles were potentially relevant to our study. By applying the exclusion criteria successively, the number of articles decreased according to the criteria, and our sample articles were left with just 81 articles that were relevant to our topic.

Fig.3: Consolidated Number of Results when Applying Exclusionary Criteria

Quality Evaluation Criteria

Table 5: Quality Evaluation Criteria

N°	Description	Does it work?
QA1	Does the article have a well-organized and explained structure?	✓
QA2	Is the article relevant to our investigation?	✓
QA3	Are the bibliographic sources reliable?	✓
QA4	Is the purpose of the research clearly explained in the article?	✓
QA5	Are the research findings clearly explained in the article?	✓
QA6	Is the item not duplicated by another item?	✓

After applying the six quality criteria to the 81 articles selected for the study, they all met the quality criteria, which ensures that they will provide the information required for the development of this study. References to these studies are included in Appendix A at the end of the document (i.e., [1], [2], ..., [81]).

Classification of Studies

Reports with Mendely from the Classified Studies

We classified 81 articles in a matrix with their Document title, Year, Research Methodology, and Authors to validate our final studies in more detail, which we will work with to conduct this study.

We decided to adopt Mendeley, in which the 81 articles were divided into two folders: Spanish and English. In each folder there is a subfolder with the name of each font that we have used for this research, in which the amount of articles is detailed by font.

Fig.4: Report with Mendely

Results

Summary of Studies

In Fig. 5, you can see that the most used words in this research are Scrum, Mobile, Agile, Application, and Development.

Fig.5: Word clouds by article title

Figure 6 shows that the USA has the most cited items, followed by India, which ranges from 15 to more citations used in the items. It should also be noted that Ecuador has an average number of articles with more than 15 citations.

Fig.6: Items and Range of Quotations by Country

A. Response to RQ

RQ1: What are the criteria for measuring the overall effectiveness of a mobile application?

Based on the literature review, there are metrics for measuring the overall effectiveness of mobile applications, as presented in Table 6:

Table 6: Criteria for measuring the overall effectiveness of a mobile application

N°	Effectiveness Criteria	References	Total Items
1	Agility	[1] [3] [4] [5] [8] [10] [11] [12] [14] [15] [17] [18] [19] [20] [21] [23] [26] [29] [31] [32] [33] [35] [36] [37] [38] [40] [41] [42] [43] [45] [46] [47] [48] [49] [51] [52] [53] [57] [58] [59] [60] [62] [63] [64] [65] [66] [67] [71] [72] [73] [75] [77] [79]	54 (67%)
2	Cost	[3] [10] [19] [23] [32] [36] [37] [40] [45] [51] [54] [55] [57] [61] [62] [65] [75] [77] [81]	19 (23%)
3	Request	[1] [3] [14] [16] [19] [20] [21] [22] [24] [25] [26] [27] [29] [32] [34] [43] [45] [46] [48] [50] [51] [55] [57] [58] [61] [64] [69] [74] [78] [79] [81]	31(38%)
4	Response Time	[22] [41]	2 (2%)

The criteria for measuring effectiveness are Agility, Cost, Requests, and Response Time. A mobile application needs a development based on agile methodologies, where agility could be found in 54 articles [1]. The adoption of the agile method has evolved from a decision between particular agile methodologies into a more complex and adaptive process, in which the various agile practices are combined and recombined when necessary, as well as adapted to each organization and their needs and contexts [40]. Unlike traditional methods, agile approaches provide high quality software continuously and consistently while minimizing project costs [32]. The booking management system is based on the ease of administering spaces and reservations, for which it is necessary to register requests with a click [20]. It is necessary to measure the response time of the mobile application in the data center for a request [22]. The effectiveness criterion mostly used by researchers is Agile with a total of 54 articles, which is 67% of 81 articles reviewed. However, the Response Time is the lowest with only 2 (2%).

RQ2: Who are the most active authors in the area?

The top five authors out of 81 articles per reference number can be observed from graphs 7 and 8.

Fig. 7: Autores más Activos en el Área 1

Fig.8: Most Active Authors in Area 2

The articles that contributed the most to our research with the resolution of the RQs are [2], [51], [52], [55] and [70]. Where [2], [51], [52], provided us a total of 12 pages that answer the RQs while[55] and [70] give us a total of 11 pages. With this, we can identify the authors who are active in this study area, and those who helped to answer our questions.

Authors	<5	≥15	≥5 and <15	Total

Fig. 9: No. of Quotations per Author and their Range

Fig. 9 also shows the authors with the highest number of citations. Kaur, A, the first author has a total of 93 citations, whereas Sea Talantisa, the fifth author, has a total of 69 citations.

RQ3: What means of publication represent the main objectives of research production in the area?

As can be observed in graph 10, we consider the number of citations and the means of publishing these articles.

Publication Name	<5	≥15	≥5 and <15	Total
Department of Computer Science and Engineering		7	1	8
Archives of Suicide Research		1		1
ASEE Annual Conference and Exposition			1	1
Central Connecticut State University			1	1
Chair for Informatics		1		1
Communication Teacher		1		1
Computer and Information Sciences		1		1
Computer Game Programming		1		1
Computer Science and Software Engineering		1		1
Total	1	58	22	81

Fig. 10: Publishing Media with more Production in the Area

The publication with more production in the area was that of the Department of Computer Science and Engineering, which stood out with eight published articles, of which seven of them had more than 15 dates and the other one had less than 15 dates.

Fig. 11: Number of Articles by Type of Publication

Furthermore, we can observe that 85.2% represents Journals, whereas 14.8% represents Proceedings found in this systematic review with a total of 81 articles.

RQ4: In what areas have mobile systems been applied?

Table 7 shows that five areas were found in this systematic review.

Table 7: Areas of Mobile Applications

N°	Areas of Mobile Applications	References	Total Items
1	Events	[2] [3] [6] [7] [9] [11] [16] [22] [31] [43] [46] [52] [55] [57] [58] [59] [60] [70] [74] [78] [81]	21(26%)
2	Hotel	[13] [16] [20] [25] [28] [61] [70] [80]	8 (10%)
3	Medicine	[13] [39]	2 (2%)
4	Software	[1] [3] [4] [5] [10] [11] [12] [13] [14] [15] [17] [18] [19] [20] [21] [22] [23] [26] [27] [28] [29] [30] [31] [32] [33] [34] [35] [36] [37] [38] [39] [40] [41] [42] [43] [44] [45] [46] [47] [48] [49] [51] [52] [53] [57] [58] [59] [60] [62] [63] [64] [65] [66] [67] [68] [69] [70] [71] [72] [73] [74] [75] [76] [77] [78] [79] [81]	66 (81%)
5	Sport	[2] [9] [20] [21] [30] [31] [44] [74] [78]	9 (11%)

Mobile applications for events are one of those technological advances that have experienced exponential growth in the last decade [70]. As the trend for everything mobile grows, modern consumers use mobile applications to make hotel and restaurant reservations, read reviews, and engage in business [70]. However, for effective application, medical researchers need an understanding of system development and design [39]. Agile principles value working software over documentation and are intended to be adaptive and responsive to changing situations [81]. To improve service and control, mobile applications in sports centers are used to make bookings [21]. Software is the area with the most items found with 66 (81%) and the least Medicine with only 2 (2%).

RQ5: What methodologies are being used to develop mobile applications?

Many methodologies could be observed when performing different types of applications or systems, but the most relevant and used are presented in Table 8.

Table 8: Most Used Methodologies with Mobile Applications

N°	Types of Methodologies	References	Total Items
1	Banana	[79]	1 (1%)
2	Kanban	[8] [14] [18] [20] [23] [32] [40] [48] [51] [58] [59] [72] [75] [79]	14 (17%)
4	Scrum	[1] [2] [3] [4] [5] [7] [8] [9] [10] [11] [12] [14] [15] [17] [18] [19] [20] [21] [22] [23] [26] [29] [30] [31] [32] [33] [34] [35] [36] [37] [38] [40] [41] [42] [43] [44] [45] [46] [47] [48] [49] [51] [52] [57] [58] [59] [60] [62] [63] [64] [65] [66] [67] [71] [72] [73] [75] [76] [77] [78] [79]	59 (73%)
5	XP	[1] [2] [3] [4] [5] [6] [7] [8] [9] [10] [11] [12] [13] [14] [15] [16] [17] [18] [19] [20] [21] [22] [23] [24] [25] [26] [27] [28] [29] [30] [31] [32] [33] [34] [35] [63] [37] [38] [39] [40] [41] [42] [43] [44] [45] [46] [47] [48] [49] [50] [51] [52] [53] [54] [55] [56] [57] [58] [59] [60] [61] [62] [63] [64] [65] [66] [67] [68] [70] [71] [72] [73] [74] [75] [76] [77] [79] [80] [81]	79 (98%)

Banana, Kanban, Scrum, and XP occupied the top 4. The first and least used was Banana with 1 (1%) item, a term used among practitioners to describe processes that produce immature products, which have to "ripen" after being sent to the customer, as in real bananas [79]. Another method that was widely observed was Kanban, which is a method for evolving, increasing the process, and identifying workflow problems [75]. Scrum was also one of the most encountered when reviewing the study. Scrum covers almost any type of project and works with the fundamental principle of agile methodologies [21]. Finally, XP was positioned as the most used methodology for the different research topics. Many authors use it because it is an evidence-based methodology and one of the most popular, as it is mentioned in 79 (98%) articles of the 81 found in the research [79], the lowest being Banana with 1 (1%) article.

Discussion

To the extent that it has been researched, this study is the first attempt to systematically review the literature on research related to hotel reservation management using mobile applications. The results obtained show a high concentration of empirical research on the study of mobile applications within the hotel sector. The other research questions received less attention. Additionally, no empirical replications were found. One of the contributions of this study to the research community is that it can guide future research, and influence the practice of mobile applications applied to the hotel sector.

For business professionals, the direct application of the results presented in the studies must be done carefully using some of the methodologies developed (Scrum, Kanban, XP, Banana). Evidence suggests that this field of research is not mature and that the direct application of the methods and instruments used may not produce the desired effects required to develop a mobile application for the hotel sector. In particular, according to Mitch Bott & Bryan Mesmer, the transition between the models and the real-life system requires development, therefore, testing the process in a pilot program will prove vital [52]. Furthermore, to assess the possibility of generalizing the results in the context of other possible environments, it is necessary to conduct a careful analysis of the environment in which the study was conducted.

Conclusions and Future Works

In conclusion, this study adopted systematic literature review (SLR), which is a repetitive process that combines all existing literature on a specific topic or research question. The goal of the SLR is to address problems by identifying, assessing, and integrating the findings of all relevant high-quality studies that address two or more research questions.

This method determines the progress of current studies on the use of mobile applications. Considering 81 articles, four criteria were determined to measure the overall effectiveness of a mobile application. The most widely used criterion is "Agility," which was used to evaluate its overall effectiveness. The study obtained a total of 81 articles between Journals and Conference Proceedings. In addition, it was determined that the most relevant studies present between 11 and 12 pages helped answer the largest number of RQs, being the publication medium of the Computer Science and Engineering Department, which had the highest production in the area of mobile applications. Five areas were evaluated to measure the use of mobile applications, with "Software" as the most utilized area. Next, the methodologies that are mostly used for the development of a mobile application were evaluated; the most with Scrum and XP being the most used. The definitions required to refer to mobile application are Application Development, Software Application, Mobile apps, and Apps. This research has some limitations. First, it does not explain the development of a mobile application in detail. However, it does explain the use, purpose, and application methods of mobile applications in different aspects already mentioned. Therefore, to ensure that the results are as expected and help researchers in general, future research should consider the development of a mobile application and better understand the SLR methodology.

Abstract

The aim of this article is to identify and assess key company competences in terms of Industry 4.0 and related challenges. In particular, it seeks to find out what personnel attributes a company should have to be able to effectively compete in a world of advanced technological strategies developed as a natural consequence of technological progress, development of production means, growing awareness and requirements of consumers, and innovation. These elements are indicated as extremely significant in the transformation of industry, reflected in the digitization of production, automation, and production plants combined into coherent and comprehensive chains based on automatic information exchange. While posing a challenge for companies, these phenomena also allow them to achieve greater results in contemporary world. Due to the multidimensional and multifaceted nature of the discussed problem, factor analysis (Principal Component Analysis) was adopted as the basic research method. This empirical study allowed us to identify areas of key personnel competences of a company, with their value, cognitive load, and impact. They were classified in six categories: professionalism, internal relations, professional preparation, risk, employees, and contractors/clients, they constitute a common ground for the company's operations that should be invested in, developed, and customer service.

Keywords: Key competences, Industry 4.0, personnel competences of the organization

Introduction

One of the most important developments that will continue to determine the operations of enterprises in the nearest future is the revolution inspired by the ongoing technological progress and known as Industry 4.0. In this concept, future development is based on digitization and automation, processual and organizational innovations, the Internet of Things, and servitization employed by production companies, which eventually lead to vertically and horizontally integrated production systems (Thoben et al., 2016). In particular, changes will be observed in fields, such as big data analysis and processing, augmented reality, 3D printing, computing, public cloud, cybersecurity, mobile industrial robots, simulation, horizontal and vertical software integration, and the Internet of Everything and its use in industry (Report 2017). Seeking to incorporate these changes, companies will face a number of challenges, including the need to reconfigure their goals, technical and technological qualities, relations with stakeholders, as well as their tangible, financial and human resources (HR). The latter are of particular importance, and must be considered through the prism of competences related to experience, skills, knowledge, culture, professionalism, etc. The current competences, based on traditional models of company management, will be subject to evolutionary changes. The new, augmented reality will enforce a new approach to tasks, internal and external relations, ethics, environment, resource management, etc. While Polish enterprises are not yet prepared for such changes, they are aware of the need to modify their long-term assumptions. This article focuses on

identifying personnel competences that may prove significant for organizational changes triggered by Industry 4.0.

Theoretical Background

The first assumptions regarding Industry 4.0, referred to as the Fourth Industrial Revolution in the literature (Stadnicka et al., 2017; Schwab, 2016), were proposed in Germany in 2011 with respect to the economic policy of the state that should be based on advanced technological strategies (Pereira and Romero, 2017; Hermann et al., 2015). The concept of Industry 4.0 includes a set of assumptions that, on the one hand, constitute a kind of challenge, but on the other hand, will allow companies to achieve great results in the future. They include as follows: cybersystems, Internet of Things, Internet of Services, robotics, Big Data, cloud computing, and augmented reality (AR). Other hallmarks of this industrial revolution also include complexity, interoperability, virtualization, decentralization of decisions, real-time capabilities, service orientation, and modularity (Ibarra, 2017). Investments in these components will contribute to the development of smarter production processes based on machines and production modules that are able to communicate with each other, creating an intelligent production environment (Pereira and Romero, 2017; Sommer, 2015). They provide a framework for the total automation and digitization of production and services, with increased application of electronics and IT (Almada-Lobo, 2016; Roblek et al., 2016; Report, 2017; Vaidya et al., 2018). According to Stock and Seliger (2016), challenges related to Industry 4.0 concern also other areas, such as equipment, workforce, organization, processes, and products.

The emerging changes result in building completely new relationships with clients, a possibility to produce new products and services, and create a new environment for collaborations, all of which contributes to the implementation of a new business model (Ibarra, 2017). This model requires adjustments in terms of standardization, work organization, availability of skilled employees and their competences, research investments, professional development, and legal framework (Thoben et al., 2017; Maslarić et al., 2016). Those related to the HR are of particular importance, as technical growth induces workforce restructuring (Kane et al., 2015). On the one hand, skills and competences of increasing levels will be required, but on the other, increased efficiency enabled by smart technologies may result in technological unemployment (Hungerland et al., 2015). In addition, Industry 4.0 introduces new types of interaction between operators (humans) and machines, which requires a specific coexistence of humans and robots, or transformation of the current workforce in the industry, to meet the changing needs and ensure the increasing variability of production (Pereira and Romero, 2017). With the ongoing nature of technological development, according to the concept of Industry 4.0, human capital will provide a link between technology and reality. Regardless of the size of the organization, human capital is argued to be the most important part of the intellectual capital (Gorustowicz, 2019). Human resources should possess unique skills, experience, qualifications, and expertise that will distinguish them from the competition (Moczydłowska, 2012). Personnel in Industry 4.0 must therefore have specific competences, both hard and soft. The former are associated with production processes and expert knowledge necessary to implement them, while the latter have an effect on the implementation of tasks, interpersonal relations, cooperation, and collaboration (Gorustowicz, 2019). They constitute new employee competences, around which respective HR processes should be developed to build the necessary competences of a company with respect to acquiring, managing, and retaining employees in the conditions of Industry 4.0.

Competences are typically defined as 'the scope of knowledge and skills, professionalism, expertise' (Kopaliński, 2006, p. 406). In practice, they are associated with synonymous terms, such as professionalism, expertness, craftsmanship, proficiency, experience, mastery, faculty, reliability, talent, etc. At the level of the organization, they should be considered in a broader context of skills as the resultant of a set of different qualities of an organization (Rokita, 2005). According to Siwak (2015), company competences comprise management competences of the company owners, employees, and associates, which altogether form the human resources of a given entity. It may therefore be said that the concept of competences covers the following aspects (Kossowska and Sołtysińska, 2002):

- Mastering the knowledge of a given field;

- Skills defined as procedural knowledge;
- Attitude of willingness and readiness to use this knowledge.

In more personalized terms, these qualities are often extended to include personal characteristics, mentality, disposition, individuality, character (Whiddett and Hollyforde, 2003), competences of the company owner and employees, and organizational memory and knowledge (Sigismund et al., 2011). The thus defined competence often appears in combination with another term to specify its meaning, such as court competence, key competence, linguistic competence, personal competence, social competence, etc. According to Coulson-Thomas (2009), the identified competences should be grouped as: personality traits, awareness of business environment, sense of responsibility, vision and strategic perspectives, knowledge of corporate governance and its requirements, understanding of the structure and principles of top management, teamwork, decision-making skills, corporate experience, ethics, and respect for other values.

The biggest challenge in implementing the ideas of Industry 4.0 in Poland is the fact that due to the extremely short period of economic modernization this country is faced with three coinciding waves of revolution: the still visible relics of the second industrial revolution, the third revolution, which is the reality of most organizations, and now the fourth revolution (Kaczmarek-Kurczak, 2020). Consequently, brining enterprises to the next level of Industry 4.0 is a truly difficult task, and to ensure the coherence of company operations it is essential to make people see and think of certain situations in a similar way. This should translate into consistent decisions and help managers work with their employees more closely, and therefore develop common patterns of thinking. Management competences and employees' competences are included in the key competences of the organization, influencing its development and value for stakeholders (Siwak, 2015). In general, core competencies have been seen as capabilities held by people within a firm that, when applied through corporate operational processes to create products and services, make a critical contribution to corporate competitiveness (Edgar i Lockwood, 2011). All of this prompts the following research question: What personnel competences, in terms of ensuring the necessary human resources and processes, are needed for a company to enter the realm of Industry 4.0?

Research Method

An empirical study was conducted in the first half of 2020 to identify key personnel competences as part of broader observations of the knowledge, awareness, and approach of Polish entrepreneurs to changes related to Industry 4.0. Because of the nature of the studied problem, quantitative methods were applied with a multidimensional comparative analysis. The analysis was based on a questionnaire consisting of two parts. The first part, metrical, contained questions about the number of employees, company's profile, sales markets, strategy, and legal form, which provided for a complete characterization of the sample. The second part offered a list of competences (Figure 1) based on the literature research (Coulson-Thomas, 2014), interviews, consultations with business representatives, and own analyses. The competences were assessed by the respondents on a 5-point Likert scale, where 1 denoted a competence that was insignificant for the company in the context of Industry 4.0 challenges, and 5 – a competence of extremely high significance. The collected empirical material was coded and converted into numerical data for detailed analyses of the studied population. The adopted scale allowed us to determine the strength and direction of the impact of each variable by calculating the arithmetic mean and determining the so-called significance coefficient N.

Due to the multidimensional and multifaceted nature of the discussed problem, factor analysis (specifically, Principal Component Analysis, PCA) was adopted as the basic research method. The decisive factor for choosing this procedure was the individualized and subjective characters of most responses. This method is used in situations where a given phenomenon is studied using a series of possibly interdependent variables. This type of analysis allowed us to eliminate insignificant variables, stemming from the original study, the effect and significance of which were difficult to determine in the initial period. Factor analysis is a set of methods as a result of which many initial variables are reduced to several mutually independent main factors. The procedure consists of several steps. Firstly, a square matrix of correlation coefficients between the initial variables is developed. Secondly, highly correlated groups of variables are identified. A strong correlation means that the

same information is repeated in some characteristics, which contributes to the distortion of the output data. In this study, the Spearman's rank correlation coefficient was used which determines the level of linear relationship between random variables. Thirdly, a factor loadings matrix is created which includes information on the value of correlation coefficients of all initial variables reflected in each of the main factors. Next, the matrix is subjected to the varimax rotation, which allows us to maximize the variance of the factor loadings for each identified main factor. As a result, a new matrix is obtained which contains information about the value of the correlation coefficient between the individual initial variables and a given main factor. Theoretically, the number of the main factors may be one less than the number of the variables, which however would be pointless from the research point of view. Therefore, the essential characteristics must be verified using one of the techniques: Cattell's scree test or the Kaiser criterion. In practice, both methods are used together: first the scree test is conducted which is then verified using the Kaiser rule. Eventually, all factors on the scree plot before the selection point ("the elbow"), for which the eigenvalues exceed 1, are admitted for further analysis. This procedure ensures the basis for the logical interpretation, which is the last step in the factor analysis. It provides for a broad and thorough explanation from the point of view of new socio-economic categories, as defined by the main factors, and the organization of the factors in the orthogonal spaces. Calculations were carried out in Statistica StatSoft 13.3, using descriptive statistics, correlations, and multivariate analyses.

Non-probability purposive sampling was applied to select typical subjects for the study. The basic criterion was the type of business, industrial activity or provision of industrial services, as verified against NACE Rev. 2[1]. The questionnaire was sent to 500 companies operating on the Polish market, with 176 sending the forms back, of which 159 (32%) were admitted for further analysis. The remaining forms were rejected as non-compliant or incomplete. The detailed characteristics of the sample are presented in Table 1. All companies participating in the study came across the issues related to Industry 4.0 in their core activity.

Table 1: Characteristics of the enterprises according to the adopted criteria

No.	Characteristic	No. of indications N=159	Share (in %)
	Enterprises		
1.	Small	78	49.1
2.	Medium	67	42.1
3.	Big	14	8.8
	Respondent		
1.	Owner/chairman	57	35.8
2.	Director / manager	15	9.4
3.	Specialist	87	54.7
	Year of foundation		
1.	Until 1990	41	25.8
2.	1991-2000	48	30.2
3.	2001-2010	31	19.5
4.	After 2010	39	24.5
	Business profile[1]		
1.	Production	53	33.3
2.	Production services	106	66.7
	Legal form		
1.	Enterprises of natural person	22	13.8
2.	Limited liability company	94	59.1
3.	General partnership	8	5.0
4.	Public limited company	27	17.0

[1] Industrial processing covers industries with codes 15 to 37.

5.	Partnership	5	3.1
6.	Other forms	3	1.9
Market[1]			
1.	Local market	80	50.3
2.	Regional market	75	47.2
3.	Domestic market	103	64.8
4.	International market	75	47.2
5.	Global market	21	13.2
Basic strategy (the company could indicate more than one option)			
1.	Quality strategy	74	46.5
2.	Price strategy (cost leadership)	89	56.0
3.	Differentiated strategy - depending on the supported regions, businesses	21	13.2
4.	Niche strategy	15	9.4
5.	Mixed strategy (average quality for average price)	9	5.7
6.	Lack of strategy	13	8.2
7.	Strategy of imitators	41	25.8

Results

The analysis revealed that the significance coefficient N of all examined variables ranged from 3.1 to 3.9. From the respondents' point of view, experience acquired at work proved to be particularly important. It gave employees the ability to perform tasks assigned to a given function, properly and correctly, without the need for consultation or supervision of the line manager. It also translated into employees' efficiency, commitment, and approach to work, which is generally reflected in the company's improved performance, trouble-free execution of the plan, reduction in production shortages, etc. According to the respondents, the next four competences were nearly just as important (significance coefficient = 3.8). The first one concerned the relationship between employees and management. The high value of this competence was confirmed by other observations, which emphasized the importance of communication, partnership, and information flow in the process of the company's adaptation to new conditions. Moreover, focusing on relationships seems to provide all employees with equal development opportunities and assessment measures, increasing employees' self-esteem and awareness of directions in the company's development. Conflicts, antagonisms, or confrontations tend to do the opposite, prompting the destruction of the entire system. The next two competences, for which the significance coefficient was 3.8, may be considered jointly, because they related to teamwork skills and partnership relations among employees. They are compatible and contain a similar information loading; after all, without proper relations there is no teamwork. In accordance with the idea contained in the variables, employees should be entrusted with tasks consistent with their competences, skills, and qualifications, and should be provided comprehensive assistance in case of complications or problems. This is because teamwork is based on collaboration, joint performance of tasks, mutual help, and facing consequences for the achieved results as a collective. The last competence that proved significant was openness and flexibility to user requirements. A company that wants to be active on the market, particularly in light of the Industry 4.0 challenges, must take into account demands, suggestions, proposals, and even requirements of its clients/contractors. Ultimately, the success of the organization depends on them. Detailed distribution of all responses is presented in Chart 1.

Out of five competences with the highest significance coefficient N, four related to the company's internal conditions, and only one to its relations with the market. However, the rather small spread of the obtained results makes it impossible to conduct a detailed analysis and identify the advantages clearly indicative of the company's position in the face of Industry 4.0. The process of identifying and assessing the personnel competences that are of key importance in terms of current changes is very complex and time-consuming, and is not always reflected in the economic reality. This problem can be solved by the reduction of initial variables and assigning them appropriate ranks (dimensions).

To this end, factor analysis was used to simplify the initially complex structure into a simpler one (with the use of factors). In accordance with the procedure, a correlation matrix was created, which was then subjected to further analysis. As a result, a large number of variables were found to reveal a high correlation with other variables. In practice, correlation between two variables is assumed to be not clear for $r_{xy} \leq 0.3$, moderate for $0.3 < r_{xy} \leq 0.5$, and clear for $r_{xy} > 0.5$ (Ignatczyk and Chromińska, 2004, p. 170).

Analyzing the data in the matrix (Table 2), a particular degree of correlation was found between the following variables:

- Strategic goals and tasks for individual work cells (0.54), and the company's attitude to employee motivation (0.53);
- Specific tasks and responsibility (0.65), and employees' qualifications (0.51);
- Responsibility and employees' skills in the use of technology (0.6);
- Qualifications and experience of managers, and qualifications and experience of employees (0.7), and experience acquired at work (0.51);
- Training, including internal training, with both individual and group learning (0.57), and employees' commitment (0.5);
- Procedures and programs, and motivation (0.59);
- Motivation and structure (0.6), learning process (0.51), commitment (0.51), work culture (0.5), and knowledge (0.53);
- Learning process and commitment (0.65), culture (0.55), and knowledge (0.6);
- Commitment and culture (0.62), and knowledge (0.59);
- Relations between employees and management, and teamwork skills (0.62);
- Teamwork and partnership relations among employees (0.59);
- Customer service and openness, and flexibility to user requirements (0.57);
- Standards and principles of management, and approach to conflicts (0.66).

Variables were numbered as shown in Figure 1.
Marked correlation coefficients are significant, with p <0.05000.
Source: own study.

Strong and moderate correlation means that the information contained in individual variables is repeated many times, which points to a hidden structure between the principal components that affects individual competences. Using factor analysis, many initial variables could be reduced to several factors containing a "synthesis" of information derived from the respective dimensions. These factors carry both a large amount of information from the initial variables and some new information.

Table 3: The eigenvalues of factors obtained in the factor analysis

Factor	F_1	F_2	F_3	F_4	F_5	F_6	…	F_n
Eigenvalues	11.3	1.9	1.7	1.2	1.1	1.0	…	27
% of variance	41.8	7.0	6.2	4.5	4.2	3.7	…	100
Cumulative eigenvalues	11.3	13.2	14.9	16.1	17.2	18.2	…	
Cumulative % of variance	41.8	48.9	55.1	59.6	63.8	67.6	…	100

Source: own analysis.

Based on the analysis of the results presented in Table 3, six factors containing the cumulative information for which the eigenvalue exceeded 1, were admitted for further work. The first factor explained nearly 42%, the second 7%, the third more than 6%, and the others (altogether) 12.4%, of total variance. Altogether, the six factors explained over 67% of the studied phenomenon, while the remaining 21 factors approximately 33%. The analysis of the remaining factors could therefore be assumed to be redundant. In order to confirm their correct selection, the six factors were verified using Cattell's scree test for the graphic determination of the selection point ("the elbow"). The elbow is where the eigenvalues seem to level off, rendering the remaining factors (to the right of this point) the "scree" and thus hardly significant.

As a result of the transformation of the primary correlation matrix, a factor loading matrix was obtained, which was subjected to the varimax rotation. In accordance with the PCA method, the subsequent factors were responsible for a smaller and smaller range of variance. This procedure made it possible to reduce initial variables (included in the analysis) to a group of six factors that characterized the studied phenomenon to a high degree. Variables were assumed to be significant for loading values (correlations) above 0.65. The rotated factor loadings are presented in Table 4.

Table 4: Factor loading matrix after rotation.

Loadings marked for values above 0.65.
Source: own analysis.

The first factor, in which a significant amount of information was cumulated, was described by four initial variables. The company's activity in the field of developing employee knowledge had the highest value (0.78), with which two more were connected: the learning process (both individual and group), and employee commitment to the performance of the assigned tasks. This factor was also influenced, to a slightly lesser extent, by training courses and various forms of additional education. As this factor is mainly related to skills and experience, it was labeled "professionalism".

The second factor was characterized by three variables, the most important of which were partnership relations among employees (0.71). Ability to work in a team (0.68), and relations between employees and management (0.66) were directly related to it. This factor referred to cooperation, collaboration, and the ability to perform tasks together, and was therefore named "internal relations".

Table 5: Factors determining personnel competences in Industry 4.0 – summary

Factor					
F1	F2	F3	F4	F5	F6
Professionalism	Internal relations	Professional preparation	Risk	Employees	Customer service
Developing employee knowledge Committed and competent employees Learning process (individual and group) External and internal training	Partnership relations among employees Teamwork skills Relations between employees and management	Qualifications and experience of employees Qualifications and experience of managers	Precisely defined responsibility Matching skills to technology	Employees in non-managerial positions Engineering staff	Openness and flexibility to user requirements Manner and methods of customer service
% of variance: 11.3	1.9	1.7	1.2	1.1	1
Cumulative %: 11.3	13.2	14.9	16.1	17.2	18.2

Source: own study.

The next, third factor gathered information from two initial variables related to qualifications of both management (0.77) and employees (0.8). It should be noted that qualifications and skills of employees, which translate into the company's operational activity, had a slightly greater impact here. This factor was identified as "professional preparation".

The fourth factor was related to the risk faced by employees in the ongoing performance of tasks. It was described by two initial variables: responsibility for implemented actions (0.74), and proper allocation of tasks and ability to operate technical equipment at a specific workplace (0.73). This factor has a significant effect on the company's operational activity, achievement of goals, asset productivity, and work efficiency.

The next two factors proved to be slightly less important. The fifth factor concerned employees as characterized by employees in non-managerial positions (0.79), and engineering staff (0.77). In particular, the ratio of the number of technical workers to that of production workers seems important. The more complicated is the production process or equipment requiring specific qualifications, the lower this ratio should be. The sixth factor was related to customer service, with all its procedures, requirements, terms of cooperation, etc. It contained

information derived from two initial variables, i.e. openness and flexibility in relations with contractors (0.73), and the manner and methods of service (0.67). A summary of all factors is presented in Table 5.

Conclusion

Focusing on key competences is a strategic and tactical approach of a company to changes triggered by the current industrial revolution. Their proper recognition and use contribute to continuous development, implementation of adopted strategies, prompt response to contractors' new demands, flexibility of response to changes in the environment, and preparation for crisis situations, conflicts or misunderstandings.

Unfortunately, it is not an easy task to define and diagnose the most significant assets, strengths, and values. It requires the involvement of all employees, both at the managerial and basic level, along with the identification of key resources, activities, functions, even relationships that make a given organization unique.

This empirical study allowed us to identify areas of key personnel competences of a company, with their value, cognitive load, and impact. Classified in six categories, professionalism, internal relations, professional preparation, risk, employees, and contractors/clients, they constitute a common ground for the company's operations that should be invested in, developed, and improved. If a company does not have any of the indicated categories, does not develop them evenly, or they are very weak, its corresponding competences are marginal and have a limited impact on the company's competitive position. Correct identification of key competences and their innovative use provide for the company's sustainable development and better preparation for changes related to the industrial revolution, which ultimately is reflected in a better competitive position.

Naturally, this study is not without limitations. It focuses on Polish companies where, firstly, approach to issues related to Industry 4.0 is relatively weak, and secondly, most entrepreneurs, particularly those from the sector of micro and small enterprises, do not diagnose the current changes, relying in their business operations on traditional methods and values.

Abstract

The aim of this paper is to develop an advanced sensor monitoring system and to corelate it with a Facility Management (FM) enterprise platform in order to support the facilities managers to make decisions regarding the use of space or the cancellation of reservations. For this purpose, a system of sensors consisting of two infrared sensors working in pairs and a sensor that measures the light intensity was developed and ARCHIBUS was chosen as the FM platform. The results received from the sensor system were correlated with the data and the reports from the FM application, having as central element the analysis of real number of participants vs planned number of participants. Various reports made in ARCHIBUS application that use the data received from the sensors are discussed and their practical utilities are listed. The sensor system is cheap, and its scalability allows the management of an unlimited number of objectives.

Keywords: FM Software, People Counting, Sensor System, Rooms Reservation.

Introduction

IoT is a rapidly expanding technology that enables devices to communicate without human intervention. In the last period the number of applications that make use of the IoT has increased dramatically and it spans areas from business and manufacturing to home, health care, and knowledge management (Nord et al. 2019). Over time, the IoT is expected to have significant home and business applications, to contribute to the quality of life and to grow the world's economy (Al-Fuqaha et al. 2015). One aspect to consider in IoT systems is how to communicate with the sensors, how they transmit data. Among the most used technologies are RFID and sensor networks, they are considered the fastest growing information and communication technologies (Gubbi et. al 2013).

According to the definition given by the International Facility Management Association (IFMA), FM is a profession that includes several disciplines helping to ensure the functionality of the built environment by integrating people, space, processes, and technology (EuroFM 2019). In accordance with the European standard (EN 15221-1 2006), FM is the integration of processes in an organization in order to maintain and develop the services it provides and to effectively improve the primary activity of the organization. A wide variety of commercial software applications are available on the market to meet FM requirements.

In the field of Facility Management (FM), the impact of IoT is growing and IoT is playing an important role in improving FM services. Although there is a lot of data, the use of sensor data recording in FM is much lower. Recently, great attention has been paid to the potential to expand the applicability of major digital technologies,

such as BIM, RFID, GIS, and real-time data capture. They can be used to capture, transfer and store big data information throughout the life cycle of the building, including the maintenance and operation of the building. Consequently, a large number of innovative approaches have been implemented in recent years (Chen et al. 2015). Among the countless aspects related to the building and especially to BIM, such as heat transfer and its simulation (Natephra et al. 2018, Pop et al. 2018), building ventilation (Sporr et al. 2019, Guitar 2018), air quality interior (Diodiu and Dogeanu 2016), the counting of the number of people (Ye 2010, Gerland and McDonald 2016), has a very big impact in FM and in its various areas.

In this context, this project aims to use an FM application and integrate it with data received from sensors by cable or Wi-Fi, thus monitoring the number of people occupying a certain room, such as a meeting room which have a continuous variability of the occupancy level throughout the day.

Following the data provided by the sensors, the variation of the real number of people counted in a meeting room will be compared with the reservations made in the FM application for that room. Using the results obtained, it will be possible to make decisions regarding the use of space or the cancellation of reservations. Similar research on the most efficient use of space in terms of the actual number of people has been done in buildings in the Australian health system (McNabb 2018).

A classification of different people counting technologies is made according to the generation to which the measurement system belongs (Sruthi 2019). Thus, we have first generation technologies (infrared beam counters), second generation (thermal counters) and third generation technologies (video & Wi-Fi counters).

Knowing that in the meeting rooms, participants from outside the company can come regularly and they may not want to be equipped with RFID cards, this technology will not be considered. The current legislation in Romania (Law192 2019) (here are located the meeting rooms in the customer's buildings that will be monitored) does not allow the use of video cameras in institutions, for this reason the people counting method with the help of video cameras will not be used. Due to the fact that thermal cameras are expensive, and the cheapest ones do not offer a sufficient resolution for the precise people counting, this solution will not be used either. Taking into account the above and the fact that people counting using infrared sensors is the most used method, it will be chosen for the study in this paper. A system consisting of 2 infrared sensors will be used, mounted on either side of the wall at the entrance to a meeting room.

This study presents a Proof of Concept (POC) project, which involves the installation in one of the customer's buildings, in two meeting rooms, of a sensor system to monitor the presence in two meeting rooms. In addition, the light intensity will be monitored in the two rooms. The customer facility management application will be modified so that it receives the data resulting from the measurements made by the sensors and uses them in completing and improving the already existing reports.

Due to the fact that the requirements were few and clear, without the risk of being modified during the project, the waterfall methodology was chosen instead of agile. Moreover, because it was a new type of project that required some research and had to be well documented, the waterfall methodology was the most appropriate.

Requirement Model was conceived in the classical structure, as being composed of *Business Requirements, Stakeholder Requirements*, and *Solution Requirements*, see fig. 1. For each category, the corresponding requirements or the subcategories that compose it have been defined, after which the requirements for the subcategories have been defined and so on. Both *Requirement Model* and other models being part of this project: *Data Model, User Interface Model* and *Deployment View* (or hardware architecture) were made using *Enterprise Architect* software (EA 2016).

Figure 1: Requirement Model, made with *Enterprise Architect* software

From the POC, only the development part is presented, respectively the realization of the sensor system, the data transmission to the application and its customization, less the installation of the sensors at the customer's location and the deployment of the customized application on the production server.

Hardware Solution

Sensor System Description

The sensor system used in this study is composed of a Raspberry Pi board, a multiplexing connection board and three sensors: a pair of two identical PIR Motion Sensors (PIR 2020) and Digital Proximity and Ambient Light Sensor (APDS-9930 2020). PIR sensors allow you to sense motion, almost always used to detect whether a human has moved in or out of the sensors range. They are small, inexpensive, low-power, easy to use and do not wear out. For that reason, they are commonly found in appliances and gadgets used in homes or businesses. Digital Proximity and Ambient Light Sensor, APDS-9930 provides digital ambient light sensing (ALS), IR LED, and a complete proximity detection system in a single 8 pin package. The ALS provides a photopic response to light intensity in very low light condition or behind a dark faceplate.

The Raspberry Pi used is a Model 4, B (Raspberry Pi4 2019). It is a credit-card-sized single-board computer. The CPU on the board is an ARM v8 processor with 1.5 GHz speed. It has a variety of interfacing peripherals, including 2 USB 3.0 ports, 2 USB 2.0 ports, 2 micro-HDMI ports, 4 GB RAM, Micro-SD Card storage and 40 pin GPIO header. For GPIO port expansion a multiplexing connection board is used.

Two monitors, keyboard, and mouse can be connected to Raspberry Pi through micro-HDMI and USB connectors and it can be used like a desktop computer. It supports a number of operating systems including a Debian-based Linux distro, Raspbian, which is used in our design. Raspberry Pi can be connected to a local area network through Ethernet cable or USB Wi-Fi adapter, and then it can be accessed through SSH remote login.

Additionally, the Raspberry Pi is equipped with a housing and a 5V fan, see fig. 2.

Figure 2:Sensor system: Raspberry PI board, 2 PIR sensors and an ambient light sensor

Deployments and the Entire Hardware Solution

In fig. 3, it is presented a complete hardware solution, including Sensor's solution. Currently, the system is made in the Local Area Network (LAN), but the solution also allows Wi-Fi connection.

As shown in the figure, the hardware sensor's system is composed of two PIR sensors, an ambient light sensor, and Raspberry Pi device, including physical interfaces (it supports both wire and wireless connection). The schematic representation in the image wants to show that the light intensity sensor is mounted on (or very close to) the Raspberry Pi Printed Circuit Board (PCB) and their assembly is considered to be *DETECTION SYSTEM*. The two PIR pair sensors are located further away from the Raspberry Pi PCB. In the customer's meeting room, they will be mounted next to the access door, on either side of the wall of which the door is part.

Figure 3: The hardware architecture of the sensor monitoring solution

The physical system is also scalable, so it can be allowed to connect any number of sensor systems.

The application server can also be connected wire and wireless in LAN. Although the figure of the hardware solution is represented schematically and the ARCHIBUS application (as "execution environment") to highlight that in addition to the existing application, was added the new sensor monitoring application, both now representing a whole, called ARCHIBUS application.

As can be seen from fig. 3, in the network layer, care must be taken when communicating and establishing data transmission protocols and other details, to successfully connect all devices in the network.

Software Solution Conception and Implementation

The solution for the ARCHIBUS integration software will be modularly designed and will be composed of three sub-solutions (applications), see fig. 4. In this structure any module could be replaced, for example another physical sensor system could be used and, why not, another application instead of ARCHIBUS (A3-Client Application). This solution was conceived on the occasion of the realization in ARCHIBUS of a monitoring and management system of indoor climate parameters (Kraus and Udrea).

Figure 4: The connections between applications

A1 represents the sensor's solution, it is composed of A1b (Sensors configuration application) - the applications of the sensors on their Printed Circuit Board (PCB) and A1a (Sensor application). Next is A2 (Sensors management application), it is a specific application for this sensor monitoring project. As can be seen from the image, it is integrated with both A1 and A3 applications. For this, A2 contains two APIs. This application was developed to ensure the independence of the A3 application from the sensor's solution. Through the configurations of the A2 application (A2 depending on the sensor's solution), it is possible that the A3 application remains unchanged regardless of the sensor system used. The A3 application (Client application) is the final application, which contains the front-end part, meaning the interaction with the user. Here the data are used effectively, and the various reports are made. In this work A3 is ARCHIBUS.

In this paper, the API of the A1a application (Sensors application) directly provides the value of people count and various network and Raspberry Pi board features. It also provides functions for resetting and modifying some features, including people count.

A SOAP web-service has been created, with the help of which data is read and transmitted to the Sensors application. Other details about the realization of the applications A1 and A2 will not be presented in this paper. Regarding the customization of the A3 application, only the main reports made will be presented. The chosen hardware solution was also be presented.

Rooms Reservation in ARCHIBUS

A wide variety of commercial software applications, including (ARCHIBUS 2015), (BIM 360 2020), (EcoDomus 2020), (ONUMA 2020), (QFM 2020) and (TRIRIGA 2020), are available on the market to meet the requirements of FM (Wong 2018).

The chosen FM software is ARCHIBUS, it is an enterprise application that provides a holistic approach to facility and infrastructure management throughout the entire life cycle of the building. It is made up of several integrated modules, allowing applications to have the same work environment and a common database. ARCHIBUS, a multilayer, 100% web application. Client layer provides intuitive web interfaces in which users can enter and view data as well as numerous reports. At application layer, ARCHIBUS can work on a Tomcat, WebLogic or other application server. For integration, many web services are developed at the application level. Back-end application development is done in java programming language. Regarding the database level (DB), the application allows the use of several types of databases. In this study, ARCHIBUS software is deployed on a WebLogic server running on Linux OS (Operating System) and the database used is Oracle. In terms of business, ARCHIBUS is composed of several modules, each module having certain applications. ARCHIBUS module *Workplace Services* consist of three applications. One of them, the application named *Reservation*, deals with planning reservation (usually for meetings) for different rooms, it is an integrated solution for scheduling shared space and associated amenities. A room reservation takes into account all the elements that can interact with these reservations, such as the time interval of the reservation, the participants in a certain meeting, the possible recurrence of the reservation and others. Fig. 5 shows the screen in which the room reservation is created.

Figure 5: Creating a room reservation in ARCHIBUS

ARCHIBUS Modules Improvement

People count, provided by the *Sensors application*, represent the real number of participants in a meeting. Determining the real start and end time of the meeting, by means of the people count is done using the rules in table 1.

Table 1: Determining *Real Time Start* and *Real Time End* for a meeting.

Determining the *Real Time Start* of the meeting
Rule 1 The latest value for "people count", registered before the start time of the reservation is searched. If the registration is found and the value for "people count" is greater than or equal to 1 then it is considered that the meeting started at the scheduled time. If no record is found that satisfies the above conditions or if the record is found but the measured value is 0 then check rule 2. **Rule 2** The oldest non-zero value for "people count", registered during the booking interval is searched. If the registration is found, then it is considered that the meeting started at the time of registration (This means that the meeting started late).
Determining the *Real Time End* of the meeting
Rule 3 The latest value for "people count", registered during the booking period is searched. If such a record is found and the measured value is 0 then it is considered that the session ended at the time of registration (It means that the session ended before the scheduled time). If the record is found and the measured value is greater than or equal to 1 then the session is considered to have ended at the scheduled time. If no record is found, then rule 4 applies.

Rule 4

The first record to the left of the record range, where the value "people count" is greater than or equal to 0 is determined. If such a record exists and its value is greater than or equal to 1 then the meeting ended with the end of the reservation. If we do not have registration or we have registration and the value for "people count" is equal to 0, then it is considered that the meeting did not take place.

The existing standard report, *Room Reservations*, which represents the list of reservations, can be filtered by various attributes. The report has been modified by adding the following information (columns in the report): *Real Time Start, Real Time End, Maximum Number of Participants*, see. fig 5.

Considering that not all the meeting rooms are equipped with people count monitoring sensors, a report was made in which to be displayed only the sessions during which readings were made with the sensors. Because it is similar to the *Room Reservations* report, differing only in the filtering of the displayed results, it is no longer presented in this paper.

Room Reservations

Reservation Code: 9[3] All[3]

	Reservation Code	Reservation Name	Room Arrangement Type	Configuration Code	Building Name	Building Code	Floor Code	Room Code	Maximum Number of Participants	Date Start	Time Start	Time End	Real Time Start	Real Time End
Report	969	Sedinta de status	CONFERENCE	TRAINING	asc-hq	ASC-HQ	ET2	TRAINING	9	16/09/2020	12:00	13:00	12:04	12:47
Report	961	Sedinta PM	CONFERENCE	TRAINING	asc-hq	ASC-HQ	ET2	TRAINING	16	16/09/2020	14:00	15:30	14:00	15:30
Report	962	Sedinta BA	CONFERENCE	TRAINING	asc-hq	ASC-HQ	ET2	TRAINING	0	16/09/2020	16:00	17:00		

Figure 6: New items added to the *Room Reservation* report, attributes: *Real Time Start, Real Time End*, and *Maximum Number of Participants* and the *Report* button.

The screen shown in fig. 6 is just one of the screens improved for this POC. There are also new developed screens for communication with A1a (Sensors application), screens for viewing the data sent by the sensors, for centralizing and systematizing them in accordance with the way ARCHIBUS manages its data.

In order for the application not to display too much information related to the past meetings, the data are archived (they are entered in the corresponding tables in the database and can be viewed only in the special screen created for archived measurements). For the database not to contain too much data, after a certain period the data are deleted from here as well.

Reports developed in ARCHIBUS

People Presence by Room

The first graphical report developed in the application displays the recorded values of the people count in a certain room. This report has nothing to do with any meeting in that room. Regarding the choice of the room, the following mandatory filters must be applied: *Building Code, Floor Code, Room Code, Date Measured - From / To,* and *Time Measured - From / To,* see fig. 7.

With broken line in the figure is represented people count and with continuous line the capacity of that room. The corresponding value of people count appears at the inflection points of the broken curve.

Figure 7: People count and room capacity for a certain room and time interval

Light Intensity by Room

Figure 8: Light intensity for a certain room and time interval

The next report developed in the application is the light intensity in a certain room, see fig. 8. Regarding the choice of the room, the same filters as in the case of displaying people count by room must be applied.

The sensor measures the light intensity and it is observed that its values are almost in the range (200, 500), recommended values for large size offices and libraries reading lounges, according to (IESNA 2000). Considering that in the displayed interval (8:00, 18:00) there is natural light, it can be assumed that the variations of light intensity appeared due to the closing and opening of the blinds.

Real number of participants vs planned number of participants

The graphs shown in fig. 9 are examples of application of the rules for determining the real number of participants in a meeting, algorithm presented in table 1. Two cases are shown, a) when *Planned Time Start* and *Planned Time End* are the same as *Real Time Start*, respectively *Real Time End* and case b) when *Start* and *End* times are different (the planned meeting interval differs from the real one).

a) b)

Figure 9: Real number of participants vs planned number of participants: a) planned meeting interval same as real meeting interval; b) planned meeting interval differs from real meeting interval

In fig. 9, a) it is observed a real number of 16 people at the meeting start (*Planned Date* and *Time Start*), which means that there is a registration of people count greater than or equal to 1 before the start time of the reservation. According to rule 1 of table 1, it is considered that the session started at the scheduled time so *Real Time Start* is equal to *Planned Time Start*. Regarding the end of the reservation, it is found that the most recent value for "people count", registered in the reservation interval is greater than or equal to 1. According to rule 3 of table 1, it is considered that the meeting ended at the scheduled time, so *Real Time End* is equal to *Planned Time End*.

In fig. 9, b) it is observed a real number of 0 people at the meeting start. According to rule 1 in table 1 we need to check rule 2. This says to look for the oldest non-zero value for "people count", recorded during the booking period. We search for it and find the value of 5 so we consider that the session started at the time of registration, which means that *Real Time Start* is 12:04. Regarding the end of the reservation, according to rule 3 of table 1, one must search for the latest value for "people count", registered during the booking period. It is found and it has the value 0 so the meeting ended at the time of recording, so *Real Time End* is 12:47.

Conclusions

Following the analysis of the current state, it results the increase of the number of IoT systems as well as the need to implement them in FM applications. It is found useful to develop a system of sensors used to count people and measure light intensity and its correlation with the module that deals with the reservation of rooms in a FM application, type enterprise. To determine the number of people participating in a meeting, a pair of two PIR infrared sensors is used, the sensors are mounted on either side of the access door in the meeting room.

The applications of the sensor system implemented in ARCHIBUS software can be multitudinous. Both comparisons can be made between the actual occupancy rate of the rooms and the planned one as well as between the actual occupancy rate and the capacity of the respective room. As sufficient data is collected, it will be seen what percentage of the capacity of the rooms is actually used, it will be possible to make statistical calculations that will estimate the occupancy rate of the rooms in the future and the related costs. Another utility of the developed sensor system could be the cancellation of a reservation if a meeting planned in a room is found not to have started. Then that reservation could be canceled, the room being available in case someone else wants it.

The light intensity can be correlated with meetings and people count and if desired one can give alerts such as, if while there is no external natural light the light intensity values show that the light is on but there are no people in the room, or if the light stays on outside office hours, and any other notifications criteria.

Abstract

The paper is oriented to methodological aspects of reporting the results of risk analysis in order to ensure the continuity of production processes. Its essence is to present the most important, current, and useful research issues and activities for the above. The reporting of outcomes from the risk analysis is understood as integrated notification on all limitations, uncertainties, assumptions, instability of legal regulations, and various areas of risk factors and their impact on the assessment of the security level of the production process. Performed literature studies allow the authors to notice a research gap in the form of a lack of effective research on improving current reporting systems, searching for and identifying sources of cyber threats, identifying threats and vulnerabilities, selecting the method of risk estimation, evaluation, and valuation in relation to ensuring the continuity of production processes. The paper describes the theoretical background and the methodology of developing a risk analysis report for the purpose of ensuring the continuity of production processes as a result of literature studies and own research. The scope of the article covers the following issues: the concept of the production process and its risk, business continuity management (BCMP) with traditional and author's approach. The key outcome presented within the paper is the proposition of an integrated risk analysis report as a key element in ensuring the continuity of the production process.

Keywords: risk, analysis and risk assessment, risk reporting, Business Impact Analysis (BIA).

Introduction

Nowadays, the concept of Business Continuity Management and ongoing improvement of production processes is growing in popularity. Currently, it would be impossible for any manger to imagine the idea of the company development without continuous improvement of its processes, as it is obvious that “those who do not evolve are left behind”. The recently developed risk reporting principles and tools show how to implement the process of integrated risk reporting and how to efficiently use it as the main source of Business Continuity Management of the production processes.

This paper attempts to introduce the most important, current, and useful issues regarding the construction and content of the risk analysis report in the context of ensuring the continuity of production processes. The following considerations were based on the authors' research, practice, and professional experience in the field of ICT security as mentioned by Ng et al (2020), Ranganathan (2012), Robyns et al (2017), Strohmeier (2016). The research results and authors' experiences presented in the article refer in particular to the conditions and specificity of the method of reporting the results of the risk analysis and estimation process. However, many of the issues and conclusions presented in this paper will give valuable general guidelines for the broadly understood security of the continuity of production processes. The current trends in reporting the results of the risk analysis process require the preparation of integrated reports. They should be covering a wide range of numerical, financial information required by law, as well as voluntary information (covering both historical and prospective periods) for all types of risk. The method of presenting reports and their availability is also changing. The vast majority of reports are electronic.

Modern integrated reporting systems impose stricter demands with respect to the level of maturity in reporting on the risk (Fig.1).

Fig. 1: Illustration of the level of maturity in reporting

Own elaboration based on Zawiła-Niedźwiecki (2007)

Accordingly to the above, the Risk Analysis Report (RAR) is a source of the integrated knowledge on the results of risk analysis and assessment. The goal of the RAR objectively reports the outcomes from the risk analysis related to all of the limitations, uncertainties, assumptions, instability of legal regulations, and various areas of risk factors and their impact on the assessment of the secutity level of the production process.

As the novelty in the proposed approach in relation to traditional risk analysis reports one can find:

1) the use of integrated reports as a new paradigm for reporting on risk analysis and risk assessment;
2) demonstrating the need to include in the construction of the RAR the results from the review of interdisciplinary sources containing assessments of cyber threats to production environments and the achievements contained in European and international normative documents.

Security engineering of production process continuity, as well as risk assessment, are increasingly important issues in the research and practice. At the same time, the importance of identified needs and directions of activities aimed at increasing the quality of RAR is still growing.

Theoretical Background

The Concept of a Production Process

Figure 2 shows a general model of the production system, which allows to understand how it functions and which role the production processes play in such system. When analyzing the above-mentioned model, it may be observed that the production system constitutes a set of elements with specific links (relations). The relations allow smooth flow of the materials and semi-products at all stages of the production process. The fact that such relations exist and have been properly defined is very important for the entire company, as it affects both the costs and completion time of the production process. The point is to detect and eliminate all redundant operations that do not raise the value of the product.

Fig. 2: Simplified model of the production system

Specialist publications and available resources include many definitions and terms used to describe the production process e.g. Feng et al (2016), Gołąb et al (2010), ISO 22301:2012, Liu (2016), Orzeł (2012) and Yin (2013).

For the purposes hereof, the following definition of the production process has been adopted from Orzeł (2012). The "production process (process of production) is the entirety of phenomena and deliberate actions that gradually change the object of work if subjected to such phenomena and actions. As the actions accumulate, the aforesaid object obtains features making it closer and similar to the desired outcome product. The production process is considered completed when all the necessary elements have been achieved".

Following by Davidson (2010) or Zawiła-Niedźwiecki (2007) the production process consists of the following elements:

- means of work, which include production machines and devices,
- human work performed by people using means of production,
- energy that sets in motion means of work.

The organization chart of the production process in a model industrial establishment is shown in Fig. 3.

Fig. 3: Organization chart of the production process

The prerequisite for smooth functioning of the production process is a flow of persons, materials, information and energy factors. The production processes may differ depending, among other things, on the applied technology.

The main characteristic of the production process is the continuity of its course or operations. To state that the production process is continuous, it is necessary to obtain the continuity related to the subject of work, object of work and means of work. The requirement of continuity may refer to each of the three factors, individually or in total. The continuity of the object of work means that once introduced to the production process, the object of work should be constantly in motion. The continuity of the means of work implies that they should be constantly used to perform production activities/tasks. However, business continuity with respect to operators - i.e. persons - is treated differently. In this case, the willingness to maintain the continuity of work of a person means that the human work should be used to the maximum, while reducing the production costs per unit.

Every production process should have a business continuity plan. The Business Continuity Management (BCM) is a comprehensive business approach that includes strategies, standards and procedures aimed at ensuring that a certain level of operations will be maintained or quickly restored even in case of failure. The purpose of the procedure is to mitigate operational, financial, legal, reputational and other losses caused by such failure. The generalized BCM model is shown in Fig. 4.

Fig. 4: Generalized BCM model

Risk Factors of The Production Process

It should be stressed that there is no single definition of risk. The adoption of a neutral concept of risk, according to which it is both an opportunity and a threat, is too general. To specify the analyzed concept with respect to the production processes or production systems, it is essential to assume that the process risk should cover a wide range of risk factor related to the following:

- knowledge and responsibility of managers supervising the course of the production process,
- quality of the documentation of the production system,
- consistency, transparency and compliance with the operational procedures,
- frauds, provisions of law, external events, including natural disasters having impact on the production process.

The characteristics of the production process risk are the following:

- it is impossible to completely eliminate the source of such risk,
- the risk is multidimensional and concerns all activities and operations distinguished in the production process,
- by reducing one type of risk, the exposure to other risks may be higher,
- the risk measurement and analysis are more difficult,
- the more complex the production process, the higher level of risk,
- the risk is not taken to derive benefits.

Such a wide range of risks caused by factors identified as the risk of the production process raises interest of both practitioners and theoreticians dealing with risk management in the production system. In line with the above concept, the following categories of the risk factors may be distinguished:

- processes - the losses incurred due to errors in the implemented procedures, insufficient number of the existing procedures or lack thereof; the losses in this category are not the result of deliberate actions, but may be the consequence of human error or non-compliance with the mandatory procedures,
- people - all voluntary or involuntary actions of former or present employees to the detriment of their employer,
- systems - the losses incurred due to failures of ICT and IT systems, including software; the losses in this category are not the result of deliberate actions,
- technologies - all failures of ICT or IT systems, interruption of technological process,
- external events - the losses caused by external factors affecting the production process or production system; the losses may be caused by both natural disasters (flood, earthquake, etc.) and activities of third parties (act of vandalism, riot, etc.),
- other - certain activities of the regulatory agencies, e.g. amendment to the laws to decrease business continuity of a company on specific markets, other factors that may potentially cause the destruction of assets connected with the production process.

Methodology

Traditional Approach Described on The Basis of Literature

The Business Continuity Management Program (BCMP) for the production processes is a set of principles, rules, procedures and instructions, in compliance with which a company manages its operations. As mentioned by Gawlik (2013) their purpose is to provide the stakeholders and regulatory bodies with access to critical production processes in case of emergency. The purpose of the BCMP is ensure that each production process, production system or organization can efficiently react to threats, such as natural disasters or infringement of sensitive data, and protect business interests of the organization.

The BCMP is not implemented only at the time of occurrence of a sudden event causing disruption of the process or company operations, but refers to all activities performed on a daily basis. Its goal is to mitigate the risk of incidents and emergency situations and to maintain readiness if such situations do actually occur. The above-mentioned issues are closely related to the identification of internal risks and external factors affecting the production system or the whole organization.

In the majority of empirical studies, popular science and educational publications, on the Internet and in daily life, the scope of the BCMP usually comes down to the implementation of the following set of processes/tasks (Fig. 5):

1. Business Impact Analysis (BIA)
2. General risk analysis,
3. Building of Survival Strategy:
   - Development of Minimum Acceptable Configuration,
   - Analysis of available and missing solutions,
   - Development of Survival Strategy (selected solutions, schedule, budget),
   - Development of emergency and recovery procedures,
   - Test and update of the Plan,
4. Implementation of the Business Continuity Plan (raising awareness among employees, audit, training schedule, etc.)

Figure 5: Stages of the Business Continuity Management Program of the production processes – traditional approach

In the traditional approach, the following statements or assertions may be often made:

1. Once the business continuity plans are ready, the organization is resistant to any disruptions.
2. The plans preceded by the BIA are adequate to actual risks, therefore, they may be considered efficient.
3. The organizations, which protect their production processes in such a manner, may openly admit that they manage their business continuity well.

Is the BIA the only and sufficient analysis that needs to be performed and is it possible to build an efficient Business Continuity Management Program (BCMP) for the production processes on the basis of the results of such analysis? A separate topic is the implementation of plans, raising awareness among workers, co-workers and other interested parties.

If the organization wants to treat the Business Continuity Management of the production processes seriously, it should modify its traditional approach by adding the following processes/tasks:

1. Risk Operating Plan (ROP),
2. Threat and Risk Assessment (TRA),
3. IT Services Continuity Management (ITSCM) Risk Analysis,
4. development work on the BCP - designation of areas in the production system, where disruptions could cause the most serious losses; such areas should be the production processes and products or services offered through such processes.

The above-described approach is reasonable only in the context of the already determined threats and properly conducted actual risk analysis. The BCMP including the aforesaid tasks is described in the following sub-chapter.

Modified approach based on own research

The Business Continuity Management Program does not like stagnation and routine. Something must always be happening and the company must be ready to react quickly. The more carefully it analyzes various types of risks and threats, the easier and more efficiently it can prepare its production processes. In case of the Business Continuity Management Program for the production processes, it is important to stay alert and carefully follow all risk analyses conducted in the organization. Other sources of valuable and helpful information are as follows:

- analyses in the field of operational risk – they validate and supplement the BIA with the information on types of process risks and their impact on the continuity of services and processes,
- analyses in the field of environmental risk – they constitute an integral part of risk analyses in the company and include the information derived from the analyses of impact on people of various chemical substances and compounds produced, used and released into the environment,
- risk analyses as part of recovery and resolution directive (RRD), i.e. plans of repair, restructuring and well-organized liquidation – they constitute the source of information on the activities planned within the liquidity and capital area, which may significantly affect the technical and organizational solutions in the company as far as business continuity is concerned,

- analyses of information security and protection of sensitive data – they may constitute a good starting or validation point for analyzing different types of the ITSCM risk,
- tests and analyses of IT system security (including "cyber" vulnerability) – the perfect complement for the TRA and ITSCM.

The above-mentioned analyses constitute the fundamental elements of the Risk Analysis Report (RAR), which are usually performed in companies, even though not always as part of the Business Continuity Management Program. Therefore, the Risk Analysis Report is the key source of information that may and should be used for the implementation of the BCMP with respect to the production processes.

With the above in mind, the authors propose the following scope of the BCMP for the production processes (Fig. 6).

Fig. 6: Stages of the Business Continuity Management Program for the production processes – original approach

Risk Operating Plan (ROP)

The analysis of operational risk is the basis for the Business Continuity Management Program for the production processes. As Grzelak (2017) mentioned the Risk Operating Plan (ROP) refers to the risk of potential loss due to maladjustment or unreliability of internal processes, inadequate procedures, human actions, system operations or external events. The operational risk also includes legal risk and reputational risk caused by an operational event.

The main purpose of the operational risk analysis with respect to the production processes is to determine the level of existing risk and possibilities of its reduction. It is relatively easy to define basic sources of such risk, but to clarify the issue in more detail seems rather challenging. The difficulty is to show different types of the production process risk in order to highlight their relations, give them weight and refer them to particular areas of operations of the production system. The methods for assessing and measuring the operational risk of the production process are different than the methods used in case of other types of risks.

A multi-faceted nature of the operational risk and difficult to assess impact on the level of income earned significantly hinder consistent measurement of such level. The losses incurred due to the operational risk seldom reflect central distribution trends, they usually occur at the "end" of such distribution, showing abnormal behaviors and situations. Some types of the operational risk, such as fraud or failure of IT system are measurable, but it is difficult to assess the level of a significant sub-area of the operational risk due to insufficient or missing historic empirical data. In practice, there are several concepts related to the measurement of the operational risk of the production process, namely:

- a volume-based approach, according to which the exposure of the production process to the operational risk is a function that includes all areas of operations of the production system; the approach is used in case of actions based on large number of uniform operations/activities of the production process;

- an approach based on qualitative risk self-assessment, including subjective assessment of all types of operations of the production process by experts, which is aimed at estimating the probability and seriousness of losses in the production process;
- an approach based on quantitative techniques, which are used for the purpose of capital provisions for potential operational losses.

The operational risk is identified on the basis of:

- internal sources, including: operational events, own risk self-assessment, assessment of processes in the process lines, assessment of high-risk products,
- external sources, including: external database of events in the field of operational risk, external studies.

The organization makes the actual assessment of threats related to the operational risks, based on:

- how the key risk indicators are developed,
- the analysis of operational events.

Business Impact Analysis

The fundamental element of the Business Continuity Management Program is the Business Impact Analysis (BIA), during which critical processes and resources necessary to maintain or renew the production processes are identified and the results of survival of such processes - determined. The key processes implemented as part of the production system constitute the basis of the BIA.

In this article, the BIA is the analysis of the production processes, allowing to determine the impact of potential serious disruption or interruption on the production system or organization. The purpose of the BIA is to identify threats (risks) in the context of the production processes, including methods for preventing potential threats. As part of the BIA, key ratios - Recovery Time Objective (RTO) and Recovery Point Objective (RPO) - are defined and Minimum Acceptable Configuration (MAC) is implemented for the production processes - see Alasas(2017).

The following elements should be included in the Risk Analysis Report:

- list of critical production processes, including a list of resources essential for resuming such processes (technical/IT, organizational, logistic, human resources, etc.);
- list of potential financial and non-financial losses in case of interruption of critical processes;
- Recovery Time Objective (RTO) and Recovery Point Objective (RPO);
- relation of the criticality of the production processes as part of the analyzed production system and with respect to the criticality of such processes or within the entire organization.

The BIA related to the Business Continuity Management of the production processes is just a “start-up kit” including the information necessary to develop the business continuity plan. However, the aforementioned kit quickly proves insufficient to determine that the plan will meet the company’s expectations and ensure its business continuity that represents the required minimum.

Threat and Risk Assessment (TRA)

Theoretically, on the basis of the BIA, it is possible to develop a general/universal strategy/plan of procedure in an emergency situation, regardless of its source and character - but the question is whether such strategy will be justified in economic, organizational and technical terms? At this stage of the Business Continuity Management Program for the production processes, it is worth performing or using (if the organization implemented the operational risk management process) the Threat and Risk Assessment (TRA). The TRA is fully integrated with the System Development Life Cycle (SDLC), which is similar to the lifecycle of the production process and analogous to the lifecycle of the security system of the production process and IT system supporting such process. The TRA method has been extended by introduction of new elements used to report on the production process risk. As part of the TRA method, the risk to security of IT technologies/systems is also assessed. The only aspect distinguishing this method from other methods is the introduction of the following elements to the analysis of the production process risk: value of vulnerability, seriousness of risk, accumulation of risks, efficiency of technical and organizational security measures.

The purpose of the TRA analysis is to identify the risks that are so serious that they should be taken into account and so probable that they may actually occur at a specific time. What is difficult in such analysis is the scope and diversity

of external and internal conditions, which should be considered (climatic, urban, infrastructural factors, organizational culture, applied technology, vulnerability, etc.). Therefore, it is worth checking, among other thing, whether such data have already been included in the Risk Analysis Report of the company. The above-mentioned scope of information regarding the post-production processes and knowledge of the analyzed production system and its environment are not yet sufficient to develop a good strategy for business continuity management and to feel safe. Information technology constitutes an integral part of the majority of modern production processes, both small and large, thus, any failure of the IT process, system or infrastructure may lead to substantial losses. Therefore, it is crucial to analyze the risk of IT Services Continuity Management (ITSCM). The ITSCM Risk Analysis based on the ITIL standard is usually performed in IT companies and departments as a procedure independent of the "business" risk assessment expressed in the form of the BIA/TRA.

ITSCM Risk Analysis

Once the BIA and/or analysis of different types of risks and threats is completed, it is necessary to develop specifications for the IT Department, which will identify all requirements and expectations related to the recovery and availability of IT systems and other resources in case of failure. The IT Department usually performs the so-called gap analysis between business expectations and real (currently available) RTO/RPO parameters. The result of such analysis is not only the list of discrepancies, but also the cost estimate of potential investments into the IT infrastructure, which may help to eliminate such discrepancies. It is a good time to conduct the ITSCM Risk Analysis, which allows to determine the criticality of the IT system or components of its infrastructure, helps to classify the data and information processed by a given system and to map the production processes and business functions implemented in a given IT system for the production process, and defines who renders which IT services for a given process. The last element of the ITSCM Risk Analysis is the analysis of risks and their potential impact on the selected production process supported by a given IT system. On the basis of the aforesaid analysis, it is possible to validate the previously prepared scenarios in case of IT failure and to verify appropriate solutions in the field of redundancy of infrastructure and mechanisms for creating back-up copies. By executing the above-mentioned tasks, it is possible to determine:

- the criticality of the production processes and resources needed to recover them,
- the criticality of IT systems supporting the production processes, including data processed by such systems,
- grid of dependency between the production processes, processed data, IT services and infrastructure.

Development work on the BCP

Another step in the BCM process is to develop the Business Continuity Plan (BCP). The BCP should be easy to implement and maintain so that all its recipients may understand it without any problems. The plan should also describe in detail the rules of procedure aimed at maximally limiting business interruption and clearly defining the situations, in which the emergency procedures should be initiated. It is especially important in terms of emergency management to explicitly determine the tasks and responsibilities of the production process owner and key personnel (including members of the crisis management center, persons responsible for the disaster recovery center and operations personnel) as well as to indicate persons responsible for initiating emergency procedures. The employees responsible for tasks included in the adopted plans should be appropriately trained in the field of emergency procedure in case of any disruptions in the production process.

When developing the business continuity plan, it is also important to specify the rules of communication between entities and prepare templates of notifications. It should be also remembered to design appropriate control procedures regarding BCM, BCP and DRP.

Disaster Recovery Plan (DRP)

It is also important to establish appropriate procedures in case of the necessity to recover business after disaster. Due to the fact that many important production processes are implemented via IT systems, special attention should be paid to careful development of the Disaster Recovery Plans (DRP) for such systems.

The Disaster Recovery Plan is usually focused on providing alternative processes and resources necessary for the proper operations of the production system. The implementation of the DRP should reduce the time necessary to restore the possibility of the functioning of the production process as well as all costs connected therewith.

Appropriate planning should mitigate the risk and effects of the most serious disasters. The disaster refers to any failure that causes the interruption of all critical IT systems for some period of time and has negative impact on the operations of the production process. It should be stressed that while the DRP is aimed at recovering the IT systems in the shortest time possible, the BCP should ensure resilience of the critical production process to all emergency situations in the long run, i.e. before the disaster, during disruptions and upon termination of unfavorable events. When developing the strategy for recovery of IT systems, the following elements should be taken into consideration: criticality level of the production process and supporting applications, cost of interruption and recovery of business, time necessary to recover business, functional and informational security of the production process.

The creation of the DRPs is closely connected with the back-up copies. The back-up copies should be stored in the primary location to ensure easy access thereto in case of events making it impossible for the bank to conduct its activities in such a location, and in an external location, if the activities must be continued outside the primary location, i.e. backup site.

Testing of the BCP

To verify the efficiency of the Business Continuity Plan, the organization should carry out the following periodic tests. Undoubtedly, one of the benefits of such tests is the possibility of assessment whether the production process is ready for actions to be undertaken in case of emergency and the opportunity to raise awareness in that respect among employees. Due to the limited resources, the practical tests usually cover only single procedures or applications and systems for the selected elements of the production system. Nevertheless, it should be checked whether the tests include appropriate – i.e. important for the operations of the production system – production processes, IT systems or organizational units of the production system. In case of preparing full tests, their implementation should be planned and executed very carefully to mitigate the risk of disruption of the normal operations of the production system or the organization.

Verification and update of the BCP

As part of the Business Continuity Management process, the subject of the production process should also periodically verify and update the Business Continuity Plan in accordance with the changes in the production system (e.g. change of risk profile and organizational structure or IT infrastructure) and its environment (including the risk related to the fact that another entity was entrusted with the performance of some activities), which change the risk factors or hierarchy of particular threats having impact on the functioning of the whole production process. The issues related to the Business Continuity Plans and emergency plans as well as those concerning Business Continuity Management, including guidelines on the preparation of the Business Continuity Plans, have been addressed in the international standards (BS 25999-1:2006, BS 25999-2:2007, ISO 31000:2012, ISO/IEC 24762) and publications like Bagiński et al (2011), Kaczmarek (2008), Sawalha et al (2012), Urbancova et al (2013) and Venclova et al (2012).

Work Results

The authors of the article suggest the use of integrated reports as the new paradigm of reporting on the risk analysis and assessment. The document should be formal, without using colloquialisms, abbreviations and words that may be unclear to the recipient. The text of the report should be precise, complete, unbiased and objective. Therefore, it is not enough to prepare and publish only traditional risk reports or registers including solely historical data or information about the risks and probability of their occurrence or materialization.

ISO 31000 also includes a few important conditions for implementing the risk reporting process and the effects of management of such process. By the ISO 22301:2012 the above-mentioned conditions are the following:

1. ensure that the risk management process is efficient,
2. ensure that the risk management process continuously support the activity of the organization,
3. implementation of the selected procedure options in terms of planning the risk management process,
4. monitoring of the results and reviews,
5. ensure ongoing communication with external and internal stakeholders,
6. ensure efficient corporate governance,
7. ensure compliance with legal requirements, regulations and corporate governance,
8. support and encouragement to assume accountability and risk ownership.

The following conditions may be added to the above list: establishment of goodwill of the organization, building of reputation, raising of capital. The risk reporting process may be implemented in different ways: periodic written reports, oral reports, periodic reporting on goals and tasks, on an ongoing basis. It is important that the information included in the risk reports was in the form of integrated reports and used while making managerial decisions. The integrated reporting process is aimed at eliminating information gaps (Fig.7).

Fig.7: Information gap versus Business Continuity Management of the production process

Table 1 includes the characteristics of the principles of risk management, whose application may contribute to significant reduction of the information gap.

Table 1: Principles of risk reporting to ensure Business Continuity Management of the production process. Source: own elaboration based on ISO 31000:2012. Principles and Guidelines on Implementation p.10-12]

Principle	Description
Content	The report must include key information about the risk: internal and external sources, short description, frequency, seriousness, financial and non-financial threats, assessed consequences, etc.
Accuracy	The information in the risk report should be provided in a clear and concise m□□□er; the reports should be comprehe□sible □□d helpful i□decisio□ making, the proportion between the data, analysis, interpretations and qualitative explanations should be adequate
Comprehensiveness	The risk report should cover □ll □re□s of m□teri□l risks i□the org□□i□□tio□; the specificity and scope of the report should be in compliance with the size and complexity of the organization and is risk profile
Frequency	The required frequency of publications and updates should reflect the needs of recipients, type of risk and its changes as well as the significance of the report in terms of appropriate risk management for the purpose of efficient decision-making process.
Distribution	The report should be distributed to relevant and interested parties and include the information that may be important for the recipients, while ensuring basic security attributes (e.g. confidentiality).
Relations	The report should present the risk of the production process/enterprise and relations between the reported elements in a consistent and comprehensive manner.

Conclusion

One of the basic elements of efficient Business Continuity Management of the production processes is appropriate risk management and maintenance of acceptable level of functional and information security. The increasing prescriptive and legal requirements regarding the production processes or production systems force the stakeholders/operators who use such production processes or production systems to undertake certain actions aimed at eliminating or mitigating the risk to business continuity. The standards on business continuity, functional security, quality or risk, e.g.: PN-EN ISO 9001:2015-10, PN-EN ISO 27000:2013-10 or PN-ISO 31000:2012 do not include any specific requirements on the methodology of risk assessment, methods of risk identification and analysis or integrated reporting on risk effects. What is more, there are not any formal requirements regarding the reporting, documentation, information or communication about the risk within the risk management system or business continuity system. Therefore, every organization should adopt their own solutions provided that they are efficient and user-friendly.

Considering the above, the authors propose the use of integrated reports as a new paradigm for reporting on risk analysis and risk assessment. It can be an approach that will encourage organizations to comprehensively oversee the threats and vulnerabilities of the production system. However, its implementation requires the use of an appropriate methodology and the involvement of an interdisciplinary team of specialists with appropriate competences. Therefore, the development of this type of reports and their practical use in managing the continuity of the production system operation is a great challenge for the organization today. The attempt to bring closer the current understanding and definition of the risk analysis report for the purposes of the safety of the continuity of production processes leads to further questions and conclusions. The key issue is to determine for whom and for what purpose the integrated risk reports might be useful? While the research, it was found that currently RAR is the most widely used in the area of ??information security. It is understood by the authors as the use of active and passive organizational and technical safeguards. This area is commonly implemented in practice in various types of organizations and is often supported by numerous predefined reports and tools for their preparation. However, in the area of ??activities related to ensuring the continuity of the operation of production systems, there is still a certain gap. Currently, RAR is used intensively in practice for the functional safety of these systems. However, its much wider use than the current use can be expected. Especially in situations where functional, information and business continuity safety of production systems are treated as one research aspect. Dedicated solutions in this area are already implemented not only for the design of the safety system in the production system, but also for the ongoing management of its resources. The conducted research shows that these solutions are still not widely used on a large scale. It can be expected that in the future, the use of RAR for the purposes of ensuring the safety of the continuity of production processes will be greater than today. The new possibilities resulting from the use of RAR allow both to maintain the required level of safety in production systems and to reduce the cost of their maintenance. Business continuity safety engineering of production processes, as well as risk assessment are increasingly important areas in research and practice of production safety. The growing needs focused on the supervision of threats and vulnerabilities of the production system are the reason for increasing the quality requirements for RAR. Above shows that there is still a great potential for the development of the concepts proposed in this article through further scientific research as well as their practical implementation in production systems.

Abstract

The article presents the concept (generalized model) of the safety system for the purposes of maintaining or measuring the required level of safety of the production system. The basic elements of the model were highlighted and characterized from the point of view of controlling risk levels in functional and information security. The proposed concept of measuring the quality and state of safety, takes into account the impact of such factors as: the level of risk of internal and external threats to the basic elements of the production system, changes in the operating conditions of both production processes and computer systems supporting these processes, the vulnerability of technical and organizational security mechanisms.

Keywords: Security, Production System, Safety Management System.

Introduction

Safe production is the basis for a standardized flow of quality assurance, reliability and safety. A lot of factors/elements have an impact on the level of quality, reliability and maintaining safety and continuity of production processes. Security problems in various areas of the production company are a very important element affecting the proper functionality of the production system. Evolving global legislation has also changed the approach to production systems or processes by emphasizing quality and safety of production. The goal of this approach is to maintain the level of potential hazards to which sensitive resources are exposed, including man and his environment at an acceptable level for a production process or system.

Along with the dynamic development of the production system, the approach to measuring its quality and safety is constantly changing. Such conclusions are drawn by authors such as Auersch (2014), Belekoukias et al (2014), Shin et al(2014), Sousa et al (2014) and Teizer et al (2013). Enterprises see a great opportunity in the application of integrated quality and safety systems. For many years, manufacturing companies dealt with the security problems of the technical safety of machines and devices operating individually. In the modern era, security issues go much deeper. The development of industry has caused that modern enterprises perceive new threats related to the security of information transmission, the use of cloud computing and the possibility of a cyber-attack in the sphere of IT cybersecurity.

Safety in production should be assessed by several parameters, e.g. safety level, technical failure rate, percentage of failure due to environmental disasters, the number of accidents during transport and storage of hazardous materials, the number of sabotage and terrorist attacks, the number of unrest social., etc. Maintaining proper working conditions of the production system requires entities to act in production processes to limit the risks and vulnerabilities that may occur during their operation to the maximum. Rationality in security management can be achieved when an effective security system enabling the measurement of a state or level of security is implemented.

The main goal of the paper is to present a new generalized security system model for the measurement of the state of reliability and information security in the production system developed over the research. This should be considered in two aspects: cognitive and practical. The cognitive aspect leads to an understanding of the essence of security in production systems and information security management systems. It also allows for the determination of the theoretical foundations enabling the creation of mathematical models for the measurement of the state of reliability and safety of the basic elements of the production system (e.g. key production processes or sensitive information resources). The practical aspect is focused on developing a procedure, method, or methodology for maintaining the required level of current reliability and the expected safety level of the production system.

The paper consists of two main parts. The first, theoretical part, describes the production system and the factors influencing its safety. The second part, which is empirical in nature, describes the concept of a safety system model for measuring the level of threats in the production system. The second part consists of several subsections describing the practical use of the proposed general quality function of the functioning of the production system to measure the state of reliability and safety of its basic elements. The article contains not only a theoretical and empirical synthesis of the problem of the impact of threats on the level of security of the production system but also constitutes a new diagnosis of the discussed issue.

The theoretical and empirical methods were used in the research. As part of theoretical methods, the following were used: abstraction, generalization, desk research (including world literature, the state of knowledge and industrial applications), systems analysis, morphological method, and inference. Methods used in the empirical part of the research was: the method of a diagnostic survey and the expert interview technique, the method of document analysis with the use of qualitative and quantitative techniques, and the method of critical analysis using the technique of qualitative analysis.

The production system and factors affecting its security

The Production System and Manufacturing Process

The production system is a deliberately designed and organized material, energy and information system operated by man and used to produce specific products (products or services) to meet the needs of consumers. The generalized model of the production system is shown in Fig. 1.

Fig. 1: Generalized model of the production system

The following production relationships are distinguished in the production system (Table1)

Table 1: Production relations

Type	Characteristic
material	delivery synchronization, provision of means of transport, storage and retrieval of materials, reduction of transport and storage losses.
energy	ensuring the supply of energy factors, neutralizing wastewater and utilizing gaseous and solid waste, measuring consumption and automatically changing the intensity of energy factor streams.
information	selection of information from the point of view of management goals, design of information connections relevant to logistics requirements, selection of equipment and software in accordance with the requirements of the information process.

From the point of view of the production system, the production process is called the transformation process, i.e. the transformation of the input vector into the output vector. The structure of the production process is illustrated in Fig. 2.The structure of the process is understood as its internal structure, i.e. the components and relations of relations between the elements.

Fig. 2: Structure of the production process

The production process is an organized set of activities coordinating the course of material, information and energy streams during the implementation of a technological process. Manufacturing process - it is a set of activities occurring during the production of the final product, taking into account the work of machines and people. Technological process - this is the main part of the production system, which involves a change in shapes, physicochemical properties, the external appearance of the processed material or a permanent change in the mutual position of individual parts included in the manufactured product, i.e. assembly of components and products.

Problems/threats affecting the security of the production system

When using production system objects, there are various unforeseen events that we generally call problems. Following by Xing et al (2013) or Wang et al (2013) the problem is a task that we cannot solve with the help of known patterns (our knowledge).

Regarding the production system, the set of problems can be classified, according to the method of their recognition, into the following groups (Table2):

Table 2: Classification of problems

Group name	Problem	Type of Analysis
Technical	- Shaping and recognition of operational features; - Consumption and recovery of functional resources; - Selection of technology and technical means of exploitation;	Loss Analysis Damage Analysis Security Analysis
Organizational	- Organizing and improving operational structures; - Harmonizing duties, powers and responsibilities; - Determining the scope and principles of operational information flow;	Relationship Analysis Conflict Analysis Event Analysis
Management	- Identifying the object as an object of operation; - Selection of indicators and operational characteristics; - Assessments and operational decisions;	Analysis of phenomena Variation Analysis Value Analysis
Other	- Recognizing the threat factors and operating costs; - Identifying threat factors and the level of security, - Identifying threat factors and business continuity levels	Reliability Analysis Risk Analysis Business Impact Analysis

The sources of the above-mentioned problems are usually hazards or threat factors, also known as risk factors, originating from various environments and the environment of the production system. Threats in production systems occur not only in the production processes themselves, but also are closely related to the organization of work and technologies and relate to the economic, human and technical sphere - such examples can be found in the articles or books written by Brosnam et al (2020), Fertsh (2011) and Syvantek et al (2016). Such a wide range of threats caused by factors identified as the risk of the production process causes interest both by practitioners and theoreticians of risk management in the production system.

According to this concept, the following categories of risk factors can be distinguished:

- processes - a category of losses incurred as a result of errors in accepted procedures, insufficient number of existing procedures or lack thereof; losses in this category are not the result of deliberate actions; may be the result of human errors or non-compliance with applicable procedures,
- people - the source of this type of risk is intentional or unintentional actions or current employees to the detriment of the employer,
- systems - refers to losses incurred as a result of failure of telecommunications and IT systems, including software; losses in this category are not the result of deliberate actions,
- technologies - refers to IT or telecommunication system failures, interruption of the technological process,
- external events - refers to losses that occur as a result of impact on the production process or production system of external factors; they can be both losses caused by natural disasters (flood, earthquake, etc.), but also by the activities of third parties (acts of vandalism, effects of unrest etc.).

Threats in production processes force making decisions regarding the use of effective production system security systems (PSSS). According to Baker et al (2008) or Vanderhoeven et al (2017) the main tasks of PSSS relate primarily to the principles of operation of the production system facilities, safety risk and compliance of work with the relevant norms, standards and regulations.

An important element of PSSS is a set of properly designed and then implemented protective processes of an active and passive nature. The existence of these protective processes allows achieving the intended economic effects along with attention to the safety of significant resources of the production process. The production process safety system forces the protection processes to be constantly improved, which usually results in increasing quality and safety (functional and information) as well as more effective work. This is indicated by the results of the research presented

in works by Jingfeng et al (2018), Rut and Kulińska (2011) or Słowiński (2007). The biggest threat to production processes is leaving them unattended, i.e. not taking any actions aimed at continuous improvement.

In yours works Jingfeng et al (2018) and Pietrzak (2002) mentioned that continuous improvement not only affects the security of the production process resources, but also the security of the entire organization. Activities including the analysis and assessment of hazards and the implementation of simple actions aimed at securing process resources, allow the elimination of the largest threats and the proper functioning of the production system in the enterprise.

Model of the security system for measuring the level of threats in the production system

In specialist publications and available sources, especially online, one can find many examples of classification of models of production process resource security systems, among which models based on technical risk, understood as the product of the probability of occurrence of a given phenomenon, scale of losses (magnitude of adverse effects) and exposure (the frequency of exposing an employee to dangerous situations).

In articles such Alkhadim et al (2018), Bastien (2010) or Nord (2014) several safety measurement models can be found, ranging from simple to developed models to the most complex ones.

These models were presented in different ways, namely how:

- numerical models written using mathematical formulas - see Zikmund et al (1977),
- graphic models saved in the form of drawings, diagrams or constructed on the basis of aggregates (lists) of questions, or constructed on the basis of matrices, tables, maps,
- integrated models (combined, mixed) - resulting from the combination of numerical models or graphic models.

Unfortunately, these models usually overlook the problem of the multi-faceted nature of criteria for assessing quality or risk of threats, and the use of data collection methods for measuring security levels. Only a few publications propose the use of multi-faceted models based on sets of assessment criteria and elements of good practices in the field of data collection for acquiring knowledge needed to conduct risk analysis and assessment.

The analysis of the possibility of using adequate models of the security system, good practices and the principles of a risk-based approach for the purposes of measuring the level of risk has not yet been the subject of detailed and separate studies.

Holistic approach based on concept that includes of measuring the quality and state of safety, takes into account the impact of such factors as the level of risk of internal and external threats to the basic elements of the production system seems to by good proposal for organizations wanting to have a properly constructed security system.

The security system model for measuring the quality or risk level of production system hazards was defined using the following expression:

$$\mathrm{MBSI} = < \{GR_i\}, \{PO_j\}, \{ZZ_k\}, \{K_m\}, \{F_n\}, \mathrm{F}^C, \mathrm{SPJ} >, \tag{1}$$

where:

- $\{GR_i\}$ - set of components of the production system; a set of key functional groups forming the structure of the production process/system, subject to protection and constituting the basis for determining the quality of the functioning of the production system (it is a set of the most important policies, procedures and practices including human resources and technical resources),
- $\{PO_j\}$ - a set of active or passive protective processes,
- $\{ZZ_k\}$ - a set of technical or organizational security features,
- $\{K_m\}$ - set of criteria for assessing the quality of production system functioning,, m $\in \mathbb{M}^{SI}$,
- $\{F_n\}$ - set of file identification functions: $\{PO_j\}, \{ZZ_k\}, \{K_m\}$,
- F^C - general function of the quality of the production system functioning determined on the set $\{K_m\}$, wherein: $\mathrm{F}^{SI} = f(U_i) \rightarrow R$,
- SPJ - method of measuring the quality of production system functioning.

A schematic illustration of the production system from the point of view of controlling its level of quality and safety is shown in Fig. 3. This figure identifies two important elements: the production system security system and the basic components of the production system.

Fig. 3: Production system from the viewpoint of controlling its level of quality and safety

Characteristics of the components of the production system

Characteristics of the production process

Production is a very broad term that can be understood in several ways. For us, the most important will be three of them; in the field of efficient operation science (praxeological approach), in the field of security science (approach in the aspect of security engineering) and in the field of management.

Kotarbiński (2003) mentioned that praxeological model of action is based on the so-called chain of action. In the production process there are many chains of activity linked to each other by specific spatial, functional, chronological and other relationships.

From the point of view of the implementation of the production process, the situation will be fully determined if the following components of the action are known - subsets of the set $\{GR_i\}$ [Fig. 4]. This approach is presented by Rut and Kulińska (2011) or Słowiński (2007).

$$\{GR_i\} = GR^{CM} \cup GR^{DT} \cup GR^{APP} \cup GR^{OT}, \tag{2}$$

where:

- GR^{CM} - Material factors: perpetrator, entity, user (who does it?), technical means - technical object (what does it do?), Method of proceeding (how does it do it?), object of action (from what, what does it affect?),
- GR^{DT} - Technical activities: processing, transporting, controlling, etc.,
- GR^{APP} - Aspects of ordering processes: technology, organization, economics, etc.,
- GR^{OT} - Environment: conditions (under what circumstances?), result (what was achieved or what was done?).

Fig. 4: Components of the production process

Characteristics of the automatic reliability control system

It is assumed that the SBSP class under consideration is equipped with automatic reliability control systems and a software control and diagnostic team that detects all types of production system emergency situations. To uniquely identify the situation, the SBSP executive subsystem uses the following identification functions:

- a set of effective protective processes, in relation to the set of current functional elements of the production process

$$\mathrm{F}_{po} : \{GR_i\} \longrightarrow 2^{PO}; \mathrm{F}_{po}(GR_i) = \widehat{PO}; \widehat{PO} \subseteq PO, \quad (3)$$

- a set of technical and organizational security features that create current security configurations in individual security processes

$$\mathrm{F}_{zz} : \{PO_j\} \longrightarrow 2^{ZZ}; \mathrm{F}_{zz}(PO_j) = \widehat{ZZ}; \widehat{ZZ} \subseteq ZZ. \quad (4)$$

In addition, it is assumed that for every" $< \widehat{GR}_i, \widehat{ZG}_i, \widehat{ZZ}_i >$, at the design stage of the security system, a set of $\{K_m\}$criteria for assessing the quality of the production system functioning was determined, according to the following rule

$$\mathcal{R} : < \widehat{GR}_i, \widehat{ZG}_j, \widehat{ZZ}_k > \longrightarrow 2^K ; \mathcal{R}\left(GR_i, ZG_j, ZZ_k\right) = K; K \subseteq \{K_m\}. \quad (5)$$

Characteristics of the components of the production system security system

The basic elements of the production system security system are:

- the production system security management subsystem,
- the executive subsystem.

The main task of the production system security management subsystem is maintaining the required level of production system security. This goal can be achieved through ongoing control of the performance of the executive subsystem. This control boils down to activating appropriate sets of protective processes, safety configurations and safety mechanisms that ensure the achievement of the required level of production safety.

In order to create the possibility of compensating for the loss of the required level of safety by the production system, it is required to specify at the design stage of the production system a set of permissible protective processes, a set of safety configurations and a set of safety mechanisms, whose appointment/initiation, by persons from the production safety team, may determine, ensure achievement of an acceptable level of production system security.

The protective process is understood as a set of actions aimed at ensuring the functionality, continuity of operations and integrity of production processes in order to prevent threats, vulnerabilities, risks or vulnerabilities and to limit

and neutralize their effects and to quickly restore this process in the event of a breakdown and other events disrupting its proper functioning.

The term security configuration is understood as a properly designed and implemented set of security mechanisms with well-defined security functions. Each safety function is precisely performed in strictly defined conditions of real threat, vulnerability and a specific time in the production system environment.

The forms of security that can be applied to the resources of the production process can be divided into three basic categories: physical, organizational, technical and hardware. Security of a physical nature consists of:

- control of the right of access to production process facilities and computer systems supporting them, especially to places where the most valuable technical devices, information resources, security copies, etc. are stored,
- introduction of monitoring and security systems,
- functioning of fire protection systems,
- limiting fraud through effective supervision,
- increased response to new threats arising as a result of technological changes.

The term security zone is associated with the term physical protection. It is a separate area of the enterprise's production system, which stores information, data and materials of strategic importance for the functioning of the production process.

Organizational methods and safeguards play a major role in the production system security process. The organizational tasks of protection include:

- developing procedures for the safe operation of the production system,
- developing specific procedures for computer system users,
- implementation of a security policy in a manufacturing company,
- IT systems purchasing policy in terms of information resource security,
- training employees in the proper operation of systems, including quality and safety elements.

The last factor affecting the security of the production system are technical - hardware and software measures. Modern production systems are equipped with the latest IT transmission technologies, such as: wired and wireless computer networks or other remote access technologies. Therefore, they pose the greatest threat to the resources of the production process. Security methods related to computer systems, data transmission, etc. include: use of information encoding and encryption, use of virtual private networks and granting rights to individual information resources; identification; authorization, etc., using a firewall. The main task of a firewall is to protect the internal network of the enterprise against unauthorized interference from outside.

General function of the quality of production system functioning

The general function of the quality of the production system functioning determined on the set $\{K_m\}$ has the form

$$\mathrm{F}^{SP}: \{K_m\} \rightarrow R\ ;\ f(K_m) = \ \mathcal{v};\ \mathcal{v} \in \mathbb{R}. \tag{6}$$

The set of $\{K_m\}$ criteria can be decomposed into various subsets depending on the adopted context of the production process or the adopted aspects allowing insight into the concept of production system security.

In this study, two types of quality criteria/indicators/safety status of the production process have been adopted: "performance criteria - $\{K_m^R\}$ " and "performance criteria - $\{K_m^D\}$" (Table3).

The criteria / result indicators are intended to assist in assessing whether safety-related activities lead to the intended results and whether such measures actually lead to a lower likelihood of accidents and/or milder consequences of accidents for people, process, environment and/or property. They are based on responses, are designed to measure the impact of actions taken to manage safety, and are similar to what is called 'result indicators' in other documents. Result criteria often reflect a change in safety over time, or a poor safety condition. Thus, the result indicators say whether the expected results were achieved (or whether the expected safety result was not achieved). However, unlike performance indicators, they do not say why the result was achieved or not.

Table 3: Sample indicators of quality and safety of the production system

Group name $\{K_m\}$	Examples of result indicators within the group - $\{K_m^R\}$	Examples of indicators of activities within the group - $\{K_m^D\}$	Measuring system
Policies, staff and general security management	1. The degree to which employees (contractors and others) act in accordance with the Security Policy 2. The extent to which security objectives have been achieved 3. The degree to which key risk assessment findings are communicated and known to employees	1. Does the Security Policy clearly state that security is a priority for the company? 2. Does management show an active commitment to safety-related activities? 3. Is there a security system?	Descriptive measurement systems: simple sums, interest, compound; Threshold measuring systems: single threshold system, multiple threshold system; Trend metering systems: simple trend, indexed for variable, indexed for data set; The range of each result indicator after normalization may take a value from 1 to 10, while for the indicator of actions 0 or 1
. General Procedures	1. The extent to which hazard identification and risk assessment are used to create relevant policies, procedures and practices regarding those threats. 2. The extent to which key information is documented and available. 3. Number of incidents resulting from inadequate change management	1. Are there procedures for systematic hazard identification and risk assessment? 2. Is there a document control system? 3. Does this system ensure that documentation is forwarded as it should be?	
Technical issues	1. The degree to which the project meets current codes and standards 2. The degree to which the plant's design, technology and construction are consistent with current standards, codes of conduct and guidelines 3. Number of incidents due to minor maintenance	1. Are there procedures for taking risk assessments, including aspects of internal security, at an early stage of the research and development process? 2. Is there a procedure to modify internal standards, including review and formal approval?	
Preparedness and response to crisis situations	1. Degree of testing the internal plan (for any test plans). 2. The degree to which enterprises support each other in responding or exercising 3. The extent to which incidents (failures and dangerous situations) are investigated in accordance with established procedures.	1. Is there an adequate internal emergency preparedness plan 2. Is the incident reporting system regularly reviewed to ensure it is functioning as expected 3. Is the incident analysis supplemented by an analysis of potential problems in similar situations in other parts of the enterprise	

The criteria/performance indicators are intended to help determine if enterprises/organizations are taking actions that are thought to be necessary to reduce the risk. Activity indicators give guidelines for activities and are similar to what is referred to in other documents as "leading indicators". Performance indicators often measure the state of safety by level of tolerance, which shows deviations from the expected state of safety at a particular moment. Action indicators used in this way emphasize the need for action to increase the effectiveness of critical safety measures when the tolerance level is exceeded.

The combination of result indicators and activities provides two perspectives on whether the basic elements of PSSS (such as policies, procedures, practices, personal resources and technical resources) from the perspective of the overarching feature, which is the quality of the production process, are useful and operate as they should.

Defining result and activity indicators and related metering systems is a recurring process for each PSSS quality attribute.

Method of measuring the quality of the information system functioning

Having defined and determined values of indicators in relation to the set of $\{K_m\}$ criteria for assessing the quality of production system functioning, we can finally introduce a definition of partial and total level of safety of the production process. Partial level of security is associated with a specific quality criterion and is defined by means of a vector $\vec{v}_m$.

The vector $\vec{v}_m$ is a linear combination of the set of indicators $w_k \in W_B^m$ with the coefficients β_k reflecting the importance or contribution of this indicator in the quality of the production process from the point of view of the m - th criterion K_m, described as follows

$$\vec{v}_m = \sum_{k=\overline{1,W_B^m}} w_k * \beta_k \,. \tag{7}$$

The total level of quality / safety of the production process can be expressed as a weighted vector $\vec{\mathcal{V}}_m$ in the form

$$\vec{\mathcal{V}}_m = \vec{\mathcal{V}}_m \otimes \vec{\mathcal{P}}_i \,, \tag{8}$$

where:

$\vec{\mathcal{V}}_m$ - vector of this quality criterion of the production process,

$\vec{\mathcal{P}}_i$ - coordinate validity vector $\vec{\mathcal{V}}_m$, wherein

$$\vec{\mathcal{P}}_i = \left[p_{q,v}\right]_{QxV} \,;\ \wedge q \in Q \ \ and\ v \in V\ p_{q,v} \geq 0{,}1;\ \sum_q^Q \sum_v^V p_{q,v} = \overline{W_B^m}. \tag{9}$$

The constraint defined by formula (7) guarantees that each of the set of indicators $w_k \in W_B^m$ in size $\overline{W_B^m}$ has a non-zero effect on the final level for m - this quality criterion, m ∈ $\mathbb{M}$.

Partial quality of the production process, in reference to K_m is the number $v_m \in \mathbb{V}$ equal to the length of the vector $\vec{\mathcal{V}}_m$ which is a weighted vector of indicators describing the m-quality criterion, m ∈ $\mathbb{M}$.

$$v_m = \|\vec{\mathcal{V}}_m\|. \tag{10}$$

Having defined and defined partial assessments of the level of safety of the production process, we can finally determine the level of system risk as a vector module

$$\vec{\mathcal{V}} = \sqrt[2]{\mathcal{V}_1^2 + \mathcal{V}_2^2 +, \dots, \mathcal{V}_m^2} \,. \tag{11}$$

An example legend for assessing the significance of risk $|\vec{\mathcal{V}}|$ is cited in Table 4.

Table 2: Assessing the significance of risk

Level	Points	Description
acceptable	1-16	this low, insignificant risk, which may cause short-term, slight disturbances in the organization's activity, is the lowest risk for achieving the goals and tasks of the production system / organization; no additional risk prevention measures are required; the risk is subject to monitoring and supervision over implemented control and security mechanisms
conditionally acceptable	17-36	this is medium risk, which causes medium disruption in the operation of the production system / organization, requires monitoring and taking possible actions to minimize the risk, probability and / or effects of its occurrence
material	37-60	this is a high risk that causes disturbances in the operation of the production system / organization, requires special monitoring; may require the use of additional control and safeguard mechanisms or the preparation of new internal regulations and the taking of actions of the so-called risk response to reduce the risk to an acceptable level

critical	61–100	this is a very high risk that is characterized by a high probability of it materializing; it poses the highest threats to achieving the objectives and tasks of the production system / organization, it absolutely requires taking additional actions to minimize the likelihood or effects of its occurrence, develop methods of so-called risk response and implement safety mechanisms, and continuous monitoring

Summary

The security of the production system is a state but also a process that allows normal development of production - the successful implementation of all production processes. This condition is usually obtained as a result of organized protection - a system protecting the production process - against all internal and external threats.

One of the basic guarantors of security is a properly constructed security system, based on properly selected security mechanisms that create appropriate security configurations. Ensuring safety in relation to the production process depends primarily on the nature, size and intensity of threats and vulnerability for key objects of this process. Ensuring the safety of the production system requires consideration of a wide range of threats, factors or events of their variability, specifics and the effects of their potential occurrence.

Emerging threats in a changing security environment force the improvement of functioning security systems, their reconstruction and even the creation of new systems. The ubiquity of security threats, their interpenetration and diversity also causes the need to rebuild thinking about security, which should take into account the risk of their occurrence and pre-emptive actions preventing their appearance and eliminating the negative effects of their occurrence, and ultimately reducing these effects to a minimum.

This work is one of many attempts to solve the extremely important problem of modern production, which is to ensure its quality and safety. This issue is particularly important due to the increasing level of threat threats, especially since they lead to serious material losses, theft or loss collected data.

The sphere of managing the safety of production processes will undoubtedly gain in importance. Pereira et al (2017) mention that its interdisciplinary, multidimensional nature requires appropriate methods, methodologies and practices to ensure an acceptable level of security. The choice of management methodologies and practices is very large, which can be a challenge in choosing the production system most relevant to the specificity and mission.

This situation also implies the need for appropriate organizational competences and specialists with interdisciplinary knowledge and skills to use these methods or methodologies and their selection and adjustment to the configuration of the production safety management system. The subject of further research in this area may relate to detailed criteria for the selection of safety models for the purpose of measuring the state of safety and its maintenance at an acceptable level.

A methodical approach to the security of production systems should take into account: critical functionalities; the resources allowing their operating; threats to which resources are vulnerable and safeguards against identified threats. This will better meet the needs of the community dependent on the services provided by production systems. The above allows to point out three main directions of development of security of production systems can be indicated:

1. A change in the approach to the design of security systems in production systems resulting from the need to include such new elements in security management (e.g. cyber environment, cyberspace, cyberthreats, cybersecurity), and the introduction the growing number of new technical elements (e.g. IT systems, industrial robots) in the production sphere for the implementation of information, and technological or operational processes.
2. Trends in the development of computer science and robotics in conjunction with the evolution of machines and technological devices, as well as control systems for production processes allows to forecast that in the coming years the substance of the production systems (and the role of man in the production process) will change significantly. As a result, the safety measurement models for these systems will also have to change.
3. The implementation of the Internet of Things (IoT) concept in production processes generates a significant impact on the security of the production system as a whole. IoT security issues should be solved not only by technological methods. One should also strive to increase the awareness of the users of the production system. There is also a necessity to develop industry standards. These should be based on the best practices, and allows reducing the level of risk to an acceptable level.

Abstract

The present is characterized by the fact that companies are increasingly interested in finding out what is their value. In most cases, the issue is addressed by experts or expert organizations who, according to the individual steps of the prescribed process, try to determine the value of the company or its individual parts. The aim of this article is to perform a financial analysis of a selected company. Financial analysis is part of the process of determining the value of a company. The article performed a vertical and horizontal analysis, which forms part of the financial analysis. The input data used to achieve the results were drawn mainly from the financial statements of the selected company. The paper provides an overview of the financial situation of the selected company through analyses, whether vertical or horizontal, but also provides information on the financial health of the company through ratio indicators.

Keywords: Process, Financial Analysis, Value, Company.

Introduction

Kurotová and Hoštáková state in their study (2019) that the issue of determining the value of property and companies has become an important and difficult part of the activities of experts - individuals, as well as expert organizations. The process of determining the value of the company itself is considered a complex discipline, which focuses on gaining knowledge about the company from various areas such as corporate accounting, macroeconomic analysis, financial analysis, and marketing.

Boutillier and Uzunidis (2014) claim that the word value is used in economics synonymously with the word price. For the economist, the theory of value is the theory of pricing or theory of exchange value. In the field of formal economic theory, the synonymous term price and value is used. For this reason, it is not necessary to explicitly define the word value. Krabec states in his study (2007) that the value can be defined as a utility that is recognized by the market and is not taken as a pure physical condition. In the book by Jakubec and Kardoš (2016) and Krabec in his research study (2009) these authors states that the concept of value can exist without significant change and is based on theoretical evaluation. The said assessment is based on a comparison of utility and arbitrage, which is performed primarily by the person interested in investing or the authorized person who performs the assessment. This process is performed exclusively for goods of the company that are available. In conclusion, it can be noted that the value therefore represents an approximate figure based on objective fact.

Jakubec and Kardoš (2016), Murphy (2020) and Borad (2019) mentioned that the value of a company is widely used as a more comprehensive alternative to market capitalization. In determining the value of the company, in addition to market capitalization, the company's short-term and long-term debts and cash available to the company are also

Cite this Article as: Jana KUROTOVÁ, Miriam JANKALOVÁ and Veronika KUČMOVÁ“ Financial Analysis as Part of The Process of Determining the Value of The Company” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

considered. By omitting many important factors that affect and enter the value of a company, market capitalization fails to correctly determine the value of a company. Based on the above, we can say that the value of the company is more informative than market capitalization because the final value of the company includes many other factors that affect the result. The resulting value of the company plays an important position for investors who want to know what the real value of a company is. In conclusion, McClure (2020) in his research study says that the value of the company represents a theoretical price. The theoretical price represents the amount of funds for which it is possible to buy and sell a company.

Jankalová and Kurotová (2020) and Harumová (2008) mentioned that there is a basic procedure for determining the value of a company that experts follow, although it may vary from step to step. This is because there are no rules that experts must follow and because each expert has their own acquired knowledge and skills. Experts' own acquired knowledge and skills can be used for the specified purpose of determining the value of the company or its individual components of assets. However, the procedure should include the basic steps of compiling a financial and strategic analysis, a financial plan and, finally, carrying out an evaluation of achieved results for the purpose of the entire valuation of a company.

The following figure shows the step-by-step process of determining the value of a company.

Fig. 1: The process of determining the value of a company

In the following section, we define the individual steps of the process of determining the value of the company. Kurotová and Hoštáková (2019) and the author Mařík (2011) describe the individual steps according to a study.

1st step: ***Definition of the task*** - in this step, the client informs the expert or expert organization, what is the aim of determining the value of the company. In addition to setting a aim, the expert is required to set up a working group to participate in the process of determination of company's value.

2nd step: ***Company knowledge and plan of work*** - this step is based on a thorough knowledge of the evaluated company. Determining the value of a company is an activity that cannot be done directly from the table, and it is important that the expert and his work team become thoroughly acquainted with the company. In addition to getting to know the company, another important step is to design a work plan, which lists the individual activities that will be performed and at the same time each task is assigned to a team member.

3rd step: ***General diagnosis*** - after obtaining the necessary information about the company, the expert and his working group must choose the appropriate approach, which is going to be used in the process of determining the value of the company. In this step, it is equally important to define the areas that the work team will focus on.

4th step: ***Accounting and financial diagnostics*** - in this step, the work team analyses the company's accounting and at the same time performs a financial analysis of the company. The focus of the work team is on the horizontal and vertical analysis. It is important to verify all the information that the expert and his team receive from the company and find out if it is true.

5th step: ***Perspective analysis*** - when determining the value of the company, it is good to start from the business plan in which the aims and visions of the evaluated company are written. It is also appropriate to consider the opinion of company managers and their perception of the company in the future.

6th step: ***Selection of methods, variables and parameters*** - after obtaining the necessary information, the work team proceeds to the choice of method, which will be used to determine the value of the company. The choice of method depends on the reason why the value is determined. Asset methods are used mainly in those cases where the company enters liquidation and the owners of the company need to determine the value of the company in order to achieve a fair distribution of the company's assets. The group of income methods is used mainly in those cases where there is an entity that would like to enter the company and wants to become part of it.

7th step: ***Calculation, evaluation and conclusions*** - in the last step, the value of the company or its individual parts and its assets is determined. In this step, the work team together with the expert obtain the final value of the company and provide the results to the customer in the form of an expert opinion. In addition to the set value, the expert and his team also state their opinion on the achieved result and at the same time provide valuable advice and steps that the company should take if it wants to increase its value, respectively if it wants to maintain its value.

To fulfil the aim of the article, we will focus on the fourth step of the process of determining the value of the company, namely financial analysis. Financial analysis must be taken as an important step in the process of determining the value of the company, because the main aim of valuing the company is to identify the key areas of business that generate value for the company. In the financial analysis, it is possible to see which parts of the company bring benefits to the evaluated company.

Methodology

The aim of the paper is to perform a financial analysis of a selected company. To fulfil the aim, it was necessary to theoretically define the issue of determining the value of the company. In order to be able to perform a financial analysis, which is divided into vertical and horizontal analysis, it was necessary to have input data which are publicly available through financial statements register – http://www.registeruz.sk/. The individual input data used in the financial analysis come from the financial statements of the selected company, which acts as a transnational distributor of electronic components for industrial production. The financial statements that we used in the financial analysis are for the years 2017, 2018 and 2019. The methods used in the present article are information collection method, synthesis method, deduction method, secondary research and analysis.

Results

The financial analysis was carried out in two steps. In the first step, a horizontal analysis was performed and in the second step, we focused on the vertical analysis.

Horizontal Analysis

Through the horizontal analysis, we focused first on the analysis of the assets of the selected company. We analysed selected assets of the company such as long-term intangible assets, long-term tangible assets, inventories, short-term receivables and financial accounts. The following table shows the analysed assets of the company.

Table 1: Basis for horizontal analysis of company assets

Company assets	Year		
	2019	**2018**	**2017**
Intangible assets	64 210	64 210	64 210
Tangible fixed assets	1 216 687	885 402	923 213
Stocks	3 844 552	3 964 938	3 578 944
Short - term receivables	732 617	914 085	1 104 945
Financial accounts	420 447	189 032	497 292

Table 2: Horizontal analysis of company assets

Company assets	2019 / 2018		2018 / 2017		Index		Growth rate	
	ABS	%	ABS	%	2019 / 2018	2018 / 2017	2019 / 2018	2018 / 2017
Intangible assets	0	0	0	0	0	0	0	0
Tangible fixed assets	331 285	37,42	-37 811	-4,10	1,37	0,96	137	96
Stocks	-120 386	-3,04	385 994	10,79	0,97	1,11	97	111
Short - term receivables	-181 468	-19,85	-190 860	-17,27	0,80	0,83	80	83
Financial accounts	231 415	122,42	-308 260	-61,99	2,22	0,38	222	38

The horizontal analysis of the company's assets from 2019, 2018 and 2017 shows that long-term intangible assets have not changed in the last three years. From the item tangible fixed assets, it can be said that its value increased by 331 285 € in 2019 compared to 2018, and in 2017 it was higher by 37 811 € compared to 2018. The values of tangible fixed assets are fluctuating. The index of tangible fixed assets represents the value of 1.37, which means that the value of tangible assets in 2019 reached 1.37 times the value from 2018, which represents an increase of 37.42%. Inventories in 2019 decreased by 10 386 € compared to 2018. The index in 2019 multiplied by 0.97, which means that the value decreased by 3.04% compared to 2018. The value of the short-term receivables item in 2019 was 732 617 € which means that it was lower by 181 468 € compared to 2018. Also, the value in 2018 was lower by 190 860 € compared to 2017. This means that short-term receivables are declining. The index in 2019 was 0.80 times higher than in 2018, which means that the value decreased by 19.85% compared to 2018. In the financial accounts we can observe that the year 2018 had the lowest value compared to 2019 and 2017. In 2019 the financial accounts were higher by 231 415 € compared to 2018. The index in 2019 was 2.22, which is a multiple compared to 2018. The value is thus increased by 122.42%.

After the implementation of the horizontal analysis of the company's assets, we switched to the analysis of selected liabilities of the company. We analysed selected liabilities of the company as equity and liabilities. The following table shows the analysed liabilities of the company.

Table 3: Basis for horizontal analysis of company liabilities

Liabilities of the company	Year		
	2019	2018	2017
Equity	3 019 361	2 607 523	2 273 907
Commitments	3 224 642	3 382 080	3 869 075

Table 4: Horizontal analysis of company liabilities

Liabilities of the company	2019 / 2018		2018 / 2017		Index		Growth rate	
	ABS	%	ABS	%	2019 / 2018	2018 / 2017	2019 / 2018	2018 / 2017
Equity	411 838	15,79	333 616	14,67	1,16	1,15	0,95	0,87
Commitments	-157 438	-4,66	-486 995	-12,59	116	115	95	87

The horizontal analysis of the company's liabilities from 2019, 2018 and 2017 shows that equity was the highest in 2019 and has been growing since 2017. Equity increased its value by 411 838 € compared to 2018. The index in 2019 had value 1.16, which means that in comparison with year 2018 it increased its value by 15.79%. Liabilities have a declining character, which means that they reached the highest value in 2017 at 3 869 075 € and the lowest in 2019 at 3 224 642 €. Liabilities have an index of 0.95, which means that the value in 2019 increased by 0.95. So, the value in 2019 decreased by 4.66% compared to 2018.

Vertical Analysis

We performed a vertical analysis for the company's assets and for the company's liabilities. The vertical analysis of assets consists of balance sheet items - long-term intangible assets, long-term tangible assets, inventories, short-term receivables and financial accounts. The vertical analysis of liabilities consists of balance sheet items - equity and liabilities.

Table 5: Vertical analysis of company assets

Company assets	Year			Total assets		
	2019	2018	2017	2019	2018	2017
				6 245 903	5 989 603	6 142 982
Intangible assets	64 210	64 210	64 210	1,03	1,07	1,05
Tangible fixed assets	1 216 687	885 402	923 213	19,48	14,78	15,03
Stocks	3 844 552	3 964 938	3 578 944	61,55	66,20	58,26
Short - term receivables	732 617	914 085	1 104 945	11,73	15,26	17,99
Financial accounts	420 447	189 032	497 292	6,73	3,16	8,10

In 2017, intangible fixed assets accounted for 1.05% of the company's total assets, in 2018 for 1.07% and in 2019 for 1.03% of the company's total assets. Tangible fixed assets in 2017 represented 15.03%, in 2018 14.78% and in 2019 19.48% of the company's total assets. Inventories represent 58.26% in 2017, in 2018, they represent 66.20% and in 2019, they represent 61.55% of the company's total assets. Short-term receivables represented 17.99% of the company's total assets in 2017, in 2018, they represented 15.26% and in 2019, they represented 11.73% of the company's total assets. Financial accounts accounted for 8.10% in 2017, 3.16% in 2018 and 6.73% of the company's total assets in 2019.

Table 6: Vertical analysis of the company's liabilities

Liabilities of the company	Year			Liabilities and Equity together		
	2019	2018	2017	2019	2018	2017
				6 245 903	5 989 603	6 142 982
Equity	3 019 361	2 607 523	2 273 907	48,34	43,53	37,02
Commitments	3 224 642	3 382 080	3 869 075	51,63	56,47	62,98

In 2017, equity represented 37.02% of total liabilities, in 2018, it represented 43.53% and in 2019, it represented 48.34% of total assets. Liabilities in 2017 represented 62.98% of total assets, in 2018, they represented 56.47% and in 2019, they represented 51.63% of total assets.

As part of the vertical analysis, an analysis of ratios was performed. We focused on the analysis of liquidity, activity, indebtedness and profitability indicators.

Table 7: Company liquidity analysis

	2019	2018	2017	2019 / 2018		2018 / 2017	
				coefficient	%	coefficient	%
Level I liquidity	0,269	0,105	0,278	0,164	155,739	-0,173	155,739
Level II liquidity	0,737	0,613	0,897	0,124	20,186	-0,284	20,186
Level III liquidity	3,257	2,817	2,901	0,440	15,632	-0,084	15,632

Level I liquidity should range from 0.2 to 0.6. The liquidity analysis shows that 2019 and 2017 meet these criteria. The year 2018 with a value of 0.105 is below the set value of 0.2. There may be a problem in repaying liabilities. Level II liquidity should in turn range from 1.0 to 1.5. The analysis shows that all three years are below the set value. Short-term liabilities should not exceed the value of financial accounts and short-term receivables. In this case, the commitments exceed these indicators each year. Level III liquidity should be in the range of 2 to 2.5. In all three years, the value is higher than 2.5. Inventories make up the largest part of current assets and are the main reason for the high value of liquidity.

For the activity indicator, we focused on two selected years (2018 and 2019) in order to be able to calculate the individual indicators falling within the company's activity.

Table 8: Analysis of company activity

	2019	2018	2019 / 2018	
			coefficient	%
Turnover of assets	2,955	2,934	0,021	0,717
Turnover of fixed assets	17,200	19,681	-2,482	-12,609
Inventory turnover	4,630	4,718	-0,089	-1,883
Inventory turnover time	77,760	76,296	1,464	1,919
Turnover of receivables	21,956	17,630	4,326	24,537
Receivables turnover time	16,396	20,420	-4,023	-19,703

The turnover of total assets shows how intensively the company uses the total assets of the company. The higher the value of a given indicator, the more advantageous it is for the company. The company's values are high, which means that the assets in sales for 2019 and 2018 turned 2.9 times. Inventory turnover indicates the number of turnovers i.e. how many times the inventory is converted into other current assets until the sale of products and the new purchase of inventory. In 2019, inventory rotated 4.6 times and in 2017 4.7 times. Inventory turnover time expresses how long stocks are tied up in a company before they are consumed or sold. In 2019, stocks are tied for 77 days before they are consumed, and in 2018, 76 days. Receivables turnover time shows the number of days for which receivables are repaid in the company on average. In 2019, on average, receivables are repaid in 16 days and in 2018 in 20 days.

The following table shows the achieved values that were achieved when calculating the debt ratio.

Table 10: Company indebtedness analysis

	2019	2018	2017	2019 / 2018		2018 / 2017	
				coefficient	%	coefficient	%
Total indebtedness	51,66	129,54	62,98	-77,88	-60,12	66,55	105,67
Long-term debt	26,61	60,63	33,91	-34,02	-56,12	26,72	78,79
Short-term debt	25,05	68,91	29,07	-43,86	-63,64	39,84	137,01
Self - financing ratio	8,56	99,87	37,02	-91,31	-91,43	62,85	169,80
Interest coverage ratio	42,46	34,77	15,09	7,69	22,11	19,68	130,36

Total indebtedness expresses how foreign sources contribute to the financing of the company. The financing of the company's assets by foreign sources has a fluctuating character. In 2018, the assets were mostly financed by foreign sources, up to 129.54%. The least was the property financed in 2019, namely 51.66%. The values of long-term and short-term indebtedness are approximately the same. The highest indebtedness was reached in 2018, where long-term indebtedness was 60.63% and short-term indebtedness 68.91%. In recent years, short-term and long-term indebtedness has ranged from 25% to 33%. The self-financing ratio shows the highest value in 2018 where it increased to 99.87%, which is 91.33% more than in 2019. In 2019, it shows excellent results, where the assets were financed by own resources to 8.56%. The interest coverage ratio refers to the ability to repay interest expense. The values in

the table for the analysed periods have an increasing character. The lowest value was in 2017 at 15.09%. The company reached its highest value in 2019, namely 42.46%.

The last indicator we analysed was the profitability of the company. Table 10 shows the values obtained, which we calculated using data obtained from the company's financial statements.

Table 11: Analysis of company's profitability

	2019	2018	2017	2019 / 2018		2018 / 2017	
				coefficient	%	coefficient	%
ROE	13,64	12,79	16,69	0,85	6,61	-3,89	-23,34
ROA	6,59	5,57	6,18	1,02	18,38	-0,61	-9,84
ROS	3,18	1,89	2,24	1,28	67,85	-0,34	-15,27
ROI	6,80	5,83	6,74	0,97	16,57	-0,91	-13,48

The return on equity indicator expresses how the company values its equity. The lowest value was in 2018 at 12.79%. The highest value was in 2017, where the return on equity is 16.69%. Otherwise, the values are not so different and range from 13% to 16%. The return on total assets reflects the return on the total capital of the company's assets. The lowest level was in 2018 at 5.57%. Otherwise, no large differences are noted. Profitability of sales describes the dependence of profit and sales. Again, in all three years, the profitability of sales is without major differences. The smallest was in 2018 at 1.89%, which shows that the company produced revenues of 1.89 euros of profit per 1 euro. Return on capital also ranges from 5% to 8%. The highest value was in 2018 at 6.8%.

Conclusions

The aim of the presented paper was to perform a financial analysis of the company, which is part of the process of determining the value of the company. The importance of determining the value of the company is growing over time. Value-creating companies are considered healthier and involved in building the economy. These companies offer more opportunities for individuals.

This stimulus therefore encourages companies to constantly improve and work to increase their value. Company also tries to create suitable conditions for the entry of a new investor into their environment with their thorough approach aimed at increasing their overall value. In addition to building the economy and creating opportunities for individuals, companies are currently focusing on sustainability, which is seen as a key point in creation of a business strategy. Sustainability is a factor that should be the subject of further research in other articles devoted to the researched issue. This factor should therefore be examined, as it can significantly affect the very basis of a company's value.

From the whole process of determining the value of the company, we focused on the implementation of the fourth step, which is the diagnosis of accounting and finance. In this step of the process of determining the value of the company, a financial analysis is performed. Through the results of the financial analysis, the expert or expert organization, together with his work team, can recommend to the client which individual areas in the company bring profit to the company and are key areas of interest for the company. From the point of view of sustainability, the financial analysis of the company serves as a source of information, which can be used as a base in finding out how the company contributes to the main focus areas of sustainability – the support of economic, environmental and social areas.

From the results obtained from the financial analysis, which in a suitable way provide the company with an overview of its financial health, we can conclude that the property binds a large amount of funds in warehouses, which are crucial for it. The company also ties a large amount of finances to the company's long-term tangible assets. However, this item considers and works only with those data on tangible fixed assets, which also participate in company activities and through these assets, the company makes a profit. From the point of view of financial health, it can be stated that the company has more liabilities than receivables and it would be more advantageous for it to reduce its liabilities at least to the level of receivables. From the data used in the analysis, we can see that the company's liabilities are increasing from year to year. The gradual increase in the liabilities and overall liabilities of the company has a negative impact on the resulting value of the company. Again – the company should try to reduce its liabilities and it should try to focus on the assets of the company, so that it is more satisfied with the determined value of the company or its individual parts of assets. Based on the data available in the financial statements of the selected company, we cannot say what the business strategy of the company is and therefore we do not know how to set recommendations for the reduction of the company's liabilities.

Acknowledgment

This research was supported by the project VEGA 1/0653/18 offered by The Ministry of Education, Science, Research and Sport of the Slovak Republic.

Abstract

There are a lot of people that after having suffered a cerebrovascular accident (CVA) remain incapacitated and bed bound, presenting different types of plegia. These people require constant assistance from either a relative or a special care worker. This paper proposes an application that will aid those who assume the responsibility of taking care of a paralyzed person that just went through a CVA. The caretaker will have access to information pertaining to different categories – both medical and therapeutical, but also information regarding the rights and facilities of those diagnosed with different forms of plegia. Moreover, in some cases the caretaker may request further information or even ask for a consult that will be given at the patient's location. This leads to having the great advantage of avoiding superfluous calls to the National Ambulance Service. The chosen methodology uses indirect research for the references study and direct research through interviews with people that have taken care of paralyzed CVA patients.

Keywords: Medical Application, Healthcare, Stroke, Homecare, Plegia.

Introduction

The cerebrovascular accident (CVA) occurs when a part of the brain has interrupted or reduced blood flow and the brain's cells begin to die. The cells from the affected area control a particular part of the body, thus leading to partial paresis, frailness, numbness and even paralysis. The cerebrovascular accident (CVA) is the second main cause of death worldwide (2).

We propose a mobile application that centers on medical care and has 2 main purposes: minimizing the excessive use of the available ambulance services and creating a platform which easily gives access to rapid, organized and useful information for patients diagnosed with CVA. While one can find plenty of data on the internet, it is not well organized and does not have verified integrity. This leads for example to a lot of wasted time searching for the documents needed in order to make the patient's handicap file.

Through the proposed application, the patient has structured in a very clear way a good amount of information which will be very useful when taking care of the patient at its bedside. It is understandable that a medic or a nurse, from any given hospital, would not have the necessary time to explain to every person that will take care of a paralyzed patient, all the effects, symptoms and complications which can occur after a cerebrovascular accident or

its prescribed medication. We believe that through the proposed application, the custodian/caretaker/relatives of the patient will be able to get the information they need about the disease's effects and treatment in a fast and sure way. The internet provides a lot of information which most of the time is presented in a chaotic way. It mostly requires a lot of wasted time allocated only for searching and one can always find outdated data or false information (for example when compiling documents for the disability form).

In Romania there are a lot of non-governmental organizations which offer services for those that require being taken care of at home. These services are settled through the National Health Insurance House. In this paper, I will focus on people that have been bedbound by a vascular accident. The NGO's can obtain the application which I am proposing, in order to facilitate the wellbeing and care of the patient but also the communication with his or her caretaker.

State of the Art

There are a lot of e-health applications designed especially for home usage and they target a vast range of diseases and treatments. In his article, Ding H. et. Al (2012), proposes a mobile application for those diagnosed with Chronic Obstructive Pulmonary Disease and it is meant to ameliorate the quality of life and reduce the costs for the treatment.

Holonec R. et. Al (2018) proposes an application for monitoring an epileptic episode and it is based on measured parameters using a bracelet with sensors which connect to an Arduino board (4). This would turn out to be very useful if implemented in the following proposed application.

Frieder Wittmann et. al (2016), completed a group research carried out on 11 hemiplegic patients and it lasted 6 weeks. These patients were taken care of at home through the use of a virtual reality system. The authors of the article confirm the fact that you can monitor daily the training of each patient and that at the same time you can also personalize the difficulty of the therapeutical workout programs, by using the home therapy portable system which is based on sensors. (7)

Application Description

The application can be useful to those that are taking care of their relatives (parents, grandparents, etc.) which have been put to bed after they had a CVA. We are taking into consideration the analysis of people that have been diagnosed with different types of plegia and also require constant care and support from another person throughout their daily activities. After a CVA there can be multiple kinds of strokes: monoplegia (when there is only one limb that is affected, be it leg or hand), hemiplegia (when both a hand and a leg are affected and are situated on the same side, leaving half of the body impaired), paraplegia (which concerns both legs), tetraplegia (when both hands and both legs have been affected).

Such an application is very advantageous because the ambulance department in Romania is more than often very busy and through the application, less urgent problems can be solved and impractical calls can be avoided; of course this also comes in favor of the patient. For example, concerning CVA patients, a common symptom is very powerful pain in the limbs that suffered paralysis. By utilizing the application, the users can find out what painkillers to administer the patient or the types of massage which can benefit the affected limbs. They can find out these types of necessary information directly through the application or they can contact a medic or a nurse to further investigate the problem (both being connected to the application). This saves the time and resources of the ambulance department and the patient gets treated much faster.

A CVA patient has a number of rights and benefits given from the government, as follows: disability certificate, home assistance, certain medical equipment like ambulatory medical devices, orthotic devices or urinary devices (for those patients that also develop a neurogenic bladder syndrome).

In order to obtain the handicap certificate, one needs to make a file which includes multiple documents (the standard application, the Identity Card, an objective neurological report (description and staging of the disease, specification of travel) + muscle strength assessment scales (MRCS or MSF) and scales for assessing autonomy and functionality (ADL, Barthel Index), original; Copies of interpreting imaging investigations: CT, MRI, etc.; Copies of hospital discharge tickets; standard medical letter, completed by the family doctor, original; employee certificate; copy of disability pension decision + copy of recent pension slip; copy of old age pension decision + copy of recent pension slip; copy of pension successor decision + copy of recent pension slip. This entire string of data can be too much raw and unexplained information for a lot of people. The application would take that into consideration and identify and explain each necessary document, what it is, what it looks like, where to find it etc..

R. Perrain et. al (2018), mentions in his paper that at a 3 month evaluation of those diagnosed with CVA, 80% of those patients suffer from depression. (6) The patient may present sleeping disorders or in some cases different forms of anxiety attacks. By using the app, the caretaker cannot only be informed that anxiety may manifest, but also find out what are the signs, how to help prevent it and most importantly how to act in case his or her patient actually goes through an anxiety attack. And of course, if it is too much, the caretaker can always call a specialist who will monitor the progression and medication of the patient.

Bedsores are very dangerous if not treated on time. The application gives advice and clear instructions on how to prevent and treat bedsores and in the case of severe bedsores a professional can be called.

Epileptic seizures can appear because of the electrical changes that happen at the brain's level after a vascular accident. There is a high chance that the patient may present ulterior convulsions as a result of cerebrovascular lesions (1),(5). It happens many times that the caretaker may not know how an epileptic episode manifests (considering that the patient is bound to bed, the symptoms are less visible than in a non CVA patient, the main difference being that the chaotic movement is not that active and obvious). Some may even confuse an epileptic episode with another vascular accident, which leads to delayed treatment and so on. This is why we propose that the application offers more information and support in this matter. The user is presented with the fact that the convalescent may have these types of episodes, how they will manifest, what types of seizures there are, how you can act in case it is a mild attack, what are the preceding symptoms for an epileptic seizure. But the user is also presented with the possibility of rapidly calling a specialist in case of a more serious and dangerous case.

Scenarios

We are considering that at the hospital release, the doctor recommends the patient's caretaker to use the app in order to better understand some of the disease's aspects, what problems may occur and how they can be managed. The user installs the application, goes through all the given information (how the anxiety attacks manifest, how an epileptic episode manifests and how to act, what types of pain may appear and how they can be ameliorated, etc.)

Case 1. The first thing that the user does is to draw up the disabled certificate file. The application gives him all the required information – he must obtain the documents: standard application, identity card, objective neurological report, copies of interpretation of imaging investigations: CT, MRI, etc .; Copies of hospital discharge tickets; standard medical letter, Copy of disability pension decision + copy of recent pension slip. At the same time, depending on the sector in which the patient resides, the application will also suggest the right address for the file's submission. After this the patient needs to be transported to the handicap evaluation commission. The caretaker/ relatives may also call through the application in order to arrange the patient's transport to the previously mentioned center in order to finalize the disability file. In the end, after obtaining the disability certificate, steps are taken in order to obtain the disability pension.

Case 2. The caretaker has gone through all the information presented in the application regarding some manifestations and treatments of some symptoms. The data has been clear and presented in both text and video format. We assume that the patient has an epileptic seizure. The caretaker knows how this seizure manifests, he remains calm and applies the maneuvers he learned earlier through the application. Being the first epileptic episode he will also call for a professional checkup.

Case 3. The patient has very strong pain in both paralyzed limbs. The patient's daughter applies the different types of massage suggested by the application but the pain persists and the patient becomes more agitated. The daughter chooses to consult a specialist available through the application. After talking and being presented with the situation, the consultant prescribes some sedatives that will be injected.

Conclusion

Even though nowadays people usually opt for taking care of their relatives and loved ones through professional institutions (nursing homes, care homes), there are still a lot of people that for various reasons (for example, especially in Romania, maybe a lot of people cannot even afford the choice of a nursing home on a financial level, or maybe they do not want to part with the patient leaving them little choice but to care for them themselves) they choose to take care of their parents, grandparents etc. from home.

Implementing the application would mean facilitating the care taking of the patient at home, both for preventing the occurrence of some complications but also for knowing how to act in different situations. The application is easy to use and offers information regarding more problems which can appear on a patient that went through a CVA and is now bedbound. Moreover, the application provides nonstop assistance, giving the caretaker the chance to ask for

professional advice in some cases. This leads to a safer and faster application of treatment to the patient and avoids swamping the ambulance department.

Acknowledgment

This work has been funded with the support of the University Politehnica of Bucharest through the project “Engineer in Europe” in an online system, through the Financial Agreement registered at the Ministry of Education and Research with 457/GP/06.08.2020, which is a found for financing special situations that cannot be integrated into the financing form for higher education state universities.

Development of Maintenance Systems in Polish Enterprises in the Context of Industry 4.0

Edmund PAWLOWSKI

Poznan University of Technology, Faculty of Management Engineering, Poznan, Poland
Edmund.pawlowski@put.poznan.pl,

Abstract

One of the important subsystems of every industrial enterprise is the maintenance system. While the development of industry began as early as in the eighteenth century, significant changes in maintenance systems occurred only after World War II. New technical, organizational and informational concepts for maintaining the technical efficiency of machinery and equipment have appeared, known as Preventive Maintenance, Condition Based Maintenance, Total Productive Maintenance, Predictive Maintenance. The research aim of this article is to check to what extent the maintenance systems used in Polish enterprises are adapted to the conditions of Industry 4.0. The questionnaire survey conducted in 2020 in 100 industrial enterprises showed that the latest maintenance systems, i.e. TPM and Predictive Maintenance are known and partly used in 19% of the surveyed enterprises, but only in two enterprises are fully implemented and prepared to the conditions of Industry 4.0.

Keywords: Industry 4.0, Maintenance systems.

Introduction

The concept of Industry 4.0 was introduced in Germany only nine years ago and is already widely used not only in the scientific literature but also in industrial practice. The first scientific publication appeared in 2012, more than 100 in 2014, more than 1200 in 2017 (Krdzalic et al (2019)) and 3813 in 2019 (according to the Scopus database). In 2016 industrial sectors planned to commit US$907 bn. p.a. to Industry 4.0 – around 5% of revenue p.a. A major focus of these investments on digital technologies like sensors or connectivity devices and on software and applications like manufacturing execution systems (2016 Global Industry 4.0 Survey). In 2019 at the Faculty of Management Engineering of the Poznań University of Technology a long-term research project "Management in Industry 4.0 (No: 11/145/SBAD/2952)" was launched. The subjects of the research are:

1. Changes in company paradigms
2. Base and development technologies Enterprise 4.0
3. Reactivity of the Enterprise 4.0
4. Agile Systems
5. Management of processes and resources of Enterprise 4.0.

The aim of the research is:

1. Developing mechanisms of the paradigm shift in the enterprise
2. Development of management methods and tools in Industry 4.0
3. Development of the opportunity theory.

This article is a presentation of the past research results of maintenance systems in industrial enterprises in Poland in the context of Industry 4.

Research problem and research aim

Maintenance systems have changed under the influence of many factors including main changes caused by successive industrial revolutions. Comparison of industrial and maintenance system development trends leads to the following questions:

Cite this Article as: Edmund PAWLOWSKI "Development of Maintenance Systems in Polish Enterprises in the Context of Industry 4.0" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

1. Whether and how industrial development influenced changes in maintenance systems.
2. What are the current development trends in maintenance systems.

The asked questions have two scopes: global and local. Industrial revolutions had different characteristics in different parts of the world. The scope of this research, including empirical research, in particular, is limited to the situation of industrial development in Poland. The main objective of the research is as follows: to what extent the maintenance systems in Poland are adapted to the support of Industry 4.0 and what factors have a positive or negative impact on the development of these systems.

Literature Review

Industry 4.0 in the context of industrial revolutions

The scientific and technical revolutions and later the IT and social revolutions were an important context for four consecutive industrial revolutions. Industrial revolutions formed a logical sequence described in the literature under the names of Industry 1, 2, 3, 4. Steam machines and mechanical looms invented in the 18th century initiated the first industrial revolution (Industry 1.0). It is commonly called the Industrial Revolution, but it was not yet industry. It was dominated by the quantitative division of labour, typical of crafts and manufactures. Industrial forms of production based on the qualitative division of labour and specialization of workers appeared only in the second half of the 19th century. The second industrial revolution (Industry 2.0) was at the beginning of the twentieth century with production/assembly lines up to several kilometers long and annual production volumes in millions of units of the same product. The dominance of the effect of production scale and minimization of the unit cost was possible and typical for the manufacturer's market. As a result of the price reduction, the product was available to a large number of consumers and socially acceptable. However, the market would have been saturated quickly if it had not been for the First and Second World Wars. The shift of industry to war production and the war damage to the industrial infrastructure sustained the producer's market. The relative balance of demand and supply emerged only in the 1960s. Customer pressure to diversify products, shorten delivery times and customize service resulted in a new competitive situation in the market. The market was expanding, the global market appeared but at the same time, the tendency to customize products was growing. The answer to these market challenges was Industry 3.0 started in the 1970s and 1980s. New production systems, new marketing systems and new organizational systems supported by the development of electronics, telecommunications and information technology appeared. The aim of the development was increased customization with costs comparable to those of mass production. The production systems were developed in other forms of production automation and robotization, flexible production systems (FMS), computer-aided systems: product design (CAD), technology design (CAM) and their integration (CAD/CAM), production management systems (MRP) and integrated enterprise management systems (ERP, CIM). There was a revolution in organizational structures and enterprise management systems. A new trend emerged in the organizational structures of enterprises - the so-called external organizational architectures: network, virtual and fractal structures (Pawlowski (2009)). Enterprises were becoming open, the boundaries between the company and its environment were blurred. For the purposes of contract execution, one-time or repeatable cooperation networks are created in which external companies and individuals, communicating by means of modern IT means, are elements. The development of nanotechnology resulted in even faster development of IT and robotics. The above-discussed trends typical for Industry 3.0 are still valid today and some researchers believe that the present day is still the third level of the industrial revolution (Geissbauer et al (2016)). On the other hand, the year 2011 is conventionally assumed to be the beginning of Industry 4.0. The concept of Industry 4.0 refers to the combined application of previously known innovations in digital technologies such as robotics and artificial intelligence; sensors; cloud computing; the Internet of Things; data capture and analytics; digital fabrication; smart phones and mobile devices, and the embedding of all these elements in an interoperable global value chain, shared by many companies from many countries (Geissbauer et al (2016), Mrugalska et al (2020), Wyrwicka et al (2017)). Only two years ago, Industry 4.0 was considered the future, today it is a widely accepted reality that changes the way companies operate and affects almost every industry around the world (Jasiulewicz-Kaczmarek et al (2020), Krdzalic et al (2019). In 2015, PwC surveyed more than 2,000 companies from 26 countries in the industrial production sectors. Adoption of Industry 4.0 measured as the advanced level of digitization and integration in operations, supply chain and other activities was 32% of the surveyed companies. At that time it was expected that in 2020 this level will reach 72% of enterprises (2016 Global Industry 4.0 Survey).

Maintenance Development

Maintenance of machines and equipment is an integral part of any production system. The development of the industry entailed changes in maintenance systems but important innovations in maintenance appeared relatively

late, only in the 1950s. Until then, machines and equipment were repaired according to the principle: it's broken so repair it. This model is called Reactive or Corrective Maintenance. The logic of further development is shown in the literature in 3 or 4 phases. The three-level maintenance system development model includes (Jasiulewicz - Kaczmarek (2005), Legutko (2009), Moubray (1996), Piersiala and (2005)):

I. The period of reactive maintenance.
II. The period of preventive maintenance – planned and preventive repairs.
III. The period of predictive-proactive maintenance – preventive inspections, technical condition monitoring, the participation of the machine operators in the operation maintenance, RCM, TPM, 5S, operator's own inspections.
The four-level development model includes (Jasiulewicz-Kaczmarek (2020)): Reactive (Maintenance 1.0 – M1.0), Preventive (Maintenance 2.0 – M2.0), Condition based (Maintenance 3.0 – M3.0), Predictive and Prescriptive (Maintenance 4.0 – M4.0).

A comprehensive look at changes in maintenance systems leads to the separation of three aspects of development:

1. Approach to the way of failure prevention (a/ none b/ scheduled, c/ based on the diagnosis of the machine condition).

2. Maintenance organization (a/ specialized services to receive maintenance, b/ combined - maintenance and production services (machine operators).
3. The purpose of the maintenance system (a/ reliability of machines and equipment, b/ productivity of the entire production system).

Considering these three aspects, the following typology of Maintenance Systems can be proposed:

M1 – Corrective Maintenance - where repair tasks were initiated after a failure.

M2- Preventive Maintenance: where repair tasks are generated by anticipating the technical condition of machines and equipment. There are two varieties here:

M2.1. Planned Preventive Maintenance –where the dates and scope of maintenance and repair activities are planned in advance in the form of so-called repair cycles. The cycle (6, 9, 12 repairs) includes service, current repairs, medium repairs and overhauls. Each of these overhauls and repairs has an established range of activities and machine parts to be replaced.

M.2.2. Condition Based Maintenance –where the anticipation of the machine's condition and the necessary repairs is based on the examination of the machine parameters such as vibration, temperature, electrical parameters, etc.

3. M3 - Total Maintenance. There are two varieties of it:

M3.1. Total Preventive Maintenance – it is a comprehensive approach to maintenance assuming the use of all available preventive tools aimed at full maintenance of machinery and equipment efficiency, and the inclusion of production machine operators in the review and diagnosis processes.

M.3.2. Total Productive Maintenance- is a higher form of the previous system. The aim is not only to maintain the technical efficiency of the machines but to maximize the use of the production assets. In practice, this means that machines and equipment are not available for repair services during the period of their disposal for production (repair works are carried out e.g. on holidays). The efficiency and utilization indicators of O.E.E. (Overall Equipment Efficiency) machines and equipment are calculated and monitored on an ongoing basis. The machine used for production should run at all times, at maximum speed and without production shortages. It is necessary to make thorough use of preventive methods (PM) throughout the life cycle of machines and equipment. Implementation and maintenance of the system is carried out simultaneously by many different organizational units of the company (production preparation, production units, and technical service - repair). The system requires the involvement of all employees, from the chief executive to the machine operators in the production system (Nakajima (1988), Pawlowski et al (2005)).

M4. Predictive Maintenance –a system dedicated to Industry 4.0. This model uses the latest Condition Based Maintenance tools to take preventive action in the event of machine or process performance deterioration in order to prevent failures. The development is directed towards intelligent machines and robots that are equipped with a

network of sensors and relays that communicate with each other and with the service. By using Big Data Analytics and the Industrial Internet of Things (IIoT) it is possible to remotely control machine parameters and outsource maintenance over long distances (Kans M. and Galar (2016)).

The models of maintenance systems presented above are still used today. Their applications can vary from country to country, in different industrial sectors. The analysis of the subject literature on the applications of maintenance systems in Poland shows that the research are mainly case studies for individual companies. Such studies concerned in particular: TPM system implementations (Duplaga and Stadnicka (2009), Switek (2017)), applications of OEE efficiency measurement systems (Drozyner and Jasiulewicz-Kaczmarek (2017), Krason (2016), Wirkus and Kufel (2014)), applications of PAMCO efficiency measurement system (Ingaldi (2016), Kardas E (2012), Borkowski (2011)). The question is still open about the state of implementation of modern methods of maintenance on the scale of the whole Poland, and what is the degree of modernity of these systems in the context of industry 4.0.

The Research

Methodology

In search of answers to the previously asked questions, a questionnaire survey was conducted in January 2020. The research covered 100 industrial companies (including 40 large companies and 60 medium-sized companies). Small companies were not included in the research because pilot studies showed a lack of knowledge and a marginal level of application of modern maintenance systems in these companies. The surveyed companies are located in 16 regions of Poland and cover 19 industrial sectors such as food, chemical, pharmaceutical, furniture, machinery and equipment manufacturing, automotive, electrical and electronic industries. The respondents were middle and senior managers managing engineering and production. Respondents answered questions on a scale of 1-5 (Likert), and a scale of 0-1. The data collected was processed using the Sperman's rank correlation test. Statistica 13.1 software was used to perform statistical calculations. The analysis of Sperman's ranks was performed with the assumption of significance level $p<0.05000$.

The questionnaire consisted of 9 blocks of questions:

B1. Identification of company size and industrial sector
B2. Changes in the macroenvironment and their impact on business
B3. Changes in industrial manufacturing paradigms
B4. Changes in manufacturing technology
B5. ICT (Information and Communication Technologies) Changes
B6. Changes in the human capital
B7. Changes in the Maintenance Systems
B8. Agility - using opportunity analysis
B9. Company's metric (company age, turnover).
Essential questions about the applied maintenance systems are contained in block 7. Block consists of 5 questions:

Q13. What maintenance systems are used in your company?

1. Corrective Maintenance
2. Planned Preventive Maintenance
3. Total Preventive Maintenance
4. Total Productive Maintenance
5. Predictive Maintenance

Q14. Which part of the machines is being overhauled according to the Planned Preventive Maintenance system?
1. All of them (100%)
2. Almost all of them (75%)
3. Half of them (50%)
4. Only some, less important (25%)

Q15. Which part of the machines is being overhauled according to the Total Preventive Maintenance system? (answers on the same scale as question 14).

Q16. Which part of the machines is being overhauled according to the Total Productive Maintenance system? (answers on the same scale as question 14).
Q17. Which part of the machines is being overhauled according to the Predictive Maintenance system? (answers on the same scale as question 14).
The answers to these questions will indicate the scope of application of individual maintenance systems. The second part of the analysis was a search for correlation of questions Q13 - Q17 with questions of other question blocks.

The Results

The scope of application of individual maintenance systems is shown in Diagram 1. Most companies use several systems in parallel. The high level of application of Reactive Maintenance (more than 50 % of the companies surveyed, both medium-sized and large) is surprising. The most frequently used system is Planned Preventive Maintenance (77 % of large companies and 62 % of medium-sized companies). Total Preventive Maintenance is used by 66% of large companies and 54% of medium-sized companies. Modern systems are used twice as often by large companies as by medium-sized companies (Total Productive Maintenance - 46% large companies and 26% medium-sized companies, and Predictive Maintenance - 29% large and 14% medium-sized companies). In summary, more than half of the companies still use the archaic Reactive Maintenance system but at the same time, almost half of the large companies use the modern Total Productive Maintenance system. The latest digital technology-based systems, Predictive Maintenance, are already known and used in approximately 30 % of large companies.

Fig. 1: Models of maintenance systems used in Large and Medium Sized enterprises in Poland in 2020

When analyzing correlations between the use of maintenance systems and other aspects of the development of Industry 4.0, we selected those relationships where the Sperman correlation index showed statistically significant values, i.e. $r_s > 0.20$. Correlation relationships were recorded in five areas:

1. Changes in macro-environment and maintenance systems (Table 1).

a/ A positive relationship between the benefits of changes for business in the political and legal sphere and the application of modern maintenance models. The more beneficial conditions the more applications – Total Productive M. (r_s= 0,25) and Predictive M. (r_s =0,32)
b/ A positive relationship between the benefits of business changes in the economic sphere and the application of Total Preventive M. The more beneficial economic conditions the more machines overhauled in this system (r_s =0,33)
c/ A positive relationship between the advantages of social change for business and the use of Predictive M. The more beneficial conditions the more often Predictive Maintenance is used. (r_s =0,30)

Table 1: Changes in macro environment (1 – Negative; 5 - Positive) versus Maintenance Systems

	Political and Legal Changes	Changes in the Economic Sphere	Changes in the Social Sphere
Implementation of TPM - Productive System	r_s= 0,25		
Implementation of Predictive System	r_s= 0,32		r_s= 0,30
Increased number of machines repaired in TPM - Preventive System		r_s= 0,33	

2. Implementation of modern management methods and concepts vs. Maintenance systems (Table 2.)

a/ Continuous Improvement. The implementation level correlated positively with the use of models - Total Preventive M. (r_s = 0.27) and the use of the Predictive Maintenance model (r_s = 0,26)
b/ Empowerment. Negatively correlated with the Reactive M model. (r_s = -0,38). The higher the level of implementation of this method the lower the application of the Reactive M model. The method positively correlated with the Total Productive M model. (r_s = 0,22)

c/ Just in Time. Positively correlated with the Predictive M model. (r_s = 0,27)
d/ Outsourcing. Positively correlated with the Predictive M model. (r_s = 0,26)
e/ Supply Chain Management. Positively correlated with Predictive M. (r_s = 0,24), however, it is also positively correlated with the number of machines serviced in the Total Preventive M. model. (r_s = 0,44)
f/ Learning Culture. Negatively correlated with the Reactive M model. (r_s = -0,21). Positively correlated with the Total Preventive M model. (r_s = 0,36) and using the Predictive M. model. (r_s = 0,22). Positively correlated with the increase in the number of machines serviced according to the Total Preventive M. model. (r_s = 0,43), Total Productive M. (r_s = 0,52) and according to the Predictive M. model. (r_s = 0,52).

Table 2: Implementation of management methods (1 - None, 5 - Full implementation) versus Maintenance Systems

	Continuous improvement	**Empowerment**	**Just in Time**	**Outsourcing**	**Supply Chain Mgmt.**	**Learning Culture**
Implementation of Reactive System	r_s= 0,27	r_s= -0,38				r_s= -0,21
Implementation of Planned Preventive System						r_s= 0,36
Implementation of TPM - Preventive System						
Implementation of TPM - Productive System		r_s= 0,22				
Implementation of Predictive System	r_s= 0,26		r_s= 0,27	r_s= 0,26	r_s= 0,24	r_s= 0,22
Increased number of machines repaired in TPM - Preventive System					r_s= 0,44	r_s= 0,43

Increased number of machines repaired in TPM - Productive System						r_s= 0,52
Increased number of machines repaired in Predictive System						r_s= 0,52

3. Types of machines used in the company and Maintenance (Table 3)
a/ Single-purpose machines (non-universal). Their use is positively correlated with the Reactive M model. (r_s = 0.23) and the Predictive M. model (r_s = 0,20).
b/ Universal, traditional machines. Their use is positively correlated with the Reactive M. model (r_s = 0.34) and Total Productive M. (r_s = 0,21).
c/ Numerically or computer-controlled machines. Their application positively correlated with the Planned Preventive M model. (r_s = 0,44)
d/ Manipulators. Positively correlated with the Predictive M. model (r_s = 0,25)
e/ Robots. No correlation at a statistically significant level

Table 3: Types of machines used in the enterprise versus Maintenance Systems

	Single-purpose machines	**Universal machines**	**CNC machines**	**Manipulators**	**Robots**
Implementation of Reactive System	r_s= 0,23	r_s= 0,34			
Implementation of Planned Preventive System			r_s= 0,44		
Implementation of TPM - Preventive System					
Implementation of TPM - Productive System		r_s= 0,21			
Implementation of Predictive System	r_s= 0,20			r_s= 0,25	
Increased number of machines repaired in TPM - Preventive System					
Increased number of machines repaired in TPM - Productive System					
Increased number of machines repaired in Predictive System					

4. Level of production automation and Maintenance (Table 4)
a/ Positively correlated with the Total Preventive M. model (r_s = 0,28) and with the Predictive M. model (r_s = 0,31)

Table 4: Level of production automation (1 – None, 5 - Full) versus Maintenance Systems

	Level of production automation
Implementation of Reactive System	
Implementation of Planned Preventive System	
Implementation of TPM - Preventive System	r_s= 0,28
Implementation of TPM - Productive System	
Implementation of Predictive System	r_s= 0,31

5. The extent to which the executive competencies of employees are important for the development of the company and Maintenance (Table 5).
a/ Narrow specialization of employees positively correlated with the use of Total Preventive M. model (r_s = 0.26), Total Productive M. (r_s = 0.20) and with the Predictive M. model (r_s = 0,30)
b/ Openness to changes in the way and place of work positively correlated with the use of Total Preventive M. model (r_s = 0.24), and Total Productive M. (r_s = 0.20)

Table 5: The degree to which executive competences of employees are important for the development of the company versus Maintenance Systems

	Narrow employee specialization	**Openness to changes in the way and place of work**
Implementation of Reactive System		
Implementation of Planned Preventive System		
Implementation of TPM - Preventive System	r_s= 0,26	r_s= 0,24
Implementation of TPM - Productive System	r_s= 0,20	
Implementation of Predictive System	r_s= 0,30	r_s= 0,20
Increased number of machines repaired in TPM - Preventive System		
Increased number of machines repaired in TPM - Productive System		
Increased number of machines repaired in Predictive System		

The latest systems based on digital technology - Predictive Maintenance - are already known and used in approx. 30% of large companies and 14% of medium-sized companies, which is 19% for the entire group of companies surveyed. Of these 19 companies, however, only two used Predictive M. and Total Productive M. in parallel. The remaining 17 companies also used other systems to varying degrees of which as many as 9 companies used Reactive Maintenance

Discussion and Conclusions

Maintenance systems dedicated to Industry 4.0 are mainly Predictive Maintenance supported by Total Productive Maintenance. A questionnaire survey conducted in Poland on a sample of 100 companies showed that 19 % of the companies are familiar with and use Predictive Maintenance but only two companies use this system together with Total Productive Maintenance as the only methodological basis for maintenance. The other 17 companies use different systems in parallel of which as many as 9 of these 17 companies use the most primitive Reactive Maintenance system. The priorities of the importance and production reliability of machines and equipment as well as economic considerations make it necessary to differentiate maintenance system applications. However, in the development of Industry 4.0, application trends for old systems are marginal. This means that the level of

adjustment of maintenance systems to the conditions of Industry 4.0 in Poland is very low. Similar conclusions can be found in the research of Trzcielinski (2020). The level of knowledge of modern maintenance systems is noticeable but the level of application is still at the initial stage of development. By analyzing the correlations between the use of Predictive Maintenance and Total Productive Maintenance systems and other context variables, it is possible to point out the following:

- positive correlations with changes in the political, legal and social macroenvironment,
- positive correlations with the implementation of modern management methods and techniques (Continuous improvement, Empowerment, Just in Time, Outsourcing, Supply Chain Management, Learning Culture),
- positive correlations with the types of machines and equipment used in the company (Single-purpose machines, Universal machines, Manipulators)
- positive correlations with narrow employee specialization,
- positive correlations with the level of production automation,

This research has its limitations. The most important are acceptable but low correlation levels. The research was carried out at one point in the time and needs to be repeated in the following years to establish trends in change. It also seems reasonable to carry out the research in a Case Study mode for selected companies qualified to Pioneer 4.0 and Industry 4.0.

Abstract

This research is mainly addressed to educational institutions of any level, whether it is a gymnasium, high school or a higher education institution, and it aims to modernize the current and future learning environment by offering an easily implementable solution for wiping board systems. The current research paper proposes a project which focuses on improving the quality of the classes and presentations through offering additional value and designing a more convenient learning environment for both students and teachers. The proposed concept product has been designed to be reproduced in any circumstance by a person or a team that has background knowledge in mechanics, mechatronics, additive technologies and electronics. This system was built based on the analysis of several criteria such as: ease of maintenance, appearance attractiveness, functionality of the writing/ wiping surface. Three main requirements of the wiping surface were to facilitate the board to be watered and to ease the movements along it, and to allow remote control. The criteria were included in a questionnaire which targeted at relevant respondents in order to collect data, to receive feedback and to analyse the competitive products. The products' components were selected from the market in order to have the most diversified functions and to meet various needs such as internet connection or the possibility of moving or changing the writing instrument. Based on these functions, multiple sets of tables have been prepared to analyse the factors that have the greatest impact; two relevant analyses are represented by Quality function deployment and conceptual analysis. These analyses ensured the development of an optimal product concept which can be effectively used both as a stand-alone product and as a learning environment for students as it represents an example of mechatronics, electronics and additive technologies.

Keywords: Automatic Wiping Board, Conceptual Design, Learning Objectives, Learning Environment.

Introduction

Nowadays making products that improve teaching is not an easy task. The audience is more and more connected to virtual life through their personal devices. In order to capture their attention, new systems must be developed which can ensure added value for potential customers. According to OECD (2018), future-ready students will need both broad and specialised knowledge, competence acquisition involving the mobilisation of knowledge, skills, attitudes and values to meet complex demands. Recent studies done by Bushweller K. (2020) show that more interest is being shown in highly technological learning environments and the audience develops faster an analytical thinking in this environment rather than in a classical one. From this perspective, even a small technological improvement brings added value in the teaching process. The institutions which still practice the classic and traditional type of teaching are in a race for technological improvements, especially in the current socio-economical context. Amongst some of the most used tools in classrooms are the communication boards, be they traditional chalkboards, flip charts or even smart boards. There is a significant progress from the traditional chalk boards in the market to marker boards which are equipped with various supports to put the accessories of the board, mobile boards or even boards that can connect

Cite this Article as: NUȚĂ Andrei-Bogdan, ULMEANU Mihaela-Elena and DOICIN Cristian-Vasile "Design and Development of An Automatic Wiping Board System" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

to the internet or can project various images and videos. Given the above, the current proposal is to introduce a system of automatic wiping of the boards; the system can be of various types, whether classic or with a marker. This system has an easily understandable operating principle which can be applied anywhere, it has low costs of construction, installation and maintenance and it can be customised. The proposed project is reproducible, and it can be used both as a tool and as an educational model. Students can study this project which can enable them to learn the principles of mechanical and electronic operation. This methodology of a smart board system can transform a classic board into a board with the function of automatic erasure with or without remote control. The knowledge needed to advance the understanding of the project and its development spans not only a broad and diverse range of disciplines, but also various fields such as mechanics, mechatronics, electronics, assembly techniques, additive technologies - 3D printing, design and simulation in various 3D software, programming (IT) and economics.

In this context, the current research focuses on delivering a product concept with the main objective of achieving a universal system for improving the quality of teaching. In terms of efficiency and simplification of the working model, these improvements will design a more convenient teaching process due to the fact it does not require any manual wiping of boards. The product design and development of automatic wiping board system was developed and implemented as a project within the POLITEHNICA University of Bucharest, Romania and it aims to be distributed nationally mainly in rural and disadvantaged areas where such a solution would bring more technologies in the classrooms and would significantly improve the quality of teaching. The main contributions of the authors to the current state of knowledge can be summarised, as follows: deployment of a comprehensive benchmarking analysis for the construction of technical specifications for automatic wiping board systems; development of a metrics – requirements matrix for an automatic wiping board system; function definition and Quality Function Deployment (QFD); Theory of the Resolution of Invention-Related tasks (TRIZ) method and Analytical Hierarchy Process (AHP) implementation for an innovative concept; detailed design concept presentation for an automatic wiping board system.

Study background and Methods

Concept development started with the definition and establishment of a specifications set which derived from an in-depth analysis. The main approach of the project was initially to establish the set of needs that this system is supposed to solve after its implementation. The most important advantage of the system is related with the need to have a proper hygiene. This issue affects both teachers and students after they manually wipe a board. Regardless of the writing instrument, the hands remain dirty and this is a completely unhygienic effect that must be eliminated, especially in the current socio-economic context of the COVID-19 outbreak. Another important need consists in the qualitative importance that is brought by a pleasant appearance of the board. This avoids the impression of a clogged environment and it eliminates the risk of having dirty and incorrectly erased boards which leads to the certainty that the information written on the board is readable.

Considering the Romanian educational system, one hour of class lasts 60 minutes, of which 50 minutes of teaching and 10 minutes of break. Based on this, it can be easily noticed the need to use the time as efficiently as possible whether it is learning time or break. By a correct programming, a short wiping time can be obtained, which will make the duration of 60 minutes to reach the full potential.

The system also addresses the need to keep students' attention. Usually, while a speaker or teacher wipes the board, the audience tends to be distracted by various disruptive factors for a few minutes. Therefore, while the system performs its own pre-set function, the teacher can continue to talk to the students and maintain their attention. Finally, everyone needs comfort and technology. Today's students are extremely connected to technology. A system that needs only a simple command to perform a boring and disliked function will be extremely well embraced as it proves its usefulness and promote interactive learning environments.

The basic assumption is that technological tools will become increasingly significant and much more complex in the following period. The fact that educational institutions do have the opportunity and the freedom to support a good teaching environment is encouraging. As institutions design their own operating models, they manage to move towards more technological approaches. This scenario emphasizes the importance to develop this kind of technological system meant to become a tool which supports complex and interactive learning within a dynamic environment.

Figure 1 highlights the elements that enter the designed system, the content of the system and what it obtains after its implementation. The inputs are set as: necessary materials, type of sheet already existing or to be mounted, the documentation that had to be followed to assemble the system and of course the analysis of current space and cost limitations. The system itself is very simple, it only fulfils the function of automatic erasing plus its accessories that

can vary depending on the desire to implement (eg. remote control, sponge, writing tools holders etc.). The benefits of using the automatic wiping board are considered the system outputs.

Based on the IN-OUT diagram several product design and development tools were selected and used in order to obtain the optimum concept for an automatic wiping board system. Ulrich K.T. and Eppinger S.D. (2012) discuss in their research the advantages of using the specifications table, the metrics – requirements matrix and the function hierarchisation within the first stages of product development. Quality Function Deployment (QFD), the Theory of the Resolution of Invention-Related tasks (TRIZ) and the Analytical Hierarchy Process (AHP) were also used to analyse a variety of features within the optimum concept that was developed.

Fig. 1: IN-OUT Diagram for an automatic wiping board system

Results and Discussions

Several competitor products were analysed to fundament the development process. Benchmarking revealed that most of them had similar added value and functions. The first product analysed was the "Optima chalk school board", hereinafter referred to as Board 1. This is a simple board, with a very widespread model in educational institutions and on which the proposed automatic wiping system can be mounted, having as the only change the removal of the current accessory holder. Next, the "Accenta magnetic board" was analysed, hereinafter referred to as Board 2. This is a board which uses a marker as a writing tool. The next product analysed is the "Multifunctional Magnetoplan board", hereinafter referred to as Board 3. This is also a board with marker, which is mounted on a support and has as a special feature the possibility of movement. It does not fit on the list of boards compatible with the automatic wiping system but brings into question a new function, that of movement. The fourth and last product analysed was the "Smart Board interactive whiteboard", hereinafter referred to as Board 4. This is the most complex system on the market, which consists of several components each with different functions, that complement each other in a complete learning environment. In addition to the writing function, this board also performs a variety of functions such as active video projector. More precisely, it allows projection of images and enables direct writing on top of them. It has a sound system that allows active learning and can connect to the internet via *wifi* or cable connection and other devices such as laptop or mobile to share images and videos. Among all these added technologies, there is no automatic wiping function, so to wipe what we have drawn or written on the board we must use a magnetic sponge in the classic way. The system proposed in the current research can also be adapted for such a smart board.

Data collected for each product was summarised in Table 1, where the technical specifications of the component products are presented. The columns of the table correspond to the identified competitive products and the rows represent the main technical specifications (metrics). The values of the metrics are inserted down the column of each competitive product. Measuring units are also specified for each metric. These metrics will continue to be used to design and manufacture the product concept. Metrics that are directly related to customer needs are the most important. The metrics were chosen based on the capabilities identified following the analysis of competitive products and the possibility of implementing the automatic erasure system was considered. Ideally, one requirement is expressed through one metric. This is not always valid. For example, "the board should be easy to wipe", which can be primarily interpreted with the type of surface of the board, like glass. But serious consideration should be given to the technical characteristics of the glass sheet, namely: sensitive to impact; upon breakage the maintenance is very expensive and requires skilled operators. Thus, to highlight this feature the following metrics were used: "Dimensions", "Writing tool", "Colour", "Wiping tool", "Special treatments". Usually, metrics are measured using

conventional units such as kilogram, second, millimetres, etc. If metrics cannot be evaluated based on those, the values can be expressed with decisions like yes/no or pass/no pass.

Table 1: Technical specifications for an automatic wiping board system

Nr.	Metrics	Units	Competing products			
			Board 1	Board 2	Board 3	Board 4
1	Dimensions	[cm]	100x200	120x180	90x120	169.20 x 128.40
2	Writing tool	Class	Chalk	Marker	Marker	Special tools
3	Colour	Colour	Black	White	White	White
4	Wiping tool	Class	Sponge	Sponge	Sponge	Special tools
5	Mobility	Yes/No	No	No	Yes	Yes
6	Accessories	No. of accessories	No	No	1	4-6
7	Manual	Yes/No	No	No	No	Yes
8	Special treatments	No. of treatments	No	No	No	2
9	Guarantee	Years	1	1	1	3
10	Thickness	[cm]	1.7	1.7	1.7	2
11	Price	Eur	70	80	85	600
12	Touchscreen	No. of fingers	No	No	No	2/4/6/10
13	Text Speech	Languages	No	No	No	English, French, German
14	Connection interface	No. of connections	No	No	No	5
15	Certifications	Type	No	No	No	EMC Directive 2004, CE, FCC, RoHS, ISO 9001, ISO 14001
16	Table surface	Material	Plastic	Plastic	Plastic	Ceramic-steel (E3) / Pre-painted Steel
17	Material	Type	Miscellaneous	Miscellaneous	Miscellaneous	Miscellaneous
18	Aspect	Type	Normal	Normal	Normal	Modern

An important stage of product design and development process is the determination of the specification's objective of the product for which the market success is possible. The concept design of the products is made based on these metrics that are determined based on the specifications of the competing products.

A correspondence between each primary requirement and the measurable metrics was performed to determine the specifications' scope. A simple requirements-metrics matrix was constructed by adding on the column, the metrics and for the rows, the requirements. The matrix is presented in Table 2 and it simplifies the identification of the values and of primary requirements they characterize.

Table 2: Metrics – Requirements Matrix for an automatic wiping board system

Requirements		Metrics																	
		Dimensions	Writing tool	Colour	Wiping tool	Mobility	Accessories	Manual	Special treatments	Guarantee	Thickness	Price	Touchscreen	Text Speech	Connection interface	Certifications	Table surface	Material	Aspect
		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
1	Wipe board efficiently		●		●		●		●								●	●

12	The system is silent in operation					●												●	
13	The system can be mount on all types of boards	●										●							
14	The system is an electrical product					●	●						●	●					

Based on these metrics and characteristics, a questionnaire was conducted which was addressed to 100 people, students and teachers at University POLITEHNICA of Bucharest (UPB). Results were analysed and interpreted, and Table 3 was put together for the identification of the most important product functions. Next, the weaknesses and strengths of the proposed concepts were identified using QFD. According to Nadiye O.E. and Omid A. (2018) QFD is a method created in Japan beginning in 1966 to help transform the customer needs into engineering characteristics for a product. Akao Y. (1994), the original developer of the method, described QFD as a "method to transform qualitative user demands into quantitative parameters, to deploy the functions forming quality, and to deploy methods for achieving the design quality into subsystems and component parts, and ultimately to specific elements of the manufacturing process". He used his work in quality assurance and quality control points with function deployment for value engineering.

Table 3: Functions and effects

No.	Function name	Possible effects
F1	Allow the board to be wet	Damage to electrical parts
F2	To allow movement along the board	Collisions
F3	Instructions for maintenance and use	Misunderstanding the instructions
F4	Allow adjustment of pressing force on the board	Breaking components
F5	To indicate when force must be increased	Increase force too much
F6	Allow remote control	Hacking
F7	Has aesthetics appearance/ Industrial Design	Rising the price
F9	Allow the device to be used for predeterminate duration	Use in excess
F10	Allows easy maintenance	Improper maintenance

Based on the ten key functions previously identified, a QFD matrix (Figure 2) was deployed by the authors to identify weaknesses and strengths of the proposed concept.

Fig. 2 : Quality function deployment (QFD) for an automatic wiping board system

One of the main identified issues was the decrease in thickness of the classic sheets to obtain a set of advantages, including weight reduction and easier handling, plus the fact that a smaller amount of material used brings after itself and a lower cost and an advantage for the environment. The following question was considered: “How could the thickness of the board be reduced safely, while maintaining optimum functionality?” Of course, this change also had negative effects such as a decrease in pressure resistance and durability. To solve this problem the TRIZ method was implemented further. According with Gadd K. (2011) TRIZ or the "theory of the resolution of invention-related tasks" is "a problem-solving, analysis and forecasting tool derived from the study of patterns of invention in the global patent literature". It was developed by the Soviet inventor and science-fiction author Altshuller G. (1999) and his colleagues, beginning in 1946. More specifically, a list of 39 parameters was used for solving the problems. Three main parameters were assigned to solve the considered problem in designing the automatic wiping board system (Figure 3).

List of 39 parameters

Weight of moving object	Power
Weight of stationary object	Loss of Energy
Length of moving object	Loss of substance
Length of stationary object	Loss of Information
Area of moving object	Loss of Time
Area of stationary object	Quantity of substance/the matter
Volume of moving object	Reliability
Volume of stationary object	Measurement accuracy
Speed	Manufacturing precision
Force (Intensity)	Object-affected harmful factors
Stress or pressure	Object-generated harmful factors
Shape	Ease of manufacture
Stability of the object's composition	Ease of operation
Strength	Ease of repair
Duration of action of moving object	Adaptability or versatility
Duration of action by stationary object	Device complexity
Temperature	Difficulty of detecting and measuring
Illumination intensity	Extent of automation
Use of energy by moving object	Productivity
Use of energy by stationary object	

Fig. 3 : List of 39 TRIZ parameters an automatic wiping board system

Given that in the proposed concept the board is a stationary object and the aim is to decrease the thickness on the entire surface, the first chosen parameter was "Length of stationary object" followed by the two effects and their parameters, "Stress or pressure" and "Strength". Based on the matrix of contradictions, the relevant principles for solving the problem were obtained (Figure 4).

So as it can be observed in Figure 4, the relevant principles are: 14 - Spheroidicity, Curvilinearity (it is the first because it is present twice), 1 - Segmentation, 15 - Dynamicity, Optimization, 26 - Copying, 28 - Replacement of a mechanical system with 'fields' and 35 - Transformation of the physical and chemical states of an object, parameter change, changing properties.

Following the analysis and identification of the solutions, the following were chosen as relevant principles 14 - Spheroidicity, Curvilinearity and 1 - Segmentation. Principle 14 proposes the addition of a radius on the surface of the sheet, which increased the resistance to pressure and shock, and the second principle proposes the segmentation of the sheet into several components. The principles can also be combined. This, the idea of segmentation and the addition of sphericity on each segmented surface is considered for analysis. Other solutions proposed under the analysis and other relevant principles are: fixing the board to several support points; change material or add reinforcements to gain better resistance; change usage parameters, such as writing or deleting tools; clean the board with a liquid to reduce friction and pressure. This is how all the problems that arose during the development process were solved.

The following step in the development process involved the design of 4 system concepts, each with its own characteristics. The four concepts were analysed by method Analytic Hierarchy Process (AHP) as per the methodology described by Joyce A. (1989) (Table 4).

17, 10, 4	1, 8, 35	1, 8, 10, 29	1, 8, 15, 34	8, 35, 29, 34	19
28, 10	1, 14, 35	13, 14, 15, 7	39, 37, 35	15, 14, 28, 26	6, 3

Decision criterion	Weight	Concept C1	Concept C2	Concept C3	Concept C4
Simplicity of operation	0.210	0.231	0.231	0.231	0.307
Ease of use	0.073	0.250	0.125	0.375	0.250
Reliability	0.210	0.333	0.222	0.222	0.222
Design and ergonomics	0.127	0.182	0.182	0.273	0.363
Universality	0.031	0.250	0.250	0.250	0.250
Ease of manufacturing	0.128	0.250	0.167	0.167	0.167
Cost	0.220	0.250	0.250	0.350	0.200
Total		0.254	0.210	0.244	0.230

According with Saaty, T.L., Vargas, L.G. (1991) the analytic hierarchy process (AHP) is an arranged technique for organizing and analysing complex decisions, based on two basic disciplines mathematics and psychology. It was developed by Thomas L. Saaty in the 1970s who partnered with Ernest Forman to develop Expert Choice in 1983 and has been extensively studied and refined since then. It represents a safe approach to decision making.

Following the AHP analysis the highest output was obtained by concept 1, hereinafter referred to as concept C1. This concept proposes as a solution for the automatic wiping of the board, a single sponge, placed longitudinally on the board, to execute one or more left-right movements. This solution was chosen as optimum, as it can be mounted on any type and size of board sheet only by adapting the dimensions of the sponge supports. The system also contains a sponge pressure sensor to indicate if the pressure is too high/ low, thus, the risk of damage to the elements can be avoided. In addition, there is a proximity sensor, which senses if someone or something is in the path of the sponge and stops it to avoid collisions and subsequent injuries to people.

All these elements are embedded in subsystems to perform their functions, as it can be seen in Figure 4. The presented detailed design concept was modelled assembled using Solid Works, in order to test the functionality and fit of all components, previous to a physical prototype. Component 2 represents the main board, the central element of the

system. This concept contains a single motor mounted at the bottom so that the long shaft 1 ensures the transmission of the rotation in the upper gears as well. Components 3, 4, 6, 7, 13 and 15 are the fixed elements of the system, which support the other smaller elements. Parts 8, 11, 12 are supports and guides for the sponge and the sponge long shaft. Some of these elements are designed to be in motion during operation. Components 5, 9, 10, 14 are mobile elements that ensure the transmission of motion and the transformation of rotational motion into translational motion.

Fig. 4: Detailed Design Concept for an automatic wiping board system

Conclusions

Current research includes the design and development of an automatic wiping erasing system in a product that can be used on its own or as a learning environment for students. A variety of methods have been used to help think and develop the proposed system. The methods involve a thorough benchmarking analysis, namely several boards and intelligent boards systems for schools. Their functions, their applications and the improvement mode were analysed by adding the automatic wiping function. Following these analyses, it was also noticed that not even the most performant current boards have such an automatic wiping function implemented. Thus, the ability to introduce a function that solves the problems of comfort, hygiene and attention of students would potentially increase the quality of the learning environment, the desire of the beneficiaries either pupils or students to get involved in the learning process. In this regard, a list was elaborated with the main functions that the new system should fulfil in order to address the consumers' needs. The ten identified functions were analysed using the QFD, TRIZ and AHP methods. The optimum developed concept - C1, was the one which fulfilled the identified functions, by using a single sponge and performing translational movements along the board, having integrated safety elements. The design of this concept has been detailed using 3D design software programs to highlight the elements need for each function. Future developments of include analyses to add more universal functions, increasing the reproducibility of both mechanical and software subsystems. Authors also considered the development of a mobile or computer application with which the system can be accessed remotely and through which the product could perform, for example, a general deletion of the available board.

Abstract

According to the market evolution, the biggest companies express the desire to create quality through satisfaction, while building a management of a real customer culture that use customer satisfaction inside the business model.
The case study presents how the customer satisfaction level influences the developing of a new product through his life cycle, in an Automotive Company proposing a model of evaluation. The purpose of the article is to highlight the influence of the customer satisfaction on each step necessary for product developing by choosing appropriate methods for customer satisfaction evaluation. Following the four stages of the product life cycle chosen as reference: Exploring, Development, Launching and Post-Launching, through the proposed model, it will be revealed how the customer decides starting from the beginning the segment and the main characteristics for a new vehicle. The model may be extended to other industries.

Keywords: Customer Satisfaction Level, Customer Feedback, Survey Methodology.

Introduction

In the last years in order to keep their position on the market, the companies tried to become more innovative and more in line with the customer needs, considering as it is documented in Mortara, 2009 and Wang, Zhao, Voss, 2016, that the customers are the key for innovative ideas.

The importance of the relation between profitability and customer satisfaction is quite debated in specialized articles (Heskett et al., 1997) having the roots in the studies for the integration of marketing and accounting (Simmonds, 1970, 1982, 1986; Wilson, 1981, 1999), but becoming more relevant today, when researchers began to consider it as a key factor in cost management. (McNair et al., 2001).

As Bill Gates said, "Your most unhappy customers are your free source of learning," the most dissatisfied customers are like a gold mine for producers, giving us that guidance on ideal products.

Although the concept has begun to grow in recent years, there are industries that are still quite poorly developed in terms of customer satisfaction, such as the service industry, as they do not have physically and well-defined a production that can cause dissatisfaction and generate costs (Caru` and Cugini, 1999; Gro¨nroos, 2000). Finally, the conclusion is the same “the quality of products/services generates, in fact, the customer satisfaction” [Silvestri, C. (2014)].

In order to control the high costs needed for developing a new vehicle, the case study proposes a model of evaluation in which the customer satisfaction is the core of business model.

A new project in terms of vehicle represent hard work in order to design, develop and test it. However, it does not start from a zero plan, without experiences and feedback from customers, contrary is gathering around everything that is related to improvement in terms of quality and reliability, as well as features that have brought a maximum level of customer satisfaction.

The study proposes a clear visibility for the link between customer satisfaction and product lifecycle key processes, contributing positively to the actual situation which shows that despite of the design community struggle among the years, to set design and quality improvement targets, is still no well-established approach to link customer satisfaction targets to vehicle-level targets, according Yadav, O. P., & Goel, P. S. (2008). Further in the study it will be taken into consideration the two types of mandatory information, the direct one provided directly by the final customer and the internal one cumulated from inside studies and analysis based on figures and costs.

Main paper objectives are to highlight for each step the contribution of customers through specific type of surveys and to offer an example of the multitude of information received during survey exploration.

The study's purpose is to bring a new perspective of customer satisfaction evaluation impact, walking step by step in new products development, using the survey balance as main type of input.

Experimental Approach

For the experimental side it was documented the applicability of the proposed model through the stages of the life cycle development for a new vehicle and how the customer feedback impacts each stage from figure 1 chronology. In order to make this possible it was used data from public database of the Romanian vehicle registration service in the period 2018-2019 and selected different type of surveys, chosen efficiently according to the automotive customer satisfaction experience.

All the information used as input in the model development had the purpose to highlight the customer influence in the creation of a new product, starting from planning and exploring and continuing with design and development, manufacturing and validation, performance measuring and improvement- launching step, serial life and after-sales-post-launching support.

Fig. 1: Product life cycle steps

Results and Comments

The five steps of a new product life cycle which are highlighted in the figure 1, are grouped in 4 major categories as Exploring, Development, Launching and Post-Launching. Each category will be described individually, keeping as priority the impact of customer satisfaction.

Planning and Exploring

First step in planning a new product is to explore the market needs and to establish the type of the vehicle which will be developed.

In this stage, different certain market studies and data research are considered; these will contribute in identifying and selecting the vehicle model and the relevant segment proposed for this study.

The input needed in the selection process was the analysis of the Romanian market trend and the perspective from automotive field. According to this data, the trend for new vehicles purchased is a positive one and the volume of cars sold shows a considerably increasing from one year to another. This trend can be observed by comparing the sales volumes from 2018 (figure 2) versus 2019 (figure 3). The data used in both figures, are extracted from the public database of the Romanian vehicle registration service in the period 2018-2019, timeslot which will be used also in exploring the market, for having a first visibility related to the preferences of brands sold in Romania.

Thus, in the first phase we identify the preferences of Romanian customers in terms of brand for vehicles purchased in 2018-2019 in order to have a consistent sample and in the second phase we follow their distribution by segments. The top sales by brand in Romania in 2018 is described in figure 2.

Figure 2: TOP 20 Brand Vehicles sold in 2018.

In this ranking Dacia is TOP 1 sales for 2018 with a number of 16.405 sold vehicle, and the brand with the lowest sales volume is Seat with a number of 421 sold vehicle. Basically, the market trend for 2018 was a positive one for the Dacia brand.

The TOP of brand vehicles sold between January and July 2019 from Romania is described in fig.3.

Figure 3: TOP 20 Brand Vehicles sold between January and July 2019

From this TOP 20, one may conclude that Top 1 sales in 2019 remains Dacia with a sales volume of 21,377 sold vehicles, and the Brand with the lowest sales volume this time is Volvo, registering a number of 493 sold vehicles.

Considering that the sales volume until the middle of 2019 is already 30% higher than the sales volume in 2018, one can anticipate basing on the actual trend that by the end of 2019 the volume of sales will double.

The next necessary step in our analysis is the study of customer behavior as well as customer segmentation according to his needs, and for this one may consider the best-selling segment of the Dacia range of vehicles. By studying the preferred segment of customers, we can see both their needs and most target customers.

The same source of information is used, the basis of the Romanian registration service, detailed on the model sold (fig.4).

Figure 4: Volume of sales on segment from 2019

The definition of the above segments is the following one:
1. Segment B- multipurpose vehicle, with similar dimensions comparing compact vehicles, they are the so-called "city" cars.

2. Segment B-SUV- "compact commercial vehicle" or "compact SUV", represent the part of "small sport utility vehicles"
3. C-MPV segment - "multi-purpose vehicle" is the translation of the compact multifunctional vehicle.
4. LCV segment - "light commercial vehicle" represent the segment of light commercial vehicles.

According to Figure 4, the Top 1 in sales per segment is the B segment, with a number of 15,000 sold vehicles in 2019. The result of the ranking highlights the profile and the needs of the customer orientated for a multipurpose car with compact urban dimensions.

In the analysis of the client's profile as well as his preferences, we will use the NCBS survey (New Car Buyer Survey) applied on generic example using as a sample a number of 500 responses.

Figure 5: Customer profile

From 500 respondents surveyed, we conclude that the customer profile outlines 70% of male customers, with an average age of 55 years old, a senior family, which explains the lack of interest for family cars, for example segment C -MPV.

After establishing the customer profile, we go further in studying his preferences.

According to Figure 6, customers are attracted firstly by the price of the car, followed by its appearance and design, manufacturer loyalty and equipment level, which leads us to analyze a "low cost" vehicle with an improved design and a level equipment to justify the framing price.

Figure 6: Customer preferences in 2018 and 2019, for B segment.

Design and Development

In order to design and develop a vehicle prototype, several aspects must be considered. First, we will refer to its existence in the factory, if we aim to launch a new version of an already existing product or if the existing products contain components similar to the product we will develop.

Most car manufacturers use at least 40% components of existing cars, avoiding a complex diversity of components and saving resources with a new portfolio of suppliers.

Considering the conclusion from the exploration phase, we will turn our attention to an already existing vehicle, following a modification of it with a maximum 50% of the components. For the choice of common parts, which we will reuse on the new model, we will take into account costs and production capacity, the potential of suppliers to increase production volumes, the feedback of customers on vehicle reliability and durability over time, as well as the technical progress and product evolution that require a mandatory improvement of those components, including legislative regulations (Herron and Braiden, 2006).

In identifying the customers feedback, we will apply in the first part the DVS survey (durability vehicle survey), for vehicles driven for 36 months. The questionnaire was sent to a number of 400 customers owners of the previous vehicle model and based on their feedback we will see which are the components that will be maintained on the future model. Thus, we will start with a list of performances that have the biggest N % (number of issues per hundred), the specific unit of measurement of this type of investigation.

According to the graph in Figure 7, the most common problems are reported on Ergonomics performances, but in our case we are interested in the return on reliability and we will consider only the performance from position 2 "Appearance and durability", in order to analyze and identify customer effects with the biggest impact over time.
According to customer feedback, we note that the main components or accessories that will be improved in the next project are the quality of paint, carpet material, materials used inside the car, exterior seals on windows and body, and the usage of a protective layer for underbody components.

Being in the phase in which we have identified what we keep and what we improve on the new vehicle model and with the aim of creating a low-cost car, we will move on to the next stage of the cycle, namely "manufacturing and validation of the new vehicle ".

Figure 7: Top 20 Performances with high number of issues, N%

Figure 8: Customer complaints on" Appearance and durability"

Manufacturing and validation, performance measuring and improvement

Using the input received from the customer in the previous phases, the car reaches the manufacturing stage, largely meeting the customers' conditions. These conditions cannot be met 100%, as priority will be given to legislative regulations and to the costs necessary for improvements.

In order to verify, validate and measure the performance of the new vehicle before reaching the customer, a series of internal evaluation methods can be applied, such as customer satisfaction fleets and technical validation fleets before launch, which will take place in the same time.

The customer satisfaction fleet is addressed to internal customers, employees and runs in order to capture the first feedback for prototype cars.

These fleets can often capture commonalities that can be found in external customer surveys, but the general perception of a user paying for a good is different from that of one who will not pay.

For our study we will use 10 prototype vehicles that will run internally as employee trips for various professional purposes. The target is to have completed at the end of the study, a minimum number of 200 questionnaires. Which means that each vehicle will be driven by at least 20 people.

Table 1: Resume of the customer satisfaction fleet

COUNTRY	NUMBER OF INTERNAL CUSTOMERS	NUMBERS OF QUESTIONARES	TIMELINE	GLOBAL SATISFACTION	PERCEIVED QUALITY
ROMANIA	**80**	**210**	**January, February, March 2019**	**9**	**7**

satisfaction, and those below 6 represent minimum satisfaction.

The evaluations between 6 and 8 were for the following services:

-evaluation of global quality
-global evaluation for the external appearance
-global assessment for seats on 2nd row
-global evaluation for engine and transmission
-global evaluation of the navigation system.
The ratings > 8 were for the following services:
-global evaluation for the external appearance
-global evaluation of the seats
-global evaluation of storage spaces
-global assessment for driving ergonomics and safety
-global evaluation for dynamics
-global evaluation for the audio system
-global evaluation of internal systems and software
-global evaluation of the systems responsible for thermal comfort

Figure 9: Radar chart for global evaluation of the prototype vehicle

After validating the vehicle model and improving performance related to problems following the technical validation fleet and customer satisfaction fleets, the vehicle is ready for launch.

Serial life and after-sales-post-launching support

After the launch of the new model, the first customer feedbacks will be identified, which will be registered through several types of surveys. The first type of input is received from incidents alerts, which are registered directly in the service when functionality problems occur. The next type of surveys applied in the same time, are the "Quick Track" type surveys - which are applied after a month of running to the client. The most complex surveys that have information related to Our competitors in the B segment, which also provide a wealth of information on customer dissatisfaction, are NVS surveys (new vehicle survey) for a 3-month turnover.

The quick track survey type will be applied for a generic example with a sample of 50 clients as shown in Table 2.

Table 2: Quick Track results

	Category	Quick TRACK Romania
Demographics	**Average age**	**50**
	Engine type	**70%Diesel 30% Essence**
	Previous car owned	**75% B 25% A**
Results	**Global satisfaction**	**9**
	Global quality	**9**
	Repurchase intention	**97%**
	Recommendation rate	**98%**
	Number of complaints	**100**

As can be seen in Table 2, customers prefer diesel cars; a good level of satisfaction and overall quality are recorded, 98% of them would recommend it and 97% would like to repurchase it.

After the socio-demographic details and the global results obtained, the issues reported by the clients will be further investigated, as follows in figure 10.

Figure 10: Customer complaints recorded in Quick track survey

The issues reported by the client in the surveys are shared in specific committees in order to decide their treatment. Not all the issues can be solved, the one with high priority are those related to quality and safety, those which are not representing a risk for customer and also are not having a big impact in the brand image are kept under surveillance, but no actions are taken for their solving.

In order to have a visibility on the current status of the complaints for our generic example we will create a global situation considering the level of coverage (fig.11).

Figure 11: Level of coverage for customer complaints

According to figure 11 we can see that there are many complaints unitary cases (single cases), for which no specific actions for improvement can be made.

The complaints without decision which represent 28% at the time of the study will be documented in the specific satisfaction committees, in order to be decided if will be solved or not.

The customer feedback is very important in the improvement of the vehicle model, as well as in the proposal of derived versions in the following years.

In order to keep these inputs constant as customer dissatisfaction or complaints, the NVS and DVS surveys can be applied constantly, during the entire life of the product, for 3 months in service to the customer if a feedback for new vehicles is needed or for 36 months in service, for durability and reliability feedback, as was done in step 2 in identifying the main performance that are considered poor by clients.

Conclusion

The paper proposes a model for customer satisfaction evaluation, created from personal perspective, using the public database of the Romanian vehicle registration service in the period 2018-2019 and the potential output that can be obtain from market competitor benchmarking and from internal evaluation.

The client is the one who guides from the beginning according to his needs the development of the entire product lifecycle process. Considering all the information gathers through the entire process it is sketched the framework of the vehicle behavior in the customer perspective.

The results confirm the research paper written by Yadav, O. P., & Goel, P. S. (2008), showing that the client's needs, company's policies, and regulatory requirements are integrated together in order to identify the potential improvement opportunities which will be reflected in the vehicle attributes.

The purpose of the study was achieved bringing in the light, through the model, how the customers decide the development of a new product made on their requirements. For each selected category, Exploring, Development, Launching and Post-Launching, the most efficient type of surveys were chosen based on the author experience with evaluation of the client satisfaction in automotive industry, in order to have lower costs and a better time application. The variety of customer satisfaction surveys in automotive industry it is vast, but each company should choose wisely the specific ones in order to maintain the focus on increasing customer satisfaction using efficient the resources and increasing their profitability.

The model may be transferred and adapted for other industries, as customer satisfaction sustains the business core irrespective the field of activity.

Abstract

As we all know, health is the most precious gift in the life of every human being, but it must be permanently preserved and protected and which once lost is difficult to recover. But this can be easily avoided or remedied, as medicine jumps to our aid.
Medicine is the branch of biological sciences that aims to analyze the human body and find solutions to diseases that can affect people's lives.
In recent years, the spread and diversification of sensors and devices with the ability to connect to the Internet and beyond, have led to the transformation of the Internet of Things (IoT) into an essential component in most areas and also in the eHealth domain. This paper aims to address the subject of the Internet of Health Things (IoHT) and to provide an overview of its applicability as a substitute for permanent care by a knowledgeable patient.
In the future, a fairly significant evolution of technology in the medical field is expected, as much better applications will appear than those already on the market, applications that will be very helpful to both doctors and nurses, one of which is the one that allows remote patient monitoring.

Keywords: IOT, medical, healthcare, patients, solution, eHealth.

Introduction

Medicine occupies an important place in our lives (Ho, et al, 2020), having the role of analyzing, discovering the human body and finding remedies and solutions designed to restore human health. However, in order for medicine to fulfill its mission, modern technologies are needed that can allow the faster detection and treatment of diseases that occur, in many cases people's lives depending on these technologies. Systems must be developed that coagulate these technologies and contribute to the improvement of medical systems (Lebedev, et al, 2020), (Misra,and Bisui, 2018).

First, doctors will be able to manage their appointments more easily, have access to patient information much faster: tests, prescriptions, diagnoses, previous consultations, and use modern devices to monitor and obtain health data. their patients.

In addition, patients also benefit from several facilities: they can schedule their next visits to the doctor, they can receive their tests and prescriptions directly, without having to go to the clinic to pick them up, they have the option to be information about what medications to take and at what time, they have the opportunity to contact the doctor, directly from the application, in case of emergency(Sánchez-Zaballos and Mosteiro-Díaz, 2020).

It is expected that in a few years mobile applications will be introduced on the market, which, in particular, will be used for emergency medicine as is the current situation. These are intended for nurses, who can vocally complete patient and resident files, they have the opportunity to report their activity via a smartphone.

If we talk about sensors, this concept is not very common in hospitals, because modern devices with sensors are available at quite high prices. We hope that, in time, we will also benefit from modern technologies that allow us to measure our blood sugar, blood pressure and heart rate in real time, without having to go to the clinic or hospital, a sensor. and a smartphone dealing with this (Matarazzo, et al, 2017), (Li and Trocan, 2019,).

The next chapter "Related work" will presents the studies existing inn other papers and the way how they solved this problem of eHealth using the sensors and IoHT. The next chapter named "Proposed Solution Implementation" presents our solution architecture and the modules of this implementation. The paper ends with the conclusions and a list of references.

Related Work

The year 2017 brought an extraordinary innovation in the world of medicine, being marked by the appearance of the first digital pill (Belluck, 2017). It is used to treat schizophrenia and depression in adults. The pill works according to the following principle: when it comes in contact with stomach acid it sends an electrical signal, and the medical staff is thus alerted, via their smartphones, if the pill has been swallowed. Thus, they will be informed whether or not the patient follows the prescription prescribed by them.

Another breakthrough in the world of medical technology is the "GPhone", a small device built into the phone's case that can measure blood sugar (Bandodkar et al, 2018). It was created by researchers at the University of San Diego in the United States, the first information about this wonder device was published in January 2018. "GPhone" works according to the following principle: initially a blood sample is placed on a support disposable placed on a small sensor, and then the results are transmitted via Bluetooth technology to the Android application. The device does not require batteries or power, as it is charged directly to the phone battery. This innovative discovery has proven to be very helpful for people with diabetes, as they can measure their blood sugar easily and quickly at any time.

A mobile application that could become a real innovation in the medical field is "BiliScreen". This is done by scientists at the University of Washington in the United States (Mariakakis et al, 2017). The application is based on a brilliant idea: with just one selfie taken with their own phone, users can find out whether or not they are prone to pancreatic cancer.

When it comes to heart rate and blood pressure, people should be very careful about what devices or applications they use to measure it. Today, there are many mobile applications that do this, but we never know if they work properly or not, they only provide indicative results. "Instant Heart Rate" (Ishikawa et al., 2017), "Cardiograph" and many others are free, easy to download applications that measure the pulse through the phone's camera, in this case the results obtained depending a lot on the position and force with which finger press on the camera (Adhikari et al, 2014).

Analyzing the technological progress made in the field of medicine, more and more people are starting to test and use new devices and applications to determine their blood sugar level, temperature and many other information related to their health, it is clear that, our lives change day by day (Gjellebæk, et al, 2020). However, there are conflicting views on the safety of new technologies. Application developers claim that they offer a fairly small margin of error of about 5-10%, while more conservative people do not give them much confidence. Physicians should take full advantage of the new technologies that have emerged in the field of medicine, as they help them to make diagnoses and treatment for their treatment much easier. The importance of Internet of Things applications and sensors in our lives should be emphasized, stating that through them, people have the opportunity to detect health problems in advance and to learn more about the human body.

Proposed Solution Implementation

In this chapter we present the functionality of a platform whose architecture consists of three major layers: (a) data collection, (b) data storing (c) data processing and using.

Data collection level relies mainly on two types of sensors – medical and environmental; data read from them is sent to the processing device.

Data storing level relies on decoding, structuring and writing modules (in NoSQL databases).

Data processing level relies on outsourcing services. This layer provides means for taking medical decision such as: (a) prescribing drugs or providing suggestions to patients, (b) providing advice based on medical evolution, (c) informing physicians and caregivers on the level of urgency and (d) general remote monitoring.

The platform basically includes 5 functional components (1 hardware and 4 software):

- The equipment for patient medical data collection: RaspberryPi device (mini-computer that runs the Raspbian-Linux miniature system) to which the medical data acquisition card (through an appropriate physical interface) and the wireless transmission interface (sending data to a server) are connected.
- The C++ application that cyclically gathers, encrypts and sends collected data.
- a Cloud-resident Web service designed to decode medical data (that has just been transmitted online), to structure and store them into a NoSQL database.
- a Cloud resident Web service intended to send back to any remote user - that makes a http request - the medical data of a particular patient, harvested within a certain time frame. It can perform various analysis of data.
- a Cloud resident Web Application that, when requested by the remote client application (this latter can be a Web browser or dedicated mobile / desktop application) asks the Web service from above to process and gather data of interest.

Figure 1 bellow suggests the overview of the structure of the IoT System.

Fig. 1: Structure of the IoT system (Alexandru et al, 2018)

The data collecting and transmitting equipment comprises:

- the e-Health Sensor Platform V2.0 for Arduino and Raspberry Pi - able to perform biometric and medical applications where body monitoring is needed by using 10 different sensors such as: pulse, oxygen in blood (SPO2), body temperature, electrocardiogram (ECG), galvanic skin response (GSR - sweating), muscle/electromyography sensor (EMG) etc.
- the Raspberry Pi to Arduino Shields Connection Bridge - compatible with Raspberry Pi 2 Model B; allows for the connection of any compatible card (e.g., e-Health 2.0); it is delivered along with the arduPi API library (arduPi.h and arduPi.cpp) to be used as the interface (at design time) between various data acquisition boards and the C++ beneficiary application.
- Raspberry Pi 2 - minicomputer running Raspbian O.S. (miniature Linux for IoT app)
- WiFi Module On chip RN-171 - enables the remote wireless transmission of collected data.

The data collecting application (hosted by the Raspbian-Linux) runs an infinite loop that executes medical (physiological) data readings by calling the C++ APIs pertaining to the medical equipment. The example below illustrates how the function attached to the thread reads the medical data.

```
setupPulsOximeter(6);
eHealth.initPositionSensor();
. . .
while(true)
{
        . . .
        delay(100); // msec between cicles of data refreshing
        int strikes = eHealth.getBPM();
        int oxsat = eHealth.getOxygenSaturation();
        float temp = eHealth.getTemperature();
        float cond = eHealth.getSkinConductance();
        float res = eHealth.getSkinResistance();
        float condVol = eHealth.getSkinConductanceVoltage();
        float ECG = eHealth.getECG();
        int EMG = eHealth.getEMG();
        uint8_t bodyPos = eHealth.getBodyPosition();
        . . .
}
```

Figure 2 bellow suggests how medical data (that is reals, integers or long integers) are being read through function calls, then encrypted, then encapsulated in the POST Request and finally sent to the Web Service running under a virtual image inside the Cloud unit.

Fig. 2: Medical data collecting and transmitting (Alexandru et al, 2018)

The Service Oriented Architecture mechanism comprises:

- The Web Service-Receiver; it decodes incoming data, then it organizes the resulting data (containing patient ID and the list with all medical parameters, each one being associated with a certain time) and finally it writes resulting structure inside the MongoDB Database.
- The MongoDB Database (NoSQL family), delivers rapid responses both at writing and querying data and can be splitted. The figure bellow suggests how medical data, after having been arrived successfully in the Cloud and decrypted, are memorized in the database; the image will show the equivalent of a classic record: the strings on the left of the ":" character are the "fields" and the strings / numbers on the right are

the “values”. The possibility of memorizing structure-like values is suggested by the value mapped to the “Heart” or “Skin” fields.

```
{
    "_id" : ObjectId("5aa78e996dfa030b28673c57"),
    "PatientID" : "01A2-57QW-3E78-FFB2",
    "Time" : "2017-03-05@16:21:48",
    "EMG" : 290.0,
    "Heart" :
    {
        "Beat" : 64.0,
        "ElectroCardio" : 2.052786
    },
    "O2Level" : 95.0,
    "Skin" :
    {
        "Voltage" : 0.513,
        "Resistance" : 75320.0
    },
    "Temperature" : 35.9
}
```

Fig. 3: Decrypted data

- the Web-Service (Inference Engine). It processes data, yielding graphs of evolution, statistic charts, analysis of critical values etc. It sends processed data to the requesting application. It is written in C#. The next code sample will exemplify creating, filling and sending a bitmap as a HTTP response.

```
// allocate Bitmap and Graphic tools in memory, ON THE SERVER !
int width = 400; int height = 300;
Bitmap bmp = new Bitmap(width, height, PixelFormat.Format24bppRgb);
Graphics g = Graphics.FromImage(bmp);

// . . .  calls to g.DrawRectangle(),g.FillRectangle() and g.DrawLine() etc
// . . .

// Send resultant Picture to client
Response.ContentType = "image/bmp";
Response.Clear();Response.BufferOutput = true;
bmp.Save(Response.OutputStream, ImageFormat.Jpeg);
Response.Flush();
```

In Figure 4 we have the conceptual representation of such response:

Fig. 4: Conceptual representation of HTTP response

- The Web-Application. It serves requests from remote clients by dialoging with de Web Service acting as a receiver (the one mentioned above).

The Web Services and the Web Application run under a virtual image of Windows 7 inside the Cloud unit, itself governed by a “supreme” Windows Server 2012.

Conclusions

We believe that the entire proposed system can be used in a medical clinic, being very helpful to both management and medical staff, providing facilities that could significantly facilitate their work. The aim of the paper is to integrate technology in all activities in the medical field, eliminating the traditional way in which analyzes are performed today.

The proposed solutions have important advantages over traditional solutions for patient monitoring and assistance activities, namely:

- implements, integrates and improves existing IoT technologies;
- create a minimally invasive environment on the patient, reduce costs;
- helps to increase life expectancy and chances of survival.

The integrated approach of IoT and Cloud technologies in the monitoring of physiological and environmental parameters and the development of predictive models of population health on the basis of the collected data allows the development of innovative personalized assistance services For the future, we aim to continue the development of new systems, introducing new features and trying to make more medical devices based on sensors that can be used instead of traditional ones, thus spreading the idea of technology evolution in the medical field.

Abstract

The article concentrates on Industry 4.0 knowledge transfer to employees who will work with Industry 4.0 technologies. The knowledge transfer starts with an introduction to Industry 4.0 technologies with the aim of motivating the employees to work within the concept. The article focuses on collaborative robots (cobots) and automated guided vehicles (AGVs). After the introduction, the employees learn to build and operate Fischertechnik STEM Kit models. The employees use the models first to understand the principles of individual components relevant to Industry 4.0 and then how to program the models. In the last part there is an explanation and practical examples of programming Industry 4.0 technologies (Collaborative robot and AGV). The article also describes the equipment in specialized laboratories where Industry 4.0 knowledge transfer can take place.

Keywords: Industry 4.0, Collaborative robots, Fischertechnik, AGV, Programming.

Introduction

One of the most popular topics in recent times is the concept of Industry 4.0, its principles, the implementation of different levels and the management of transitions between the levels in manufacturing companies. The goal is most often to achieve complete fulfilment of this concept according to current technical and technological possibilities. From the point of view of employees, sociologists and governments, there is often talk of the need for job security and the fear of rising unemployment, this is mentioned by Basl (2017). A frequently mentioned measure is unconditional income, reorientation of these employees to services, etc. Here, however, it must be said that even in companies operating on the principles of Industry 4.0, employees are and will continue to be needed in the future. This means employees who know the company, the production of goods and related services, technologies used and technical equipment, production processes, etc. These employees are in companies now and their knowledge is adequate for the current state of the manufacturing company. With the advent of Industry 4.0 there is a need not to eliminate these people, but to start training them in accordance with the needs of developing and implementing the principles of Industry 4.0. If the company is just beginning a gradual transition to the principles of Industry 4.0, it is necessary to first train employees and only then begin to make gradual structural, procedural, technical and technological changes. Here it can simply be stated that this procedure cannot be otherwise, because if so, it would achieve a state where the company is at least technically and technologically able to operate on the principles of Industry 4.0, but there would be no one who would be able to maintain it and keep it alive (in the sense of production). With regard to the content of Industry 4.0, it will be necessary for almost all employees of such manufacturing companies, in addition to their specializations, to have a cross-sectional orientation in such fields as reading, processing, storage and exchange of data, IT security, programming and scripting, basics of robotics, advanced data processing, simulation and visualization, etc. It was mentioned by Horejsi et al (2020). This knowledge needs to be passed on to key employees, maintained and especially further developed adequately to the needs of the company and its development of Industry 4.0 (in this case key personnel in terms of employees needed for the smooth running of the manufacturing company after its transition to Industry 4.0).

Fischertechnik STEM Kit

The version used at our department (Fishertechnik education - STEM Engineering) is a polytechnic kit enabling the construction of the skeleton of models from building blocks and mechanical components (including gearboxes, gears, etc.), power components (electric motors, valves, compressors, USB camera, optical colour sensor, light modules, etc.) and components for data collection/evaluation (e.g. NTC resistor for temperature measurement). If necessary, the kit can be expanded with additional mechanical and power components and sensors. The programmable control unit is used to activate and control the models, and the creation of control programs primarily takes place in the ROBO Pro development environment, where it is programmed by creating flowcharts in the form of assembling programming blocks. If necessary, the control code can also be programmed in C/C++ mentioned on Fischertechnik GitHub (2020) or Python mentioned online on https://cfw/ftcommunity.de (2020). The BBC micro: bit can also be used as a control unit mentioned by ReiVilo's Fischertechnik Corner (2020). Models of an automated warehouse, automated product sorting, robotic arms, and an AGV (automated guided vehicle) can be assembled from the kit only according to the supplied instructions, mentioned by Fischertechnik STEM Engineering (2020).

The control unit is a small computer with performance comparable with mobile phones from 2008. It has parameters mentioned by Fischertechnik TXT Controller specification (2020) as a dual processor ARM Cortex A8 (32bit, 500mHZ), 128 MB RAM and 64 MB flash memory. The flash memory can be extended by a Micro SD card up to 32GB. The control unit has its own coloured 2.4"touch screen with resolution 320x240 and a speaker. Communication with the control unit, or between control units, can be via USB cable, infra-port, Bluetooth or Wi-Fi. This means the models can communicate together, or can be controlled by mobile phone, notebook/tablet/PC, TV remote, etc. A Linux based operating system runs in this unit and it offers 8 universal inputs, 4 digital counting inputs and 4 motor outputs which can be used as 8 outputs for LEDs, bulbs, etc. The kit includes a battery set which provides the power supply. It contains a NiMH 8.4V/1800mAh battery and a charger. This battery supplies energy to all parts of the model and to the control unit. A mains adapter can be purchased separately.

Industry 4.0 Technologies (Cobot, AGV)

The Department of Industrial Engineering and Management not only has models from Fishertechnik, but also real industrial solutions - a collaborative robot (cobot) and an automated guided vehicle (AGV) located in the special Industry 4.0 laboratory.

The cobot is a CR-7iA/L type with R-30iB Mate controller and is produced by FANUC. It is a collaborative robot, so it can cooperate with human operators without the special protective equipment required by classical industrial robots (cages, etc.) It was mentioned by Broum and Simon (2019). It is equipped with force sensors that detect potential collisions with objects and stops the cobot when the risk of a collision occurs. It is also equipped with passive safety elements (rounded edges, etc.), mentioned by Broum and Simon (2020). The CR-7iA/L is a relatively small cobot, able to move weights up to 7 kg, with a maximum theoretical speed of 1000 mm/s. The maximum reach is 911 mm. The cobot basic joint working range is 370° with repeatability: ± 0.018 mm. It is driven by an AC servo. It was specified in Small Collaborative Robot (2020). It is also equipped with an iRVision camera system that enables it to identify objects – their position and also colour. The cobot complies with ISO standards and the EC Machinery Directive, mentioned by Poor and Basl (2019), and is shown on the following figure.

Fig. 1: Cobot ang AGV in the laboratory

The cobot is also provided with software as an off-line tool to set up the cobot directly from a personal computer. The workplace and the cobot can be simulated in 3D and a program can be created that can be transferred to the cobot. It was mentioned by Trojan et al (2019). It is also possible to program the cobot directly using the R-30iB Mate controller which has the advantage of allowing the positioning of the cobot's arm manually and saving having to position it in the program.

The AGV located in the laboratory is a 'Weasel' from Schaefer. It can transport up to 35 kg and its maximum speed is 1 m/s. The minimum turning radius is 600 mm. It is battery driven with the possibility to run up to 12 hours on one battery charge. It is a one direction AGV that follows its trajectory using optical sensors. It needs a black line on a white background which it follows. Commands are given to the AGV in two ways, either by RFID tags next to the path of the AGV that it reads and executes, or by radio signals with the potential of tracking the current AGV location. It was mentioned by WEASEL (2020).

The basic idea demonstrated in the Industry 4.0 laboratory is that the cobot fills a rectangular plastic pallet with 20 positions for metal cylinders – each position has one of four possible colours (yellow, green, red, blue). Metal cylinders (with the same colours) are in a magazine next to the cobot. The AGV brings the empty pallet to the cobot, then the cobot puts the pallet onto a conveyor belt that delivers the pallet to a suitable location for the cobot. The pallet is photographed by the cobot's iRVision camera system to identify the colours of the metal cylinders and their locations on the pallet. The cobot then fills the pallet with metal cylinders of the right colours in the right places. Then the cobot can empty the pallet or the pallet is sent to the manual workplace where a human operator empties the pallet, depending on which program is running. The last part is sending the empty pallet by conveyor belt to the AGV. The AGV can then deliver the empty pallet again to the cobot and the cycle starts from the beginning. It was mentioned by Poor et al (2019).

Employee training related to Industry 4.0

This chapter concentrates on employee training at the Department of Industrial Engineering and Management using the technologies described above. Employee training will be carried out in the following steps:

- Introduction to Industry 4.0 Technologies (Cobot, AGV)
- Fischertechnik STEM Kit – assembly, programming
- Industry 4.0 Technologies (Cobot, AGV) – programming

Introduction to Industry 4.0 Technologies (Cobot, AGV)

The first part, Introduction to Industry 4.0 Technologies (Cobot, AGV), concentrates on basic information about the technologies of Industry 4.0 in general on the one hand, and on the other hand specifically on the technologies used in the laboratory. The target is to clarify the information about Industry 4.0, showing employees the potential of

Industry 4.0 and its technologies, eliminating any fears and doubts about Industry 4.0 technologies and in total motivate the employees to use Industry 4.0 technologies.

Fischertechnik STEM Kit –assembly, programming

Fischertechnik STEM Engineering kits are used in the second part. This part focuses on understanding the principles of operating individual power components such as electric motors, compressors, solenoid valves, phototransistors, light emitting elements, thermal sensors, analogue colour sensors, cameras, etc. After learning the principles of operating these items and introducing their possible uses, we move on to programming simple models. Due to the employees' differing knowledge of programming, the ROBO Pro development tool is used. This IDE enables programs to be developed by composing graphic elements (similar to today's very popular 'Scratch' for children). The advantage is the speed and especially the clarity of the creation of control programs even for employees who are not familiar with programming. We give as an example one of the first, absolutely basic models demonstrating the use of an optical colour sensor and LED, where the goal is the recognition of the colour of a sheet of paper colour. Other practical examples are e.g. item detection with a camera, hand dryer, synchronized indicators using step motors, wind power plant, etc. mentioned by Malaga, M. and Ulrych Z., 2020. More complex examples used are Fischertechnik models such as AGV, Automated warehouse, Robotic arm, and the Item colour sorting robot. Work with the models is done in a maximum of 6 teams with a maximum of 6 employees in each team in the laboratory in the Department of Industrial Engineering and Management. The laboratory is equipped with components relevant to the models used. Every team has a laptop, a big screen and their own Fischertechnik STEM kit.

The connection of the components for the colour detecting model is shown in the following figure. An optical colour sensor is connected to the I1 and + 9V input, a light bulb with a red cover is connected to the O1/O2 output (M1), and a light bulb with a green cover is connected to the O3/O4 (M2) output.

Fig. 2: Basic Fischertechnik colour sensor model

How we want the colour controller to behave:

1. When green paper is loaded, the green light turns on.
2. When red paper is loaded, the red light turns on.
3. When paper is not loaded, or paper other than red or green is loaded, nothing happens and the model waits for another piece of paper to be loaded.
4. The program will be in a cycle so that the colour evaluation takes place continuously.

The optical colour sensor returns a number that matches the colour of the object presented to it. The first task is to find out what numbers the sensor reads for red and green sheets of paper. A good way is to create a very simple program that will only print the number read from the sensor and we use it for calibration in the final control program. The program for displaying the read data by an optical colour sensor is shown in the following figure.

Fig. 3: Colour variable display in RoboPro IDE by Fischertechnik

In this particular case, under given lighting conditions, the optical sensor returns a value of about 237 for red colour and a value of about 325 for green colour. With values fluctuating approximately ± 50.

If we know the approximate values for both colours, we can use the following sorting algorithm:

1. When reading the values using the optical sensor in the interval (0, 200), we do nothing and we further evaluate the read colour. These values do not correspond to the colours we are evaluating.
2. When reading the values with the optical sensor in the interval (200, 270), we evaluate it as red and turn on the red-light bulb for 1 second. Lighting for 1s is sufficient. When the coloured sheet is removed, the light bulb will go out within 1 second at the latest, which is a sufficiently fast reaction of the system for us.
3. When reading the values with the optical sensor in the interval (270, 350), it is evaluated as green and the green light bulb is turned on for 1 second.
4. When reading the values with the optical sensor 350+, we do nothing and we further evaluate the read colour. These values do not correspond to the colours we are evaluating.

The whole program is shown in the following illustration. We left the display of the read colour by the optical sensor as a part of it. While the program is running, we can check on the computer monitor what values the optical sensor is reading.

Fig. 4: Final colour reader program in RoboPro IDE by Fischertechnik

Industry 4.0 Technologies (Cobot, AGV) – programming

In the part of training related to the Fischertechnik STEM Kit (assembly, programming) the employees acquire practical knowledge and experience of programming and assembly. This knowledge makes the programming of industrially used Industry 4.0 technologies significantly easier. The programming concentrates first on a cobot and later on an AGV, both in the laboratory.

The programming of the cobot can be performed in two ways – graphically, or writing the code of the program directly. The graphical part is easier to understand, and this part is the one that the employees start with. In the beginning the cobot, its specification and environment is explained. Then there is an explanation of the user interface. The cobot from FANUC can be programmed by iPendant (a device with a touchscreen and keyboard - directly connected to the cobot) and by specialized SW (in this case ROBOGUIDE) running on a personal computer (the data needs to be exported afterwards). Using iPendant is the first part of the graphical programming training, and the employee is guided by a graphical interface and creates a program step by step. They directly see the impact of each program step on the cobot and can perform this step on the real robot. The advantage is that the cobot arm can be moved manually to the positions needed and these positions can be saved in the program. The graphical programming in the PC using ROBOGUIDE SW is very similar. The SW uses a 3D model of the cobot and a model of the iPendant, and you can perform basically very similar activities virtually, and finally export the data to the real cobot. It is intended that the employees will try both modes with the programming of the application concentrated on moving the laboratory's metal cylinders.

The second part of cobot programming concentrates on coding the program itself firstly by iPendant, secondly by PC, which is shown in the following figure. The main advantage of coding is that complex programs can be created more clearly, faster and in a more organized way, however, the graphical (visual) part is missing. The employee also needs to know this part if they are programming because, for example they may be asked to merely modify an existing program and it would be counterproductive to program it again from the beginning. The programming training in this case starts with basic commands and easy programs to show their functions and ends with the application of moving the metal cylinders to the pallets in the laboratory as described in the previous chapter. The collaborative setting of the positions can also be used (setting the positions by hand and saving the position by pressing the button to save the position).

Fig. 5: Cobot programming by PC

The last part of programming Industry 4.0 technologies concentrates on AGV programming, which is easier than cobot programming. The AGV can be programmed manually by using the black line to guide its path and by positioning RFID tags where special commands for the AGV need to be performed (for example: waiting for a button to be pressed, decreasing the speed of the AGV). The second part of AGV programming concentrates on specialized SW programming using Wi-Fi to communicate with the AGV. The AGV is tracked by Wi-Fi and simple commands can be send to it by Wi-Fi directly or automatically. The training is planned so that the employees first create a track using a black line in the laboratory with the RFID tags and then they connect the AGV to the Wi-Fi to program it.

Conclusion

The paper describes a possible approach to employee training about the Industry 4.0 concept. This training consists of 3 main parts, namely motivation, understanding the basic principles and basics of programming and finally working on a large collaborative robot. Motivation of the employees is supported by demonstrating a collaborative robot at work and a demonstration of the interesting tasks which a collaborative robot can perform. The basics of theoretical knowledge, i.e. the possibility of using sensors and power elements, including the basics of programming them, is supported by working with the robotic STEM kit Fishertechnik education - STEM Engineering kit. Finally, the employees go back to the collaborative robot where they learn how to work with it using the basics they acquired in the previous step. This will greatly simplify the beginnings of working with a real collaborative robot.

Arrhythmia Classification: A Review of Machine Learning-based Techniques for Electrocardiogram Signals using Wearable Technologies for the Elderly

Elena A. PARASCHIV
National Institute for Research and Development in Informatics, Bucharest, Romania

elena.paraschiv@ici.ro

Abstract

The electrocardiogram (ECG) is one of the most important medical exams that could display, in form of a trace on a paper, the electrical activity of the heart. Different wearable technologies have been lately developed to monitor and transmit the ECG or other medical parameters of a patient to the medical professionals and are integrated into smartwatches or bracelets in order to be easily used by all types of patients, including the elderly. As they are more exposed to cardiovascular diseases, machine learning-based methods have been implemented, throughout the time, to better and faster classify ECG signals into normal or arrhythmia-related for a quick and correct response. Considering the fact that atrial fibrillation is the most known arrhythmia that could increase the risk of strokes and heart failures, an early detection and prevention can be vital, especially for an elder patient. Therefore, the aim of this article is to present some of the most recent methods of collecting the ECG signals using wearable devices and different machine learning-based techniques used for arrhythmia classification. Moreover, there are highlighted some methods meant to be used for the ECG data acquisition in the ongoing project, entitled "RO-SmartAgeing", which aims to monitor and evaluate the daily activities and medical parameters of an elder patient.

Keywords: Cardiac Arrhythmia, Electrocardiogram, Machine Learning, Wearable Devices.

Introduction

The electrical activity generated by the heart can be easily measured with the electrocardiogram (ECG), a non-invasive and painless medical investigation. Electrical impulses generated by the specialized cells are spread through the heart muscle and can be detected using a machine which shows the ECG signals as a trace on a paper (Jambukia et al., 2015). Thus, any heart abnormalities or irregularities can be detected based on the ECG, including cardiac arrhythmias (ventricular tachycardia, atrial fibrillation, ventricular fibrillation etc.).

Cardiac arrhythmias appear when electrical impulses do not work properly and can cause irregular beats, leading the heart to beat too fast or too slow. As not all of these cardiovascular diseases present certain risks, there are some types of arrhythmias such as atrial fibrillation that is known as the main cause of acute stroke or ventricular tachycardia which can lead to shock or sudden cardiac death.

A normal ECG has a specific shape whereas irregularities on the ECG are being interpreted by doctors as one of the different types of arrhythmias. An early detection of these cardiovascular diseases is very important as it can provide a suitable treatment and can save people's lives. Moreover, considering the fact that most of the elder people are very vulnerable to certain cardiovascular diseases, it is vital to daily monitor their heart activity in order to prevent heart strokes or even death.

That is why, a lot of wearable monitoring devices have been recently developed and can detect changes in one patient's ECG, sending a trigger if the patient is experiencing some problems. The data collected from these wearable devices can further help in building machine learning algorithms for cardiovascular diseases classification in order to faster detect and prevent most of the heart failures.

This is planned to be implemented in the context of RO-SmartAgeing (Ianculescu et al., 2019), a project which aims to monitor and evaluate an elder patient's health. It is being developed a cardiac kit that uses sensors to collect cardiac data (for ECG and pulse). Thus, many heart abnormalities can be early detected in order to prevent any strokes or even cardiac death. Furthermore, the collected data is then being processed and automatically classified as normal or related to a cardiovascular disease based on machine learning and deep learning algorithms.

PARASCHIV "Arrhythmia Classification: A Review of Machine Learning-based Techniques for Electrocardiogram Signals using Wearable Technologies for the Elderly" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Therefore, the aim of this paper is structured as to present a review of recent wearable technologies, machine learning and deep learning methods for ECG signals data acquisition and classification in order to early detect cardiac arrhythmias. Furthermore, this paper also presents the methods meant to be used in RO-SmartAgeing project for the collection of an elder patient's ECG.

Electrocardiograms & Arrhythmias

As it is generally known, every beat causes an electrical impulse to be transmitted and to travel through the heart, forming a wave which makes the muscle to shrink and to pump blood. Thus, an ECG is a graphic representation of the electrical events in a cardiac cycle and it represents an essential diagnostic tool for cardiac arrhythmia detection.

A normal heartbeat on an ECG, presented in Figure 1, shows the timing of the atria and ventricles. The upper chambers (right and left atria) forms the first wave, called the "P wave" on the ECG, when the impulse goes from the top to the bottom chambers. The "PR interval" is represented by the time in which an electrical impulse moves from the atria to the ventricle, whereas the "QRS complex" is formed based on the bottom chambers (right and left ventricles) and it corresponds to the depolarization of the right and left ventricles. The "T wave" corresponds to the ventricular repolarization and the "ST segment" represents the time between ventricles' depolarization and repolarization, as in the ventricular contraction.

Fig. 1: A normal ECG

Source: adapted from (Rajkumar et al., 2019)

An ECG is usually done in order to measure if the electrical activity is normal, fast, slow or if it has irregularities and, based on measuring the amount of electrical activity that goes through the heart muscle, the cardiologist can find if some parts of the heart are too large or too overweighed. So, it is an important tool for cardiovascular diseases detection.

According to the World Health Organization, cardiovascular diseases represent the first cause of death all over the world (approximately 17.9 million of people died in 2016, which represent approximately 31% of all global deaths) (World Health Organization, 2016). Most of them are caused by different risk factors, such as the use of tobacco or alcohol, obesity, the lack of physical activity or unhealthy diets and an early detection and prevention of such diseases are mandatory for a patient's life.

When it comes to irregularities in the heartbeats rate or rhythm, arrhythmias are the most representative family of cardiac distortions (Zheng et al., 2020). Different manifestations, such as slow or fast heartbeats, may appear and are represented by sinus bradycardia (low heart rate) and atrial tachycardia (fast heart rate). Moreover, an abnormal rhythm with absent or deformed wave segments and intervals can be diagnosed as premature ventricular contraction, but the most common and risky type of arrhythmia is represented by atrial fibrillation, cardiac disorder frequently met in elder patients (75-85 years old). This can lead to a 5-fold increase in the risk of stroke and a 3-fold increase in the incidence of heart failure. Atrial fibrillation, presented in Figure 2. (the absence of the "P" wave) influences the increase of blood in the atria and forms blood clots which can lead to heart strokes or to heart failures due to the overworking the heart muscle.

Fig. 2: The example of an ECG with atrial fibrillation

An arrhythmia represents a challenging situation, especially for the elderly, but an early detection and prevention can be life saving for most of the people. That is why, throughout the time, researchers have developed different wearable devices and computer aided diagnosis-based methods and techniques.

Wearable devices for arrhythmia detection

With the continuous development of different wearable technologies, ECG monitoring have started to become very important as it can provide an early detection of certain cardiovascular diseases, thus helping and preventing serious cardiac damages. Such sensors help both medical professionals and patients as it reduces the healthcare services costs and improves the quality of life.

The automatization of ECG analysis has recently become an essential part of any Internet of Things (IoT)-based healthcare monitoring device as it assumes the implementation of different algorithms that are embedded in wearable devices.

An interesting device is presented in (Chun et al., 2016) and it includes two electrodes. One of them is in contact with a finger on one hand and the other is placed on the wrist of the second hand. The pre-processing of the ECG signals contains a bandpass Butterworth filter with order 14. The features were investigated using Short Time Fourier Transform and a user authentication system was developed. A Euclidean distance for wearable devices has been proposed that has the property of not being able to give the access to others' ECG information.

Another solution is developed in (Azariadi et al., 2016) and it provides the implementation of an IoT-based embedded platform. The proposed algorithm is formed based on a wearable ECG diagnosis device that can monitor the electrical activity of a patient for 24 hours. The ECG analysis is performed using Discrete Wavelet Transform and Support Vector Machine for classification, which achieved an accuracy of 98.9%. This device and the embedded platform could be further used in heart activity monitoring.

Lately, more and more wearable technologies for the heart health monitoring have been developed on a lot of smartwatches. One of these, used in the RO-SmartAgeing project, for the early detection of arrhythmia in the elder patients, is the Withings Move ECG. It corresponds to a non-invasive way of acquiring ECG signals and it is able to diagnose different heart issues, such as arrhythmias (especially atrial fibrillation). The ECG measurement on the Withings smartwatch is made possible due to two electrodes placed on the back of the watch case and an electrode on the metallic ring bezel. When the button is pressed and the hand is placed on the ring electrode, the Withings Move ECG smartwatch begins to record the heart's electrical activity of the patient.

Thus, rather than placing electrodes on skin, more and more people incline to use such devices for a daily monitoring of the heart as it can early predict certain disorders and are more user-friendly through the easy to use mobile applications.

Machine Learning & Deep Learning for Arrhythmia Classification

The ECG databases that have been proposed during the past decade have been used for the development of different approaches and techniques based on machine learning and deep learning for ECG arrhythmia classification. The importance of this classification is more and more highlighted as a lot of medical applications have been developed consider that the analysis and classification of ECG data collected from different wearable devices are essential tasks.

Machine Learning and Deep Learning have recently become very successful in image classification, signal processing and speech recognition tasks and they are continuously rising as the technology has started to improve in terms of healthcare and clinical practices.

A method was proposed in (Alfaras et al., 2019) and it presents a machine learning technique related to a supervised learning principle for Recurrent Neural Networks (RNNs), known as Echo State Networks (ESN). A recurrent neural network is a type of artificial neural network, frequently used in speech recognition and natural language processing. It is suited to process time-series data and to recognize sequential characteristics and, based on the resulted patterns, it predicts the next scenarios. The developed idea is based on driving a random and large RNN with the input signal

and combining the requested output signal by a trainable linear combination of all the response signals. The classifier assumes a feature processing that needs a single ECG lead and the final results can be aligned with the data collected from heart-monitoring wearable devices and sensors. The MIT-BIH Arrhythmia Database (MIT-BIH AR) (Moody et al., 2001) and the AHA Database (Goldberger et al., 2000) were used for the evaluation of the proposed classifier. The MIT-BIH Arrhythmia database, publicly available at *PhysioNet*, is known to be used in different machine learning and deep learning algorithms. As it consists of 2 channels of ECG data, the method only uses the first one. It was obtained a sensitivity of 92.7% for the MIT-BIH AR database, using the single lead II and a sensitivity of 95.7% using the lead V1'. They concluded that the ESN method is suited for long-term recordings and large databases and they also checked the timing of the classification algorithm on CPU and GPU, the last one offering a faster computing than 11 hours for the CPU.

Another classification approach was implemented in (Singh et al. 2019) for four different types of arrhythmias based on the MIT-BIH Database and machine learning techniques. The data was first pre-processed as it might have contained noises (wandering noises, respiratory muscle noises etc.) using mean-shift and an average filter (with kernel size = 10). The detection of heartbeats is developed using three features: amplitude, area with non-overlapped sliding window and area with overlapped sliding window and the classification part is implemented using five classifiers (Support Vector Machine, Decision Tree, Random Forest, Naïve Bayes and Artificial Neural Network). The results suggested that the Artificial Neural Networks with pre-amplitude features provide the best results with an accuracy of 99.59% and Support Vector Machine with non-overlapping sliding window features performed an accuracy of 98.97%. They also suggest the development of a comprehensive module that could be used for mobile.

The automatic diagnosis of heart disease is also emphasized in (Huang et al., 2019) using the MIT-BIH Arrhythmia Database and the implementation is represented in Figure 3. The method proposed an ECG arrhythmia classification using two-dimensional (2D) deep convolutional neural network (CNN) receiving as input the spectrograms of the five arrhythmia types being transformed from the time domain signals of ECG with the help of Short-Time Fourier Transform (STFT). The STFT is derived from the discrete Fourier transform and is designed to explore instantaneous frequencies and amplitudes of localized waves with characteristics that vary over time. The ECG signals are converted into time domain and are represented as spectrograms in time-frequency. The proposed neural network includes three Convolutional layers, followed by three MaxPooling layers. The averaged accuracy was 99.00% and they also compared the model to a 1D-CNN model and with other existing techniques concluding that the method of classifying the ECG spectrograms without any pre-processing can achieve good performances.

Fig. 3: The proposed 2D-CNN for arrhythmia classification

Source: adapted from (Huang et al., 2019)

Arrhythmias are also detected using deep learning in (Işın et al. 2017). A general image dataset is used for training in order to automatically classify the patient's ECG into the corresponding cardiac condition. After pre-processing the data, the method assumed the detection of QRS complexes as they are the most representative for the ventricular activity. Consequently, for feature extraction, a transferred deep convolutional neural network, called AlexNet, is being used and the features represent the input for a simple back propagation neural network. The main idea of the method is to develop a deep learning technique which can accurately classify three conditions of ECG waveform selected from the MIT-BIH arrhythmia database. Therefore, this deep learning implementation for feature extractions

combined with a simple back propagation neural network obtained a recognition rate of 98.51% and a testing accuracy of 92% making it possible for this technique to be further used as an accurate application.

RO-SmartAgeing: Electrocardiogram Data Acquisition

In the context of the "Non-invasive monitoring and health assessment of the elderly in a smart environment (RO-SmartAgeing)" ongoing project designed to monitor and support the active life of elder patients at home, early detection and prevention of age-related conditions and dysfunctionalities can improve their health, helping them to have a normal and active life.

Being an IoT-based project, RO-SmartAgeing aims to collect all the medical and ambient data through wearable devices or sensors and send them to a Cloud where they can be visualized by the doctor or alert the medical professionals if there are any abnormalities. At the same time, all the data collected is meant to be processed and used in different predictive models for a faster classification and prediction of medical conditions. Thus, considering the fact that the elderly is more exposed to heart failures or strokes, it is necessary to daily monitor the cardiac activity in order to prevent certain heart abnormalities.

The electrical activity of the heart will be monitored with the AD8232 sensor, compatible with Arduino, a single-board microcontroller or Raspberry Pi module. The single-lead, heart monitor device, AD8232, is able to extract, amplify and filter small and noisy biopotentials signals.

Fig. 4: ECG data acquisition

Three electrodes are placed on the patient's body to gather the electrical signals, as it is represented in Figure 4, and send them to the cardiac monitor. The data is then transmitted to the Arduino board which is connected to a single-board computer, named Raspberry Pi which has built in WiFi for a better and faster transmission of the data to be visualized by medical professionals. In case of an emergency, the system is also developed to send alarms to the doctor, as shown in Figure 4.

It is important to place the electrodes closer to the heart in order to achieve better measurements, two of them being placed on the forearms and the last one on the leg, as it can be seen in following figure.

Electrode Color	Signal
Black	**RA (Right Arm)**
Blue	**LA (Left Arm)**
Red	**RL (Right Leg**

Fig. 5: The Electrodes placement

Conclusion and Future Work

As the continuous increasing of technology has started to gain territory in most of the fields, the healthcare system has also become more and more technologized through the development of different wearable devices or machine learning and deep learning algorithms. Considering the fact that the elderly is the most vulnerable, especially to cardiovascular diseases, nowadays, an early detection and prevention of them is mandatory. Arrhythmias are considered to be the most severe cardiovascular diseases as they can influence the appearance of strokes and heart failures, leading to different heart problems or even cardiac death. That is why, wearable technologies for ECG and heart pulse, as well as machine learning-based techniques for arrhythmia classification, have lately gained a lot of attention as they can help to early detect the occurrence of any irregularities on the ECG and, eventually, transmit a trigger to the medical professionals in case of an emergency.

This paper has presented a review of the wearable devices recently developed for ECG data acquisition, some machine learning and deep learning methods used for arrhythmia classification and the technique meant to be implemented in the ongoing project, RO-SmartAgeing, for collecting ECG signals from elder patients. Therefore, the collected data can be further used in the development of different machine learning algorithms for an automatic classification of arrhythmias, thus helping patients to early detect and prevent this disease.

Abstract

Marathon is one of the fastest growing sports disciplines and it generally boasts a large number of participants from around the world. As the organization and management of large-scale running events poses a real challenge, risk evaluation should always precede the decision-making regarding the safety and precautionary measures. The purpose of the research was to identify and assess the risk factors of large-scale running events on the example of marathons organized in Poland. Fourteen of the largest marathons held in 2017 in Poland were considered in the study. Fifteen experts were questioned using the Delphi method to carry out the multistage identification of risk factors for organization of a large-scale run, while 31 practitioners - the representatives of marathon organizing teams - conducted the risk assessment. Considering the effect and likelihood of the appearance of an adverse event, the most important turned out to be risks related to the financing of marathons, organization issues, including the event start date, the acceptance of the local community, the organization of the finish line, delayed start, cyber security, disclosure of personal data and problems with the measurement of time. The obtained results may serve as reliable input data for the efficient risk management of sporting events (runs in particular). Professional risk management, based on the risk factors database worked out as a result of the research, may become a starting point to provide the highest possible level of safety and satisfaction for all the stakeholders involved in the event.

Keywords: Risk Management, Risk Factors for Marathons, ISO 31000, Safety, Satisfaction.

Introduction

Recreational running as one of the most accessible forms of exercise is not only a physical activity that contributes to a preventive health action, but a widely practiced sport (Petridis, 2015).

The popularity of running arrived in Poland with a certain delay - in the West it was already popular in the 1970s, whereas it appeared in Poland at the beginning of the 21st century. Approximately 20% of the adult population of Poles is now practicing recreational running, which is the highest percentage in Central and Eastern Europe (Poland Runs, National Runners Survey, 2014). Most runners, within less than a year after the start of regular training, begin to passively and eventually actively participate in mass running events (Dzięgiel & Lubowiecki-Vikuk, 2013; Petridis, 2015). Interestingly, the runners rarely choose to take part in one or two marathons a year. They often participate in a few or even several large-scale running events in the course of a year (Hitchings & Latham, 2017).

Large-scale running events arouse a lot of emotions and are associated with great expectations of the organizers, participants, spectators and sponsors. Engaging large funds also carries a lot of uncertainty in many organizational aspects (Fuller & Drawer, 2004; Leopkey & Parent, 2009). Their complexity results from legal and formal

Cite this Article as: Jacek ŁUCZAK, Małgorzata MIŚNIAKIEWICZ and Jose M. SAAVEDRA " Identification and Assesment of Risk Factor for Large-scale Running Events from the Organizers' Perspective. Marathon Case Study" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

requirements as well as the fact that each event and even each subsequent edition is different, which limits the possibility of using standard solutions. The specificity of a running event also results from the limited possibility to introduce changes during its duration, which excludes the improvement of the plan during its implementation. The diversity of the number of participants and their sporting level, as well as limited time and date of the event should also be taken into account (Scheerder, Breedveld & Borgers, 2015). All of that explains why professional management of sporting events is a necessary element to carry out the project, such as organizing a running, effectively.

Participants of marathons, in addition to professional runners, are more often amateurs. An ever-increasing amateur participation in marathons driven by the will to compete, test themselves, experience something new and extreme also creates a certain risk, which is now becoming ever important and hard to control. 'When the person is inexperienced, it is likely they do not understand the potential risk that may be presented during the competition' (Miller, Pauline & Wendt, 2013, p. 18). The acceptance of the risk of the event may be the result of ignorance of the actual levels of risk involved (Fuller & Drawer, 2004). Therefore, the sporting event managers have a major responsibility for identifying and managing the risk associated with the running event. Risk management becomes crucial when the participation in a sporting event, such as a long-distance run, requires neither a certain level of experience, nor a medical certificate of good health to enter it.

Although large-scale sporting event risk management policies have been analysed and discussed in general, little research has been conducted regarding risk management in running events (Miller, Pauline & Wendt, 2013; Moyle, Kennelly & Lamont, 2014). That is why, an answer to the following research question has been sought: How can the organizers of running events ensure a safe and satisfying environment for the participants (mostly amateurs) and manage the risk for a long-distance run professionally The long-term goal of the research was to add to the evolving industry of large–scale running events in Central and Eastern Europe the knowledge about practical aspects of risk management, so the records of risk as identified by the experts and verified by the practitioners could be mitigated and controlled.

Research problem in the context of literature

Risk can be treated as a threat of 'any future incident that will negatively influence the event' (Bowdin et al., 2006, p. 318), or neutrally as a tool useful to 'minimize liabilities and maximize opportunities" (Silvers, 2008, p. 22). It is worth emphasizing that the word risk comes from the Latin word 'riscore', meaning - dare, which means that it should be perceived as a conscious choice, not a necessity. However, it should also be noted that risk is often not fully realized (Appenzeller, 2005; Boo & Gu, 2010). Running events' organizers carry risks that are both known and unknown to the administrator. While running event directors have the responsibility to provide the safest conditions possible, participants have an equally important responsibility to ensure their own physical readiness to undertake such activity (Boo & Gu, 2010; Fuller & Drawer, 2004).

Sport events are carried out in conditions of uncertainty, which is built by internal and external factors (DSDM Consortium, 2010); however, there is no unambiguity as to the relation between risk and uncertainty. It happens that both terms are used interchangeably, but it can also be stated that the uncertainty in the shorter periods takes the form of risk, or that 'the risk is a specific uncertainty' (DSDM Consortium, 2010, p.12). The ISO 31000 standard defines the risk as the effect of uncertainty in pursuing a set goal (ISO 31000, 2018) and draws attention to the management of diversified risk. The standard also emphasizes the need for an individual approach to the definition adjustment as well as to the consideration of specific needs. Risk management includes the context determination, risk assessment (including risk identification, analysis and evaluation) and risk treatment (ISO 31000, 2018).

In the literature on the event organization, risk management is often referred to as an action that aims at controlling the impact of unforeseen issues or accidents that take place within an event; thus, it is a proactive process (Ammon & Brown, 2007; Hanstad, 2012; Leopkey & Parent, 2009).

It is indicated that risk management in large-scale sporting events is becoming increasingly important and should be explored from different perspectives, as the holistic approach is recommended (Moyle et al., 2014; Leopkey & Parent, 2009; Emery, 2010). However, governing bodies are the authorities of major responsibility for identifying and managing the risks associated with the event (Fuller & Drawer, 2004). In Europe the problem of the organization of large-scale running events and their risk assessment was rarely analyzed (Miśniakiewicz & Łuczak 2014; Kose, Argan & Argan, 2011). Most papers on events risk management and reports on sport event risk come, however, from the US, Canada and Australia (Appenzeller, 2005; Nohr, 2009; Leopkey & Parent, 2009; Matheson, 2006).

Various studies have been conducted in the field of sport and sporting event risk management. The researchers have usually centered their interest around security and crowd control (Appenzeller, 2005; Giulianotti & Klauser, 2010; Zoltak, 2001), injuries (Fuller & Drawer, 2004; Hespanhol, Pena Costa & Lopes, 2013), facility management (Preuss, 2007), effect of terrorism (Giulianotti & Klauser, 2010; Toohey & Taylor, 2008), actual losses caused by an event (Crompton, 1995) and lack of organizational planning (Getz, 2002). Special attention was paid to an overall impact of a sporting event on stakeholders (Leopkey & Parent, 2009) and risk management strategies by stakeholders, as well as on practices (manager profile, skills required and critical success factors) in sporting events (Emery, 2010). Different perspectives have been taken into account within risk management – the stakeholders in general (Leopkey & Parent, 2009) and participants in particular (Hanstad, 2012; Fuller & Drawer, 2004). Sporting event managers' attitude, beliefs and constraints have been analyzed (Reid & Ritchie, 2011).

Furthermore, risk issue categories by stakeholder groups have been identified (Leopkey & Parent, 2009). The study provided the list of 15 risk issue categories important when dealing with risk management in sporting events: environmental, financial, human resources, infrastructure, interdependence, legacy, media, operations, organizing, participation, political, relationship, visibility and human resources. It was a starting point for the research on the assessment of risk management in large-scale running events.

Until now, the researchers were mostly focused on sporting events of international importance that were considered in the social, economic, promotional or planning context (Boo & Gu, 2010; Toohey & Taylor, 2008). There are few studies on events carried out for amateurs (i.e. Miśniakiewicz & Łuczak 2014). The intention of the authors was to fill this gap. In the light of critical evaluations of the legitimacy of the organization of mega events - debatable social and financial benefits that most often demonstrate the legitimacy of their organization (Crompton, 1995; Preuss, 2007) it can be concluded that the smaller sporting events of national and local importance will be those that shall gain popularity in the future (Matheson, 2006).

Methods

The paper bases on the preparatory research (1) conducted in 2017 and the main research (2) conducted in 2017-2018. They aimed at identifying risk factors and estimating the risk related to organizing marathons (Table 1).

Table 1. Characteristics of the preparatory and the main study

	Preparatory research	Main research
Research method, conducted analyses	Delphi method	Reliability analysis, risk assessment; cluster analysis, factor analysis
Research tool	Discussed questionnaire	Questionnaire
Size of population sample	15 experts	31 representatives of 14 marathons
Duration of research	2017	2017-2018
Research objective	Identification and grouping of risk factors related to organizing marathons. Preparation of the proper research	Risk assessment and analysis in reference to organizing marathons
IT tools, form of research realization	E-mail contact, meetings	e-risk app

Source: own research.

Within the preparatory research the Delphi method (Thangaratinam & Redman, 2005) was applied. The research involved fifteen experts in organizing long-distance runs. They were experienced participants (5), marathons organizers (5) and researchers in the areas of sports and project management (5).

The authors prepared a list of risk factors on the basis of the relevant professional literature (Leopkey & Parent, 2009), own experience and legal requirements in Poland and grouped them with the use of the Ishikawa diagram. The list of factors arranged in this form was sent via Internet to research participants, who shared their remarks, i.e. confirmed the validity of the included risk factors or considered them inadequate. They also proposed other factors and additional risk factor groups. After having taken participants' remarks into account, the material was sent again several times. The remarks were exchanged a few times (5-9) with most experts, which led to the modification of the factor list. These actions amounted to the basis of the research questionnaire

Reliability analysis (Cronbach, 1951; Peterson, 1994) of questionnaire was applied with the use of the Cronbach's

alpha statistics to confirm the adequacy of the applied research instrument (Peterson, 1994). The Cronbach's alpha statistics result reached the level of 0.933 (21 positions). According to the classical interpretation the coefficient should have the minimum value of 0.6, whereas the preferable value of the coefficient is approx. 0.9. Thus, the internal cohesion of the research instrument was confirmed.

Within the main research agreed risk factors were evaluated on the scale ranging from 1 to 4, according to their significance (impact) and probability of occurrence (Table 2).

Table 2: Characteristics of selected values in the proper research.

Scale	Probability		Impact	
1	Marginal and low (0-30%)	• Risk will not occur or will occur occasionally • Expected number of occurrences within a period: fewer than 1 time in 5 editions.	Insignificant	Difficulty in realizing a sporting event, which influences its course and objective realization in an insignificant way
2	Medium (31-60%)	• Risk occurrence is real, but does not exceed 60%. • 1 occurrence in the last two editions.	Medium	Clear and tangible impact on the organization and the course of a sporting event as well as objective realization
3	High (61-80%)	• There are rational premises that the risk will materialize. • It occurred once in the last edition.	Large	Significant impact on the organization and the course of a sporting event as well as the realization of objectives, including the ones related to health, large impact on an event's reputation
4	Very high (81-100%)	• There are rational premises that the risk will almost surely materialize. • In the last edition it occurred at least 2 times.	Very significant	Related to health and life of participants, the necessity to terminate the event, no objectives are achieved.

Source: own study based on ISO 31000.

The research was supported by the IT tool e-risk (e-risk.pl). It allows for multi-dimensional configurability in reference to the methodology and risk factors. Moreover, it enables the full control of the activity of research participants. Three experienced representatives of selected marathons carried out the risk assessment. All fourteen analysed marathons were city runs held on flat or moderate terrain in Poland. Therefore, the events were similar in many aspects, e.g. climate conditions, participant profile, the declared standard of organization, legal regulations relevant to the organization process.

Research Results

The research resulted in approving 75 risk factors divided into nine groups: Safety (1), Budget and finance (2), Information (3), Comfort and satisfaction of participants (4), Organization (5), Start package (6), Recovery and energy support (7), Reputation (8), Environment and force majeure (9). Within each factor group, more specific risk factors were further indicated (Table 3).

Table 3: Groups and risk factors – the result of the preparatory research

Group 1. Safety	Group 2. Budget and finance	Group 3. Information
1.1. A serious accident on the route 1.2. An intrusion of a third party onto the running route 1.3. A participant of insufficient	2.1. Insufficient income from participant fees 2.2. Insufficient funding from sponsors 2.3. Insolvency	3.1. Obsolete news on the website 3.2. Lack of/insufficient contact with potential participant 3.3. Insufficient promotion/information on

health condition 1.4. A collision between people, people and objects, etc. on the running route 1.5. A terrorist attack 1.6. Intentional pollution/spoilage of food/beverages available along the route/in the finish zone 1.7. Insufficient medical support	2.4. Lack of profit at the planned level 2.5. Time overlapping with another rival event 2.6. Large participation fee	external web sites 3.4. Unintended disclosure of personal data 3.5. Personal data theft 3.6. A cyber attack - modification, blocking of the website 3.7. Lack of a clear, interactive map of the route 3.8. Lack of early information about the result
Group 4. Comfort and satisfaction of participants	Group 5. Organization	Group 6. Start package and medal
4.1. Lack of free accommodation 4.2. Poor organization of the deposit office 4.3. Difficulty in reaching the start of the marathon 4.4. Lack of parking space near the start 4.5. Inability to receive start packages on the day of competition 4.6. Mass start (not in waves) 4.7. An inappropriately narrow route, narrows 4.8. Lack of/unclear information about the covered distance 4.9. An unattractive route 4.10. An unattractive export, a poorly-located expo 4.11. Lack of access to showers after the competition	5.1. Inappropriate running route identification 5.2. Insufficient access to toilets 5.3. Unattractive catering at the finish 5.4. Impossibility of gathering spectators in the start and finish zones 5.5. Inappropriate organization of the run - jams after the start 5.6. Inappropriate organization of the finish 5.7. Lack of the appropriate atmosphere during the event 5.8. Problems related to organization, time of the event etc. with the local community and the administration 5.9. Delayed start 5.10. A smaller than usual number of nutrition points 5.11. Inappropriate organization of nutrition points 5.12. An insufficient number of volunteers 5.13. Lack of volunteers' engagement 5.14. Faulty time measurement 5.15. Lack of established procedures 5.16. Limited human resources 5.17. Incompatibility of the running route capacity with the number of participants	6.1. An unattractive start package 6.2. An unattractive design of the medal 6.3. An insufficient number of medals 6.4. An insufficient number of start packages
Group 7. Recovery and energy support	Group 8. Reputation	Group 9. Environment and force majeure
7.1. Lack of access to massage in the finish zone 7.2. Lack of appropriate hydration of participants 7.3. An insufficient amount of water at recovery points 7.4. An insufficient number isotonic drinks at recovery points 7.5. An insufficient number of	8.1. Unfavorable media information on the national scale 8.2. Unfavorable media information on the local scale 8.3. Lack of information about the event in the national media 8.4. Lack of information about the event in the local media 8.5. An insufficient number of	9.1. Downpour 9.2. Strong wind 9.3. An overly low temperature 9.4. An overly high temperature 9.5. Difficult conditions of the running route 9.6. Traffic in the direct vicinity of the event 9.7. Force majeure

energy gels, fruit etc. at recovery points 7.6. Random choice of nutritional products at recovery points and the finish 7.7. Low health quality of the offered nutritional and recovery products 7.8. Lack of nutritional awareness of participants 7.9. Lack of nutritionists' support 7.10. Lack of/insufficient number of cooling points along the route	participants 8.6. A rival local event	

Source: own research.

Experts emphasized the importance of factors related to the physical safety of participants and organization. They also stressed risks linked with accidents on the route, bad health condition of participants, as well as terrorist and bioterrorist threats. Furthermore, personal data protection, especially compliance with GDPR, turned out to be significant. Experts clearly recognized the risk related to not assuring participant satisfaction – in the questionnaire they took account of issues linked with start packages, start organization, route attractiveness and deposit organization. Finally, the risk factors resulting from the preparatory research were used in the risk assessment conducted in the main research.

The average values of risk factors were calculated considering the ones of the highest risk and the largest frequency. Five groups of risk factors were distinguished:

- The most significant (15) – the average value from 5.10 to 6.23,
- Less significant (21) – the average value from 4.14 to 4.94,
- Neutral (18) – the average value from 3.14 to 3.90,
- Of little significance (9) – the average value from 2.48 to 2.95,
- Insignificant (13) – the average value from 1.33 to 2.24.

Respondents indicated the risk related to financing a marathon as the most significant one (insufficient income, profit at an unsatisfactory level, insolvency), followed by: organization (limited human resources, inappropriate organization, delayed start, incompatibility of the running route capacity with the number of participants), safety issues related to terrorist threats, cyber safety and participant's health condition (Table 4).

Table 4: The most significant and the less significant risk factors of organizing a marathon

Code	The most significant risk factor	Average	Range	Standard deviation
2.2.	Insufficient funding from sponsors	6.23	7.53	2.50
5.16.	Limited human resources	6.03	5.00	1.56
5.8.	Problems related to organization	6.01	7.50	2.35
9.7.	Force majeure	5.97	6.00	1.96
2.5.	Time overlapping with another rival event	5.93	3.00	0.92
5.6.	Inappropriate organization of the finish	5.92	6.00	1.67
3.4.	Unintended disclosure of personal data	5.79	6.75	2.39
5.14	Faulty time measurement	5.77	7.50	2.55
2.1.	Insufficient income from participant fees	5.71	5.89	1.86
6.3.	An insufficient number of medals	5.71	4.50	1.45
2.4.	Lack of profit at the planned level	5.27	7.00	2.13
3.6.	A cyber attack – modification, blocking of the website	5.26	6.75	2.34
5.9.	Delayed start	5.26	3.44	1.00
5.17.	Incompatibility of the running route capacity and n° participants	5.17	5.50	1.69
2.3.	Insolvency	5.10	7.78	2.69

Code	Less significant risk factor	Average	Range	Standard deviation
6.1.	An unattractive start package	4.94	4.50	1.54
8.1.	Unfavorable media information on the national scale	4.85	6.50	1.74
4.5.	Inability to receive start packages on the day of competition	4.79	6.89	1.99
5.13.	Lack of volunteers' engagement	4.69	3.25	0.99
5.5.	Inappropriate organization of the run – jams after the start	4.68	3.67	1.05
9.1.	Downpour	4.68	4.75	1.48
3.5.	Personal data theft	4.61	4.00	1.39
8.5.	An insufficient number of participants (too little interest)	4.56	6.00	1.79
3.3.	Insufficient promotion/information on external websites	4.53	4.25	1.40
4.7.	An inappropriately narrow route, narrows	4.51	4.50	1.57
5.1.	Inappropriate running route identification	4.41	5.00	1.74
5.12.	An insufficient number of volunteers	4.40	4.50	1.45
9.4.	An overly high temperature	4.37	5.25	1.64
1.1	A serious accident on the route	4.36	3.25	1.14
7.3.	An insufficient amount of water at recovery points	4.35	5.00	1.72
1.2	An intrusion of a third party onto the running route	4.23	3.75	1.21
4.3.	Difficulty in reaching the start of the marathon	4.19	5.00	1.89
4.2.	Poor organization of the deposit office	4.17	2.50	0.92
8.6.	A rival local event	4.16	8.00	2.36
1.5.	A terrorist attack (an explosion, shooting, ramming)	4.15	6.00	1.89
1.7.	Insufficient medical support	4.14	5.50	1.55

Source: own research.

These findings may be found useful when focusing on specific factors and making organizational decisions. It can be observed that problems with funding and organization (limited human resources) are important. For participants and spectators likewise, it is a big festival; however, cyclical events disorganize the life of the local community. What is more, the substantial number of events and the season "limited" by the calendar often lead to a decrease in the number of participants due to rival marathons organized at the same or similar time. It is worth noting that the importance of threats to the safety of participants and viewers, the risk of a terrorist attack, and the need to protect personal data are increasing nowadays (Lamont & Kennelly, 2012; Toohey & Taylor, 2008) as suggested by the obtained results.

Conclusions

The presented research has pioneered the systematic and methodological risk assessment of organizing large-scale running events on the example of marathons held in Poland. It may become a starting point for conducting further studies in reference to risk analysis and taking mitigation actions as well as examining their efficiency.

As a result, a database of risk factors (75) was developed regarding the organization of long-distance runs (marathons) and they were divided into separate groups (Security, Budget and Finances, Information, Comfort and Satisfaction of Participants, Organization, Starter Pack and Medal, Regeneration and Energy Support, Reputation, Environment and Force Majeure).

After assessing the risk, taking into account the effect and the likelihood of a given factor, 5 groups of risk factors were identified (the most important, less important, neutral, not important and insignificant). The most important factors are related to the financing of marathons, organization issues, including the start date, the acceptance of the local community, the organization of the finish line, delayed start, cyber security, disclosure of personal data, problems with the measurement of time.

The research resulted in obtaining unequivocal data of risks on which mitigation actions should be centered. The risks are related to assuring funding for marathons, physical safety and personal data protection. The substantial number of marathons (and other sporting events) makes it extremely difficult to find such an event date that does not overlap with other runs and is favorable in the context of weather conditions. The most significant factors included threats leading to accidents on the route, which call for security measures, but also generally point to an insufficient number or lack of security service's engagement.

The research findings have led to the development of the elementary database of risk factors and the verification of the applied methodology (including the e-risk application). Moreover, the research may serve as a methodological source for any marathon organizer.

The emerging industry of large-scale running events, as the example of Poland shows, needs a mature approach to risk management. Although the "consideration of risk only from the perspective of event organizers is myopic" (Moyle et al., 2014, p. 102), there must be something to start with, as the organizers should "expect the best and prepare for the worst" (Moyle et al., 2014, pp.102-103). The risk assessment of marathons from the organizers' point of view seems to be a step in the right direction. Taking into account the perspective of a large-scale running event organizer, the analysis and evaluation of risks associated with the organization and execution can help to develop more effective ways to minimize these threats. The most significant risks that should always be appraised by the management system were indicated in the study. If duly considered, they surely increase the security of mass participation races and the level of confidence of both organizers and participants.

Disclosure Statement

The authors reported no potential conflict of interest.

Abstract

Entrepreneurs are the ones who are the basis of the economy. Through their activity, they allow the development of transactions, create products and services, and offer them to consumers internationally. At the same time, the activity of the commercial companies ensures the incomes necessary for the functioning of the state.

A challenge for entrepreneurs is to ensure the financing of the company's activity.

The state offers the possibility to some companies to benefit in certain conditions from the necessary funds for carrying out the activity. The present study follows the evolution of some companies that benefited from such funds in the first edition of Start-Up Nation held in Romania. The study of the 25 companies shows that many entrepreneurs relied on this financing to run the business, and only a few understood that the success of the business does not consist only in this money (which are few anyway). These funds allowed the purchase of equipment, they were a plus, but the success of the company did not depend on them.

Keywords: Entrepreneurship, Performance, Evolution, Non-Reimbursable Funds

Introduction

Entrepreneurs are people who use the knowledge they have in order to develop a business. Through the activity carried out, they allow the creation and delivery of goods and services to the other participants in the economy. At the same time, they allow job creation. These jobs created and the activity carried out involve debts with various taxes (profit / income tax, VAT, salary tax, other salary taxes). These taxes represent state tax revenues. Thus, a company supports the functioning and development of the economy.

For entrepreneurs, a very important role is played by education, both formal and informal. This education must be continuous.

A crucial role in the life of a company has the financial resources that ensure the continuous development of the activity. The absence of a positive cash flow makes the activity difficult.

According to the study conducted by Ernst & Young (2019), 1 in 2 Romanian startups has been on the market for less than 12 months and 7 out of 10 founders are at the first established company. Approximately one third of startups fail to reach the second year of activity according to data collected in the three editions of the Barometer.

The most important criterion in evaluating the start-up result was considered by 72% of the respondents of the study conducted by E&Y, the financial criterion (profit, turnover).

The mentality and the fear of failure occupy the first place in the top of the most important obstacles for those who want to start and develop a business in Romania. Compared to the previous edition, there is a decrease in the

Cite this Article as: Cristina Elena BIGIOI and Mirabela Andreea BUDULAN "Study on Start-ups in Romania" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

importance of access to finance (7% considered it the most important obstacle), but this does not mean that this premise has been solved or improved at national level.

The financing sources of an entrepreneur in starting the startup are:

- Own funds
- European funds
- Non-reimbursable financing from the Romanian state or other institutions
- Family and friends
- Sponsorship
- Angel investor
- Bank credit
- Other source (grants, supplier credit, crowdfunding, etc.)

A possible source of financing is the structural funds, the subsidies received under certain conditions. It is true that most of the time the amounts received from this source are not enough, but they can boost the development of the business if the entrepreneurs know exactly how to use them.

According to the study conducted by E&Y, a significant increase in the share of state funding can be observed (Fig. 1).

Fig. 1: Sources of financing used in starting the startup

Source: Own processing of the data extracted from study of E&Y

Government programs and European funds remain at the top of start-up options as a source of funding for the next 12 months, with significant increases over previous years. (Fig.2)

Fig. 2: Source of funding for next years

Source: Own processing of the data extracted from study of E&Y

71% of entrepreneurs consider that the funds offered by the Romanian state within the specific programs for SMEs are the form of financing that would have a very big impact in supporting business initiatives. European funds are a second important source of funding for the development of long-term entrepreneurship in Romania, say 58% of survey respondents.

In the present study we considered the Start-Up Nation financing program carried out in Romania, more precisely its first edition, the one from 2017.

The non-reimbursable funds possibly to be won were in the amount of 44,000 euros (200,000 lei). One of the conditions was that the companies should employ at least 2 full-time people, at the time of the statement of the state aid, and to keep those employees for at least 3 years.

Literature Review

Panigrahi and Joshi (2016) studied entrepreneurship education in India and identified the following challenges for it: cultural barriers, long time to open a business (89 days), high costs, incomplete entrepreneurial education, lack of a standard framework, dependence on government.

Farayibi (2016) proved the role of entrepreneurs in economic growth in Nigeria. Increases in entrepreneurial financing (through loans to SMEs) have significant effect on economic growth.

Gregova and Dengoy (2016) analyzed the impact of startups on the Slovak economy. The analysis led to the conclusion that the development of startups will have an important role for the development of the Slovak economy and its economic recovery.

Yusuf (2017) find a significant positive influence of entrepreneurship eduction, technologu and globalisation on performance of SMEs in Nigeria. It was also concluded that is very important to continously acquire newer entrepreneurial skills.

Nicolae and Bigioi (2017) identified a weak interest of human resources in Romania for training. The percentage of those who are concerned about lifelong learning is only 1.3% (in 2015), compared to the European average of 10.7% (EU). The interest to become an entrepreneur is great among young graduates in Romania, but the difficulties encountered for this purpose are too little taken into account.

According to a study conducted by European Central Bank (2019) during April-November 2019, access to financing sources is considered the least important obstacle. Concerns about access to finance remained higher for SMEs as a whole than for large companies. . Banks remained the most relevant source of finance. The same study conducted between Oct 2019-March 2020 shows that SMEs expect a sharp deterioration in access to bank loans, due to the international pandemic of covid-19.

Vrincut and Irimia (2018) studied the role of banks in the Start-up Nation program. The study provides a critical perspective on the issues faced by participants in this program in 2017, especially those related to the quality of banking services. It also emphasizes the role of the strategic vector of the quality of banking services in the context of their involvement in national development.

Research Methodology

In 2017, the first edition of the Start-up Nation program was launched in Romania by the Ministry of Business, Trade and Entrepreneurship.

The goal of the program was to support 10,000 beneficiaries, to stimulate the development of small and medium-sized enterprises. The target results pursued refer to: new jobs created, disadvantaged people, graduates and unemployed inserted into the labor market, investments in new and innovative technologies. The interest was very high, so that over 3000 companies obtained the maximum score in the evaluation stage of the proposed project.

Through this study we want to analyze the evolution of 25 companies that were accepted and agreed to benefit from grants related to this program. The analyzed period refers to the financial years 2017, 2018 and 2019.

The research was conducted in the following stages:

- the data was selected
- the data was been grouped according to specific objectives
- the data was processed
- the results were centralized
- the results were analyzed and interpreted
- the conclusions were drawn.

The methods by which this analysis was performed, were: investigation, identification and interpretation.

The companies that were accepted to benefit from these subsidies were published on the website www.fonduri-structurale.ro and was created by the Department of Entrepreneurship and Programs for SMEs. From these companies, we selected 25 based on the following algorithm: the list in PDF format had 249 pages with the winning companies. We selected the first company on each page, resulting 25 companies that will be included in this study.

The financial data were collected from the website www.mfinante.ro, data that are included in the financial statements submitted by the company according to the legislative requirements.

Results of the Study

14 companies among those included in the study have as object of activity the production of various goods. The others have as object various other activities: general mechanics operations, dental assistance, software development, photographic activities, engineering and consulting activities, fitness center, restaurant, travel agency (Fig. 3).

Fig. 3 : Activity of the companies

Source: own processing based on the extracted data

I marked each company with Si, where i ={1; 25}.

The companies were established in 2017. Given that the financing contracts were signed at the end of the year, most companies (16) did not carry out activity this year, probably waiting for financing in order to start the activity.

The first company to be studied is notable, which, although it was also founded in 2017, managed to make a profit from the first year. Moreover, it was the only one that had a growing profit from year to year, and values much higher than the next ranked.

8 companies out of the 25 failed to make a profit in any of the 3 years studied.

The evolution of the profit for the 3 years taken into account was as follows (Fig. 4)

Graph 4: Profit- evolution

Source: own processing based on the extracted data

In 2018, only one company has no employees, and in 2019 the number of these companies is 3. The first company also has the largest number of employees and maintains it in 2018 and 2019 (49 employees).(Fig. 5)

Fig. 5: Number of employees

Source: own processing based on the extracted data

9 companies achieved turnover in the first year (that of establishment). 80% of the companies registered an increase in turnover in the period 2018-2019 (Fig. 6).

The first company S1 also stands out from the point of view of this criterion.

Fig. 6: Turnover evolution

Source: own processing based on the extracted data

Return on equity (ROE) is a measure of financial performance calculated by dividing net income by shareholders' equity. ROE is considered a measure of how effectively management is using a company's assets to create profits.

ROE= Net income/ Shareholders' equity.

Most investment books recommend an ROE of at least 15%.

14 companies did not register a profit in 2019, which is why ROE cannot be calculated.

For the other companies, the first company S1 stands out, which managed to have an ROE of 99.9% and to maintain it for the analyzed period.

4 companies had a loss in the first 2 years, and in 2019 they register an ROE over 99% (companies S7, S14, S19 and S24) due to the profit obtained this year which covers the previous losses. (Fig. 7)

Fig. 7: Evolution of ROE

Source: own processing based on the extracted data

Return on assets (ROA) is an indicator of how profitable a company is relative to its total assets. ROA gives a manager, investor, or analyst an idea as to how efficient a company's management is at using its assets to generate earnings. The ROA figure gives investors an idea of how effective the company is in converting the money it invests into net income. The higher the ROA number, the better, because the company is earning more money on less investment.

ROA= Net income/ Total assets

Only two companies have ROA values registered for each of the 3 years. S1 has ROA values over 49% in the 3 years, and S4 has very low values of the indicator (below 10%). 8 companies cannot determine ROA in any year (Fig. 8).

Fig. 8: Evolution of ROA

Source: own processing based on the extracted data

The total debt ratio divides the total liabilities with the total assets. It shows the proportion of the assets that are financed with debt.

Total debt ratio =Total liabilities/ Total assets.

It is generally considered that a degree of indebtedness of less than 60% is very good and reflects a long-term balance between internal and external sources of financing.

Evolution of level of indebtedness is represented in Fig. 9.

Fig. 9: Evolution of indebtedness

Source: own processing based on the extracted data

We analyzed the degree of indebtedness for two years 2018 and 2019, after receiving the financing. 3 companies have a degree of indebtedness over 100%. Two hold the pointer over this ceiling. 48% of companies have a degree of indebtedness below 50%.(Table no 1)

Table 1: Number of companies and total debt ratio

	2018	**2019**
Total debt ratio <50%	13	12
Total debt ratio 50-100%	9	10
Total debt ratio >100%	3	3

Source: own processing based on the extracted data

We defined the function F(i)
F(i)= fi1+fi2+fi3+fi4+fi5,
i={1;25}

fi1=1 if the profit increases

fi2=1 if the the company i makes a profit in both years 2018 and 2019

fi3=1 if ROA in 2019 >20%

fi4=1 if ROE in 2019 >15%
f
i5=1 if total ratio debt is <60%

The commercial companies subjected to the study obtained the following values for the F function (Fig. 10).

Fig. 10: Value of function F

Source: own processing based on the extracted data

8 commercial companies obtained the value 0. 7 commercial companies (28%) obtained the maximum value of the function F.

Conclusions

The interest to open a start-up is growing in Romania. However, the sources of financing for development are too little considered.

The Start-up Nation 2017 program was a possible source of funding that could stimulate the activity of the beneficiary company. The study of the 25 companies shows that many entrepreneurs relied on this financing to run the business, and only a few understood that the success of the business does not consist only in this money (which are few anyway). These funds allowed the purchase of equipment, they were a plus, but the success of the company did not depend on them.

Only one company stood out; it made a profit in all 3 years, even in the first year of activity. Moreover, it was the only one that had a growing profit from year to year. 8 companies out of the 25 failed to make a profit in any of the 3 years studied.

80% of the companies registered an increase in turnover in the period 2018-2019.

14 companies do not have financial performance (according to ROE indicator)

Most companies do not use its assets efficiently to generate earnings.

48% of companies have a degree of indebtedness below 50%.

7 companies increase their profitability in the last two years, use assets efficiently to generate earnings, have financial performance and have a low degree of indebtedness. We can conclude that they used the granted financing efficiently.

For a better overview, the study can be improved by following the indicators over a longer period of time and by including several beneficiary companies in the study.

Implementation of FMEA to Risk at Workstation Analysis

Roma MARCZEWSKA-KUŹMA

Faculty of Engineering Management, Poznan University of Technology, Poznan, Poland
roma.marczewska-kuzma@put.poznan.pl

Abstract

The paper presents arguments according to which the application of the FMEA method to an in-depth risk analysis for a selected workplace - a bottling line operator, allows to identify significant potential threats against which preventive measures should be introduced. These measures should not be limited only to the use of personal protective equipment, but also apply to technical and organizational solutions. The performed occupational risk analysis allows for the introduction of solutions improving risk management in the examined enterprise, and the implementation of the suggested corrective actions will increase the safety level and awareness of operators.

Keywords*:* Risk Analysis, Professional Risk Assessment, Identification of Threats, Risk Assessment.

Introduction

Along with the development of industry, mechanization and automation of production processes, a demand for innovative solutions related to broadly understood management emerged in industrial plants. The consequence of changes related to the way work is carried out and to the equipment of workplaces is a new approach to the issues of occupational health and safety, and above all, the need to systematize activities undertaken in this area. Such actions, implemented as procedures of conduct, require the enterprise to set specific strategic goals, which should have a specific time horizon for their implementation. "Managing risk is iterative and assists organizations in setting strategy, achieving objectives and making informed decisions " (Řeháček, 2019). In order for the company to be able to effectively implement and maintain a safety policy, it should set itself goals, i.e. improve the comfort of work at each position, reduce or eliminate all identified threats at work, prevent accidents at work and reduce economic losses and staff fluctuation caused by employee absenteeism (Marczewska-Kuźma, Mazur, 2015).

The aim of the article is to indicate the possibility of using the FMEA method for an in-depth risk analysis for a selected workplace - a bottling line operator. The use of the FMEA method allows identifying significant potential threats in the implementation of processes, against which preventive actions should be introduced despite the acceptable risk value in relation to their occurrence, obtained in the Risk 20 method or their omission in the analysis with this method. Appropriately, selected preventive actions should ensure the reduction of the employee's exposure to various types of factors that hinder work, disorganize it or may cause an accident.

The article is structured as follows: In the first part, the definitions related to the topic of the article are presented, the basic legal requirements, which imply the need to ensure safe working conditions for the employee, the standard methods used to assess occupational risk are indicated, and the need for an in-depth risk analysis for workplaces is justified.

The second part presents the methodology of the conducted research, then presents the research results and their interpretations. Discrepancies in the results of occupational risk assessment for the position of the pouring line operator carried out using the Risk Score method and the FMEA method were indicated. Preventive measures have been suggested for the selected threats, or rather their causes.

Literature Background

Every company constantly makes decisions related to, among others with human resources management, technical equipment, or technology of performed works. The implementation of these decisions takes place in the internal

environment of the company, however, being aware of their impact on the company's environment, i.e. external stakeholders. This influence plays a key role in the success of the company's operations, increasing the brand's prestige or building one's own culture and identity.

The organization, associations, micro and macro enterprises in each sphere of their activity are subject to obligatory provisions contained in superior acts, i.e. laws, regulations, normative acts. The most important of them is the Constitution of the Republic of Poland in force in Poland, established on April 2, 1997 by the National Assembly. Due to Poland's membership in the European Community and the adoption of the principles of Directive 89/391 / EEC, it has become necessary to mention the issue of occupational health and safety in the most important decree. The answer was article 66^1 saying that (...) "Everyone has the right to safe and hygienic working conditions, and the manner of exercising this right and the obligations of the employer are specified in the law" (Article 66^1 of the Constitution of the Republic of Poland of April 2, 1997). "Nowadays, business environment forces enterprises to search constantly for the new opportunities and chances in order to fulfill the customers' demands as well as being more competitive.Providing the safe and ergonomic environment at the workplace is one of the basic task of employer" (Mrugalska, et al., 2020)

With regard to enterprises with an implemented occupational health and safety management system, the target group of stakeholders consists of all employees whose involvement in process activities is a key condition for achieving the intended goals. A separate group of stakeholders is made up of institutions operating within the Polish labour protection system, such as the minister responsible for labour and other ministers establishing the provisions of law on safety and health protection at work, and the relevant supervisory and control bodies over working conditions.

The interested party should therefore be understood as "a person or organization that may influence, be influenced by decisions or actions, or which sees itself as being influenced by decisions or actions" (ISO 45001: 2018 Occupational health and safety management systems - Requirements with guidance for use).

An effective occupational safety management system should be based on the full integration of the newly applicable ISO 45001: 2018 standard with other standards in this group, i.e. ISO 9001: 2015 related to the quality management system and ISO 14001: 2015 regarding environmental management (Pratikno, Kusnadi, 2020). The strategic goal of the operation of each company is to maintain a designated market position, which consequently leads to profit maximization and loss minimization. Therefore, it is necessary to build synergies between occupational safety and health and productivity (Leppink, 2015).

This modern approach to solving potential production, economic or social problems is an integral part of the company's management. In the context of occupational safety, the main goal is to prevent accidents that could lead to serious losses, having a direct impact on the financial result, defined in the USA as *loss prevention*.

Over the years of changes in Polish regulations on occupational health and safety and their adaptation to European standards, many companies have lowered the accident rate, which proves they implemented conscious management of the company and benefited from improving the qualifications of all employees, as well as reliable analyses of occupational risk.

Occupational risk is defined in various ways in the literature, e.g., "the combination of the probability of a work-related hazardous event (s) or exposure (exposures) and the severity of the injury and health conditions that may be caused by the event (s).) or exposure (s)" (ISO 4500: 2018, p. 15).

Another definition used in Poland comes from the regulation of the Minister of Labour and Social Policy of September 26, 1997 on general health and safety regulations, as amended rev .: "Occupational risk is the probability of the occurrence of undesirable events related to the work performed, resulting in losses, in particular the occurrence of adverse health effects in employees as a result of occupational hazards occurring in the work environment or the manner of performing work" (Journal of Laws 11.173.1034 § 1).

The main goal of the occupational risk assessment is to determine the measures that must be applied by the enterprise to ensure compliance with the requirements of health and work protection law, and to minimize the number of potential injuries that may be suffered by employees and their severity. "Risk assessments should be recognized as integral to systemic efforts to improve occupational safety. To enhance the effectiveness of actions taken, affecting the minimization of onerous employment must be applied ergonomic criteria underlying the pro-humanistic approach organizations, consistent with modern principles of social responsibility. Risks should also be assessed with the use of proper risk management tools so as to ensure continuous improvements in that process" (Gorny, Sadlowska-Wrzesinska, 2016).

It is also important that the risk assessment must also include those who may be exposed to it during their stay in the enterprise. The stages of risk assessment are (Hughes, Ferrett, 2007):

1. Finding threats.
2. Identify which can cause an injury and how it can occur.
3. Assessing the risk and deciding whether to introduce solutions to reduce the risk, and if so, what.
4. Record any significant risks found.
5. Review and monitor risk assessments made and repeat them if necessary.

The risk assessment process can be easily divided into six segments, i.e.

1. Hazards identification.
2. Identification of people at risk.
3. Assess the level of risk.
4. Developing preventive solutions.
5. Writing the occupational risk assessment card.
6. Continuous risk control, assessment and updating.

In the process of the level of risk assessment, the team may notice that corrective actions have already been taken, hence what to do to minimize residual risk should be considered. The aim of the assessment is to achieve the lowest possible risk as possible. "The key benefit of this process is the documentation of existing risks and the knowledge and ability it provides to the project team to anticipate events" (Řeháček, 2017). There are two types of risk assessment methods (Romanowska-Słomka, Słomka, 2008):

- Quantitative, consisting in measuring the risk by determining its probability and severity of consequences resulting from its occurrence and assigning a numerical value to the risk. These methods are used in the petrochemical, aviation and maintenance industries.
- Qualitative - methods used more often, based on the visual judgment of the process team. The result is a risk assessment as low, medium, high. The consequence is to identify the actions that must be taken because of the assessment.

The next step is to suggest corrective actions (Hughes, Ferret, 2009):

- creating workstations and processes allowing to avoid risk,
- assessing the risk that cannot be avoided,
- removing the risk source,
- designing workstations tailored to the employee, selecting work methods, work equipment, designing processes in such a way as to avoid monotony,
- adjusting workstations to technical progress,
- substituting hazardous substances, tools with those causing less exposure,
- developing a policy focused on prevention, focusing on technology, work organization, working conditions,
- suggesting collective protective measures, with priority over the use of personal protective measures,
- giving appropriate instructions to employees.

The list above covers the examples of corrective actions that can be taken to mitigate risks.
Whereas typical methods used in occupational risk analysis include:

- ALARP- As Low as Reasonably Practicable/Achievable - the method refers to a sceptical approach and the use of common sense when introducing solutions aimed at reducing the level of occupational risk. The assumptions for the application of this method describe the approach to incurring expenses that the enterprise makes in order to achieve an acceptable risk. It should be noted that the amount of enterprise expenditure in order to achieve a tolerable risk level must be economically justified (Bedford, 2014),
- PHA - Preliminary Hazard Assessment is a preliminary hazard analysis carried out with the use of a matrix. The two most common values of the probability of an event and the severity of the consequences are used to estimate the risk. The result is the quotient of these elements. Using the method, it is necessary to define the boundaries of the object being assessed, define the hazards, and estimate the effects and probabilities of the event (Ostrom, Wilhelmsen, 2019),
- JASA - Job Safety Analysis is one of the qualitative methods. The assumptions for the use of the analysis refer to hazardous events and situations, as well as threats that employees may encounter in the course of

their work. The mathematical probability of the consequences of an event is defined as the sum of the frequency of threats, the probability of an event, and the possibility of avoiding or limiting harm (Ostrom, Wilhelmsen, 2019),

- Risk Score is one of the most frequently used methods of occupational risk assessment in enterprises, it is characterized as qualitative and quantitative method. Its main goal is to determine material or human losses resulting from a given event, which leads to the estimation of the risk associated with the occurrence of adverse events. The value of the risk index is calculated as the quotient of the probability of a threat, the effect of the occurring threat and the time spent in exposure to a given factor (Oestrum, Wilhelmsen, 2019).

In the company under research, the occupational risk assessment is carried out using the Risk Score method.
An in-depth risk analysis for the bottling line operator's workstation was performed using the FMEA method. The military standard MIL-P 1629 - Procedure for Performing a Failure Mode, Effects and Criticality Analysis, developed and published in the United States in November 1949, can be considered the first publication that comprehensively covered the analytical issues presented in the FMEA (Braglia, Rosalina, 2007). The most recognized use of the FMEA instruments was the Apollo project, conducted in the 1960s in the United States. Then, the FMEA method was being implemented in various industries, in particular in the automotive industry, where the Ford Motor Company (1970s) can be considered the precursor of the application of the discussed methodology (Teng et al., 2012).

Hamrol points out that the FMEA method implemented for processes - PFMEA (Process Failure Mode and Effects Analyzes) concerns the processes of manufacturing products and their parts or assemblies, as well as the processes of use or servicing, including service provision processes. The purpose of using the method should be to indicate factors that may hinder the fulfilment of the requirements contained in the product or service specification, or hinder the course of the process. Due to the universality and flexibility of the method, it is possible to apply it to the analysis of threats in service processes, software development and logistics concepts" (Hamrol, 2005).

Activities implemented within FMEA method should be divided into three coherent processes, i.e. the preparation process, the analytical process and the improvement process.

Research Framework

Until now, the analysis and assessment of occupational risk in the surveyed enterprise was made solely with the Risk Score method. The characteristics of the workstation, requirements, activities performed by people employed in the position were outlined; tools, machines and chemicals used for work were compiled. The methods and rules of performing work were also determined, and then the risks that accompany its performance were assumed. Risk assessment was performed by assigning numerical values to individual values, such as probability, exposure or severity of consequences, determined for the Risk Score method, in order to estimate the risk size. Then, depending on the risk value score, corrective actions were suggested. Documents were reviewed annually to update the occupational risk assessment.

In order to conduct risk analysis using the pro-quality FMEA method, data was collected in September and November 2019. In-house occupational risk assessments results were collected; Records were made of the observations of the working day and free interviews with the bottling line operators. Observations were applied consisting in daily inspections of the areas of workplaces during the performance of typical tasks. Data contained in documents, such as occupational risk assessment or auxiliary records of the analysis of threats at the workplace, was subjected to secondary analysis.

Then, the FMEA method was used to carry out an in-depth analysis of the causes and effects of potential hazards occurring at the bottling line operator's position. As the method's name suggests, it can be used to identify potential faults and their causes. The research used a data system typical for process analysis - it was assumed to identify threats to the employee, their effects and causes by assigning data to individual activities performed at the workplace. As a result of the analysis, the accompanying hazards and their causes were assigned to the successive activities. The risk level was determined using the formula:

$$R = P * I * D$$

where:

R – risk level,
P – probability of risk cause appearance,
I – importance of risk consequences for employees
D – detectability rate.

Then, corrective actions were suggested and the risk level was re-estimated after introducing these solutions to improve the examined process. Summarizing the research results, the conclusions were compared with those developed on the basis of the Risk Score method.

Research Results

Based on internal documents of the surveyed company, the characteristics of the bottling line operator's workplace were developed. There are four men employed in this position. The basic task of the operator is to carry out work on the operation of production installations located in a closed facility - the production hall. The work is performed in a single shift mode, during eight hours with one break of 30 minutes. The predominant scope of work requires physical effort, defined as dynamic. The activities performed by the bottling line operator include:

1. Preparation for work - incl. changing into work clothes.
2. Operations on bottling lines.
   - The phase of preparing the line for filling the packaging - supplying the appropriate product (connecting the hose to the appropriate tank), preparing the cartons and packaging into which the product will be poured, setting the line for the type of packaging to be poured, placing empty packaging on the conveyor,
   - Filling - constant supervision of pouring: weight control, visual inspection of packaging, adding corks to containers, transporting empty packages and cartons, pallets to ready cartons, visual control of the pneumatic capping machine (foil welding, twisting) and printing,
   - Finished product phase - packing full containers in cardboard, sealing with tape, labelling the cardboard, wrapping pallets with cardboard boxes with foil, transporting ready pallets to the warehouse by means of forklift trucks.
3. Service of the filling line directly from the tanks:
   - Visual inspection of the product,
   - Taking the hose out of the pumping station, connecting it to the tank valve,
4. Preparation of containers:
   - Container condition control: drain valve, tightness, cleanliness,
   - If necessary, drying the container,
   - Sealing the drain valve on command,
5. Other activities:
   - Checking the technical condition of machines and devices,
   - Cleaning works in the hall and outside,
   - Removing oil from the floor,
   - Interchangeable hose between the tanker's chambers.

The following measures are used at the described workstation: hand pallet trucks, wrappers, crusher, sealer, scanner, hoses, hand tools, raw materials for production: pallets, plastic, metal and paper packaging, adhesive tapes, degreasers.

The employee is provided with access to personal protective equipment, i.e. a protective helmet, work shoes with a reinforced toe cap and non-slip sole, protective gloves, protective gloves resistant to chemicals, protective glasses, protective helmets, work hat, harness for work at height.

In the Table 1, data on general hygienic working conditions at the described workstation is described.

Table 1: General hygienic working conditions at the bottling line operator workstation

General hygienic working conditions at the workstation	
Location of the workplace	warehouse, production
Workplace lighting	natural and artificial, in line with the standard
Type of ventilation of rooms and workstations	natural (open space), gravitational and mechanical ventilation

Source: Gwiazda S. (2020), research results included in Master Thesis supervised by R.Marczewska-Kuźma

According to the data obtained in the company on lighting (table 1), the assessment of the compliance of electric lighting with the standards took place 6 years ago. The provision "compliant with the norm" may therefore be controversial, as not exactly currently valid.

In the working environment, noise control from works carried out in the production hall and from forklifts moving around the room is defined as the multiplicity of NDN 0.21-LEX, 8h [dB] = 74.1 ± 1.2 dB. Therefore, the permissible value of the employee's daily exposure to noise is not exceeded.

It was found that work as a filling line operator should not be performed by sight, hearing and speech impediments, heart defects, and musculoskeletal disorders.

Table 2 presents the lists of threats to their sources and the effects characteristic for the bottler operator, prepared in the enterprise for the need to conduct risk analysis by the means of the Risk Score method.

Table 2: Risk score method after using personal protective equipment (PPE) and others

No	Threat	Source	Process/workstation	Consequences	PPE*/others	Risk according to Risk Score
1.	Collision of human and moving vehicle	communication traffic	In-house area	Injury, disability, death	reflective elements on clothing	**low**
2.	Changeable weather conditions	Weather conditions	Outside the halls	fainting sunstroke colds frostbite absenteeism	protective clothing hot / cold drinks	**acceptable**
3.	contact with material factor	Tools, machines, installations	Tool manipulation, operation of machines and devices, repair work	injuries: cuts, impact, contusions, crushing, others. absenteeism disability death	protective gloves protective helmet	**low**
4.	Fall from a height	Platforms, ladders	Moving around, staying on the tank of the tanker	limb fracture, dislocations, bruise, disability, death	PPE against falls protective helmet	**low**
5.	contact with chemical factor	chemicals for equipment maintenance	production	skin dryness or cracking, eye irritation, irritating effect on the respiratory system and mucous membranes.	chemical resistant gloves, goggles protective hand cream (degreaser) if recommended	**acceptable**
6.	Contact with thermal factor	Hot surfaces, hot liquids	Production, kitchen	thermal burns	Work gloves	**low**
7.	Injuries, a fall on the same level, a fall down the stairs, a slippage.	Slippery surface	Moving around the production area, warehouse, outside, around the premises in the office	bruises, dislocations, fractures	Non-slip work shoes	**low**

Source: Company's records

According to the data presented in Table 2, the level of risk for seven identified hazards at the operator's position after the application of personal protective equipment and other additional solutions is treated in the company as low or acceptable risk level.

In the Table 3 the risks arising from the subsequent stages of activities that are performed at the bottling operator's station were analysed, their causes were identified, and the risk before and after the implementation of corrective actions was estimated.

Table 3: Risk analysis on the bottling operator's station performed using the FMEA method

Stage of the process	Threat	D2	Consequence	I3	Cause	P1	Control method	R1	Corrective action	Responsible	P2	D2	I2	R2
Changing into work clothes Meeting with the manager and adopting a daily work plan	Work in unfastened work wear	2	Breaking	6	No artwork of correctly dressed employee	5	Visual inspection of the employee's clothing	5x2x6=60	Implementation of information in a graphic form presenting the appearance of a properly dressed employee	Area manager,	2	2	6	24

Carrying out the occupational risk analysis for a bottling line employee using the FMEA method, the stages of typical activities performed in this position were implemented. In relation to this aspect, potential threats that may occur at the workplace were assigned, and then possible causes of these threats and the effects of threats were identified. After determining the risk level of R1, improvement actions were proposed, taking into account the recalculation of the risk level denoted as R2.

Discussion

An important problem in operating the bottling line is the monotony and repetitiveness of the tasks performed, as a result of which there is a distraction and lack of due attention during the preparation and positioning of packages, and also during the continuation of the process. The consequences include injuries, muscle pain and joint problems resulting from maintaining the same posture for a long time. The main causes of monotony and repetitiveness are the way the bottling process is implemented, requiring the employee to perform the same activities in the same position, resulting from the lack of process automation and investment in technology development. As part of the corrective actions, it was suggested to pay more attention to the interchangeability of tasks.

Another significant problem is the misinterpretation of data provided by management. As part of the corrective actions, the participation of employees in the morning briefing was suggested, which will take place according to a previously agreed plan.

Low awareness of contact with chemical substances has also been classified as high-risk hazards. The following corrective actions were recommended: a bonus system dependent on the use of protective measures and training to increase the awareness of working with chemical substances. Unfortunately, the chemical substances used in the company cannot be replaced with other, safer ones, because they are part of the product. At the moment, it is not possible to fully automate the process limiting the employee's contact with the substances in question. In order for the training to bring the intended results, it is necessary to ensure prevention in the field of machine inspections, easy access to the safety data sheets of chemical substances, awareness of the effects of chemical substances on humans by both the operator and the management, control of the use of personal protective equipment.

The operator's job also involves visual assessment of the product. The operator's decision-making may result in psycho-nerve stress and errors in the controls performed. As part of the corrective actions, laboratory product controls were proposed as part of quality assurance.

Important stages of the work are all maintenance and cleaning works, work at height, work related to wrapping and labelling the product. In this scope of tasks, attention was drawn to the lack of use of personal protective equipment and recommended management supervision, bonus systems dependent on the use of personal protective equipment, or training to raise employee awareness.

The results of the FMEA analysis, due to the evaluation following the steps of the process, often direct the analyst to introduce technical solutions. The following technical solutions were suggested to introduce: points with work clothes at the hall exits to minimize exposure to work in changing weather conditions without appropriate clothing, laboratory control of the product, introduction of poka-yoke control for packaging.

As a result of the FMEA analysis, organizational solutions were also proposed, including conducting checks in accordance with the scheduled schedule and ensuring that all necessary procedures are available.

Conclusion

As a result of the literature analysis and the research results presented in the research part of the article, the following conclusions were defined:

1. The FMEA analysis due to the process approach allows for directing the team to consider a greater number of threats than the classic occupational risk assessment - Risk Score.
2. The analysis with the use of the pro-quality method applied can be considered more detailed due to the results of the risk value, before and after the assumed implementation of solutions. Different values are assigned to different causes and effects for a given threat, which allows for a more precise definition of how to prepare preventive actions.
4. Risk analysis with the use of FMEA, due to the process approach, more often forces the suggestion of technical and organizational solutions, where the classic analysis often focuses on corrective actions concerning the use of personal protective equipment.

6. According to the FMEA, the key problems related to the risks analysed at workplaces include misinterpretation of the transmitted data, low awareness of staff about the effects of contact with chemical substances, monotony and monotype of the performed tasks.
7. As a result of the risk assessment using the Risk Score, the following were indicated as key threats:
human collisions with a moving vehicle, fire and contact with a material factor.
The conducted in-depth analysis of the occupational risk for the position of the bottling line operator will allow the improvement of risk management in the examined enterprise, and the implementation of the suggested corrective actions will increase the level of safety and operator awareness.

Abstract

Given the incessant number of project failures in the construction industry in both developed and developing nations alike, it becomes increasingly important to examine the literature to determine possible factors that can be accounted for the massive project failures in construction projects. A review of the literature revealed that majorly a lack of competence by project managers was a crucial factor in determining construction projects success or failures. Over the last decade, a large number of studies have been carried out on project managers' competencies, however systematic literature reviews (SLR) are still scare in this area. Hence, the purpose of this paper was to conduct a systematic literature review to determine firstly the critical success factors for construction projects as well as identify what project managers' competencies were associated with project success in the construction industry. A synthesis of the findings in the SLR revealed several project managers competencies of which communication, commitment, experience and leadership were considered the most critical competencies for project success. The review revealed that there is a lack of empirical studies establishing the relationship between project managers' characteristics (i.e., their competencies, experience in managing projects as well as their adherence to the critical success factors) and project success, which can be avenues for more empirical investigations in the future.

Keywords: Project Manager Competency, Critical Success Factors, Project Success. Construction projects.

Introduction

The construction industry is a complex sector of the economy that is characterized by a wide range of stakeholders and has wide-ranging associations with other activities such as production, material use, energy, finance, labour, instrumentation and so on (Osei 2013). Construction activities are constantly evolving due to the changing dynamics of technology and the business landscape, and as a result, more complex construction projects are now being undertaken than ever (Abouen et al. 2014, Anantatmula 2010). With the complexity of construction projects now evident, the challenges that come with such complexity are also now more apparent (Omran 2015, Abouen et al. 2014). Notwithstanding, project managers and stakeholders are still expected to deliver projects successfully according to the specific requirements that bounds such project. Traditionally, project performance, as well as success, have been evaluated by some criteria that include delivering a project within schedule, within budgetary constraints (cost) and with the expected quality (Gerges 2015). Several scholars in the field of project management acknowledge the importance and critical role of project managers' competencies in determining a project's performance or outcome (Ahmadabadi and Heravi 2019, He et al. 2019). In the words of Ahmed and Philbin (2020), project managers' competencies have been cited as a critical success factor for determining the success or failure of a project. This thus implies the indispensable role of project managers' competency and its influences on project success. Ahmed and Philbin (2020), asserts that competence is an area of work, competency, on the other hand, is the behaviour supporting an area of work while competencies are the attributes underpinning a behaviour.

Competencies according to Garman and Johnson (2006) are characteristics of employees with behavioural implications that are thought to be associated with the successful performance of their jobs. Similarly, Draganidis and Mentzas (2006) define competencies as a combination of tacit and explicit knowledge, behaviour and skills that gives an individual the potential for effectiveness in task performance. In the context of project management, competencies are defined as a cluster of related knowledge, attitudes, skills, and other personal characteristics that affect a major part of one's job; correlates with performance on the job; can be measured against well-accepted standards; can be improved through training and development (Project Management Institute 2013). Crawford and Turner (2007) assert that the competencies of project management personnel are closely related to project success. Howbeit their close relationship, research (Ahadzie et al. 2009, de Carvalho et al. 2015, Tabassi et al. 2016) has shown that although project managers' competencies may directly or indirectly influence project success, the later is essentially different from project managers competencies and the criteria upon which both concepts are based may also be different (Nixon et al. 2012, Ahmed and Philbin 2020).

Attaining project success is ultimately the goal of every construction project. Abdullah and Ramly (2006) stated that defining project success is quite illusive. Several authors have attempted to define project success, but the concept of project success remains quite unclear. Ika (2009) also affirmed that project success is particularly difficult to define, given that the criteria used to define this concept is dependent on those selected by the project team or stakeholders. Traditionally, in project management, project success is measured against performance criteria such as cost, time, scope and quality; whereas in the present era, project success is measured against the overall goals of the project-which may include in addition to the performance criteria (cost, schedule, scope and quality), the end user's satisfaction, the strategic aims of the client, profits to the stakeholders and project staff, among others (Ika 2009).

Given that fundamental differences exist between project managers competencies and project success, although the former may be a direct or indirect antecedent to the latter, critical questions such as what are the critical success factors for construction projects? What specific project managers' competencies are associated with project success? How do the competencies required for project success differ from the critical success factors for project success? To answer these questions empirically would at a starting point require an in-depth analysis of the literature to determine exactly what has been done regarding the project managers competencies that are associated with project success. A literature review is an important tool for researchers to manage the diversity of knowledge emanating from academic research. A systematic literature review (SLR) on the other hand differs from traditional literature reviews since SLRs adopt a scientific, transparent and repeatable process to mitigate bias and provide an audit trail for the conclusions of the study (Ahmed and Philbin 2020). According to Klassen et al. (1998), "a systematic literature review is "a review in which a comprehensive search for relevant studies on a specific topic, and those identified are then appraised and synthesized according to a pre-determined explicit method". This enables the collection of existing data relative to a topic that allows for objective, comprehensive, and transparent integration and synthesis of research findings. Given that Ahmed and Philbin (2020) asserted that systematic literature review is limited especially with studies on project managers' competencies that influence project success, it is particularly important to explore from an SLR point of view the topic of project managers' competencies affecting project success. To guide the systematic literature review, the following guiding questions are put forward, they include;

1. What critical success factors underscore construction projects in the project management literature?
2. What are the project managers' competencies associated with project success in the construction industry in the literature?
3. Based on a synthesis of the literature, what empirical research pathways regarding the competencies required for project success in the construction industry can be explored?

Methods

Research Approach

A Systematic Literature Review approach was used in this paper. The systematic literature review provides an organized and systematic procedure for critically analyzing research papers (Petticrew and Roberts 2008, Pickering and Byrne 2014). Similarly, Klassen et al. (1998) stated that SLR is a review in which a comprehensive search for relevant studies on a specific topic, and those identified are then appraised and synthesized according to a pre-determined explicit method. Furthermore, Evans et al. (2017) explain that a systematic review process enables researchers to utilise transparent review procedures to source for, evaluate, analyse and synthesise the results of relevant research well in advance to ensure that the process can be repeated and replicated. The SLR approach was used in this review as a systematic tool to analyse and critically evaluate the project manager literature to ascertain

firstly what the literature considers critical success factors for construction projects as well as evaluate the project managers competencies that are directly or indirectly associated with project success in the construction industry. Based on the analysis of the literature, the researchers proceeded to synthesize some research pathways that can be validated using empirical research methods.

Searched Keywords

Published research articles investigating project manager's competencies, critical success factors for construction projects and related areas were searched from different databases. The researchers utilized Padalkar and Gopinath (2016) approach in searching for relevant materials for the review. However, the focus of the search was limited to titles and abstracts of articles published in the project management literature in the last decade. This was done to ensure that the articles contained a sufficient level of detail on project management and associated project managers' competencies as well as critical success factors. de Araújo et al. (2017) suggested that in executing the SLR, an initial search using adequate keywords should be performed to gain a sense of the output generated by such keywords. Hence following de Araújo et al. (2017) recommendations a search was performed through various databases using the following keywords and combined with Boolean Operators where necessary. The keywords include: "Project manager competencies", "Project Success", "Project manager competencies" AND "Project Success", "Project Success" AND "Construction".

Article Sources

The researchers took cognisance of the fact that the topic of Project Managers' Competencies and Project Success is not particularly new; hence ensured that databases with majorly vast research articles and exposure were used to source for studies that were used as data sources for the SLR. The Scopus database is the largest in the scientific community for academic literature. Hence was selected as a source for articles in this review. The second-largest database is the web of science. The web of science was also selected as an article source for the SLR. The researcher employed the use of the two largest research databases in order to gain access to the plethora of studies encompassing project managers' competencies and project success.

Research Design

Research papers were first identified using the following keywords (1) project manager competency, (2) project success, (3) critical success factors, (4) project manager competency and project success, (5) project success and construction. Doing this allowed the researchers to reach the needed coverage of project managers competency and project success. Figure 1 shows the systematic review flowchart for the study. Identified studies using the above keywords were then limited by the field of study as shown in Figure 1.

n = number of articles meeting specified selection criteria
Ex. = number of articles excluded

Figure 1: Systematic Literature Review Flowchart

The researchers then proceeded to screen the article titles and keywords to identify those that included relevant keywords. Those which included relevant keywords were pooled in category A and those which did not include this criterion were pooled in another category B. The abstract of articles in category A was further screened to determine if they met the purpose and significance of the study. Articles which were deemed important and significant were retained, while those that did not meet the eligibility criteria were deleted. At this stage articles which met the eligibility criteria for the paper were thoroughly read and critically reviewed. Few articles (n=8) which included relevant keywords but did not meet other criteria such as the study's scope as well as did not contribute to the objective of the review were later deleted. Hence, at this stage, a total number of 29 studies were then used for the review.

Selection Criteria

In developing the selection criteria for articles, Riaz and Igarashi (2013) approach was used. The initial search mandated that the articles included in the review meet the following criteria: (1) be published in the English Language; (2) be published in a peer-reviewed journal; (3) be related to the construction, engineering or project management field; and (4) include the specific searched keywords. The resulting number of articles found using the specified keywords in the selected databases were 1222 Furthermore, the researcher examined the resulting papers from both

databases to determine whether there were any duplicate articles. Given that the search for articles was made in two of the largest scientific publication databases, some duplicates were found and deleted accordingly. Subsequently, the researcher conducted a second screening to ensure that selected articles conformed to the selection criteria before the full-text articles were retrieved from the aforementioned databases

Analysis and Discussions

In our analysis of the literature, we put forward several questions to guide the review. Based on those guiding questions, the following information was abstracted from each reviewed article (1) the critical success factors that underlie construction projects based on the findings from the research literature (2) projects managers' competencies that are associated with construction projects (3) the empirical research pathways regarding project managers' competencies that can be inferred from the analysis of the literature.

Critical success factors for construction projects

As a starting point in the analysis of the literature, we sought to critique the literature to determine the critical success factors that are crucial for construction projects. Jari and Bhangale (2013) defined critical success factors for construction project as factors that can increase performance, improve success likelihood, and prevent critical delays during construction. The CSFs are crucial for taking proactive measures for the success of construction projects. Ahmadabadi and Heravi (2019) highlighted that the most important critical success factors within the project life cycle include: project mission, client consultation, technical tasks, client acceptance, supervision, and feedback, problem-solving, project manager's interpersonal competence and leadership skills. Table 1 shows a matrix of the critical success factors for construction projects based on existing project success frameworks.

Table 1: An overview of critical success factors for construction projects

Framework	Factors
Pinto and Slevin (1987)	Project mission, top management support, project schedule/plan, personnel, technical tasks, client acceptance, client consultation, communication, monitoring and feedback, and troubleshooting.
Belassi and Tukel (1996)	Project organisational structure, functional managers' support, project champion, Top management support, Project manager, and project characteristics, project team members, and the external environment (political, social, economic, and technological).
Holland and Light (2002)	Project mission, top management support, project schedule/plan, client consultation, personnel, technical tasks, client acceptance, monitoring and feedback, communication, troubleshooting, legacy systems, ERP strategy, business process change and software configuration.
Bradford and Florin (2003)	Perceived complexity, top management support, organisational objectives consensus, business process reengineering, training, and competitive pressure, technical compatibility.
Belout and Gauvreau (2004)	Project mission, top management support, project schedule/plan, client consultation, personnel, technical tasks, client acceptance, monitoring and feedback, communication, and troubleshooting.
Nah, Islam, and Tan (2007)	Top management support, project management, enterprise-wide communication ERP teamwork and composition.
Bradley (2008)	Project manager "full time, experience and reporting level'', top management evolvement, use of consultants, user resistance, champion and steering committee, ERP integration, and training quality and quantity.
Boo Young Chung et al., (2008)	User related variables (output, job relevance, image, result demonstrability, compatibility and system reliability) and project-related variables (internal support, function and consultant support).

El Sawah, El Fattah Tharwat, and Rasmy (2008)	Top management support, company-wide support, organisational culture, effective project management, users‟ training and involvement, consultants‟ and vendors‟ support, business process reengineering, careful package selection and minimal customisation.
Tarawneh (2011)	Experienced project manager, user involvement, formal methodology, standard software infrastructure, clear business objective, executive support and minimised project scope, reliable estimates, understanding requirements and managing requirements changes, organisational culture.
Abdulaziz and Mayhew (2015)	Top management support and commitment; strategic planning; project management; project team competencies; communication management; stakeholder management; partner and supplier management; training and education
Bond (2015)	Project mission, top management support, project schedule/plan, personnel, technical tasks, client acceptance, client consultation, communication, monitoring and feedback, and troubleshooting, Leadership Styles (Transformational Leadership Style, Transactional Leadership Style, Passive/Avoidant Leadership Style**),** Years of Experience

The matrix above shows that a critical understanding of the project mission, support from top management, a good project plan/schedule, experience, technical skills, project managers with proficient competencies, adaptive methodology/strategy, clear business objectives, monitoring and feedback, training and education, organizational culture, use of technology are some of the critical success factors for construction projects (Almajed and Mayhew 2015, Bond 2015, Chung et al. 2008, Bradley 2008, Bradford and Florin 2003, Belout and Gauvreau 2004, Tarawneh 2011, Nah et al. 2007, Holland et al. 1999, Belassi and Tukel 1996, Pinto and Slevin 1987, Ahmadabadi and Heravi 2019, Jari and Bhangale 2013). These identified critical success factors can summarily be referred to as the competencies that project managers require to achieve project success in the construction industry given that competencies according to PMI (2013) imply a cluster of related knowledge, attitudes, skills, and other personal characteristics that affect a major part of one's job, correlates with performance on the job, can be measured against well-accepted standards, and can be improved through training and development. The particular interest to project managers is how can these core competencies for project success be developed and harnessed to bring about project success in the construction industry? The literature also has reported on project managers' competencies that are crucial for project success. The next section discusses the identified project managers' competencies that are associated with construction project success.

Project Managers Competencies associated with Construction Projects

The researchers examined the literature to identify those core competencies that are associated with project success. Our review of the literature revealed a "shopping list" of these core competencies (Stevenson and Starkweather 2010, Moradi et al. 2019, Meredith and Mantel 2009, Kerzner 1998, Fisher 2011, Dillon et al. 2011, Dainty et al. 2005, Cheng et al. 2005, Alvarenga et al. 2019, Ahsan et al. 2013, Ahadzie et al. 2008, Project Management Institute 2013). Wen and Qiang (2019) explain that knowing what project managers do and what competencies they need is a critical step in their selection and development. Hence, Table 2 shows a matrix of the project managers' competencies associated with project success in the construction industry. These competencies range from experience to technical competence, communication, time management, adequate planning/scheduling, interpersonal skills, productivity, teamwork, monitoring and controlling in terms of cost, time, risk, quality and scope, project definition/specification, functional and contextual competencies, conflict management among others.

de Rezende and Blackwell (2019), explored project managers competencies and concluded that some of the most important competencies required by project managers for project success are; the capacity to influence, communication skills, emotional intelligence, contextual skills, managerial skills, cognitive abilities, professionalism, knowledge and experience, project management knowledge, and personal skills and attributes. In a similar vein, Alvarenga et al. (2019) explored the core project managers' competencies that are crucial for project success and proposed seven broad categories of competencies which includes: leadership, self-management, interpersonal, communication, technical, productivity and managerial competencies. However, Alvarenga et al. (2019) made claims that three of the most crucial and important competencies were communication, commitment and leadership. Furthermore, Joslin and Müller (2015), investigated the leadership competency profiles of successful project managers and found that the competencies crucial for project success were managerial, emotional and intellectual competencies. Also, the experience of project managers was one of the key competencies for project success that

several authors mentioned in their studies (Keren et al. 2014, Hoxha 2017, Bredin and Söderlund 2013, Armstrong 2015). This implies that project managers in addition to developing core competencies such as communication, leadership, and even technical skills must gain experience in order to successfully execute and complete construction projects. Experience is no doubt a critical competency for project success given its influences on knowledge, training and performance (Silva et al. 2019, Paton and Hodgson 2016, Jeong and Bozkurt 2014). Blixt, Carley & Kirytopoulos, (2017), researched the competencies of project managers in Australian public services where the results showed that a lack of experience was a major factor in failed project completion.

Some Empirical research pathways emanating from the review

Given the review of the literature examining project managers' competencies for project success, some gaps in the literature are no doubt evident. Hence, these identified gaps present opportunities for some empirical research investigations. Several studies in the project management literature acknowledge the importance and role of project managers' competencies, leadership, and the potential they can have in determining a project's performance or outcome. However, a review of the current literature reveals that there is a lack of empirical studies establishing the relationship between project managers' characteristics (i.e., their competencies, experience in managing projects as well as their adherence to certain critical success factors) and project success (He et al. 2019, Ahmadabadi and Heravi 2019, Ika 2009, Jitpaiboon et al. 2019). In a study conducted by Turner and Zolin (2012), it was revealed that the literature on project success did not essentially include an account of project manager's competencies, capabilities as well as adherence to some specific critical success factors (CSFs) as criteria that may lead to project success in the construction industry. The authors revealed that this was a direct contrast to the general management literature, which considers project managers' competence and other managerial characteristics such as experience and project manager's adaptation of the CSFs as important parameters for success in the management of organizations; thus, necessitating the need for further study in this area. Similarly, Anantatmula (2010), argues that there is a grey area in the literature because the specific competencies required by project managers and their roles in project success, especially in a developing country context has not yet been sufficiently addressed.

He et al. (2019) provided more support for research in this area when they argued that considerable effort had been expended in investigating the barriers to project success and strategies in the construction industry in developed nations like the United Kingdom (UK), whereas in examining the factors for improving the likelihood of construction project success in developing areas, so little has been done, which has consequently led to massive failures in construction projects in developing countries. He et al., (2019) also argued that the variations in social and cultural contexts of countries could result in errors in the application of project success theories or may necessarily require more region-specific strategies. This provides more grounds for more contextualized and region-based research in this area, in order to help contribute to research that may improve the practice of project managers in the construction industry.

Conclusions

The review sought to examine the project management literature to identify project managers' competencies that were associated with construction projects. A list of project managers' competencies was identified. Planning and organizing were critical success factors that are considered significantly important for an engineering project manager to achieve the project objectives of delivering a project in accordance with budgetary, schedule, scope, and quality constraints. Furthermore, in the review, our synthesis of project managers competencies that were crucial for project success revealed that communication, leadership as well commitment as the most critical CSFs for project managers. These skills are important for a project manager to effectively and efficiently manage construction projects as well as the teams and stakeholders involved in these project types. The SLR revealed that a project manager possessing certain of these competencies may achieve success, however, that does not necessarily guarantee the successful delivery of construction projects. Nonetheless, the adoption of critical competencies (such as communication, leadership skills, experience, adhering to some critical success factors as well as possessing technical competence, the ability to lead and develop teams, managing resources, as well as planning, were critical to the successful delivery of construction projects. These competencies would arguably improve the probability of project success and help to mitigate project risks. Besides, the success, or failure, of any construction project will be dependent on the specific project characteristics as well as less tangible aspects, such as the attitude adopted by the project manager, willingness to accept and respond to unforeseen changes as well as personal resilience. It is also worthy of note, that technology use/digitization was also one of the core competencies project managers require to successfully deliver construction projects especially in the 21st century. Knowledge/competence in applying and utilising technology tools to solving problems in and off construction sites is critical to the success of construction projects. Technological advancement in the 21set century has developed rapidly, and it would be interesting to explore how project managers' knowledge/competency on several technology tools impacts project performance or success in the construction industry. This can be further explored empirically. The review culminated with some suggestions for further research that became evident as a result of some gaps which were identified in the literature.

Acknowledgement

This research was supported by the Ministry of Higher Education, Libya and Universiti Teknologi Malaysia. Special thanks go to my academic supervisors Associate Prof. Dr. Aminah Md Yusof and Dr. Nur IzieAdiana Abidin for their invaluable insights and feedback in carrying out and writing this SLR paper.

Abstract

The speed at which COVID-19 has altered global education systems is unprecedented. In an effort to enhance support systems during the prolonged crisis period, and to better prepare Higher Learning Institutions (HLIs) for similar future events, this survey was conducted to capture the state of Universiti Tun Hussein Onn Malaysia (UTHM) students' well-being in the context of university support during the COVID-19 pandemic. The main objective of this paper is to help the university to formulate effective policies to respond to the coronavirus (COVID 19) outbreak they can further improve on communication with students to ensure the latter is updated frequently. Considering the survey findings, recommendations are made for administrators, lecturers, and students to address student well-being and continuity of learning during the coronavirus pandemic situation.

Keywords*:* Higher Learning Institutions, student learning, learning resources, COVID-19

Introduction

At the outbreak of the Covid-19 global pandemic, few educational institutions were fully prepared for a global pandemic, including UTHM. UTHM students are located at UTHM Parit Raja and Pagoh campuses. UTHM Parit Raja is the University's main campus with six faculties and the Pagoh campus is a satellite campus with three faculties located 84km north of the main campus. To enhance current support systems and responses during the prolonged crisis period, and to better prepare for future similar events, this survey was conducted to capture the state of students' well-being and learning effectiveness during the COVID-19 pandemic. At the time of writing the crisis is still ongoing. This report thus aims to help the University better understand the challenges that students are facing, and continue to face, as the crisis plays out. Having 'real-time' data can help the University formulate more effective and

responsive policies to ensure that student well-being and educational quality are given the highest priority by the University.

Literature Reviews

During the implementation of the third phase of Movement Control Order (MCO), university students play an important role in the effort to slow down the COVID-19 outbreak in the country. Despite appeals from students in public and private Higher Learning Institutions (HLIs) that are still stranded on campus and off-campus to return home, the government has decided that they need to remain in their respective universities (Endan, 2020). According to Guo (2020), the fear factor also significantly affects the family decisions on the students' mobility during the outbreak. Meanwhile, Elmer, Mepham, and Stadtfeld (2020) pointed out that the COVID-19 has forced universities management to take drastic measures that affect students to interact and socialize with each other. They discover that there is an effect of social isolation and the development of mental health problems among students during the COVID-19 crisis. Here, it is important for university management and the government to closely monitor the situation with the strategy for helping students in fighting the COVID-19 pandemic (Zhai, & Du, 2020; Chesser, Drassen Ham, & Keene Woods, 2020).

Methodology

The survey aims to help UTHM's leadership team understand the potential impact of the outbreak on students, providing greater clarity on what kinds of technological and psychosocial support are needed to address their students' needs. The survey included 4,221 undergraduate and postgraduate students from different faculties within UTHM. Invitations were sent to all students by messaging through each respective faculty's WhatsApp [an android based messaging mobile application] group coordinated by the Deputy Dean for Academic Affairs. The message contained a hyperlink to the online survey for subjects to complete that included a description of the project. The online survey method was used because it is easily accessible in the time of crisis and cost-effective. The survey was administered using the online survey portal, Survey Monkey (Online survey services, San Mateo, CA, USA). Anonymous responses were collected, and the completed survey was tabulated in Microsoft Excel

Results and Discussion

The survey included 4,221 undergraduate and postgraduate students from different faculties within the University. The mean age of the sample was 22 years comprising 47.9% males and 52.1% females. In terms of the perceived severity of COVID-19 on their well-being and learning readiness, most students were very concerned and found it difficult to work effectively at home or their campus hostels during the early period of the outbreak. Despite the difficulties experienced, the students were optimistic about their future and the university leaders' ability to manage the crisis and provide adequate support to students. Challenges faced by students include difficulty undertaking online learning due to internet connectivity especially to those staying at home and available means to communicate. A critical success factor for students to engage in online learning during a crisis is their technological capacity to use online tools. The findings indicate that UTHM students reported an average of data capacity to carry out online learning and a level of accessibility to learn via popular social media apps. Despite the challenges of internet connectivity, the students took the effort to use their data capacity to access the learning resources provided by lecturers.

While UTHM has formulated effective policies to respond to the coronavirus (COVID 19) outbreak they can further improve on communication with students to ensure the latter is updated frequently. Considering the survey findings, recommendations are made for administrators, lecturers, and students to address student well-being and continuity of learning during the coronavirus pandemic situation.

Our first concern was to gauge students' perceptions of their general well-being during the crisis. This was obtained through questions about how worried they felt about the outbreak, their perceived difficulties in completing their work, the biggest challenges they faced, how long they could see themselves working under the movement restrictions, and their sense of optimism about their future. Figure 1 illustrates that most students were staying at home (79.8%) during the crisis period, with 10.4% near to the UTHM campus and 9.8% staying on campus. As a result, a large percentage of students were staying with their parents and siblings at home.

Figure 1: Student location and with whom they are staying

Most students reported staying with parents (76.5%) and siblings (60.4%). 17.6% reported staying with friends.

As illustrated in Figure 2, 46.2% of students felt that the university should communicate with them a few times per week, while another 26.3% preferred receiving news updates from the university once a week. One-quarter (25.3%) preferred daily updates from the university regarding the crisis.

Q20: Residence near campus	1.00	4.00	2.00	1.95	0.82

Figure 2: Preferred frequency of university communication with students

When compared across the three groups, students staying at home preferred more frequent communication from the university -- at least a few times a week (M = 2.08). Surprisingly, students staying in and around campus preferred daily communication from the university (M = 1.94 and M = 1.95).

As illustrated in Figure 3, most students reported a high level of confidence with university management's ability to manage the current crisis (44.2%). 14.9% said they felt very or extremely confident with the university management. Only 32.3% of students reported feeling somewhat confident and 8.7% had little or no confidence at all.

Figure 3: Students' confidence with the university leadership's ability to manage the current crisis

Like the previous finding, Figure 4 shows that most students were very confident in the level of assistance provided by the university during the crisis (93.6%). Only 1% of respondents reported having no confidence in the resources provided

Figure 4: Confidence in the resources and assistance provided by the university

Considering the findings, we propose the following recommendations for UTHM administrators, lecturers and students to address student well-being and continuity of learning during the coronavirus pandemic situation

University Administrators

- University Administrators should ensure that the university COVID 19 response team's governance structure enables them to effectively handle the crisis and provide support to internal and external clients efficiently, with a high degree of accountability and transparency.
- University administrators should empower their response team by using daily real time data as a source for executing and monitoring policies and delivery strategies to respond to student needs.
- Considering the students' reported concern regarding their wellbeing and learning trajectory, University administrators should consider working closely with lecturers and student counsellors to provide online or telephone counselling to address students' emotional and psychological needs.
- University Administrators should prioritize regular and consistent communication with students to update them on the latest developments relating to the crisis, including the implementation of university responses and policy updates. UTHM should be applauded for having a dedicated COVID-19 website link that is visible, interactive and comprehensive. The university might consider ensuring that the links are integrated with the latest information and frequently asked questions regarding academic, support services for students' and staff members' reference. This link would also continue to serve as the main line of communication for UTHM decision-makers to share the latest news and policy updates related to the crisis.
- University Administrators should maintain close collaboration with internal and external stakeholders to ensure that adequate resources related to effective crisis management are allocated.
- University Administrators should ensure that the university has the appropriate cost model and capital efficiency to address the financial needs of the university community during the crisis.

Lecturers

- University lecturers should communicate regularly to ensure students' well-being and to provide intellectual and emotional support.
- University lecturers should make full use of online discussion platforms and social media like WhatsApp, Facebook, and other online meeting apps to communicate and collaborate. They should also accumulate online learning resources including virtual reality VR contents that can be shared with fellow lecturers and students.

Students

- University students should communicate frequently with peers to provide and receive updates on each other's well-being and to provide intellectual and emotional support during the crisis period.
- University students should make full use of technology to ensure that they are accessible to lecturers and peers and can undertake online and distance learning whether they are on or off campus.
- University students should prepare themselves for social distancing, staying at home and engaging in beneficial activities. They should continuously communicate with their peers to combat boredom, depression and anxiety during the isolation period.
- University students should make use of online and phone counselling services if needed.

Conclusion

While the university has formulated effective policies to respond to the coronavirus (COVID 19) outbreak, nearly half of the sampled students 26 expected the university to communicate more frequently with them to ensure that they are updated with the latest information and instructions on dealing with the crisis. Perhaps surprisingly, students staying in and around campus wanted more frequent communication from the university. University Administrators should prioritize regular and consistent communication with staff and students to update them on the latest developments relating to the crisis, including the implementation of university responses and policy updates. UTHM should be applauded for having a dedicated COVID-19 website link that is visible, interactive, and comprehensive. The university might consider ensuring that the links are integrated with the latest information and frequently asked questions regarding academic, support services for students' and staff members' reference. This link would also continue to serve as the mainline of communication for UTHM decision-makers to share the latest news and policy updates related to the crisis.

Abstract

The purpose of this paper is to highlight the potential impact of the outbreak on students learning in one of the public universities in Malaysia, providing greater clarity on what kinds of technological and psychosocial support are needed to address their students' needs. A set of online questionnaires distributed to students through social media, using the online platform Survey. Data were collected during the early stages of the COVID-19 Mandatory Control Order (MCO) period from 26th March to 3rd April 2020. The survey included 1,450 undergraduate and postgraduate students from different faculties within one university in Malaysia. Results indicated that some of the challenges faced by students include difficulty undertaking online learning due to poor or unreliable internet connectivity, unfamiliarity with online learning mode, and difficulty completing online learning tasks assigned by lecturers. In light of the survey findings, recommendations are made for administrators, lecturers, and students to address student well-being and continuity of learning during the coronavirus pandemic situation

Keywords*:* Higher Learning Institutions, student learning, learning resources, COVID-19.

Introduction

To meet with the COVID-19 challenge, Higher Learning Institutions (HLIs) require primary data combined with real-time analytics to gain insight into the well-being and learning needs of their students. HLI leaders need to know the most effective ways to innovate and adapt to best support their students and ensure continuity in providing high-quality teaching and learning experiences. HLIs' decisions on how best to continue serving their students should be based not only on the collective wisdom of HLI leaders but also on data from the students themselves. Real-time data is critical for providing HLI leaders an accurate picture of the situation, resulting in effective responses to the crisis. This paper thus aims to help the University better understand the challenges that students are facing, and continue to face, as the crisis plays out. Having 'real-time' data can help the University formulate more effective and responsive policies to ensure that student well-being and educational quality are given the highest priority by the University.

Literature Reviews

Viner, Russell, Croker, Packer, Ward, Stansfield, and Booy, (2020) highlighted that in order to overcome the transmission of COVID-19, many countries had instituted large-scale or national closure of learning institutions by March 2020. Due to that, the students' anxiety about COVID-19 has an impact not only limited to their health but also on their studies as well as employment (Cornine, 2020; Cao, Fang, Hou, Han, Xu, Dong, & Zheng, 2020; Wang, Horby, Hayden, & Gao, 2020).

As for learners and trainers, the eduction via a virtual world has become a new challenge for them. The global crisis due to the spread of the COVID-19 outbreak not only results in conventional teaching and learning postponed but also becomes increasingly challenging as they need to adapt to the new norms and habits that require the learning process to be implemented online (Berita Harian, 2020). Mamat (2020) argued that the world needs to elect the virtual learning process as an alternative to face-to-face learning 'mode' although the move may be seen as slightly challenging and limited. As for that, the implementation of e-learning should be utilized preferably during the limitations of movement caused by the COVID-19 pandemic (Abas, 2020).

Methodology

To ensure that the data collected would be relevant, this survey was compiled in the midst of the crisis. The initiative began in the middle of March 2020 with a target of one month from conceptualization to publication of findings. More specifically, data were collected during the early stages of the COVID-19 Mandatory Control Order (MCO) period from 26th March to 3rd April. As everyone was working under the same isolation restrictions, the research team took full advantage of online research and collaboration tools in the planning, communication and conduct of the research activities. The online surveys were password coded and secure so that only one respondent was able to access the survey at a time. Data were managed by one of the research team members and kept confidential at all times. All responses were anonymous -- no identifying information was collected. The findings are presented according to percentages, to acquire a general profile of students' experiences during the crisis.

Results and Discussion

The mean age of the sample was 22 years and the gender makeup of the sample closely followed the university as a whole, as 80% of respondents were female. As illustrated in Figure 1, 81.6% of students reported feeling were worried or extremely worried about the trajectory of their studies given the situation. Of note, students reported feeling more concerned about the impact of the outbreak on their studies, than on their general well-being (53.6% to 43.8%). Clearly, this is a serious issue for students that requires attention from decision-makers.

Figure 1: Impact of Coronavirus on students' anxiety

As illustrated in Figure 1, the vast majority of students (81.2%) were either very or extremely worried about the impact of the pandemic on them personally. This indicates that the perceived severity of the situation is very high. It also indicates a strong awareness of the threat that the outbreak poses to different aspects of their lives.

Figure 2: Impact of Coronavirus on students' learning

As illustrated in Figure 2, more than half of the students (55.6%) felt that carrying out their learning was at least somewhat difficult. Only 16.5% of those sampled felt that the current situation was easy for them.

Figure 3: Perceived difficulties learning these days

The findings from Figure 3 indicated that the students have difficulty adapting to the learning process during the COVID-19 pandemic. Here, the teaching and learning methods have changed from face-to-face or traditional modes to the virtual learning activities. Therefore, many factors influence the students' readiness and awareness of virtual learning and these factors might cause some difficulty to the students.

A critical success factor for students to engage in online learning during a crisis is their technological capacity to use online tools. The findings indicate that out of five stars, students reported an average (three stars) data capacity to carry out online learning. The results suggest that there is a limited ability for the students to use online learning during the COVID-19 pandemic.

	1	2	3	4	5	TOTAL	WEIGHTED AVERAGE
☆	7.8% 71	15.3% 139	34.8% 316	25.8% 234	16.3% 148	908	3.27

Social media can be leveraged to support online learning. Our students reported (four out of five stars) a high level of accessibility to learning via popular social media apps. Social media have a big influence on the approach of teaching and learning processes and is found to be very popular among students. Indeed, social media also can become a platform for students and lecturers to be closer and friendly bring up the process of teaching and learning.

	1	2	3	4	5	TOTAL	WEIGHTED AVERAGE
☆	6.0% 53	11.7% 103	29.3% 258	24.5% 216	28.6% 252	882	3.58

In light of the survey findings, we propose the following recommendations for administrators, lecturers, and students to address student well-being and continuity of learning during the coronavirus pandemic situation.

University Administrators

- University Administrators should consider reconfiguring the university calendar to limit lost learning time. Students expressed deep concerns over the prospect of the crisis derailing their academic progress. This can be facilitated through the widespread application of web-based, online, and distance learning support to students on and off-campus.
- Following the practice of other universities, the University website can be further enhanced by having a dedicated Covid-19 crisis link for students and staff that is visible, interactive, comprehensive, and integrated with all of the latest information and frequently asked questions regarding academic, support services and student affairs. This link would also serve as the main line of communication for University decision-makers to share the latest news and policy updates related to the crisis.

Lecturers

- University lecturers should use technology-based and alternative pedagogical tools to conduct online and distance learning.
- University lecturers should use alternative assessment approaches for student learning to account for the diversity in students' level of access to the Internet, geographical location, and other basic facilities.
- University lecturers should make full use of online discussion platforms to communicate and collaborate. They should also accumulate online learning resources that can be shared with students.
- University lecturers should find ways to prepare students for social distancing and to encourage beneficial activities while at home. They should employ strategies that will allow students to be able to communicate with their classmates to combat boredom, depression, and anxiety during the isolation period.

Students

- University students should make full use of technology to ensure that they are accessible to lecturers and peers and can undertake online and distance learning whether they are on or off-campus.
- University students should be ready to participate in different forms of teaching and learning, not only through face-to-face interaction but also alternative modes of learning and assessment.
- University students should learn from their peers and share learning resources to ensure that they are up to date with the lessons and course content.

Conclusion

Despite the difficulties experienced, the students were optimistic about their future and the university leaders' ability to manage the crisis and provide adequate support to students. Challenges faced by students include difficulty undertaking online learning due to poor or unreliable internet connectivity, unfamiliarity with online learning mode, and difficulty completing online learning tasks assigned by lecturers. While the university has formulated effective policies to respond to the coronavirus (COVID 19) outbreak they need to improve on communication with students to ensure the latter is updated frequently especially in relation to teaching and learning methods.

Quality Management of The Human – Machine System - Why Is Worth Developing the Ergonomic Designing?

Edwin TYTYK

Poznan University of Technology
Poznan, Poland
edwin.tytyk@put.poznan.pl

Abstract

In the paper defined is the concept of ergonomic engineering as a type of prospective engineering measures, which change the world of technical objects (artifacts) in the direction of increased ergonomic quality, safety for humans, and care for the environment. To effectively achieve this goal, it is necessary to make changes in thinking about the proposed system and the structure of the design process. The „check lists" used by designers serve to check the level of ergonomic quality, mainly of well-known design solutions and, to some extent, enable the improvement of this level through the correction of the faults observed in these designs. This approach is of little effectiveness. Radical improvement of the ergonomic level of products in this way is not possible. Modification of the aim should be obtained, implies the necessity for adequate modification of the method of obtaining it.
Important elements of the new structure of the design process of anthropo-technical systems are decision criteria, in terms of content belonging to the area of ergonomics. The paper presents the formulation of the principles of ergonomic decision criteria, tailored to the specific steps of design procedure and expressed in the engineering language.
Designing of anthropo-technical mega-systems encounters major methodological difficulties due to the multi-interdisciplinary nature of problems to be solved, incompleteness and uncertainty of knowledge of a prospective nature, and the risk of the appearance of unforeseen, adverse effects of engineering measures, which may become apparent in the long term.
The paper presents a concept of the structure of decision criteria that are relevant in the design process of elementary human-machine system and mega-systems of an industrial nature.

Keywords: Ergonomics, Design Criteria, Design Process, Ergonomic Quality.

Introduction

Costs of achieving high and satisfactory ergonomic quality of machines and other technological devices are considerable. They can be lowered, however, by the taking of proper decisions, from the point of view of ergonomics, already at the earliest stages of the product (e.g. machine) existence - i.e. at the phase of formulating project assumptions and in design process. In order to do that it is necessary to apply new design method which would ensure that the machine being designed meets the assumed proper ergonomic quality requirements.

The best known and used way of increasing the ergonomic quality level of products has been the „check lists" used by designers. They serve to check the level of ergonomic quality, mainly of existing design solutions (e.g. in the form of design documentation or prototypes of machines and devices) and, to some extent, enable the improvement of this level through the correction of the faults observed in these designs. This approach is of little effectiveness for methodological and psychical reasons. Radical improvement of the ergonomic quality level of products in this way is not possible. Modification of the aim which should be obtained (i.e. obtaining the product on high level of ergonomic quality), implies the necessity for adequate modification of the method of obtaining it.

Methodological Premises of The Ergonomic Design

The ergonomic design conception is based on the following methodological premises (Tytyk, 2001):

Cite this Article as: Edwin TYTYK " Quality Management of The Human – Machine System - Why Is Worth Developing the Ergonomic Designing?" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

1. Handling of the design object as a human - machine system and taking the interaction with environment into consideration – as well in case of automated systems which are characteristic for *Industry 4.0* (Figure 1d).
2. Ergonomic criteria ought to be treated with priority in relation to technical and economic criteria;
3. For each step of the design process, corresponding criteria should be assorted individually, by selecting them for the whole morphological space.

The ergonomic design strategy is most effective and allows to avoid many faults and deficiencies in technical solutions that have decisive influence on forming work conditions at the stage of the technical object exploitation.
The new approach to the design process, which is proposed here, is based on the three methodological assumptions:

a) The object being designed is a system: human - machine (or: human - technical object), acting in definite environment and time;
b) In the whole design process of the system, beginning from the stage of studying the problem and formulating assumptions, the decision criteria that are of a human-centric nature are taken to be as more important, having at least the same influence on the creation and selection of the concepts of design solutions, as the technological and economic criteria;
c) The ergonomic criteria, as the integral components of the design procedure, are properly selected for each step of the procedure. They contain information indispensable for designing each element of the system and connection between them, in such a way, that the demanded ergonomic quality level of the system is achieved.

The new method of creating of „user friendly" products has been called „ergonomic design".

Fig. 1: The different configurations of elementary human - machine system (Tytyk, 2005)

In traditional design processes dominate a linear sequences of steps linked by iterative loops. There exist a justified view that iterations in the technical design process are a necessary and inevitable evil, and their presence proves that our knowledge of the essence and results of design decisions is very superficial. The structure of the technical design processes well reflect the construction processes of such technological objects and their elements, which are not closely related to human while being in operation.

Morphology of Ergonomic Criteria

An integral component of the ergonomic design procedure (Figure 2) are ergonomic design criteria (Table 1). The contents and sequence of criteria should be matched defined phase of design process. Design criteria have been

elaborated in detail and included to the structure of ergonomic design process. It makes possibility to applying computer to design process, even taking into account their heuristic character (Butlewski, 2013).

Ergonomic criteria of design decisions are of very great importance in methods of design. These criteria differ from those of evaluation, applied in methods of ergonomic diagnosis. This difference depends on the difference which separates the diagnostic process from the design process. In the diagnostic process there is a finite (most often real) object of analysis and estimation; in the design process, on the other hand, the object is *in statu nascendi* as an unfinished and incomplete mental product. Therefore, in design criteria the most important are their informative and implicative aspects; in diagnostic criteria, however, it is the imperative aspect (Tytyk, 2001).

The primary ergonomic criterion is the optimization of matching machines, tools, technological devices, work environment and work organization to psychical, physiological and anthropometric features of a human. The criterion (meta-criterion) formulated in such a general way cannot be used in the design process of work-stands. It is necessary to decompose the meta-criterion into a set of more detailed criteria that could be measured and which would have a psychical form (real standard). There can be many ways of decomposition, but not all of them will be of good help in the design process.

There are many lists of criteria used for ergonomic estimation of work-stands. The common defect of these methods is the fact that they can be used only for estimation of a ready-made project, in the form of technical documentation, or a prototype. The design process still remains without the „ergonomic supporting". The hope for improving the existing situation can be associated with working out criteria that would have such a form and essence which would be adequate for a definite design decision. It is one of main assumptions of methodology of *ergonomic design*.

Each ergonomic criterion can be considered as an element of *n*-dimensional space, constructed of the following dimensions:

1) hierarchical;	4) essential;
2) functional;	5) subjective;
3) logical;	6) ranking.

1) *Hierarchy* deals with the degree of criterion generality and allows us to distinguish the strategic, tactical and operative degrees. Ergonomic criteria for design decisions can have a strategic character considering their effects on further stages of the design process (for instance: division of tasks between the human and the machine, selection of technologies, etc.). Carrying on this way of thinking one can distinguish decisions (and adequate criteria) of tactical and operative character with imply consequences of relatively little importance to the final effect of designing.

2) *Functions* in the design process state the primary matter performed by a criterion in the decisive process. The following functions have been distinguished:

* the informative function: consist in informing the designer about problems important from the point of view of ergonomics and in enriching his knowledge in this field;
* the imperative function: resolves itself into ordering the designer to apply standard solutions, ergonomically correct, obtained from the „bank of ergonomic solutions" (maybe created in future);
* the implicative function: assumes directing the designer's thoughts to ergonomic correct solutions thanks to the use of heuristic principles.

3) The *logical* form of a criterion is determined by the locus of this criterion in the continuum: cause – effect. In each point of this continuum the effect of the action of a certain phenomenon is the cause of occurrence of the next phenomenon.

4)The *essence* of a criterion is closely connected with the logical dimension of the morphological space. The distinguished phenomena have the following contents which is the basis for elaborating criteria:

* macrosocial phenomena (on the level of the society);
* microsocial phenomena (on the level of the factory);
* individual phenomena (on the level of a human organism);
* direct phenomena (on the line of contact: human – technical environment);
* micro-technical phenomena (on the level of technological and organizational structure of a plant);
* macro-technical phenomena (on the level of a branch of industry, regional or national economy, social policy).

It is obvious that not all types of criteria can be applied to the design process. Middle types of above list are worthy of special interest.
5) The *subjective* dimension states precisely from what point of view, or rather in whose interest ergonomic criteria are formulated. It is a not trivial problem, because we can distinguish without any difficulties many recipients of criteria, for example:

* performers of the technical devices (e.g. machine);
* operators of the machine;
* workers controlling the machine;
* repair and maintenance workers;
* aiding and transportation workers;
* natural environment.

During the selection of the criteria that takes into account this aspect, it is necessary to adopt certain preferences and compromises. The basic data for this can be, for instance, planned *time* of human's (recipient's) stay by the designed machine.

6) The *rank* of criterion arranges criteria in order established on the basis of values of ranks. The problem of rank stating is most often solved in the way of more or less arbitrary evaluation, although there are attempts to make ranking objective. It seems to be proper to base ranking of ergonomic criteria on quantitative description of the following features:

* pathogeny;
* cumulativeness;
* inclination to synergy;
* susceptibility of a human to the factor;
* the effects for the natural environment;
* and the like.

At the same time, these features deal with the factor which is the essential basis of the criterion.

The list of the ergonomic design criteria

The ergonomic criteria are the factors aiding and directing the design decisions. They constitute an integral component of the procedure. The contents and sequence of criteria appearing in the design

Table 1: Indications of the group of ergonomic criteria (acc. to: Tytyk, 2001)

Indication (see Fig. 2)	Design phase	Group of the ergonomic criteria
E-1	Work process design	1.1. Work contents 1.2. Work methods 1.3. Functions of technical equipment
E-2	Design of work area	2.1. Conditions of body posture 2.2. Area of movements and eyesight work 2.3. Architecture of technological object
E-3	Design of the signalling and controlling elements	3.1. Information and signalling elements 3.2. Controlling elements
E-4	Design of the physical, chemical and biological environment	4.1. Sources of air pollution 4.2. Sources of microclimate disturbance 4.3. Sources of vibrations and noise 4.4. Sources of injurious radiation 4.5. Light sources 4.6. Sources of injurious substances

process result from the order of problems occurring during the designing of the system: human - technological object. They have been put together, formulated at the general level, are shown in Table 1 (acc. to Tytyk, 2001).

Structure of The Ergonomic Design Process

The structure of the ergonomic design process has a different shape to that of the traditional structures of technical design processes, where it is dominated by a linear sequence of steps linked by iterative loops. The structures of the

technical design processes well reflect the construction process of such technological objects and their elements, which are not closely related to human while being in operation. The process of ergonomic design has a twofold structure with a close and direct links of the both trends. This dualism is an effect of the necessity to treat differently the „human" and „technical" elements of the designed system, and to division of tasks between „human" and „machine" (Tytyk, 2001). The ergonomic design procedure assumes that the designer will exactly realise its successive steps in a consistent and correct way. This procedure can also make use both: of the CAD software and of heuristic procedures. Ergonomic designing caused a considerable modification of the traditional design process structure (Figure 2).

Designing of the „human" component contributes to the procedure certain invariable resulting from the recognised (average and extreme) psychological, physiological and anthropometric properties of the population of prospective users of the technological object. Those invariable constitute, at the same time, limits and definite of specific solutions within the designed technological object.

At the stage of formulating assumptions for a design the most essential ergonomic problem is the division of the tasks, which the system is supposed to perform, between a human and the technological object. The traditional approach resolves itself to the definition of the level of mechanisation and automation of the work and the decisions being made are based on technical-economic premises such as: the permissible cost of the technological object, realisation possibilities, technological destination (to realisation of the technology in piece, series or mass production), the possibility of assembling the object into production lines, labour market, required qualifications of an operator, etc. It is necessary to include into this set of conditions, a set of ergonomic criteria, called at the strategic level „Work process" (indication E-1, in Figure 2 and Table 1).

At the stage of creating concepts of technical solutions and initial designing, the criteria comprising other spheres of ergonomic problems are helpful. After the division of tasks between the two components of the system and initial definition of the work methods of human (taking into account, among others, biomechanical rules of performing work movements), it is necessary to define the recommended and allowed body postures of a human at work and rest pauses, making use of the anthropometric data and information from the field of work physiology (criteria set E-2). On that basis an initial design of space configuration of the technological object can be made, realising one of the essential requirements of ergonomics: „design adjustment" of a machine to human. At that stage it is also necessary to elaborate activity concepts of the indispensable functional units of the technological object and take into account certain esthetical requirements, mainly concerning the form, in connection to the function of the designed unit.

Next, on the basis of the information concerning the ergonomic features of destination, construction and configuration of the definite types of checking, information and control devices (criteria set E-3), it is necessary to work out an initial design of the control-checking unit. It is also necessary to design, with the use of anthropometric data (E-2), the sphere of human manipulation of the tool unit, in such a way that the tasks performed by the whole system would proceed safely, for both: human and environment, and moreover – efficiently.

Figure 2: General structure of ergonomic design (acc. to: Tytyk, 2001)

The first step in the detailed designing is the prognosis of the size of human-load in the system on the basis of the predicted ergonomic attributes of the functional units. This is the physical load (dynamic, static, monotypic, hypokinetic), psychological load (intellectual and emotional) and sensory load (sight, hearing and other). If the prognosis is successful, i.e. if the possibility of excessive or insufficient load is excluded (taking into account the time of exposure to danger), the transition to the next step of the procedure will be justified. The particular functional units of machine should be treated as the emission sources of harmful energy and substances. The basic directions of searching solutions are marked out by the set and content of the strategic criteria belonging to the group E-4, whereas specific criteria from that group can indicate concrete ways of solutions.

Designing of an anthropotechnical mega-systems

It is easy to imagine the structure of the systems of a higher complexity, composed of many elementary human – technical object systems, (Figure 3). They can be called "anthropotechnical mega-systems" (ATMS).

Figure 3: Anthropotechnical mega-system (Tytyk, 2012)

In practice, these can be for example a production department, office, hospital, school, neighborhood, and even a mega-system called a technical civilization. Here we enter into the area of scientific study called macroergonomics (Hendrick at all, 2002). The environment of systems with a higher degree of complexity is different than for the elementary system: here factors come into play that belong to economics, sociology, ecology, politics, also culture (Wyrwicka, 2011). To make a macro-ergonomic evaluation of ATMS, one must take into account the criteria belonging to many different areas of meaning. Conditions for the formulation of criteria are provided in Table 2.

Based on the assumptions presented in Table 2, one can formulate ATMS evaluation criteria or the decision criteria used for making design decisions. The lean framework of this article does not permit for the further development of this problem. However, one can assume that the individual criteria areas (column 2 in Table 2) will be evaluated on a scale of relative values in the range (0-1), where zero means an extremely poor score, and one – an extremely good score.

A problem will arise for the aggregation of these indicators. Aggregation models based on averaging (algebraic, geometric, weighted) can be considered inappropriate, because one cannot find a logical justification for the hypothesis of one-way interaction of the criteria belonging to different areas. Therefore, a graphical interpretation of the aggregation of criteria belonging to different areas of meaning is proposed. For the example shown in Table 2, which highlights eight areas of ATMS criteria, a graphical illustration of the aggregation model is shown in Figure 4. The individual "rays" (1-8) represent the values of criteria areas on a scale of (0-1).

Table 2: Principles for the formulation of macroergonomic evaluation criteria (Tytyk, 2012)

No.	Criteria area of meaning	Substantive grounds for the formulation of criteria
1	Ergonomics	psychology, physiology, anthropometry, medicine, technology, work organization, management, work economy, occupational risk, qualitology
2	Ecology	ATMS' impact as a relatively isolated whole and its components on ecosystems (human, animal, plant) in various stages of ATMS and its components
3	Economy	ratio of output to input, efficiency, productivity, costs of reliability and resistance to changing operating conditions
4	Sociology	professional qualifications and education of people, professional ethos, gratuities for work, market demand for labor in the profession, worker mobility, interpersonal relationships, social behavior
5	Culture	moral principles, ethical and religious beliefs, family ties, traditions, compliance of corporate principles with one's own system of values
6	Well-being	subjective feeling of "ones place," an understanding of the world, acceptance of the rules of functioning in society, health, stability, perspective of personal and professional development, social interaction
7	Social safety	salary and other gratuities, job security, health care, social security, pensions, pro-family policy
8	Public safety	lack of danger to themselves and their families from other social, political, or religious groups, protection against natural disasters and technological, biological, chemical, or energy disasters

The maximum aggregate score is equal to the surface area of a regular octagon with radius equal to unity (R = 1), namely:

$$S_{\Sigma 8} = \frac{1}{2} \cdot 8\, R^{\overline{2}} \sin \alpha = 2 \cdot \sqrt{2} \qquad (1)$$

The aggregate measure of the macroergonomic quality of ATMS can be defined as the relation of surface area of an inequilaterally octagon, formed from the assessed criteria areas in order of decreasing values of score indicators, to the surface area of an equilateral octagon with sides equal to unity (maximum). After simple mathematical transformations, for any number of areas of evaluation criteria (*i*) it could be in the formula (2):

$$Q_{ATMS} = \frac{1}{8} \Sigma\, x_i \cdot x_{i+1} \qquad \text{if:} \quad x_i \geq x_{i+1} \qquad (2)$$

Figure 4: Graphical interpretation of the aggregation model of macroergonomic quality assessments

For example: using the formula (2), for the eight sub-points, in order of decreasing value: 0.9 – 0.8 – 0.6 – 0.5 – 0.5 – 0.3 – 0.2 – 0.1 we receive the aggregate scores of marcoergonomic quality with the value Q_{ATMS} = 0,25875 (Figure 4).

Conclusions

At the present time it is necessary or perhaps even indispensable to create a new quality approach to the process of designing in the field of technology. There is an urgent necessity for designers, constructors and engineers to acquire ergonomic knowledge so that they can create human- and environment-friendly technology. That kind of knowledge, in a specific way, influences evaluation of solutions to technical problems and generates modification of designing methods and its practical effects can be observed on the market of technical products.

Ergonomic knowledge implies the necessity of changes as far as designing methods are concerned. That is owing to the fact that we cannot reach the new goal (which is constructing a machine well-adjusted to a human being), using old, traditional methods of technical designing. The methods of ergonomic designing develop, following evolution principles – from "ergonomic assistance" of geometric designing and informative interface "human–machine" through an ergonomist assisting further steps of the designing procedure, to a radical rebuilding of the whole structure of the designing process. The above-mentioned methods can be computer aided as far as modeling and providing the designer with ergonomic information collected in computer banks of knowledge and ergonomic decision support system is concerned. However, it is still impossible to create simulation models of the human–machine systems that would accurately describe the real work systems, because the well-known mathematics tools are still inadequate for this purpose.

Abstract

Revolution of industry 4.0 led to rapid changes in various fields of life, including the world of education and 21st-Century skills are required to meet the demand of it. As education has been transformed from pedagogy to andragogy and heutagogy learning, students should be able to think critically and solve problems, creative and innovative as well as communication and collaboration skills. From information science perspectives, these skills should be incorporated with digital literacy skills where students be able to find, manage, and use information and skilled use information technology. However, previous studies found that with digital literacy will lead to less motivation and student to become a more independent learner. Based on the literature review, this paper aims to propose a conceptual research framework for the relationship between heutagogy learning and student motivation among secondary school students. Besides, digital literacy skill is introduced to gain understanding, to what extent, it has a moderating relationship between the independent variables and dependent variable. Its hope that this proposed framework can argue in heutagogy learning necessary understanding of digital literacy skill to enhance student motivation

Keywords: Digital Literacy, Heutagogy Learning, Student Motivation

Introduction

Every aspect of human life is currently affected by information communication technologies (ICT). They play importan t roles in workplaces, companies, education and entertainment (Ratheeswari, K., 2018).. Technology evolution and expansion translate into expanded access in education through devices used to deliver distant and online education. ICT also has changed the traditional way of teaching and learning to the new method and experience It means the new method allows the teachers and students to explore more resources and flexible way. However, not all teachers and students can utilize all the information provided on ICT. Also, to adopt ICT as an innovative teaching and learning practices, the transformation of the education system also needs to be considered. The current form of education is heutagogy, which is focused on self-determined learning (Halsall, Powell, & Snowden, 2016) Heutagogy required students to be a more independent learner, and the role of the teacher only as a guidance and student have the freedom to set their own learning experience (Shuhidan, 2013) . In addition, (Hase, S., & Kenyon, 2013) stated heutagogy is appropriate to the needs of

learners in the 21st-century, particularly in the development of individual capability. Therefore to cope with the current situation, the student needs to equip with digital literacy skill.

Studies found that there is a relationship between digital literacy and student motivation (Chan, Churchill, & Chiu, 2017; Kane, 2017; Niemi & Multisilta, 2016). Student motivation is essential in facilitating a desire to begin to engage in and pursue educational goals (Reeve, 2016). Student motivation is defined as a process where the learners' attention becomes focused on meeting their academic objectives, and their energies are directed towards realizing their academic potential student motivation. Also, (Bilal, 1999) as cited (Shuhidan, 2013) found that student will have a motivation, if their teachers allowed them to find their way for study. Student must have a freedom to choose their interest course or topic that related to their own interest. For example, students can utilize technology such as internet as facilitator for studying. The freedom method of study allows a student to explore and expand not only in experience but also in their knowledge with regards to some areas and fields of interest. Then, a student shows their high confidence and motivated to search the topics which is they are interested with.

Research Background

Heutagogy learning approach looks to the future in which knowing how to learn will be a fundamental skill given the pace of innovation and the changing structure of communities and workplaces. The method of heutagogy aims to prepare learners for the self-determined lifelong learning that is important for survival in the 21st century era (Ashton & Newman, 2006). Furthermore, in 21st century student requirements to gain new skills, method of learning, knowledge in line with living and working demands in a complex information atmosphere (Kuhlthau, C. C., Maniotes, L. K., & Caspari, 2015). As a result, digital literacy is an important skill for learners and teachers when they want to implement heutagogy in the school. The definition of digital literacy has expanded by some scholar. For instance, according to (Calvani, Fini, Ranieri, & Picci, 2012) state that "Digital literacy merges capabilities: purely technical aspects, intellectual competences and also competencies related to responsible citizenship. They all allow individuals such as students or teachers to develop themselves completely in the information society". For this reason, digital literacy competencies impact to enhance the student motivation term of capabilities, social emotional, copyright and ethical principles.

Education in the digital age demands students to have adequate literacy skills. Literacy in Indonesia is still low compared to other countries. Therefore, digital literacy, as part of 21st-century education is important since elementary school. The review of this article will further discuss the application of aspects of the digital literacy domain in primary school learning. In the end, the implementation of digital literacy requires the synergy of various parties; they are government, schools, parents, and society (Dianimdri, S. D., & Yuliani, 2018). Digital literacy education for the millennial generation is necessary. The technology can provide beneficial and harmful for the young generation. For example, the case of the hoax or the fake news, the millennial generation must have an ability to filter the true of false information. Another example, from a prior study, found that social media user is unmatured to select the information that provided by social media, which lead to bad impact of their behaviour.

Literature Review

Previous studies (Hase & Kenyon 2000; Blaschke, 2016; Eshet-Alkalai, 2010; Hargittai, 2010; Rhema & Miliszewska, 2014; Abdullah, 2015) show that heutagogy learning approach is to prepare the students to be a self-determined and it's a require a new set skills especially to deal with complex information age. This section will discuss the literature review from heutagogy, digital literacy and student motivation.

Heutagogy Learning

The way of teaching and learning is continually experiencing changes in simultaneous with the development of the country's vision in creating younger generations that are occupied in facing new challenges in the era of globalisation. Heutagogy methods addressing the self-directed learning needs of the autonomous professional learner include distance learning and use of technologies. The PAH continuum was devised as a way of understanding the processes of learning that might increase learner agency as the learner develops new learning skills. Thus, Luckin et al. (2011) define the PAH continuum as one in which learners develop cognitively, metacognitively, and epistemically within the learner context, arguing that learners need to be assisted to manage their own learning.

Digital Literacy

Today the topic of digital literacy is widely discussed in this era. Students and teachers are raises in social knowledge. Being advanced digital literacy is an existence skill they need computerized education abilities in each part of their life. To be educated in the modern sense, it is essential to be digitally literate (Eshet-Alkalai, 2010; Hargittai,

2010). The prior study defines digital literacy as the utilized of digital devices to establish meaning and communicate efficiently with some accessories such as digital texts, navigate non-linear digital documents and evaluate digital information (Bulger, M. E., Mayer, R. E., & Metzger, 2014; Eshet-Alkalai, 2010; Ng, 2012). In addition, (Fraillon, J., Ainley, J., Schulz, W., Friedman, T., & Gebhardt, 2014) defines digital literacy as the utilize of computers as a accessible and productive devices to collect, build, transform, and securely use information. Furthermore, ICT and DL as pre-mandatory of digital world. Consequently, it can be concluded that technological devices can be enhanced student motivation and attitude and the DL of students.

Student Motivation

Motivation can affect how students approach school in general. Student learning motivation must be a serious concern in developing 21st century skills. The learning environment needs to be developed in such a way as to make it more interesting so that learning does not merely transmit knowledge ('standard transmission'). Motivation to learn is enhanced by: greater involvement in and control by the learner in the learning process; self-initiated learning; the opportunity to develop and share patterns; and relevance (C. Hase, S., & Kenyon, 2000). Ferrari (2012) argue that "being digitally literate today involves the knowledge, attitudes and skills needed for operating technologies, using the internet, understanding the media and managing information. However, the convergence of literacies into the digital is, however, more than the sum of its single elements". Research finding has shown that a student's skill in technologies is a significant predictor of attitudes towards ICT. This attitude may influence the students' perceived and actual DL and ICT skills. Better ICT skills are seen to have a positive impact on students' motivations and attitude (Rhema & Miliszewska, 2014). Thus, a better DL enhances positive attitude towards technology (Abdullah, 2015).

Methods

This article uses the literature review method, which critically examines the knowledge, ideas, or research findings contained in the scientific literature, and formulates theoretical and practical contributions to a topic (Narbuko & Achmadi, 2005). The findings of the research are focused on the study of the effect of heutagogy learning on learning motivation that is moderated by digital literacy among students. Research articles were obtained and collected from google scholar, DOAJ, the Scopus database, and several electronic databases subscribed to by library. The purpose of using this approach is to find evidence through review and analysis of the content of the literature which helps in identifying key concepts, issues, problems, methods, findings and models/ frameworks. Several selected keywords and phrases were used in an effort to retrieve relevant articles such as "digital literacy", "information-digital literacy", "digital literacy skills", "digital literacy learning", "digital measurement literacy", "motivation learning" , "Student motivation", "heutagogy learning", "Pedagogy learning", Andragogy learning "," student learning ", and" student learning behavior ". There are four procedures used in writing this article. The four procedures are from Nakano & Muniz (2018), namely: (1) Organize, which is organizing the literature to be reviewed. The literature reviewed is the literature that is relevant to the problem. The stages in organizing literature are looking for ideas, general objectives, variables taken and conclusions from the literature and classifying literature based on predetermined categories; (2) Synthesize, which is to unify the results of the literature organization into a summary so that they become one unit, by looking for linkages between literature sources; (3) Identify, namely identifying the problems studied in the literature. and (4) Formulate, namely formulating questions that require further research.

Proposed Conceptual Framework

Figure 1: Proposed conceptual research framework

From underpinning theories and models of Heutagogy Learning, Digital Literacy and Student Motivation derived the proposed framework as Figure 1.0. The proposed framework aims to investigate the relationship between heutagogy learning and student motivation. The independent variable in this study is Heutagogy learning which has four (4) dimensions, namely linear agency, capability, reflection and non-linear design which will be considered to have an influence on student learning motivation which includes dimensions of attention, confident and satisfaction. An important addition to the framework is digital literacy skills which are expected to be strongly correlated with the use of electronic resources among students. Thus, digital literacy skills have been identified as a moderating variable whose introduction is expected to strengthen the effect of the four (4) dimensions on the independent variable. As the dependent variable it is predicted to have a relationship with the above independent and moderating variables.

Conclusion

The proposed framework is expected to provide useful and insightful findings about the relationship between heutagogy learning and student motivation. Furthermore, digital literacy skills are a moderating variable that is anticipated to have an influence on the relationship between both the dependent variable and the independent variable. It's hoped that, this research framework will offer research methods as well as instruments to collect and analyze data on the relationship between heutagogy learning and student motivation and the mediator role of digital literacy among students in Indonesia.

Modern Concepts of Management Toolbox for Market's Pioneers and Operators

Krystian PAWLOWSKI

Poznan University of Technology, Faculty of Engineering Management, Poznan, Poland
krystian.pawlowski@put.poznan.pl

Abstract

In the literature related to strategic analysis and strategic choices, we find a very broad discussion on the interaction between an enterprise and its environment, situational selection of the enterprise's strategy depending on the conditions of its environment. The operational expression of the adopted strategies are concepts, methods and techniques of business management. On the other hand, internal conditions affect the scope and results of implementing management methods both on the side of barriers and factors favouring implementation. The following paper, out of many internal factors shaping the situational selection of modern management methods, assumes that leading ones are: standard (SSD) or non-standard (NSD) mode of operation related to the level of enterprise's innovation. A group of 150 medium and large enterprises of the industry in Poland were examined as a part of the research. The goal of the study was to identify the modern management methods which are used and their correlation with achieved economic results. The practical implications of the work results is the development of modern concepts of management toolboxes for Pioneers and Market Operators.

Keywords Innovation, Modern Concepts of Management Toolboxes, Market Pioneers, Market Operators.

Introduction

Companies, including both large multinationals, small and medium-sized enterprises operating on the local market, are forced to monitor changes in the environment and adapt their strategies to these changes. The need to adjust enterprises to the environment is indicated by P.R. Lawrence, I.W. Lorsch (1974), G. Stonenhouse (2001). In the literature related to strategic analysis and strategic choices, we find a very broad discussion on the interaction between an enterprise and its environment, situational selection of the enterprise's strategy depending on the conditions of its environment. The operational expression of the adopted strategies are methods and techniques of business management. They should be consistent with the strategies used by the company. Lists of typical management methods and techniques assigned to organizational strategy are well known and approved, e.g. Lean Management (Lean Toolbox), as well as general taxonomies of contemporary management methods, such as the work of Miller and Roth (Bolden at al., 1997), taxonomy developed by P. White (White, 1996), and the work of R. Bolden, P. Waterson, T. Wall, P. Warr, and Ch. Clegga (Bolden at al., 1997). However, there are no lists of management methods and techniques related to the operationalization of the strategy of market Pioneers and Market Operators. Internal conditions affect the scope and results of implementing management methods both on the side of barriers and factors favouring implementation. Empirical research on the application of management methods was carried out in the context of:

- internal conditions of enterprises and institutions: (Flieger, 2009, Firlej, 2011, Bieńkowska, Zgrzywa Ziemak, 2011, Walentynowicz, 2013),
- co-existence of management methods in enterprises (Bieńkowska, Zgrzywa- Ziemak, 2013),
- popularity of applications (Bieńkowska, Zgrzywa Ziemak, 2011, Bain and Company, 2017).

The following paper, out of many internal factors shaping the situational selection of modern management methods, assumes that leading ones are: standard (SSD) or non-standard (NSD) mode of operation related to the level of enterprise's innovation. It was assumed that the non-standard way of operating is associated with the "Pioneers" enterprises in which innovation leads to change or creation of new business segments in which there is

Cite this Article as: Krystian PAWLOWSKI "Modern Concepts of Management Toolbox for Market's Pioneers and Operators" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

yet no competition. On the other hand, the standard way of operating is associated with the "Market Operators" enterprises functioning in segments characterized by intensive competition, where innovation is focused on reducing costs or improving the quality of products. A group of 150 medium and large enterprises of the electromechanical industry in Poland were examined as a part of the research. The goal of the study was to identify the used modern management methods and their correlation with achieved economic results. Four groups of enterprises were distinguished for the needs of the research model: Pioneers with market success, other Pioneers, Market Operators with market success and other Market Operators. For each of the above groups, leading and positively correlated with economic results groups of modern management methods were identified. The practical implications of the work results is the development of modern manufacturing practices toolboxes for Pioneers and Market Operators. Additionally, during the research work, an original model was developed to differentiate between the inclusion of individual methods in the meta-concept (organizational strategies) lean and agile.

Research Problem

To sum up, the paper analyses the following research problem: what modern management methods are beneficial for high economic results in groups of Pioneers and Market Operators.

Literature Review

The Innovation of The Enterprise

D. Depperu and L. Gnan (2006) conducted a study on the correlation between formulation strategy and competitive pressures. These studies have positively verified two hypotheses:

• As demand increases, the need to obtain new resources and the need to innovate the business formula increases as well as the need to rationalize and modify the business formula and the need for consensus among stakeholders decreases.
• With increasing volatility of customers' needs, the need for the innovative business formula is growing.

The research of M.J. Ruiz Ortega and P.M. Garcii-Villaverde (2008), on the other hand, combined the level of innovation of the company with the selection of marketing strategy and key skills and the economic and financial results of the company. From the point of view of this work, it is important that the above-mentioned studies have shown the importance of the relationship between the levels of innovation and the strategies and skills of the company, as both strategies and skills have their designators used in the management methods.

Organisational Strategies

The organizational strategy is one of the functional strategies of the company. It converts the strategic objectives of the company and the objectives of the strategic business units into organisational objectives of the company. Organizational strategies concern both the organizational structure and business processes, including management methods and techniques. The meta concept of management in this paper is related to the organizational strategy of Lean and Agile understood in this paper as company paradigms. At the general methodological level, they are treated as meta management concepts, which means that they are more general in relation to concepts, methods, techniques, management tools. (Trzcielński, 2011, pp. 24-25).

In the subject literature, the management methods presented in Table 1 are also described in the context of meta concepts (methods) Lean Management or Agile Enterprise, but generally, the authors do not provide criteria differentiating the inclusion of individual methods into a given meta concept. With regard to Lean Management, there is extensive literature justifying the link between this concept and the 29 management methods and techniques described by Walentynowicz (2013). The relationship with Agile Enterprise is much less clear, and even less common application of methods by both meta concepts. During the research work, an original model was developed to differentiate between the inclusion of individual methods presented in Table 1 into the meta concepts of lean and agile. The basic assumptions of the model are presented below:

- The Lean strategy may be operationalised in the realisation of the following five interdependent phases (principles) of Lean (Womack and Jones, 2001, pp. 10-12), (Walentynowicz, 2013, pp. 54-59):

- Customer-defined value determination principle (*Specify Value)* - (V)
- Identification principle of the value stream *(Identify the Value Stream)* - (VS)
- The principle of harmonious flow *(Flow)* - (F)
- Principle Just In Time /Pull *(Pull)*- (P)
- Principle of excellence (Kaizen/KAIKAKU) (K)

- The operationalisation of the Agile strategy can take place in two main areas:
  - The realization of the enterprise's agility characteristics and the level of agility (Trzcielński, 2011, p. 75, and p. 133-150). The criteria related to the achievement of the enterprise agility features are cleverness, flexibility, intelligence and cunning.
  - Realization of the level of enterprise agility where we can distinguish four levels of enterprise agility development (Trzcielński, 2011, pp. 133-157): Reactive model (Mr), Proactive model (Mpa), Network model, Virtual enterprise.

Table 1: Scope of research - a group of 36 contemporary management methods included in the research model

No	Management Method	No	Management Method

The Research

Research sample

The research sample consisted of one hundred and fifty companies. The respondents were people directly managing enterprises (board members, directors). The survey was carried out with the help of an external company which was commissioned to conduct an interview. The answers collected in the research contain information on internal and external conditions of enterprises related to the implementation of new management methods and techniques, implemented modern management methods and tools and the economic situation of enterprises.

Scope of Research

Table 1 shows the range of tests. The list includes 36 contemporary management methods.

Research Methods

In order to verify the raised research problems, research was conducted in the theoretical and empirical sphere. In the theoretical sphere, a critical analysis and synthesis of the literature was made. In the empirical sphere, a questionnaire survey was conducted. The research was conducted in the form of an interview. The majority of answers were given according to the Likert's scale (1-5).

Data Processing Methodology

Identification of Pioneer/Operator companies

The entire sample of N=150 companies was divided into two groups of companies, Pioneers operating in a non-standard manner and Market Operators operating in a standard manner. In order to divide companies according to their level of innovation, the respondents were asked the following questions:

1. Is your company building a competitive advantage focused on:

    1. Increasing the efficiency of your processes and minimising costs.
    2. Creating innovative solutions.

In order to identify a group of pioneers an additional strengthening question was asked:

2. Changes in technique and technology result from improvements in existing solutions. (Respondents responded using a five-point scale, where 1 - definitely not, and 5 - definitely yes.)
The companies that simultaneously indicated answer 2 in question 1 and indicated answer 4 or 5 in question 2 were qualified to the group of pioneer companies with a high degree of innovation. By way of exclusion, the remaining companies were qualified to the group of Market Operators.

Analysis of the economic performance of enterprises

In order to divide the companies into groups: companies with good economic performance - company group A, and companies with bad economic performance - company group B - the rest, the respondents were asked a question:

Please tell me if:

1. In 2013 the value of sales was higher than in 2012.
2. The company has implemented its sales plan for 2013.
3. The company has fulfilled its financial targets for 2013.
4. The company has met its financial targets for the last 2 years.

Group A included those companies which answered all four questions on financial performance in the affirmative way. All the other companies were allocated to company group B on a debarment basis.

Determination of indicators for the level of implementation of modern management methods in the surveyed companies

In the questionnaire the respondents determined the degree of implementation of particular methods according to the Likert's scale, where 1 - meant no implementation, 3 - partially implemented, 5 - a given method was fully implemented. For the purposes of the research, the answers in the scales 4 and 5 were assumed to correspond to full implementation of a given method. In order to calculate the implementation rates of individual methods, fully implemented (response scale 4.5) methods were identified in each research sample. Then, the number of fully implemented individual management methods was divided by the number of a given sample in the segment. In the above procedure, an indicator was obtained which indicates the level of implementation of a given method.

Identification of modern management methods conducive to high economic performance in Pioneer and Operator groups

The following methodology was used to identify modern management methods conducive to high economic performance in Pioneer and Operator groups:

- Indicators were set for the implementation of modern management methods in groups of companies with high and low economic performance among Pioneers and Market Operators.
- The methods implemented to a higher degree in the group of enterprises with high financial results than in the group of enterprises with low economic results were identified.
- Supported by statistical dependencies and organizational strategies, the Toolbox for Market's Pioneers and Market Operators was built

Statistical link between the rate of implementation of methods and the economic performance of enterprises

In order to check if there is a statistical link, a correlation analysis was conducted. Since the variables take values on the ordinal scale, Sperman's rank correlation was applied. If, as a result of the analysis, methods positively correlated with the economic results of enterprises were identified, it can be assumed that the increase in the level of implementation of given management methods is accompanied by an increase in the economic results of the enterprise.

Results and Discussion

Identification of Pioneer/Operator Enterprises

Based on the adopted data processing methodology, 53 companies were qualified as Pioneers, which represents 35.33% of the surveyed sample. The group of Market Operators included 97 companies, which represents 64.67% of the surveyed sample.

Classification of Pioneers and Market Operators based on economic performance

In the Pioneers' group of enterprises, twenty enterprises were qualified to enterprises "A" obtaining high economic results, which constitutes 38% of the Pioneers' group. The remaining thirty-three companies were qualified to the group of companies "B" with low economic results. In the group of Market Operators' enterprises, twenty-four enterprises have been qualified as "A" enterprises with high economic results, which constitutes 25% of the group of Operators. The remaining seventy-three companies, accounting for 75% of the Operators, were qualified to enterprise group "B" with low economic performance.

Identification of modern management methods conducive to high economic performance in Pioneer and Market Operator groups.

Analysis and synthesis of implementation indicators of fully implemented management methods in the Pioneer group:

- The number of enterprises allocated: 53
- The number of enterprises allocated group A: 20
- The number of enterprises allocated group B: 33

Table 3 presents fully implemented management methods in the group of Pioneers , divided into groups A and B of enterprises. It presents, in order from the left, the name of the management method, the method implementation rate in enterprise group A presented as a percentage, the method implementation rate in enterprise group B presented as a percentage (described in detail in point 2.4.3.). In the last two columns the organizational strategy, Lean or Agile, to which a given method is assigned, is presented. At the bottom of the table in the last row, there is a summary showing in percentage scale the leading organizational strategies for the given segment. In the table yellow marked lines are methods implemented in a higher degree by group A than by group B and only this methods are taken into consideration in the analysis. Additionally red colour is to show which methods correlated positively with the economic results of enterprises (Sperman's rank correlation was applied).

Fig 1 presents modern management methods implemented in the group of Pioneers divided into groups A and B of enterprises. The Y axis indicates the level of implementation of modern management methods presented as a percentage (described in detail in point 2.4.3.). The X axis shows modern manufacturing practices and the organizational strategy to which a given method is assigned L - lean, A – agile.

Fig. 1: Management methods implemented in the Pioneer group

Source: Own study

After the analysis of the results presented in Table 3 and Fig 1, we can come to the following conclusions:

- The share of Lean and Agile strategies is almost the same.
- The implementation of the nine methods that implement the organizational strategy of Lean among successful companies (in particular JIT, Heijunka, Flow) is most likely due to the high importance of production processes in the segment of electrical-machine enterprises in which the survey was conducted.
- The implementation of nine methods among successful companies that implement the Agile organizational strategy is in line with the expectations of the survey authors. A high level of innovation, a non-standard way of actions related to the creation of new markets should be supported by methods that increase the agility of the enterprise.

Table 4 presents the results of the implementation of modern management methods among Market Operators. Data are provided in the similar way to table 3.

Table 4: Methods fully implemented in the group of Operators

Methods	Implementation rate		Organizational Strategy	
	Group A	Group B		
1. Just in Time	8%	10%		Lean

The X axis shows modern manufacturing practices and the organizational strategy to which a given method is assigned L - lean, A – agile.

Fig. 2: Management methods implemented in the group of Market Operators.

Source: Own study.

Analysis and synthesis of implementation indicators of fully implemented management methods in the group of Market Operators.

- The number of enterprises allocated: 97
- The number of enterprises allocated gr. A: 24
- The number of enterprises allocated gr. B: 73

After the analysis of the results presented in Table 4 and Fig 2, we can come to the following conclusions:

- In the group of Market Operators, the share of Lean strategy prevails to a small extent.
- The implementation of the fourteen methods implementing the Lean organizational strategy among successful companies is in line with the expectations of the survey authors. The low level of innovation and the standard way of operating related to market penetration should be supported by methods that increase process efficiency.
- It should be noted that thirteen methods have been implemented among successful companies to implement the Agile organizational strategy. However, given the implementation rate of each method shown in the picture 2, a significant advantage of leading lean management methods should be noted.

Statistical link between the rate of implementation of methods and the economic performance of enterprises

In order to check if there is a statistical link between the level of implementation of modern management methods and economic performance, a correlation analysis was carried out. Since the variables take values on the ordinal scale, Sperman's rank correlation was applied. Statistica 13.1 software was used to perform statistical analyses. The analysis of Sperman's rank was performed with the assumption of significance level $p<0.05000$. The correlation coefficient does not give a causal effect response, however, it indicates the existence of a statistical relationship between the variables under study and is one of the conditions for the occurrence of a causal effect relationship (Małkowska Borowczyk, 2011).

The results of the analysis are presented in Table 3 and Table 4 presenting the implemented methods in the Pioneer and Operator groups.

Conclusions

The result of the study was the identification of groups of modern management methods that favour the high economic results of Pioneers and Operators. The practical implications of the work results is the development of modern manufacturing practices toolboxes for Pioneers and Market Operators. Table 5 shows modern manufacturing practices toolboxes for Pioneers and Market Operators. Red colour indicates methods that show a statistically positive correlation between the level of implementation and economic performance of companies (Sperman's rank correlation coefficient at the level of significance $p<0.05000$). In the group of the Pioneers dominate the methods that favour increase in the reactivity of companies looking for new markets and technological solutions by using methods such as Marketing Research, SWOT, Evaluating Market Attractiveness, Concurrent Engineering, Business Process Management, Virtual Organization. In the group of Operators, it is worth pointing out a significantly higher degree of implementation of methods that build an almost complete Lean Management toolbox, which leads to an increase in the effectiveness of the implemented business processes. To sum up, the developed toolbox is suitable for the electrical-machine industry, whereas its usefulness in other industries would have to be determined by further research. The research scope of the work was narrowed down to the electro-machinery industry mainly for the following three reasons:

- Lean Management was established and operated in the electrical engineering industry (Womack, Jones, Roos, 1990).
- The Agile Enterprise concept was developed for manufacturing systems that are specific to the electrical engineering industry (Goldman, Preiss, 1991).
- An examination of a wider range of industrial sectors could lead to non-comparable results due to significantly different conditions in individual sectors.

The State of Adaptation of Enterprises in Poland to the Paradigms of Industrial Production Industry 4.0

Krystian PAWLOWSKI

Poznan University of Technology, Faculty of Engineering Management, Poznan, Poland

krystian.pawlowski@put.poznan.pl

Abstract

Industry 4.0 from the vision of the future has become a widely accepted reality for industrial companies, not only on a European but also worldwide scale. Taking into account the robotization rate, Poland is at the end of the European list with 42 robots out of 10 000 employees (data from 2019). However, the research conducted in 2018 shows that in the sector of micro, small and medium production enterprises located in Poland 60% of entrepreneurs have not heard about the concept of Industry 4.0 before. Therefore, a research problem was undertaken concerning the adjustment of Polish enterprises to the requirements of Industry 4.0, and in particular the adjustment to new paradigms of industrial production. The empirical research conducted in January 2020 covered 100 medium and large companies operating in Poland in various industries. This paper focuses on three issues related to the technological and business aspects of the digital transformation. The research covered the level of product agility, changes in manufacturing technology and the level of application of Lean Management methods and tools. The aim of the study is to determine the level of adjustment of enterprises in Poland to the requirements of industry 4.0 and to indicate whether the implementation of Lean Management methods and tools supports this adjustment.

Keywords Industry 4.0, paradigms of industrial manufacturing, lean management, Cyber-Physical Systems, Internet of Things, Internet of Services, Smart Factory.

Introduction

The modern business environment is characterized by the reallocation of wealth and industrial production from Europe and the USA to Asia (European Commission, 2009), cost-cutting and profit pressure, market risk and, in the macroeconomic perspective, weaker and more volatile growth of the global market (EY, 2013), or the disintegration of traditional economic chains and the establishment of networks of enterprises (Małkowska - Borowczyk, 2011). The IT revolution has led to a radical transformation of the world, comparable to the impact of new energy sources and mechanization on the first and second industrial revolution. After the introduction of the new Internet protocol IPv62 in 2012, it became possible to create the Internet of Things and the Internet of Services, and this allowed to create a network covering the entire production process, transforming the factory into Cyber-Physical Production Systems. This system includes, on the one hand, intelligent machines, storage systems, production facilities integrated through ICT and on the other hand, logistics, production and marketing processes (Kagermann, Wahlster, Helbig, 2013, p. 13 - 14). The vision of the future of Industry 4.0 has become a widely accepted reality, which affects the way companies operate (Jasiulewicz-Kaczmarek, Legutko , Kluk, 2020, pp. 74).

According to Smart Industry Poland research in 2018, over 60% of entrepreneurs representing the sector of micro, small and medium-sized production enterprises located in Poland had not heard of the concept of Industry 4.0 before (Research report of the Ministry of Entrepreneurship and Technology / Siemens). Another measurable indicator to compare the degree of robotization of economies is the number of industrial robots installed in relation to the number of employees in the industry. In Europe, Germany remains the leader (328 industrial robots out of 10,000 industrial processing workers), followed by Sweden (247), Denmark (240) and Italy (200). Poland is at the end of the list with 42 robots out of 10,000 employees (Grzeszak, Sarnowski, Supera-Markowska, 2019, p 11).

Research Problem

Cite this Article as: Krystian PAWLOWSKI "The State of Adaptation of Enterprises in Poland to the Paradigms of Industrial Production Industry 4.0" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The research problem undertaken in this paper concerns the adjustment of Polish enterprises to the requirements of Industry 4.0 and in particular the change of paradigms of industrial production. This paper focuses on three issues related to technological and business aspects of the digital transformation:

- The first problem is the level of product agility (business paradigm). M. Porter distinguishes the shortened product life cycle as one of the features of modern competition (Grudzewski, Koźmiński, 1996, p. 4). M. Bruce and L. Daly (2004), on the other hand, point out the increase in the turbulence of the environment and decrease in profitability of the sectors (Bruce, Daly, 2004, p. 151 - 170). Changes in the environment have resulted in an increase in the level of product customization (adapting products to individual customer needs) while shortening the delivery cycle. In practice, this means that changes in specification and, consequently, in design and technology appear during production. The results of research carried out on a large group of companies from eight countries (including the USA and Japan) indicate that mass customization is a very important mechanism that can be used in many manufacturing and service industries (Salvador, De Holen, Piler, 2009, p. 71-79). The concept of mass customization is defined as a system that uses information technology, flexible processes and organizational structures to deliver a wide range of products that meet specific customer requirements (often by choosing from a specific set of options) at costs comparable to those of mass production. Mass customization might be considered when the price of such a product does not exceed 10-15 % of the standard article price (Bednarz L., 2010, p. 105). Companies must use new product development as a strategy for remaining competitive in the market place, providing a new generation of products in response to changing consumer demands (Miranda, Pérez-Rodríguez, Borja, Wright, Molina, 2019, p 4392). Therefore, this paper asks whether companies are increasing their range of newly introduced products in existing and new markets.
- The second problem - changes in manufacturing technology towards automation, robotization and machine communication - (technological paradigm). Cyber-Physical Production Systems covering intelligent machines, storage systems and production facilities integrated through ICT is one of the Industry 4.0 paradigms (Kagermann, Wahlster, Helbig, 2013, p. 13 - 14). The second of the questions asked in the paper concerns changes in manufacturing technology.
- The third problem is the application of Lean Management methods and tools (business paradigm). The integration of industry 4.0 solutions is a major investment but is particularly beneficial in those areas where the cost reductions resulting from Lean Management are not sufficient to meet today's requirements. On the other hand, Lean Management production processes are standardized and transparent, which in turn simplifies the integration and implementation of industry 4.0 solutions. By analyzing the ideas of industry 4.0 in details we can find many links and similarities to Lean Management concepts:

    - Smart Product can support Kaizen (Continuous Improvement) by collecting data from the entire product life cycle, visualization, value stream mapping or Kanban (Kolberg, Zühlke, 2015).
    - Smart Machine can support Kaizen and pro-quality methods like Poka Yoke by collecting data,
    - Plug'n'Produce supports the implementation of the method SMED.
    - Augmented Operator should shorten the time between the occurrence of a failure and its reporting. A real-time message with a description and location of the failure helps Andon and Jidoka (Mrugalska, Wyrwicka, 2017).
    - Whereas the application of advanced analytical techniques on big data concerning technical condition, maintenance, use of manufacturing means is supported by TPM (Jasiulewicz - Kaczmarek, Gola, 2019, p 91).

The third question raised concerns the application of Lean Management methods and tools by companies and the impact of their application on the adaptation of companies to industry 4.0 requirements.

Objectives

The research aim is to find the answer to the question: are medium and large enterprises in Poland adapted to the new paradigms of industrial production of Industry 4.0 and whether the use of Lean Management methods and tools supports this adaptation. In order to achieve this goal, three questions were asked:

- Do companies aim to increase their product agility.
- Are companies turning manufacturing technologies into automation, robotization, and machine communication.
- Do companies use the basic methods and tools of Lean Management and whether their application is beneficial for the adaptation of companies to industry 4.0.

Literature Review

Situational approaches in organizational theory describe the impact of the environment on the organization and the resulting consequences for the management process. The need for companies to adapt to their environment is indicated, among others, by P.R. Lawrence, I.W. Lorsch (1974), G. Stonenhouse (2001), N. Najda (2009), P. Bórawski (2009), J. Skalik (2011), A. Bieńkowska and A. Zgrzywa-Ziemak (2014), K. Wach (2010).

In the development of companies in the industrial era, we can distinguish four phases. The first phase of production in the manufactures began with the industrial revolution. The second phase of industrial production, mass production, was initiated by the implementation of the technology of producing standardized and replacement parts at Cadillac Motor Car Company in 1904. The start of the third phase of industrial production based on the paradigm of eliminating waste was initiated by Toyota and the assumption that it is possible to reduce car production costs without economies of scale. As a result of the progressing industrial revolutions, the development of technology was followed by new demands. On the technological side, the third industrial revolution used the development of electronics and information technology (IT) to achieve increased automation of production processes, relating not only to mechanical but also mental work. This revolution was called "the Digital Revolution" (Trzcieliński, Kałkowska, Pawłowski, Włodarkiewicz-Klimek, 2016, pp. 9 -12), (Trzcieliński, 2020, pp. 25 – 26).

The paradigm of eliminating waste turned out to be an insufficient defence against another acceleration of environmental volatility. The company's agility has been defined as the ability to succeed in a competitive environment, where unpredictable changes that create market opportunities constantly take place. The essence of an agile enterprise is its focus on the opportunities that arise from the changing environment. In the literature on the subject, this paradigm is called agile or reconfigurable (Trzcieliński, 2011, pp. 10-12), (Trzcieliński, Kałkowska, Pawłowski, Włodarkiewicz-Klimek, 2016, pp. 9 -12), (Goldman, Nagel, Preiss, 1995, p. 8, 42-43), (Kagermann, Wahlster, Helbig, 2013, pp. 13 – 14), (Herman, Pentek, Otto, 2015). Thus, from a technological point of view, industrial companies entered the fourth revolution, industry 4.0. The main ideas of industry 4.0 were first published in Germany in 2011 (Kagermann, Lukas, Wahlster, 2011).

There is no single definition of industry 4.0 in the literature on the subject, despite the fact that it is one of the most discussed topics among practitioners and scientists from the German-speaking area (Herman, Pentek, Otto, 2015), (Mrugal, Wyrwicka, 2017, p. 469). Significant work in the definition of Industry 4.0 and key principles was done by M. Hermann, T. Pentek, B. Otto (2015). In the study, they conducted an analysis of literature and databases. On the basis of 51 selected publications, they have described the key elements and principles of Industry 4.0. Thus the authors have defined four basic elements of Industry 4.0: Cyber-Physical Systems, Internet of Things, Internet of Services, and Smart Factory. In addition, the authors have developed six principles supporting the adaptation of the company to the requirements of industry 4.0. These are interoperability, virtualization, decentralization, real-time capability, service orientation, and modularity (Herman, Pentek, Otto, 2015). Alcácer and Cruz-Machado, on the other hand, mention among the key technologies of industry 4.0: The Industrial Internet of Things, Cloud Computing, Big Data, Simulation, Augmented Reality, Additive Manufacturing, Horizontal and Vertical Systems Integration, Autonomous Robots, Cybersecurity (Alcácer, Cruz-Machado, 2019, pp. 901 – 912).

It is important to note that the assumptions that coincide with industry 4.0 were already developed at the end of the 1990s by Hans Jurgen Warnecke (Jurgen-Warnecke, 1999), who put forward the first hypothesis of fractal companies in which independent teams work together as a client-supplier both inside and outside the organization. The keynote for a fractal organization is to create self-regulating organizational working groups. A computer-aided information and communication system is used to control the input and output of fractals. H. Warnecke formulated the definition and basic characteristics of fractal units: "A fractal is a self-contained unit of a company whose objectives and performance can be clearly described (Warnecke, 1999, pp109-113):

- Fractions are self-like, everyone performs services.
- Fractions are self-organized.

The Research

Research Sample

The research sample included 100 industrial enterprises (including 60 medium-sized enterprises and 40 large-sized enterprises) operating in various industries in Poland. The respondents were people directly managing the

production and engineering area (middle and senior managers). The surveys were collected with the help of an external company, which was responsible for conducting interviews.

Scope of Research

The scope of the research included the types of offered products, the level of changes in the area of manufacturing technology towards automation, robotization and machine communication, and the scope of implementation of Lean Management methods: Outsourcing, Continuous Improvement, Empowerment, Just In Time, Supply Chain Partnership or Learning Culture. The selection of management methods was based among others on a research study by Bolden at all (1997); Bicheno, (2000); White, (1996); Walentynowicz, (2003, 2013, 2014).

Research Methods

To solve the research problem a questionnaire survey was conducted on a sample of 100 industrial companies in Poland. The research was conducted in the form of an interview, the research sheet in the scope of the research discussed here included 6 complex questions. Respondents provided answers on a scale of 1-5 (Likert), and a scale of 0-1. The data collected was processed using the Sperman Rank Correlation Test.

Data Processing Methodology

The following data processing methodology was developed in empirical studies.

- For the whole research sample was determined the level of intensity of the examined features which proves the adaptation of companies to the paradigms of industrial production 4.0.
- From the whole research sample, a group of companies adapted to the paradigm of industrial manufacturing 4.0. was identified based on the level of product agility and technological changes. For the identified group 4.0 and other companies from the sample, the level of implementation of Lean Management methods and tools was determined and compared.
- Correlation tests of Sperman's Rank were conducted for selected features

Level of Product Agility

The following question was asked about the level of product agility:
Q1. From which types of products does most of your company's profits come?
1. Existing products for existing buyers.
2. Existing products for new buyers.
3. Modified products for existing buyers.
4. New products for existing sectors.
5. New products for new sectors.

Responses on a scale of 3,4,5 were evaluated as a high level of product agility characterizing enterprises adapted to the requirements of the industry 4.0. and in accordance with the adopted research methodology to qualify these enterprises to test sample 4.0.

Changes in the area of manufacturing technology towards automation, robotization and machine communication

The following questions were asked about the level of changes in the area of manufacturing technology towards automation, robotization and machine communication:

Q2. What is your company's policy on machines/devices that communicate with each other? (single selection)
1. We do not plan to introduce such machines.
2. Perhaps we will introduce in the undefined future.
3. Decisions were made to implement them within five years.
4. Decisions were made to implement them within two years.

5. We have such machines and will increase their number.

Responses on a scale of 3,4,5 were evaluated as a characterizing enterprises adapted to the requirements of the industry 4.0. and in accordance with the adopted research methodology to qualify these enterprises to test sample 4.0.

Q3. What is the level of automation of the basic production process in your company? (single selection)
1. There is no automation/robotization.
2. There is automation/robotization, but human work dominates.
3. Automation/robotization is in balance with human work.
4. There is human work, but automation dominates.
5. Fully automated.

Responses on a scale of 3,4,5 were evaluated as a characterizing enterprises adapted to the requirements of the industry 4.0. and in accordance with the adopted research methodology to qualify these enterprises to test sample 4.0

Q4. What types of machines/devices are used in your company in the basic production process? (single selection)
1. Single-purpose machine/equipment (not universal).
2. Universal machines/devices - traditional.
3. Numerical or computer-controlled machines/devices.
4. Manipulators.
5. Robots.

Responses on a scale of 3,4,5 were evaluated as a characterizing enterprises adapted to the requirements of the industry 4.0. and in accordance with the adopted research methodology to qualify these enterprises to test sample 4.0.

Level of implementation of Lean Management methods and tools

Q5. To what extent are the following Lean Management methods implemented in your company?

1. Continuous Improvement (kaizen).
2. Empowerment (executive employees have relatively broad decision-making powers).
3. Just in Time (deliveries and sales of products are made with the physical omission of the warehouse).
4. Outsourcing.
5. Supply chain management (Supply Chain Partnering).
6. Culture promoting learning (investing in the development of employees; not just adaptation to the job).

Respondents gave answers in the Likert scale, where 1 - total lack of implementation, 2 - implemented to a small extent, 3 - half-implemented, 4 - implemented to a large extent, 5 - full implementation. Answers on a scale of 3,4 and 5 were considered to be implementations of a given Lean Management method. The rate of implementation of a given method was determined as a percentage indicator of the number of implementations (with a value of 3,4 or 5) of a given method in the examined sample to the total sample size according to the formula below:

$$P = \frac{n\,(3,4,5)}{N}\,[\%]$$

where:

P – the rate of implementation of a given method,

n(3,4,5) – number of implementations of a given method in a research sample of 3,4,5 according to the Likert scale.

N – sample size.

Statistical link between the rate of implementation of methods and the economic performance of enterprises

In order to check if there is a statistical relationship between the rate of implementation of Lean Management methods and tools and the level of intensity of the features that indicate the adaptation of the company to the requirements of industry 4.0 Sperman Rank correlation was used. To perform statistical analyses, Statistica 13.1 software was used. The analysis of Sperman's Rang was made assuming the level of materiality $p<0.05000$.

Results and Discussion

Level of Product Agility

Based on the adopted data processing methodology, 32% of companies from the surveyed sample N=100 offer new or changed products on existing and new markets. In the face of changes in the enterprise environment, this is a low result.

Changes in the area of manufacturing technology towards automation, robotization and machine communication

In the sample, 22% of companies declared that they use and plan to increase the number of communicating machines, another 11% of companies plan to buy within the next 2 years and another 10% plan to buy within the next 5 years. The data is presented in detail in Fig 1. 43% of companies declared their willingness to buy or current use of communicating machines.

Fig. 1: Use of communicating machines

Source: Own study

Analyzing the level of automation, 19% of companies declared that half of the processes are automated, robotic, 13% of companies declared that there is human work but automation is dominant, while none of the respondents declared full automation and robotization of the manufacturing process. Whereas 35% of companies declared the use of manipulators or robots.

Level of implementation of Lean Management methods and tools

On the basis of the level of product agility and changes in the area of technology, a group of companies adapted to the paradigm of industrial manufacturing 4.0 was identified. Out of the whole research sample, only 8 companies were identified to meet all the adopted criteria to adjust to the paradigms of industrial manufacturing 4.0. For a

selected group 4.0 and for the rest of the companies, the level of implementation of Lean Management methods and tools was determined and compared from the sample. Fig 2. shows the level of implementation of Lean Management methods and tools in a separate group of 4.0. companies and the rest of the companies. The study included six Lean Management methods and tools. Out of the methods studied, only Outsourcing was implemented to a lower degree in group 4.0 compared to the rest of the companies. The other methods: Continous Improvement, Empowerment, Just In Time, Supply Chain Partnership or Learning Culture were implemented in group 4.0 to a higher degree than in the rest of the sample. The highest differences were noted in the methods Empowerment, Supply Chain Partnering and Learning Culture. The methods of Learning Culture and Empowerment support the following principles of industry adaptation 4.0: interoperability, virtualization and decentralization, making easier to introduce changes in the area of technologies leading to the creation of Cyber-Physical Systems and Smart Factory. Supply Chain Partnering arranges the logistic and production processes and simplifies product agility by increasing modularity. Just in Time i Outsorcing increase real-time capability and service orientation, however, these two methods were implemented to the lowest extent in the examined groups 4.0, and in the rest of the enterprises as well as in the whole population.

Fig. 2: Level of implementation of Lean Management methods and tools in Group 4.0 and other companies.

Statistical relations between changes in the area of technology and the level of implementation of Lean management methods

In order to check if there is a statistical relationship between the increase in product agility and changes in the area of technology, and the level of implementation of modern management methods, a correlation analysis of Sperman's Rang was conducted. The results of the analysis are presented in Table 1. The table from the left shows the Lean Management methods, then in the columns respectively the results of the Sperman Rank correlation analysis for questions Q1, Q2, Q3, Q4.1 and Q4.2. Red was marked with correlation values, which are statistically significant with $p<0.5$ (and only these results are taken into account). In the interpretation of the results, it was assumed that the value of the correlation coefficient at the level of $0.2 < r \leq 0.4$ is interpreted as a low linear dependence but clear (Ostasiewicz, Rusnak, Siedlecka, 2000, p. 311). The increase in product flexibility (question Q1) is only positively correlated with the Learning Culture method. Whereas Q2 and Q3 questions (related to automation and development of communicating machines) show correlation with methods: Continuous Improvement, Empowerment, Supply Chain Partnership, Learning Culture. The use of manipulators is correlated with Just in Time and Supply Chain Partnership. The correlation coefficient does not give a cause-and-effect response, but it does speak about the existence of a certain statistical relationship between the variables under study and is one of the conditions for the existence of a cause-and-effect relationship (Małkowska Borowczyk 2011).

Table 1: Correlation level between Sperman Rank for technological changes and product flexibility and adapted Lean Management methods. Source: Own study. Where: Q1. The question about the types of products from which most of the company's profits come from. Q2. The question about introducing communicating machines. Q3. Question about the level of automation. Q4.1 Question about the use of manipulators. Q4.2 Question about the use of robots.

Correlation of Spearman's rank order, BD removed in pairs the marked coefficients of correlation are significant with p <.05000	**Q1.**	**Q2.**	**Q3.**	**Q4.1**	**Q4.2**
Continuous Improvement	0,050781	0,285160	0,243663	0,126755	0,070232
Empowerment	0,106226	0,212038	0,215555	-0,007087	-0,020772

Conclusions

The aim of this work is to answer the question whether medium and large companies in Poland are adapted to the new paradigms of industrial manufacturing - Industry 4.0, and whether the use of Lean Management methods and tools is conducive to this adaptation. In the area of increasing product flexibility and agility, the results show a low degree of adaptation, only 32% of the sample declared introducing changes in products. In the area of technological changes, the level of adjustment is higher, as a total of 43% of companies declared their willingness to buy or presently use communicating machines. As for the level of automation, 32% of enterprises have at least half of the automated processes, with 35% of enterprises declaring the use of manipulators or robots. The majority of the examined characteristics of the adaptation of enterprises to the paradigms of industrial production in industry 4.0 are at the level of 30% - 35%. Considering that industry 4.0 is a new industrial revolution, the above results, together with the index of 42 robots per 10,000 employees (Grzeszak, Sarnowski, Supera-Markowska, 2019, p. 11), indicate the overall low level of alignment of enterprises to industry 4.0. Moreover, out of the sample, only 8 companies met the cumulative condition of qualifying companies to the analyzed group 4.0. The results of comparative studies between the group of companies 4.0 and the rest of the population indicate that the use of Lean Management methods is conducive to the adaptation of industrial companies to the requirements of industry 4.0. The correlation analyses of Sperman Ranks also confirm this dependence.

Abstract

The study of the manufacturing systems maintenance is mandatory and essential in order to grow the production efficiency and competitiveness. Therefore, the monitoring of performed maintenance activities is an important process in production setups and a blockchain can be the solution to share full transparency of the maintenance parameters. This research focuses on building a maintenance policy, considering that the products defects are caused due to machine malfunction in order to predict the availability of the system. More precisely, we present a modeling scenario for two types of failures: mechanical and electrical. The failure and repair behavior of a machine was modeled using Markov chains. An applied example is presented to illustrate the method. Arena software has been used to fit the statistic distribution concerning the time between failures and repair time, and CodeBlocks software to solve the equations from Markov chains.

Keywords: Failure, Modeling, Markov Chain, Blockchain.

Introduction

Nowadays, in the automotive industry, an important maintenance strategy is the implementation of predictive maintenance. Predictive maintenance allows monitoring the condition of the in-service machine and predicting potential failures. Moreover, the application of blockchain technology increased maintenance efficiency and automation through the reduction of the downtime of machinery using secure data and full transparency. Basically, the blockchain serves as a public and decentralized registry to record all the operations in an efficient, verifiable and permanent manner, without the use of a trusted central authority or central servers (instead, the distributed database are centrally controlled by a service provider). Therefore, the blockchain is a decentralized and distributed database with double security: asymmetrical cryptography, which requires two different keys - the public and the private key - and the mining process which suppose the exchange validation in the form of blocks. For this purpose, in this paper, new ideas of predictive maintenance with secure data are presented. The objective of the article is to monitoring the unexpected failures without worrying about the version changes or losing the latest records by keeping a good availability of the machines. The paper gives an overview of maintenance processes and describes some research studies from the literature concerning blockchains in Maintenance 4.0. We provide a case study from an automotive company where is presented secure maintenance data integration into a blockchain and a Markov chain methodology to estimate the availability of each machine from the flowline. This paper presents some conclusions and provides a standpoint for future work.

Around the unreliable systems, many maintenance strategies have been studied in the literature. The application of Markov chain model can be a solution to evaluate the availability of the system consisting of K repairable subsystems by the methods under various maintenance strategies (Kim, H.G. and Kim, W.S, 2016). In the manufacturing industry, the maintainability and reliability parameters can be considered: Mean Time to Repair (MTR), Mean Time Between Failures (MTBF), Mean Time To Failure (MTTF). Mean Time To Repair (MTTR) makes reference to the amount of time required to repair a system and restore it to complete functionality. MTBF assess the forecast time that passes between one previous failure of a manufacturing system to the next failure

Cite this Article as: Elena-Iuliana GINGU (BOTEANU) and Cristina MOHORA " Availability Modeling with Two Types of Failures using Secure Data Maintenance from a Blockchain" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

during normal operation. Mean Time To Failure (MTTF) establishes the period of time that a workpiece is expected to last in operation until it fails. All these parameters were studied with different methods. J. Stodt et al. (2019) provided a formal description of optimized maintenance processes using blockchain technology and integrated smart contracts for the automated triggering of activities. X. Wang et al. (2016) applied a semi-Markov model for the maintenance policy of a system consisting of two machines with a finite buffer. S Lee et al. (2013) demonstrated the optimal interval for inspection concerning the availability and productivity of a system based on Markov Maintenance Planning. G.K. Chan et al. (2006) presented an optimal value of the mean time applied in preventive maintenance by maximizing the availability of a single component. S Bloch-Mercier (2002) computed the long-run availability and gave sufficient conditions for the preventive maintenance policy. D Chen et al. (2001) presented the steady-state analysis of the periodic preventive maintenance problem with general failure and repair time distributions illustrated by numerical examples. A. K. Agrawal (2019) considered that maximum availability can be obtained by increasing the reliability and maintainability of the equipment. Q. Qiu et al. (2019) adopted an inspection-based maintenance policy in order to investigate the availability for a Markov repairable system with downtime threshold.

Methodology used for estimating the availability by machine integration into blockchain - study case

Maintenance secure data by applying blockchain

In the manufacturing systems, maintenance workers have to record the maintenance parameters from the machines. These technical records have to be issued and timely updated. Involving blockchain technology in maintenance, all the data are automated uploaded on the shared ledger. It is an intelligent platform accessible to all the stakeholders without worrying about the version changes or losing the latest records. Blockchain provides a secure solution because all the data are encrypted using hash functions and the nonces get the proof of work. The Secure Hash (SHA) algorithm with an output size of 256 bits (SHA-256) is the hash function used in many blockchains.

Fig.1: Encryption of the word "failure" with SHA 256 algorithm
Source: https://passwordsgenerator.net/sha256-hash-generator/

A cryptographic nonce is an arbitrary number used only once, and the process of determining the nonce value required to generate valid hashes is called *mining*. This technique is used in the consensus proof of work model which can help validate only correct identities. A blockchain starts with the Genesis block. Then, new blocks of data are added in the chain and the mine button validates each block in the network. The blocks are interlinked through the hash function, i.e. the hash function of the block is the previous hash function for the next block. The transfer of machine maintenance parameters is done through the Internet of Things (IoT), an implementation of sensors that are integrated into the manufacturing system and secure the collection of data (Albano et al., 2018, Vacca, 2019, Alladi et al., 2019, Miller, 2018, Gingu et al., 2020). In our study case, the machines failures are classified into two categories: mechanical (F_1) and electrical (F_2). Once a failure occurs, a recording of the time (down-time) of the failure is made in the blockchain and then a classification of the type of the failure according to the previous two categories is done (an example of blockchain is presented in Figure 2).

Modeling scenario for two types of failure

This article presents a real-life example, a production line that manufactures "crown wheel white parts" from a local company. The "crown wheel white parts" line is an automated line, made up of technological systems that function as a unitary whole. Figure 3 shows the process flow. Operators will only have to make adjustments and supervise the control equipment.

Fig.3: Production line operations

Input data are the key ingredients of the simulation modeling. The entire process flow had specific times for failure and repair for each equipment. The idea is to try to optimize the production taking into account all those accidental problems and to prevent them. Times to failure and repair times are random times and are specified via their distributions or probability laws (e.g., Markovian transition probabilities). The stages of modeling activity are:

- Stage 1. Data collection.
- Stage 2. Data analysis.

- Stage 3. Time series data modeling.
- Stage 4. Goodness-of-Fit testing.

The data collection stage brings observations of system characteristics over time. The analyst collects the data from the blockchain and the sample size collected should be representative and large enough. The analysis stage involves the computation of various empirical statistics from the collected data. In the data modeling stage, a probabilistic model is fitted to empirical time series data collected in Stage 1. The statistics give the analyst information about the collected sample, and establish the empirical statistics against which a proposed model will be assessed for Goodness-of-Fit. Arena software offers data analysis facilities through Input Analyzer tool, whose main goal is to fit statistical distributions to an established sample. The Goodness-of-Fit of a distribution to a sample is evaluated by a statistical test, where the null hypothesis H_0 shows that the distribution is a sufficiently good fit to the data, while the alternate hypothesis H_a asserts that it is not. The Chi-Square test and the Kolmogorov–Smirnov test are the most widely used tests for Goodness-of-Fit of distribution to sample data which compute the corresponding test statistic and the associated p-value (Altiok el al., 2017). In our case study, the machines failures are F_1(mechanical) and F_2 (electrical). The global failure rate is λ. With probability α, the failure is of type F_1 and with probability $(1-\alpha)$ it is of type F_2. An example of the Goodness of Fit test analysis is shown for machine M with the operation 110. Figure 4 shows the results of the Goodness of Fit test for the time between failures. The statistic distribution is $BETA(\beta, \alpha) = BETA(511.8,\ 504.26)$, as is shown in Figure 4.

```
        Distribution Summary

Distribution:   Beta
Expression:     501 + 5 * BETA(2.16, 0.652)
Square Error:   0.016837

Chi Square Test
  Number of intervals   = 4
  Degrees of freedom    = 1
  Test Statistic        = 5.87
  Corresponding p-value = 0.0172

Kolmogorov-Smirnov Test
  Test Statistic        = 0.184
  Corresponding p-value = 0.0234

        Data Summary

Number of Data Points   = 64
Min Data Value          = 501
Max Data Value          = 506
Sample Mean             = 505
Sample Std Dev          = 1.15

        Histogram Summary

Histogram Range         = 501 to 506
Number of Intervals     = 8
```

Fig.4: Statistic distribution for time between failures

Table 1 lists the global failure rate value for machine M.

Table 1: Failure rate value

Machine	MTBF (Mean Time Between Failure)	MTTR (Mean Time To Repair)	MTTF (Mean Time To Failure)	Failure rate $\lambda = \frac{1}{MTTF}$
M	511.8	1.26	510.54	0.00196

The probability for the failure F_1 is $\alpha = 0.4$ and for the failure F_2 is $(1 - \alpha) = 0.6$.

When a failure of type F_1 occurs, the repair is done by the operator; the repair duration is exponentially distributed with rate μ_1. When a failure of type F_2 occurs the operator calls for a repairman. The waiting time for the repairman is exponentially distributed with rate μ_w. When the maintenance operator (repairman) repair the machine, the duration of the repair is exponential with rate μ_2.

The most appropriate distribution for repair time is Exponential with the value of EXPO (1.26) (Figure 5). The repair rate μ_1 is calculated as $\mu_1 = \frac{1}{MTTR} = \frac{1}{1.26} = 0.79365$.

```
        Distribution Summary

Distribution:   Exponential
Expression:     EXPO(1.26)
Square Error:   0.010468

Chi Square Test
  Number of intervals   = 4
  Degrees of freedom    = 2
  Test Statistic        = 4.23
  Corresponding p-value = 0.131

Kolmogorov-Smirnov Test
  Test Statistic        = 0.219
  Corresponding p-value < 0.01

        Data Summary

Number of Data Points   = 64
Min Data Value          = 0.31
Max Data Value          = 5.16

```

Figure 5: Statistic distribution for repair time

Table 2 lists the repair time values.

Table 2: Repair rates values

μ_1	μ_w	μ_2
0.79365	0.04897	0.52083

At first glance, three situations are identified: the machine is working, the machine is under the failure of type $F_1$and the machine is under the failure of type F_2. The two first situations are indeed states while the third is not. In fact, knowing that we are under the failure of type F_2 is not sufficient information to predict the future of the machine; this depends on the presence of the repairman. The situation should then be shared into two states, which finally gives four states:

The graph of the Markov chain is designed in Figure 6.

Figure 6: Markov chain graph

The balance equations are:

$$\pi_1\lambda\alpha = \pi_2\mu_1$$
$$\pi_3\mu_w = \pi_1\lambda(1-\alpha) \tag{1}$$
$$\pi_4\mu_2 = \pi_3\mu_w.$$

The normalisation equation is:

$$\pi_1 + \pi_2 + \pi_3 + \pi_4 = 1. \tag{2}$$

Using numerical values, it is obtained:

$$\pi_1 = 0.973463;\quad \pi_2 = 0.002198;\quad \pi_3 = 0.023377;\quad \pi_4 = 0.000962. \tag{3}$$

The availability of the machine M is equal with $\pi_1 = 0.973463$, since x_1 is the only state where the machine works. The data for the all line are presented in Table 3.

Table 3: Input data for the "crown wheel white parts" line

	OP110	**OP120**	**OP130**	**OP140**	**OP160**	**OP170**	**OP180**	**OP220**	**OP230**
	Turning roughing 1st & 2st side	Semi Finish Turning	Notching	Finish Turning of 2 faces	Control Marking	Hobbing	Chamfe-ring	Shaving	Washing
Cycle time	0.76	0.7	0.4	0.92	0.32	1.05	0.33	0.5	0.34

Tcy (min)									
MTBF	511.8	729.2	81.3	958.3	196.3	201.5	139.8	121.1	809.5
MTTR	1.26	0.96	4.92	0.96	1.63	1.49	2.36	4.13	0.42
MTTF	510.5	728.2	76.4	957.4	194.7	200.0	137.5	116.9	809.1
Failure rate λ	0.00196	0.0013	0.01309	0.00104	0.00514	0.0050	0.00727	0.0085	0.00124
Repair rate μ_1	0.79365	1.0416	0.20325	1.04167	0.61350	0.6711	0.42373	0.2421	2.38095
Waiting time rate μ_w	0.04897	0.1781	0.23810	0.2041	0.19050	0.1575	0.1000	0.1053	0.07480
Repair rate μ_2	0.52083	0.1111	0.11110	0.2041	0.10000	0.1429	0.0968	0.2000	0.09090

Making the calculus for each machine, we obtained the following availabilities results presented in Figure 7.

Figure 7: Availability for each operation

Therefore, the time of the machine's availability is predicted based on Markov chains modeling with two types of failure: electrical and mechanical.

Conclusions

In this article, the basic mathematical model and a practical application of Markov chains for manufacturing system availability analysis using two types of failures were examined. When the information on the system states is available, Markov chains provide an alternative to the standard availability calculations. The information about maintenance parameters is recovered from a blockchain platform. Blockchain offers great benefits where stakeholders need to share, store or capture critical data. The distributed blockchain register save all documentation related to the history of each machine in order to improve equipment reliability and facility equipment monitoring. Then, the data are statistical modeled using the Input Analyzer tool from Arena software in order to include the fitting of distribution to sample data. Therefore, a fitting statistical distribution was generated and tested with Chi-Square and Kolmogorov-Smirnov Goodness of Fit tests to assure high confidence. We had integrated the data into a Markov chain model to predict the availabilities for each machine in the "crown wheel white parts" line. The model is based on two types of failures with different probabilities, but also depends on the presence of the repairman. The results of the availabilities are including in the interval (0.88; 0.994). Starting from these results, the maintenance policy provide that there are no major downtimes. The benefits using these innovative methods (blockchain, fitting distribution, Markov chains) could bring advanced planning and control with relevant, real-time data, higher quality, flexible production, increased productivity, costs and wastes reduction. A topic for future research will include the consideration of failure prediction using regression analysis. This method could be conducted to predict the next coming failure given that a product's defect occurred.

Fourth Industrial Revolution – Changing the Manufacturing Paradigms

Maciej SIEMIENIAK

Poznan University of Technology, J. Rychlewskiego 2 Str., 60-965 Poznan, Poland
maciej.siemieniak@put.poznan.pl

Abstract

The article briefly presents the most important paradigm changes in the manufacturing process in terms of industrial revolutions. The starting point was an attempt to explain the concept of paradigm in a short and general way and an attempt to consider it from the point of view of management science. The essence and significance of technology in the company's processes was also presented. A contemporary view of technology requires perceiving it as an environment in which there are resources enabling the design and implementation of solutions to problem situations, and to a greater extent contributes to the development of technical, technological and organizational innovations, which are the basis for revolutionary changes in the industry. The most important point of the article is a concise description of the most important changes in the methods of production for each stage of the industrial revolution, with particular emphasis on the conceptual assumptions that create a new production paradigm in the new industrial reality.

Keywords: Paradigm, Technology, Industrial Revolutions, New Manufacturing Paradigms

Introduction

The fourth industrial revolution is closely related to Industry 4.0, which is a difficult concept to precisely and unambiguously define. It is described by the changes that occur as a result of technological development and the use of advanced tools in the production processes of enterprises. The main feature of this revolution is the change in the manufacturing paradigm, i.e. changes in the product architecture, manufacturing system and business model, i.e. the method of delivering a new product to the market. New solutions are the result of the evolution of technological processes. The combination of the real and virtual world, transforming data into highly valuable information and knowledge, autonomy of industrial facilities, highly advanced automation and robotization of machines, a new form of human-industrial cooperation, constitute the basis for a change in the production paradigm that results not only from technological changes, but also from changes in the company's environment. Product personalization, i.e. the departure of enterprises from mass production towards the implementation of individual projects and new product solutions, is one of the changes in the manufacturing paradigm. An important change is also the departure from the models of centralized production, in which the product had a described technological route (assigning the product to specific machines), towards decentralized systems, i.e. systems in which the product, having information stored in it, communicates with industrial facilities and selects optimal manufacturing process. The new business model, which is an improvement of the lean manufacturing concept, is characterized by direct contact with the market thanks to the digitization of processes and an efficient flow of data and information from the client to the enterprise. The information obtained in this way about consumer needs allows for quick reaction of producers with the use of flexible production systems. The utilization of robotic objects in the manufacturing process creates a new human-machine relationship. Traditional operation and control of machines is transformed into technically and socially advanced cooperation (Łuciów, 2018).

The fourth industrial revolution changes the perception of manufacturing processes by transferring them to virtual reality and by free and autonomous data exchange between industrial facilities. Cyber-physical systems, Internet of Things and smart factory, properly designed, implemented and connected in the network, form a coherent whole. Technically advanced facilities that create complex systems and processes turn out to be very logical in their assumptions and allow the concept of Industry 4.0 to be seen as extremely homogeneous.

Paradigm

In epistemology, there is a belief that reality can be explored, described, and shaped through paradigms. The concept of a paradigm, as defined by the philosopher Thomas Kuhn, means a set of concepts and theories that form the basis of a given science. He proves that science is not a steady cumulative acquisition of knowledge, but rather a series of quiet periods interrupted by violent intellectual revolutions. Then there is a change of the current world view into a new one. The paradigm term popularized by Kuhn was described as a set of views shared by a group of scientists and a general agreement, agreement on the understood issues. The paradigm guides the research of the scientific community. The phenomenon related to the transition in the process of evolution from one new paradigm to another has been noticed as a typical path of scientific development. Science thrives on the scientific community that works on the basis of one or a set of interrelated paradigms, and the result of creative work solving the problems of the current paradigm is progress. The process of development of science is an evolution from primitive beginnings, through successive stages that are characterized by increasing detail and a better understanding of the environment (Kuhn, 1962).

Generalizing the ambiguity of this concept, one can say that a paradigm is a pattern, model, or accepted way of seeing reality in a given field. People concentrated in organizations try to understand the reality around them through team actions, mutual information, sharing experience, and formulating judgments that are important for them for some reason. In this way, a set of beliefs deeply rooted in people's consciousness is created, which is the code of the organization, which can be called a paradigm (Woźniak-Sobczak, 2015). Paradigm shifts can occur in two cases: changes in the nature of reality and changes in the methods of studying it. Changes in the nature of reality can be a primal, basic premise. The process of change may also begin with the discovery and application of a new method that will result in learning about as yet undiscovered attributes of reality. A new paradigm does not have to exclude the old one, it can develop, improve or periodically replace it. A success of a paradigm does not mean that it has solved all of existing problems. The new paradigm, however, must find anchorage (dissemination, consolidation) in the scientific community and in products of its activity (Lichtarski, 2011). Paradigms in management sciences are practical in nature and are characterized by the ordering of patterns and principles of behavior in solving problems, as well as a scientific generalization of theories that arise on the basis of these paradigms to explain reality. It is assumed that a paradigm is a commonly accepted model for the description of reality, possible to be described with the use of specific research instruments appropriate for a given scientific discipline (Woźniak-Sobczak, 2015).

A Paradigm Shift

The key issues of the new reality in management include diversity, flexibility, adaptability, quick response to changes in the environment and meeting customer expectations. The rapidly changing technological, social and economic environment creates challenges for the creation of modern and advanced management systems. The growing complexity of the world of technology and the necessity to spread and transfer information and knowledge require the implementation of new solutions in the field of technology enabling its use (Jamali, 2005). The level of technological complexity of modern production systems and management systems implies disposition to have a higher level of knowledge needed by the employee and disposition to engage in a multidisciplinary manner (Boyett J.H., Boyett J.T., 2000). Enterprises operating in the knowledge-driven economy willingly use the achievements of science, technology, organization and management, as well as the skills and dynamically developing competences of employees. Old methods and management systems do not ensure employees the proper use of their knowledge and skills to create new solutions and take initiatives (Stallings, 2000). On the other hand, it should be noted that current customers are richer in knowledge, more inquisitive and critical, and this means greater requirements in terms of products and services offered by enterprises (Chapman, 2001). Thus, products in the new reality should be characterized by a high level of quality and functionality, their production costs should be low, and the product life cycle on the market should be as short as possible (Grudzewski, Hejduk, 2011).

Technology

The literature shows a wide use of the term technology. The analysis of various definitions of this concept allows to conclude that the proper understanding of the essence of technology, its role and meaning in the processes and systems of an enterprise requires considering it in a specific context. In engineering science, technology is defined as knowledge related to the methods of producing products. The elements that define the technology are physical objects (machines and devices), processes (they transform materials and components into finished products) and human knowledge (necessary to use physical objects and processes). The basis of technology is knowledge - scientific, empirical, material and immaterial. The modern view of technology requires that it be perceived as an environment

where resources exist to design and implement solutions to problems. The essence of technology is therefore the combination of physical objects with processes, knowledge, social, organizational and management aspects (Wiśniewska, 2015).

The implementation of technological innovations should be not only new, but also cost-effective. This is crucial for taking advantage of market opportunities. New, innovative products, services and processes enable the achievement of better economic indicators in the enterprise (Krusinskas, Norvaisiene, Lakstutiene, Vaitkevicius, 2015). A manifestation of the use of technological innovations are modern, advanced production technologies that provide benefits, e.g. in the form of savings (material, energy, labor) or reduction of pollutant emissions. Modern technologies contribute to the increase in production efficiency, process flexibility, product quality, work safety, reduction of the number of production shortages, computerization and automation of production processes. New reality technologies, such as e.g. artificial intelligence, virtual reality, cloud computing, autonomous robots, coming with the fourth industrial revolution, can provide new, significant values for the enterprise (Baruk, 2018).

Conceptual Assumptions of The New Industrial Reality

The basis for the creation of the new generation industry is the construction and development of cyber-physical systems, i.e. interconnected components of physical infrastructure (machines, devices, sensors) and ICT infrastructure (computers and software) based on algorithms. Devices operating in cyber-physical systems have digital counterparts in the computing cloud, where machines are simulated on the basis of data supplied from sensors in real time. Machine models in the cloud are exemplary for future analytical processes. They also enable monitoring of industrial facilities and individual stages of the production process. The process of creating a virtual model of industrial objects in the cloud computing consists of several stages: integration, conversion, virtualization, perception and configuration. In the first stage, the condition of machines and devices is self-identified thanks to the installed sensors. In the conversion stage, the data collected by the sensors is sent to the cloud, processed there and stored in a database. The virtualization stage allows, on the basis of the collected data, to create a virtual model of industrial facilities that is updated in real time. The perception stage is the archiving of data in a central database and presenting them on demand in the form of infographics. The last stage – configuration, is used to change the operating parameters of industrial facilities on the basis of given criteria in order to minimize the probability of failure.

The idea of cyber-physical systems assumes networking of industrial facilities, allowing for its remote control and configuration. This process takes place in the Internet of Things environment, which allows for communication, i.e. the exchange of information between machines (machine-to-machine – M2M) not only within one cyber-physical system, but can cover and integrate many such systems. Intelligent communication between industrial facilities requires the existence of systems that will enable remote monitoring, configuration and parameterization of networked facilities. This means the use of a two-way communication model that sends commands from the central computer to objects and allows remote configuration without human intervention. (Domińska, 2017).

Essence of The Industrial Revolutions

The first industrial revolution began at the end of the 18th century and lasted until the second half of the 19th century (Fig. 1). New technical inventions contributed to the transition from workmanship and manufactory production to mechanized factory production. The greatest importance was the invention of the steam engine, which was used on a large scale in mining. Another important invention was the spinning and weaving machine, which gave rise to mass production in the textile industry. In the steel industry, charcoal has been replaced with coke. The development of the steel, mining and textile industries contributed to the development of the machine industry. The steam engine was used to build steam locomotives and steam ships. The first industrial revolution increased the energy potential of workers - from that moment on, machines supported human work. There was an organizational breakthrough in factories, the aim of which was to rationalize work. This contributed not only to the increase in workers' productivity, but also prepared the industry to introduce modern techniques and technologies.

Fig.1: Technological changes in the evolution of industry [own]

The second industrial revolution began in the second half of the 19th century and lasted until the beginning of the 20th century. The biggest innovations that revolutionized the industry at the time were two new energy sources: electricity and the internal combustion engine. The age of mass production with the division of labor has begun. A method of refining crude oil was developed, which meant that it began to be used as a fuel. Oil displaced coal, aluminum and copper smelting developed. The invention of the light bulb made it possible to spread electricity and lighting not only in factories but also in households. Another breakthrough was the construction of the internal combustion engine. The world's first assembly line was launched at the Ford car plant. Until now, the entire vehicle was assembled on one workstation, since then the vehicles were produced in stages on a conveyor, which significantly accelerated the process and reduced costs.

The third industrial revolution is known as the scientific and technical revolution. Great changes in technology, science and industry have occurred since the 1950s. The most important aspects of this revolution include computerization, the use of alternative energy sources, the improvement of telecommunications and transport, and the development of industrial applications of programmable controllers. This opens an era of industrial automation based on advanced electronics, IT and work process automation. Innovations that shape the industry, increase production efficiency and speed, and reduce costs. As a result, mass production becomes possible.

The fourth industrial revolution will start with the development of new digital technologies. One of the most important will be the Internet of Things (IoT), through which huge amounts of data will be sent on machines, industrial facilities, work in progress, inventory, etc. Therefore, advanced methods of data processing will be required, which is why techniques of Big Data analysis in cloud computing are being developed. The technologies that complement the new industrial reality include advanced simulations, virtual and augmented reality, additive (3D) printing, autonomy of industrial facilities, a new level of communication and full integration of enterprise IT systems. One of the main effects of the fourth industrial revolution will be the flexibility of production systems. The fourth industrial revolution will intensify activities aimed at digitization and computerization of production. Cyber-physical systems (CPS) will be created, and these will contribute to the creation of smart factories.

New manufacturing paradigms in aspect of the industrial revolutions

The development of technique and technology, which contributed to the industrial revolution, is a factor enabling changes in the production paradigms, i.e. standards and adopted methods of organizing and controlling the production process. In terms of the industry-market relationship, four paradigms can be distinguished, dominant in subsequent periods of industrial reality (Fig. 2): craft production, mass production, mass customization and personalized production (Furmanek, 2018).

In craft production, each product was designed and manufactured for a specific customer by skilled craftsmen using universal tools, machines and devices.

Mass production was characterized by the production of a large number of identical products. Specialized machines and movable assembly lines were used for this purpose. The scale of production lowered the unit cost of manufacturing a product, and thus also lowered product prices, diversified the offers and increased the demand. The production of the product developed by the manufacturer had to effectively utilize the production system in the factory. The sales units were supposed to launch a mass product to the market (Furmanek, 2018).

Fig.2: Four paradigms of manufacturing in different periods of the industrial reality [own]

The next stage in the evolution of industry is the paradigm of mass customization. It was created in response to social demand related to the increased choice of products offered by the manufacturer. The use of modular product architecture facilitated the creation of variants in the design of finished products. The use of programmable controllers and computerization of industrial facilities contributed to the automation of production lines and made it possible to extend the product range with a family of predefined modules. The product offer is very diverse thanks to the possibility of choosing a specific product configuration from the catalog of available options (Furmanek, 2018).

In the currently developing paradigm of personalized production, the customer becomes an active participant in the product design process. From the modules available from the manufacturer, the customer creates his own product configuration, usually with the use of special design tools. Effective implementation of this concept is possible thanks to the use of reconfigurable production systems. In the new reality, shaped by the fourth industrial revolution, smart products will determine the configuration of production systems. The fourth industrial revolution will change the way industrial systems are managed and controlled. The centralized production paradigm used so far meant the implementation of complete production tasks in one factory or multi-plant organization. The new decentralization paradigm will arise as a result of creating autonomous networks and intelligent process units that will exchange information and configure themselves to optimally run the production process and achieve results. The functioning of the production unit in the network forces the company to focus on its own key competences and transfer the remaining ones to cooperation. This then leads to a change in the business model from product orientation, when the organizational unit produces products, to service orientation, i.e. offering the best service in the network for the implementation of a part of the manufacturing process (Furmanek, 2018).

In the traditional approach to the value chain according to M. E. Porter the product moves one-dimensionally to the next organizational units, and each one adds value (Magretta, 2014; Gierszewska, Romanowska, 2017). Industry 4.0 provides for multidimensional networks of values in which the source of value is a combination of network elements based on interaction. Value networks in the new reality are related to the concept of a platform, meaning a business model that creates value by connecting suppliers, producers and consumers, and thus enables the exchange of values created by network participants and facilitates cooperation.

The paradigm shift also affects the human-machine relationship. The role of the worker will shift towards managing the activities performed by robots and highly automated machines. New technical solutions will be related to increasing the possibilities of employees. The development of competencies will be continuous and will be integrated with production processes, and will be supported by digital worker assistants. The ability to remotely communicate the worker with industrial facilities will contribute to more flexible work time planning.

Advantages of the new manufacturing paradigm

The new manufacturing paradigm shows a high level of functional integration. The data generated by IT systems is easily accessible and highly useful for management, and the new reality environment allows to create new business models. Thanks to the networking of industrial facilities and the quick exchange of data between machines and devices, enterprises can produce more economically and respond faster to individual customer needs. Changeovers and the preparation of machines for new needs is reduced to a minimum, so that the production system becomes more flexible. Machines, devices and production facilities communicate with each other and modify the performed task. Cases of wastage and loss of working time in the production process are detected thanks to better transparency of the value chain and access to current data, and this significantly increases production efficiency. The new industrial reality environment also supports workers by providing them with access to information about the production process and the value chain at any time and from anywhere.

Considering the business effects at the enterprise level, it should be noted that the implementation of the new reality principles will contribute to more precise recognition and better adaptation to market needs, thanks to combining external information with internal data about processes and flexible configuration of the manufacturing process. The increase in the company's profitability will be the result of the precise and timely fulfillment of customer expectations. The most important operational effect will be a better efficiency of using the company's resources, thanks to the flexible and quick preparation of resources and processes to the current needs and task accomplishment. The following will also improve: product quality (thanks to the immediate availability of data, the possibility of analyzing it on an ongoing basis) and the condition and availability of machines in the process (thanks to prediction methods in maintenance, ongoing data analysis, quick identification of problems and anticipating problem situations).

Summary

The most famous thought of the Greek philosopher Heraclitus of Ephesus, which tells us that the only constant thing in the universe is change, and that everything that surrounds us is constantly changing from one state to another, is still valid and can apply to all areas of human activity, including industrial activity. To paraphrase this concept, it can be said that the evolution of the production paradigms is a natural right of the changes resulting from the needs of various areas of human activity.

The change of production paradigms is the result of the accumulation of evolutionarily developed technological innovations, which mean that the current model of functioning in a given area requires a change. The basis of changes are technological innovations, market trends and socio-cultural changes. The accumulation of these factors leads to another breakthrough in the history of the evolution of industrialization, known as the fourth industrial revolution. Product customization, reconfigurable and decentralized manufacturing systems, full automation and robotization of manufacturing processes, a network of autonomous industrial facilities, a new level of communication, cyber-physical systems creating smart factories, the ubiquitous Internet of Things and Cloud Computing, as well as virtual and augmented reality are the elements creating the new manufacturing paradigm in the new industrial reality. The factor stimulating changes and enabling their development are technical, technological, organizational and managerial innovations, or more precisely, their interconnection and synergistic operation based on information and communication technologies.

Abstract

The resent trends in the development of the Russian insurance market are favorable on the annual growth of insurance premiums. However, a detailed analysis allows us to conclude that the growth is mainly due to the rapid development of the investment life insurance segment. The main risks associated with the protection of housing, movable property, health are not the subject of an insurance contract due to the low level or lack of insurance interest of citizens.The article examines the issues of insurance protection of the interests of citizens of the Russian Federation in the context of reducing the possibilities of the state budget and other centralized funds for compensation of damage. The main aim of this article is to study the factors that determine the increase in the propensity to insurance among individuals and to identify the relationships between them.
Special attention is paid to the development of a system of measures to ensure an increase in citizens' interest in using the insurance mechanism. The directions that will increase the level of insurance penetration among the population have been identified.

Keywords: insurance, propensity to insurance, savings, welfare of citizens.

JEL Classification: G22; E21

Introduction

Insurance coverage in large part determines the ability of citizens to recover losses associated with loss of property or ill health in a market economy. Catastrophic events associated with forest fires and floods raise the question of using the insurance mechanism. It must be noted that most of the property items owned by individuals have not been insured. Citizens often demonstrate a leading-strings mentality, largely due to the expectation of compensation for damage from the state, the implementation of the constitutional right to housing. However, the state's ability to finance damages is limited by the existing tax burden. In addition, the formation of insurance funds provides financing for investment processes in the economy.

Cite this Article as: Gulnara N. KAIGORODOVA, Alfiya A. MUSTAFINA, Guzel K. PYRKOVA, Ruslana MAMCHUR , Iryna M. ZELENITSA, Tatyana N. KUL and Larisa V. BELINSKAJA" Growth Factors of Insurance Interests of Russian Citizens" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The strategy of the insurance industry development of the Russian Federation for the period from 2019 to 2021 provides the implementation of a number of target indicators (All-Russia Insurance Association, 2020). It is expected to increase the share of insurance penetration from 1.4% to 1.7% of GDP by 2021, and the volume of insurance premiums per capita from 8.7 to 14 thousand rubles, that is by 60.9%. The need to achieve these indicators is due to the state's desire to reduce the burden on the budget, to use actively market mechanisms to cover damages from the insurance risks implementation.

Legislative norms that determine the need for home insurance against natural emergencies came into force on August 4, 2019. Regional programs may cover other risks as well: domestic gas explosion, flood, fire. It should be understood that the program is voluntary and the amount of the insurance premium will be included in utility bills by default. The homeowner has the right to decide whether to purchase this insurance policy or not. In fact, the traditions of fire insurance have been restored in Russia (Trynchuk, 2011), (Trynchuk, 2017).

There are positive trends in accident insurance, voluntary health insurance, home insurance against all types of risks and Transport Insurance. However, the level of coverage is insufficient, especially in emergency situations.

The article examines the factors that determine the development of citizens' propensity to insurance, systematizes possible points of growth, identifies directions for further researches in this area.

Literature Review

Considerable attention to the study of issues of increasing the citizens' interest in insurance is given in the works of scientists.

Some scientists consider the relationship between consumption and insurance (Hambel, et.al, 2017). Thus, the issues of long-term life insurance, consumption problems, investment and household insurance have been investigated. It is concluded that the presence of unresolved issues in consumption, the expectation of expensive purchases reduces the demand of insurance products. In particular, young families tend to avoid purchasing of long-term life insurance policies.

The scientists note that expected utility theory does not always work in the modern world. Increasingly, it gives the way to behavioral theories, for example, when government purchases of goods and services, including insurance, and non-price factors are not taken into account (Baranovsky et.al, 2020), (Tkachenko, et al, 2020). So, (Richter et.al, 2019) consider the well-established behavioral models, substantiate their relevance for the insurance industry. They note the importance of predicting customer behavior, understanding the influence of consumer behavioral factors in the insurance industry (Polinkevych, 2016), (Polinkevych & Kamiński, 2018). In particular, it has been noted that when choosing a particular service, priority is given to the one that impresses the customer on a psychological level and evokes certain emotions (Horyslavets et.al, 2018).

The questions of the influence of legislative changes on the insurance industry are investigated. In particular, (Heaton, 2017) considers this aspect in the area of auto insurance and notes that the relaxation of civil legislation does not lead to the increase in auto insurance coverage. Therefore, the issues of protection the rights of insurance services consumers (Horbova et al., 2018), (Ostrowska-Dankiewicz, A., 2019), improving of insurance culture, popularization of the institution of insurance are very important.

It is interesting to study the question of how the transparency of the formation of the insurance rate affects the propensity to buy an insurance policy. (Huber et.al, 2015) consider this problem using the example of endowment life insurance. It is concluded that no relationship has been identified between «price transparency» and a positive decision to purchase the policy.

The problems relating to the low level of population demand are studied in the works of Russian scientists. Kuznetsova N. considers separate definitions of this issue and also analyses the relationship between the well-being of citizens and the level of demand for insurance services in her work (Kuznetsova, 2016). The author concludes that the costs of high-risk insurance are considered by families as an expense for saving, not consumption. When studying the conditions for the formation of an insurance portfolio (Kokh et. al, 2016), it is noted that its structure is determined not only by the insurer's strategy, but also by the interest of consumers in individual or interrelated insurance types. A low level of insurance culture, lack of insurance interest, low quality of insurance services have been noted. At the heart of the strategy of insurers is dominated by marketing (Klapkiv, 2016).

The importance of the institution of insurance is obvious (Kaigorodova, et.al, 2018), since its development in large part determines economic growth of the state. The authors have identified the factors that determine the low level of demand for insurance services from the population in Russia.

Considerable attention is paid to the study of insurance behavior of the population. Modeling (Sinyavskaya & Tregubova, 2018) has shown that insurance behavior is determined by a number of socio-demographic, economic and behavioral characteristics. It is concluded that insurance behavior is not considered by Russians as a method of risk management, but manifests itself only if there is a financial opportunity. It is noted (Płonka et. al, 2020) that interest in insurance coverage increases with the approach of the retirement age.

The work (Spletukhov, 2019) is devoted to the study of the social factors of the interest of Russian citizens in insurance services, the criteria which are guided by insurance services consumers when choosing an insurance company. Various mechanisms of attracting the population to the purchase of insurance policies are considered (Kaigorodova et al, 2020; Horyslavets, P. et al, 2018), including digital technologies (Klapkiv et al, 2018) use, however, cyber risks of the insurer (Łyskawa et al, 2019) are noted. Insurance companies must take care of their customers trust, implementing the concept of social responsibility in relation to customers and partners to ensure their own development (Khovrak, et al, 2019), (Glonti, V. et al, 2020).

Hypotheses

The increase in the propensity of the Russian population to insurance depends on two factors: (1) the average per capita income of the population; (2) opportunities to save. Savings activity of the population can be manifested in various directions (purchase of financial products, currency in cash savings). Household deposits as the most frequently used product have been employed for the analysis.

Methodology and Data

It is necessary to investigate the change in the welfare of Russian citizens. First of all, we assess this by such indicators as the average per capita income of the population; housing per capita; the number of vehicles owned by individuals; individuals' deposits, as well as consumers loans. The data are shown in Table 1.

Table 1: Indicators characterizing the change in welfare of Russian citizens

Indicators	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Average per capita income of the population, thous. rub.	19.0	20.8	23.2	25.9	27.4	30.3	30.9	31.9	33.2	35.2
Real disposable cash income of the population, % of the previous year	105.9	100.5	104.6	104.0	98.8	97.6	95.5	99.5	100.1	101.0
The total area of residential premises per inhabitant on average, sq. m.	22.6	23.0	23.4	23.4	23.7	24.4	24.9	25.2	25.8	26.3
Trucks owned by citizens, mln. units	3.0	3.1	3.3	3.5	3.8	3.8	3.8	3.9	4.1	4.0
Passenger cars owned by citizens, mln. units	32.6	34.6	36.9	39.2	41.4	42.3	43.2	44.8	46.1	46.3
The share of savings in the structure of using the population's monetary income, %	14.8	10.4	9.9	9.9	6.9	14.3	11.1	8.1	1.7	3.0
Individual deposits, trn. rub.	7.5	11.6	14.2	16.9	18.7	23.3	24.3	26.1	28.6	30.5
Loans to individuals, trn. rub.	3.6	5.4	7.2	8.8	12.0	11.3	11.5	13.0	15.9	17.7

Source: compiled by the authors, based (Official site of Central Bank of Russian Federation, 2020 & Official site of Rosstat, 2020)

The most significant changes were revealed in deposits and loans of individuals in 4.07 and 4.92 times, respectively. Significant growth was revealed in the indicator of passenger cars owned by the citizens, a change over the period of 142%. The provision of housing has slightly increased (in terms of the area of residential premises per inhabitant). The essential aspects that need to be analyzed in the process of pricing in the Russian housing market are regional characteristics and features of the impact of macroeconomic risks (Ermilova & Finogenova, 2017). The growth in the average per capita income of the population is noticeable, but for the study it is advisable to consider the change in the real disposable monetary income of citizens, that is, incomes adjusted for the inflation rate. According to this indicator, we observe insignificant, but a decrease in income. The share of savings in the structure of the use of monetary income is sharply reduced. It should be kept in mind that insurance services are implemented at the phase of GDP redistribution, as a rule when the consumers decide on the proportions of the budget between consumption and savings. If preference is given to consumption , then the decision to purchase insurance products for voluntary types of insurance, as a rule will be negative. In addition, when distributing the household budget, a person takes into account the emerging current situation, predicts its change. In particular, he may give preference to protection from social risks and risks associated with a possible deterioration of health not by purchasing an insurance policy, but by the services of sanatorium treatment and health improvement (Mustafina et.al, 2017).

In general, we can conclude that there is an increase in housing volume, vehicles owned by the citizens, and savings in the form of deposits are growing. The decrease in the share of savings indicates the increase in the current needs of households, inflationary expectations, and the increase in the share of income allocated to servicing loan obligations. The growth in the loans volume to individuals can be assessed in two ways. On the one hand, this indicator characterizes the empowerment of the citizens, the increase in aggregate demand in the market. On the other hand, a comparison of this indicator with a decrease in the real disposable income of the population may indicate the replacement of sources for meeting the needs of the citizens from their own to borrowed ones.

We will focus on the characteristics of insurance services use by the citizens. Unfortunately, statistics do not allow separating premiums paid by individuals and legal entities. Therefore, we will use the data of official statistics for the analysis, distiling such areas of insurance as life insurance, pension insurance, insurance against accidents and illnesses, and others, as they are related to insurance protection of the citizens' interests (Table 2).

Table 2: Insurance premiums accumulated on insurance products for individuals

Insurance premiums, bln. rub	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Life insurance (except for pension insurance)	21.3	33.8	51.8	83.3	106.9	128.2	214.3	330.1	450.8	407.3
Pension insurance	1.4	1	1.1	1.6	1.6	1.5	1.4	1.4	1.6	2.1
Insurance against accidents and illnesses	36.6	48.8	75	93.8	95.5	80.9	108	121.2	169.5	187.4
Property insurance of the citizens	n.d.	n.d.	25.8	29.8	38.6	43.9	51.4	57.4	64.8	71.9
Total insurance premiums for insurance of individuals	59.3	83.6	153.7	208.5	242.6	254.5	375.1	510.1	686.7	668.7

Source: compiled by the authors, based (Official site of Central Bank of Russian Federation, 2020).

Life insurance as the accumulative direction of insurance shows significant growth in the researched period. The main growth driver is investment life insurance. However, there is a decrease in growth rates in this area due to a lower actual level of profitability of investment life insurance products compared to the declared levels in 2019. Such risky types of insurance as insurance against accidents and health insurance are developing dynamically, especially in the last three years. Mortgage insurance and the inflationary rise in the value of the insured property are determining factors of the increase in premiums for insurance of citizens property.

The key factors influencing the increase in the propensity of citizens to insurance, in our opinion, are:

- growth in real disposable money income of the population;
- decrease in rates for mortgage lending, which leads to the increase in the volume of mortgages;
- participation of the employer in the formation of contributions for accumulative types of insurance;
- introduction of new types of compulsory insurance («fostering a culture of insurance»);
- stimulation the acquisition of new property by citizens (for example, the programs «First car», «Family car», etc.) and it encourages a person to take measures to save this property.

Correlation analysis has showed a high relationship between insurance premiums accumulated for insurance of interests of individuals and the total area of residential premises per one inhabitant, with deposits of the population, as well as with the number of cars owned by the citizens. The relationship with money income of the population is moderate.

The main share of insurance premiums for interests insurance of individuals is on life insurance in recent years, that is, accumulative types of insurance. It is advisable to construct a linear regression equation for two variables, i.e insurance premiums accumulated for insurance of interests of individuals and deposits of individuals. It should be noted that investment life insurance policies (which have the main share in the life insurance segment) are usually medium-term, and often short-term. However, the study of deposits structure of individuals also shows their short and medium term orientation. Regression analysis has allowed us to obtain the results shown in Figure 1. The accuracy of the approximation is satisfactory ($R^2 > 0.8$), high reliability of the results (significance F = 0.000705).

Fig. 1: Interrelation of insurance premiums for insurance of individuals interests and individuals deposits

Source: compiled by the authors.

Thus, we can note that the increase in the propensity of the population to save increases the interest in purchasing insurance services. We understand that the increase in accumulation and savings of citizens makes them think about the safety of financial well-being, about improving the level of financial culture. Further research requires the construction of a multivariate model, taking into account additional parameters, including a qualitative one.

We can offer the following points of growth of the insurance market with respect to insurance protection of individuals (Table 3).

Table 3: Directions for increasing the propensity of citizens to insurance

Growth factors	Possible ways of ensuring
1. The level of monetary income of citizens	– macroeconomic stability; – control over ensuring the basic constitutional rights of citizens, including the right to remuneration for work without discrimination; – state measures to support families; – retraining system.
2. Citizens' awareness of the potential danger of risks that threaten their financial well-being	– carrying out activities to improve the level of financial literacy, financial culture of the population; – establishing clear target criteria for the provision of state support in unfavourable events; – introduction of compulsory types of insurance for the most significant risks (including transferring home insurance against natural emergencies from voluntary to compulsory).
3. Trust in insurance companies	- further implementation and improvement of the system of Basic Standards for the provision of insurance services; - expanding the participation of the financial ombudsman in the settlement of insurance disputes; - formation of guarantee funds for socially significant types of insurance; - expansion of the reinsurance protection system; - activating the work of law enforcement agencies with insurance fraud; - improvement of Compalsory Automobile Liability Insurance system.
4. Availability of insurance services	- implementation of financial marketplace project; - maximum availability of purchasing insurance policies via the Internet, regulation of legal obstacles; - expanding the availability of online claims settlement procedures; - measures of economic stimulation of citizens to insurance protection of interests through tax incentives; - formation of healthy competition between life insurers and non-state pension funds; - microinsurance development.

Source: compiled by the authors.

The axiom seems reasonable that the monetary incomes of the population have an impact on the insurance market development. Such a relationship has been found in our research, although the correlation is moderate. However, it should be kept in mind that the official statistics do not take into account the income received in the «gray» labor market. According to various expert assessements, it takes up to 1/3 of the officially recorded income of Russians.

It is necessary to take into account a number of qualitative factors. The propensity to insurance is different among people of different age groups. Young people are actively interested in various services of the financial market. People of active working age, often face with mistakes or fraud in insurance, they are careful in purchasing insurance policies. However, they are the main (in terms of cost characteristics) consumers of goods and services. Both of these groups of the population are active users of the Internet, digital technologies, so access to them is the widest. Older people with lower incomes, however, tend to be more anxious about various dangers. This encourages them to purchase insurance policies, for example, real estate or homeowner liability.

Approaches to insurance development in different regions will be different. Despite the horizontal alignment of fiscal capacity, the level of economic development of the regions is different. This fact should be the basis for determining priorities in the development of certain types of insurance. It would be reasonable to form a kind of hierarchy of needs in the types of insurance services because Russians first of all care about the property safety and only then about compensation for health damage.

Results and Conclusion

Two mechanisms based on the use of state financial resources and with the help of a market mechanism for risk insurance can be distinguished in the damage compensation system. The current situation with systemic financing

of citizens' damages at the expense of centralized funds does not allow improve the insurance culture of the population, does not contribute to the development of insurance as a full-fledged market institution. The insufficient level of citizens monetary income is largely refuted by the growth in sales of consumer goods, durable goods, real estate, an increase in the volume of tourist trips, etc. There is a danger of missing a favourable moment and maintain leading-strings mentality in society.

There are several areas that will increase the level of insurance penetration among the population:

1) development and implementation of new compulsory types of insurance. This mechanism was used even in the post-war years in developed countries in order to form an insurance culture among several generations;
2) widespread use of the principle of the owner's responsibility for compensation for damage caused to his property, clear targeted support of socially unprotected property owners;
3) development of legal practice of compensation for damage and harm caused to property and/or health of third parties;
4) control by the state and self-regulatory organizations on compliance with the rules of business conduct of insurers and, in particular, insurance intermediaries;
5) stimulation of the development of accumulative life insurance, including pension insurance, creation of equal competitive environment with non-state pension funds;
6) consciously and competently make the transition to a truly insurance model of financing medicine.

Discussion

Realization of natural and technological risks, reduction of the budgetary system's ability to finance damages should increase the state's interest in using the insurance system as a mechanism for compensation for losses. The social insurance function is underutilized. Obviously, macroeconomic conditions are largely decisive in the formation of citizens' propensity to insurance. At the same time, the delay in improving the insurance culture of the population may result in a number of problems:

- irrevocable loss of property values when the state is unable to compensate for damage from centralized funds;
- a decrease in the level of compensation for damage for insured risks in the context of insurance fraud, the work of auto lawyers, etc .;
- further decrease in the level of insurance liability in conditions of unfair competition, dumping of federal insurers.

To form a behavior model, it is necessary to take into account:

- psychological characteristics and motivations of people of different ages;
- features of the development of the economies of specific regions;
- «the state must help» paradigm in society;
- the possibility of pursuing a purposeful government policy to «instill» insurance culture through the introduction of compulsory types of insurance.

The use of the insurance mechanism in terms of protecting the welfare of citizens will help reduce the burden on the state budget, form a responsible citizens' attitude to property, and expand the possibilities of using insurance funds as investment resources.

The Classification of Households with Respect to the "Family 500+" Benefit

Agnieszka SAMSEL

University of Szczecin, The Faculty of Economics, Finance and Management, Szczecin, Poland
agnieszka.samsel@usz.edu.pl

Abstract

Pro-family policy in Poland has changed since April 2016. The programme described as "Family 500+" has been introduced and it has provided financial support for Polish households. A household, taking advantage of the programme, may treat it as an additional financial support (apart from remuneration for work performed) or the main source of income. The purpose of this article is to explain the concept of a household from an economic point of view, as well as to indicate the differences between related concepts. Additionally, the work aims at characterizing the pro-family policy of Poland (also over the years). The main purpose is the division of households (classification) on the basis of the financial use of the funds from the "Family 500+" benefit. The research methods used in the article include: critical analysis of literature, examination of documents, a questionnaire and statistical analysis.

Keywords: Households, Pro-Family Policy, "Family 500+", Household Finances.

Introduction

Households are the most numerous entities in the economy. It happens, however, that the terms: household, family, family household and a consumer are used interchangeably in scientific studies. A household needs financial resources to achieve its main goal, which is maximization of satisfaction of needs. A household can receive income from work performed or a profit from its business activities. In addition, a household can receive financial assistance in the form of a social or a family benefit, or a benefit for bringing-up a child . The "Family 500+" programme, which was implemented in Poland in April 2016, is the example of a benefit for bringing-up a child (a child-support benefit). Its main goal is to reverse the negative demographic trend, as well as to help in raising children. A lot of households treat additional financial resources as an opportunity to meet the children's needs (e.g. educational, leisure), which, due to current financial limitations, were impossible to satisfy before. It occurs, however, that households use the "Family 500+" benefit and other social benefits for current maintenance of the whole household, often giving up employment. Apart from the "Family 500+" programme, in Poland there are many forms of financial, material and non-material support for households in terms of pro-family policy. The purpose of this article is to classify households on the basis of the way the funds from the "Family 500+" programme are used. The additional aim is to characterize the pro-family policy in Poland, including the historical outline. As mentioned before, a household is identified with many other, related concepts. Separating the concept of a household is another goal of this work.

A Household and Related Concept

An attempt to define a household was made by numerous authors. In the literature, which was subjected to criticism, the definitions proposed by Polish and English-language authors were analyzed. A household in the economic literature was defined by Cz. Bywalec (Bywalec, 2017), K. Gutowska (Gutowska, 2003), T. Zalega (Zalega, 2007), or B. Świecka (Świecka, 2009). Among foreign authors, G.S. Becker (Becker, 1976), L. Beaman, A. Dillon (2012) or M. Tomás (Tomás 2013) tried to define a household. The presented authors present their definitions based on various criteria. The following criteria for defining the concept of a household can be distinguished:

- the criterion of living together,
- kinship criterion,
- decision-making criterion,
- criterion of satisfying consumer needs,
- fundraising criterion.

After analyzing the available definitions, taking into account various criteria, the most universal definition of a household is the one proposed by the OECD. For the purpose of this article, a definition proposed by the OECD has been adopted. According to the definition, a household is an individual (a single person household) or a group of people (a multi person household), who reside together in a given dwelling unit (a house, a flat, a room) and, above all, share the funds necessary for subsistence (OECD, 2017). It can be stated that the criterion determining a household is both a common budget and a shared place of residence. Still, there are exceptions from this definition, a good illustration being pupils or students living in one household with other members but temporarily staying in another place of accommodation. Or to take another example, a household head who is employed away from the place of residence of persons included in his/her household. In both of the exceptions mentioned, the criterion of joint management of cash remains unchanged, but the criterion of cohabitation is impaired.

As previously mentioned, a household may be identified with a number of related concepts. It should be pointed out, however, that a family, a family household or a consumer are not synonymous. Table 1 presents the differences between the terms associated with the concept of a household.

Table 1: A household and related concepts

The concept	Explanation
Consumer	A household is identified with an individual, namely a consumer. The decisions made by a household in practice are taken by an individual, i.e. a consumer (Galbraith, 1979).
Family	This is a sociological category. A family is defined as the basic social group, in which the bonds connecting family members (parentage, marital relationship, blood kinship or adoption) play a very important role. Another characteristics include: an internal structure and positions occupied by family members (e.g. the family head, the child), as well as interactions between family members (Gelles, 2000).
Family household	Persons who are related or related by marriage, living together and maintaining a common household. A family household jointly uses durable goods, and collects and disposes of financial resources. Simultaneously, educational, culture-creating and caring activities are undertaken by members of a family household (Zalega, 2012).
Consumer household	A household that does not have its own means of production. It supports itself on work done by its members beyond household, and fulfills the household production function at the same time. This term is used as a synonym of a household (Zalega, 2012).

Source: Own work

Despite differences between the related concepts, for the purpose of this article, the terms: a household and a family have been unified and simplified, and used interchangeably. According to the common definition, a household and a family is a group of people living together or not, connected by blood ties (or adoptions or marital bonds), jointly making decisions regarding the disposition and distribution of an income in such a way that the common goals of the household as well as individual needs of individual household members could be satisfied in the fullest possible way. In literature, an interchangeable use of the terms: a household and a family can also be found. It was used by Paul Samuelson (Samuelson, 2004), and Lidia Beskid (Beskid, 1977). Despite the simplification and the use of the concept of household for the purposes of the article, the author decided to indicate related concepts. The distinction between concepts is to show that there are concepts that are related and similar to households, but still have different features.

The main purpose of a household is satisfaction of needs of its members. In order to achieve this goal, a household divides its income in order to meet obligations, satisfy current consumption and have savings. Financial plans, financial statements and household budgets are the techniques which facilitate control over income and expenses (Gitman, Joehnk, Billingsley, 2014). A household budget is used to monitor and control the household income and expenditures, as well as to supervise purchases and savings within one month. A household budget may also be prepared for several months, a year or even several years (for a short or long period). Moreover, a household budget allows to determine the level of income and expenditure in a given week, month or year and, simultaneously, creates the opportunity to estimate the amount of savings (Hammonds, 2006). Also, in the case of a household and its budget, the expenditure side is equal to the income side. According to the Central Statistical Office, a household budget is a systematic statement of revenues and expenses, both monetary and non-monetary

Let us now examine revenues and expenditure of a household. Disposable income is the sum of current monetary and non-monetary revenue of all members of a given household, reduced by advance personal income taxes.

Disposable income is reduced by social and health insurance contributions, too. This income is earmarked for all kinds of expenses, including consumption expenses and savings. Disposable income is also called spendable household income, which is reduced by other expenses (e.g. taxes and fees paid to the state and local government). In general, expenses are expenditures on consumer goods and services and other expenses (mentioned above). Expenditures on consumer goods and services are incurred to satisfy a household's needs (Świetlik, 2011). The examples of a household's revenues and expenditures, included in a household budget, have been presented in Table 2.

Table 2: The examples of revenues and expenditures in a household budget

The examples of revenues	The examples of expenditures
Remuneration for work (wage), bonuses and payroll allowances, pension, retirement benefits, non-returnable social and family benefits, benefits for bringing-up a child, profit from a household member's business activity, inheritance and donations, interest on bank deposits, rent income (beyond business activity), revenues from investment funds and participation units	Food, clothing and footwear, durable goods (e.g. domestic appliances and electronics, furniture), sport (e.g. sport equipment and training passes), holidays and leisure activities, cultural goods (e.g. cinema, museum and theatre tickets), health care and purchase of medicines, educational needs (e.g. books, extracurricular activities), children's needs (e.g. toys), alcoholic beverages, entertainment and exploitation of a flat.

Source: Own work

Additionally, a household's revenues include all kinds of financial benefits that are social, family-oriented or child-support. The "Family 500+" programme, implemented in April 2016, is the benefit like that. Financial resources, obtained due to the programme, increase the income side of a household budget. Increased household income results in the change of expenditure structure, i.e. more current needs can be met or the level of savings can increase.

Family policy in Poland

For the purposes of this article, a number of documents were analyzed, including acts and draft acts on family policy in Poland and Europe. The analysis of current and archival documents helped to develop the characteristics of the family policy. Moreover, the analysis of the documents made it possible to distinguish the instruments of family policy. Family policy is the part of social policy of the state. The term 'family policy' was first used in the 1940s during debates on social policy in Europe. The first actions addressed to families were taken in France and Sweden at the turn of the 20th century. Pro-family policy is defined as all kinds of measures, actions and legislation that are introduced and adopted by the state; they are aimed at creating appropriate conditions for functioning of a family: its creation, proper functioning and fulfilling its all important social roles. In the subject literature, two types of family policy are mentioned: indirect policy (implicit), and direct policy (explicit). As for implicit family policy, actions are aimed neither at families nor households directly, but have important consequences for their functioning. These are, for example: unemployment prevention or tax policy. Explicit family policy consists of clearly defined actions, programmes and benefits aimed directly at families.

Family policy in Poland, has undergone a lot of modifications and transformations over the years. Between 1989 and 2015, three major periods can be distinguished: transformational (1989 - 1997), transitional (1997 - 2005), and mature (2005 - 2015). The first one (the transformational period) was characterized by limited family policy. Actions of the state were directed mainly at the unemployed and aimed at counteracting high unemployment. In the first phase of the transformation, there were neither explicit programmes nor strategies for families; what is more, a decrease in the number of places in nurseries and kindergartens could be observed. In the next period, from 1997, family policy took the form of programmes aimed directly at families. This can be illustrated by prolonging the maternity leave, tax relief for a child and a single payment birth grant (so-called 'newborn allowance'), as well as the gradual growth in the number of places in nurseries and kindergartens. In the last, mature period, the solutions introduced in previous years, have been improved and family policy has been aimed at both compensating families with expenses that they have had to cover in order to run a household and facilitating the reconciliation of professional life with bringing up children.

Family policy is implemented by means of instruments like: legal measures (i.e. all legal norms that regulate the relationships between families and the state or other institutions), cash benefits (all kinds of benefits and

allowances), payment in kind (material goods transferred to families), as well as services (e.g. nurseries, kindergartens, community centers). Table 3 presents selected instruments of family policy operating in Poland.

Table 3: The instruments of family policy in Poland

The type of the instrument	The name of the instrument
Monetary benefits	• Family allowance with supplements • Carer's allowance (related to care of a disabled child) • Single payment birth grant (so-called 'newborn allowance') • Child Tax Credit • Maternity allowance • Benefit for bringing-up a child • The "Family 500+" programme
Non-cash benefits (services, payment in kind)	• The nationwide Big Family Card • Paternity leave, maternity leave • Care for a child under 3 years: nurseries, toddler clubs, daytime babysitters • Preschool education

Source: Own work

The "Family 500+" programme, which has been operating in Poland since April 1, 2016, seems particularly noteworthy. In accordance with its assumptions, the programme provides universal and long-term support for families. The programme is designed to help raise children; and the monthly benefit aims to cover, at least partially, costs connected with meeting basic needs and child rearing. Next goal is to improve the material situation of Polish families, and to increase fertility in Poland. Broad eligibility criteria allow all kinds of families to apply for the benefit. It is granted for every family, i.e. parents or guardians of children until they reach 18. The "Family 500+" benefit is paid in the amount of PLN 500 per child each month. The "Family 500+" benefit is paid by town councils, community councils, social welfare centres or social benefit centres. However, in order to receive the benefit, a family have to submit an application to one of the above-mentioned institutions. After granting, a similar request have to be submitted every year. The benefit is paid from the month the application was submitted.

What seems essential, the benefit assigned (in the amount of PLN 500 and more) is not counted as family income while establishing entitlement to other benefits, e.g. alimony fund, family benefits, or various types of housing benefits. Moreover, the "Family 500+" benefit is tax-free, therefore parents of children for whom the benefit was granted receive PLN 500 per child and have no obligation to pay any taxes or contributions on this amount. This rule also applies to parents who run a business. Families who receives funding of a similar nature abroad are not entitled to the benefit.

The classification of households

The classifications presented in the literature

The classification of households is the division of these business subjects according to specific criteria. One household can be matched simultaneously to several types of classification. There are a lot of different criteria. The simplest criterion for the division is the size, namely the number of people making up a household (a single-person household and a multi-person household). In another classification, households are grouped into: rural and urban households. Here, the distinguishing criterion is the area of residence. Rural households are subdivided into typically agricultural households, primarily farming households and non-agricultural rural households. Likewise, households in urban areas are subgrouped into metropolitan households, mid-sized town households and small-sized town households Taking into consideration relationships between household members one may distinguish: single person households, family households, family households with other people and non-family households (based on different ties than family relationships). Similarly to the division of rural and urban households, family households are divided into several separate subgroups., namely: one-generation households, two-generation households and three-generation households (and more). Another classification proposed in the literature is based on the age of a household, i.e. the duration of a household. According to this criterion, there are newly established households (e.g. young married couples), medium-aged (e.g. married couples with small children), and incumbent - old (households of elderly people or after children leave the family home). The classification may also depend on the level of education of household members. According to this criterion, there are households at a low level of

education, medium level of education, high level of education and a very high level of education. According to the socio-economic classification, households can be categorized into households of employees, households of farmers, households of self-employed persons, households of pensioners and households living on transfer incomes (e.g. unemployment benefits, social benefits, family benefits, alimony) (Bywalec, 2017).

Although there are a number of household classifications, it clearly does not exhaust the topic. Taking into account other fields of knowledge (e.g. sociology, psychology), other household classifications may also be mentioned (e.g. depending on shopping preferences, religious beliefs, political orientation). Besides, households can be grouped according to the use of funds obtained due to pro-family policy. This classification has been presented below.

The classification of households - primary research

As was mentioned earlier, households can be divided on the basis of many different criteria. In accordance with the purpose of this article, the division of households has also been made according to the use of aid received under the generally-understood pro-family policy. In addition, households that benefit from the "Family 500+" programme were classified and characterized in detail.

For the purposes of this article, a questionnaire survey was conducted own and original on a purposive random sampling. The questionnaire was addressed to households that receive the "Family 500+" benefit. Households that do not receive benefits were not examined. Purposeful sample selection based on the tasks set out in this article - classification of households taking into account the 500+ benefit. Households that do not receive this benefit cannot be classified. The study was carried out using the PAPI and CAWI methods. 400 questionnaires were prepared, of which 368 were completed. Thus, 92% of the households, to whom the study was directed, answered. 285 questionnaires were filled correctly (71.25% of all prepared questionnaires). Errors were identified so there was no need to reject some questionnaires from the ones which were filled properly. The errors included: the lack of answers to some questions, the selection of several answers in the question (where only one answer was required), and adding some information in the questionnaire by people who do not receive the "Family 500+" benefit. The study was conducted in accordance with the following stages:

1. Development of theoretical issues.
2. Defining the research sample.
3. Development of questionnaire questions.
4. Conducting a pilot study.
5. Refining the questions of the questionnaire.
6. Conducting a proper examination (PAPI, CAWI method).
7. Analysis of the obtained research material.
8. Development and presentation of research results.

The table below presents the research group in detail in terms of socio-demographic characteristics.

Table 4: Characteristics of the research sample

Feature	Percentage of respondents
Gender	Female: 92.63% Male: 7.37%
Age	18 and under: 2.46%; 19 to 25: 37.89%; 26 to 32: 31.58%; 33 to 40: 22.11%; 41 to 48: 5.61%; over 49: 0.35%
Area of inhabitation	City area: 84.21%; Rural area: 15.79%
Number of children	1 child: 34.04%; 2 children: 47.37%; 3 children: 11.58%; 4 children: 5.26%; 5 children: 1.05%; 6 children and more: 0, 70%
Household income	Less than PLN 800 per person per month: 50.53%; from PLN 1,500 to PLN 2,200 per person per month: 13.68%; from PLN 2,200 to PLN 3,000 per person per month: 4.91% ; from PLN 800 to PLN 1500 per person per month: 27.37%; more than PLN 3,000 per person per month: 3.51%

Source: Own work

The result of the primary survey is the original classification of households. The aim of the study is to present the classification of households in terms of using family support, which has not been available in the domestic and

foreign literature so far.The presented classification complements the knowledge gap regarding the previously unavailable classification of households in terms of family benefits.

The following diagram presents the classification of households according to the use of pro-family aid. Simultaneously, this scheme allows for the analysis and review of available forms of assistance in terms of pro-family policy in Poland. The next diagram (Diagram No. 2) is a response to the objective set in the article – the classification of households with respect to the aid received in the form of a child-support benefit.

Diagram 1: The classification of households depending on the use of pro-family policy tools
Source: Own work

Diagram No 2 presents the classification of households that receive the "Family 500+" benefit. Besides, it contains a short description of households.

Diagram 2: The classification of households receiving the "Family 500+" benefit

Source: Own work

Conclusions from the analysis and the conducted research:

- the presented author's classification of households allows for filling the knowledge gap regarding the classification of households in terms of services supporting child upbringing,
- the largest group of respondents in terms of gender are women, which allows for the conclusion that they are the ones who manage the benefit received,
- the highest percentage of households stated in the study that the childcare benefit should be extended,
- child benefit is very important for households in rural areas than for households in urban areas,
- the smallest percentage of households (regardless of the area of residence and earnings) indicates that the 500+ benefit has no significance for household finances,
- households with an income lower than PLN 800 per person are of great importance in the finances of a household, and households with an income in the range of PLN 800 to 1,500 per person indicate a neutral importance.

Summary

A household, being the most numerous economic entities, can be defined in many different ways, depending on the author's point of view. The concept of a household is identified with other related concepts, too. The term 'family' seems to be the closest to the term 'household'. A family, as an entity, comes under the influence of pro-family

policy. This policy, by means of its different instruments, may directly or indirectly affect households (families). One of the instruments is the "Family 500+" programme, which is support for families of a universal and long-term nature. This programme, however, has caused a lot of controversy since the beginning of its operation Doubts have arisen over whether households will continue to be interested in performing paid work, and whether the quality of life of Polish families will improve. Still, additional financial resources from the programme have increased an available household budget.

As it was mentioned before, households can be classified in many different ways. One household can simultaneously be found under a number of classifications. Nonetheless, after the introduction of a child-support benefit, it seems important to classify households with respect to the “Family 500+” benefit. The classification like this allows to know the real purpose of the funds. Moreover, the classification of households with respect to the "Family 500+" benefit enables us to learn about the importance of this provision for a household budget, and know how the programme is perceived by households.

Abstract

The current research aims to reveal how this period of online classes has affected students' lives professionally and socially and what learning methods they have approached during the pandemic to cope with the information received in various ways.
Due to the pandemic, teachers had to develop new methods and tools to approach laboratory work and courses taking into account the particular characteristics of student classes, level of learning, methods of information delivery and even available technology. Thus, the content of the teaching materials was delivered through a variety of online learning tools, in correspondence with the format of the materials developed, as follows: the Google Drive account of the department to monitor the entire teaching activity; Google feedback forms; Faculty website; PDF Guides for applications, the Moodle educational platform of the faculty; product design software, Microsoft Teams.
To highlight this online impact on students' competencies and lives, a questionnaire with explicit questions about the learning methods approached by the students and the strategies of teachers to support the courses and laboratories was used. The questionnaire contains four different sections as follows: identification of student participants, organizing online teaching activities, home themes/ projects/ applications and the impact of online learning on professional skills and social relationships.
The online classes were analysed with the help of this feedback in order to improve teaching and learning methods and the teaching materials also.

Keywords: Teaching and Learning Methods, Competencies, Online Classes/ Laboratories

Introduction

Talking about innovation today has become an exciting preoccupation for us all. According to Rees M. (2020) our daily working approach and socializing style has entirely changed, with imminent and permanent consequences into the future. The coronavirus outbreak has already put the world at a standstill - entire states placed under quarantine and many borders were closed. Currently, without leaving our homes, we are taking part to webinars, classes, laboratories and online scientific lectures from all over the world. Research cited by Li C. (2020) suggests that online learning has been shown to increase retention of information, and take less time, meaning the changes coronavirus have caused might be here to stay. In an introductory article for Scientific Journal TURBO, Vol. VII, no. 1, Banea (2020) concluded that nobody knows when the pandemic is going to end, but we agree to one certain fact: the world will bring many changes in our lives, as it happened after the World Wars. Everything we all did before has somewhat transposed into the online environment; all areas have had to adapt to the new rules. Therefore, the higher education environment has adopted new learning strategies to ensure the development of classes at the same standards so that students' competencies are not affected.

According to Ulmeanu M. et al. (2019) delivering a successful course is a matter of balancing between the educators' competency level, efficient and targeted teaching materials, effective use of instructional strategies, and even available technology and students' interest. The importance of teaching materials in the learning process is highlighted by Fry H. et al. (2009) in their work, stating that efficient teaching materials should lead to increasing student achievements and to the development of targeted competencies. The United Nations (2020) recommends, through its policy brief released in august 2020, that educators and academic entities should build resilient education systems for equitable and sustainable development and reimagine education and accelerate change in teaching and learning. This paper aims to highlight the change that has been made in higher education institutions for online classes and laboratories, and the impact of new online learning strategies on students' lives.

Methods and Materials

The materials used in teaching online courses are very important because they must be developed so that students understand the content and be able, through individual study, to make connections and reach their maximum learning potential.

If in face-to-face learning mode, visual interaction is one of the most important ways to transmit information and create a connection with students, in online learning this aspect is highly diminished. Thus, the development and implementation of the courses becomes much more difficult.

The current study presents a thorough analysis of the process through which a higher educational institute in the field of technical sciences adapted to online and mixed teaching strategies.

In order to ensure the continuity of the learning process, teachers used new methods and strategies for transmitting information through social media and educational platforms. At university level, official ways of communicating with students and monitoring the entire activity had to be addressed. Thus, the entire educational process was changed, and everyone had to adapt to the new rules imposed by the pandemic. Laboratories are the most important practice that students have at hand to maximize the information received in classes. Thus, the development of these online laboratories was different from the normal one. Laboratory classes, which normally took place in rooms with specialized equipment, were replaced by videos, sketches, images and online presentations, but all at a level where students understand the whole process.

This moment could be the one through which the interdisciplinarity of scientific research should be transformed into a very important development factor in the field of innovation. It is the moment when globally, new solutions and directions are sought, especially in the medical field. Regarding this priority, the other areas suffer, so that the skills of engineering students accumulated during the pandemic have also become a priority for teachers.

With all these new issues affecting the entire world, the impact on financial markets, business and society, Covid-19 is still a surprise. From this point of view, individual study acquired a new meaning for students who had to be able to develop their learning style in order to keep pace with the requirements of employers in the field of interest.

The **target audience** for the current study consists of 344 participants: 331 students (96% of the target audience) and 13 teachers from the University POLITEHNICA of Bucharest (UPB). Students were selected from different years of study and different specializations of the Faculty of Industrial Engineering and Robotics. At UPB all classes and laboratories were made online using the available technology. The questionnaire was shared online and based on the answers, certain aspects of distance learning were counted.

To create a coherent and easy-to-follow set of teaching materials, teachers also considered innovative ways to integrate available technology. Thus, the content of the teaching materials was delivered through a variety of online learning tools, in correspondence with the format of the materials developed, as follows: the Google Drive account of the department to monitor the entire teaching activity; Google feedback forms; Faculty website; PDF Guides for applications, the Moodle educational platform of the faculty; product design software, Microsoft Teams.

Methods used in online teaching to transfer information from teachers to students were mainly based on the official methodology of the faculty, namely the **Moodle educational platform**. This platform fully ensures the continuity of the learning and teaching process as it allows an individual monitoring of students on its assessment, safe conduct of online exams, uploading various types of files to ensure a good understanding of the course and permanent information of students. Each student has access using their own account which ensures their visibility in the class of students to which they belong.

For the examination of the students during the semester, complex tests were developed by the teachers. The platform allows the creation of a library of questions and the generation of individual tests for each student using a certain number of questions, displaying in a random order the possible questions and answers, but also uploading files to solve a given topic. The test allows hiding the visibility to students, displaying at the set date and time, a certain duration and a limited number of attempts.

The official way to connect in real time (live) with students was the **Microsoft Teams** application. UPB has created an organization that includes all students enrolled at each faculty from the campus. Thus, the classes were carried out in an organized way, of which only those targeted were a part of. By restricting access to people outside the UPB, all information about courses, labs and applications was safe. Taking into account the advantages offered by this application, teachers and students were able to: record a certain segment of the course; resume the recorded course at a certain time; connect audio and video to establish eye contact and better interaction; quickly transfer different types of files.

To ensure appropriate assessment of all students, the university management proposed three main options of examinations (Figure 1).

Fig. 1: Options for students' examinations

Pilot Test and Feedback

The target audience was comprised of 74.1% bachelor students, 22.1% master students and 3.8% teachers. The questionnaire was created in Google Forms tool, it contained 5 sections and 21 quick and different types of questions regarding the main topic. 82.3% of the respondents choose urban as the environment where they carried out most of the teaching activity, while the rest rural. The meeting point for the students and teachers, as it turns out from the responses, were the video interactions on the online platforms (Zoom, Microsoft Teams, Meet, Adservio, 24Edu, etc.) and the educational platform from the UPB university (Moodle). Most of the target group used the computer, laptop and phone in order to participate to online teaching activities, and a small part of them (4.9%) the tablet.

A significant element to take into consideration was the timetable. 59.9% claimed the timetable was kept the same as before the pandemic, while 38.4% of the participants suggests that the timetable was adjusted. The best way to transmit information through the teacher-student way, according to the answers, were the online meeting through MS Teams, Zoom etc. and using the educational platform Moodle. 77.6% of the audience participated to all the teaching activities, while 22.4% of them only at the mandatory activities. The main reasons for the absence were the poor internet connection, the lack of interest or the missing/inappropriate devices.

The volume of topics and projects received or requested during this period was divided in three: 30.5% of the students and teachers considered satisfactory, 29.7% as bulky and 38.7% of them believe there was an imbalance between the disciplines. Regarding the deadline for submitting the projects and homework, most of the target audience was on the chart. The most frequently used method for awarding grades for projects and home tasks was the educational platform Moodle (81% of the participants).

Learning and teaching materials were evaluated for their attractivity, structuring of information, utility and interactivity (Figure 2). Online classes affected the social relationships with colleagues for 37% of the respondents, while the rest of them did not feel drastic deteriorations of the actual relationships. The pandemic was a "blessing in

disguise" for 27% of the participants, while 52% considered the quality of learning and teaching methods did not improve. An engineering faculty involves demonstration laboratories with developing practical skills and learning how to use a machine or different tools; 47% of the target group believes that online teaching activities affected the understanding of the process due to the absence of students in the laboratories, while 21% were neutral.

The assessment of the impact of online activities on the skills acquired during this period was done by designing several multiple answer questions, addressing the following: digital skills, information capacity, time management, synthesis capacity etc. (Figure 3).

Fig. 2: How do you evaluate the materials (courses, applications) from the following points of view? 1 - very weak, 5 – very good

In order to evaluate the assessment for the whole semester, 76% of the participants choose as a suitable method the written exam (on Moodle platform), the oral exam on online platforms as Zoom/MS Team (4.4%) and the rest a combination between these two methods. The student's ability to adapt to change was demonstrated during pandemic, judging from the teacher's responses. 57% of the students and teachers showed enthusiasm for a face-to-face returning of academic activities.

Fig. 3: How do you assess the impact of online activities on the skills acquired, during this period, compared to their face-to-face development?

Conclusion

Worldwide, this pandemic is seen an unprecedented crisis, a time when we all must do things differently and learn from ongoing experience. Our research highlights the fact that the students and teachers' performance and satisfaction with online courses have been an efficient alternative to classical, face-to-face teaching. Regardless of the studies and methods used, in the end the following question arises: "Is the performance of students who participate in online courses better or worse, compared to those who participate in traditional courses?" The impact of e-learning on schools will be constantly changing. Using e-learning methods in education, significant innovations are applied in information transmission and reception techniques. Technology leads to the personalization of the learning process, in which the contents are adapted to the students, regardless of the influence of the environment. The academic performance of students depends also on the methods of teaching and assessment, regardless of the environment in which they take place.

Development of academic activities is certainly facing a permanent chance. It is up to all educational process stakeholders to test, select and implement only the tools and methods which bring the most benefits and promote positive future development.

Abstract

Due to technological peculiarities, the development of oil and gas sector adversely affects the environment, significant contribution being made by associated gas flaring. To solve this problem, the Government has set a maximum allowable rate of associated gas utilization and introduced the payment for its above-limit flaring. The effect of this payment on the income of low-level employees working at the state-funded organization is investigated. The objects under research are oil-producing regions of the RF, where the share of oil and gas sector in the regional industry and GRP is approximately the same and hydrocarbon resources possess similar characteristics. The hypothesis of the research relies on the idea that diversification of economy of oil-producing regions indicates the level of negative impact caused by the reduction in the funds entering the budget. The findings have revealed that the payment for negative environmental impact has a dual effect on the sustainability of socio-economical development of the oil-producing regions as, on the one hand, it contributes to better environmental situation, but, on the other hand, reduces the revenue of the budgets of the entities of the RF. This decreases the investment potential of oil-dependent regions. Such effect is insignificant in the regions with diversified economy.

Keywords: Payment for Negative Environmental Impact, Associated Gas Utilization, The Entity of The Russian Federation, Revenue, Budget.

Introduction

Due to technological peculiarities of exploration activity, oil and gas production, refining, and sales, development of oil and gas sector affects the environment. Flaring of associated gas is one of the pressing problems as it leads to a severe environmental impact, has negative effects on human health, wastes an energy resource and contributes to the loss of potential revenue that could be gained if the associated gas were rationally used. This runs counter to the concept of sustainable development which implies that the needs of present generations should be satisfied without prejudice to the needs of future generations and their rights to live in a clean and safe environment (Knizhnikov, 2017).

Since 2012 the Government has taken steps to tighten the regulation in rational use of associated gas, precisely, the payment for air pollutant emissions caused by gas flaring and/or venting has been introduced. The Government has also set a target to increase the rate of associated gas utilization up to 95% and initiated additional coefficients for higher-than-normal gas flaring volumes (table 1). In addition, the payment for flaring emissions is 120 times higher unless the emission control equipment is installed.

Cite this Article as: IRINA A. MAKAROVA, Irina V. SHARF and MARGARITA R. TSIBULNIKOVA“ Dual Effect of Payment for Negative Environmental Impact on Sustainable Development of Oil-Producing Regions” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Table 1: Additional coefficients to the payment for the volume of flared gas exceeding a 5% indicator

	2012	2013	2014	2020
Additional coefficient	4.5	12	25	100

Obviously, such policy has affected the activity of oil and gas companies which have accelerated implementation of technologies and equipment for associated gas utilization. According to the data provided by the Ministry of Natural Resources and Environment of the Russian Federation (RF), the investment amount of oil and gas companies exceeded 358 billion rubles over the period 2013-2018, which allowed them to reduce the payment for negative environmental impact.

At the same time, such policy has primarily resulted in lower income of low-level employees working at the state-funded organizations, which receive most of this payment (40% in 2005-2015, 55% in 2016-2019). This fact worsened their difficult financial position (Sharf, 2018).

However, these trends differentially affect the budget of oil and gas producing entities of the RF, which has stipulated the current research. The hypothesis of the research implies that diversification of economy of oil-producing regions indicates the level of negative impact caused by the reduction in budget revenue.

Methods and Materials

The research is based on the documents as follows: laws and regulations on environment protection, the data provided by the Federal State Statistic Service and the Integrated Budget System of the RF, the opinions of experts and reviews prepared in the course of the project by WWF Russia on preventing associated gas flaring. As for the methods applied, they are the structural and trend analyses, comparison and grouping. The objects under research are oil-producing regions of the RF, where the share of oil and gas sector in the regional industry and GRP is approximately the same and hydrocarbon resources possess similar characteristics (Filimonova, 2020).

Results

The payment for the negative environmental impact includes the charges on: 1) air emissions; 2) water contamination; 3) disposal of wastes produced in the course of production and consumption; 4) emissions caused by associated gas flaring and/or venting. It should be noted that in Russia payments for negative impact on the environment are established by the Law on Environmental Protection, and not by the Tax Code of the Russian Federation. Moreover, this fee is administered by the Federal Service for Supervision of Natural Resources. Therefore, in Russia, payments for emissions are related to non-tax budget revenues. Globally, emissions taxes are viewed as incentive-based instruments. (Makarova, 2007, Goulder, 2008).

Figure 1 shows that, in general, the government revenue from payments for the negative environmental impact tends to decrease in the regions under the study (except for particular years).

Fig. 1: Regional government revenues from payments for the negative environmental impact in oil-producing entities of the RF, billion rubles

The structural analysis of the payments for the negative environmental impact showed that since 2013 the government revenues in Tomsk Oblast and the Komi Republic have derived mostly from the charge on emissions caused by associated gas flaring. Meanwhile, in Samara Oblast, the Tatarstan Republic and the Udmurt Republic the revenues have derived mostly from the charge on disposal of wastes produced in the course of production and consumption, and in Khanty-Mansi Autonomous District – from that on air emissions.
The trend analysis indicates a sharp increase in the regional budget revenues in Tomsk Oblast and the Komi Republic over the period 2013–2015. After this period, the revenues reduced (Figure 2).

Fig. 2: Regional government revenues deriving from the charge on emissions caused by associated gas flaring and/or venting in oil-producing entities of the RF, billion rubles

Despite the strengthening of the requirements of the Russian legislation for associated gas flaring, a 95% indicator of associated gas utilization has been achieved in the Tatarstan Republic (Table 2), which is due to the available transport infrastructure of Volga Federal District and petrochemical facilities built during the time of the USSR (Eder, 2018). The set level has been also achieved in the Komi Republic due to the joint project of LUCKOIL and Gazprom for associated gas utilization, which was implemented in 2011. Within the project, Ukhta gas processing plant has been renovated. Since 2015 gas produced in the fields of LUCKOIL-Komi has been supplied to Sosnogorsky refinery, which has resulted in the increased refinery utilization rate. Until then, the refinery was reducing its capacity because of resource depletion.

Table 2: The level of associated gas utilization per oil-producing entities of the RF, %

	2012	2013	2014	2015	2016	2017	2018	2019
Russian Federation	75.9	79.5	85.5	87.6	87.5	86.6	84.4	80.9
Tomsk Oblast	72.7	81.1	80.3	84	84.3	84.7	83.9	83.4
Samara Oblast	72.4	75.7	83.7	83.2	87.2	83.2	91	88.6

the Tatarstan Republic	94.4	93.5	94.6	94.8	95.7	94.3	95.7	95.8
the Udmurt Republic	35.2	44.7	67.6	72.6	76.2	79.9	77.2	77.7
the Komi Republic	65.8	64.3	64.5	75.8	81.7	91.1	95.2	95.6
Khanty-Mansi Autonomous District-Yugra	-	90.9	92.7	94.1	95.5	95.6	94.9	94.4

Source: compiled by the authors on the basis of the data provided by the Federal State Statistic Service

Khanty-Mansi Autonomous District-Yugra is a region with unique resource potential. There are huge hydrocarbon deposits which allow the region to achieve significant funds from oil and gas industry and invest them into various endeavors including the associated gas utilization projects.

In some oil fields located in the Udmurt Republic, utilization of associated gas is problematic due to low gas combustion heat caused by high nitrogen content (up to 90% according to volume composition) (Chernov, 2017).

Samara Oblast is a leader in the number of small and very small hydrocarbon deposits which are proved to be marginal. Therefore, it is rather hard to achieve the set rate of associated gas utilization. The specialists of OOO "RITEK" suggest construction of pipelines for multiphase flows, i.e. simultaneous transportation of oil and gas to the processing facilities. A positive factor is high population density, which ensures gas supply from the closest locations.

In Tomsk Oblast the following associated gas utilization methods are applied: loading into trunk pipeline (76%), energy generation (15%), technological needs (6%) and others (3%) (Tomskaya oblast': trudnyy vybor svoego puti, 2014). The problem is that it is impossible to increase the volumes of gas transported via pipelines due to the set pipeline throughput, while the surplus of generated energy could be hardly used due to low population density of oil-producing regions. In addition, production of crude oil declined from 11.745 mln tons in 2012 to 8.5 mln tons in 2019. This fact also leads to the decrease in need for technological gas.

It is noteworthy that there is also a decline in production of crude oil in the Udmurt Republic production (from 11.025 mln tons in 2016 to 9.5 mln tons in 2019). In other regions there is a decrease in production of crude oil.

The comparison of the data presented in Figure 2 and Table 2 indicates an inverse dependence: the increase in associated gas utilization rate is accompanied by the reduction in budget revenue, particularly from the payments for emissions caused by associated gas flaring and/or venting.

Let us analyze the indicators which characterize the amount and dynamics of payments for negative environmental impact in Tomsk Oblast.

Fig. 3: Consolidated budget revenue from the payments for negative environmental impact in Tomsk Oblast, billion rubles

As is obvious from Figure 3, the dynamics of the charges on negative environmental impact is primarily affected by the charges on emissions caused by associated gas flaring and/or venting. Since 2013 charges on air emissions

caused by associated gas flaring and/or venting have dramatically increased due to additional coefficients. These charges have been falling since 2015. Compared to other examined oil-producing entities of the RF, the rate of associated gas utilization is the lowest during the period 2013-2018 (Table 2).

To prove the research hypothesis, it is essential to compare the share of extractive industries and hydrocarbon processing sector in GRP of the regions under the study (Table 3).

Table 3: The share of extractive industries and hydrocarbon processing sector in GRP

	Production of mineral resources	Processing industry
Tomsk Oblast	27.6	10.3
Samara Oblast	16.5	22.2
the Tatarstan Republic	25.2	17.2
the Udmurt Republic	24.5	20.5
the Komi Republic	37.2	11.7
Khanty-Mansi Autonomous District-Yugra	67.1	2.4

The data provided indicate a multifaceted impact on the budget revenue from payments for negative environmental impact in various entities of the RF (TEK Rossii-2018, 2019).

Discussion

The findings of the research partially prove the stated hypothesis based on the following aspects:

1. The most significant decline in the revenue from the payments for negative environmental impact is registered in Khanty-Mansi Autonomous District-Yugra, Tomsk Oblast, and the Komi Republic (Figure 1).
2. The reason for the sharpest decline in the payment for negative environmental impact in Khanty-Mansi Autonomous District-Yugra is due to unique resource potential of the region and, as a consequence, financial and investment opportunities of oil-producing companies.
3. The revenue from the payment for negative environmental impact in the entities of Volga federal district (Samara Oblast, the Tatarstan Republic, and the Udmurt Republic) is lower, which is explained by the large share of hydrocarbon processing sector.
4. The socio-economical factors (such as population density, availability of production infrastructure and trunk pipeline network) significantly affect the rate of associated gas utilization.
5. Oil and gas production in sparsely populated regions, particularly in Siberia and the Komi Republic, contributes to oil-dependent economy, therefore the decline in revenue of such entities of the RF, caused by the reduction in payment for negative environmental impact is the most painful (Sharf, 2019).

What are the future prospects of increasing the rate of associated gas utilization and how would this trend affect the regional budgets and the consolidated budgets of the entities of the RF? The Ministry of the Natural Resources and Environment of the RF considers the prospect to increase the rate of associated gas utilization up to 97.5%, which would attract investments into production-infrastructure projects related to associated gas utilization, but would not resolve the issue of replenishing different budgets. Due to awareness of the fact that this source of income is crucial for the regions and entities of the RF, the Budget Code of the RF has been amended. According to these amendments, the revenue of regional budgets from the payments for negative environmental impact should increase up to 60%. However, this solution, in our opinion, would not contribute to sustainable development of the entities of the RF over the long term.

Conclusion

Thus, the dual effect of the payment for negative environmental impact on the sustainability of socio-economical development is obvious. On the one hand, there is better environmental situation due to associated gas utilization; on the other hand, there is a decline in budget revenue, which is of particular significance for the entities of the RF. This also reduces investments into the various projects essential for local economy and society (Kloke, 2006). As a result, sustainable development principles require revision of the approaches to environmental payments due to implementation of environmentally sound technologies, precisely associated gas utilization, both in oil and gas

industry and other manufactures. It is an essential step in ensuring stable revenue in the medium and long term (Beuermann, 2006).

Abstract

The article describes a methodology for identifying priority areas of scientific and technological development of national economy industries. The analysis of patent activity in the article is based on such indicators as industry IP-capital intensity, industry IP-balance and industry IP-labor capacity. The choice of indicators is determined by the relationship between GDP, the average number of researchers and the level of application of intellectual property results. According to the comparison of the proposed coefficients with the average value for the national economy groups of high, medium and low intellectual property intensity industries are defined. To support industries, identified in the article as low intellectual property intensity industries, the authors propose amendments to the state policy tools in the field of intellectual property, earlier defined by the national project «Science» in the Russian Federation.

Keywords: Intellectual Property, Scientific Development, Patent, Industrial Analysis, IP Intensity

Introduction

The intellectual property market is a legal, economic and scientific component of the country's economy, since research and development field contribute to the competitiveness of national products and technologies. That is why its comprehensive analysis is important for national economy development.

At the same time, the level of intellectual property institute advancement depends on whether the economy is provided with enough research personnel, infrastructure and legal intellectual property protection instruments [6, 8]. In case the state and corporate sectors do not pay attention to these elements, the products and services of the national economy cannot be regarded as competitive for the domestic or foreign market [5, 13].

Modern economy conditions confirm the importance of analysis of patent statistics such as the filing of patent applications, the issuance of protection documents for intellectual property objects and their maintenance in force [4, 9, 11, 12].

Cite this Article as: Irina ILINA, Andrey KLYPIN, Sergey VYUNOV, Alexey VASYUKOV and Roman TIKHONOV "Intellectual Property Intensity Analysis of Economy Industries" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

To simplify the process of making managerial decisions, the article sets the task of preparing a methodology for identifying priority areas of scientific and technological development of national economy industries.

Indicators based on patent data, contribute to the methods of evaluating the research activities productivity, allow to identify new points of technological growth and select promising areas for international collaborations.

The issues of studying and analyzing technological progress have been studied by the scientific community for many years.

M. Chimili, D. Dosi, R. Mazzoleni and B. Sampat (2011) note the high role of a patent as a source of technological information for those industries in which patenting will allow innovators to assess the possible profitability of inventions [3].

However, in the Russian Federation, statistical data of Russian Federal Service for Intellectual Property, the Federal Institute of industrial property (FIPS) and the Federal state statistics service (Rosstat) is presented only by territorial point. There are almost no statistics showing the relationship between IP and the number of researchers in a particular industry, income and export indicators.

Thus, in order to correlate the number of protected intellectual property results with the number of employed researchers, it is necessary to develop a model that allows to compare the development of industries by the criterion of IP usage.

Based on the analysis results, the authors propose a method for studying the degree of intellectual property use by industries of the Russian economy or, in other words, a study of the IP intensity of economy industries.

Materials and Method

IP intensity analysis of the intellectual property market in the article is conducted according to conversion keys of Russian classifier of economic activities NACE (OKVED) and codes of the International patent classification (IPC).

In order to define the specific industry as IP-intensive, the correlation of the number of intellectual activity results with the inputs and the number of researchers was performed [1].

Thus, the industry analysis of patent activity in the article is based on such indicators as industry IP-capital intensity, industry IP-balance and industry IP-labor capacity. The choice of indicators is determined by the relationship between GDP, the average number of researchers and the level of application of intellectual property results [2]. The analysis is mainly based on information of the Orbit Intelligence patent database. The indicator values correspond to 2018.

Results

Industry IP-capital intensity refers to the ratio of the number of patents and the volume of internal R&D expenditures, carried out within a given industry of the economy (or country in general) over a certain period of time, regardless of the source of funding (formula 1):

$$K_{IP\,i} = \frac{\mathrm{N\,p}\,i}{\mathrm{R\&D}\,i}, \text{ где} \qquad (1)$$

K_{IP} – coefficient, reflecting industry IP capital intensity;

N p i - number of patents in the industry;

R&D i – amount of internal R&D expenditures in the industry.

Industry IP-balance describes the ratio of the number of national patents, registered in foreign patent offices, and the number of foreign patents, registered in Russian patent office. Thus, this indicator allows to assess the degree of dependence of a certain industry upon foreign counterparties (formula 2).

$$\text{Ip-balance } i = \frac{\mathrm{N\,p}\,i\,\mathrm{Ex}}{\mathrm{N\,p}\,i\,\mathrm{Im}}, \text{ где} \qquad (2)$$

Ip-balance - indicator that characterizes industry export and import balance in relation to intellectual property;

N p i Im – number of industry foreign patents, registered in Russia;

N p i Ex – number of industry Russian patents, registered in foreign patent offices.

Competitive industries of the economy with a significant weight in GDP tend to attract labor resources. That is why it is necessary to analyze the efficiency of industry researchers, determining the value of industry IP-labor capacity, based on formula 3.

$$\text{IP-labor capacity}_{\,i} = \frac{\text{N p } i}{\text{N reserchers } i}, \text{ где} \qquad (3)$$

IP-labor capacity – indicator that characterizes the number of patents per 1 researcher in the industry;

N reserchers i – average number of researchers in the industry.

Comparison of the industry specific indicators of IP-capital intensity, industry IP-balance, and industry IP-labor capacity to average values of corresponding coefficients, calculated for the economy allowed the authors to verify:

• high-intensity intellectual property industries that exceed the average economy values more than 20%;

• medium- intensity intellectual property industries with indicators in the range of ±20% of the average for the economy;

• low- intensity intellectual property industries with indicators lower than the average value for the economy by more than 20%.

Based on the results of calculating the IP-intensity indicator for Russian economy industries, the following is determined.

The average value of the IP capital intensity indicator for the Russian economy was 1.18 patent / million rubles in 2018. The leading industry concerning this indicator is «Electricity, gas, steam and air conditioning supply», since 1 million rubles of intramural R&D expenditure in this industry accounts for 10.6 of issued patents in 2018.

Industry «Agriculture, forestry, hunting, fishing and fish farming» also had the value 20% higher than the average and can be categorized as highly intensive in terms of capital intensity.

The value of IP capital intensity for the «Transportation and storage» industry in 2018 was higher than average, but less than 20%, which is why this industry is considered medium-intensive according to the accepted classification.

Such industries as «Mining and quarrying», «Administrative and support service activities», «Manufacturing», «Water supply; sewerage, waste management and remediation activities», «Wholesale and retail trade; repair of motor vehicles and motorcycles», «Information and communication», «Real estate activities», «Education», «Human health and social work activities», «Arts, entertainment and recreation», «Other service activities» are characterized as low-intensity in accordance with the proposed classification (Fig. 1).

Fig. 1: IP-capital intensity of Russian economy industries in 2018

Source: Compiled by the authors based on Orbit Intelligence database

The average value of the IP balance indicator for the Russian economy was 0.148 in 2018.

The industry «Wholesale and retail trade; repair of motor vehicles and motorcycles» industry is considered to be the leader by this indicator, since 1 imported patent in this industry equaled 2.27 exported patents in 2018.

The value of the indicator for other industries is lower than the average by more than 20%. Thus, the industry «Wholesale and retail trade; repair of motor vehicles and motorcycles» is the only Russian high-intensity industry in terms of IP balance in 2018 (Fig. 2).

Fig. 2: IP balance for Russian economy industries in 2018

Source: Compiled by the authors based on Orbit Intelligence database

The average value of the IP-labor capacity of the Russian economy in 2018 was 0.95 units/person. The industry «Electricity, gas, steam and air conditioning supply» industry had the leading position by this indicator in 2018.

Also, the industries «Water supply; sewerage, waste management and remediation activities», «Mining and quarrying», «Transportation and storage», «Agriculture, forestry, hunting, fishing and fish farming» represented the indicator values higher than the average by more than 20%, and therefore are characterized as highly intensive in terms of labor capacity.

Other industries are characterized as low-intensity (Fig. 3).

Fig. 3: IP-labor capacity of Russian economy industries in 2018

Source: Compiled by the authors based on Orbit Intelligence database

According to the authors, the calculation for the industry «Professional, scientific and technical activities» requires individual approach, due to the fact that this industry corresponds to the activities of research centers, institutes, that unite scientists and inventors of various profiles, conducting research in multiple sectors of the economy. Thus, the funds allocated to such research correspond to other industries of the economy as well.

Conclusion

Industry analysis of patent activity is proposed to be carried out on the basis of such indicators as industry IP-capital intensity, industry IP-balance and industry IP-labor capacity.

In relation to the Russian economy the research defines the industries «Electricity, gas, steam and air conditioning supply», «Agriculture, forestry, hunting, fishing and fish farming» as highly intensive in terms of IP, which means that these industries effectively use funds and personnel in terms of creating intellectual property objects. The industry «Wholesale and retail trade; repair of motor vehicles and motorcycles» is characterized as highly intensive in terms of IP balance.

At the same time, to support other industries, including the «Manufacturing» industry that had one of the lowest value of every indicator proposed, it is necessary to implement measures, developing the sphere of intellectual property.

State scientific and technical policy of Russian Federation in the field of intellectual property are defined by the national project «Science». According to the results of the analysis, the authors propose amendments to the content of the relevant policy tools:

1. Focus on the development of National technological initiative centers not only in economic megacities such as Moscow and Saint Petersburg, but in all regions of the Russian Federation, taking into account their scientific and technological features, the needs of organizations in the real sector of the economy, available infrastructure and production base [10].

2. Correlate the choice of topics and areas of research transfer with the needs of the business sector, provided freedom in the field of fundamental research.

3. Create world level research centers, performing research and development on priorities of scientific and technological development, based on achieved scientific results, cooperation of science, business and state.

4. Link the creation of innovative infrastructure objects not only to quantitative (and financial) indicators, but qualitative as well such as favorable conditions for agricultural activities, effective technological activities, human resources, and demand from organizations in the real sector of the economy [7].

5. Develop IP-related educational disciplines for programs and projects, implemented by world-class research centers, taking into account the needs of organizations in the real sector of the economy for appropriate specialists.

The proposed amendments for implementing the state policy in the field of intellectual property, contained in the national project «Science», will provide a qualitatively new level of technological transfer mechanisms for the development of science and technology of the Russian economy.

Acknowledgements

The research was prepared with the Ministry of Science and Higher Education of the Russian Federation financial support for RIEPL state assignment for 2020 №. 075-01402-20-02 of April 7, 2020 (project "Organizational, technical, scientific and methodological support for the formation of a technological Atlas based on the analysis of patent activity").

Abstract

The paper studies the problem of modelling and forecasting economic crises. The fractal dimension local values time series serves as an indicator of the economic system stability. The paper analyses the fractal characteristics of exchange rates time series of 20 national currencies in different time periods. The relationship between the dynamic stability violation and the deviation of the fractal dimension currency fluctuations from the optimal value has been proven. The boundaries of the normal state of economic systems was also obtained. These stability boundaries are built on the basis of a linearly weighted moving average and fractal dimension time series. The crisis predicting was reduced to determining the intersection points of the fractal dimension local values curve with the curve of the normal system state boundaries. The informative ranges of time scales reflecting short-term and long-term tendencies in violation of information efficiency of foreign exchange markets have been determined. The macroeconomic systems were classified by the efficiency level of foreign exchange markets.

Keywords: Economic Crises, Fractal Dimension, National Currencies, Stock Indexes.

JEL Classification: C53; C68; E27.

Introduction

Today, one of the most popular methods of forecasting crisis phenomena is the "signal" method, which consists in developing threshold values for a selected indicator or a set of indicators, the intersection of which with a certain probability signals the threat of a financial crisis [Kaminsky & etc., 1998; Kaminsky, 1999]. Kaminsky, Reinhart (1999) proposed to use the exchange market pressure index (EMPI); however, it should be noted that EMPI is now being used more widely and is considered in a number of studies as an index of financial pressure, which allows the use of EMPI. to identify crisis situations in the economy as a whole, and not only to identify currency crises. Fedorova E.A. and Afanasev D.O. (2014) in their work propose to use a complex indicator to predict crisis phenomena in the Russian economy based on the Markov regime-switching model.

To build an adequate model predicting further changes in any system, you need to know the principles of this system. However, in nature, we often encounter self-organized systems, the principle of operation of which is very complex and at the time of research, in principle, is not known. Moreover, the main information about this system is only the time series, which is the dependence of the output value of the system on time. Therefore, the choice of an indicator for building predictive models is an extremely urgent task. Researchers propose to use as private indicators as an indicator of forecasting financial crises - net capital inflows and US military spending, the state of the US budget, oil prices, dynamics of stock indices, prices of precious metals, national currency rates, etc. (Ozer-Imer, I. and Ozkan, I., 2014; Ivanyuk V.A. & etc., 2019). Hristov N. and Roth M. (2019) proposed a structural vector autoregression model for a set of four euro area countries in order to investigate the dynamic responses of shocks to uncertainty,

Cite this Article as: Anton V. GOLUB and Natalia A. SHCHUKINA " Forecasting Economic Crises Using Fractal Characteristics" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

which showed that drop in uncertainty, while driving up real economic activity, prices, and stock market indices, induces crisis indicators to increase after about two years.

One of the most universal and objective indicators of the state of the economic system of any state is the price of its monetary unit in the international market - the rate of the national currency, which can serve as both an indicator of the development of the country's economy and an object of purposeful public administration. The mechanism of the floating exchange rate of the national currency, adopted by many states, makes it possible to analyze the state of macroeconomic systems based on the study of currency time series containing information about the foreign exchange equilibrium market and the economy as a whole.

In the general case, the mathematical analysis of currency crises, as a particular case of economic crises, should take into account the entire set of factors influencing changes in the exchange rate. The exchange rate is determined by banking and financial mechanisms both within the country and abroad, and is constantly influenced by international currency speculation. As a result of the interaction of these processes, a complex picture of currency dynamics arises, the stability of which has a fundamentally non-equilibrium nature and requires the use of new methods of analysis focused not on assessing the average values of state parameters, but on determining the conditions for maintaining the expected dynamic mode of functioning of the currency system.

Materials and Methods

To assess currency crises, an analysis of the dynamics of the fractal dimension of exchange rates is carried out and the ranges of fluctuations in the exchange rate are determined, within which the market is in a stable state. The dynamics of the exchange rate before and after the crisis is analyzed. Rates of national currencies represent the average daily values of the cost of 1 unit of the currency in question to the US dollar.

Source: Authors

When studying economic time series, some preliminary transformation is traditionally used to bring the original series to stationarity. However, in the case of fractal analysis, the primary transformation of a series into a series of increments or returns may lead to an erroneous conclusion regarding the presence of long memory and the nature of

persistence. In this connection, the analysis is carried out to the initial data, which are not reduced to a stationary form. For the classical random walk process, the spectral dimension is β = 2, and for a process of the "white noise" type, β = 0. Thus, numerical differentiation of the time series corresponds to a decrease in β by 2, and numerical integration, on the contrary, to an increase in β by 2. This relation acts not only for integer values of the spectral dimension and order of integrability (β = 0, d = 0 - white noise; β = 2, d = 1 - random walk), but also for intermediate fractional values. Thus, the time series and its increments have different, but related, values of fractal characteristics, and a different nature of persistence and long memory. Therefore, the determination of the characteristics of persistence and long memory will be carried out for the initial time series.

An important class of signals with no scale dynamics has autocorrelation or power spectral density (PSDs, which follow the power law C | F | -α for some positive constant C and some power α. In some cases, the signal of interest exhibits a power-law PSD. series we will find an estimate of the spectral power density (PSD) using an estimate of the averaging of the overlapping Welch segments.Plots of the spectral power density for the time series GBP / USD, CNY / USD, CHF / USD and RUB / USD in double logarithmic coordinates are shown in Figure 1.

Note that the autocorrelation functions of the analyzed national currency rates time series gradually decrease, however, they decay rather slowly for all considered time series. This behavior of the autocorrelation function is typical for most time series. Separately, we note that even with lag = 300, the values of the correlation coefficient exceed 0.85 for all the series of time currencies under study. In this connection, autocorrelation functions are not informative for differentiating time series. The obtained information about the autocorrelation function of the studied time series also confirms the presence of the phenomenon of long memory in the analyzed time series. The calculated values of the exponent α PSD and the autocorrelation coefficients with a lag of 300 are presented in Table 2.

19	SGD/USD	0.5707	1.8984	0.9245
20	RON/USD	0.5643	1.8462	0.8571
21	AZN/USD	0.0604	1.8666	0.8740
22	AMD/USD	0.2667	1.8960	0.8702

Source: Authors

Note that the AZN / USD and AMD / USD series are not persistent, the Hurst exponent of these series is 0.0604 and 0.2667, respectively, which is lower than 0.5. Therefore, these time series are excluded from further research. Also note that the Hurst exponent for CNY / USD and KZT / USD are 0.465 and 0.4514, respectively, which is also below 0.5. However, it is not possible to test the hypothesis that the exponent value of these series is greater than 0.5, as well as to carry out interval estimation of the Hurst exponent, due to the fact that the final, prior distribution has not been proven for fractal characteristics. In connection with the above, the time series CNY / USD and KZT / USD were not excluded from further analysis.

Let's find out how different the signals are. To do this, we will calculate the values and plot the graphs of the multifractal spectra of the signals under consideration. The multifractal spectrum effectively shows the distribution of the scaling factors for the signal, i.e. provides a measure of how much the local regularity of a signal changes over time. A signal that is monofractal exhibits nearly the same regularity throughout time and therefore has a narrowly supported multifractal spectrum. Conversely, a multifractal signal exhibits changes in signal regularity over time and has a multifractal spectrum with wider support. Let us determine the singularity spectra D(h) and Hölder exponents h for the signals under consideration. The singularity spectrum and global Hölder exponents are estimated for linearly spaced moments of structural functions from –5 to +5 and are presented in Table 3.

Table 3: General range of scale indicators

No.	Time Series	The scale interval of the indicator	The range of the indicator scale
1	AUD/USD	[0.5211; 0.7164]	0.1953
2	GBP/USD	[0.0716; 0.8803]	0.8087
3	CNY/USD	[0.2425; 0.8028]	0.5603
4	NOK/USD	[0.3881; 0.6267]	0.2386
5	TRY/USD	[0.1825; 0.9948]	0.8123
6	CHF/USD	[-0.0106; 0.6160]	0.6266
7	SEK/USD	[0.3990; 0.5699]	0.1709
8	JPY/USD	[0.3558; 0.7427]	0.3869
9	INR/USD	[0.4788; 0.6859]	0.2071
10	PLN/USD	[0.0554; 0.6343]	0.5789
11	RUB/USD	[0.5985; 0.7903]	0.1918

Source: Authors

As you can see, the ranges of variation of the Hölder exponent of the studied time series are different. For example, AUD / USD and RUB / USD have similar ranges for the Hölder indicator, while SEK / USD, despite a similar range, has a smaller range. Note that the maximum swing among the analyzed time series belongs to KZT / USD and is 1.7425. In turn, some series are characterized by a rather small range of the scaling factor (less than 0.2). These time series include AUD / USD, SEK / USD, RUB / USD, SGD / USD. Figure 2 shows graphs of the multifractal spectrum of some time series.

Figure 2: Graphs of the multifractal spectrum (singularity spectrum) of several time series

Source: Authors

The analysis of the multifractal spectrum makes it possible to suggest that the time series of national currencies rates considered in the framework of the work are multifractals, and, therefore, their fractal characteristics, including the fractal dimension, are not constant over the entire time period.

Results

Let's consider the fractal dimension at different time intervals in order to reveal whether the fractal dimension of the time series of currency pairs changes during the crisis. The period of the global economic crisis that began in 2008 was chosen as the crisis periods. The fractal dimension was estimated by the Higuchi method. Based on the results of the analysis of the fractal dimension before the crisis, during the crisis and after it, we note that in some time series, no significant change in the fractal dimension is observed. Such time series include GBP / USD, NOK / USD, CAD / USD. Some series changed their fractal dimension during the crisis, but after its end, the value of the fractal dimension recovered, such series include CNY / USD, EUR / USD. In turn, some of the series under study have different fractal dimensions in each of the 3 periods (Table 4). Note that both national economies and the rates of their national currencies reacted differently to the global crisis.

Table 4: The Fractal Dimension Values in different time periods

No.	Time series	The Fractal Dimension Values			
		before 2008	at 2008 – 2012	after 2012	2006-2020
1	AUD/USD	1.4838	1.4248	1.5407	1.4630

Analysis of the obtained values of the fractal dimension allows us to draw the following conclusions. The dynamics of exchange rates of developed countries is characterized by a more stable fractal structure. The fractal dimension takes values close to 1.5. In contrast, the exchange rates of developing countries' currencies before currency crises have overestimated or underestimated values of the fractal dimension in relation to 1.5. In most cases, the fractal dimension deviates from the value of 1.5 downward, which indicates the formation of "herd" behavior by investors. After the end of the currency crisis and the onset of the post-crisis stabilization phase, the fractal dimension values again approach 1.5. Thus, the fractal dimension can be an indicator of crisis phenomena.

For further investigation of the nonstationary dynamics of fractal dimension, the "sliding window" method was applied, the essence of which is as follows. First, a sequence of n values is selected in the time series of the currency rate, and for these data the fractal dimension is calculated using the Higuchi method. After that, the interval is shifted to the right along the time series by one value and the fractal dimension is calculated again. Repeating this procedure throughout the entire study period, we obtain the local values of the fractal dimension. Let us study a number of local values of the fractal dimension of the studied time series.

Analysis of the fractal dimensions of national currency time series rates dynamics indicate the existence of a limiting fractal dimension, when approaching which instability and possible crisis manifestations arise in the future. To predict the critical states of the system, it is important to establish the boundaries of the threshold of the normal state, which

depend on the current local values of the fractal dimension and the fractal dimension of the entire time series. In the work of Gafarova E. A. & Dobikova D.V. (2012) when analyzing the dynamics of the fractal dimension of the exchange rates of developed and developing countries, it was shown that the lower and upper boundaries of the fractal dimension for a crisis-free state are 1.3 and 1.7, respectively. However, these boundaries of the normal state of the system do not always allow one to judge about the violation of stability and can determine a sufficiently large number of false signals. The value of the lower and upper thresholds will affect the appearance of signals. The wider the border of the normal state interval, the fewer signals will appear. With a narrow interval of the normal state, the number of false signals will increase. It should be noted that a high value of the fractal dimension of the time series indicates a less stable state of the system, the time series will be characterized by sharp jumps, and the threshold of the normal state will be less sensitive to changes, which will avoid a large number of false signals. A low value of the fractal dimension indicator indicates a more stable state of the system, with a relatively low value of this indicator, the initial series of stock quotes will be characterized by a fairly smooth trend change and the absence of sharp drops and jumps, the threshold of the normal state will be more sensitive, which will allow not to miss the appearance of a critical point.

Calculations show that for financial series, the upper and lower boundaries of the normal state of the system can change. Therefore, it is necessary to determine the boundaries of the normal state in such a way that the critical states of the system can be identified for both an unstable and a stable period of the time series. A signal will be considered false if, after its appearance, there are no further points of trend change or sharp jumps. The threshold values of the normal state of the system for the initial time series are determined on the basis of moving averages and the total fractal dimension of the series. As a result of the experiments, the boundaries of the normal state were established as follows:

$$FD_{up}(t) = \frac{1}{4n}\sum_{k=1}^{4n} FD(t-k) + K_{up}FD;$$

$$FD_{dn}(t) = \frac{1}{4n}\sum_{k=1}^{4n} FD(t-k) - K_{dn}FD,$$

$FD_{up}(t)$, $FD_{dn}(t)$ – upper and lower boundaries of the normal state of the system,
$n = 250$ – width of the window for calculating local values of the fractal dimension,
FD – fractal dimension of the time series calculated by the Higuchi method,
$K_{up} = 0.15$, $K_{dn} = 0.165$ – empirically determined coefficients.

The algorithm for predicting the crisis state of the system is based on the analysis of the dynamics of local values of fractal characteristics and boundaries of stability. the lower boundary of stability, it is expected to rise or fall by more than 10%.

This algorithm demonstrates well the changes in the original series dynamics. Let's compare the dynamics of the GBP / USD rate with the dynamics of local values of the fractal dimension and the boundaries of the time series stability (Figure 3).

As you can see in Figure 3, approximately on the 600th trading day, there is a crossing of the local fractal dimension line of the upper stability border, followed by crossing the lower border and further high amplitude of the indicator. In the dynamics of the exchange rate in the period from the 610th to the 800th trading day of the studied period, there is a serious fall, followed by a period of instability. Starting from the 1000th trading day, the local values dynamics of the fractal dimension becomes less amplitude, and the periods of the growth alternation and fall of the fractal dimension values becomes small. The period of relative stability of the exchange rate fell on the 1100-1600th days.

Further, the dynamics of the fractal dimension local values shows increase in the amplitude of oscillations. The crossing of the lower boundary occurs at about the 1440th day, however, the periods of fluctuations are still small, this signal can be regarded as a signal for a subsequent increase in the periods of fluctuations of local values of the fractal dimension accompanied by a high amplitude, which is observed. Within 100 days (from about 1580 to 1670), there is a crossing of both the upper and lower boundaries, accompanied by a drop in the rate in the period 1700-1800 days. Further, we see 2 crossings of the upper border: the first - around the 1820th day, predicting a change in the trend from a relatively constant to a growing one; the second - on the 2010th day, signaling a new downward trend. Later, over 400 days, the dynamics of the values of the local fractal dimension is again characterized by small periods of low-amplitude fluctuations. An increase in the amplitude of fluctuations observed since the 2400th day predicts a fall in the rate of the 2600th day with a subsequent decline.

Figure 3: Dynamics of the GBP/USD exchange rate, local fractal dimension values, and the stability boundary of the currency exchange rate

Source: Authors

For the CNY / USD series, the boundary of the fractal dimension change during the crisis (sinusoid) is clearly visible, which is practically invisible for the time series of other exchange rates (Figure 4).

Figure 4: Dynamics of the CNY/USD exchange rate, local fractal dimension values, and the stability boundary of the currency exchange rate

Source: Authors

For the time series CNY / USD, one can observe false signals that indicate the unstable dynamics of the national currency rate. Therefore, it is possible to classify the fractal structure of currency series and distinguish groups of countries with high and low levels of efficiency of foreign exchange markets.

Countries Classification by the level of efficiency of foreign exchange markets

The countries were classified using the fractality index. Informative time ranges were determined, reflecting short-term ($\tau = 15$ days, index α_1) and long-term ($\tau = 60$ days, index α_2) trends in the violation of the information efficiency of foreign exchange markets.

The values of the fractality indices α_1и α_2 are determined in a sliding window with a width of 250 days and a shift of τ days. This allows us to classify the fractal structure of currency series and identify groups of countries with high and low levels of efficiency in foreign exchange markets. Table 5 shows the results of calculating the fractality index $\alpha_1$and α_2.

Table 5: Fractality Indices Values that assess short-term and long-term trends in the violation of the information efficiency of currency markets.

No.	Country	α_1	α_2
1	Australia	1.5921	1.5860
2	Great Britain	1.6877	1.7023
3	China	2.1248	2.1330
4	Norway	1.6138	1.6158

Source: Authors

A preliminary analysis of the obtained fractality indices $\alpha_1$and α_2 showed a sufficient heterogeneity of the structure of currency series. To determine homogeneous groups of countries by the level of efficiency of foreign exchange markets we could classify them by their fractality indices $\alpha_1$and α_2. To obtain a stable classification, a step-by-step clustering procedure was carried out. At the first stage, the nearest neighbor method was applied. This made it possible to identify countries that differ from the majority. These include China and Kazakhstan. At the next stage, for the remaining 18 currency pairs, using the methods of hierarchical cluster analysis, a division into clusters is obtained. This breakdown was refined by the successive application of the -means method, which made it possible to obtain a stable classification and divide countries into three homogeneous groups and identify 2 atypical states in terms of the efficiency of foreign exchange markets. The resulting distribution of states according to the selected homogeneous groups is presented in Table 6 and Figure 5. The countries that most clearly reflect the main characteristics of the group are highlighted in bold.

Table 6: Clustering Results

Group number	Number of elements in the group cluster	Centroids	Countries included in the group
Group 1	12	(1.6473; 1.6482)	Australia, Great Britain, Norway, Switzerland, Sweden, **Japan**, Russia, South Korea, Bulgaria, Canada, European Union, South Africa
Group 2	3	(1.5213; 1.5189)	Turkey, Poland, **Brazil**
Group 3	3	(1.8434; 1.7682)	India, **Singapore**, Romania
Atypical	2		China, Kazakhstan

Figure 5: Graphical representation of clustering results

Source: Authors

According to the results of clustering, the currencies of the countries of the first group are characterized by the most stable and homogeneous fractal structure. The fractal dimension of these series remains practically constant over a fairly wide range of time scales. For the countries of the second and third groups, various forms of violations of the fractal structure in the pre-crisis period were revealed. As a rule, the currency crisis was preceded by both abnormally low and abnormally high values of the fractal dimension. These results can be interpreted as manifestations of violations of stability conditions during the formation of pre-crisis states of macroeconomic systems.

Conclusion

Crises are one of the most difficult phenomena in economics. Their manifestations are manifold. To assess currency crises, an analysis of the dynamics of the fractal dimension of exchange rates was carried out and the ranges of fluctuations in the exchange rate were determined, within which the market is in a stable state. The paper analyzes the fractal characteristics of the time series of the rates of national currencies of 20 states in different periods of time. The relationship between the fractal dimension of the dynamics of national currency rates and their trend has been established. The time series of local values of the fractal dimension serves as an indicator of the economic stability of the economic system. The boundaries of the normal state of economic systems have been established. A high value of the fractal dimension of the series indicates a less stable state of the system.

To predict the critical states of the economic system, an algorithm has been developed for determining the upper and lower thresholds of the normal state of local values of fractal dimension. The stability boundaries are built on the basis of a linearly weighted moving average and fractal dimension of the time series. Forecasting is reduced to determining the points of intersection of the curve of local values of the fractal dimension with the boundaries of stability. The developed algorithm for analyzing the fractal properties of economic indicators is implemented in the

MATLAB software environment. This algorithm is applicable both for analyzing currency time series and for analyzing time series of micro and macroeconomic indicators.

The conducted research demonstrates good results of analyzing the stability of economic systems and forecasting their critical states. The proposed algorithm for applying the methods of fractal analysis can act as one of the tools for crisis analyzing and forecasting.

Abstract

Current paper concentrates on research of exchange rate shocks of Ukrainian hryvnia caused by inflows of remittances and vice versa in 1996-2019. We employed VAR model and found that real exchange rate (REER) is affected by values of itself and remittances with one-lag delay, which led to appreciation of REER. At the same time, remittances are affected only by its values with one-, two- and three-lag delays. Impulse response functions showed that positive shock in remittances leads to rapid appreciation of REER in one quarter. Finally, positive shock in REER causes increase in remittances in first two quarters.

Keywords: Remittances, Real Effective Exchange Rate (REER), Impulse Response Function.

Introduction

One of the noticeable factors influencing Ukrainian economy is significant labor emigration, caused by low wages, misbalanced labor market and political instability. As the result, share of remittances in GDP of Ukraine in 2018 reached almost 11% (fig.1). The other peculiarities of the Ukrainian economy are constant depreciation of exchange rate and steady remittances increase. Considering the high share and importance of remittance inflows into the Ukrainian economy the idea of the current paper is to investigate the influence of remittance inflows on Ukrainian real effective exchange rate (REER) and vice versa. To reach research objective we employed VAR/ VECM model. Additionally, we built impulse response functions (IRFs) in order to reveal possible shocks caused by rapid changes in chosen variables. As the result of conducted research, rapid change in remittances was found, that led to the short-term appreciation of the real exchange rate with one quarter. Rapid change in REER led to the increase in remittance inflows in two quarters. Finally, we delineated future research.

Literature Review

Significant inflows of remittances are usually associated with Dutch disease, which results in appreciation of exchange rate of national currency (Caceres and Saca (2006), Bussolo and Medvedev (2007), Vargas-Silva (2009)). Some researchers found that inflows of remittances cause shocks in exchange rates and other macroeconomic indicators in recipient countries. For instance, Caceres and Saca (2006) reported that remittances lead to appreciation of real exchange rate in the short run, growth of consumer prices, interest rate, and volumes of imports in El Salvador using VAR model. Acosta, Baerg and Mandelman (2009) argued that appreciation of exchange rate caused by remittances depends on how financial system of recipient country channels them into investments. The research conducted for Small Island Developing Countries (SIDCs) conducted by Amuedo-Dorantez, Pozo and Vargas-Silva (2010) found that remittances tend to depreciate the real exchange rate, and appreciate the exchange rate if broader sample of countries are selected. Roy and Rahman (2014) supported the idea, that remittances engender inflationary pressure in Bangladesh. Contrary Oleksiv et al. (2020) reported that remittances inflows lead to depreciation of nominal effective exchange rate of Ukrainian hryvnia. For now, there are lack of research investigating influence of remittances on the exchange rate of Eastern European countries. Therefore, the research objective of the paper is to estimate short and long run effects of remittances on real effective exchange rate (REER) of Ukrainian hryvnia.

Methodology and Data

For the research, we have chosen two variables, which re the following: real effective exchange rate and remittance inflows. Real effective exchange rate was preferred to nominal, as it takes into account level of inflation and weights of different currencies in international trade of the country.

Depending on cointegration in sample of data, we will select either vector autoregression model (VAR) (1) or vector error correction model (VECM) (2).

$$\begin{aligned} REER_t &= a + \sum_{i=1}^{k} \beta_i REER_{t-i} + \sum_{j=1}^{k} \varphi Remit_{t-j} + u_{1t} \\ Remit_t &= \gamma + \sum_{i=1}^{k} \beta_i REER_{t-i} + \sum_{j=1}^{k} \varphi Remit_{t-j} + u_{2t} \end{aligned}, \quad (1)$$

where a, γ – constants; $REER_t$ – REER values in current periods; $REER_{t-i}$ – REER values in previous periods; $Remit_{t-i}$ – volumes of remittances in previous periods; β_i, φ_i – regression coefficients; u_{1t},, u_{2t} – errors.

$$\begin{aligned} \Delta REER_t &= a' + \lambda_1 ECT_{t-1} + \sum_{i=1}^{k} \beta_i' \Delta REER_{t-i} + \sum_{j=1}^{k} \varphi' \Delta Remit_{t-j} + u'_{1t} \\ \Delta Remit_t &= \gamma' + \lambda_2 ECT_{t-1} + \sum_{i=1}^{k} \beta_i' \Delta REER_{t-i} + \sum_{j=1}^{k} \varphi' \Delta Remit_{t-j} + u'_{2t} \end{aligned}, \quad (2)$$

where a', γ' – constants; $\Delta REER_t$ – REER differenced values in current periods; $\Delta REER_{t-i}$ – REER differenced values in previous periods; $\Delta Remit_{t-i}$ – differenced volumes of remittances in previous periods; β'_i, φ'_i – regression coefficients; λ_1, λ_2 – speeds of adjustment; ECT_{t-1} – error correction term; u_{1t},, u_{2t} – errors.

Before the estimation of VAR/VECM model, we are going to conduct Dickey-Fuller test for unit-root developed by Dickey and Fuller (1979) and to do the cointegration test (Johansen (1991). In order to reveal existence of shock caused by rapid increase of remittances we built impulse response functions (IRFs) based on results of VAR/VECM

model estimation. Quarterly data used for the analysis include volumes of remittances inflows and REER values for the period from 1996 to 2019 extracted from IMF International Statistics Database, IMF Balance of Payments Databases. In total, 90 observations were extracted for VAR/VECM model. As chosen variables are calculated in different measures, we normalized data by dividing values on relevant average value of each variable.

Results and Discussion

Basing on Akaike criteria, we selected the optimal lag of data at first difference, which is four lags or in the current case four quarters. Moreover, results of Dickey-Fuller test showed that both data on REER and on remittances are stationary at first difference (tab.1).

Tab.1: Dickey-Fuller test. Source: authors' research.

Variable	Test statistics	Critical values			MacKinnon approximate p-value for Z(t)	Conclusion
		1%	5%	10%		
REER	-4,389	-3,532	-2,903	-2,586	0,0003	Stationary
Remittances	-3,030	-3,532	-2,903	-2,586	0,032	Stationary

In order to decide VAR or VCEM model to choose Johansen cointegration test was employed (tab.2). Results of this test showed that there is no cointegration in data sample, which means that we can proceed with VAR model.

Tab.2: Johansen cointegration test. Source: authors' calculations

Maximum rank	Trace statistic	5% critical value	1% critical value	Maximum statistic	5% critical value	1% critical value

Results of VAR estimation showed existence of positive short-term relationship between REER as dependent variable and remittances as independent variable with one lag delay (tab.3). At the same time, REER in current period is affected by the value of REER in previous period.

Tab.3: VAR model estimation. Source: authors' research.

Dependent variables / Independent variables	REER	Remittances
$REER_{t-1}$	**1,077 (0,000)**	0,275 (0,447)
$REER_{t-2}$	-0,143 (0,365)	-0,023 (0,964)
$REER_{t-3}$	-0,059 (0,558)	-0,395 (0,24)
$Remittances_{t-1}$	**0,069 (0,031)**	**0,991 (0,000)**
$Remittances_{t-2}$	-0,083 (0,067)	**-0,383 (0,011)**
$Remittances_{t-3}$	-0,0005 (0,987)	**0,415 (0,000)**
Constant	**0,131 (0,003)**	0,185 (0,197)
Log-likelihood 185,963		
R squared	0,92	0,98

Finally, remittances are affected only by their lagged values: positively with one-lag delay and negatively with two- and three-lag delays, as REER variables are not statistically significant. For better interpretation of received results, we built impulse response functions (IRFs) for REER as impulse variable and remittances as response variable and vice versa (fig.2).

Fig.2: Impulse response functions for remittances and REER of Ukrainian hryvnia
Source: authors' calculations.

Built IRF graphs demonstrate that positive shock in REER causes a short-term increase in remittances in first two quarters and further decrease. In this case, remittances can be considered as stabilizers of consumption and income in conditions of exchange rate appreciation. At the same time, shock in volume of remittances leads to rapid appreciation of REER in the short run, which is approximately one quarter. However, in the third quarter REER depreciates. Such findings can be related to the ways of how population use received remittances, for instance the increase of consumption as the result of remittance inflows. Finally, the received results do not confirm the Dutch disease in Ukrainian economy in the long-term perspective. Moreover, depreciation of exchange rate of Ukrainian hryvnia cannot be considered as a threat for competitiveness of national export and international competiveness overall as was found for many developing countries (Bussolo and Medvedev (2007), Vargas-Silva (2009)). Considering the short-term mutual positive shocks of remittance inflows and REER we can delineate, two directions of regulation policy of Ukrainian government. They are inflation targeting and expansion of national export. In addition, government needs to understand and if possible to control, how the additional income is spent. Moreover, the latter partly confirms findings that "remittances can smooth consumption, increase business cycles volatility and lead to shortage of labor" (Gapen et al., 2006), which were identified as the result of Ramsey's policy investigation.

Conclusion

Conducted research found that significant inflows of remittances into Ukrainian economy lead to short-term appreciation of real effective exchange rate, followed by depreciation effect in future periods. The latter means that remittances do not cause Dutch disease effects. At the same time, positive shock in REER causes increase in volumes of remittance in two quarters. These findings delineate future directions of research, such as policy regulation of inflation and enhancement of export potential.

Perception of The Social Economy and Social Entrepreneurship by Students as Potential Entrepreneurs

Malgorzata REMBIASZ

Poznan University of Technology, Poznań, Poland
malgorzata.rembiasz@put.poznan.pl

Abstract

The article is an attempt to describe the perception of the social economy and social entrepreneurship as well as evaluate their prospects and obstacles to their development in the context of entrepreneurial intentions of students. From the point of view of academic research, the social economy is a broad and multifaceted phenomenon. Social enterprises try to combine activities complying with typical market mechanisms with social justice. The social economy is an element of policies aimed at ensuring sustainable development of the global economy. Local and national authorities, organisations (including the European Union) as well as international agencies and foundations launch different types of support instruments designed for social enterprises. The study carried out by means of an auditorium survey on a selected group of students has shown that they do not fully understand the concept of social economy. It is therefore worthwhile to take steps to enrich their knowledge about this sector and its benefits as part of a new approach to entrepreneurial education. Current socio-economic changes, including those recently caused by the coronavirus pandemic, call for new innovative solutions that would contribute to building a stronger society. Social entrepreneurship can develop fast if it is taken up by young, educated and creative people who are open to the world and social problems.

Keywords: Social Entrepreneurship, Social Economy, Entrepreneurial Intentions of Students.

Introduction

There are many definitions of the social economy and social entrepreneurship in the literature. The social economy is described as alternative economy as it provides a framework for non-financial exchanges, ethical trade and setting up enterprises that work for the benefit of the local community (Amin, 2009).

Social entrepreneurship is an important element of the social economy. Its functions include not only the provision of goods and services, but also galvanising social capital, innovating and actively involving excluded groups (such as disabled people) in social and economic life. Importantly, this does not exclude economic efficiency as such social enterprises may become very competitive in the market. Even so, profit maximisation is not their main objective.

Social entrepreneurs often work in areas different from those where traditional entrepreneurs are active. The latter are driven mainly by commercial logic whilst the former typically operate at the intersection of the social, commercial and public sectors (Thornton, and Ocasio, 2008). The goal of social entrepreneurs is not to maximise economic profit but to maximise social welfare and create social capital (Zahra, Gedajlovic, Neubaum, and Shulman, 2009).

Brief overview of selected research problems concerning the social economy and social entrepreneurship - literature review

Enterprises operating in the social economy try to combine typical market mechanisms and economic laws with social conscience. Social companies should also strive to grow to be better able to meet their objectives and achieve success (di Domenico, Haugh, Tracy 2010).

As it has already been mentioned, social entrepreneurship does not exclude operating for profit. It may therefore be difficult to strike a balance between social and business objectives which presents a major challenge for any social enterprise A study carried out in 2013 showed clearly that social objectives prevail over economic ones, proving that Polish social enterprises behave "typically" and are similar to other such companies in the world. Moreover, NGOs

who are also social enterprises declared firmly that they pursue business objectives in order to achieve those in the social domain. (Batko and Bogacz-Wojtanowska, 2015).

Social economy enterprises should be treated as important actors involved in public policies targeting the labour market. That the potential inherent in this sector is great can be observed in the current labour market where, compared to previous years, there is an increasing number of entities (mainly social cooperatives) that do well under open labour market conditions (Frączek 2018). Much involved in activating the unemployed, the social economy should also be perceived as an employment opportunity for people who are professionally inactive.

In the current and coming socio-economic situation there is a need for new employment strategies. In order to deal with the crisis it is necessary to provide more support for social entrepreneurship through institutional and even fiscal means. It is precisely enterprises operating in the area of the social economy that offer an opportunity to provide stable employment for disadvantaged social groups which suffer the most during recession. Moreover, such enterprises pursue social justice and gender equality objectives that are commonly considered to be beneficial. This includes greater representation of women in the total number of people employed in managerial positions compared to commercial companies (Núñez Bandeira and Santero-Sán, 2020).A study carried out among Polish entrepreneurs proved that the level of knowledge about the social economy is low. Only 28% of the entrepreneurs involved in the study declared that they knew of the concept of “social economy". Further, commercial entrepreneurs believe that social enterprises are ill-conceived economic ventures kept afloat thanks to state aid and focused on supporting those who struggle in their private and professional lives. Due to these negative associations entrepreneurs do not see any possibility of cooperating with the social economy sector. (Społeczna odpowiedzialność.., 2019).

Other studies carried out in Poland have confirmed the positive impact of entrepreneurial acumen on success measures and financial stability. This means that, if a social enterprise wants to be successful, it must pay attention to factors such as innovation, proactive attitude and risk-taking. Developing and strengthening their competitive advantage will allow them to increase their potential and then use it to solve social problems (Wronka-Pośpiech 2015).

The phenomenon of the social economy is also related to social innovations. Research results confirm that these are perceived as an important factor contributing to increased productivity and competitive edge of companies that operate in the market as well as those that are part of the social economy (Furmańska -Maruszak, Sudolska A. 2016). Even though social entrepreneurship offers an opportunity to efficiently channel social engagement of different social groups, this business model is not common in Poland. Studies have shown that the potential resulting from a socially engaged attitude of the young generation of Poles is not fully used which can be explained, among others, by the lack of knowledge about the social entrepreneurship model. (Stępczak 2020).

Hence, it seems that a major challenge for the social economy and social entrepreneurship is the introduction of these subjects in broadly-defined entrepreneurial education including at universities. According to M. Popowska (2018), young people who start their academic education in today’s Poland have grown up in the reality of market economy and are thus aware of its basic principles. This offers a unique opportunity to equip them with knowledge and skills related to the social economy as part of a new model of entrepreneurial education..

The author was encouraged to carry out the study by the postulate to teach students about social entrepreneurship as well as the already mentioned results of research conducted among entrepreneurs which showed that they do not know much about the social economy and have negative attitudes towards enterprises that operate in that sector. The purpose of the study being to examine the knowledge about the social economy concept as well as evaluate its prospects and obstacles to its development in the context of entrepreneurial intentions (plans to become self-employed) among students In order to solve the identified research gap, empirical studies were carried out.

Evaluation of social economy and social entrepreneurship – results of empirical research

Description of the research method and the research sample

The study was conducted in January 2020 among a selected group of students of management pursuing part-time studies at one of Polish private higher education institutions. The study was carried out by means of an auditorium survey. The author is aware of the limitations of survey studies. The respondents were asked to react to the statements included in the survey to reveal their opinions about the social economy. The results could have been influenced by the place where it was conducted (lecture hall), its timing (after students learned about the grades they obtained for one of the subjects) and perhaps by the fact that some of the respondents might have tried to guess the kind of results that the author expected. The questions that were selected for the survey were inspired by the already cited research among Polish entrepreneurs (Społeczna odpowiedzialność…, 2019). This helped to compare the responses provided by active businessmen with those supplied by potential entrepreneurs.

This article presents the results concerning a rather homogeneous group of 103 students aged 21 – 30. Data from six surveys have not been included in this study because of incomplete responses or the respondents' age (over 30 years old). Table 1 shows results related to entrepreneurial intentions of the students involved in the study.

Table 1: Responses to the question: "Are you interested in running your own business?"

Answers:	Percentage of responses (%)
Yes	36.9%
I already run a business	3.9%
No	24.3%
I don't know	34.9%

Source: own research

The table above shows that a relatively large number of respondents (as much as 36.9%) are interested in running their own company. The author obtained similar results in her 2019 study on student entrepreneurship in the context of business knowledge (Rembiasz 2019). Only four people were already running their own businesses which can be explained by the young age of the respondents. A rather high percentage of students with active entrepreneurial intentions (40.8%) is due to the respondents study management, a program they chose consciously. In addition, 98% of the respondents earned their living. Most respondents (73.8%) were women.

In order to verify hypotheses stated in this research and answer research questions IMB SPSS Statistics (v25) was used to analyze the data. First of all basic descriptive statistics were computed as well as Shapiro-Wilk test for normality of variables' distributions. Test results were significant in all cases. This means the distributions of variables were different in shapes then Gaussian curve. Nonetheless distributions were assumed normal based on absolute value of skewness not greater than 2 (George, Mallery, 2016) thus parametric models were used to verify hypotheses.

Differences in social economy perception based on willingness to run an own company

The table 2a, 2b I 2c show the results concerning the awareness and understanding of the social economy phenomenon. The surveyed students were divided into three groups: students who want to run their own business or already do so, those who do not plan it and students who do not know whether they want to become self-employed. Comparing the results of the three tables above yields the following conclusions. The great majority of the students to one of the fundamental assumptions of the social economy, i.e. combining economic and social objectives. The survey contained one false statement equating the social economy with state aid for the poorest, i.e. social assistance. Unfortunately, this statement was considered to be true by 47.6% of people with active entrepreneurial intentions, 48% of those who do not plan to be self-employed and 55.6% of those who do not know yet whether they will start a business. Based on the results of the study presented above, it may be concluded that the concept of social economy is not fully understood by students and needs to be included in economic education.

Table 2a : How respondents with active entrepreneurial intentions understand the concept of the "social economy"

In order to verify differences in social economy perception between examined groups an one-way analysis of variance was conducted. Assumptions of normality of dependent variable's distribution among compared groups as well as homogeneity of variances were met. Based on results shown in table 3 not any statistically significant difference was found. Compared means were illustrated in figure 1.

Differences in perception of the social economy's hampers based on willingness to run an own company

The tables 4a, 4b, 4c show how prospects and barriers related to the development of the social economy in Poland are evaluated by three different groups of students participating in the study broken down according to their declared intentions of running a business.

The results show that students with active entrepreneurial intentions evaluate the role of the social economy as a factor in the country's economic development lower than other students. This may be explained by associating the social economy with support for people in need and the budgetary resources this requires as well as the negative attitude towards social enterprises as economically ineffective and requiring different types of subsidy (as seen in a previously cited study). Declared future entrepreneurs reported less positive responses to the statement that the development of the social economy is hampered by the lack of interest among consumers. The obstacle to corporate social responsibility initiatives that was most often mentioned in the 2018 study was the lack of sufficient knowledge about the subject (Społeczna odpowiedzialność…, 2019). The same opinion was shared by a large group of students involved in the current research. Students with active entrepreneurial intentions and those who do not plan to start a business decided that, in the coming years, companies in Poland will take more social actions than they do now. Those who do not know yet whether they will be self-employed were least convinced about the statement.

In order to verify differences in social economy's hampers perception between examined groups an one-way analysis of variance was conducted. Assumptions of normality of dependent variable's distribution among compared groups as well as homogeneity of variances were met. Based on results shown in table 4 not any statistically significant difference was found. Compared means were illustrated in figure 2.

Figure 2: Means of social economy's hampers perception scores with 95% confidence intervals divided by compared groups

Differences in beliefs and attitudes towards social economy

At the end of the auditorium survey students were asked about their willingness to run a social enterprise or be employed in an enterprise of this type. The results are presented in the tables 6.1, 6b. 6.c.

6a. Evaluation of social entrepreneurship from the perspective of setting up or working in a social enterprise: students with active entrepreneurial intentions

Statements I am interested in...	Percentage of responses (%)				
	Strongly disagree	Tend to disagree	Hard to say	Tend to agree	Strongly agree
setting up an enterprise operating in the social entrepreneurship sector	14.3%	16.7%	31.0%	28.6%	9.5%
working in an enterprise operating in the social entrepreneurship sector	11.9%	11.9%	31.0%	26.2%	14.3%

Source: own research

6b. Evaluation of social entrepreneurship from the perspective of setting up or working in a social enterprise: students who do not plan to start a business

Statements I am interested in...	Percentage of responses (%)				
	Strongly disagree	Tend to disagree	Hard to say	Tend to agree	Strongly agree
setting up an enterprise operating in the social entrepreneurship sector	36.0%	28.0%	24.0%	12.0%	0.0%
working in an enterprise operating in the social entrepreneurship sector	12.0%	8.0%	48.0%	20.0%	8.0%

Source: own research

4c. Evaluation of social entrepreneurship from the perspective of setting up or working in a social enterprise: students who do not know whether they will be self-employed

Statements I am interested in...	Percentage of responses (%)				
	Strongly disagree	Tend to disagree	Hard to say	Tend to agree	Strongly agree
setting up an enterprise operating in the social entrepreneurship sector	13.9%	33.3%	38.9%	13.9%	0.0%
working in an enterprise operating in the social entrepreneurship sector	8.3%	27.8%	33.3%	25.0%	2.8%

Source: own research

According to the obtained results, a rather high percentage of students with active entrepreneurial intentions (38%) were interested in setting up an enterprise in the social entrepreneurship sector, which means that some of them see an opportunity to achieve their business objectives in this sector in spite of the related obstacles and negative stereotypes. Moreover, about 28% of the students who are not interested in running their own business do not exclude working in social enterprises in the future. The results confirm the thesis that it is worthwhile to teach students about the social economy as part of a new approach to entrepreneurial education.

In order to verify differences in scores of beliefs and attitudes towards social economy between examined groups an one-way analysis of variance was conducted. Assumptions of normality of dependent variable's distribution among compared groups as well as homogeneity of variances were met. Based on results shown in table 6 a statistically significant main effect for willingness to run an own company operating in the social entrepreneurship sector was found. To further investigate the differences *post-hoc* comparisons (with Tukey's correction) were performed. Statistically significant (p = 0,003) difference was found only between groups of respondents interested in running own business and respondents not interested in running own business. Rest of comparisons were statistically insignificant. This effect explained 10% of dependent variable's variance. Compared means were illustrated in figure 3.

Table 6. Comparison of scores of beliefs and attitudes towards social economy

	Interested in running own business (n = 42)		Not interested in running own business (n = 25)		Not sure (n = 36)				
	M	*SD*	*M*	*SD*	*M*	*SD*	*F*	*p*	η^2

Figure 3: Means of beliefs and attitudes towards social economy scores with 95% confidence intervals divided by compared groups.

Conclusions and Discussion

The social economy is often portrayed as a counterbalance to neo-liberalism, but in fact, from the perspective of academic research, it is a broad and multifaceted phenomenon. Researchers should concentrate on showing its impact and social value in a creative and attractive way in order to foster its development and promote it among young people. Local and national authorities, agencies and international foundations have long been involved in the social economy as part of their activities aimed at sustainable development, recognising the potential of this type of economy to eradicate poverty in the word (Waghid, Oliver, 2017). The development of SSE has also been a permanent theme of the Polish economic policy (Act No. 11…, 2019). What is more, social enterprises can benefit from a number of EU support schemes (Ekonomia społeczna…, 2019).

The new "second wave of the social economy constituted one of the fundamental institutional responses to the crisis of the welfare state as well as the challenges of globalisation" (Rymsza 2007). This raises the question whether there will be a "third wave of the social economy" in response to the economic crisis sparked by the coronavirus pandemic. Will this type of economy change its nature and can we expect a stronger presence of innovative companies? For this to happen, the social economy would have to be made attractive for young, educated and creative people who are open to the world and social problems.

Current socio-economic changes call for new innovative solutions that would contribute to building a stronger society. On the one hand, it is claimed that the ongoing coronavirus pandemic, global economic lockdown and local restrictions on economic activity, all of which decrease company revenue, increase unemployment and exacerbate the related social problems, may contribute to strengthening social bonds and pro-social behaviour as people want to help those in need. On the other hand, there is a rise in aggressive and criminal behaviour and a return to the principles of "hard" capitalism manifested in restricted employee rights and job cuts. The research presented in the article was focused on the opinions that students, as potential entrepreneurs, have on the social economy and social entrepreneurship. Unfortunately, awareness of the benefits resulting from this type of activity is not high among young people. Hence, it seems that it is worthwhile to strengthen educational efforts in this area. Courses teaching the fundamentals of classic economics should also focus on meeting social needs not only though social transfers but also by professional activation of people who are unemployed and professionally inactive. Students should be aware that while the market is an important element organising social life and the exchange of goods, "market alone is not the answer to all the problems of the modern world" (Manifest, 2008)).

The author hopes that the case study results presented in the article will enrich knowledge about young people's awareness of the existence of the social economy and improve their attitude towards it. Moreover, the author plans to repeat the study at the beginning of 2021 in order to verify how the experiences of young people related to the global pandemic might have influenced their attitude to the growth of the social economy.

COVID-19 Lockdown and IT-Powered Reporting: An Enabler, Irrelevant Factor, or Something in Between?

Abstract

This practitioner research insight explores how the usage patterns of reports targeted at internal decision-making evolved upon imposing COVID-19 restrictions Europe-wide that led to temporary Home Office conditions in a number of countries. The experiences of a multi-national Facility Management group are discussed. The contribution identifies some short-term corrective measures and provides the rationale for permanent post-lockdown changes.

Keywords: Reporting, Business Analytics, Facility Management, COVID-19, Organizational Change.

Introduction

Facility Management (FM) might be considered a profession targeted at enhancing business productivity and efficiency of customer companies while focusing on the specific needs and demands of workplaces as well as managing corporate social responsibility (Caryl, 2018). In recent years, managing the built environment began to be associated with newer and newer areas – just to mention in-depth data analysis (Konanahalli et al., 2018) as well as setting up telemetry and power consumption benchmarking (Gawin and Marcinkowski, 2017). The trend is expected to continue, as the necessity to integrate extensive knowledge management services for both internal and external use is highlighted by reputable bodies that monitor the FM market (Mehdi, 2018). Therefore, it is without little doubt a multi-disciplinary and highly IT-reliant business domain.

Whereas a bulk of FM companies still struggle with improving traditional FM services, integrating distributed IT solutions, increasing the quality of data being collected, setting up telemetry infrastructure, and backing up these activities with adequate staff competencies, the current market landscape calls for establishing effective mechanisms for making decisions based on data. Increasing the maturity of Big Data solutions in current use or under development shall enable broadening the range of determinants used within the analytics of how a given facility or group of facilities works, forecasting the life cycle of assets more reliably, increasing the transparency of reporting and shifting the center of gravity for compliance with standards and best practices from manually filled-in reports towards digitization and automatically calculated indicators. According to Ankerstjerne (2019), FM shall act in the future more as a provider of adequate data – and FM departments in organizations will probably know more about what is happening in the workplace than any other department, including Human Resources (HR) and IT. From both a final recipient and an operational employee point of view, reporting is at the heart of this process.

The outbreak of the COVID-19 pandemic caused by the SARS-CoV-2 virus in late 2019 and progressive lockdown in various countries significantly influenced the availability of retail and office spaces and flows of FM services, leading to a reviewing of current FM industry forecasts. Thus, the purpose of this contribution is confronting the utilization of FM reports put to work internally by a multi-national FM company to support decision-making with the reality of remote

work forced by the lockdown – along with its implications for the post-lockdown era. As the current contribution focuses on the practitioner's perspective, empirical data were collected as a part of a single-unit case design (Yin, 2017) that constitutes a useful method for exploring typical and/or extreme cases (Molka-Danielsen, Engelseth and Le, 2017) across various industries. After the introduction, the business setting is discussed. Subsequently, findings are presented, followed by conclusions.

Business Setting

The SESCOM Group provides a diverse portfolio of FM services to its European partners through several subsidiaries. Group's Operations departments organize, supervise, and settle the performance of field works throughout distributed commercial facilities networks. These works are carried out by technical services specialized in many fields; just to mention air conditioning, ventilation, heating, refrigeration, electricity, and energy efficiency. To monitor the course of FM processes at their various stages, SESCOM employees use a number of reporting templates, e.g. regarding the monitoring of service events, material flows, and progress in clearing FM activities. In particular, the aforementioned report templates enable the staff to monitor:

- operational processes (e.g. monitoring of failure response times);
- logistics processes (e.g. monitoring of component delivery times);
- management processes (e.g. monitoring of task accomplishment times by employees).

The measures undertaken across the European Union due to the spread of SARS-CoV-2 forced SESCOM management to rely heavily on remote work. Such mode covered not only the entire staff of the headquarters but all the contractors and offices located in Poland. Not all subsidiaries were affected equally, as the Polish containment strategy might be considered firm compared to other major markets that SESCOM Group operates on. It included the closure of borders (that impacted the logistics), shopping facilities (which constitute a significant share of customers), cinemas and cultural institutions, educational institutions – and ultimately resulted in a general confinement policy.

Switching the headquarters to remote work and handling business processes for the entire organization remotely required preparatory steps in a couple of areas: HR and technical. As HR is concerned, it proved vital (1) to make the staff at all levels ready to perform tasks safely while being restricted to their homes, which included a series of targeted training sessions; as well as (2) to establish mechanisms for setting goals (for management staff) and tasks (for specialists) and verifying the progress of their accomplishment. On the other hand, preparations that fall into the technical area featured (1) equipping employees with hardware and specialized software for remote work; and (2) providing the staff with access to a teleconferencing environment with other employees and customers. A Crisis Unit was established for the duration of the pandemic. It was tasked with monitoring the development of the situation constantly, analyzing input from the business environment, and taking actions that correspond with fluctuations in the impact of the lockdown on the business.

Findings

Home office conditions are associated with the risk of introducing distractions and thus reducing the productivity of the workforce due to fear and anxiety (de Oliveira, Orrillo and Gamboa, 2020). Nevertheless, losing access to key information and disrupting the decision chain pose equally high risks. As remote work in isolation – depending on the lockdown measures in force at a given moment – prevented or limited the possibilities of organizing face-to-face meetings, maintaining the hindered information flow relied solely on the contents of reports. Such a shift of reporting role from an input to a discussion towards a major decision-making factor did not necessarily have to radically affect the total number of downloaded reports, as the group widely used such content before. That being said, a number of changes in habits and usage patterns were detected after benchmarking the average number of daily report downloads across Q1 of 2020 against Q1 of 2019. First of all, the hourly distribution of downloads changed visibly (Fig. 1). Whereas in the previous year the employees used report-based analytics more eagerly in the afternoon, after the lockdown measures were forced, the download peaked in the early morning.

Fig. 1: Report downloads per hour

Secondly, report usage per user changed significantly. Generally speaking, in order to make themselves prepared for online meetings and back up decisions with relevant data, most of the 55 users that downloaded at least a single report during any of the quarters under analysis either intensified their report usage or initiated working with reports from scratch. Yet some users ceased their report usage altogether. After more in-depth analysis it was revealed that in some organizational units selected employees positioned themselves as a kind of “report hubs”, causing huge spikes and bringing down the downloads of other members of these units. The phenomenon arose around users who had already routinely used such analyses before. In the most extreme cases, an increase in report downloads of 320% and 275% respectively was observed (see Fig. 2). Users positioned as managers tended to narrow down their report-related activity. While such a phenomenon leads to enhancing communication within the organization both along horizontal and vertical paths, top-level management considered such voluntary data exclusion in terms of an organizational issue.

Fig. 2: Report downloads per user (excerpt)

On top of that, it was observed that people working in the same positions switched their reporting-related needs to a significant degree (see Fig. 3). Whereas managers focused more on high-level reporting, a wider portfolio of reports was put to use across the entire staff base. Among a total of 180 available reports, the coverage increased from approx. 57% to 69%. Whereas more state comparison and margin-related reports were requested, the peak related to the analytics of international phenomena. On the other hand, some reports targeted at certain customers and/or events were discontinued during the lockdown.

Fig. 3: Report downloads per report type (excerpt)

Conclusions

The reporting potential in place proved to be a factor that without doubt assisted the company to successfully adjust its operations to the lockdown conditions. Superiors expressed the opinion that despite meetings being virtual and lack of direct access to a large share of hardware and facilities, employees at various levels were better prepared for meetings and had information enabling them to make effective decisions. That being said, neither did the COVID-19 pandemic revolutionize the workflows, nor the experiences of the SESCOM Group justify considering it to be a main driving force behind setting up market-ready solutions for supporting remote work in such a short timeframe. It should be noted that the fact is analysis was based on a single company inhibits the possibility to generalize the results (Lech and Zamojska, 2017). However, the findings may induce businesses that lack similar solutions to initiate their organic development in this regard or to purchase a generic reporting solution from one of the vendors. It can also drive, as it was in SESCOM's case, increasing both technological and organizational maturity in that regard in the long run.

Scrutinizing reports' usage made the management aware that the company needs to develop highly targeted procedures for working with reports that improve work efficiency (including dealing with "time thieves" during Home Office) and transparency. In particular, the company expects a 15% increase in future operational event handling times due to their more accurate verification, analysis, and monitoring. The feedback led to identifying office positions that achieved benchmarks for performance during the Home Office – ultimately enabling the establishment of groups that carried on performing their duties remotely in post-lockdown conditions and limiting office and parking spaces.

Relationship Between Internet Use and Student Academic Engagement: Analysis on Romanian Youth

Laura BENCHEA

laura.benchea@rei.ase.ro

Abstract

In this age of technological imperative, the Internet has significantly impacted all areas of society and has transformed the ways things are done, businesses are conducted and educational goals achieved. The rapid expansion of information and communication technologies (ICT) in the educational field (schools and universities) over the latest decades demonstrate that new technologies are highly integrated within the educational process, with a huge impact on learning and teaching. Moreover, the internet has gained significance as a socializing tool, becoming a solid virtual platform for entertainment and social interaction. The benefits of the Internet have been highly praised in numerous research papers (such as rapid access to information and other learning resources), but a growing literature has demonstrated its negative effects especially related to its excessive use which adversely affects one's health (addiction, psychological distress exhaustion), social life (social isolation) or academic performance (lower engagement and lower grades). From this perspective, the internet as an educational tool can be a double-edged sword, which can either develop or impede students' academic engagement and, consequently, their educational performance. In this context, the study aims to analyze the dynamics of Internet use among Romanian youth and to assess the relationship between the Internet use and their academic engagement.

Keywords: Learning, Internet, Academic Engagement.

Introduction

Over the latest decades, the Internet has gained a significant role in the educational process, being one of the most used technologies for learning, teaching or research purposes. The introduction of the Internet in the educational system was intended to promote learning and knowledge acquisition through the easy access to information and different learning resources. All these useful educational tools came along with opportunities of entertainment and distractions which, misused or incorrectly understood, have a negative impact on the educational process and students' psychological development. Based on such observations, this study aims to determine the relationship between the Internet use and student academic engagement of Romanian youth. The hypothesis is that students mainly use the Internet for entertainment (movies, games, news, online shopping) and social media (Facebook and Instagram) to the detriment of proper online learning. Greater awareness of student practices inside and outside the classroom could inform the development of pedagogical tools meant to assist students' cognitive development while drawing on those practices in a way which makes them more relevant for student learning. Research findings as well as personal observations revealed decreasing student engagement in academic activities because of, among other factors, their intense preoccupations in the online sphere. This issue could inform the implementation of learning experiences that are more appealing to students. Based on my experience and observations, I have developed the following hypothesis which underpins the present study: students who spend more time on online activities (internet) will have less time to study and therefore their academic engagement and performances will diminish.

Research Questions

1. What do Romanian youth use the Internet for?
2. Are there any gender differences in the Internet use?
3. Is there any relationship between the internet use and the academic engagement of Romanian youth?

Cite this Article as: Laura BENCHEA "Relationship Between Internet Use and Student Academic Engagement: Analysis on Romanian Youth" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Objectives:

1. To identify students' main purposes and interests for Internet usage;
2. To illustrate the positive and negative effects of the Internet usage on youth (from psychological, social and intellectual perspective);
3. To examine the relationship between Internet usage and the academic engagement of Romanian youth.

Methodology

This research is based on a secondary analysis of the data collected in 2014 by the Friederich Ebert Stiftung (FES) - a cultural non-profit institution, at a country level. Based on the data collected, a report entitled "Romanian youth: concerns, aspirations, attitudes and lifestyle" was issued in 2014. The data was collected using face-to-face interviews, questionnaires and focus-groups with Romanian youth (1302 respondents, aged 15-29, from different Romanian regions) with the purpose of identifying their values, lifestyles, aspirations, educational achievements or political implication. For the current study, I selected the data related to the topic, respectively information about the Internet use and their academic engagement (for those who are enrolled in the educational system).

Internet as an instrument for Education

There is a growing literature which studies the use of the Internet for educational purposes, underlying its important role in providing academic and scientific information, as well as social connection and entertainment. It is unquestionable that the Internet has shaped the way how teaching is provided and learning is achieved, and it also stimulated the change of mentalities, opened new opportunities for acquiring and delivering information, and enlarged the access to unlimited knowledge.

The benefits of Internet in education

Numerous studies have focused on the positive impact that the Internet has on teaching and learning. It was invented in the early 1960 with the scope of exchanging information on R&D in the military and science. Currently, it is the largest information infrastructure, holding more than 1.8 billion websites (www.internetlivestats.com, 2020) and other technological related products.

Supporters of the Internet as an essential tool for nowadays education believe that it provides major benefits in terms of academic performance. It provides an ocean of information on almost any subject nearly instantly. According to Deore (2012), having access to almost any information and the latest news keep students connected to the real world and this helps them make better decisions for their lives. An early and consistent report on the impact of Internet on education was issued by UNESCO in 2003. Back then the report identified the advantages as well as the drawbacks of the Internet in the education sphere and the scientific work. Among the advantages, the report mentions the quick access to information, data and references, rapidity in information retrieval, networking between participants, access to diverse databases, didactic efficacy by delivering materials through electronic means.

Internet in Education: Negative Outcomes

Cognitive and psychological effects of Internet usage

A number of researches demonstrate that a human's learning capacity may be severely damaged by brain overloading with diverse online stimuli. More information doesn't necessarily imply more knowledge. How do all the ingenious apps we depend influence us to find and assess the relevant information and to fulfill our cognitive tasks? In 2008, a Dutch psychologist, Cristof van Nimwegen carried out a study using computer-based learning in which two groups of volunteers had to solve a complicated puzzle. One of the two groups received soft-based assistance while the other group was given no help, suggestions or any other assistance to solve the puzzle. Initially, the soft assisted group made more rapid moves but as the game advanced, the skills of the other group developed as they were forced to rely only on their own intellectual capacities. Results showed that those who worked without assistance were able to anticipate the game, to design a strategy, were more focused and eventually identified better solutions. On the other hand, the more the other participants relied on software guidance in task solving, the less they learned and were able to rely on their own cognitive abilities. In van Nimwegen's conclusion, the more we

"externalize" problem solving to computers, the more we reduce the brain's capacity to build stable structures of knowledge (schemes) which can subsequently be applied in new circumstances (Carr, 2012).

The perils of Multitasking

Web browsing implies an intense form of multitasking because every time one shifts their attention from one subject to another the brain must reorganize, using more mental resources. As Maggie Jackson explains in "Distracted" (2008), a book on multitasking, the brain needs time to switch tasks, to remind the rules needed for the new task and to block the cognitive interference of the previous task, still in force. Even more, a simple exchange between two tasks may significantly increase the cognitive load, hindering thinking and increasing the probability to overlook or misinterpret relevant information (Foerde, Knowlton and Poldrack, 2006).

Studies in the field also emphasize that people tend to move quickly from one web page to another. A longitudinal study conducted by a group of researchers from the University College in London examined two popular research sites that give access to scientific articles, electronic books and other academic tools. They discovered that users displayed a "discontinuous form of activity" in which they rapidly jumped from one source to another, reading one or two pages at most from one article or book before moving to another site. "It is apparent that users do not read online in the traditional way; it seems that there emerge new types of reading and people go online to avoid traditional reading" (Carr, 2012). Students developed the ability to rapidly scan the needed information, but the time spent with deep and focused reading constantly diminished. According to Anderson (2009), the reasons why people spend so much time online is that there are numerous benefits in terms of work and pleasure and it is already too late to retreat in quieter times. On the other hand, Jordan Grafman a physician specialized in neurological disorders explained that improvement in the human capacity to solve multiple tasks impedes their deep thinking and creativity (Carr, 2012). Certainly, the Roman philosopher Seneca resumed it better 2000 years ago when he asserted that "Being everywhere means being nowhere".

Internet Addiction

The benefits of the Internet have been highly praised in numerous research papers, but a growing literature has demonstrated its negative effects especially related to its excessive use which adversely affects one's health, social life or academic performance. A study form 2006 (Mafe and Blass cited in Akhter, 2013) showed that the university students (aged 19-24) are more at risk of becoming Internet addicted as, during this period, they have more spare time and they are less monitored by their parents.

Akhter (2013) investigated the relationship between Internet addiction and academic performance of university undergraduates. He discovered that the excessive use of the Internet has a negative impact on the academic performance as it increases the probability to miss classes and, consequently, to get lower grades. Good academic results imply physical health, time management and hard work (for exams, assignments or group projects). This is why students who spend much time in online activities have little or no time for studies (Griffith, 2000 cited in Akhter, 2013). Other explanations point out that students lose their concentration most probably as a result of late night Internet sessions (Frangos and Frangos, 2009 cited in Akter, 2013).

Among the most important psychological disorders associated to Internet addiction, psychologists pointed out to depression, anxiety, loneliness and social isolation (Akhter, 2013). One of the most important studies on the relationship between depression and internet addiction was carried out by Young and Rogers in 1998. They discovered that there is a connection between Internet addiction and some characteristics attributed to depressives (low self-esteem, weak motivation, fear of being rejected and need of approval). One reasonable explanation is that the Internet, especially online communication, might help them overcome the interpersonal communication deficit in real life.

Student Engagement in the Internet Era

The concept of *student engagement/involvement* was coined by Astin in 1984 and defined as "the amount of physical and psychological energy that the student devotes to the academic experience. Thus, a highly involved student is one who, for example, devotes considerable energy to studying, spends much time on campus, participates actively in student organizations, and interacts frequently with faculty members and other students." (Astin, 1984). Today, engagement is no longer confined to the time and energy dedicated to educational

achievements, but includes investment in collegiate experience, online interactions with peers and involvement in other educational activities.
As social media are conceived as platforms for engagement and because students spend much time using these networks, several researches tried to examine the relationship between Facebook use, for example, and student engagement and how it affects students' success in the academic sphere. A study carried out in 2011 and entitled "Too much face and not enough books: the relationship between multiple indices of Facebook use and academic performance" (Junco, 2011) addressed this issue and found out that students who spend more time on Facebook have less time to study and therefore achieve lower academic performance (reflected in lower grades). These results are consistent with other findings (Astin, 1984) which demonstrate that academic success is dependent upon the time and energy invested in academic work. Therefore, the time spent on social media (Facebook, Instagram) might not be in itself a problem, but it prevents students from engaging more time in studying and researches show clear that engagement influences academic performance.

There are other studies which demonstrate that the amount of time students spend on Facebook (the most popular social networking) significantly influences their academic success. A survey conducted in the United States (Dahlstrom et al., 2011) on 3000 students reported that 90% of the college students were using Facebook and this *over involvement* had a negative impact on their academic performance as they had decreased time to study and a lower attention channeled towards academic activities (Ellore, Niranjan and Brown, 2014).

Data from Internet World Stats (2017) show that, in Romania, Facebook is the social network with an explosive growth over the past years, registering 8,900,000 users at the end of 2018. Even though not much research has been conducted on how social media impacts students' learning, it is apparent that it has become almost ubiquitous in Romanian universities. Some researches show that the reason why this social networks are so popular among students resides in the positive relation with forming and increasing social capital (Ellison, Steinfield and Lampe, 2011) while others (Valenzuela, Park and Kee, 2009) discovered that there is a relationship between civic participation, social trust and the intensity of Facebook use (studies cited in Junco, 2015).

Related to the relationship between the Internet use and academic engagement, there was a study carried out in 2011 on Romanian students who benefited a governmental voucher to purchase a computer. The study showed that students used the computers mainly for playing games, therefore remaining little time for homework, reading or other educational activities. Consequently, these students registered a decline in their academic achievement, scoring lower grades at Math, English and Romanian (the main subjects studied in schools). The study emphasizes that, despite the good intention to achieve educational purposes and increase knowledge, most of the students used their computers for entertainment and this attitude led to lower academic results (Malamud, Pop-Eleches, 2011).

Results

This research is based on a secondary analysis of the data collected in 2014 by the Friederich Ebert Stiftung (FES) - a cultural non-profit institution, at a country level. Based on the data collected, a report entitled "Romanian youth: concerns, aspirations, attitudes and lifestyle" was issued in the same year. The data was collected using face-to-face interviews, questionnaires and focus-groups with Romanian youth (1302 respondents, aged 15-29, from different Romanian regions) with the purpose of identifying their values, lifestyles, aspirations, educational achievements or political implication. For the current study, I selected the data related to the topic, respectively information about the Internet use and their academic engagement (for those who are enrolled in the educational system).

Data show that Romanian youth use the Internet mainly for social networks, but also as a source of information. Those aged over 25 are using the Internet for information related to their jobs or for online shopping. Not surprisingly, 9 out of 10 teenagers use the Internet for the social media platforms.

Table 1: Main purposes for Internet use

For work	23%
Reading news online / getting information	20,2%
Access to social networks (Facebook, Instagram)	40,4%
Looking up information	3,4%
E-mail	1,0%
Watching videos /listening to music	1,0%
Downloading films/books	2,0%
Video games	5,0%

About half (46,5%) of the young Romanians who were involved in this study were integrated into an educational structure (school, high school, university, master or PhD). The other half (over 25 years old) graduated at a certain level, most of them entering the job market. According to the survey, the young Romanian people devote little time to individual study. About half of the youth surveyed spend less than two hours per day on educational activities outside the classrooms, and only 21% study three hours or more per day (Table 2).

Table 2: Time devoted to study per day

Up to 1 hour	11,3%
1-2 hours daily on average	12,4%
2-3 hours daily on average	11,4%
3-4 hours daily on average	6,4%
More than 4 hours daily	3,4%
DK/NA	1,5%
Total	**46,2%**

An interesting aspect derived from the data analysis is that the TV and Internet use among the Romanian youth is correlated with some family characteristics such as parents' level of education and the perceived social class they belong to. Briefly, the more educated the parents are or the higher the class they belong to, the lesser time their children spend in front of the TV and the more time for online activities. For example, almost one third (32,4%) of the young people interviewed whose fathers have postgraduate studies never watch TV, but almost 30% of them spend more than 6 hours a day on the Internet. It can be underlined that TV is preferred by young people whose parents have a lower educational level or belong to a disadvantaged social class while the Internet is mostly used by those whose parents have superior educational attainments or belong to a better social class (FES, 2014). A possible explanation could be that poorer families can afford TV stations as compared to computers, the cost of utilization is cheaper and it doesn't require too much knowledge. In addition, the Internet usage is closely related to some liberal professions and its associated educational forms.

Analyzing the gender differences, data show that 30% of women spend three or more hours per day engaged in individual study as compared to 13% of men. Moreover, the data illustrate that 50% more women than men study between two and three hours per day. This outcome along with the extra effort and enthusiasm engaged by girls in accomplishing their educational activities may indicate the gender discrepancy in terms of educational results.

Consistent with other studies (Tsai et al., 2009; Akhter, 2013), the data collected on Romanian youth show that men spend more time than women in online activities (about 43% of men spend more than 4 hours a day on the Internet as compared to 34% of women). According to FES (2014), young men usually use the Internet for news or online games while women tend to browse for work related activities or for social media.

Table 3: Gender difference in Internet use

	Up to 1 hour	**Up to 2 hours**	**Up to 3 hours**	**4 hours or more**
Men	12,4%	19,2%	25,7%	**42,7%**
Women	19,4%	20,9%	25,5%	**33.9%**

Related to the academic results, the average score obtained by the interviewed in the previous year is 8.35 (FES, 2014). The best average score (8.4) is obtained by the group associated with undergraduates and graduates (college and master students, aged 20-24) On average, women in the sample got 0,6 points more than men, a statistically significant difference (the average female score is 8.63 while male got 8.01 in the year before the study).

The data show that here are also differences between the educational forms (levels). Overall, postgraduate students (enrolled in master or PhD programs) have better grades than the others (Figure1). However, the differences are not statistically significant because of the reduced sample of the students enrolled in post university courses (3%).

Figure1: Grade point average on educational level

The hypothesis which underpins the present study is that students who spend more time in online activities (internet) will have less time to study and therefore their academic engagement and performances will diminish. In order to establish if there is any relationship between the Internet use and student academic engagement, I had as reference the theory of student engagement elaborated by Austin (1984) and the analysis of the data presented in the current study. According to Austin, a student's involvement in the academic work, for example, can be measured quantitatively (how many hours the student spends studying - the theory suggests that "the extent to which students can achieve particular developmental goals is a direct function of the time and effort they devote to activities designed to produce these gains"). In essence, the more time students spend on learning, the more they learn and the better their marks are. In order to identify if there is any relationship between the time spent on the Internet and the academic engagement (measured in time devoted to studying), two variables are measured and the relationship between them: the average number of hours spent a day on the Internet and the grade point average of the previous

year. Figure 2 indicates that there is a negative correlation between the two variables analyzed (Pearson Coefficient, -.062).

Correlations

		How many hours a day on average do you spend on the Internet?	What was your grade point average last year?
How many hours a day on average do you spend on the Internet?	Pearson Correlation	1	-.062
	Sig. (2-tailed)		.167
	N	1181	502
What was your grade point average last year?	Pearson Correlation	-.062	1
	Sig. (2-tailed)	.167	
	N	502	518

Figure 2: Correlation between the time spent on the Internet and the average grade point

Therefore, the analysis supports the hypothesis and shows that the more time young people spend on the Internet (for non-educational purposes), the lower their grades would be and consequently their overall academic performance.

Conclusions

The rapid expansion of information and communication technologies (ICT) in the educational field (schools and universities) over the latest decades demonstrate that new technologies are highly integrated within the educational process, with a huge impact on learning and teaching. The purpose of this study was to analyze the dynamics of Internet use among Romanian youth and to assess the relationship between the Internet use and their academic engagement. In this respect, I have formulated three research questions:

RQ1: What do Romanian youth use mostly the Internet for?
RQ2: Are there any gender differences in the Internet use?
RQ3: Is there any relationship between the internet use and the academic engagement of Romanian youth?

Research question 1:
Data show that Romanian youth use the Internet mainly for social networks, but also as a source of information. Those aged 25 and more are using the Internet for acquiring information related to their work or for online shopping. Not surprisingly, 9 out of 10 teenagers use the Internet for the social media platforms (Facebook and, more recently Instagram). These findings reveal that, irrespective of age, Romanian youth mostly use the Internet for entertainment purposes in the detriment of scientific and educational work and this prevents them from achieving better academic results. Other previous researches in the field (Ravizza, Hambrick and Fenn, 2014) showed that the Internet used for non-academic purposes influences learning and the overall student's academic performance.

Research question 2:
The data collected on Romanian youth show that men spend more time than women in online activities (about 43% of men spend more than 4 hours a day on the Internet as compared to 34% of women). Moreever, young men usually use the Internet for news or online games while women tend to use it for social media or for work related activities.

Research question 3:
Data analysis indicates that there is a negative correlation between the Internet use and the academic results of Romanian youth, which leads to the conclusion that the more time is spent on online activities, the lower the academic results would be. These findings are supported by other studies (Astin, 1984; Akhter, 2013) which demonstrated that the more time students spend on the Internet, the possibility to get lower grades is higher, as there is no much time left to invest in studies or other educational activities.

Abstract

In the last years, higher education institutions have joined the top international rankings to "measure" their performance, through comparisons. The aim of this study is to identify the main indicators and criterions that international rankings pursue to classify the universities around the world. Moreover, this study also proposes to identify the similarities and/or differences among the rankings. At the same time, where similarities will be identified, a higher attention will be directed towards the indicator's significance/magnitude. The study follows the impact of rankings that analyses higher education institutions which addresses larger fields such as research, technological innovation, the prestige of the institution etc. The study analyses five ranking systems, most relevant indicators, valuable input on the top of the first 10 universities for each ranking in 2019, provides the junction point of the 5 rankings taken into account and interprets the obtained results with respect to the context.

Finally, based on the worldwide universities analysis, an overview on these classification and ranking systems will be obtained in order to provide a clearer general picture.

Keywords: Ranking, Higher Education, Research, Innovation

Introduction

In order to understand this paper, a very clear description of the used terms is mandatory. Thus, classification, due to the Explanatory Dictionary of the Romanian Language, the term represents "the action of classifying itself and its results; distribution or systematic distribution through different criterions such as class or in a certain order; categorization", while *hierarchy* implies "to place in a hierarchical order; to establish a hierarchy (system of subordination of the lower elements, degrees, functions, authorities, etc. towards higher ones". Therefore, it can be noted that classification does not represent a ranking, compared to the hierarchy which, by definition, generates a ranking.

In his paper (2013), David Robinson [2] stated that "university hierarchies have minimized the complexity of higher education institutions, their outcomes and practices, on a simple value scale, which cannot really be a valid indicator of quality". Thus, it can be assumed that such hierarchies measure the financial well-being of higher education institution rather than their quality.

Looking at the history of the emergence of international rankings, it can be observed that the US News and Report Ranking appeared in 1983, concomitantly with the ranking of the Business Week MBA program. In 2003, the Academic Ranking of World Universities (ARWU) was introduced by Jiao Tong University from Shanghai, and nowadays is the most popular and elitist international ranking. The ARWU have designed this ranking in order to

Cite this Article as: Roxana - Adriana MECHNO, Cristian - Vasile DOICIN, Gabriel PETREA, Diana SCURTU and Alexandru - Ionut BUZATU "Comparative Analysis of International Ranking Systems for Universities" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

position Chinese universities in relation to the best international universities. In 2010, two other rankings that classifies universities around the world occurred, namely Times Higher Education World University Ranking - Thomson Reuters and QS World University Ranking. This was closely followed by the Center for World University Ranking (CWUR) which implemented their own top and classification of international universities.
Based on the statement above, and analyzing five international rankings, the present study focuses on the following aspects:

- similarities between the 5 most important and significant international rankings,
- ranking's elements of differentiation,
- comparation between rankings,
- comparation between universities,
- interpretation of the indicators.

US News and Report Ranking

Approximately 30 years ago, US News began ranking universities in the United States, which nowadays is expand globally. In this ranking, the indicators are divided into 3 categories, depending on their type, as follows [7]:

1. Bibliometric indicators (65%);
2. Institutional reputation (25%);
3. Scientific excellence (10%).

The assessment of indicators is performed using the data processed by Clarivate Analytics InCites™ or Web of Science and a logarithmic scale. Figure 1 depicts the main indicators for US News and Report ranking.

Figure 1: Indicator for US News and Report Ranking

As it can be seen in Figure 1, the US News and Report Ranking is based on the Bibliometrics, which is the strongest indicator when it comes to make a ranking. While for the institutional reputation and the scientific excellence a much lower percentage is attributed, of 25% and 10%, respectively, suggesting that attention is concentrated on publications, citations, books, conferences etc.

In table 1 are presented the top 10 institutions ranking, at the end of 2019, according to the US News and Report Ranking.

Table 1: Ranking of universities according to US News and Report Ranking

Number	*Name of institution*	*Country*	*Overall score*
1.	Harvard University	United States of America	100
2.	Massachusetts Institute of Technology	United States of America	98,4
3.	Stanford University	United States of America	94,9
4.	University of California - Berkeley	United States of America	90,3
5.	Oxford University	United Kingdom	87,2
6.	California Institute of Technology	United States of America	87,1
7.	Columbia University	United States of America	86,5
8.	Princeton University	United States of America	85,6
9.	Cambridge University	United Kingdom	85,5
10.	University of Washington	United States of America	85,3

Academic Ranking of World Universities – ARWU

As previously mentioned, ARWU is the most popular and known ranking of higher education institutions in the world. Given the city in which it is made, it is also known as the Shanghai Ranking. The indicators taken into consideration by those who compile this ranking refers to [4]:

1. Quality of faculty (40%);
2. Research output (40%);
3. Quality of education (10%);
4. Academic performance (10%).

In figure 2 are presented the main indicators taken into consideration by Academic Ranking of World Universities system.

Figure 2: Indicator for Academic Ranking of World Universities

As shown in Figure 2, in the case of the international ARWU ranking, the most important indicators, Quality of Faculty and Research Output, respectively, have an equal share of 40%, while the Quality of Education and the Academic performance just 10% were attributed to each other.

In table 2 are presented the top 10 institutions ranking, at the end of 2019, according to the to ARWU.

Table 2: Ranking of universities according to ARWU

Number	*Name of institution*	*Country*	*Overall score*
1.	Harvard University	United States of America	100
2.	Stanford University	United States of America	75,1
3.	Cambridge University	United Kingdom	72,3
4.	Massachusetts Institute of Technology	United States of America	69
5.	University of California - Berkeley	United States of America	67,9
6.	Princeton University	United States of America	60
7.	Oxford University	United Kingdom	59,7
8.	Columbia University	United States of America	59,1
9.	California Institute of Technology	United States of America	58,6
10.	University of Chicago	United States of America	55,1

QS World University Rankings

QS World University Rankings is one of the classifications and ranking systems that is audited and approved by the Academic Ranking and Excellence (IREG) Observatory, being thus one of the most known such systems. In order to achieve a hierarchy, the following indicators are considered [6]:

1. Academic reputation (40%);
2. Total citations (20%);
3. Ratio between staff and students (20%);
4. Employer reputation (10%);
5. International faculty ratio (5%);
6. International student ratio (5%).

In figure 3 are presented the main indicators taken into consideration by QS World University Rankings system.

Figure 3: Indicator for QS World University Rankings

Figure 3 shows that Academic Reputation (40%) is the strongest indicator for the international QS World University Ranking. The papers citations and the ratio between the staff number and the students correspond to 20%, while with

equal weights, of 10%, are found to be the indicators that refer to the employer reputation and the internationalization of the respective higher education institution/university.

In table 3 are presented the top 10 institutions ranking, at the end of 2019, according to the QS World University Ranking system.

Table 3: Ranking of universities according to QS World University Ranking

Number	*Name of institution*	*Country*	*Overall score*
1.	Massachusetts Institute of Technology	United States of America	100
2.	Stanford University	United States of America	98,4
3.	Harvard University	United States of America	97,4
4.	Oxford University	United Kingdom	97,2
5.	California Institute of Technology	United States of America	96,9
6.	Swiss Federal Institute of Technology	Switzerland	95,9
7.	Cambridge University	United Kingdom	95
8.	London University College	United Kingdom	94,8
9.	Imperial College London	United Kingdom	94,1
10.	University of Chicago	United States of America	92

Time Higher Education World University Rankings

Times Higher Education World University Rankings (THE WUR) is another tool for ranking the higher education universities around the world, which is audited by PriceWaterHouseCooper and follows several indicators, grouped by classes as following [5]:

1. Teaching process has several indicators (30%);
2. Total number of citation (research influence - 30%);
3. Research (volume, income and reputation - 30%);
4. International outlook (7.5%);
5. Technology transfer (2.5%).

In figure 4 are presented the main indicators taken into consideration by THE World University Rankings system.

As the number of THE World University Ranking indicators is larger, compared to other systems, an illustrative overview reflecting the 5 main classes is depicted in Figure 4. It can be seen that, with equal weights, of 30% each, the first 3 indicators are found as fallowing, Teaching process, Research and Citations. With a much lower weight, of only 7.5% is considered the indicator that refers to the International outlook of a higher education institution/university, while the least significant is that of Technology transfer to industry.

Figure 4: Indicator for THE World University Rankings

According to THE World University Ranking, the global ranking of institutions, at the end of 2019, is as follows:

Table 4: Ranking of universities according to THE World University Ranking

Number	*Name of institution*	*Country*	*Overall score*
1.	Oxford University	United Kingdom	95,4
2.	California Institute of Technology	United States of America	94,5
3.	Cambridge University	United Kingdom	94,4
4.	Stanford University	United States of America	94,3
5.	Massachusetts Institute of Technology	United States of America	93,6
6.	Princeton University	United States of America	93,2
7.	Harvard University	United States of America	93
8.	Yale University	United States of America	91,7
9.	University of Chicago	United States of America	90,2
10.	Imperial College London	United Kingdom	89,8

Center for World University Ranking

When conducting a classification, the Center for World University Ranking (CWUR) considers the quality of students education and training, as well as the prestige of the scientific community within the university through the quality of the conducted research. CWUR uses 7 carefully selected indicators to rank universities around the world, namely [3]:

1. Quality of education (25%);
2. Alumni employment (25%);
3. Professors with Nobel Prizes and Fields Medals (10%);
4. Research performance (40%).

In figure 5 are presented the main indicators taken into consideration by Center for World University Ranking system.

Figure 5: Indicator for Center for World University Ranking

Figure 5 shows that Center for World University Ranking focuses on the research performance (40%), the quality of education and alumni employability with equal percentages, of 25% each. The least important indicator with a percentage of only 10%, is considered to be the teachers who have obtained international distinctions.

In table 5 are presented the top 10 institutions ranking, at the end of 2019, according to the Center for World University Ranking system.

Table 5: Ranking of universities according to CWUR

Number	*Name of institution*	*Country*	*Overall score*
1.	Harvard University	United States of America	100
2.	Massachusetts Institute of Technology	United States of America	96,7
3.	Stanford University	United States of America	95,2
4.	Cambridge University	United Kingdom	94,1
5.	Oxford University	United Kingdom	93,3
6.	Columbia University	United States of America	92,6
7.	Princeton University	United States of America	92
8.	University of California - Berkeley	United States of America	91,6
9.	University of Pennsylvania	United States of America	91,1
10.	University of Chicago	United States of America	90,7

Point junction of the 5 international rankings

Figure 6 depicts the point junction of the 5-international ranking. As it can be noted from Figure 6, it is obvious that there are some similarities among the indicators taken into account by the international rankings, such as, the top 10 universities mentioned in all ranks, in most cases are the same, and only their position in the ranking may differ.

Figure 6: Intersection between the 5 international rankings and interpretation

Analysing the first two rankings, one can see similarities between US News and Report Ranking and Academic Ranking of World Universities. Some small difference of only 5% were noted in terms of bibliometric indicators and for the indicator regarding the academic reputation. Thus, based on these findings it can be assumed why the rankings, for 2019, of US News and Report Ranking and Academic Ranking of World Universities is similar. Moreover, the following can be said:

- if we take into consideration the first position of each rank, it can be observed that the same university is found, namely, Harvard University,
- if we refer to the first 10 position in the rankings, the same 9 higher education institutions are found in both rankings, the only difference being their occupied position in the ranking (e.g.: Stanford University is ranked 2nd in the US News and Report Ranking and 3rd in Academic Ranking of World Universities);
- it we take into consideration the 10th position the difference is given by the Washington University which according to the US News and Report Ranking occupies the 10th position, while in the Academic Ranking of World Universities occupies the 11th position, and by the Chicago University which occupies the 10th position in Academic Ranking of World Universities and the 13th position in the US News and Report Ranking.

Analyzing all 5 international rankings, both, similarities and certain differences, between them are highlighted, as follows:

- all 5 rankings have included the bibliometric indicator, even though at different rates as following: 65% for US News and Report Ranking, 60% for Academic Ranking of World Universities, 42% for THE World University Rankings, 40% for Center for World University Ranking and 20% for QS World University Rankings;
- all 5 rankings refer to academic reputation, in the following percentages: 40% for QS World University Rankings, 33% for THE World University Rankings, 30% for Academic Ranking of World Universities, 25% for US News and Report Ranking and 10% for Center for World University Ranking
- three of the 5 rankings take into consideration the indicator regarding scientific excellence, namely: 25% for Center for World University Ranking and, in equal ratio of 10% US News and Report Ranking and Academic Ranking of World Universities;
- two of the 5 rankings have also implemented indicators regarding students, this being THE World University Rankings in a percentage of 22.5% and QS World University Rankings in a percentage of 20%;
- in a rate of 25% and 10%, the Center for World University Ranking and QS World University Rankings, respectively, also take into account the employer reputation, which represents the perception of the universities among employers, as indicator when ranking universities,
- the only ranking that takes into consideration the international/global reputation is the QS World University Rankings;

- even though at a very small rate, of 2.5%, the technology transfer is a significant indicator when universities register to be ranked in THE World University Rankings.

If the indicators presented in Figure 6 are analyzed in detail, for each ranking, things are as follows:

Bibliometric Indicators

The ranking that most considers Bibliometric Indicators is US News and Report Ranking. The 65% percentage is divided for another 7 sub-indicators, which in turn consist of different percentages: publications that are among the 10% most cited (12.5%), publications in the most prestigious journals (10%), normalized citation impact in Clarivate Analytics (10%), percentage of total publications in the most 10% cited journals (10%), international collaboration (5%), total citations (7.5%), written books (2.5%) and conferences (2.5%). It can be seen how detailed is the indicator that analyzes the bibliometry.

For the Academic Ranking of World Universities, the bibliometry is described by 3 sub-indicators, one referring to the total number of citations (20%), within the Quality of Faculty indicator. Percentage of publications published in the most cited journals (Nature and Science) and papers indexed in Science Citation Index - Expanded and Social Science Citation Index, in equal percentages, of 20% each, come from the Research Output indicator.

THE World University Rankings is the next to consider the Bibliometric Indicators in a fairly high percentage of 42%. The percentage comes from a main indicator that refers to the Total number of citations, in percentage of 30% and two other sub-indicators, coming from Research indicator: research income and articles in Scopus, both having a percentage of 6%.

The Center for World University Ranking is also close to THE World University Rankings. The 40% percentage is defined by the research performance indicator, which describes the indicators with equal ratios: publications in prestigious journals (10%), publications in the most cited journals (10%), total number of citations (10%) and impact of citations (10%).

For QS World University Rankings, the Bibliometric Indicators refer strictly to total citations, the percentage being 20%.

Academic reputation

The ranking which highlights the great academic reputation is QS World University Rankings. The indicator has a percentage of 40% and it is based on a survey, which collects the opinions of experts of over 100,000 people in higher education on the quality of teaching and research at universities around the world.

For THE World University Rankings the percentage of 33% for Academic reputation indicator is described by two sub-indicators, coming from two different categories of main indicators, as follows: global research reputation (18%) which comes from research indicator and academic reputation (15%) which comes from the teaching process indicator.

ARWU is also close to THE World University Rankings. The 30% come from the sub-indicator professors with Nobel Prizes and Fields Medals, in a percentage of 20%, and from the academic performance indicator, in a percentage of 10%.

US News and Report Ranking describes Academic reputation indicator as having two sub-indicators, of equal proportions of 12.5%: global and regional reputation in terms of research.

For the Center for World University Ranking, the Academic reputation indicator is only 10% and refers to professors with Nobel Prizes and Fields Medals.

Scientific Excellence

CWUR is the ranking that emphasizes the most the Scientific excellence indicator. The Quality of education (25%) is measured by the number of a university's alumni who have won major academic distinctions relative to the university's size.

Two other rankings that consider this indicator are US News and Report Ranking, in 10%, where the indicator is measured by the scientific outcomes, and ARWU, also in 10%, in which the emphasis is on quality of education. for the students.

Indicators Regarding Students

Two of the 5 rankings analyzed consider indicators regarding students, as follows: THE World University Rankings describes this indicator both in the teaching process (15%), number of awarded PhD's (6%), ratio between staff and students (4.5%), ratio between PhD and bachelor (2.25%), institutional income (2.25%), as well as the international outlook, that consists of three sub-indicators with the same proportion, namely: ratio between local students and foreign students (2.5 %), ratio between employee and foreign student (2.5%), international collaborations (2.5%).

QS World University Rankings also has an indicator that refers to students, namely: ratio between staff and students, in proportion of 20%.

Employer reputation, International reputation and technology transfer

Employer reputation indicator appears in CWUR, in percentage of 25% and is called alumni employment, as well as QS World University Rankings, in percentage of 10%.

International reputation is an indicator considered by QS World University Rankings, which, in turn, is described by two other sub-indicators, of equal proportions (5%): international faculty ratio and international student ratio.

Even if the percentage is very small (2.5%), the only ranking that focuses on technology transfer is THE World University Rankings. This indicator refers to industry income, knowledge transfer, the ability of a university to help industry with innovations, inventions and consultancy has become a core mission of the contemporary global academy.

Figure 7: Percentage of the 7 indicators in the 5 international rankings

Analyzing the data from this paper and considering Figure 7, it can be seen how Bibliometric Indicators occupy almost half (45.4%) of the importance given to these rankings, globally. The other half is described by: the highest percentage identifies the indicators that refer to academic reputation (27.6%), followed by scientific excellence (9%), indicators regarding students (8.5%) and indicators which refer to employer reputation (7%) and the last two, in very small percentages: international reputation (2%) and technology transfer (0.5%).

Conclusions

Based on the analyzed data, the diversity and the evaluating mean of the higher education institution by these international classification and ranking systems was highlighted. Among all proposed indicators, research is the only common point, and each such system designates a significant percentage for this indicator. Based on the scientific collaboration between the analyzed university other university/institutes, it was noted that another common element

that appears in these systems is the one that refers to internationalization. Nevertheless, it is worth mentioning that these rankings (sometimes completely missing) do not follow up the impact of teaching and learning activities, this being considered only indicator of perception.

At the same time, it can be said that most of the classification and ranking systems follow a particular branch of study fields, which is in good agreement with the country institutional evaluation of which the university is part of, as it happens in our country, Romania.

However, it can be said that the universities consider that a good positioning in these rankings entails a better visibility and a higher impact of the international higher education institutions (attracting human and/or financial resources etc.), but it also allow the possibility to identify the university status, development level by comparison with other universities around the world.

Thus, the existence of such large number of classification and ranking systems reflects the different points of view which the academics community has on the manner and purpose that these mechanisms have in achieving university rankings at the international level.

Abstract

This paper provides a background for studying the willingness of ordinary travellers to work as an occasional courier. The aim of the research is to determine the factors influencing the potential willingness of people to become occasional couriers (non-professional couriers) for the delivery of goods using crowdshipping technology. The research results show that the socio-demographic characteristics of non-professional couriers (age, gender, gender, income, travel time) significantly influence the decision to participate in the bulk delivery market. The relationship between these parameters and the maximum weight of the load was determined, which the respondents should translate for the trip. Regression models that characterize the described relationships are presented. The frequency of expected to pay value per delivery was determined for respondents of different genders. The document helps to assess the potential of the courier market (motivation, incentives, potential cost of the service) for companies that are going to use the crowdshipping service.

Keywords: Gender, Crowdshipping, Regression, Questionnaires, Parcel

Introduction

Population growth, and its urbanization, the rapid development of e-commerce and the proliferation of fast delivery options require innovative solutions and business models to ensure the economic, environmental and social transportation of goods (Galkin, Dolia, Davidich, 2017). The development of logistics systems promotes the integration of services and infrastructure exchange, which represents new trends in sustainable transport development today (Galkin et al, 2019). With the advancement of information and communication technologies and the promotion of personal, mobile smart devices, there is a transition to new ways of sharing and sharing (Dril, Galkin, Bibik, 2016). Such an example is crowdsourcing – the process of transferring some functions or operations to a circle of people outside the company (external source) (Halkin, et al, 2019). Crowdsourcing is a modern concept unknown to many people (about 43% have never heard of crowdsourcing) (Rai, Verlinde, Merckx, Macharis, 2017) .Crowdsourcing - involves attracting people who are already traveling from points A to B, take from a package, thus creating new informal logistics networks (Carbone, Rouquet, Roussat, 2015).

Among other issues related to modeling the demand and supply of crowdsourcing, an important aspect is the study of the behavior of random couriers. Similar studies have previously been conducted to determine people's interest in being non-professional couriers. Thus, the maximum willingness to work as crowd-shippers (Galkin et. al, 2018), expected to pay value per delivery (Al-Saudi, Himpel, 2020), travel time tolerance issues (Yan, Lin, Lai, 2013) was studied.

To study the potential readiness of people to be couriers using survey methods (Al-Saudi, Himpel, 2020), interviews (Nyaga, 2017), regression and correlation analysis (Al-Saudi, Himpel, 2020), modeling (Miller et al ., 2017). As variables, the researchers used: age, gender, race, income, and education level, etc.

When using interview and survey methods, frequently asked questions include: willingness (desire) to become a courier (Nyaga, 2017), route (Binetti et al, 2019), the amount of remuneration for work performed (Dupljanin et al, 2019) , the maximum deviation (both in time and distance) that the respondent would take for consent and rejection of the package (Miller et al., 2017).

The results of the research show that the socio-demographic characteristics of non-professional couriers (age, sex, race, income and level of education) significantly influence the decision to participate in the mass transportation market. Thus, about 50% of respondents of different sexes want to be random couriers for a certain amount of money (Gatta et al, 2019). Couriers were interested in supporting the environment (Dai, Jia, Liu, 2020), as well as reducing the impact on public transport in the city (Vakulenko, et al, 2019). the benchmark solutions for the crowdshipping, helping to adjust the business model and market offer of other providers to the needs of different groups of stakeholders (Rześny-Cieplińska, Szmelter-Jarosz, 2019.

However, the potential for mass delivery of goods on crowdshipping technology in various respects is not yet clear. Existing methods never concentrate on the gender and did not assess its influence on willingness to work courier. Moreover, the obtained research has been limited in Determining the maximum weight of the parcel, which agrees to carry a courier of different genders depending on its socio-economic characteristics and order parameters. The issue remains: “Who is ready to work as a crowd partner? Are there any special socio-demographic characteristics associated with potential crowd partners? What motives and factors influence them? “How does gender affect the desire to be a courier? What fee do they expect? ” Studies of willingness to work as an occasional courier in Bratislava have not been conducted before. In particular, in Therefore, the aim of the research is to determine the factors influencing the potential willingness of people to become random couriers (non-professional couriers) for the delivery of goods by crowdshipping technology. Therefore, the specific objectives of this paper are:

1. Determine the impact of gender on the potential readiness to become a courier
2. Determine the maximum weight of the parcel, which agrees to carry a courier of different gender depending on its socio-economic characteristics and order parameters.
3. Determine the expected to pay value per delivery, for couriers of different genders depending on its socio-economic characteristics and order parameters.

Research Method

To obtain the original data was used as a method of data collection - questionnaires. To understand the courier's behavior and motivation, questions were developed:

1. Place of residence (territorial location) _____
2. Place of work, study (territorial location) _____
3. Do you cross the city center (old town) when moving (underline): Yes No.
4. Travel start time (morning / evening) (specify as a fraction) _____
5. End time of the trip (morning / evening) (specify in fractions) _____
6. Do you agree or do you have such an opportunity to transfer the parcel from the area of your residence to the area of work, study, etc. or vice versa? YES or NO
7. For what minimum amount did you agree to transfer the accompanying parcel? (underline the answer): up to 1 euro (fare); 1-2 euros; 2-5 euros; 5-10 euros; more than 10 euros.
8. Your average monthly income per family member, Euro _____:
9. Your age __ 10. Gender __ 11. What is the maximum weight of the parcel you agree to take __ kg.
The survey was attended by 79 respondents living in the city of Bratislava, aged 21 to 30 years.

Measuring the potential willingness of people to change status from regular passengers to partner passengers is of interest for sustainable transport and mobility. The simulation method involves the quantitative assessment of willingness to work (willingness to work) as non-professional couriers in hypothetical scenarios with different parameters (in different delivery conditions).

Results

Characteristics of the obtained personal data are given in table. 1.

Table 1: Characteristics of the original data

Experiment number	Origin	Destination	Do you pass the Old Town on your trip		Overall travel time in the morning, min		Overall travel time in the evening, min		Years	Gender	Monthly income, Euro	Travel time, min	Expected to pay value per delivery, Euro	The maximum weight of the parcel, kg
			Yes	No	Start	End	Start	End						
1	Petržalka	Bratislava	+	-	6:15	6:30	16:00	17:00	24	Muž	900	15	1	2
2	Staré Mesto	Staré Mesto	+	-	9:00	9:10	15:00	15:10	21	Muž	750	5	2	3
3	Petržalka	Nové Mesto	+	-	6:30	7:00	15:00	15:30	26	Žena	400	30	4	4
…	…	…	…	…	…	…	…	…	…	…	…	…	…	
40	Stare Mesto	Stare Mesto	-	+	7:45	8:00	15:00	15:15	22	Muž	750	45	3	3

The results of the survey of respondents on the performance of courier functions of crowdshipping is: 51% of respondents agree to consider such a possibility and 49% do not consider such a possibility. Further processing of the results was focused on 40 respondents: 22 men and 18 women, who answered that they potentially agreed to become couriers.

The maximum weight of a parcel that a courier of different genders agrees to carry was determined depending on its socio-economic characteristics and the characteristics of the orders. Under the characteristics of orders, the delivery route, its cost, and time frame were considered. The results of statistical processing of the results for the two types of gender are given in table. 2 (male) and table 3 (female). Regression models are developed.

The model maximum weight of the parcel that respondents agree to translate was obtained according to processing survey data via Statgraphics X64. The degree of influence of variables factors on maximal weight of parcel ware analysed. The regression coefficients were calculated using the least-squares method.

Table 2: Characteristics of the models for male (*Source:* Authors' own research)

Attributes	Value			
Variable	Monthly income, Euro (*I*)	Expected to pay value per delivery, Euro (*V*)	Age, years (*E*)	Overall travel time, min (*T*)
Model	$Q_{male} = (\frac{978,13}{I})^2$	$Q_{male} = (0,695\sqrt{V})^2$	$Q_{male} = (0,063E)^2$	$Q_{male} = \frac{1}{0,016T}$

Mean absolute error	0,58	0,45	0,77	0,45
Standard Error of Est.	0,77	0,58	0,86	0,56

The obtained results allowed to draw a conclusion about the admissibility of using the obtained model of maximum parcel weight for the design of the delivery process of the occasional courier. The analysis of factors that affect the maximum weight of a parcel that a random courier agrees to transport is shown in Fig. 1.

A) The maximum weight of the parcel from the monthly income of the respondent

Male

Female

B) The maximum weight of the parcel that Crowd Partners agree to carry from Expected to pay value per delivery

Male

Female

C) Age

Male

Female

D) The maximum weight of the parcel on overall travel time of the respondent

Male Female

Fig. 1: Patterns of the maximum weight of the parcel affects parameters

Analysing fig. 1 a it can be concluded that there is a relationship between monthly income and the maximum weight of the parcel, which respondents agree to transfer. Thus, with a decrease in monthly income, the maximum weight of the parcel decreases, and vice versa for couriers of different genders. The increase in monthly income for men more moderately (gradually) reduces the maximum weight of the parcel, in contrast to women where the increase in income reduces it more straightforwardly.

Analysing fig. 1 b it can be concluded that there is a relationship between expected to pay value per delivery and the maximum weight of the parcel that respondents agree to transfer. So from expected to pay value per delivery increases the maximum weight of the parcel and vice versa for both genders. The increase in expected to pay value per delivery in men more moderately (gradually) increases the maximum weight of the parcel, in contrast to women where the increase in expected to pay value per delivery increases the willingness to take more weight of the parcel.

Analysing fig. 1 c it can be concluded that there is a relationship between age and the maximum weight of the parcel, which respondents agree to transfer. So with age the maximum weight of a parcel increases and vice versa. According to the results of the assessment of the dependence of the maximum weight of the parcel on the age of the possible courier, it can be concluded that the younger the executor, the larger the volume of the parcel he agrees to deliver. According to the graphical display of answers, it can be concluded that with the age of potential couriers decreases their potential capacity (capacity).

Analysing fig. 1 d, it can be concluded that there is a relationship between the total time of movement of the respondent and the maximum weight of the parcel that the respondents agree to transfer. According to the graphical display of answers, we can conclude that with increasing travel time decreases the maximum weight of the parcel and vice versa.

Also on the official Slovak website https://www.stavebnyportal.sk/ there are rules of procedure regarding the maximum allowable weight for the transportation of men and women. So for men under favourable conditions 15 kg, and unfavourable – 10 kg. For women 10 kg and 5 kg respectively. The data obtained indicate that the range of change in the weight of the parcel for men is from 1 to 10 kg, for women from 0.5 to 7 kg.

For couriers of different genders, the expected to pay value per delivery was determined, fig. 2.

Fig. 5: Distribution of the cost at which respondents agree to deliver the parcel to:

a) Male b) Female

Accordingly, Fig. 5 (a), 22.73% of male respondents agree to provide the service in the range of 1 to 2 euros; 27.27% from 3 to 4 euros; and the same from 5 to 6 euros; 18.18% from 7 to 8 euros; and 4.55% agree to provide a service of at least 9 euros. Accordingly, Fig. 7 (b), 16.67% of women respondents agree to provide the service in the range of 1 to 2 euros; 27.78% for 3 or 4 euros; 33.33% of respondents from 5 to 6 euros; 11.11% from 7 to 8 euros; and the same percentage agree to provide a service of at least 9 euros.

Discussion and Conclusions

A preliminary study of willingness to work as an occasional courier was conducted in Bratislava for the first time. A survey was conducted to determine the desire to work as a random courier using crowdshipping technology. As a result, respondents of different genders were interested in performing the functions of a courier and the main factors influencing the choice.

The data processing results showed that the occasional courier's gender plays an important role in making willingness to work as an occasional courier. Of the 81 respondents wishing to work, most were interested in earning money. The results of the survey showed that 51% of respondents would be willing to work as an occasional courier for a certain amount of money.

In addition, it was found that expectations to pay mass shippers are reasonable and somewhat consistent with the literature on the value of time (Miller et al., 2017). Researchers point to a different range of variation in expected courier payment for a delivery service from $ 9.2 to $ 19 per hour (Miller et al., 2017; Le, Ukkusuri, 2019). The research was conducted in the United States, where the standard of living is higher than in Slovakia. Analysis of the logistics services market (Galkin et. Al, 2018) indicates that the average fee for courier delivery in Bratislava is from 4 euros per 1 kg. The detected range of expected payment costs will allow shipping companies to form a compensation scheme that matches the expectations of random couriers. This will potentially increase the recruitment and retention of crowd partners in the system.

The obtained dependences partially coincide with the previously known ones (Le, Ukkusuri, 2019; Gatta et al, 2018) where "age" is not a significant parameter. This is, in part, a correct statement when considering male couriers. If we consider the interest of women in the desire to work as couriers, then for them the age factor is

significant. It is also possible that the results obtained may be related to the traditional foundations of society and the individual behaviour of the people of Bratislava (Galkin et al, 2019). When considering a wider range of age parameters, it will be possible to refine the results.

This document helps to assess the potential of the Bratislava market for the use of the crowdshipping service, as well as for freight companies to better understand how to motivate staff and determine the potential cost of the service. This work provides a basis for analysing the application and effectiveness of crowdsourcing by studying the propensity of ordinary travellers to willingness to work as an occasional courier in Bratislava. Further research is still needed to validate the results in different contexts and to expand knowledge in this area.

Résumé

L'évolution que connait, actuellement le secteur bancaire au Maroc, accentuée par la concurrence acharnée entre les banques, la multiplication des offres et le développement technologique notamment au niveau de la stratégie multicanal, sont autant d'éléments qui accentuent la volatilité des clients et posent la problématique de la rétention des clients «rentables ». C'est dans ce contexte que s'inscrit notre recherche, elle s'intègre dans le cadre des relations B to B et plus particulièrement aux relations banques - PME.
Eu égard à la spécificité de la relation client fournisseur dans le secteur bancaire et à l'importance du maintien des relations sur le long terme, nous avons opté dans notre recherche pour une étude qualitative exploratoire, basée sur l'observation, le recueil et l'interprétation de données qualitatives.
Cette exploration, nous a permis de dégager les variables principales qui conditionnent la qualité de la relation entre les banques et les PME, et le maintien des relations collaboratives performantes sur le long terme dans le contexte marocain.

Mots clés : Qualité De La Relation Client-Fournisseur, Relation Banque –PME, Etude Exploratoire.

Abstract

The evolution which the banking sector is currently undergoing in Morocco, accentuated by the fierce competition between the banks, the multiplication of offers and technological development, especially at the level of the multi-channel strategy, are all elements which accentuate the volatility of customers and pose the problem of the retention of "profitable" customers. It is in this context that our research fits into the framework of B to B relations and more particularly bank - SME relations.
Given the specific nature of the client-supplier relationship in the banking sector and the importance of maintaining relationships over the long term, we opted in our research for an exploratory qualitative study, based on the observation, collection and interpretation of qualitative data.
This exploration allowed us to identify the main variables that condition the quality of the relationship between banks and SMEs, and the maintenance of successful collaborative relationships over the long term in the Moroccan context.

Keywords: Inter-Organizational Relationship Quality, Banking-SME Relationship, Exploratory Study.

Introduction

Au cours des dernières décennies, les relations d'échange client-fournisseur sont passées d'une vision transactionnelle basée sur un transfert de propriété pure et simple, à une perspective relationnelle privilégiant le développement de la relation et intégrant une dimension sociale (Dwyer & al, 1987; Day, 2000).

L'approche relationnelle envisage les échanges sur le long terme et la relation dans sa globalité, et met en évidence les interactions entre les acteurs. Elle se distingue par rapport à l'approche transactionnelle par l'intégration d'éléments sociaux et non économiques qui conditionnent la réalisation de l'échange et qui permettent la réduction de l'incertitude et la maîtrise des coûts de transactions.

Dans cette perspective, les entreprises recherchent l'efficience à travers l'optimisation d'une série d'échange étalée sur le long terme, et la construction d'une relation forte et stable (Ramkumar & Savanan 2007) ainsi que la réalisation des bénéfices mutuels grâce à des relations gagnant/gagnant (Ivens & Mayrhofer, 2003).

C'est dans ce cadre que le concept de la qualité relationnelle a émergé pour devenir un construit central du marketing relationnel.

Dans cet article, nous allons dresser, en premier lieu, une revue de littérature sur le concept de la qualité relationnelle et sur les principaux antécédents et conséquences qui la déterminent.

Puis, en second lieu, nous présenterons les résultats de l'étude exploratoire effectuée auprès de dirigeants de PME marocaines, pour déceler les principales variables liées à la qualité relationnelle dans le contexte bancaire marocain et affiner notre champ de recherche.

La Qualité De La Relation

Objet Et Définition

La qualité de la relation est un construit central du marketing relationnel, qui prend de plus en plus de l'ampleur, que ce soit au niveau académique ou managérial (Jiang & al., 2016). L'intérêt pour l'étude de la qualité relationnelle s'est manifesté suite à la prolifération des travaux sur l'approche relationnelle à partir des années 80 (Dwyer et al., 1987 ; Crosby et al., 1990, Vieira, 2008).

Les études ont démontré que la qualité relationnelle rassure les partenaires sur les interactions et performances futures et les encourage à faire évoluer la relation d'échange à un niveau supérieur (Crosby et al., 1990 ; Rajaobelina, 2009 ; Lahiri & Kedia, 2011 ; Ghzaiel & Akrout, 2012). Elle reflète, ainsi, le résultat des efforts du marketing relationnel déployés par l'entreprise (Garbarino & johnson, 1999 ; Lahiri & Kedia, 2011 ; Jiang et al., 2016) ainsi que la force et la réussite des relations d'échange.

Au-delà des performances financières escomptées sur le long terme, la qualité relationnelle crée pour l'entreprise un avantage compétitif intangible et difficilement imitable par la concurrence, qui lui permet de différencier son offre par rapport à celle du marché et qui l'immunise contre les aléas de l'environnement (Rajaobelina, 2009).

Toutefois, malgré l'accord général sur l'importance du concept, il semble ne pas y avoir de consensus entre les chercheurs sur une définition exacte du concept de la qualité relationnelle ou sur le nombre et la nature des variables qui la déterminent et la composent (Dorsch et al., 1998 ; Garbarino & Johnson, 1999 ; Huntley, 2006).

En effet, le sujet de la qualité relationnelle a été étudié et opérationnalisé dans des secteurs variés. Sa conceptualisation diffère selon le contexte de l'étude, l'angle d'analyse et la perception du chercheur (Crosby et al., (1990), Kumar et al., (1995) ; DeWulf et al., (2001) ; Huntley, 2006 ; Vieira, 2008 ; Athanasopoulou, 2009 ; Jiang et al., (2016).

Certains auteurs envisagent la qualité relationnelle comme une évaluation globale de la force de la relation (Smith, 1998 ; Garbarino & johnson, 1999 ; DeWulf et al., 2001 ; Woo & Ennew, 2004 ; Palmatier et al., 2006, Vesel & Zabkar, 2010).

Alors que d'autres comme Boles et al.(1997), la définissent comme une évaluation des liens personnels et professionnels qui résultent des différentes interactions entre client et fournisseur.

Hennig-Thurau & Klee (1997) et Huntley (2006), par contre, suggèrent que la qualité de la relation reflète le degré de satisfaction global du partenariat.

Eu égard à ces éléments et dans le but de faire avancer les recherches, Woo & Ennew (2004) suggèrent qu'il serait judicieux d'accepter une conceptualisation générale et de se concentrer sur l'identification et l'étude des composantes de la qualité relationnelle.
Ainsi et de manière générale, la qualité relationnelle est considérée comme un construit d'ordre supérieur, composé d'un minimum de deux dimensions, qui reflète la nature de la relation entre les partenaires (Kumar et al., 1995 ; Dewulf et al., 2001 ; Hennig-Thurau 2002 ; Roberts et al., 2003) .

Les dimensions de la qualité relationnelle

Le concept de la qualité relationnelle fût introduit la première fois, respectivement, par Gummesson (1997) et Dwyer et al. (1987), puis opérationnalisée par la suite grâce à l'étude de Crosby et al. (1990) dans le secteur des assurances.

Crosby et al., (1990), stipulent que la qualité est un construit d'ordre supérieur composé d'au moins deux dimensions, qui sont la confiance et la satisfaction. La confiance se manifeste dans le fait que le client s'attend à un comportement bien défini lors des échanges futurs, de telles manières que ses intérêts seront préservés ou au moins pris en considération. Alors que la satisfaction est atteinte suite à l'évaluation des interactions et expériences passées.

L'étude de Croby et al., (1990) a servi de support à un nombre important de recherches, appliquées à des contextes diversifiés (services, industrie, distribution, B to B et B to C). Certains de ces travaux ont élargi le champ de recherche pour inclure de nouvelles variables, autres que la confiance et la satisfaction.

En effet, les recherches ultérieures ont révélé de nouvelles dimensions comme l'engagement (Huntley, 2006), l'éthique (Lagace et al., 1991), la communication (Anderson & Narus, 1990), l'opportunisme (Dorsch et al., 1998), l'équité (Kumar et al., 1995), les objectifs communs (Wilson, 1995), la coopération (Leonidou, 2006), l'adaptation (Woo & Ennew, 2004), l'atmosphère (Woo & Ennew, 2004), le pouvoir (Naude & Buttle, 2000), le partage d'information (Lahiri & Kedia, 2011), l'orientation à long terme (Jiang et al., 2016)...etc.

A l'instar de la plus part des recherches et étant donné que notre objectif est l'exploration des antécédents et conséquences de la qualité relationnelle et non les dimensions, nous avons choisi de considérer la qualité de la relation comme un construit composé de deux variables, à savoir la satisfaction et la confiance.

Les antécédents et conséquences de la qualité relationnelle

La qualité relationnelle a fait l'objet de plusieurs travaux de recherche, visant à mieux cerner ses différents déterminants et conséquences (Parsons, 2002 ; Holmlund, 2008 ; Athanasopoulou, 2009). A titre d'exemple, il est possible de citer la recherche méta-analyse effectuée par Palmatier et al., (2006), et qui ont réparti les antécédents et conséquences de la QR en trois catégories, décrites comme suit :

- Les antécédents centrés sur le client incluant les bénéfices de la relation et la dépendance vis-à-vis du vendeur.
- Les antécédents centrés sur le vendeur, qui sont l'investissement dans la relation et l'expertise.
- Les antécédents dyadiques, à savoir : la communication, la similarité, la durée de la relation, la fréquence d'interaction et le conflit.

En ce qui concerne les conséquences, elles ont été répertoriées de la manière suivante :

- Les résultats centrés sur le client composés de la fidélité, du bouche à oreille et de la continuité de la relation.
- Les résultats centrés sur le vendeur comme la performance objective du vendeur.
- Les résultats dyadiques : la coopération.

Selon Leonidou et al., (2014) et d'après une étude sur 76 cas empiriques, les déterminants de la qualité relationnelle sont l'absence d'opportunisme, la gestion du conflit, la communication, la distance ainsi que l'adaptation. Tandis que la principale résultante en serait la performance (relationnelle et financière).

Dans la même optique, Izogo (2016) suggère que l'orientation-client, l'expertise et le partage d'information sont les principaux antécédents de la qualité relationnelle et génèrent le ré-achat et la bouche à oreille positif.

Jiang et al., (2016) stipulent que la qualité relationnelle est composée de l'intensité de la communication, l'orientation à long terme et de la satisfaction, qu'elle soit économique ou sociale.
De manière générale, la revue de littérature que nous avons effectuée, nous a permis de constater les éléments suivants :

Les antécédents de la qualité relationnelle peuvent être regroupés en quatre catégories principales (Athanasopoulou, 2009 ; Ghzaiel & Akrout, 2012):

- **Les caractéristiques et les comportements des parties** comme l'expertise, l'éthique, la similarité, l'empathie, l'orientation-client, l'orientation relationnelle.
- **Les caractéristiques de la relation**, à savoir la durée de la relation, les fréquences d'interactions, la gestion du conflit, le comportement opportuniste, la coopération, le pouvoir/ dépendance, l'adaptation, la personnalisation.
- **Les caractéristiques de l'offre** qui comprennent la qualité de service, le service après-vente et la performance du produit.
- Et finalement, une quatrième partie relative **aux attributs de l'environnement**.

Il en est de même pour les conséquences, qui varient selon le secteur d'activité, et peuvent être de nature économique comme la performance financière, ou de nature non économique ou relationnelle comme par exemple la continuité de la relation et la fidélité.

Etant donné la variété et le nombre des variables recensées dans la littérature, il apparait opportun de procéder à une étude exploratoire afin d'en faire ressortir les déterminants et conséquences principaux qui conditionnement la qualité relationnelle dans le secteur bancaire marocain.

Méthodologie de Recherche

Eu égard à la spécificité de la relation client-banque et à l'importance du maintien des relations sur le long terme, nous avons choisi dans notre recherche, de procéder à une étude qualitative exploratoire, qui nous permettrait de faire ressortir les principaux déterminants et conséquences de la qualité de la relation Banque-PME.

Ainsi, dans le cadre de notre étude, nous avons opté pour un entretien semi directif basé sur un guide d'entretien avec des questions ouvertes préalablement définies, dont les thèmes ont été inspirés de la revue de littérature.

Ainsi, notre guide se compose de trois rubriques principales et se présente comme suit :

Une rubrique introductive, pour présenter l'objet de la recherche et le cadre de l'étude aux personnes interviewées, en leur assurant que leurs identités resteraient anonymes et en leur précisant la possibilité de mettre fin à l'entretien à tout moment.

Suivie d'une rubrique principale traitant les axes suivants :

- La perception de la banque de manière générale.
- La relation avec la banque principale du répondant (ancienneté, fréquence de contact, appréciation globale, relation avec le personnel, expériences positives et négatives, services utilisés, contraintes, problèmes rencontrés, attentes…etc).
- La perception d'une relation de qualité, les facteurs-clé de réussite la relation banque-PME et les conséquences qui en résultent.

La dernière partie du guide d'entretien est relative à l'identification de l'entreprise et aux caractéristiques socio-démographiques des répondants.

Pour réussir nos entretiens et obtenir le maximum d'information de la part des répondants, nous avons respecté les recommandations suggérées par Hlady Rispal (2002 :

- Laisser parler la personne le plus librement possible en évitant de poser des questions.
- Laisser l'interlocuteur utiliser des temps morts pour réfléchir.

- Relancer le répondant pour détailler les points déjà évoqués ou pour mettre fin à des temps prolongés.
- Adopter une attitude d'écoute totale en évitant de fournir des informations, de prendre des décisions, d'évaluer les idées développées ou encore d'interpréter de manière directe les propos évoqués.

L'échantillon

Comme il a été cité précédemment, notre recherche s'articule autour de l'étude de la relation client-fournisseur, en l'occurrence dans notre cas, l'étude des relations Banque-PME/TPE.

Pour pouvoir effectuer notre enquête, cerner notre échantillon et procéder à la collecte des données, nous avons utilisé la technique des informateurs-clé.

La collecte par le biais des informateurs-clé, est une technique qui consiste à identifier, au sein de l'entreprise, une personne qui possède les informations requises. L'interlocuteur principal doit être représentatif du groupe et doit avoir une expertise particulière, ainsi qu'une expérience dans le domaine étudié (Marshall, 1996). Cette technique, permet, ainsi, de collecter des données en interviewant un nombre de répondants pré-sélectionnés, qui sont choisis selon le statut, l'expertise, la connaissance ou l'accessibilité (Phillips,1981).

Ainsi et pour les besoins de notre enquête, et afin d'assurer la fiabilité et la qualité des données à collecter, les répondants n'ont pas été choisis de manière aléatoire, mais selon des critères bien définis. Pour cela, notre étude a été destinée à la personne (au sein de l'entreprise), qui se charge de la gestion des opérations bancaires et de suivi de la relation bancaire dans sa globalité. Elle doit justifier d'une ancienneté dans le poste et avoir des contacts réguliers avec la banque (tableau 5).

Le statut de la personne clé diffère d'une entreprise clé. Selon la taille et l'organisation de chaque entité, la gestion de la relation bancaire peut être assurée par le gérant, ou déléguée, éventuellement, à l'un de ses collaborateurs, qui se charge de l'aspect financier de l'entreprise (responsable financier, trésorier, comptable, responsable administratif…etc).

Notre tâche consistait à identifier et entrer en contact avec cette personne clé, pour éviter d'altérer ou de biaiser nos résultats de recherche. De même, le répondant a été invité à donner une opinion sincère, en fonction de sa propre expérience.

Au cours de cette phase exploratoire, nous avons opté pour un échantillon de convenance composé de six hommes et quatre femmes, opérant dans domaines variés dans la ville de Tanger et ayant une ancienneté bancaire minimale de trois ans (tableau 5).

De manière générale, et comme il est stipulé dans la littérature académique traitant les études qualitatives, la taille de l'échantillon doit répondre à un objectif de diversification des cas et non de représentativité statistique. Dans ce cas, le critère à respecter n'est pas le nombre d'entretien mais le principe de saturation sémantique.

Dans cette optique, nous avons veillé à varier notre échantillon en le composant de femmes et d'hommes, ayant des âges, des expériences et des profils différents. Cette variété vise à élargir et enrichir le contenu de notre étude (tableau 5).

Pour le critère de saturation, il est recommandé d'arrêter la collecte des données quand les derniers entretiens n'apportent plus d'informations pertinentes ou complémentaires (Thietart, 2007). A partir du huitième questionnaire, nous avons remarqué que les informations recueillies s'apparentent et tendent vers une même perception et réflexion.

Résultats de la recherche

Après avoir abordé le cadre théorique et méthodologique de notre étude, nous allons nous intéresser dans la partie suivante, aux résultats obtenus de l'enquête exploratoire.

La revue de littérature que nous avons effectuée (tableau 6), nous a permis de recenser un nombre important de variables liées à la qualité relationnelle, dont le nombre et la nature dépendent fortement du secteur étudié et de la perception du chercheur.

Ainsi, l'étude exploratoire que nous avons entreprise, nous a révélé cinq déterminants principaux qui influent directement sur la qualité de la relation banque-PME à savoir, l'orientation-client, l'expertise du personnel, la communication, les liens sociaux et la résolution du conflit. Ainsi que deux conséquences majeures qui sont la continuité de la relation et le bouche à oreille (tableaux 1, 2, 3 et 4, traitement effectué par le logiciel Nvivo 12).

Les antécédents de la qualité relationnelle

- ***L'orientation-client***

L'orientation –client (OC) est la variable qui a été citée le plus par la totalité des participants. Elle fait référence à la capacité et la prédisposition du prestataire de service à vouloir aider ses clients et adopter une attitude qui vise à comprendre et satisfaire leurs besoins, en œuvrant dans la réalisation des bénéfice conjoints, et en évitant les comportements opportunistes (Vieira, 2009).

L'OC est définie par Saxe & Weitz (1982) comme la concrétisation du concept du marketing au niveau individuel, que ce soit du côté du consommateur ou du vendeur. En d'autres termes c'est l'orientation de tous les acteurs d'une entreprise (managers, employés et actionnaires) vers la mise en place d'objectifs communs avec ses clients et la réalisation de bénéfices mutuels sur le long terme, malgré l'attrait du gain sur le court terme (Wray, 1994 ; Vieira, 2009 ; Al-alak, 2014).

Lors des entretiens avec les clients, nous avons remarqué que l'ensemble des interviewés ont souligné le rôle important de la banque, en tant que partenaire et non comme une entité dont la finalité se limite à l'intermédiation financière. En effet et selon les clients :

« La banque doit agir avec ses client comme un partenaire et non comme un exécutant financier ».

« La banque devrait prendre le devant et proposer un accompagnement financier et des offres qui s'adaptent à ses clients, au lieu, de se focaliser sur la ventes de produits standards et inadaptés ».

« Il faut que les banques proposent des offres adaptées aux caractéristiques des PME, formulées dans le sens du partenariat ».

De même, la revue de la littérature a révélé qu'il existe une forte relation entre l'OC et la QR ainsi que les variables qui la composent (Parsons, 2002 ; Kim, 2006). Elle a un effet positif sur la satisfaction (Brady et al., 2001) ainsi que sur la confiance (Kim, 2006).

- ***L'expertise :***

L'expertise est défini comme la perception qu'une personne possède le savoir et la qualification requis dans un domaine spécifique (Shamdasani, 2000 ; Rajaobelina, 2009). Il désigne, ainsi, les compétences techniques et les connaissances mais aussi, la capacité de transférer son savoir au client lors d'un échange donné (Wray, 1994 ; Palmer & Bejou, 1994 ; Boles et al., 2000).

L'étude de Crosby et al., 1990 a révélé le rôle majeur de l'expertise du vendeur dans l'appréciation de la qualité relationnelle et sur l'anticipation des ventes futures. L'expertise et les connaissances du vendeur peuvent réduire l'incertitude du client lors des transactions (Rajaobelina, 2009).

« Quand on s'adresse à un banquier, on s'attend à avoir des informations pertinentes et fiables. Il doit être à la hauteur des attentes des clients ».

A travers les études qui se sont succédées à celle de Crosby et al., 1990**,** il a été maintes fois prouvés que la compétence des employés influent directement sur le degré de satisfaction et de confiance du client (Izogo, 2016), et conditionne les échanges futurs (Lagace, (1991). Les clients ont, donc, tendance à nouer et à construire des relations fortes avec les partenaires jugés compétents (Izogo, 2016).

« Un banquier compétent inspire confiance : je ne peux pas confier mon argent et mon entreprise à une personne qui n'est pas crédible ».

L'expertise est, aussi, essentiel pour expliquer le produit ou le service au client et le convaincre de son utilité (Dampérat & Jolibert, 2009).

« Les qualités techniques liées à la fonction sont tout aussi importantes que les qualités humaines dans l'offre de service ».

- ***La communication***

Dans la littérature marketing, la communication est considérée dans les relations inter-organisationnelles (RIO) comme l'activité de base dans les interactions et échanges entre clients et fournisseurs (Vieira, 2014).

Anderson & Narus (1990) ont définit la communication comme un partage formel et informel d'informations significatives et ponctuelles entre les entreprises. C'est un aspect important de la relation qui reflète les dispositions bilatérales de parties, à fournir des informations utiles et qui leur permettent de coordonner leurs efforts pour l'atteinte des objectifs communs (Jiang et al., 2016).

La communication renvoie, donc, au dialogue interactif qui se développe tout au long des différents stades de la relation (Ndubisi, 2006). Elle englobe, aussi bien, les échanges de données formelles, verbalisées et structurées que les informations personnalisées et non planifiées qui se réalisent tout au long des interactions.

« …Il y' a aussi, la communication, l'échange d'information et la prise en charge dans les meilleurs délais en cas de réclamation. Des fois, même si la réponse risque de tarder, mais un simple feed back de la banque confirmant la prise en charge de notre demande peut avoir un impact positif sur la qualité de la relation et reflète la considération de la banque pour ses clients ».

Dans le secteur bancaire, la qualité de la communication est décisive pour la réussite des relations avec les clients professionnels.

D'ailleurs l'un des répondants à mentionner la « communication » comme l'un des éléments les plus importants dans la réussite de la relation Banque-PME : *« La communication : il y'a certaines banques qui ne communiquent pas l'information avec leurs clients et qui capitalisent sur le savoir, pour maintenir un pouvoir sur les clients et assurer leur dépendance »*

La communication permet de construire une forte relation et permet la résolution rapide des éventuels conflits, l'atteinte des objectifs et la création de nouvelles opportunités d'échange.

- ***Les liens sociaux :***

Tout au long de l'évolution de la relation d'échange et en fonction de la nature et la qualité des interactions, des amitiés se créent entre le personnel en contact et les clients (Wilson, 1995 ; Smith, 1998). Il s'agit de connexion, de sentiment et d'attachement personnel qui se nouent entre les acteurs (Paulssen, 2014), et qui reflètent leur degré d'amitié et d'appréciation mutuelle (Wilson, 1995).

Les liens personnels et relationnels se forgent à l'issue des processus de socialisation, d'adaptation et de personnalisation entre les partenaires de l'échange et dépassent la stricte relation d'échange de biens ou de service et (Holmlund & Kock, 1996).

En effet, 70% des personnes interviewées ont suggéré que les liens sociaux se tissent et se développent avec le temps et tout au long de la relation avec la banque.

« …Avec le temps et par la force des choses, la relation a dépassé le cadre professionnel pour intégrer des relations personnelles d'amitié ».

« Quand vous êtes en contact permanent avec une personne, forcément, il y' a des affinités qui se créent. Des fois, on se rencontre à l'extérieur pour prendre un café et discuter de chose et d'autres, qui n'ont rien à voir avec le travail ».

Dans la même optique, les liens sociaux influent sur les émotions et les sentiments associés à l'expérience du service (Chiu et al., 2005) et rend les clients plus enclin à l'écoute et à l'engagement sur le long terme.

« …Avec certaines personnes, vu leur gentillesse et leur traitements personnalisés, Ça nous arrive de discuter des choses personnelles avant d'entamer celles professionnelles : on prend mutuellement des nouvelles sur la famille. On se félicite pour les fêtes…etc ».

« A force des échanges et des contacts dans le temps, la relation avec le personnel a depuis longtemps dépassé le cadre professionnel pour intégrer des relations personnelles et amicales, sans arrières pensées et sans qu'il y'ait un intérêt commercial derrière ce comportement ».

- ***La résolution du conflit :***

Le conflit est inévitable dans les relations inter-organisationnelles, et peut être dû à plusieurs raisons, allant des contraintes économiques ou politiques, aux facteurs culturels et comportements des acteurs.

Le conflit est généralement défini comme un désaccord entre les partenaires de l'échange (Dwyer et al.1987 ; Anderson & Narus, 1990). Il fait référence, aussi, à tout comportement qui pourrait nuire au développement et la réussite de l'une des parties.
S'il n'est pas bien pris en charge, le conflit peut avoir un impact destructif sur la relation d'échange. En effet, il peut mettre en péril le climat de confiance déjà instauré entre les partenaires, et décourager les intentions d'investissement futures.

D'ailleurs, l'un des répondants l'a clairement mentionné lors de l'entretien : *« En cas d'incident grave, je m'attends à ce que mon banquier me trouve rapidement une solution efficace. Avant, quand il y'avait un problème, je devais moi-même intervenir auprès des responsables, pour faire accélérer les choses. Et j'avoue que je n'appréciais pas beaucoup cela. D'ailleurs, si cela avait continué, j'aurais envisagé de changer de banque ».*

De même, les entretiens effectués, nous ont révélé que les clients sont plus disposés à maintenir la relation avec leur banque actuelle, si leurs réclamations sont traitées à temps et de manière efficace.

« …Avec le temps, quand le banquier a une bonne connaissance de ses clients, les incidents ou les réclamations potentielles sont gérées de manière proactive, c'est-à-dire qu'il fait en sorte d'éviter les problèmes avant qu'ils ne se réalisent ».

« La disponibilité en cas de problème et la rapidité de prise en charge. Il est important d'avoir un interlocuteur à la banque qui soit joignable et qui prend en considération vos demandes et qui vous apporte des solutions efficaces et rapides ».

Les conséquences de la qualité relationnelle :

Les conséquences de la qualité relationnelle varient selon le contexte de l'étude, la perspective d'analyse du chercheur et de l'objectif de la recherche escompté. Dans notre cas, et à l'issu de notre étude exploratoire, nous avons pu constater que la continuité de la relation et le bouche à oreille sont les conséquences principales de la qualité de la relation Banque-PME.

- ***La continuité de la relation***

De manière générale, la continuité de la relation désigne la volonté des parties de prolonger l'accord de coopération sur une période donnée (Biong & Selnes, 1995 ; Kim, 2002). Elle reflète, ainsi, l'intention des parties à maintenir la relation dans le futur (Verma et al, 2015).

L'orientation sur le long terme reflète l'engagement des parties dans une relation stable orientée vers le futur et vers la réalisation de bénéfices conjoints sur le long terme (Ganesan, 1994). Dans cette optique, les entreprises sacrifient les gains financiers ponctuels au profit de partenariat et d'échange étalés dans le temps (Anderson & Weitz, 1992).

« Je suis client depuis 4 ans déjà. Je pense maintenir la relation avec cette banque tant qu'il n'y'a pas d'incident majeur qui nuit à l'intérêt de ma société ».

Les travaux de recherche ont démontré que la continuité de la relation est fortement conditionnée par le niveau de confiance qui règne entre les parties ainsi que le niveau de satisfaction résultant de l'historique des échanges (Selnes, 1998).

« Il est important qu'il y'ait un contact régulier entre la banque et ses clients, ça facilite l'échange et crée un climat plus favorable au développement des relations sur le long terme ».

Dans les relations bancaires, la continuité de la relation est considérée comme un indicateur du niveau de satisfaction des clients par rapport aux prestations servies. Elle garantit ainsi de revenus stables générés par des clients fidèles malgré l'attraction des offres de la concurrence.

« Le personnel est très sympathique avec moi et fait de son mieux. Je suis satisfait des services fournis et je n'ai pas de raison pour changer de banque »

« De manière générale, je pense que les banques offrent, pratiquement, les mêmes, produits et services, ce qui fait la différence pour moi, c'est la qualité des prestations offertes par le personnel. Si je suis toujours client de la banque X, c'est par égard au personnel, avec lequel j'ai développé des liens d'amitiés et de confiance tout au long de mes années d'activités ».

- . ***Le bouche à oreille (BAO)***

En marketing le bouche à oreille (BAO) est défini comme toute communication informelle d'une entreprise donnée, avec d'autres clients sur les caractéristiques d'un produit, d'un service ou d'un employé d'une entreprise donnée (Anderson, 1998). Il peut inclure les avis, les commentaires positifs ou négatifs, les attitudes ou les réactions vis-à-vis du produit, du personnel ou d'une marque donnée (Jansen & Zhang, 2009).

Les études ont démontré que le BAO à une forte influence sur l'image de marque de l'entreprise, beaucoup plus que les actions marketing qu'elle déploie. Ainsi, les clients ferait confiance, plus facilement, aux opinions de leurs proches ayant déjà expérimenté le produit ou service (Jansen & Zhang, 2009).

Ceci a d'ailleurs, été confirmé par l'un des répondants : *« Des fois, c'est le chargé d'affaire qui me demande de lui prescrire des connaissances personnelles. Ça ne me dérange de le recommander car je le connais, je lui fais confiance et je sais qu'il ne va pas me décevoir avec mes amis ».*

Le BAO permet, ainsi, de réduire l'incertitude liée à la première utilisation d'un produit, particulièrement lors des achats à risque (Kumar et al., 2003). Le bouche à oreille influence le processus de décision et le comportement d'achat du consommateur (Litifi & Najjar, 2015. Le client devient, alors, un partenaire actif et une source fiable d'information au service de l'entreprise (Hennig-Thurau et al., 2002**).**

« Je recommande toujours cet établissement à mes connaissances, vu la compétence et l'amabilité du personnel, le traitement personnalisé et la simplification des procédures. D'ailleurs, je leur ai apporté pas mal de clients ».

Discussion des résultats

A travers la revue de littérature effectuée sur le thème de la qualité relationnelle, nous avons pu constater un nombre important de variables qui impactent la qualité de la relation entre les clients et fournisseurs et qui sont tributaires du contexte de l'étude.

L'étude exploratoire réalisée nous a permis de ressortir cinq principaux déterminants adaptés aux particularités du secteur bancaire et qui sont l'orientation-client, l'expertise du personnel, la communication, les liens sociaux et la gestion du conflit.

De même, il a été constaté que la continuité de la relation et le bouche à oreille en sont les principales conséquences.

Au niveau managérial, cette étude permettrait aux gestionnaires de :

- D'orienter les efforts Marketing vers des actions susceptibles de développer le partenariat avec les clients.
- Proposer des produits adaptés aux attentes des clients et qui préservent leurs intérêts.
- Former les employés pour être à l'écoute des clients et fournir un service de qualité.
- Répondre aux requêtes des clients de manière rapide et fiable
- Encourager la gestion proactive visant à anticiper et à solutionner les incidents négatifs qui risquent de nuire à la relation client.
- Pérenniser les relations avec les clients sur le long terme.
- Accéder à de nouveaux prospects grâce à la recommandation des clients existants.

Limites et voies de recherche

La majorité des travaux de recherche abordent la qualité de la relation du point de vue du vendeur, et peu l'ont traité du côté de l'acheteur. Il serait intéressant de procéder à une analyse dyadique pour mieux cerner la divergence de point de vue des deux parties.

L'échantillon reste limité. Il serait opportun d'élargir l'étude à d'autres villes et à d'autres secteurs d'activités, en prenant en considération les caractéristiques culturelles de chaque contexte d'étude, pour valider les résultats.
De même, le cycle de vie de la relation mérite une attention particulière car il peut impacter le choix et l'importance des variables pour les acteurs.

Du point de vue académique, et afin de pouvoir confirmer les résultats préliminaires, il serait opportun de procéder à une étude empirique quantitative sur un échantillon plus large.

Abstract

This article considers the pertinent issue of building a model of a person-oriented urban educational environment for teachers. As a prerequisite for building this environment for teachers, the authors consider a University Educational Complex organized in 1990, which in various years included such divisions as a multidisciplinary college, a pedagogical lyceum for rural schoolchildren, the V.G. Belinsky Pedagogical University school of early development, a kindergarten, a teacher training college, and a graduate school The authors describe the basic principles of forming an urban person-oriented educational environment, as well as the main opportunities that this environment opens up. The result of building this environment is a significant increase in the professional competence level of teachers.

Keywords: Model, Person-Oriented Urban Educational Environment, Competence, Teacher

Introduction

Education supports those social institutions of society where the quality of employees objectively determines progress. Consequently, the training of teachers must be adequate to promote national development. Global changes in education involve large-scale, long-term experiments. Therefore, it is necessary to form teachers' competences encompassing a set of professional and personal qualities.

The urban person-oriented educational environment is an open system of information resources structured for particular specifics of the subject-pedagogical activity of the teacher. This environment gives teachers the opportunities to integrate (combine in various ways) the content, technologies, and type of resources used depending on the current pedagogical situation. It contributes to the expansion of interaction between participants in the educational process and to the formation of new methodological approaches providing a new quality of learning outcomes.

Background of the study

In 1990, the University Educational Complex (UEC) was created. This complex was conceived as as a voluntary association of educational institutions at various levels based on the continuity of stages and levels of professional training. The interaction of all institutions is based on the coordination and consistency of pedagogical activities. The Educational - Methodological Council was created as a coordinator for this process at the Penza State Pedagogical

GAVRILOVA and Zhanna DEDOVETS "Model of Urban Information and Educational Space of Pedagogical Interaction" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

University (PSPU). When it was created, the University Educational Complex included: a school (a multidisciplinary college at PSPU, added later), a pedagogical lyceum for rural schoolchildren, and the V. G. Belinsky Pedagogical University itself. In subsequent years, a school of early development, a kindergarten, a teacher training College, and a graduate school were added (Figure 1).

Established in 1990, the system of educational institutions was designed to ensure the continuity and integrity of professional training of teachers on the basis of common conceptual approaches. This system ensures the optimal content, forms, and time of training and strengthens the subject professional-pedagogical orientation, which contributes to the formation and development of professional competence of teachers.

Fig. 1:Structure of the University Educational Complex (UEC)

The Purpose of the research

Transformation of UEC into an open forum for interaction between educational organizations and the creation of an urban educational environment for teachers.

Model

The urban person-oriented educational environment provides teachers with new opportunities for self-education, development of new learning technologies and new avenues for pedagogical communication, and increases the external motivation for their professional development.

The following principles were used in the formation of the urban person-oriented educational environment:

- multi-media (space must function in any standard operating environment);
- availability of space and its resources (the ability to access any module);
- openness (the ability to constantly supplement and modify information);
- adaptability (the ability to modify information in accordance with the specifications of the topic being studied);
- efficiency (structuring information reduces the time spent to search and convert it);
- invariance (compliance with the level of modern information products, the ability to use without additional improvements).

The urban person-oriented educational environment includes the following system modules: information - methodological center;

digital communication, interdisciplinary communication; subject-pedagogical growth.

The information- methodological system module is in the form of a multi-level structure of digital educational resources, control and diagnostic materials and provides:

- creation, modernization and adaptation of resources to specific subject-pedagogical conditions;
- creating a resource base, searching for resources based on emerging user requests and requirements;
- efficiency of the user's work with the resources provided to him, obtaining derived information;

The digital communication module contains constantly updated information that provides:
organization of dialogue, subject-pedagogical interaction, and information exchange.

organization of professional networking and contains reports, messages, publications, experimental materials, projects, and electronic resources.

The module of subject-pedagogical growth contains constantly updated information that provides:

- organization of scientific and methodological research;
- organization of project activities of participants in the pedagogical process;
- formation of an electronic library, media library;
- Refresher course

The meta-subject communication module includes

general pedagogical, psychological webinars, materials aimed at digitalization of the educational process.

The role of the coordinator is performed by the City Scientific - Methodological Center (CSMC), which accumulates all materials, ideas, and helps to establish cooperation. This center provides information support for all processes, promotes the creation of creative groups, laboratories, experimental and training sites, ensuring interaction between teachers, University staff, schoolchildren, and CSMC specialists.

The city's person-oriented educational environment is constantly expanding and supplemented by participants in educational activities. Various remote forms of working with the materials of each module are provided.

- The instrumental capabilities of the environment allow for rapid modification of educational materials, repeated use for different purposes, and replication of the prepared materials in different forms. The environment makes learning materials easily accessible at any time, regardless of location, i.e., it makes the materials mobile.

Working in the city's person-oriented information educational environment involves the use of remote work formats (online). The most popular are video conferences, video lectures, and digital materials.

In addition, the content of the educational module is constantly filled with special educational electronic resources created by the teacher independently or in collaboration with students or other teachers:

- simulators designed for students of different levels of training;
- diagnostic material, tests;
- textbooks designed for students who want to make a deeper study of mathematics;
- training program;
- interactive tutorial;
- reference books and encyclopedias.

Most of the resources have the necessary online links that allow you to quickly make contextual inquiries or go to the desired section of the complex of materials, which increases the information saturation of the content.

Methods

Since 2015, the authors have been monitoring the development of the city's person-oriented information and educational space and the effectiveness of its impact on the formation and development of teachers' competence. Table 1 shows the criterion for the effectiveness of the urban person-oriented educational environment.

Table 1: The criteria for the effectiveness of the urban person-oriented educational environment

Criteria	Monitoring by indicators	Diagnostics
Resource saturation	Fullness and Breadth of content	Expert evaluation
Content of teaching material	Systematization and updating	Expert evaluation
Availability and timeliness of information	Resource provision	Observation
Consistency of the resources of a college teacher with other educational environments	Interaction with other environments	Analysis
The degree of implementation in the educational process using the resources of the environment	Educational environment	Statistical analysis
The distribution of teaching time	Amount of time saved	Map of observations
Using technologies for training	Availability of new ICTs	Introspection
Intensity of using ICT	The use of interactive forms	The map of observations
Activity of teachers and students engaged in scientific research	Initiative	Statistical analysis
	Number of participants	
Interaction with other teachers	The degree of readiness of teachers to develop activity	Statistical analysis
	Shared experience	

The results of the assessment of the urban person-oriented educational environment are presented in diagram 1, which reflects the development of this process for each performance criterion.

Figure 2

Results and Innovation

An urban person-oriented information educational environment supports:

- systematic use of digital educational resources;
- the process of subject-pedagogical self-development of a teacher on an individual trajectory;
- the process of interpersonal, network interaction, exchange of experience with colleagues;
- joint expert evaluation and development of electronic teaching resources.

An urban person-oriented information educational environment provides:

- inclusion in the professional activity of the teacher of the experience of using modern equipment, gadgets, and technologies in the preparation and conduct of lessons;
- formation and support of an informal community of teachers aimed at professional growth;
- material and moral incentives for teachers by increasing their rating indicators and implementing internal needs for new teaching activities;
- development of personal and professional qualities through the use of communication interaction, which modifies and expands the activity of the teacher.

The professional level of teachers in the following positions has significantly increased:

- ability to work in a team;
- ability to work with a variety of technical devices;
- ability to adapt depending on the pedagogical situation;
- ability to build an individual educational trajectory;
- ability to carry out network communication interaction;
- readiness for self-education, self-control.

Conclusion

The creation of an urban person-oriented educational environment has made it possible to effectively form and develop the professional competence of teachers and their ability to carry out multi-functional activities in dynamically developing modern education.

Abstract

This study critically examined the effect of eustress on academic staff performance. To accomplish this goal, a total of 171 academic staff drawn from covenant university Ogun State, Nigeria, were sampled. The data were analysed using regression analysis. The result showed that eustress has positive significant influence on performance of academic staff in the selected university. An implication of this study is that university management should ensure that academic staff performance appraisal should focus on research output, teaching effectiveness and community service engagement bearing in mind international standards and parameters and more emphasis should be put on adopting an internationally competitive reward mechanism for academic staff commensurate to performance demands.

Keywords: Eustress, Academic Staff, University, Nigeria.

Introduction

Eustress is the good stress that motivates employees to perform well and to work with interest. This stress can be a motivator and it provides an incentive to get the job done. The good stress is what everyone enjoys while performing work. Everyone needs a little bit of stress in life in order to continue to be happy, motivated, challenged and productive (Folkman, 2013). Furthermore, eustress improves the confidence level of people but at the same time it never makes them overwhelmed. It also instils in them a feeling that the goal is not too far away and out of reach but still slightly difficult for them to handle. This feeling is responsible for the focused action. As the goal is visible and can be reachable, it fosters challenge and motivation to realize the goal (Farber, 1991; Folkman, 2013). The outcome of eustress experience by academic staff may be quality and enhanced performance among academic staff in scheduled time (Allen, 2015). Currently, much of the traditional research on academic staff stress have focused mainly on negative stress which is considered harmful to employees over all wellbeing (Anthony, 2015; Figen & Tatjana, 2015; Akanji, 2013; Mark & Smith, 2012). The predominant mind set towards stress is that stress is debilitating and disruptive and negatively affect performance, but this mind set can be changed (Crum, Salovey & Achor, 2013). Musrrat (2013),

Cite this Article as: Adeshola PETER, Anthonia ADENIJI, Kehinde OLADELE, Fred PETER, Maxwell OLOKUNDUN and Henry INEGBEDION "Eustress and Academic Staff Performance: A Study of Covenant University Nigeria" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Ahlam and Hassan (2012), Agbu and Olubiyi (2011) and Reda and Rania (2016) have advocated a more robust and holistic approach in exploring the negative and positive stress in order to gain subjective lecturers reports of stress and coping mechanisms resulting in a fuller picture on academic staff stress with future recommendations grounded in research. However, the aim of this study is to examine the influence of eustress on the performance of academic staff of tertiary institutions in Nigeria.

Therefore, the following hypothesis was formulated:

H_0: Eustress does not affect Academic staff performance.

Literature Review

The Concept of Eustress

Quick, Wright, Adkins, Nelson, and Quick (2013) identified eustress as a healthy, positive and constructive results of a stressful event and stress response. The positive side of stress is that it can jump-start your adrenalin and motivate you to perform your tasks more quickly in response to impending deadlines. Thus, eustress is considered the result of the body's positive response to a stressor. Eustress could be regarded as an increase of the buffer zone, with the effect of improving health and decreasing morbidity and mortality. Thus, it is the transition of the internal body system from a high level of allostatic load to a lower level of allostatic load. This process results in an increase of the bodies adaptive capabilities (Kupriyanov & Zhdanov, 2014). A second approach to eustress was the one of Lazarus (1993). According to him, eustress was more than an adaptation process but the positive cognitive appraisal of the response to a stressor which is experienced when the outcome is positive and when it preserved or enhanced well-being. Furthermore, eustress could be experienced when a challenge occurs, because such an event is considered as a potential for growth (Simmons & Nelson, 2001). Previous studies focused on general stress, where the concept of eustress has been overlooked. This has brought about an inadequacy of knowledge about eustress which obstructs the development of positive stress (Li, Cao & Li, 2016). Distress and eustress represent distinct constructs and are not at opposite ends of a continuum, because they cannot be distinctively separated (Keller, 2013). This is consequent upon the fact that the presence of eustress does not indicate lack of distress. They are mixed together like water in a bathtub and when combined the water temperature will be determined by the quantity of hot or cold water (Jarinto, 2010). However, there is an opinion that eustress and distress may occur simultaneously. Nelson and Simmons (2003) consider eustress and distress as two different reactions to the stress which can occur simultaneously supposed that eustress and distress represent separate and independent aspects of the overall response to stress. Lovallo (2015) also believes that the influence of stress is largely dependent on how a person interprets the situation. Therefore, in the university context, eustress associated with role demands for academic staff as an is literally the "good stress" that is associated with a positive outcome and enhanced well-being.

Job Performance

Job performance is a commonly used, yet poorly defined concept in industrial and organizational psychology (the branch of psychology that deals with the workplace). Nowadays, it's a part of Human Resources Management and refers to whether a person is performing his job well or not. Despite the confusion over how it should be exactly defined, performance is an extremely important criterion that relates to organizational outcomes and success. Job performance can be defined as how well an employee is performing at his work. Byars and Rue (2006) define performance as the extent to which an employee accomplishes the tasks that make up his or her job. Dolan & More (2002) defines performance as a record of outcomes produced during a specific job, over a specific time. According to Borman and Motowidlo (1993) and Campbell, Gasser and Oswald (1996), it is widely agreed that job performance is considered as a multidimensional construct. Dessler (1983) suggests that work performance is a measure of how well an employee meets the standards that are required for a specific job. Performance is the accomplishment of a given task measured against pre-set standards of accuracy, completeness, cost and speed. The behaviour of an individual directed towards goal accomplishment may be considered as his work performance. According to Jamal (2007), work

performance is the degree to which an individual executes his or her role with reference to certain specified standards set by the organization. Therefore, in the context of academic staff in the university context, meeting demands for research, teaching and community service based on certain specified standards set by the institution is termed as performance.

Methodology

A descriptive research design was used to obtain data from employees of the selected university. Data was collected through the administration of structured copies of questionnaire to academic staff of Covenant university Ogun State, Nigeria. The study population comprised the academic staff of Covenant University, with a population of 530 employees. Covenant university is a front-line private university in Nigeria with a drive and focus for excellence. The vision of the university to turn out to be one of the best ten universities in the world inspires a corporate drive to achieve the vision which can be associated with eustress as theorised by this study. The emphasis on the academic staff of the organization was founded on the fact that academic staff of any university are the foremost crop of work force that drive performance hence, the concept of eustress may be more applicable to them. The data collected was essentially quantitative in nature and a sample size of 171 employees was used. Regression analysis was employed to test the hypothesis stated. Eustress was measured using a three-item measure. These items are: teaching role demands; research and publication demand; community service role demands. Academic staff performance was assessed using a three-item measure. These items are; teaching effectiveness; research output; community service engagement. Responses ranged by 5-point Likert scaling from 1= “Strongly disagree” to 5= “Strongly agree

Data Analysis and Presentation of Results

Table 1: Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.344[a]	.118	.108	.64107
a. Predictors: (Constant), Eustress				

Source: Field Study Result (2018)

The above table is the model summary. It shows the extent to which the dependent variable variance (academic staff performance) is explained by the model (eustress). In this case, the R square value is .118 expressed by a percentage, this means that our model (the effect eustress has on academic staff performance) explains 11.8% of the variance on academic staff performance.

Table 2: ANOVAa

Model		Sum of Squares	Df	Mean Square	F	Sig.
1	Regression	4.787	1	4.787	11.648	.001[b]
	Residual	35.755	87	.411		
	Total	40.542	88			
a. Dependent Variable: academic staff performance						
b. Predictors: (Constant), eustress						

Source: Field Study Result (2018)

The table above shows the assessment of the statistical significance of the result. The ANOVA table tests the null hypothesis to determine if it is statistically significant. From the results, the model appears to have a good fit, indicated by positive value F value of 11.648. Also, the table shows a statistically significant relationship between eustress and academic staff performance ($p < 0.01$). The implication of the statistical result is that driving eustress in the organization will result in high academic performance. Hence the null hypothesis should not be accepted.

Table 3: Coefficients[a]

Model		Unstandardized Coefficients		Standardized Coefficients	T	Sig.
		B	Std. Error	Beta		
1	(Constant)	2.334	.386		6.054	.000
	Qual_Conscie	.325	.095	.344	3.413	.001
a. Dependent Variable: academic staff performance						

Source: Field Study Result (2018)

The table above shows the simple model that expresses the extent to which eustress affects academic staff performance. In this table, the beta co-efficient which relates to is .344. It makes the strongest contribution to explaining the dependent variable. Findings from this result showed that eustress has an effect on academic staff performance. Hence, we are accepting the alternative hypothesis (eustress has an effect on academic staff performance).

Discussion of Findings

The findings from this study shows that driving a culture of positive stress (eustress) in the university environment motivates performance of academic staff. This extends the work of Salvendy (1982) and Caitlin (2013) who carried out a sequence of experimental studies and results revealed that effective management of occupational stress is capable of increasing performance. Effective management of occupational stress in this context may suggest driving a culture of positive stress (eustress) to motivate performance of workforce. The findings of this study also re-echo the work of Ashimi, (2014) who argued that stress may not always be associated with negative outcomes because not all stress is harmful and dysfunctional in nature. In this regard it is assumed that stress can be a positive stimulus when one is helped to understand how stress occurs, what the consequences of stress are and how it can be coped with. However, as identified in literature, the positive side of stress is that it can jump-start adrenalin and motivate a workforce to perform tasks more quickly in response to demands. This owes to the fact that eustress motivates a positive cognitive appraisal of the response to a stressor which is experienced when the outcome is positive and when it preserves or enhances well-being. Therefore, in the context of this study the focal point is that if academic staff of a university hold a positive cognitive appraisal of the demands associated with research, teaching and community service based on the rewards and fulfilment anticipated, this can motivate a positive response resulting in increased performance.

Theoretical Implications

This study has contributed to existing studies by empirically showing the relationship between eustress and academic staff performance, especially in a developing economy, such as Nigeria. Therefore, subsequent scientific studies in the area of stress and performance research can gain insights on factors related to positive stress that motivate performance.

Recommendations

The findings of this study have important implication for university management in Nigeria. Motivation policy should be made differently according to the needs of the different academic staff. Academic staff performance appraisal should focus on research output, teaching effectiveness and community service engagement bearing in mind international standards and parameters. More emphasis should be put on adopting an internationally competitive reward mechanism for academic staff commensurate to performance demands

Conclusion and Further Studies

This research was undertaken to examine the influence of eustress on academic staff performance of covenant university. The study concludes that academic staff in universities in Nigeria will respond positively to stressors actuated by performance appraisal demands if the anticipated outcome is deemed commensurately rewarding. Further studies could explore other antecedents of academic staff performance.

Acknowledgement

Authors of this research work express sincere appreciation to the Management of Landmark University for giving full sponsorship to the publication of this research work.

Abstract

The article describes the implementation of the main principle of the activity of catering enterprises, or any other company for that matter – the continuity principle. The factors influencing the continuity of business are considered. The authors analyse the ways of managing and reducing the economic risks of catering enterprises.
The authors propose a method of provisioning as the most efficient way to reduce the economic risk. For the business activity of enterprises to remain continuous, it has been suggested to create a complex of reserves. Different approaches to the concepts of "uncertainty", "risk", and "reserve" have been considered.
In the process of solving the set tasks on achieving the goal of the research, the scientific provisions have been worded, which serve as the ground for improving the accounting and the internal control of reserves at catering enterprises, what aims at ensuring the continuity of business activity of these companies.

Keywords: catering enterprises, principle of business continuity, reserves.

Introduction

The accounting principle of business continuity of enterprises is stipulated by Art. 8 of the Federal Law "On the Accounting" and by para.6 of the Provision on Accounting "Accounting Policy of an Organization": "…the organization shall continue its business activity in the foreseeable future, and it has no intent of or need for liquidation or significant reduction of its activity and, therefore, the obligations will be duly discharged (continuity assumption)".

The business activity of catering enterprises is susceptible to the influence of internal and external factors, which could play a significant role in managerial decision making and affect the continuity of an organization's business activity.

The external factors of catering enterprises include the general economic situation in a country, demand for an enterprise's products and services in the market, changes in the prices for the raw materials being purchased, failures in food products deliveries, dishes not sold before their date of expiry, etc.

The internal factors of catering enterprises comprise the qualification level of specialists, technology of cooking dishes and semi-finished products, availability of the required equipment, quality of the raw materials being used, following the sanitation and hygiene standards, etc.

Since the results of activity of an economic entity are to a large extent determined by the environment of its functioning, the entity needs to know this environment and be able to adequately react to the changes in it. The main characteristics of the financial and economic environment are the interrelatedness of its factors, the complexity, the flexibility, and the uncertainty.

Scientific literary sources define the uncertainty as incomplete and inaccurate information on the conditions of fulfilling a managerial decision, an impossibility of making accurate forecasts on the changes in the business environment, the unpredictability in the actions of contractors, etc.

The continuity of business activity of a catering enterprise means the ability of the catering enterprise to continuously maintain its technological processes on processing and cooking food products, and the absence of its intent for liquidation or termination of activity.

There can be different reasons for uncertainty: unstable situation in the economic and political spheres within a country and in the world in general; the uncertainty in the actions of contractors; the uncertainty in the demand for goods; inaccuracy of information, etc.

In the conditions of uncertainty, it is difficult for catering enterprises to make managerial decisions. The fulfilment of the made managerial decision is related to the concept of "risk".

Meanwhile, the risk can be related not only to losses, but also to possible extra income, that is why the specialized literature does not provide a unified approach to the concept of "risk".

The following main definitions exist for this concept *(Giliarovskaya, 2003)*:

"…1) danger of possible losses;
2) phenomenon related to the economic activity aimed at making the maximum profit based on satisfying the needs and demands of buyers in compliance with the market requirements;
3) uncertainty (income variability) in the return of capital employed;
4) risky activity performed with the hope of a successful outcome;
5) probability of a mistake or success from making this or that choice in a situation with several alternatives…".
Thus, risk, to put it simply, is a deviation of the expected result from the actual one, which can turn out to be either positive, or negative.

Main Problem

The problems of functioning of the accounting systems for various types of activity were considered in the works by the following Russian scientists: P.S. Bezrukhikh, N.A. Bereslavtseva, V.G. Get'man, N.P. Kondrakov, V.F. Paliy, Ya.V. Sokolov, V.I. Tkach, A.D. Sheremet, V.B. Ivashkevich, E.A. Mizikovskiy, A.M. Ilyshev, N.N. Ilysheva, I.V. Zyrianova, and others. Among foreign scientists dealing with the problems in accounting, reporting and analyzing, we should mention D. Middleton, B. Needles, G. Richard, P. Samuelson, E.S. Hendriksen, R. Anthony, and others. The research studies by these scientists are very important for the development of accounting. However, they were considering the concept of "reserves", its content and the methods in accounting in general, without sector-related specifics of an enterprise's business activity.

The problems of ensuring the continuity of business activity of enterprises are described in the works by such scientists as I.T. Balabanov, P.G. Grabovyi, M.G. Lapusta, E.A. Utkin, A.S. Shapkin, A.E. Shevelev, E.V. Sheveleva, and others. These researchers were considering such concepts as "continuity of business activity", "uncertainty", and "risk", and were proposing the methods of ensuring the continuity of business activity of enterprises. However, the considered types of risks and their classification are mostly inapplicable to catering enterprises that is why further research is required.

The accounting of financial reserves was studied by a number of foreign and Russian authors, including R. Adams, J. Bethge, D. Middleton, R. Anthony, S.V. Romanova, L.T. Giliarovskaya, Ya.V. Sokolov, A.D. Sheremet, L.R. Robinson, A.P. Rudanovskii, I.M. Ageev, L.A. Melnikova, E.V. Riabova, E.A. Popova, and others. The scientists were defining the concept of "reserves", proposing their evaluation and accounting of various types of enterprise's

business activity. However, these specialists were considering the reserves of enterprises either in general, or as applied to separate sectors of business activity of enterprises. In this context, various approaches were formed, which are practically not acceptable for the sphere of catering.

Methods

Due to the fact that the financial and economic activity of the market participants is becoming more and more complicated, there is a risk of unforeseen material and financial losses, or negative payoffs from various projects. Business activity of catering enterprises is especially susceptible to the risks, among which the production risks should be specifically mentioned as these are related to cooking of food products and a distinctive technological process.
The procedure of making a decision on the risk reduction at catering enterprises implies several stages.

At the first stage, the enterprises working with contractors inform the accounting office on the external environment. Production departments inform the accounting office on the internal environment.

At the next stage, the quantity and quality of the revealed risks are assessed by the specialists of the accounting office, internal control department. After that the analysed data are forwarded to the enterprise top managers.

Next, based on the analytical data, the enterprise top managers decide on the method of the risk reduction.

The assessment methods are chosen by the economic entity independently this is the responsibility of a top manager or a person in charge of risk management. Once the risks are assessed, the methods of risk management should be chosen:

– risk avoidance;
– risk transfer;
– risk acceptance; or
– risk reduction.

Risk avoidance is a method, which implies the development of measures completely eliminating a certain type of risk. Such measures may include:

1) avoiding the operations with high level of risk. Most of the economic operations within an enterprise's main type of activity are risky, that is why it is impossible to implement such measures all the time as the enterprise will see neither losses, nor profits;
2) avoiding the use of big loan funds. These allow gaining extra profit, but at the same time may lead to the enterprise's losing its financial stability.

Thus, the method of risk avoidance deprives catering enterprises of the extra profits and has negative effect on their rates of economic development. That is why risk avoidance should be rational if the following is true:

– avoiding one risk does not lead to emerging of another risk;
– level of the risk is incommensurable with the income gained as a result of this operation;
– losses from this type of risk cannot be compensated at the enterprises own expense.

Risk transfer in modern practice is fulfilled using the following methods.

1. Risk transfer by signing a factoring agreement.
Under this agreement, the enterprise's credit risk is transferred to a bank or a specialized factoring company. The use of this method is not typical for catering enterprises due to the fact that their business activity does not imply receivables from customers, and therefore, there is no credit risk. It is very rare that catering enterprises deal with loan funds.

2. Risk transfer by signing a guarantee agreement.
Article 361 of the Civil Code of the Russian Federation stipulates a possibility of signing a guarantee agreement. Under this agreement, the guarantor stands surety to the creditor for the third party's partial or complete fulfilling of its obligations. The use of this method is also not typical for catering enterprises due to the absence of credit risk.

3. Risk transfer to the suppliers of raw materials and semi-finished products.
Transferred are the risks related to spoiling or loss of the material and production stocks in the process of storing and transporting them, or performing associated works. Meanwhile, the losses caused by the drop in the products' market price cannot be transferred and are incurred by a catering enterprise.
Thus, risk transfer is possible if the parties sign an agreement, which has a specific section on transferring certain risks to the contractor.

The most dangerous risks which may lead to grave consequences for an enterprise shall be neutralized through insurance. In this case an insurance company shall act as the party accepting the risks.
When accepting a risk, an enterprise searches for the possible sources of the required potential loss reserves. In this case the loss reserves are taken both from the in-house resources, and from the loan ones. Meanwhile, if having used the loss reserves due to a risk, an enterprise lacks the assets; it may lead to a decline in production, and in the worst-case scenario to a bankruptcy.

The main methods of risk reduction are hedging, diversification of activities and investments, provisioning, and others.

Hedging is practiced in such spheres as stock-exchange, banking, and commercial activity. E.G. Dolan et al. in a book Money, Banking, and Monetary Policy define hedging as a "system of concluding fixed-term contracts and transactions, which takes into account the future probable changes in the exchange rates and aims at avoiding the unfavourable consequences of such changes". This method is not used at catering enterprises.

Diversification is a process of allocation of the capital between different investments directly related to each other. Diversification allows to partially avoiding risks when allocating the capital between several types of activity. Other types of activity different from the main one are rare at catering enterprises that is why this method is practically inapplicable.

Provisioning (self-insurance) is a method of risk reduction, which is based on an enterprise's reserving part of its resources and which allows to overcome the possible negative consequences.

Provisioning is essential in the following cases:

– there is an economic gain from its implementation, as compared to other methods of risk reduction; or
– it is impossible to implement some other method of risk management.
Thus, we can conclude that the latter risk reduction method is the most suitable one with regard to the business activity of catering enterprises.
Also, there are non-economical methods, such as the preliminary check on contractors, control over following the technology of cooking the products of own make, checking the expiry dates of raw materials, and so on.
The preliminary check on contractors implies the following security measures:

1) before the beginning of the contractual relationship, checking on a contractor in the extract from the Unified State Register of Legal Entities;

2) checking on the authorities of the contractor's representative by asking to submit relevant documents (Power of Attorney, Decree, Protocol of the Meeting of Founding Parties, Decision of a Sole Founder, and others) and comparing them against the passport data;

3) verifying the identity of the contractor's representative by asking him/her to produce his/her passport, making a copy of this passport, and saving all the data on all the contractors.
Among all of the described methods of risk reduction, provisioning is the most acceptable one as it means that an enterprise prefers to be on the safe side all on its own, thus saving on the insurance expenses. Creation of a separate

reserve fund to compensate for possible negative consequences of the catering enterprise's activity is the essence of provisioning, the main task of which is a prompt overcoming of temporary difficulties in the economic activity.

Results and Discussion

In order to implement the principle of the continuity of business activity of catering enterprises, it is necessary to use a reserves complex, a complex comprising a group of known and special reserves, to create which an enterprise should use accounts for the accounting of reserves, evaluate them and determine the actions required on the procedures of accounting and reporting.

Special reserves mean the reserves, which meet the specifics of catering enterprises' business activity, and which are created to cover possible losses related to the technological processes of processing and cooking food products, non-observance of the sanitation and hygiene regulations, and so on.

A specific feature of catering enterprises is the necessity to follow the requirements imposed on them by the society and the government and influencing their activity, such as holding of the required licenses as stipulated by the legislation; certification of the catering products; observing the sanitation and hygiene regulations; and the regulations on rendering catering services.

Thus, the non-observance of the regulations on rendering catering services, or the sanitation and hygiene regulations with regard to the business activity and products may result on the clients' addressing a sanitation and hygiene service, which in its turn can check on the enterprise, and fine or even close it. Not following the rules of the produce storage and transportation may result in its changing its consumer properties or spoiling. The mentioned factors lead to economic risks of the catering enterprises, and those affect the continuity of their business activity.

In this regard, the procedure of forming the group of reserves, which are used to build the reserves complex, has been adjusted to include the following actions:

1) determining the specifics of the catering enterprises' business activity;
2) identification and quality assessment of the risk caused by these specifics; and
3) determining the required reserve using the reserves classification.

Various situations related to the specifics of catering enterprises' business activity create certain types of risk. Depending on the situation, it is possible to accept a number of risks, but other risks require action to reduce undesirable consequences.

Let us consider the consistency of the specifics of the catering enterprises' business activity with the risks and reserves (Table 1).

Table 1: Consistency of the specifics of the catering enterprises' business activity with the risks and reserves

Specifics of the catering enterprises' business activity	Type of risk	Type of reserves
Technology of products processing and manufacturing	Risks of violating the technology of processing and cooking food products and manufacturing of goods	Reserves for the costs to be incurred related to the production activity of catering enterprises
	Risks of violating the sanitation and hygiene regulations	Reserves for the economic activity contingency
Using of food raw materials	Risks of using bad quality raw materials or the shelf life expiry	Reserves for the economic activity contingency

	Risks of decrease in the source raw materials	Reserves for natural losses
Short term of the products storing and selling	Risks of the products spoiling	Reserves for products spoiling
Taking goods on commission	Risks of spoiling or shortage of the products taken for the commission	Reserves for the guarantees issued

(Source: compiled by the authors based on practical experience)

Based on the performed analysis of the catering enterprises' reserves, a conclusion has been made that they need to be systematized to choose from them correctly while processing the accounting information.

Conclusion

Therefore, among all of the described methods of risk reduction, provisioning is the most acceptable one as it means that an enterprise prefers to be on the safe side all on its own, thus saving on the insurance expenses. Creation of a separate reserve fund to compensate for possible negative consequences of the catering enterprise's activity is the essence of provisioning, the main task of which is a prompt overcoming of temporary difficulties in the economic activity.

Abstract

In the current research, we validated the abusive supervision scale in Polish organizational setting. In two studies, we tested a full and a short form of the scale, and examined its psychometric properties. In study 1 ($N = 934$), we explored one-factor structure of both forms of the abusive supervision scale. In study 2, using an independent sample of employees ($N = 463$), we have confirmed the one-factor structure of both forms of the scale. Reliability parameters have yielded satisfactory levels for both forms. The two studies provided support for the predictive validity of the abusive supervision scale in the context of various work-related variables. We have found significant relationships between abusive supervision and perceptions of low trust in management and coworkers, diminished organizational justice ow effectiveness and low satisfaction. Heightened stress indicators such as somatic, cognitive, and emotional responses, offensive behaviors among co-workers like gossiping and conflicts, counterproductive work behaviors like sabotage, abuse, withdrawal and theft and low work engagement were positively related to abusive supervision. The abusive supervision scales, in a full and a short form, are thus valid and reliable measures of the perception of abusive supervision in Polish organizations.

Keywords: Scale Development, Scale Validation, Abusive Supervision, Employees' Psychological Well-Being

Introduction

Abusive Supervision

Abusive supervision has been defined as "subordinates' perception of the extent to which supervisors engage in the sustained display of hostile verbal and nonverbal behaviors, excluding physical contact" (Tepper, 2000, p. 178). Destructive forms of supervision, referred to as derailed leadership, destructive leadership, laissez-faire leadership, tyrannical leadership, supportive-disloyal leadership, toxic leadership, authoritarian leadership bullying, narcissistic (see Schyns and Schylling, 2013; for review) have been documented as increasingly pervasive in the current organizational reality (Mackey et al., 2017; Tepper et al., 2017). The list is by no means exhaustive here. As frustrating as it sounds some of the abusive behaviors may be perceived as worse than others. Pelletier (2010) presented weighted means of negative behaviors, among which ridiculing an employee's work in public had the highest value.

Comparably assessed was lying. Less harmful behaviors included reprimanding for mistakes or not participating in a meeting (Pelletier, 2010). Some researchers make a valid point however that the detrimental effects of abusive supervisors may vary due to differences in employees' perception of the magnitude and significance of the abuse. Some individuals may tolerate and endure much more of leaders' harsh behaviors than others (Schyns et al., 2018). Academics and practitioners have acknowledged detrimental impact of abusive supervision on employees' well-being and organizational effectiveness. In the literature, abusive supervision has generated the most substantial research

Cite this Article as: Jolanta BABIAK and Beata BAJCAR "Validation of A Full and A Short Form of The Abusive Supervision Scale in Polish Organizational Context" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

from among any other concept of destructive leadership (Mackey et al., 2017; Martinko et al., 2013). In fact, abusive supervision scale developed by Tepper (2000) is one of the widely used measurement tool. Other instruments designed to gauge negative leadership behavior include Toxic Leadership Scale (TLS; Schmidt, 2008) and Destructive Leadership Questionnaire (DLQ; Shaw et al., 2011; Shaw et al., 2014). These measures however have not been as widespread in research (e.g. Babiak and Bajcar, 2019a; 2019b) as the abusive supervision scale.

The concept of abusive supervision and the resultant measurement tool have been validated across many studies. According to Tepper (2000; 2007), the phenomenon of abusive supervision stems from violation of justice and organizational norms. As such, perception of injustice at any organizational level has been recognized as a core contributing factor of abusive supervision (e.g. Hoobler and Hu, 2013). The mechanism of abusive supervision proliferation may result from frustration with the unjust behavior of one's bosses, "the higher-ups", (Liu et al., 2012), which, if unresolved, often leads to retaliation against other co-workers, especially those who are less powerful (Aryee, et al., 2007; Lin et al., 2013; Park et al., 2015). Antecedents of abusive supervision are many and the main categories relate to supervisor (e.g. personality, childhood experiences), organization (e.g. a steep structure), subordinate (e.g. ways of coping), as well as demographic characteristics of supervisors and subordinates (e.g. clash of generations) (Zhang and Bednall, 2015).

The drama of abusive supervision relates to its detrimental consequences for workers' personal and professional life spheres. Due to abusive supervision employees' well-being, health, work-life balance, job satisfaction may be seriously jeopardized (Skogstad et al., 2014; Wang et al., 2020; Zhang and Liao, 2015). Studies show that abusive supervision leads to such negative emotional outcomes as negative affect, anxiety, depression, lower self-esteem (e.g. Schmid et al., 2018), serious health issues, like paranoia (Lopes et al. 2018), or work-family conflicts (Mackey et al., 2017). These experiences may cause distress, emotional exhaustion, and burnout ultimately undermining commitment and engagement (Mackey et al., 2017; Zhang and Liao, 2015). Organizational loss due to tolerating abusive leaders aboard translates into lower performance (e.g. Chen and Wang, 2017; Zhang and Liao, 2015), counterproductive work behaviors (An and Wang, 2016; Sulea et al., 2013), like sabotaging organizational goals, stealing or high turnover intentions and departure of valued employees (Schyns et al., 2018). Undoubtfully, the consequences of abusive supervision, which is a current and vital theme of academic and practical considerations, shall be recurrently researched upon so that the knowledge is brought up to date for the organizational management to be fully informed about this real organizational problem.

The main aim of this research was two-fold: to examine the full Tepper's (2000) abusive supervision scale, develop its short form in the Polish organizational context, and assess the psychometric properties of both forms of the scale. We thus addressed two objectives to fulfill this aim: (1) to determine the factor structure of both forms, and (2) to examine the reliability and predictive validity of the full and a short form of the scale. In order to allow for enhanced universality in the use of the validated scales, we employed a cross-validation process (de Rooij and Weede, 2020) by conducting two studies using independent samples of participants.

Study 1

In study 1 we examined the factor structure of the 15-item abusive supervision scale. We also developed a short version of the scale. Next, we assessed the reliability of both forms of the scale in terms of the internal consistency, item-total, inter-item correlations, and temporal stability. Then, in order to investigate predictive validity of the abusive supervision full and short forms of the scale we examined their associations with employees' work effectiveness, work satisfaction, values at work, stress symptoms, and offensive behavior.

Participants and Procedure

The sample consisted of employees working in Polish organizations of different sectors and business operations. An online questionnaire was distributed using an electronic platform, with the link being provided to the participants. The anonymity and confidentiality of the answers were guaranteed. All participants provided informed consent before they have had begun to fill out the forms. A total of 932 individuals completed the survey, which yielded responses from 505 women and 427 men, aged between 18 and 63 (M = 29.07, SD = 12.80). The participants' mean tenure was 15.67 years (SD = 9.87).

Measures

Abusive supervision. The abusive supervision scale developed by Tepper (2000) consists of 15 items, which measure subordinate's perception of her supervisor's abusive attitudes and/or behaviors. Each item is rated on a 5-point Likert scale ranging from 1: "I cannot remember him/her ever using this behavior with me" to 5: "He/she uses this behavior very often with me" (Tepper, 2000).

Work effectiveness. The employees' work effectiveness was assessed by one item 'How would you rate your work effectiveness?' on a 5-point scale from 1 – very low to 5 – very high.

Work satisfaction. The employees' work satisfaction was assessed by three items referring to satisfaction with the leader, work, and relations with peers (e.g. 'How satisfied are you with your leader?'). Participants rated their satisfaction on a 5-point scale, ranging from 1 - completely unsatisfied to 5 – completely satisfied. In this study we considered a total score of work satisfaction. In this sample, the coefficient alpha reliability for the total score (α = .79) was acceptable.

In this study we used the Copenhagen Psychosocial Questionnaire (COPSOQ II; Pejtersen et al., 2010) adapted in Poland by Baka (2019) that measures various psychological and organizational variables in three categories: values at work, offensive behaviors, and emotional responses.

Values at work. The organizational justice, mutual trust between coworkers, and trust regarding management as values at work were measured by the COPSOQ subscales (Baka, 2019; Pejtersen et al., 2010). Each of these subscales consisted of several items assessed on a 5-point scale (from 1 – very little to 5 – very much). The organizational justice included 4 items (e.g., "Are employees appreciated when they have done a good job?". Mutual trust between employees is represent by 3 items (e.g., Do the employees in general trust each other?). Trust regarding management consisted of 4 items (e.g., Can you trust the information that comes from the management?). The reliability of these measures in this study were satisfactory (Cronbach α = .73 - .87).

Offensive behaviors. The offensive behaviors measured by COPSOQ II items (Baka, 2019; Pejtersen et al., 2010) included unpleasant teasing, conflicts and quarrels, and gossip and slander. Unpleasant teasing was assessed by a single question "Have you been exposed to unpleasant teasing at your workplace during the last 12 months?" Conflicts and quarrels were measured by item: "Have you been involved in quarrels or conflicts at your workplace during the last 12 months?" Gossip and slander were expressed in item: "Have you been exposed to gossip and slander at your workplace during the last 12 months?" Participants responded to these questions on a 5-point scale (from 1 – no to 5 – yes, every day).

Stress symptoms. To measure employees' stress symptoms at work four subscales from COPSOQ II (Baka, 2019; Pejtersen et al., 2010) were used: (1) stress (e.g., "How often have you had problems relaxing?), (2) somatic stress symptoms (e.g., "How often have you had a headache?", (3) cognitive stress symptoms (e.g., "How often have you had problems concentrating?"), and (4) burnout (e.g., How often have you been emotionally exhausted?"). Respondents answered on a 5-point scale (1 – at all to 5 - all the times). The internal consistency of these subscales ranged from .74 to .82.

Control variables. We included demographic (i.e. gender and age) and work-related (i.e. tenure) background variables.

Results

The abusive supervision scale was translated into Polish language by three independent translators with psychometric experience. After comparing all translated versions, individual items were assessed to meet the criteria of content validity, linguistic correctness and coherence, as well as common use in the Polish language. The final Polish version was back translated and used to test a group of bilingual individuals and English-speaking students (N = 18). The inverted version of abusive supervision scale showed satisfactory level of convergence with the original version. No statistically significant differences were noted in responses to items between the Polish version of the scale and its back translation.
In Table 1 the mean, standard deviation, item loadings and inter-item correlation for each item are presented. In the first step, the exploratory factor analysis was conducted (using IBM SPSS 25.0) to identify the internal structure of

abusive supervision measure. Bartlett's test for sphericity was significant (at the level 8993.39, df = 105, $p < 0.001$, and the KMO = .96) and suggested that the data were suitable for factor analysis. As depicted in Figure 1, an one-factor model was extracted, which explained 56% of variance. The fifteen items of the abusive supervision scale were then submitted to a principal component analysis, with free extraction of factors, which revealed one factor with an eigenvalue of 8.47. As displayed in Table 1, loadings of each item were above .55.

Table 1: Descriptive statistics, factor loadings, and discriminating power for abusive supervision items

		Factor loadings	Item-total correlation	*M*	*SD*
1*	My boss ridicules me.	.79	.74	1.58	.90
2	My boss tells me my thoughts or feelings are stupid.	.74	.68	1.56	.96
3	My boss gives me the silent treatment.	.55	.50	2.38	1.33
4*	My boss puts me down in front of others.	.82	.78	1.82	.84
5	My boss invades my privacy.	.73	.68	1.52	1.00
6*	My boss reminds me of my past mistakes and failures.	.78	.74	1.88	1.05
7	My boss doesn't give me credit for jobs requiring a lot of effort.	.70	.67	2.36	1.36
8*	My boss blames me to save himself/herself embarrassment.	.77	.73	1.72	1.11
9*	My boss break promises he/she makes.	.77	.73	1.97	1.11
10*	My boss expresses anger at me when he/she is mad for another reason.	.77	.73	1.91	1.18
11*	My boss makes negative comments about me to others.	.79	.75	1.55	.97
12	My boss is rude to me.	.75	.72	1.62	1.10
13	My boss does not allow me to interact with my coworkers.	.75	.70	1.41	.91
14	My boss tells me I'm incompetent.	.73	.68	1.47	.95
15*	My boss lies to me.	.79	.75	1.78	1.12

*Note. * Item included to short version of abusive supervision scale. Factor eigenvalue = 8.47.*

Fig. 1: Scree plot of eigenvalues for the factorial solution of abusive supervision scale (*N* = 932)

Next, according to validation standards (Ziegler et al., 2014) we developed a short form of abusive supervision scale. Items inclusion was based on the following criteria: 1) highest factor loadings, 2) impact on subscale internal consistency, 3) discriminating power of items (in terms of item-total correlations), and endorsement rates (i.e., items with considerable floor and ceiling effects were excluded). In cases where items demonstrated similar psychometric

properties, items were considered in terms of their length and content, with preference given to short and clearly worded items, and those deemed applicable to the widest range of respondents. In result, a short form consisted of 8 items with highest loadings (above .75) and highest discriminating power. Items with the lowest or highest mean score were excluded (see Table 1). The 8-item model explained 64% of the variance.

Reliability and validity of the abusive supervision measures

The reliability of abusive supervision measure was assessed using the internal consistency, item-total, inter-item correlations, and temporal stability. The internal consistency of the extracted factor was high. All parameters (i.e., Cronbach α, item-total correlation range, inter-item correlation mean, inter-item correlation range, inter class correlation) for the full and short form of the scale obtained high levels, indicating satisfactory reliability (see Table 2).

Table 2: Reliability parameters for abusive supervision measures in study 1 and study 2

	Study 1[1]		**Study 2[2]**	
	Full form (15 items)	**Short form (8 items)**	**Full form (15 items)**	**Short form (8 items)**
Cronbach α	.94	.92	.91	.88
Item-total correlation range	.50 - .78	.71 - .76	.41 - .73	.60 - .73
Inter-item correlation mean	.53	.59	.49	.48
Inter-item correlation range	.41 - .75	.52 -.75	.24 - .66	.31 -.66
ICC	.94	.92	.91	.88
Temporal stability[3]	.87	.85		

[1] N = 932, [2] N = 463, [3] N = 80. ICC - Inter class correlation.

Predictive validity of abusive supervision measure was assessed through correlation analysis between abusive supervision and three outcome variables, i.e. values at work, stress symptoms, and offensive behavior. As depicted in Table 3 abusive supervision correlated highly with offensive behavior and moderately with stress symptoms. Moreover, abusive supervision correlated negatively with values at work, such as organizational justice, mutual trust between employees and trust regarding management.

Table 3: Intercorrelations between variables analyzed in study 1

Variables	***M***	***SD***	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**	**12**	**13**	**14**

*Note. N = 932. * p < .05, ** p < .01.*

To check the differences between gender, age, and tenure and perception of abusive supervision the ANOVA was conducted.

Table 4: The effects of the control variables on abusive supervision measures in study 1 and study 2

	Abusive supervision scale					
	Full form (15 items)			**Short form (8 items)**		
	Women ***M (SD)***	**Men** ***M (SD)***	***F***	**Women** ***M (SD)***	**Men** ***M (SD)***	***F***
Gender						
Study 1	26.40 (10.82)	26.25 (12.93)	.04	13.83 (6.21)	12.71 (7.10)	.08
Study 2	22.50 (8.66)	21.89 (7.59)	2.72	11.74 (5.07)	11.15 (4.39)	2.11
Age[1]						
Study 1	-.05			-.03		
Study 2	.08			.10*		
Tenure[1]						
Study 1	-.01			.02		
Study 2	.09			.12*		

*Note. Study 1: N = 932; Study 2: N = 463; [1] Pearson correlation with abusive supervision * p < .05.*

The ANOVA results did not show significant differences between genders in terms of abusive supervision perception. Correlations of the abusive supervision with age and tenure were also non-significant (see Table 4).

Discussion of Study 1

In this study we have found a single-factor solution of the full form of abusive supervision scale, which explained 56,4% of variance. This result corroborates with the factorial solution found in other studies (e.g. Gatti et al., 2019; Mitchell and Ambrose, 2007). Furthermore, based on the EFA solution for the full, 15-items form, we extracted 8 items with the highest factor loadings and used it in subsequent analysis as a short form of the scale. The reliability indices, such as Cronbach α, item-total correlations, inter-item correlations, inter-class correlations, test-retest, for 15-item and 8-item forms of the abusive supervision scale represented satisfactory levels (Cronbach, 1951). These results correspond to previous findings showing adequate levels of the scale's independent reliability measures (cf. Gatti et al., 2019; Mitchell and Ambrose, 2007).

In preliminary support of the scale's predictive validity, we have found significant associations of abusive supervision with low trust in management and coworkers, and low organizational justice. This result is in line with previous findings on the relationships between abusive supervision and analogues variables like retribution (e.g. Park et al.,

2015; Zhang and Liao, 2015). Likewise, our findings of negative relationship between abusive supervision and trust between coworkers as well as display of behaviors such as gossiping, conflicts, unpleasant teasing gives further evidence to associations between abusive supervision and hostile behaviors of employees (Michel et al., 2015). Revealed in this study positive relationships between abusive supervision and stress symptoms provide evidence to support previous findings on the positive associations between abusive supervision and subordinates' psychological distress (Tepper et al., 2007; Wu et al., 2012; Zhang and Bednall 2015), reduced well-being (Lin et al., 2013; Zhang and Liao, 2015), and increased emotional exhaustion (Wheeler et al., 2013; Wu and Hu, 2009). At last, gender, tenure and age did not differentiate employees in terms of abusive supervision perception. The magnitude of the yielded correlations is low to moderate. Of note, many other factors, not considered in this study, also play an important role in the relationship between studied variables. They include personality characteristics of supervisors and employees, past experiences of abusive supervision, current or past mental health issues (e.g. Mackey et al., 2017). Other influences notwithstanding, the current findings add to the body of knowledge on the one factor structure of the full and short forms of Tepper's (2000) abusive supervision scale. Also, the results of study 1 provide preliminary verification of the predictive validity of the full (15-item) and a short (8-item) abusive supervision measure in the Polish organizational context.

Study 2

In study 2, we verified the factor structure of the full and a short form of abusive supervision scale. According to recommendations for cross-validation in the process of the scale validation (de Rooij and Weede, 2020), a confirmation of the factor solution of abusive supervision scale (a full and a short form) was performed using an independent sample of employees. We examined reliability, predictive validity of both forms of the scale in terms of their correlations with various relevant constructs, e.g. counterproductive behaviors, leadership quality, employees' work engagement.

Participants and Procedure

Data were collected in an online mode as in Study 1. Of the 463 participants 208 were female (44.8%). The average age of the participants was 29.8 (*SD* = 9.25). On average, the participants had an employment length of 6.67 years (*SD* = 8.20).

Measures

Abusive supervision. To measure abusive supervision a Polish version of Tepper's (2000) scale, as in Study 1 was used.

Counterproductive work behavior. Counterproductive work behavior was measured with 4 subscales from the short version of the *Counterproductive Work Behavior-Checklist* (CWB; Spector and Fox, 2005) in Polish adaptation (Baka et al., 2015). This included four subscales: 1) *abuse* (14 items; e.g., "Started or continued a damaging or harmful rumor at work."), 2) *sabotage* (7 items; e.g., "Purposely dirtied or littered your place of work."), 3) *theft* (5 items; e.g., Took supplies or tools home without permission."), and 4) *withdrawal* (6 items; e.g., "Taken a longer break than you were allowed to take."). Respondents answered on 5-point scale (from 1 – *very little* to 5 – *very much*). The reliability of the subscales ranged from .68 to .81 in this study.

Leadership quality. To measure leadership quality a subscale of COPSQ II (Baka, 2019) was used, which consists of 4 items, such as "To what extent would you say that your immediate superior gives high priority to job satisfaction?" Respondents answered on 5-point scale (1 – *very little* to 5 – *very much*). The reliability of this measure in this study was satisfactory (Cronbach $\alpha = .81$).

Work engagement. Work engagement was measured using the 9-item version of Utrecht Work Engagement Scale (UWES-9; Schaufeli et al., 2006). This scale consists of three subscales: *vigor* (6 items), e.g., "When I get up in the morning, I feel like going to school"; *dedication* (5 items), e.g., "I am enthusiastic about my job"; and *absorption* (5 items), e.g., "When I am working, I forget everything else around me." Respondents answered on 7-point scale (1 – *never* to 7 – *always*). Scores are summed, with higher scores indicating higher levels of work engagement. In this study Cronbach's alpha coefficients for the three-dimension subscales ranged from .88 to .91.

Results

Confirmation of the factorial structure of abusive supervision measures

The single-dimensional structure obtained in EFA was verified in the confirmatory factor analysis (Brown, 2015), with maximum likelihood estimation method using AMOS software (IBM AMOS 24.0). According to Kline (2015), the model is well fitted to the data, if fit parameters meet the following criteria: χ^2/df is between 2-3; root mean-square error of approximation (RMSEA) is below .08, standardized root-mean square residual (SRMR) is near 0; whereas comparative fit index (CFI), Tucker-Lewis index (TLI), goodness-of-fit index (GFI), and adjusted goodness-of-fit index (AGFI) are above .90.

The results obtained in CFA indicated that the model's goodness of fit was very good ($\chi^{2/}$df = 2.23, RMSEA = .052, GFI = .96, AGFI= .93, CFI = .97, SMSR = .036). These results suggest that the model is very well fitted to the empirical data (though very close to the threshold proposed in the literature). Since the fit indices presented acceptable values, we decided to not re-specify the model. Figure 2 shows the retained factor structure of the full form of the scale, in which all estimated parameters are statistically significant and the loadings of the items are much higher than .50. We also tested the model for the short form of abusive supervision. The 8-item model of abusive supervision scale has also yielded very good parameters of fit to the data ($\chi^{2/}$df = .86, RMSEA = .001, GFI = .99, AGFI= .98, CFI = .99, SMSR = .015).

Reliability and validity of the abusive supervision measures

All reliability parameters of the full and short abusive supervision measures (as Cronbach α, item-total, inter-items, and inter-class correlations) were comparably high and acceptable, although lower than in study 1 (see Table 2). Assessment of the predictive validity of the full and short forms was conducted through correlation analysis between abusive supervision and quality of leadership measure. Results, presented in Table 5, showed significant negative moderate (-.47 and -.45 respectively) correlations between measured variables. In order to test the predictive validity both form of the scale were correlated with 4 measures of employees' counterproductive work behavior, and three measures of work engagement and their total score.

Table 5: Intercorrelations between the analyzed variables in study 2

	M	*SD*	1	2	3	4	5	6	7	8	9	10	11
1. Abusive supervision (15 items)	21.59	7.59	1										
2. Abusive supervision (8 items)	11.15	4.40	.96**	1									
3. Leadership quality	16.55	3.70	-.47**	-.45**	1								
Counterproductive work behavior													
4. Sabotage	8.26	2.414	.24**	.23**	-.23**	1							
5. Abuse	17.25	5.65	.32**	.30**	-.21**	.67**	1						
6. Withdrawal	9.25	3.19	.25**	.23**	-.21**	.52**	.49**	1					
7. Theft	5.79	1.64	.22**	.20**	-.20**	.70**	.63**	.43**	1				
Employees' work engagement													
8. Vigor	10.55	2.64	-.23**	-.21**	.31**	-.09	-.05	-.21**	-.08	1			
9. Dedication	11.74	2.68	-.18**	-.16**	.27**	-.13**	-.14**	-.25**	-.10*	.70**	1		
10. Absorption	11.44	2.79	-.17**	-.16**	.22**	-.17**	-.12*	-.19**	-.12**	.58**	.70**	1	
11. Work engagement (total)	33.73	7.13	-.21**	-.20**	.30**	-.15**	-.11*	-.25**	-.11*	.86**	.91**	.87**	1

*Note. N = 463. * p <.05, ** p < .01.*

Results presented in Table 5 confirm predictive validity of the full and short versions of abusive supervision scale, showing that both forms of the scale correlated significantly and positively with dimensions of counterproductive work behaviors and significantly negatively with dimensions and the total score of work engagement. The correlations were of low to moderate magnitude.

In addition, the ANOVA results showed no significant differences in abusive supervision perception between women and men. Correlations between abusive supervision and employee's age and tenure for the full form were non-significant, whereas for the short form these relationships were significant but weak (see Table 4).

Discussion of Study 2

In study 2, using an independent sample of participants, a single-factor solution of the full and a short form of the abusive supervision were confirmed. In addition, both abusive supervision scale forms revealed high reliability for all measured indices. The level of independent measures of reliability were high and resembled those reported in study 1. These findings provide additional support for the reliability of the Polish version of abusive supervision scale.

Test of the predictive validity indicated that abusive supervision measure was related to perceived low leadership quality. It corresponds with findings that emphasize the associations of abusive supervision and lack of trust in management (e.g. Chen and Wang, 2017). We also found positive and moderate correlations between abusive supervision and counterproductive work behavior. This result corroborates previous studies on the relationship between abusive supervision and counterproductive work behavior (e.g. An and Wang, 2016; Zhang and Liao, 2015) and further supports the evidence that workers who are victims of abusive supervision engage in a supervisor-directed and organization-directed deviance (e.g., Michel et al., 2015). These relationships may represent a specific retaliation mechanism directed at the personal sources of abuse (like supervisors) or impersonal sources, i.e. organization. Consistent with previous research (e.g. Lyu et al., 2016; Sungu et al., 2020), the current study provides further evidence to negative relationships between abusive supervision and employees work engagement. It seems possible that employees' psychological strain due to abusive supervision consumes the resources of energy, vigor and positive attitude towards fulfilling tasks thus resulting in diminished work engagement. In sum, study 2 confirmed the single-factor structure of the full and a short form of abusive supervision scale, its high reliability and predictive validity in the context of Polish organizations.

Conclusions

In the present research we have validated a full and a short form of the abusive supervision scale in the Polish organizational context. In study 1, we investigated one-factor structure of the full, 15-item form of abusive supervision scale thus supported previous studies (Tepper, 2000; 2007). Additionally, we developed a short, unidimensional form of the scale, that consists of 8 items. As such, the short abusive supervision scale appears to be a viable alternative to the full version. Developing shorter scale forms accords with a long-standing recommendation to strive for parsimonious solutions in scale development research (Boateng et al., 2018). In study 2, using an independent sample, we have confirmed one-factor solution of a full and a short form of the scale. Thus, support for unidimensional structure is convincing for both forms of Tepper's scale. In the two studies both forms of abusive supervision scale revealed high reliability in terms of internal consistency, discriminating power, and temporal stability.

Our findings provided support for high predictive validity of both forms of the abusive supervision scale (e.g. Skogstad et al., 2014; Wang et al., 2020; Zhang and Liao, 2015). In study 1 and in study 2 we established relationships between abusive supervision and employee work-related variables. Specifically, in study 1 we found that abusive supervision is significantly negatively related to trust regarding management, mutual trust between employees, organizational justice, work effectiveness, and work satisfaction. These results correspond with previous findings, which demonstrated associations of abusive supervision with analogues variables like management unjust behavior (e.g. Liu et al., 2012), retaliation against other co-workers (e.g. Park et al., 2015), job satisfaction (e.g. Wang et al., 2020), low performance (e.g. Chen and Wang, 2017; Zhang and Liao, 2015) and confirm predictive validity of the full and a short scale of abusive supervision. Also, study 1 revealed that abusive supervision is significantly positively related to stress symptoms such as somatic and cognitive, and offensive behaviors, like gossip and slander, conflicts and quarrels, and unpleasant teasing. The level of the relationships was low to moderate. Similar results were provided by Tepper et al., (2007), Wu et al., (2012) or Zhang and Bednall (2015) in relation to abusive supervision and

employees distress. In study 2, we have found that abusive supervision significantly negatively correlated with leadership quality, employees work engagement including vigor, dedication, and absorption. Also, abusive supervision significantly positively related to counterproductive work behaviors, like sabotage, abuse, withdrawal or theft. These findings are consistent with earlier studies showing that abusive supervision is associated with negative perception of leadership (e.g. Mackey et al., 2017), counterproductive work behaviors (e.g. An and Wang, 2016), personal problems that undermine commitment and engagement (e.g. Zhang and Liao, 2015), and further substantiate predictive validity of the full and a short scale of abusive supervision. In sum, this research indicates that a full-length- and a short scale of abusive supervision are psychometrically sound instruments to measure abusive supervision in Polish organizational settings. The preliminary characteristic of this research shall prompt to initiate studies to further validate the scales as well as additional studies into the pervasiveness of abusive supervision in organizations. This is especially important, because substantial amount of research has proven how detrimental abusive supervision may be for organizations and employees alike.

Abusive supervision scale may be a useful instrument in management research as well as in human resources management practice. It may help to identify undesirable organizational behaviors among managers and supervisors in the context of Polish organizations. By acknowledging that supervisory abuse does take place in the workplace this research is yet another statement that the negative organizational processes, to some extent, are still widespread, but often neglected by organizational decision makers. The enormous amount of research on destructive forms of leadership may be striking, researchers however shall investigate it deeper, further and more coherently in order to understand better the subtle differences between various kinds of destructive leadership, its antecedents, outcomes, and consequences, to challenge the organizational decision-makers and redirect their focus to these highly consequential social processes. For practical purposes, in cases where workers perceptions of abusive supervision are sound, managers should be trained to deal with the sources of the abuse.

Our research contributes to the current body of knowledge in three ways. First, we have provided a Polish version of the scale to measure abusive supervision in organizational context. Second, we developed a short form of this scale with good psychometric properties. Given its further verification, the short form may be a practical alternative to the full scale, both, in research and practice. Third, we have confirmed predictive validity of the full and a short abusive supervision scale. Since our data were collected in a different culture in comparison to data from the existing studies, we have also added support to the universality of Tepper's abusive supervision scale.

Limitations

The present study, like any other, has certain limitations. First, the measurement pertains to the perception of the attitudes and behaviors of abusive leaders. Perceptual inferences made by individuals may be influenced by a series internal i.e. personality characteristics, past experiences, and external factors i.e. organizational norms or type of industry. Nevertheless, the confirmation of this study's results with prior studies enhances our confidence on the generalizability of conclusions. The data set analyzed in this research was gained from organizations of different sectors. While this is important in order to gain a broader image of the abusive supervision structure, it limits conclusions for the contextual knowledge. Certainly, it would be noteworthy to see whether yielded in this study exploratory factor analysis model can be replicated in different contexts, like sectors, e.g. manufacturing, business services, government institutions or professional groups, e.g. IT, medical, public safety or educational.

Abstract

The article deals with a number of application models that lead to the use of the apparatus of continued fractions, and the algorithms for the obtained models. This is, in particular, the model of the mechanism of genetic control, the model of the mechanism of infectious disease, the task of optimal regulation and proposes approximate methods for the expansion of nonlinear integral equations by continued fractions operator. To understand nonlinear aspects of reality in the scientific method, it can be used a description of such non-linearity, including using nonlinear equations of differential and integral equations. To solve such equations can be used as state-dependent Riccati equation (SDRE) as periodic function to study interactions. This work discusses continuous fractions operator (OCF) to solving non-linear integral equations. That approach can be used in iterative procedures and in engineering software packages. General nonlinear equation can be express by continuous fractions operator (OCF), and subset of it - equation of Low type – by periodic OCF. Then the operator of branched continued fractions (OBCF) can be used for more general nonlinear integral equation. Considering the indicated signs of convergence of OBCF indicate the ability to calculate solution of non-linear integral equations with the given accuracy based on the given inequality checking.

Keywords: Nonlinear Integral Equations, Continued Fraction Operator, Convergence of The Computational Process.

Introduction

Most of the complex phenomena of the world around us is nonlinear. To understand such aspects of reality in the scientific method, we use a description of such non-linearity, including using nonlinear equations of differential and integral equations. A variety of methods, including calculation methods, are used to solve such systems of equations (Volterra, 1982). One such method is the state-dependent Riccati equation (SDRE), which can reduce computational load online (Bernat et al, 2018; Gad-El-Hak, 2019; Znoijil, 1989). Another recently proposed method of solving differential equations of nonlinear systems, which are also non-linear and can be solved using iterative procedures, is the use a periodic function to study interactions (Sobczyk and Radzik, 2018). This article proposes a different approach to this problem. The application of continued fractions operator (OCF) to solving non-linear integral equations is discussed. This solution can be used in iterative procedures and in engineering software packages.

Main Results

Model of The Mechanism of Genetic Control

The mechanism of genetic control can be described using a primary gene product *X*, a winter protein *Y* defined by this genome, and a metabolite produced by the metabolic *Z* activity of the protein. Let *x, y, z* be the concentrati enetic product is described by equations

$$x' = \frac{1}{1+z} - \alpha x, \quad y' = x - \beta y, \quad z' = y - \gamma z \tag{1}$$

where α, β and γ are the positive steels. The solution of this system can be written in the form of an integral continued fraction. To do this, write down system (1) in matrix form

$$\Omega'(t) = A\Omega(t) + f(t) \tag{2}$$

where

$$\Omega = \begin{pmatrix} x \\ y \\ z \end{pmatrix}, \ f = \begin{pmatrix} \frac{1}{1+z} \\ 0 \\ 0 \end{pmatrix}, \ A = \begin{pmatrix} -\alpha & 0 & 0 \\ 1 & -\beta & 0 \\ 0 & 1 & -\lambda \end{pmatrix}$$

The Cauchy problem for system (1) is reduced to a nonlinear Volterra integral equation

$$\Omega(t) = \Phi_A(t,0)\Omega_0 + \int_0^t \Phi_A(t,s)f(s)ds \tag{3}$$

Here $\Phi_A(t; s)$ is the matriciant of the square matrix A

$$\Omega_0 = \begin{pmatrix} x(0) \\ y(0) \\ z(0) \end{pmatrix} \equiv \begin{pmatrix} \omega_1^{(0)} \\ \omega_2^{(0)} \\ \omega_3^{(0)} \end{pmatrix}$$

If

$$\Phi_A = \begin{pmatrix} \Phi_{11} & \Phi_{12} & \Phi_{13} \\ \Phi_{21} & \Phi_{22} & \Phi_{23} \\ \Phi_{31} & \Phi_{32} & \Phi_{33} \end{pmatrix}$$

then

$$z(t) = \sum_{i=1}^{3} \Phi_{3i}(t,0)\Omega_i^{(0)} + \int_0^t \Phi_{31}(t,s)\frac{ds}{1+z(s)} \tag{4}$$

The relation (4) allows us to construct the expansion into an integral continued fraction

$$b_0(t) + \int_0^t \frac{\Phi_{31}(t,\tau_1)d\tau_1}{1 + b_0(\tau_1) + \int_0^t \frac{\Phi_{31}(t,\tau_2)d\tau_2}{1 + b_0(\tau_2) + \ldots}} \tag{5}$$

which

$$b_0(t) = \sum_{i=1}^{3} \Phi_{3i}(t,0)\Omega_i^{(0)}$$

It is easy to check that the periodic integral continued fraction (5) is positive within variable boundaries of integration. Therefore, it is convergent and its value is equal to the solution *z(t)* of system (1).

The simplest model of infectious disease.

Consider a delayed model that effectively describes not only the body's immune response but also the dynamics of the disease as a whole, developed by G. Marchuk and co-authors (5)

$$\begin{aligned} \frac{dv}{dt} &= (\beta - \gamma F)V, \\ \frac{dC}{dt} &= \xi(m)\alpha F(t-h)V(t-h) - \mu C(C - C^*), \\ \frac{dF}{dt} &= pC - 10\eta\gamma FV - \mu_F F, \\ \frac{dm}{dt} &= \sigma V - \mu_m m, \end{aligned} \tag{6}$$

where V – is the amount A_r in the body; C – the number of plasma cells that reproduce antibodies *F; m* – relative characteristics of the diseased part of the body. All the constants that are in the equation system are inalienable.

Consider the process of chronicity of the disease, which is one of the pressing problems of modern medicine. In this case $\xi(m) = 1$:, in system (6), we replace the independent variable $t = \tau + h - 1$. Next we denote

$$V(\tau+h-1) = x_1(\tau),\ C(\tau+h-1) = x_2(\tau),$$
$$F(\tau+h-1) = X_3(\tau),\ m(\tau+h-1) = x_4(\tau).$$

Then after approximati[illegible]cheme of the previous point, we obtain a system of ordinary differential equations. This system is a system with quadratic non-linearity. It can be solved according to the scheme of the previous paragraph.

The problem of the optimal linear controller.

Let the state of a linear stationary control system be described by the equation

$$x(t) = Ax(t) + Bu(t) \tag{7}$$

Here A – $n\times n$ matrix, and B – $n\times m$ matrix, and the quality criterion is set using functional

$$J(u) = \int_0^\infty \left(x^T Qx + u^T Ru\right)\, dt,$$

where Q,R –- are symmetric matrices, R – positively defined, Q – additionally half-defined.

Then system (7) is reduced to the Riccati equation:

$$XBR^{-1}B^T X - A^T X - XA - Q = 0. \tag{8}$$

For a discrete stationary control system, the problem of the optimal controller is reduced instead of (7) to the discrete Riccati equation (all the coefficients of this equation are valid:

$$A^T XA - X - A^T XB\left(R + B^T XB\right)^{-1} B^T XA + Q = 0. \tag{9}$$

Here, the matrix A and B describes the state of the system

$$x(k+1) = Ax(k) + Bu(k),\quad A - n\times n,\quad B - n\times m,$$

and symmetric matrices Q and R set the quality criteria

$$J = \sum_{k=0}^{\infty}\left[x^T(k)Qx(k) + u^T(k)Ru(k)\right].$$

The R is positively defined, and Q additionally half-defined.

The solution of system (9) may be represented by a periodic matrix fraction.

$$X = -\frac{(A^{-1})^T Q|}{|E + BB^{-1}A - A} - B\frac{RB^{-1}A|}{|R} - B^T\frac{(A^{-1})^T QB|}{|E + BB^{-1}A - A} - \\ - \ldots - B\frac{RB^{-1}A|}{|R} - B^T\frac{(A^{-1})^T QB|}{|E + BB^{-1}A - A} - \ldots; \tag{10}$$

Considering a nonlinear equation.

Let us consider a nonlinear integral equation

$$X(u,v) = A(u,v) + \int^b\int^b X(u,\tau_1)B(\tau_1,\tau_2)X(\tau_2,v)d\tau_1 d\tau_2 \tag{11}$$

It is known that the concept of the product of two square matrices $||a_{i;k}||$ and $||b_{k,j}||$ for ($i = 1, 2, \ldots, n$; $j = 1, 2, \ldots, n$; $k = 1, 2, \ldots, n$) can be generalized in the case of matrices with an infinite number of elements. For this purpose (Syavavko, 1994), for the notion of the compositional product of the second kind of two functions $f(x, y)$ and $g(x, y)$ the rule is introduced

$$K(x,y) = \int_a^b f(x,\xi)g(\xi,y)d\xi$$

where a and b are constants.

Given this, equation (11) can be rewritten in the form

$$X(u,v) = A(u,v) + \int_a^b \left(\int_a^b X(u,\tau_1) B(\tau_1,\tau_2) d\tau_1 \right) X(\tau_2,v) d\tau_2 \tag{12}$$

Then fixing v, we will introduce the operation

$$(I-K)^{-1} f(u) = f(u) + \int_a^b R_K(u,\tau_2) f(\tau_2) d\tau_2$$

where $R_K(u, \tau)$ is the resolvent core of the function $K(u, \tau)$. Then (11) can be rewritten in the form

$$X(u,v) = A(u,v) + \int_a^b R_{k_1}(u,\tau_2) A(\tau_2,v) d\tau_2 = (I-K_1)^{-1} A \tag{13}$$

where

$$K_1(u,\tau_2) = \int_a^b X(u,\tau_1) B(\tau_1,\tau_2) d\tau_1$$

X can be symbolically written in the form

$$X = \frac{A}{I - XB}$$

Using this expression, we can develop X in the next OCF

$$X = \cfrac{A}{I - \cfrac{AB}{I - \cfrac{AB}{I - \ddots}}} \tag{14}$$

Equation of Low type.

Equations of type (11) also include a nonlinear singular integral equation of Low type (Znoijil, 1989). This class of equations arises when describing $\pi - N$ amplitudes of sifting in relativistic energies.

$$X(u,v) = A(u,v) + \int_0^\infty \int_0^\infty \tau_1^2 \tau_2^2 X(u,\tau_1) B(\tau_1,\tau_2) X^*(v,\tau_2) d\tau_1 d\tau_2 \tag{15}$$

where

$$A(\tau_1,\tau_2) = \tau_1^{-2} \delta(\tau_1 - \tau_2) S(\tau_1),$$

$$S(\tau_1) = \frac{1}{E(\tau_1) - E(v) - ie},$$

$$E(z) = (M_w^2 + z^2)^{1/2} + (M_\pi^2 + z^2)^{1/2}$$

For the compactness of equation (15), we can use the operator statement

$$X = A + XBX^*$$

and, consequently,

$$X(I - BX^*) = A,$$

or

$$X = A(I - BX^*)^{-1}$$

In addition,

$$X^* = (I - XB^*)^{-1}A^*$$

So,

$$X = A(I - B(I - XB^*)^{-1}A^*)^{-1} \tag{16}$$

Applying relation (16), we will receive the following development in the periodic OCF

$$X = A\cfrac{I}{I - B\cfrac{I}{I - A\cfrac{I}{I - B\cfrac{I}{I - A\cfrac{I}{I - \ddots}B^*}A^*}B^*}A^*} \tag{17}$$

More general equation.

This approach can be applied to a more general nonlinear integral equation

$$X(t) = f(t) + \int_0^b K_1(t,\tau)X(\tau)d\tau + \int_0^b\int_0^b K_2(t,\tau_1,\tau_2)X(\tau_1)X(\tau_2)d\tau_1 d\tau_2 \tag{18}$$

Let us consider some elements of the analytic theory for the operator of branched continued fractions (OBCF) in general form, suitable for both formulas (14) and (17). To this end, we introduce the notation

$$\begin{cases} D_1 = \sum\limits_{k_1=1}^{n} a_{k_1} b_{k_1}^{-1} c_{k_1}, \\ D_2 = \sum\limits_{k_1=1}^{n} a_{k_1}(b_{k_1} + \sum\limits_{k_2=1}^{n} a_{k_1k_2} b_{k_1k_2}^{-1} c_{k_1k_2})^{-1} c_{k_1}, \\ \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots \\ D_m = \sum\limits_{k_1=1}^{n} a_{k_{(1)}} \left(b_{k_{(1)}} + \dots + \sum\limits_{k_m=1}^{n} a_{k_{(m)}} b_{k_{(m)}}^{-1} c_{k_{(m)}} \right)^{-1} c_{k_1}, \end{cases} \tag{19}$$

where $k(i) = k_1k_2\dots k_i$ – are abbreviations for multi indices, $a_{k(s)}$, $b_{k(s)} \in X$ – restricted nonsingular operators over a field X.

<u>Definition 1</u>. The finite fraction $D_m.(m = 1, 2, \dots)$ is called the approaching fraction of the infinite OBCF

$$D = \sum_{k_1=1}^{n} a_{k_{(1)}} \left(b_{k_{(1)}} + \dots + \sum_{k_m=1}^{n} a_{k_{(m)}} (b_{k\{m\}} + \dots)^{-1} c_{k_{(m)}} \right)^{-1} c_{k_1}, \tag{20}$$

Introduce the notation:

$$\begin{cases} D_{k_{(m)},m} = b_{k_{(m)}}, \\ \dots\dots\dots\dots\dots\dots\dots\dots \\ D_{k_{(s)},m} = b_{k_{(s)}} + \sum\limits_{k_{s+1}=1}^{N} a_{k_{(s+1)}} \left(b_{k_{(s+1)}} + \dots + \sum\limits_{k_{(m)}=1}^{n} a_{k_{(m)}} b_{k_{(m)}}^{-1} c_{k_{(m)}} \right)^{-1} a_{k_{(s+1)}}, \quad (s < m) \end{cases} \tag{21}$$

Before we consider the signs of convergence for OBCF, we formulate the assertion needed to prove their convergence.

Lemma 1. If for OBFC, all $D_{k(s),m}$ $(k_s = 1, 2, \ldots, n;\ s = 1, 2, \ldots;\ m = s, s + 1, \ldots)$ have an inverse to all $k_s = 1, 2, \ldots, n;$ $s = 1, 2, \ldots, m-1;\ l = 1, 2, 3, \ldots;\ m = s, s+1, \ldots;$ equality is valid

$$D_{k_1k_2..k_s,m+l} - D_{k_1k_2..k_s,m} = (-1)^{m-s+1} \sum_{k_{s+1},..k_{m+1}=1}^{n} \prod_{j=s+1}^{m} D^{-1}_{k_1k_2..k_j,m} \times \\ \times \prod_{j=s}^{m} D^{-1}_{k_1k_2..k_{m+s+1-j},m+l} a_{k_1k_2..k_{m+s+1-j}} c_{k_1k_2..k_{m+s+1-j}} \tag{22}$$

Corollary 1. If the conditions of Lemma 1 are satisfied for the OBFC, then the difference $m = 1, 2, \ldots;\ l = 1, 2, 3, \ldots$ between its approach fractions can be calculated by the following formula

$$D_{m+l} - D_m = (-1)^{m+1} \sum_{k_1,k_2,\ldots,k_{m+1}=1}^{n} \prod_{j=1}^{m} D^{-1}_{k_{(j)},m} \prod_{j=1}^{m+1} D^{-1}_{k_{(m+2-j)},m+l} a_{k_{(m+2-j)}} c_{k_{(m+2-j)}} \tag{23}$$

Corollary 2. If for the OBFC the conditions of the lemma are fulfilled, then all of the residual term R_m can be calculated by the formula

$$R_m = D_\infty - D_m = (-1)^{m-1} \sum_{k_{(m+1)}=1}^{n} \prod_{j=1}^{m} D^{-1}_{k_{(j)},\infty} \prod_{j=1}^{m+1} D^{-1}_{k_{(m+2-j)},m} a_{k_{(m+2-j)}} c_{k_{(m+2-j)}} \tag{24}$$

where $D_{k(j),\infty}$ – the remains of the infinite OBFC for $m = 1, 2, \ldots$.

Definition 2. OBFC is called absolutely convergent, if the following series, composed of its approach fractions is conver $\sum_{\nu=0}^{\infty} \|D_{\nu+1} - D_\nu\|$

Definition 3. Let's say that one OBFC G has a higher value than another OBFC D, if there exists such an integer and positive number n_0, which for all integers M is such that for the ratio $n > n_0$ and $m > n_0$ the inequality

$$\|D_n - D_m\| \le M \|G_n - G_m\| \tag{25}$$

is true, where D_i, G_i – the apl BFC.

Convergence signs of OBCF.

A series of sufficient signs of convergence has been obtained for operator BFCs (Nedashkovsky, 2004).

Theorem 1. (Sign of Majority.) If the condition of Lemma 1 is satisfied for OBFC and there is such an absolutely convergent numerical branching fraction

$$\hat{b}_0 + \mathop{D}_{s=1}^{\infty} \sum_{k_s=1}^{n} \frac{\hat{a}_{k_{(s)}}}{\hat{b}_{k_{(s)}}} \tag{26}$$

with signified partial numerators that

$$\hat{D}^{-1}_{k_{(s)},m} \ge \|D^{-1}_{k_{(s)},m}\| > 0; 1 \le k_s \le n; s = 1, 2, \ldots; m = s + 1; s + 2, \ldots, \\ \|a_{k_{(s)}}\| \le |\hat{a}_{k_{(s)}}|; 1 \le k_s \le n; s = 1, 2, \ldots, . \tag{27}$$

then this OBFC is also absolutely convergent.

Definition 4. Let M be a subset of a Banach space $X \times X$. We will call M the domain of convergence of the branched continued fraction (20) with operator elements, if for all $a_{k(s)} \in M$ and $b_{k(s)} \in M$, the given OBFC coincides.

Definition 5. A closed subset of the linear space, which includes the value of the branched chain fractions, as well as the value of all of the approach fractions of OBCF (20), provided that all $a_{k(s)}$, $b_{k(s)} \in M$, is called the domain of the fraction (20) .

Theorem 2. OBFC (10) with elements satisfying the conditions

$$\left\| b_{k_{(s)}}^{-1} \right\| < \frac{1}{\left\| a_{k_{(s)}} \right\| \left\| c_{k_{(s)}} \right\| + n}, \quad (1 \le k_s \le n, s = 1, 2, 3, ...) \tag{28}$$

absolutely coincides, and its plural of values is an area

$$\{z \in X : \|z\| \le n\}. \tag{29}$$

Theorem 3. If the OBFC elements (20) satisfy the condition

$$\left\| b_{k_{(s)}}^{-1} \right\| < \frac{1}{1 + \sum\limits_{k_{s+1}=1}^{n} \left\| a_{k_{(s+1)}} \right\| \left\| c_{k_{(s+1)}} \right\|} \quad (1 \le k_s \le n, \quad s = 1, 2, ...) \tag{30}$$

then the fraction is absolutely identical, and its set of values is an area

$$\left\{ z \in X : \|z - b_0\| \le \sum_{k_1=1}^{n} \|a_{k_1}\| \|c_{k_1}\| \right\}. \tag{31}$$

Signs of convergence for OBFC of a special form.

By analogy with the features of (29) and (31), we can obtain a number of convenient enough criteria for convergence for fractions with operator elements of a special form.

$$\sum_{k_1=1}^{n} a_{k_{(1)}} \left(E + ... + \sum_{k_m=1}^{n} a_{k_{(m)}} (E + ...)^{-1} c_{k_{(m)}} \right)^{-1} c_{k_1}, \tag{32}$$

Theorem 4. The fulfillment of the condition

$$\|a_{k_1 k_2 ... k_i}\| \|c_{k_1 k_2 ... k_i}\| < \frac{1}{4n} \quad (i = 1, 2, ..; \quad k_i = \overline{1, n}) \tag{33}$$

is sufficient for the absolute convergence of the operator branched chain fraction (32).

Theorem 5. If conditions are satisfied for all $i = 1, 2, ...; k_i = 1, 2, ..., n$

$$\sum_{k_i=1}^{n} \|a_{k_1 k_2 ... k_i}\| \|c_{k_1 k_2 ... k_i}\| < \frac{1}{4} \tag{34}$$

then the operator BFC (23) is absolutely convergent.

The sufficient features offered are simple and easy to use. They can find practical use, in particular in computer algebra systems, and serve as the basis for obtaining other sufficient features for OBCFs. In fact, the same signs of convergence for matrix branching chain fractions have already been submitted (Nedashkovsky, 2004), but it is equally important to obtain reliable criteria for completing iterations and the convergence of the computational process (14) or (17) precisely to the solution of a particular equation.

Signs of convergence of operator branching chain fractions to solutions.

It is assumed that the solution of some equation (14) or (17) is on a certain interval of convergence of OBCF. Of course, the corresponding fraction will be convergent, and even more so, converging to a solution only under certain conditions. To study the problem of convergence in the solution of such developments, let us consider the non-canonical operant branch continued fraction (20) and formulate the criteria for making a decision on the termination of iterations and the convergence of the process precisely to the solution of specific equations.

Conclusions

Thus, the approaches to calculating the tuples of solutions of matrix polynomial equations are given, and sufficient criteria for the completion of iterative processes and their convergence to the solution are formulated.

Theorem 6. If there is only one solution of the polynomial integral equation (1) or (5) in the interval, then its corresponding expansion (4) or (7) under the iterative procedure in the OBCF with the elements satisfying the conditions

$$\left\|b_{k(s)}^{-1}\right\| \leq \frac{1}{\left\|a_{k(s)}\right\| \left\|c_{k(s)}\right\| + n} \quad (1 \leq k_s \leq n; s = 1, 2, ...) \tag{35}$$

converges to this solution.

Theorem 7. If in the range

$$\left[-\sum_{k_1=1}^{n} \|a_{k_1}\| \|c_{k_1}\|, \sum_{k_1=1}^{n} \|a_{k_1}\| \|c_{k_1}\|\right],$$

there exists only one solution of the integral equation (11) or (15) , then its development (14) or (17) under the iterative procedure in the OBCF with the elements satisfying the conditions

$$\left\|b_{k_{(s)}}^{-1}\right\| \leq \frac{1}{1 + \sum\limits_{k_{s+1}=1}^{n} \left\|a_{k_{(s+1)}}\right\| \left\|c_{k_{(s+1)}}\right\|} \quad (s = 1, 2, 3...). \tag{36}$$

converges to this solution.

The indicated signs of convergence indicate the ability to calculate Xm with the given accuracy based on inequality checking

$$\|X_m - X_{m-1}\| \leq \varepsilon$$

if one of the following sufficient signs of convergence to the solution is fulfilled. In this case

$$\|X_m - X\| < \|X_m - X_{m-1}\|$$

and therefore $X \subset (\|X_m\|, ; \|X_{m-1}\|)$.

It should be noted that in practice iterative computation processes are often convergent under significantly less stringent conditions. And numerous results of computational experiments convincingly confirm this fact.

Abstract

Entrepreneurs have to compete to survive in the ever-changing business environment especially during this Covid-19 Pandemic. Hence, there is an urgent need to find out solutions and survival strategy that can help cushion the effect of this crisis so that the SMEs can have a soft-landing at best. The study thus seek to find the influence of customer orientation on market dynamism. The study employed the qualitative approach where 12 top executives of registered four indigenous SMEs associations in Nigeria were interviewed. The study found out that customer orientation has a significant effect on market dynamism and the study recommended that entrepreneurs should involve in thorough analysis and modelling of the business during any market change and the customers satisfaction should be taken as top priority.

Keywords: Market, Customer, Pandemic, Dynamism, Entrepreneurs

Introduction

In Nigeria today, there is a need for the entrepreneurs to respond actively to the ever-changing market and business environment. The government, consumers and producers influence market changes greatly in this country (Chinwuba, Luke, Marcus & Kenechi, (2018). This has however, become a very great challenge for small and medium scale enterprises, who have a lot at stake especially at the start-up stage of their business. Many businesses are struggling to survive because there has been a severe fluctuation in the demand, supply and prices of goods and services especially due to the current ongoing corona virus pandemic (Omar, Ishak & Jusoh, 2020) Business survival has become topmost on the list of all SMEs owners at this crucial time, especially in Nigeria, where the government have done little or nothing to assist the entrepreneurs to sail through the pandemic (Musa & Aifuwa, 2020). To achieve a successful business in a dynamic market environment, (Islam, 2020) asserted that business owners should be able to identify the changes, understand the consequences and evaluate their resources and capabilities to fit into the emerging changes. This is especially challenging to organizational managers since they have to design and implement strategies

that can achieve and sustain higher performance levels (Uchegbulam, Akinyele & Ibidunni, 2015). A dynamic market can affect the effectiveness of the firm's behavior and changes in customer behaviors are difficult to predict at this time (Zehir &Balak, 2018). Market dynamism can offer new and broader perspectives that will help to solve the firm's problems and capture new opportunities (Zehir &Balak, 2018). Apart from environmental conditions, market dynamism is emphasized as another important factor that affects firm performance (Zehir & Balak, 2018). Studies have also shown that reconfiguration plays a very significant role for entrepreneurs in achieving global account competitiveness when market dynamism is high (Shi & Wu, 2011).

Research has shown that for the business to succeed there is a need to focus more on the customers (Gerald, Obianuju & Chukwunonso, 2020). This can be by ensuring that the product, services, discoveries, innovation and creativity is all about the customers. This is important because without the customers, the business have no reason for existence. It is not easy to recognize and satisfy the consumers' needs, expectations and habits, and knowing them doesn't guarantee success on the market, because consumer behaviour is not rational (Biesok & Wyród-Wróbel, 2011). Customer orientation is perceived by Domi, Capelleras and Musabelliu (2020) as a business approach in which a business focuses and solves for the customer first. Consequently, there is a need to investigate if adopting a customer-oriented approach can help SME owners to survive the ongoing market fluctuation. If so, what are the necessary things to put in place to ensure the success of this approach? Hence, this study aims to establish the influence of customer orientation on market dynamism with reference to SMEs in Nigeria. The hypothesis of the study is therefore, written as:

H_0: There is no significant relationship between customer orientation and market dynamism

Methodology

The paper adopts an exploratory research design in which the researcher had an in-depth interview with twelve top executives of the Association of Micro Enterprise (AMEN), NASME Women Group (NASME), National Association of Small Scale Industrialist (NASSI) and NECA's Network of Entrepreneurial Women (NNEW). The interview responses were analysed using the thematic coding method.

Analysis and Findings

Four (4) participants opined that their approach to addressing issues with **customer relations** is based on the common philosophy that the "customer is always right" The participants were also of the view that making one customer happy impact on the extent to which a business is able to retain and attract new customers. Therefore, the participants discoursed that it is important to maintain business relations that keep customers happy by trying to resolve any problem or challenges related them. This suggests that the participants were not only interested in resolving customer issues but they were also concerned about them having positive emotions towards the business. Quotations from the participants' statements are documented below;

We are in business because of our customers, so whenever we have a difficult customer we make sure we find a way of resolving the customer's problem and make him or her happy. (Participant 9).

We understand that without customers there is no us so we try as much as possible to make our customer happy no matter what. (Participant 5).

We always look for ways to solve all customers' problems no matter how difficult they are. We understand that we are in business to solve their problems not to make them unhappy. (Participant 4).

Customers are always right, due some customer are very funny but we always look for a way to make our customer happy and have good relationship with them. (Participant 6).

However, three (3) of these participants were assertive with the fact that all attempts to satisfy customers, make them happy or resolve challenges related to customer complaints **should not be at the detriment** or expense of their business. Excerpts from the participants' statements are documented in the quotes below;

"As the say goes "customer is always right" so for our customers we always do what will make them happy because we believe a customer can tell five others that will also become your customers. So we always make sure our customers leave our environment happy no matter what happens we always try our best to solve their problems. Therefore, customers can be difficult but we are always ready to hear them out and find the best possible ways to solve their problem. Note we treat our customers well but not to our own detriment". (Participant 4).

"We are in business because we want to solve people's problems, so as for difficult customers we always find a way to make them happy but not at the detriment of the organisation". (Participant 1).

"You can do without difficult customers in your business but customers are always right. So our business tries as much as possible to satisfy our customers on any complain but we won't want any customer to ride on us thinking that we are weak or something, we don't take nonsense". (Participant 9).

Similarly three (3) of the participants opined that the interest of customers must be **prioritized** hence they look for all possible ways to solve customers' problems. However, responses from these participants suggests that customer relations may not really be about the emotions of customers, rather they were more focused on solving customer problems and challenges which to them is overarching and predominant. Excerpts from participant statements is documented in the quotes below;

"Our customer is our number priority because they are the reason we are in business. We make sure that we look for all possible ways to solve their problems". (Participant 7).

"One of our core values is good customer relations. We are in business to solve people's problems no matter how difficult the customer may be. (Participant 9).

A bad person also have a soft part. We tend to look at people from a positive angle always. However our major objective to all our customers is to make sure we solve their problems". (Participant 2).

Customers Involvement in providing Solutions

In contrast, two (2) participants were of the opinion that customer relations and dealing with challenges associated with customer complaints should be tackled by patiently and painstakingly explaining the position of the business to customers on various issues. The statements from these participants suggests that the position of their businesses over rules or supersedes the dissatisfaction or customers. Excerpts from participant statements is documented in the quotes below;

"Most of my clients are online because I sell my products online. Whenever a customer types an angry response I always take time off and I try to be patient with the customer no matter how angry they are. It is not easy at first to cultivate this habit but you know one has to move the business forward by rendering good customer service". (Participant 8).

"There is nothing like a difficult customer to me all you need to do is to explain things to them and I believe they will understand. I believe one on one marketing is a good way to go when it comes to difficult customers". (Participant 2).

Market Changes

Among the twelve (12) participants interviewed, five of them were of the opinion that adopting a customer focused orientation is the most suitable approach to adjust to market changes in the business environment. They were of the view that knowing what the customer wants and keeping a healthy customer relationship and sustaining customer satisfaction cannot be overemphasized. They were also of the belief that although competitor analysis, market analysis or innovation is necessary for adjustments to market changes however, these should be implemented with the sole aim of satisfying customers. Excerpts from the interviews are documented in the following paragraphs;
"Change is very important in this dynamic business world. I believe that as a business the world and the Nigeria business environment is changing and one of the ways to adopt to these changes is to know what our customer want and know if the change will not affect our relationship with them and to make sure that when implementing any change that has been adopted it brings about satisfaction for our customer and also our business" (Participant 9).
"I do market analysis to know what customers want to improve. I innovate to satisfy our customers because that is the reason we are in the market". (Participant 12)

"Market changes is all I have been doing since I started business. I started business because a friend asked where he could get coconut oil and I sold to that person and from that time there has always been market changes in the quantity of product demand, material and so on. What I do is to listen to customers and find out what they want to adjust". (Participant 7).

"The best way I adjust to changes in the market is to look at what my competitors are not doing and do it, with that it gives me an edge. For example I bring my product into small pack that it affordable. I listen to the customers and find out what they want in order to adjust". (Participant 3).

"The way I adjust to the market is to go to study the product of my competitor look at what they are not doing well, see what we are not doing, improve on our product and serve our customer better". (Participant 2).

In contrast, four (4) of the participants were of the opinion that an **analysis of the business model** with a view to developing and implementing a more suitable one is the appropriate approach to adjust to market changes in the business environment. They were of the opinion that how their businesses will gain from the changes should be the focus. Excerpts from the statements of the entrepreneurs are quoted as follows;

"I believe change is one of the things or catalyst you need to be prepared for as an entrepreneur, because of the very dynamic business environment. However my business is always open to change so whenever there is any change we first sit down look at what are the pros and cons of the change and how our business tend to gain form the change after the proper analysis". (Participant 1).

"As for changes in the market, what we do is to do analysis on how our organisation can benefits from the change and then we implement it into our business model". (Participant 4).

"We will come up with a model to work with immediately thereafter we implement" (Participant 8).

"In the Nigeria business environment it is good to know that it is not predictable so we are always for change and as entrepreneurs we will work on the existing business model and implement all necessary actions to adapt and adopt the change in our business environment" (Participant 11).

Three (3) participants were of the view that adjustments to market changes in the business environment should focus more on **reduction in cost of production** as well as deliberate and intentional actions to ensure that the business operations are sustained without incurring debts. This is depicted by the excerpts from the statements of participants below;
"Whenever there is change in the business environment we look at the way we can cut down cost of product of the material we use and other things such as advert, branding and so on. This is because the only constant thing in the business environment is change. (Participant 5).

"The only thing that happens is that we do analysis on how we can improvise and to adopt and adapt the changes to remain in business. We also look for other means to improve our business with incurring debt for our business" (Participant 10).

"Well, the best way I adjust to change in my business environment is to first sit down do a proper analysis of the change in question for example if there is increase in the price of materials we sit down to know what and what we need to cut down on any still give our customer a good and better serve". (Participant 6).

Implications and Conclusion

Customer focus is one of the ways to solve the market changes, but not the only solution. Other solutions based on the findings of this study includes reduction in cost of production, weighing the effect of current change on the business venture, analysis of the business model and involving customers in preferring solutions to the emerging state of the business environment. Based on the findings of the study, entrepreneurs must be ready to do the following:

i. A thorough market analysis;
ii. Development of a business model that can handle the emerging situation;
iii. Positive emotions towards the change;
iv. Building a strong customer relations;
v. Make customers the top priority.

This is in line with the study of Ogunnnaike, Salau and Adeniyi (2014) who asserted that customers are not only satisfied when they get good quality but how much they enjoy the product and services rendered by the entrepreneurs. This implies that the entrepreneurs should ensure that customers are get the best out of all their decisions despite any emerging change in the business environment.

Abstract

The article discusses the features of organizing employment through Internet platforms. The authors identify the main employment models, the advantages and disadvantages of working through platforms and the risks of social pollution of labor relations. To identify the main difficulties faced by employees, the ratings of the most popular platforms and services in Russia (Uber, YandexTaxi, YandexFood, Profi, Delivery Club) were studied, the least satisfaction was revealed in such parameters as career growth and relationships with managers. The overall assessment by platform workers does not exceed 2.5 points on a 5-point system, which allows us to conclude that there is a high level of social pollution. Based on the content analysis of the feedback from Delivery Club employees, the problem of illegal fines and deprivation of bonuses was diagnosed. The results of the study led to conclusions about the need to improve the legal regulation of labor relations in sphere of work based on digital platforms.

Keywords: Internet Platforms, Employment, Telework, Social Pollution, Rating, Content Analysis

Introduction

In the context of the development of the information society, along with the traditional "employee-employer" relationship, new non-standard forms of employment appear, including the organization of work through Internet platforms. Such platforms are most widely used in the field of transport (taxi ordering services Yandex, Uber), services (for example, the Profi.ru website). Researchers are also very active in analyzing the experience of Amazon (Irani, 2015), Airbnb (Schor, Attwood-Charles, 2017) and others. The model for the evolution of such relations became possible thanks to the information technology progress and it is considered to be a phenomenon of the fourth industrial revolution and globalization (Beerepoot, Lambregts, 2014). It can be assumed that in the digital economy, this form of organization of activities will become more widespread. The Uber model has already become common (Hill, 2015).

The creation of Internet platforms leads to the formation of new mechanisms for organizing and controlling labor. Internet platforms allow selecting performers, assessing their work, collecting feedback, and conducting training. The point of view is put forward that such a platform assumes the functions of a leader (Möhlmann, Zalmanson, 2017). The main advantages of organizing employment through the Internet platform include: 1) flexibility and mobility, 2) the ability to attract specialists from different cities not only of one country, but also of the world, 3) reducing the cost of organizing work spaces (Constantinides, Henfridsson, Parker, 2018).

The Internet platform also provides certain advantages for performers. First of all, this is the opportunity to get quick money. Whereas in traditional forms of employment, wages are usually paid twice a month, when working

Cite this Article as: Marina CHUDINOVSKIKH, Alena FEDOROVA, Ilona POLENTS and Aleksandr OVCHINNIKOV "Digital Labor Platforms as a Source of Social Pollution" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

through the platform, remuneration can be paid right after the order is completed. Internet platforms can provide jobs for residents of small towns, distanced areas.

Research interest is increasingly focusing on the disadvantages of digital labor platforms. Organization of work through Internet platforms has a number of organizational and legal problems that can be covered by the concept of "social pollution". In the framework of the study, social pollution is considered as the process of decreasing the quality of life, associated with damage to the well-being and damage to the physical and psychological well-being of workers as a result of internal and external economic activities of organizations (Fedorova, Menshikova, 2014, Koropets, 2019). Macklem points out that toxic jobs are characterized by "unquestionable demands, excessive pressure and cruelty" (2005). Factors of social pollution include: 1) violation of labor laws, 2) development of employment precarization, 3) the use of toxic human resource management practices, including toxic human technologies, toxic management and toxic jobs (Fedorova, Parsiukevich, 2013).

Internet platforms are transforming labor patterns, increasing the risk of labor law violations. The most important question is the status of a person who provides services through the Internet platform. The prevailing point of view is that there is no labor relationship between the contractor and the organizer of the Internet platform. Thus, in one of the Russian litigations, the driver, in order to substantiate claims for recognizing the relationship as labor relationship, provided printouts from his personal account - the orders that were completed by him through platforms of GetTaxiRus and Uber. However, the court decision states that “the execution of orders received from mobile applications does not indicate that the plaintiff has performed work under the labor contract during the disputed period,” including the part of it about “compliance with the Internal Labor Regulations, Labor Discipline, Work Regime time "(Appeal ruling of the Moscow City Court dated 12.04.2018 N 33-15213/2018). The taxi driver's claims for recognition of the relationship as labor relationship were denied. Working through Internet platforms can lead to precarization, that is, to the substitution of stable labor relations with unstable ones and then to the loss of social and labor rights.

A common position has not been developed in other countries either. So, there are court decisions on recognizing persons working through Internet platforms as self-employed. However, the development of such platforms causes formation of the opposite of above practice and a rethinking of the position of the judiciary. The example of UBER and other aggregator portals is illustrative. Appeal No. UKEAT / 0056/17 / DA, which has been ruled by the UK Employment Tribunal, may change the approach to business for Uber and other platforms that aggregate ads from individuals providing services. The plaintiffs were London Uber drivers who, along with others, filed lawsuits with the Employment Tribunal. They demanded to be recognized as workers with the aim of applying to them the 1996 Employment Rights Act, Working Time Regulations and the 1998 National Minimum Wage Act. The court concluded that any driver who had the Uber app turned on, was in an area that was allowed to work and was able and willing to accept assignments, worked for Uber London Ltd within the scope of an employment contract (Judgment of the Paris Court of Appeal (Cour d ' appel de Paris) dated December 13, 2017 in relation to drivers of "La Cab" company) (Adam, Bremermann, López, 2016). In general, most countries have not yet developed approaches to strict control over the activities of digital labor platforms, which allows a number of researchers to talk about the failure of legislative regulation (Collier, Dubal, Carter, 2017).

The peculiarity of the organization of labor using digital labor platforms is that instead of traditional bilateral relations (employee-employer), multilateral ties arise. Organization of work through Internet platforms provides for the participation in legal relations of at least three participants. Within such a legal relationship, the Internet platform provides the performer with information about the order and charges a certain commission. Potential performers respond to the emerging order. The execution of order can be occurred both with direct contact between the performer and the customer (for example, taxi services, tutors), or without it.

Another model implies that at least four types of participants are involved in legal relations. In the second model, the fourth participant is a legal entity or an individual entrepreneur who concludes an employment contract with direct executors. Such a four-part model is necessary if the activity, for example, is subject to compulsory licensing. For example, the field of transportation that involves not only the platform itself, the customer and the driver, but also the taxi stations. From a legal point of view, such a model gives an opportunity to achieve an optimal balance between employment flexibility and labor guarantees. In addition, in this case, the employer is obliged to comply with the standards for labor protection, safety of the services provided. However, from an economic point of view, such a model is less effective than a tripartite. An increase in the number of links in the chain of persons providing

services leads to an increase in cost and a decrease in competitiveness. Also, an increase in the number of participants and intermediaries leads to a dilution of responsibility. So, the registration of employees on the staff of logistics contractors is a normal practice for delivery aggregators or taxis: this allows the company to scale up faster. However, when disputes arise, Internet platforms often try to shift responsibility for problems onto intermediaries. For example, delays in payment for work performed are explained by the failure of settlements on the part of intermediaries.

Other challenges faced by digital platform workers include: difficulties in forming trade unions and collective defense of workers' rights (Vandaele, 2018; Bederson, Quinn 2011); hiring employees for short-term work and reducing the share of long-term labor relations (De Stefano, 2016).; a decrease in the level of social protection of employees (for example, in terms of the minimum wage, social and pension insurance, the provision of vacations and other guarantees) (Forde, Stuart, Joyce, 2017; Wood, Graham, Anwar, 2019); increasing intercountry, racial and gender inequality (Irani, Silberman, 2016; van Doorn, 2017; Schor, Attwood-Charles, 2017)

Thus, flexible forms of employment have become not only a phenomenon of the times, but also a huge challenge (Stone, 2006). Improving legal regulation should be aimed at solving the most pressing problems related to work through digital platforms, protecting workers' rights and reducing the level of social pollution. The development of directions for improving the legal framework should be promoted by highlighting the problems that workers most often face.

Methods

In order to determine the factors of social pollution connected with working through digital labor platforms, a number of methods can be used. In 2015, the http://faircrowd.work platform was launched, targeting workers in Germany, Austria and the Scandinavian countries (Harmon, Silberman, 2019) On this platform, employees rate platforms on a five-point scale. Several years of work of the platform showed that the rating is significantly influenced by the duration of work on the platforms, national and cultural characteristics. In order to provide more accurate information, the rating can be supplemented with a questionnaire (Adam, Bremermann, López, 2016) or a detailed review. Analyzing feedback and conducting employee interviews complements quantitative research methods and delineates more clearly the range of problems employees' face (Aloisi, 2016).

In the Russian Federation, employee reviews on the specifics of interaction with digital labor platforms are presented on a number of websites (https://pravda-sotrudnikov.ru/, https://antijob.net/, https://otrude.net/ and others). We chose the website https://otrude.net/ as the most informative and objective. Employee feedback was analyzed using a quantitative method (rating assessment of working conditions) and qualitative analysis (content analysis of the narrative part). The main goal of the study is to highlight problem areas and factors of social pollution.

Results

At the first stage, with the help of the website https://otrude.net/, a basis for the assessment was formed. The sample includes 5 most popular services in Russia – Uber, Delivery Club, Profi, YandexFood, YandexTaxi. For each service, the number of reviews, their time and geographic range, the total rating of each company and its detailing by separate components (remuneration, relations with management, workplace, team, career growth) are determined.

Table 1: Assessment of the largest digital labor platforms in Russia according to employee reviews on the website https://otrude.net/*

Features	Uber	Delivery Club	Profi.ru	Yandex Food	Yandex Taxi
Range of reviews	2017–2019	2020–2012	2014–2020	2018–2020	2017–2020
Total number of reviews	372	234	199	61	44
Overall rating on a 5-point scale	1,8	2,5	2,5	1,9	2,3

Including salary	1,6	2,2	2,6	1,8	2,2
Relationships with management	1,8	2,2	2,3	1,6	2,0
Workplace	2,3	2,8	2,6	2,0	2,9
Team	2,1	3,3	2,6	2,7	2,7
Career	1,4	2,2	2,2	1,3	1,9

**Authors' elaboration*

As the data shows, the largest number of reviews is presented for Uber, but since 2019, the website has not generated any actual reviews. In second place is the Delivery Club service. There were 199 reviews about the Profi platform, 61 reviews about Yandex.Food, 44 reviews about YandexTaxi. The presented data show that, in general, the level of employee satisfaction with working conditions through the platforms is low (does not exceed 2.5 points on a 5-point system). The lowest degree of satisfaction, regardless of platform, was recorded for the components "Relations with management" and "Career". From a geographical point of view, reviews are most often left by residents of cities with a population of more than 1 million people (Moscow, St. Petersburg, Novosibirsk, Yekaterinburg).

Next, we carried out a content analysis of the narrative parts of the reviews about Delivery Club. The choice of the company is explained by the largest number of reviews for the period from 2012 to 2020. The share of Delivery Club in the ready-made food delivery market at the end of last year was estimated at 48%, together with Yandex. Food they control 80% of the market. The main owner is JV Mail.Ru Group and Sberbank O2O Holding (98.1%), revenue in 2019 - 4.46 billion rubles. It is significant that 69 out of 234 employees of the Delivery Club Company recommend work in the company, 64 do not recommend the company for employment and 101 abstained from the assessment. The results of content analysis of the semantic core of feedback from Delivery Club employees are presented in the table

Table 2: Semantic core of feedback from Delivery Club employees *

Semantic core	Frequency of mention	Frequency of mention, %
Shift	98	1.15
To work	88	1,15
Order	76	1,04
Courier	74	0,89
Fine	61	0,87
Work	52	0,72
A lot	49	0,61
Salary	41	0,58
Hour	38	0,48
Month	33	0,45
Week	26	0,39
Sweat	18	0,31
Chat	18	0,21

**Authors' elaboration*

The semantic core allows you to accurately characterize the work even if you do not name the company and the specifics of its activities. The main staff is couriers who deliver food from restaurants. The fifth most frequently mentioned word is "fine". Also, indicative is the word "sweat" and the combination of the words "a lot" and "work". A more detailed study of the narratives shows that fines are set for lateness, unauthorized departure from the shift, refusal to fulfill an order, failure to fulfill an order on time. Some replies note that many foreign citizens work in the delivery service who are not familiar with the law, do not know Russian well and do not know how to defend their rights.

When analyzing the reviews, a trend of gradual decrease in ratings was also indicated. At the initial stage of the platforms' operation, workers in general showed higher satisfaction, which contributes to the flow of personnel from offline jobs. After 2-3 years of work and the completion of the phase of successful market launch, the

platforms change working conditions and wages downward, which causes a sharp downgrade in ratings. A significant part of employees during this period already lost contact with employers in traditional spheres. In the context of the spread of COVID-19, this problem has become even more acute due to the closure of many industries and areas of activity in the off-line format.

The high level of dissatisfaction with the working conditions led to the fact that in June 2020 Delivery Club employees began to threaten a strike, and also began to file complaints with law enforcement agencies. The Moscow Prosecutor's Office planned to start checking the observance of labor rights, since the current Russian legislation does not allow the introduction of disciplinary sanctions in the form of fines. Tasks that were assigned to employees were deliberately impossible. Under pressure from employees and regulatory authorities, the company took measures to change the payment and fines policy. In mid-June 2020, the company announced that information from social media had been considered. The company admitted that some couriers received fines for refusing to accept orders with an increased distance, which caused their dissatisfaction. These fines have been reimbursed to couriers, they will not be applied in the future, and testing of the enlarged zones has also been completed.

Conclusion

The conducted research confirmed the hypothesis that digital labor platforms pollute labor relations, use illegal and toxic practices. The level of social pollution is quite high, as the rights of workers are violated, there are numerous abuses, fines, and excessive control is recorded. Digital labor platforms use rigid, often even excessive, methods of monitoring employee activities, create a sense of surplus labor force among users and devalue labor (van Doorn, 2017).

There are a number of constraints and assumptions to consider when analyzing reviews:

- a small number of reviews reduces the reliability and relevance of ratings;

- websites collecting feedback on digital labor platforms policies are gradually beginning to affect the labor market;

- a large number of negative feedback from employees reflects real problems in the field of labor relations;

The study proves the need to form a legal framework for digital labor platforms in order to protect the rights of workers and ensure sensible level of social guarantees. Based on foreign experience, it seems necessary to pursue an open information policy to explain the specifics of non-standard forms of employment and create a single website for digital labor platforms. Every citizen has the right to know about the advantages and disadvantages of working through digital labor platforms. The website may also collect employee complaints and appeals. Analysis of complaints can become the basis for conducting inspections of compliance with the law and calling the violators to account.

Operational Risk - From Spectator To Main Actor In The Risk Management Process

Maria-Alexandra CRISTEA

Bucharest University of Economic Studies, Bucharest, Romania
marialecsandra@gmail.com

Abstract

Operational risk can be generated by a multitude of factors and the potential financial losses that can be generated are significant. The appearance, in a short time, of numerous prudential regulations for an adequate operational risk management led to the inclusion of this risk in the top of the most important risks in the banking activity. This paper presents the components of operational risk, the stages in the risk management process and the causes of operational risk. Prudential regulations in the field of operational risk and methods for calculating the minimum capital requirement for operational risk are presented and highlighted within a case study on a Romanian bank. Crisis simulations are presented as an integrated part of operational risk management. An analysis was performed of the evolution of the minimum capital requirement for operational risk calculated in the Romanian banking system in the period 2008-2018, in parallel with the evolution of the minimum capital requirement for operational risk calculated in the European banking sector. This analyze conclude that in 2018 the basic indicator approach is used mainly for the calculation of the minimum capital requirement for operational risk, but during the analyzed period, the constant increase of the share of standardized approach use, as well as of the share of use of advanced measurement approach was observed.

Keywords: Operational Risk, Capital Requirements, Prudential Regulations.

Introduction

The financial crisis of the past decade has affected the financial stability of the banking systems, and the effects of this crisis were much more severe than all the scenarios used by the banks in their stress tests, proving that the financial institutions were governed by an inadequate risk management, in which the risks have not been correctly identified, managed and monitored.

In order for a banking system to be considered stable, it must function in balance in the context of different economic circumstances, without the need for external resources to support its activity. In order to ensure this stability, in the last years there has been an increasing concern of the supervisory authorities for the development of prudential regulations and of the instruments used in the process of supervision and continuous evaluation of banks.

It is well known that any activity carried out by a credit institution involves the occurrence of risks, especially of the operational risk. The operational risk events can be generated in all bank processes and operations, and all assets and activities of a bank are in one way or another the subject of operational risk.

The financial losses caused by the materialization of the operational risk events and the weakening of the financial stability of the credit institutions have led to an increased attention to this risk, both from the point of view of banks, and from the point of view of the supervisory authorities.

This paper presents the component elements of operational risk, the stages in operational risk management, along with the causes of this risk. The most important prudential regulations in the field and the calculation methods for the minimum capital requirement for operational risk are presented, materialized in a case study conducted by the author for a bank in Romania. Crisis simulations for operational risk can influence the analysis of the capital planning process, a fact highlighted by another case study conducted by the author. The article continues with the

presentation of an analysis of the evolution of the minimum capital requirement for the operational risk calculated in the Romanian banking system, from 2008 to 2018.

Component Elements of Operational Risk and Their Management

Operational risk is that risk of loss registration that results either from the use of inadequate processes, persons or internal systems or that have not fulfilled their function properly, or from external events, as defined by the Basel Committee.

Neifar and Jarboui (2017) mentioned that considering the major technological progress in banking activities, globalization and deregulation, operational risk is one of the most important banking risks.

All possible sources of risk generation can be divided into 4 broad categories: human actions, inadequate functioning of software and hardware systems, inadequate functioning of internal processes, and external events.

Among the components of operational risk are legal risk, model risk, information technology risk and uncontrollable risks, being also an important link between operational risk and other risks, such as strategic risk and reputational risk.

The legal risk can be generated by both internal and external factors. The main factors that generate this risk are the improper application or non-application of the legal and contractual provisions by the employees, the non-correlation of the internal regulations with the legislative changes in the field, internal fraud, legal actions formulated by clients, employees, creditors or formulated by bank, external fraud.

Information technology risk is the most important component of operational risk. The computer system not only represents the network of computers and telecommunications, but includes all electronic computing, printing, display devices, systems and protocols for communications, security, storage units, and all associated data and activities (computers, servers, network environments, telephones, faxes, printers, programs and data for creating, recording, processing, storing, receiving, displaying, transmitting information in electronic format).

Model risk can materialize after using decisions based mainly on the results of internal models, the loss being caused by errors in the development, implementation or use of these models.

The uncontrollable risk is that risk for which the institution has no possibility to prevent its occurrence. External events such as natural disasters, terrorist actions or vandalism are included in this category. For this category of risks, a bank must create business continuity and disaster recovery plans, which should include stipulations related mainly to the definition of crisis situations, the crisis management model, roles and responsibilities, the system of business continuity management, critical activities and recovery times of activities at the level of organizational structures, communication strategy in crisis situation, business continuity plan testing, plan testing and test performance.

Like any risk, the operational risk must be evaluated from 3 points of view: from the perspective of the causes that can materialize it, from the perspective of the events and from the perspective of the impact. Also, according to Lu. (2013), the operational risk management involves the following steps: risk identification, risk analysis, risk mitigation and risk monitoring.

Stages in the operational risk management process

A number of factors relate directly to the definition and identification of operational risks, such as: development of banking technologies and practices, increasingly frequent use of automated technologies - decreasing the risk of manual processing error, while increasing the risk of the informational system by using electronic trading systems, risk of internal and external fraud, the involvement of a large number of personnel in complex activities that require a higher training, but also a higher concentration on the current activities, the mobility of the regulatory framework and the need to adapt quickly to its requirements.

The principles of an operational risk management policy must take into account:

i) identification of sources of risk,
ii) assessment of potential losses,
iii) monitoring,
iv) managing exposures to operational risk, as shown in Figure 1.

Fig. 1: Principles of an operational risk management policy

For the beginning, each product or service offered by the bank, any technical system and any processing flow used must be evaluated in terms of operational risk. Once the sources of materialization of the risk have been identified, the credit institution must evaluate the degree of exposure to the operational risks, thus deciding the acceptable level of risk. This degree of exposure is evaluated taking into account both the volume and the complexity of the processes and operations carried out by the bank. Also, at this stage of the evaluation, the degree of sensitivity of the information systems is considered in order to establish including the maximum acceptable duration of remediation of the deficiencies or the duration of failure of these systems, so that the productivity of the institution not be affected or maximum limited.

Operational risk monitoring is a continuous process that must be carried out both at the level of each flow or each operation (for the rapid detection of deficiencies that can lead to the occurrence of the risk and their correction), as well as at the level of the entire bank. This stage also involves establishing key operational risk indicators (Figure 2) and limits for them, with the purpose of identifying risk exposures, before these risks turn into losses. Keeping under control/ mitigating risk implies, among other things, that if certain risks cannot be managed or controlled, the credit institution can decide whether to accept them or to diminish or cease their activity that generates such risks, being transferred to the category of uncontrollable risks.

Fig. 2: Key Operational Risk indicators

Banking practices involve the management/ control of the operational risk according to the frequency of the events that can generate the risk and according to their severity, as shown in the table below:

Table1: Methods of managing operational risk, based on frequency and severity

ACTION	FREQUENCY OF APPARITION	SEVERITY
Assumption	low	low
Diminution	high	low
Transfer	low	high
Elimination	high	high

Contributory factors and causes of operational risk

Operational risk is a general concept that encompasses a number of other important risks. This risk is not only generated by the current operations of a bank. The main categories of factors and causes of operational risk are divided into nine categories, as follows: quality of employees, quantity of employees, internal communication, customer, model errors, external or caused by third parties, providers, IT systems and equipment and utilities. Chernobai et al. (2020) shows that the magnitude and the frequency of operational risk events increased significantly with bank complexity.

For a better example, a number of contributing factors and causes of operational risk are presented in the boxes below (Figure. 3 a, b, c).

The multitude of factors generating the operational risk led to the creation of sub-divisions of this risk. We thus encounter the risk of internal fraud, the risk of external fraud, the risk generated by employment and safety practices, the risk of damage to tangible assets, the risk associated with customers, products and business practices, the risk of business interruption and improper operation of systems and the risk generated by the execution, delivery and process management.

Quality of employees
Lack of experience needed to fill the job
Failure to perform the training specific to the job occupied
Neglect/ human error
Deviations from regulations for personal benefit
Inadequate training for the use of IT systems
Lack of professionalism
Inadequate supervision of employees
Deviations from personnel regulations, for the benefit of the organization
Quantity of employees
Lack of staff
Conflict of interests
Non-optimal allocation of staff
Lack of segregation of duties
Insufficient staff motivation
Dependence on "key" staff
Keeping the employee in the same position for a long time
Internal Communication
Inadequate cooperation/ communication between the units/ structures of the bank
Delays in transmitting data/ information/ solutions etc.
Inadequate escalation of process/ problem to management
Model errors
Model errors
Lack of standardized procedures
Incomplete/ outdated procedures
Procedures that do not comply with best practices
The complexity of the process
Inadequate project planning and management
Improper product design
The complexity of the product
Inadequate controls
Lack/ inadequacy of disaster recovery plans/ continuation of activity
Customer
Improper management of the client's relationship with the bank
Failure to fulfill the contractual obligations
Supply of fake documents
Liability to customers/ non-customers
External or caused by third parties
Business/ market conditions
Social events (demonstrations, protests, etc.)
The environment of legal/ regulatory control
The political/ social environment
Natural phenomena/ disasters
Third-party negligence/ error

Fig. 3 a,b,c : Contributing factors/ causes of operational risk production

Prudential regulations in the field of operational risk

The diversification of the transactions types and the increase of their volume, the innovation in the financial field, but also the territorial extension and, implicitly, the need for personnel in the banking system created the premises for increasing the probability of materializing the operational risk. Thus, the prudential regulations of the banking activity, with emphasis on maintaining an appropriate capital adequacy, have undergone a continuous evolution according to the economic-financial events that have manifested worldwide.

Barakat and Hussainey (2013) mentioned that the determinants of the quality of risk reporting in banks must explicitly consider how the governance, regulation and supervision of the bank interact in this context.

In this regard, in 2004, the Basel Committee published the Basel II Agreement (its full version being published in July 2006), whose main contribution is the introduction of minimum capital requirements for credit risk, market risk and operational risk, in contrast to the Basel I Agreement, which took into account when assessing the adequacy of capital only the credit risk. This is the moment when the operational risk became the third most important risk in the banking activity.

The Basel II Agreement is built on 3 pillars, thus creating a close connection between (1) minimum capital requirements, (2) prudential supervision process and (3) market discipline.

Methods for calculating the minimum capital requirement for operational risk

The minimum capital requirement for the operational risk of a credit institution must be optimally calculated so that it plays a protective role and allows a rapid absorption of potential losses.

The provisions of the Agreement propose three approaches for calculating minimum capital requirements for operational risk: basic indicator approach, standardized approach and advanced measurement approach.

In case of using the basic indicator approach (BIA), the credit institutions will determine the capital requirement by applying a percentage of 15% to the gross average income of the last three years. The relevant indicator is calculated as the sum of the following items, extracted from the profit and loss account:

a) Interest income and similar income, including those related to fixed income securities;
b) Interest expenses and assimilated expenses;
c) Income from shares and other securities with variable income;
d) Income from commissions;
e) Commissions expenses;
f) Net profit or loss from financial operations;
g) Other operating income.

In the case of the standardized approach (SA), the operations of the banks will be divided by types of activities, to which the percentages established by the Committee apply (12%, 15% and 18%). The total capital requirement corresponds to the sum of all the results obtained for each type of activity identified previously. In order to be able to use the standardized approach, it is important for banks to have adequate operational risk management systems that meet the minimum criteria imposed in Basel requirements.

In 2017, the Basel Committee introduced the new standardized approach for calculating the capital requirement for operational risk, which replaces all operational risk approaches in the Basel II Agreement. Thus, according to this new approach (Figure 4), operational risk capital is the product of the business indicator component (BIC) and internal loss multiplier (ILM), where

- BIC = Business Indicator x Marginal Coefficients
- ILM = Loss Component / BIC, and
- Loss Component (LC) = 15 x average annual loss of operational risk over the last 10 years
-

Fig. 4: New approach for operational risk capital introduced by the Basel Committee (data source: BIS, Operational risk standardized approach – Executive Summary*)*

According to Basel Committee, this new approach must be implemented by January 1, 2022 and is applicable to all banks operating internationally, but supervisory institutions can apply this approach also to local credit institutions.

If they opt for the advanced measurement approach (AMA), banks may use internal risk assessment systems, which require validation from supervisory authorities.

Fig. 5: The degree of sensitivity and complexity of the models

The figure above (Figure 5) illustrates the degree of sensitivity and complexity of the models. Thus, it can be stated that the use of a more complex method can more accurately quantify the operational risk impact on the bank's activity, and the minimum capital requirement can be calculated with greater accuracy.

Case Study

To illustrate that the use of a more complex method can more accurately quantify the impact of operational risk on the bank's activity, and the minimum capital requirement can be calculated with greater accuracy, we will analyze the case of one of the Top 5 banks in the Romanian banking system.

According to the Transparency Report for the year 2018 published on the website of the credit institution, the minimum capital requirement for the operational risk was in the amount of 588,487 thousand lei, this value being resulted from the use of the AMA.

The next step is the analysis of the Profit and Loss Account (for the years 2015, 2016 and 2017) and the extraction of the necessary values in the calculation formula of the relevant indicator for the BIA. After calculating the average for the 3 years and applying the percentage of 15%, for the minimum capital requirement for the operational risk, a value of 437,868.45 thousand lei resulted.

- *Calculating the requirement according to the AMA (used by the bank) = 588,487 thousand lei*
- *Calculating the requirement according to the BIA = 437,868.45 thousand lei*
- *DIFFERENCE = 150,618.55 thousand lei*

We can thus conclude that a bank offering a wide range of products and services for clients, with multiple categories of activities must pay greater attention to the accuracy of calculations of the minimum capital requirement, by creating internal models in which to include both internal and external data, macroeconomic evolutions, business environment and control factors.

Crisis Simulations - Early Warning Tools

On the line of prudential supervision, based on the legislation and regulations in force, the National Bank of Romania continuously evaluates the risk profile and the viability of credit institutions. This assessment is done by identifying the risks to which credit institutions are exposed or can be exposed, by monitoring the key indicators, by analyzing the business model and by evaluating the internal governance and the control system.

Regulation of the National Bank of Romania no. 5/2013 devotes an entire section to operational risk, drawing clear and well-defined lines on aspects of this risk. Thus, the Regulation provides for the obligation of credit institutions to carry out properly crisis simulations for operational risk and to consider the extent to which crisis scenarios for operational risk influence the analysis of the capital planning process. Also, credit institutions are required to carry

out assessments at the level of historical and hypothetical, but plausible, operational risk events, whose probability of production is low, but which causes a major negative impact.

Crisis simulations for operational risk are performed based on the evaluation of operational risk events (ORE). In this regard, starting from the database of operational risk events, respectively from the results of the annual risk self-assessment process, the bank analyzes the impact of recording some losses from open operational risk events (including legal risk, information technology risk, model risk and uncontrollable risks). The bank thus considers the extent to which the crisis scenarios for the operational risk and the global exposure of the bank to the operational risk can impact the profitability of the bank.

The crisis simulations should be performed according to the nature, extent and complexity of the bank's activity, as well as according to its risk profile.

Depending on the frequency of occurrence of operational risk events and their degree of severity, credit institutions may simulate changes such as: increasing financial losses from labor disputes, increasing financial losses from interruptions of information systems, increasing losses caused by natural disasters, increasing the losses caused by external events (vandalism, for example) or increasing the losses caused by the use of inappropriate models.

Performing regular crisis simulations may warn the credit institution of weaknesses that may affect profitability, solvency or compliance with the regulatory framework, and the bank's management structure may provide recommendations for remedial measures or actions, where appropriate.

Case Study

Crisis simulations for operational risk can influence the analysis of the capital planning process. For example, we have the following data from the table below (*due to confidentiality clauses, the name of the bank will not be disclosed):*

Table2: The relevant data for the operational risk events of a bank

Year	ORE	Financial Impact	Recovery	Financial impact achieved (net value)	Non materialized loss related to closed events	Potential loss
2012	6	2,646,660	-	-	2,646,660	-
2013	4	-	-	-	-	-
2014	39	7,467,155	538,334	374	6,924,447	4,000
2015	19	681,834	-	140,437	541,397	-
2016	21	1,090,741	47,776	12,267	226,519	804,179
2017	35	1,391,193	-	3,353	307,224	1,080,616
2018	35	1,194,970	113,795	8,603	-	1,072,572
Total	**159**	**14,472,553**	**699,905**	**165,033**	**10,646,247**	**1,072,572**
Percentage in total financial impact			**5%**	**1%**	**74%**	**7%**

For the period 2012-2018, are presented the relevant data for the operational risk events of a bank: the gross financial impact, the recoveries, the realized financial impact, the non-materialized loss related to the closed events and the potential loss related to the calculation year.

For the operational risk events opened in 2018, the bank constituted a provision amounting to 1,072,572 lei (100% of the amount in dispute). The initial estimated loss chances are 80%.
The stress scenario considers 3 hypotheses: increase with 25% of the estimated loss chances, increase with 35% of the estimated loss chances and increase with 50% of the estimated loss chances. In addition, for each hypothesis, the

bank performs simulations by increasing by 25%, 35% and respectively 50% the value of the potential loss. The results obtained are as follows:

Table3: Crisis simulations

Provision constituted	1,072,572.00		
Stress scenario hypothesis	25% increase	35% increase	50% increase
Loss value according to the scenario	1,072,571.76	1,447,971.87	1,608,857.63
Difference from the provision already established	**0**	**375,399.87**	**536,285.63**

The results of this simulation highlight the full coverage of the potential losses by establishing a provision in the first stress scenario, but in the other two scenarios it is necessary to allocate additional economic capital.

Analysis on the minimum capital requirement for the operational risk calculated in the Romanian banking system

For this study, I used the annual data on operational risk published by the National Bank of Romania, based on which I analyzed the evolution of the minimum capital requirement for operational risk in the period 2008 - 2018. I also analyzed the evolution of the minimum capital requirement for operational risk in the European banking sector, from 2015 to 2019, using annual data from European Central Bank.

Analyzing the Romanian banking system (Figure 6), between 2008 and 2018, most of the credit institutions used the basic indicator approach (BIA) regarding the calculation of the minimum capital requirement for operational risk, the other two approaches being used on a very small scale. It can be seen that since 2009, the share of standardized approach (SA) utilization has increased considerably (from 3.03% to 12.5%), and, starting with 2011, the standardized approach (SA) and the advanced measurement approach (AMA) had relatively equal weights, being up to 2017, at values between 9.09% and 10.71%. Banks have understood the importance of proper operational risk management, thus developing advanced internal models.

Fig. 6: Distribution of credit institutions by approach – Romania
(data source: National Bank of Romania)

Although the available data cover only the period 2015-2019 it can be observed in the European banking sector (Figure 7) the predominant use for calculating the minimum capital requirement for the operational risk of SA

(68.18% in 2018 versus 8% in Romania), but also a slight increase of weight of using AMA (from 17.95% in 2015 to 20% in 2018).

Fig. 7: Distribution of credit institutions by approach – European Banking Sector
(data source: European Central Bank)

Even though in 2008 approximately 93% of the total minimum capital requirement for operational risk at the level of the Romanian banking system was calculated using the BIA, the increasing share of the capital calculated using the AMA may be due to the fact that the banks active on the Romanian market which are subsidiaries of international institutions are using the internal models elaborated at the level of the Group they belong to. Thus, in 2017, the capital requirement calculated with the aid of AMA represented about 39% of the total capital requirement for operational risk (Figure 8).

Fig. 8: Share of own funds requirement on Operational Risk depending on the approach – Romania
(data source: National Bank of Romania)

From the same point of view, at the level of the European banking sector (Figure 9), it is observed during the analyzed period the decrease of the share of the minimum capital requirement for the operational risk calculated using the BIA (from 8.27% in 2015 to 5.23% in 2018) in the total minimum capital requirement for the operational risk. Thus, in 2018, 55.24% of the minimum capital requirement for operational risk was calculated using AMA (versus 34.23% in Romania) and 39.53% was calculated using SA (versus 3.85% in Romania).

Fig. 9. - Share of own funds requirement on Operational Risk depending on the approach – European Banking Sector

(data source: European Central Bank)

Awareness of the financial impact that the materialization of operational risk events can have on the stability of both the bank and the banking system in Romania is equivalent to the interest for capital adequacy to the operational risk, translated by increasing the share of the capital demand for this risk in the total minimum requirements of capital, as can be seen below in Figure 10.

Fig. 10: Share of own funds requirements for Operational Risk in Total own funds requirements – Romania

(data source: National Bank of Romania)

At the same time, in the process of supervision, the National Bank of Romania periodically evaluates the capital adequacy to risks for all credit institutions and issues warnings and, where appropriate, sanctions for cases where the level of capital was not correlated with the significant risks the banks are exposed to. In this regard, during 2014-2016 and in 2018 (for 2017 there are no data available), within the supervision actions, the National Bank of Romania issued 66 measures for holding own funds in excess of the minimum capital requirements.

At the level of the European banking sector, lower weights of the minimum capital requirement for operational risk are noted in the total minimum capital requirement, as can be seen in Figure 11. Thus, in 2018, the minimum capital requirement for operational risk in the European banking sector accounted 10.54% of the total minimum capital requirement, compared to the Romanian banking system, where the share was 14.01%.

Fig. 11: Share of own funds requirements for Operational Risk in Total own funds requirements – European banking Sector

(data source: European Central Bank)

Considering the multitude of factors contributing to the production of operational risk, and the measures that can be taken along the lines of managing this risk are directed to several areas.

A first measure can be represented by the improvement of the process of identifying and collecting the operational risk events in order to report them in an efficient and standardized way, along with the revision of the operational risk indicators and the limits established for them.

From the point of view of the human resources component, the increase of the visibility and the degree of awareness of the operational risk at the level of the whole bank through courses dedicated to the persons responsible for its management/ reporting and testing of all employees to establish the level of assimilation of the knowledge regarding the operational risk must represent concerns for all banking institutions.

In the regulations area, banks must review internal policies and regulations so that they are constantly aligned with the new requirements of the competent supervisory authorities. Also, the constant updating/ development and testing of disaster recovery plans and ensuring the continuity of the activity must be among the priorities of the banks.

The operational risk management and measurement system must also be constantly reviewed, in accordance with the regulatory requirements, with the evolutions of the financial-banking system and of the macroeconomic environment, but also with the development of the credit institution's own activity. Also, each new product or service that the institution wants to promote, must have, in its analysis, the operational risk component.

Conclusions

The global financial crisis of the past decade can be perceived as a contributor to the banking institutions regarding the awareness of the importance of good risk management.
The multitude of factors that can generate the risk and the financial losses that it can bring to a credit institution, have led to the introduction of the operational risk (and its sub-categories) in the category of the three most important risks in the banking activity, besides the credit risk and market risk.

In the last 15 years, numerous regulations for operational risk management have been elaborated, the most important of these being the Basel II Agreement, whereby credit institutions have the obligation to calculate minimum capital requirements for operational risk, being proposed, within the same agreement, 3 calculation methods: basic indicator approach - BIA, standardized approach - SA and advanced measurement approach - AMA.

The calculation methodology is different for all 3 methods, so the basic indicator approach - BIA is preferable to be used by the local credit institutions, whose activity is not very complex and whose portfolio of products and services is not sophisticated. Standardized approach - SA assumes that the bank's operations are broken down by types of activities. In order to be able to use the standardized approach, banks must have adequate operational risk management systems that meet the minimum criteria imposed in Basel requirements, which makes this method more suitable for a medium-sized bank. The advanced measurement approach - AMA is the most complex method of calculating the minimum capital requirement for operational risk and involves the elaboration of internal models, being used, generally, by internationally active banks, which are part of a group of financial institutions.

In the Romanian banking system, in 2018 the basic indicator approach - BIA is used mainly for the calculation of the minimum capital requirement for operational risk, but during the analyzed period, the constant increase of the share of standardized approach - SA use, as well as of the share of use of advanced measurement approach - AMA, was observed.

The establishment of the minimum capital requirements is not sufficient for managing the operational risk. Banks use early warning tools, in this sense being able to use crisis simulations: regularly performing crisis simulations can warn the credit institution about weaknesses that may affect profitability, solvency or compliance with the regulatory framework, and the bank's management may provide recommendations for remedial measures or actions where appropriate.

The efficient management of the operational risk must also consider the application of measures for the most important factors that can generate operational risk events: improving the process of identifying and collecting the operational risk events in order to report them in an efficient and standardized way, reviewing the operational risk indicators and the limits set for them, courses dedicated to the persons responsible for the management/ reporting of the operational risk and testing all the employees to establish the level of assimilation of the knowledge regarding the risk, the constant alignment with the new requirements of the competent supervisory authorities, the constant updating/ developing and testing disaster recovery plans and ensuring the continuity of the activity.

The continuous development of banking technologies and practices, the increasingly frequent use of automatic technologies, the digitalization of the banking system, but also the fluctuation of personnel (present in most economic fields) are important factors that can generate operational risk events. The numerous studies in the field also show the importance of this risk and the continuous need to improve models, methods and tools for the identification, evaluation and efficient management of operational risk.

This article proposes future research topics, especially in the context of the coronavirus pandemic. Working from home, limiting face-to-face meetings, giving up the use of physical documents as much as possible are just some of the measures taken by credit institutions to prevent the spread of the virus. In this respect, being in an unprecedented situation, the chances of operational risk have increased considerably. Although each credit institution has Business Continuity Plans in case of disaster, the current reality could not be predicted and translated into action plans. Future research may study the evolution of the minimum capital requirement for operational risk in the context of the global pandemic and the response of the banking system to this health crisis.

Abstract

There are the preservation of significant interregional differentiation and weak connectivity in the innovation sphere of Russian regions. This presupposes the study of the reserves of innovation dynamics: taking into ac-count the uniqueness of accumulated assets; comparative innovation advantage in resources, production and results of innovation; territorial location to relatively innovative growth centres. The authors propose a methodological approach for assessing the type of spatial environment of regions, which was tested on the example of subjects of the Russian Federation with a single-industry metallurgical specialization.
The proposed approach is based on a set of indicators characterizing the socio-economic and innovative conditions of regional development, determining the spatial status of regions of the Russian Federation, assessing the connectivity between regions within the macro-zone. The types of local innovation spaces are highlighted using cases of macro-zones in mono-specialized regions, limiting or stimulating interregional cooperation; promising partners for innovative interaction have been identified. The spatial approach to assessing innovative development allows expanding understanding of potential drivers of growth, directions and organizational formats that activate the innovation dynamics of regions. A verbal model of the development of interregional innovative relations and a real case on the example of the regions "Chelyabinsk region - Sverdlovsk region", determined by the actual innovative conditions and results in the innovation sphere of the regions, are presented.

Keywords: Innovative Development of Regions, Innovative Space, Innovative Macro Zone, Regional Connectivity, Innovative Profile.

Introduction

The current economic situation in the world commodity markets has actualized the problem of maintaining the high dependence of the Russian economy on energy prices and the need for a transition to a new technological order, search for production factors and, ultimately, a change the orientation in the economic development. Increasing the technological involvement of regions in the process of accelerating innovative development is one of the real

Cite this Article as: Irina DANILOVA, Irina SAVELYEVA, Irina KILINA and Anzhelika KARPUSHKINA "The Profilization of Regions Innovative Development in The System of the Economic Space of the Russian Federation" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

mechanisms for creating competitive advantages, especially for mono-specialized regions, capitalization of regional assets to gain economic stability.

The definition of trends in the innovative development of countries is carried out using the information panel of data from international ratings Global Innovation Index *(Global Innovation Index | Who Will Finance Innovation?, 2018)*, European innovation scoreboard *(European Innovation Scoreboard 2019, 2019)*, Regional innovation scoreboard *(European Innovation Scoreboard 2019, 2019)*. And the positioning of Russian regions and identification of restrictions is based on the data from sources: Rating of innovative development subjects of the Russian Federation *(Rating of innovative development of constituent entities of the Russian Federation, 2017)*, Rating of innovative regions of Russia *(Rating of innovative regions of Russia, 2020)*. The ratings focus on the internal parameters of individual territories from the position of the conditions and results of innovative development, resource availability, involvement of business and industrial complex in the innovation process, productivity of scientific and research organizations, etc.

There is an insufficiently studied sphere of spatial innovation potential which was studied: the economic advantages of territorial location, direct and feedback correlation with other territorial actors, promising partners of interregional innovation cooperation.

In foreign studies, the innovative development of regions is analysed both from the standpoint of assessing the influence of endogenous factors by Arnault Morisson, Mathieu Doussineau (2019), Robert Hassink (2019), and taking into account the factors of the location of territories relative to innovation centres (authors are Daniel Coronado, Manuel Acosta, Ana Fernández (2008)). The results of the study by Petr Hajeka, Roberto Henriquesb, Veronika Hajkovac (2014) showed that the diversity of regional innovation systems is related, among other things, with inter-territorial relationships. While the works of De Nonic, Luigi Orsia, Fiorenza Belussib (2018) noted the positive spatial influence of regions that intensively generate new knowledge. The role of interregional cooperation in overcoming the technological gap is revealed in the publications of Mariachiara Barzotto, Carlo Corradini, Felicia M. Fai, Philip R. Tomlinson (2019). The implicit effects of innovation in the activation of inter-sectoral cooperation and the influence of the spatial proximity of the subjects of innovation are investigated in the works of Stephan J. Goetzab, Yicheol Hanc (2020). Different scales of territorial diffusion of innovations are classified in the article by Mokter Hossaina, Henri Simulab, Minna Halmec (2015):

- local and neighbouring diffusion (between regions with the same level of socio-economic development),
- distance diffusion,
- global diffusion.

The prospect of partnership relations for achieving a cumulative positive effect in the field of innovative development is based on the example of the Chinese regions by S.L. Zhaoa, L. Cacciolattic, S.H. Leeb, W. Songa (2015).

The productivity of inter-territorial relations in the direction of strengthening specialization in key stimulating technologies and their spatial diffusion is considered as an actual factor of regional economic growth by Rinaldo Evangelista, Rinaldo Evangelista, Valentina Meliciani, Valentina Meliciani, Antonio Vezzani (2017). The emphasis on the specifics of local conditions is assessed as an additional source of innovation dynamics by Markus Grillitsch, Björn Asheim (2018). Spatial “neighbourhood” facilitates the exchange of information and represents a source of creating radical innovations that are relevant from the standpoint of public administration efficiency *(Oerlemans and Mees, 2000)*.

Methodology

Each separate region is a structural unit of the innovation space, characterized by a specific level of intensity of production, scientific and technological, commercial, logistic connections with other regions, including those that are part of the territorial environment (with or without borders with the analysed region). The authors' position is that the innovation dynamics of a region depends on both its general level of socio-economic development (including innovation) and the quality of the country's innovation space as a whole, including the quality of the local innovation space (macro-zone). Within the framework of the study, to characterize the territorial environment, the concept of “local innovation space” or “macro-zone” was used, which includes the reference region (studied)

and regions that have a common border with the reference one (Fig. 1). The structural diagram of the innovation space and its components (local innovation spaces, as a reference region, an object of analysis, and territorial "neighbours") is shown in Figure 1.

The units of the meso-level are regional innovation systems, which differ in the conditions and effectiveness of innovative development, which directly affects the activity, the strength of innovative impulses "outside", the speed and degree of their territorial "absorption", innovative "conduction" into the economy of the macro-zone regions.

Fig. 1: The structural diagram of the innovation space and its components in the federative country
(Source: compiled by the authors)

Figure 1 formalizes the innovation space and the innovation system of a particular region: A - local innovation space (macro-zone), including the supporting region and the bordering regions of the Russian Federation; B - innovation space of the country as a whole, uniting the entire set of regions interacting with each other; C - lines of interaction between macro-zones, D - innovation system of a separate region.

Different models of potential neighbourhood are possible (Fig. 2) in the local macro-zone: 1) the reference region and border regions have polar levels of innovation development (in the matrix they are highlighted in bold); 2) the support and border regions are characterized by a similar level of innovative development (in the matrix they are italicized).

Table 1: Matrix of options for innovative situations in the macro-zone

У↑/ Р↑	**PP⁻**	*C*	*C*	*C*
У↑/Р↓	*P⁻*	**PP⁻**	**PP**	*C*
У↓/ Р↑	*K*	**PP**	**PP⁺**	*C*
У↓/ Р↓	*K*	*K*	*PP⁺*	**PP⁺**
Border region / Reference region	**У↓/ Р↓**	**У↓/ Р↑**	**У↑/ Р↓**	**У↑/ Р↑**

(Source: compiled by the authors)

Legend:
У↑ *– good innovative conditions;*
У↓ *– insufficient level of parameters of innovative conditions;*
accordingly, ***Р↑*** *– good innovative performance;*
Р↓ *– low innovative performance,*
C *– the possibility of full cooperation;*
K *– critical "neighbourhood",*
PP *– potential partnership is limited*

From the perspective of interaction, option "C" assumes the possibility of potential cooperation, the reference and neighbouring regions have a high level of innovative development (they can become "donors" of innovative achievements for each other). Situation "PP" shows the presence of polar innovation statuses of the regions, that is, the reference or border regions are radically superior in terms of conditions or innovative performance; partnership is limited, associated with the risk of an outflow of personnel and financial resources (PP+ is a form of communication, when the reference region has a status higher than the neighbouring regions, PP– is an inverse relationship). The quadrant “K” environment means functioning in an innovative vacuum.

The position of the region and the type of local innovation space determine the uniqueness of the driving forces of the innovation dynamics of each subject of the Russian Federation, including the dominant type of local innovation spaces in the context of macro-zones:

a) a space **favourable for** the innovation dynamics of the reference region;
b) the space is **unfavourable for the innovative development** of the reference region due to the low innovation parameters of the regions surrounding the reference region in the macro-zone.

State support measures will be more effective only when the type of environment and the situation in a given local innovation space are identified, in connection with which the authors have developed a methodological approach to assessing the situation in macro-zones. This approach includes 6 stages.

1) Specification of the subjects of the Russian Federation that share a common border with the reference (study) region, which allows you to structure the subjects of the macro-zone.
2) Systematization of intraregional indicators of innovation dynamics into groups that characterize the conditions and effectiveness of innovation development; the parameters for assessing the local innovation space are highlighted.
3) To determine the promising lines of interregional relations, an applied model of the actors of innovative development was used, which includes stakeholders, researchers, innovators and technological production.

Stakeholders are defined as customers of innovations, the business sector (as consumers and investors); researchers are research, scientific and educational organizations, scientific and educational centres; innovators - innovation centres, innovative business incubators, accelerators, engineering centres, technology parks; technological production includes production sites, industrial enterprises, collective use centres, innovative technology clusters, etc.

To assess the potential and directions of interaction between regions, intraregional indicators of innovative development are highlighted (Table 2).

Table 2: A set of intraregional indicators in the context of actors of innovative interaction

X_{m2} – The coefficient of serviceability of fixed assets	X_{m4} – The number of advanced production technologies used in the region, per million population, units	X_{i2} – The number of personal computers per 100 employees, including those with access to the Internet	X_{i4} – The use of electronic document management in organizations, including electronic data exchange between their own and external information systems, by exchange formats), %

(Source: compiled by the authors)

To assess and compare the regions of the macro-zone, the following indices are proposed:

1) to characterize **the stakeholders** - group indices characterizing economic conditions and an index for assessing the results of innovative development of the constituent entities of the Russian Federation (I_e and I_r);
2) to characterize **the researchers** - indices of personnel and social conditions (I_h and I_s);
3) to characterize **the innovators** - indices of financial conditions and innovative activity (I_f and I_d);
4) to characterize **technological production** - indices of material and information conditions (I_m and I_i).

For a generalized assessment of intraregional factors of innovative development, two indices were used such as the integral index of conditions and the integral index of the effectiveness of innovative development, which are calculated as the average geometric group indices of the corresponding block. Group indices are aggregated from

individual indicators, taking into account the weighting coefficients calculated by concordance of parameters within each group separately *(Savelyeva, 2019).*

To assess the positions of the regions with respect to the average situation in the Russian Federation, the average values of the integral indices of conditions and effectiveness of innovation activity were allocated (the average level was determined and fixed by the year of the beginning of observations in 2013). As a result of the classification of the constituent entities of the Russian Federation by intraregional parameters of innovative development, 4 typological groups were identified. Group I is a group with characteristics of conditions below average and performance above average, II - both conditions and performance above average, III - conditions above average, performance below average , IV - conditions and performance are simultaneously below average.

1) Estimation of spatial parameters (Table 3). Diagnostics of the general processes of innovative development was carried out based on the assessment of convergence and connectivity. With the help of convergence, the presence of a tendency of convergence of regions in terms of the level and pace of innovation parameters (whether the innovation space of the macro-zone is levelled out) is assessed. It is important to take into account how the space is levelled by reducing the level of strong regions of the macro-zone or "pulling up" the weak *(Danilova and Kilina, 2019)*. Convergence was analysed in terms of GRP (per capita), the cost of technological innovation in GRP, the number of personnel engaged in research and development per 10,000 populations, the volume of innovative products in GRP, and the share of organizations engaged in technological innovation. The assessment of potential infrastructural and innovative links between regions was carried out using a gravity model according to indicators that characterize economic (GRP, investments, volume of production of innovative products) and innovative development (high-tech products and manufacturing industries). The assessment of density (the degree of saturation of the territory with innovative parameters) and homogeneity (the degree of endowment of the constituent entity of the Russian Federation with innovative factors relative to other regions of the country) are calculated by indicators of GRP, investments, costs of technological innovations, including small enterprises, the number of personnel engaged in research and development in high-tech industries, the number of innovative enterprises and the volume of innovative products.

Table 3: Methodology for calculating the properties of the innovation space

Characteristics of innovative space	**Indicators used to assess the quality of the innovation space of the macro-zone**	
Convergence	**Sigma-convergence** is calculated based on the coefficient of variation: $k_{var} = \frac{\sqrt{\frac{\sum_{i=1}^{n}(x_i-\bar{x})^2}{n}}}{\bar{x}} \cdot 100\%$ (1), where x_i – value of the indicator of the i-th region, $\bar{x}$ – average value of the indicator for all analyzed regions. To diagnose the presence of the sigma-convergence process, the values of the variation indicator are compared by year, if the equation $k_{var}^{t} < k_{var}^{t_0}$ is correct, then sigma-convergence is observed.	
Connectivity between regions in terms of innovation indicators	Gravitational model: $M = \frac{p_i \times p_j}{r^2}$ (2), where M – is the index of gravity (attraction), p_i, p_j – are innovative parameters	
Indicators used to assess the spatial parameters of regions in macro-zones		
Density by innovative parameters	$\rho = \frac{A_i}{S_i}$ (3), where ρ – is the density of the innovation space of the i-th region, A_i – is the value of the innovation parameter in the i-th region in the n-th period, S_i – is the area of the i-th region.	**Aggregated index of innovative development of regions by spatial parameters** $I_{\text{in sp}(i)} = \sqrt{I_{\text{density}(i)} \times I_{\text{str}(i)}}$ (7), where $I_{\text{in sp (i)}}$ – is the aggregated index of the innovation space (calculated by the spatial indicators of the constituent
Uniformity in innovative parameters	$d = \frac{A_i}{A} \times 100\%$ (4), where d – is the share of the i-th region in the total indicator for the Russian Federation	

Group indices of density and structure by innovative parameters	$I_{density(i)} = \sqrt{I^{\text{cond}}_{\text{density }(i)} \times I^{\text{perform}}_{\text{density }(i)}}$ (5), where $I_{\text{density (i)}}$ – is the density index of the innovation space of the i-th region; $I^{\text{cond}}_{\text{density }(i)}$ – group index of the density of conditions; $I^{\text{perform}}_{\text{density }(i)}$ – group performance density index. Innovation space structure index: $I_{\text{str}(i)} = \sqrt{I^{\text{cond}}_{\text{str }(i)} \times I^{\text{perform}}_{\text{str }(i)}}$ (6).	entities of the Russian Federation), i – is region. By the value of the aggregated index of innovative development of regions, the constituent entities of the Russian Federation are classified into 4 quartiles: Q_1, Q_2, Q_3, Q_4. Q_1 contains 25% of the best regions, Q_4 – 25 % of the worst regions.

(Source: compiled by the authors)

2) Assessment of the systemic innovation profile of the reference region and the border regions of the macro zone.
3) Identification of promising innovative partners in the structure of the macro-zone. An example of a verbal model that reveals the directions of interregional innovation processes is presented by a case on the example of a supporting region - the Chelyabinsk region and its macro-zone.

Results

The information base for the collection of the analysed indicators is the statistical collection Regions of Russia - Socio-economic indicators *(Regions of Russia. Socio-economic indicators, n.d.)* and the Unified Interdepartmental Information and Statistical System, UIISS *(Unified interdepartmental information and statistical system, n.d.)*.

The methodological approach has been tested on the example of 73 constituent entities and 4 macro-zones of the Russian Federation. Moscow, Sakhalin, Tyumen regions (including Khanty-Mansiysk and Yamalo-Nenets Autonomous Okrug), Nenets Autonomous Okrug due to abnormally high economic indicators. Sevastopol, Republic of Crimea, Magadan Region, Chukotka Autonomous Okrug, Chechen Republic, Republic of Ingushe was excluded from the total sample of regions due to the lack of data on a number of indicators.

Macro-zones are allocated for regions of the same type in the industry structure-subjects of the Russian Federation with domination in GRP of products of the manufacturing industry (metallurgical production): Chelyabinsk (35.3 % of the manufacturing industry in GRP in 2017 *(Regions of Russia. Socio-economic indicators, n.d)*, including 61.5% of metallurgical products), Lipetsk (39.4% and 67.4 %, respectively), Vologda oblast (38.1% and 62 %) and Krasnoyarsk territory (31.4% and 74.5 %).

Analysis of intraregional factors of innovative development showed (Table 4) that the Chelyabinsk, Lipetsk regions, Krasnoyarsk Territory have relatively strong positions within their local innovation spaces. While in the macro-zones of the Chelyabinsk and Lipetsk regions there are regions with a high level of innovative development: the Sverdlovsk region in macro-zone of the Chelyabinsk region and Voronezh, Kursk, Tambov, Tula regions in the macro-zone of the Lipetsk region. Consequently, we can say that there are potential partners to activate innovative interaction and a favourable environment for interaction. The weak Vologda region is surrounded by strong regions such as Yaroslavl, Novgorod, Kirov regions. The strong Krasnoyarsk Territory is surrounded by partners with a low level of innovative development; in fact, in such conditions the strategy of self-reliance is relevant for it.

Table 4: Typology of regions of macro zones by intraregional parameters innovative development, 2017

Macro-zone	Region	Group	Macro zone	Region	Group
I	**Chelyabinsk region**	**III**	II	**Lipetsk region**	**II**

(Source: compiled by the authors)

Legend* the supporting regions of macro- zones are highlighted in grey, strong regions are in bold type, which have both performance and (or) conditions for innovative development above average level.

The analysis of convergence processes in the analysed macro-zones showed that for the period from 2010 to 2017 the levelling of space (reduction of interregional differentiation) is observed in 3 macro zones with supporting regions - Chelyabinsk, Lipetsk, Vologda regions (Table 5). A detailed analysis showed, for example, that the convergence in the macro-zone of the Chelyabinsk region in terms of costs for technological innovation was caused by a decrease in the average value of the indicator from 2.2% to 1.8%, which was largely influenced by the deterioration of the position of strong regions: for example, in the Chelyabinsk region the share of costs decreased from 6.08% to 1.6%, in the Sverdlovsk region - from 2.16% to 2.08%. At the same time, relatively weaker regions in this macro-zone (Orenburg Region and the Republic of Bashkortostan) increased their indicators from 1.4% to 2.8% and from 0.9% to 2.1%, respectively. In general, despite the pulling up of outsiders, the general background of the macro-zone in this parameter is unfavourable. The opposite trend is observed in terms of the "number of personnel engaged in research and development". Here the growth of the position of all regions is recorded.

Table 5: Fragment of assessment of sigma convergence of macro zones of alternative cases

Macro zone (reference region	Indicators	GRP per capita, million rubles		Costs for technological innovation of small enterprises, % to GRP		The number of personnel engaged in scientific research and development per 10,000 people		Volume of innovative products,% to GRP		Coefficient of innovative activity	
		2010	2017	2010	2017	2010	2017	2010	2017	2010	2017
Lipetsk region	Average value of the indicator for the macro-zone	158	↑**210**	2.4	↓1.7	0.13	↓0.12	5.4	↑**7.5**	7.2	↑**8.7**
	σ-convergence by macro-zone, %	17	14	155	58	81	71	67	47	33	52
Krasnoyarsk territory	Average value of the indicator for the macro-zone	254	↑**292**	0.66	↑**1.18**	0.14	↑**0.14**	0.87	↑**1.83**	8.2	↓5.6
	σ-convergence by macro-zone,%	84	93	4	25	31	32	20	39	54	55

(Source: compiled by the authors)

*Legend** The values of indicators for which convergence within the macro-zone is observed are highlighted in grey. Indicators are highlighted in bold, the average values of which have increased in the macro zone*

In the Lipetsk region the convergence in terms of GRP and the volume of innovative products was caused by an improvement in the position of the weaker regions of the macro-zone, while in terms of costs for technological innovation and the size of the population involved in research and development, the alignment of the innovation space is achieved in by reducing the parameters of strong regions.

The carried out qualitative and quantitative assessments of the intraregional and spatial characteristics (density and homogeneity, as well as connectivity) of the innovative development of regions allowed us to build a system innovation profile for each reference region.

Such an innovation profile includes integral indices of conditions and effectiveness of innovative development of the supporting and bordering regions; aggregated indices of spatial parameters of subjects of macro zones; indicators of connectivity (gravity) between the reference and border regions for innovative indicators. An analysis of the systemic innovation profiles of the Chelyabinsk, Lipetsk, Vologda regions and the Krasnoyarsk Territory showed that the subjects of the Russian Federation of the same sectoral orientation may find themselves in a different spatial environment.

Table 6: Qualitative characteristics of innovative development of macro-zone in regions

Macro-zone	Reference region/boarder region of the macro-zones	Region positions		Indicators for assessing the force of gravity

(Source: compiled by the authors)

Table 6 presents a summary characteristic of the systemic innovation profiles of macro-zones. The most promising partners are identified for each region. It turned out that the greatest potential connectivity is observed between

regions with a higher aggregated index of innovative development of regions in terms of spatial parameters, that is, the rank within quartiles.

Taking into account the statuses of the selected subjects of the Russian Federation, similar types of innovation space were identified according to the innovative profile of the region, which include: Lipetsk (typological group II according to the basic classification and Q1 - according to spatial parameters) and Voronezh (II, Q1) regions, Chelyabinsk (III, Q1) and Sverdlovsk (II, Q1) regions. The regions that are polar in terms of innovative development are also highlighted, where one region can be a potential donor of innovations, the other - a recipient. The latter type includes pairs of the Vologda (IV, Q4) and Yaroslavl (II, Q1) regions, the Krasnoyarsk territory (II, Q4) and the Kemerovo (IV, Q2) region, where there is a different type of interaction in the innovation sphere.

Accordingly, each region, depending on the innovative status and the level of innovative development of border territories, has additional incentives for innovative dynamics. So, in a macro-zone with the presence of pairs of regions with a high level of innovative conditions and performance, both partnerships and competitive interregional relationships can develop.

In the macro-zone, where the supporting and promising counterparty (one of the regions is a pronounced dominant), there is a high risk of resource flow from strong regions to weak ones. Decomposition of data on the weak and strong characteristics of each region of the macro-zone, both in terms of resource opportunities, innovative returns, and the availability of competencies, can serve as additional information for organizational decisions of the authorities.

Within the framework of this study, potentially possible directions of interregional innovative interaction were modelled and the case of the "Chelyabinsk - Sverdlovsk" region was considered (Table 6). Comparison of indicators showed that researchers and innovators of the Sverdlovsk region have higher parameters and strong positions than in the Chelyabinsk region, and technological production in the economy of the Chelyabinsk region has the best values in terms of the provision of material resources with insignificant differences in information conditions. As you can see from the Table 6, each region may be of interest for enhancing interregional cooperation, it is promising to include links of the innovation system of a neighbouring region, if their characteristics are better than the parameters of the region under consideration (in Table 7 they are highlighted in bold). Potential directions of interregional innovative interaction in a pair of regions of the Sverdlovsk (S) – Chelyabinsk region (Ch) are highlighted.

Table 7: Characteristics of the interregional innovation process

→ – inclusion of the subjects of the Chelyabinsk region in the innovation system of the Sverdlovsk region
↔ – cooperation

Conclusion

The use of a spatial approach to assessing the innovative development of regions made it possible to draw attention to additional reserves for stimulating the innovative dynamics of territories. Quite often, regions implement projects and innovations with a similar industry theme, which, in cooperation, would contribute to saving resources and increase the innovative return. A distinctive feature of the proposed approach from existing research is the ability to identify key points of spatial growth (cores, centres of space*) (Rumyantsev, 2015)* and the use of information about the systemic innovation profile in the economic space of the Russian Federation.

The proposed and tested methodological approach allows identifying the features of macro-zones, to develop a set of measures, adapted for a specific region, for regional authorities to enhance innovation dynamics. Strengthening inter-regional connectivity in the innovation sphere will eliminate the dilution of resources, duplication of functions, increase the efficiency of the use of innovation infrastructure, inter-production cooperation, which will help to intensify innovation diffusion processes, reduce the uneven development of the Russian regions, and create a single innovation space for the country.

The Phenomenon of Students' Work Precarisation In an International Perspective. A Comparative Analysis of Work Experience of Polish, Czech And Slovak Academic Youth

Piotr CZAKON

University of Silesia, Katowice, Poland
pczakon@us.edu.pl

Abstract

This paper presents some quantitative data from research among Polish, Czech and Slovak academic youth. One of the main aims of the project was to establish to what extend work experience of students from three adjacent countries has been marked by the burden of precariousness. To answer this question roughly one thousand students from selected seats of learning were surveyed in 2018. Based on the findings, six main categories of working students were distinguished. As it turns out, there are significant discrepancies between work evaluation and precarisation experience among employees representing different segments of the labour market. The awareness of those differences can be seen as a crucial premise for shaping state economic policies.

Keywords: precarious work, work values, academic youth.

Introduction

The issue of young people coping with the reality of work is now recognised as one of the most important problems of collective life in many countries. The process of introducing younger generations to professional duties is fundamental by its very nature as it is associated with ensuring intergenerational continuity of social structures. However, the above issue has gained additional importance in the face of the increasing economic globalization, work automation (Fleming 2018; Therborn 2013) as well as the consequences of the financial crisis of 2008 (Santamaria 2019).

The young adults' category representatives (aged 20 - 35) are particularly exposed to difficulties in finding employment (Standing 2011). Unlike people from older age cohorts, they are less connected with the world of work, do not have many years of experience and do not function within the bodies of staff representation. Many of them, due to problems with employee activation, face the need to undertake multiple internships and work placements (Hunt 2020). Statistics from 2018 suggested that the percentage of unemployed young people (aged 20-29) in Poland, the Czech Republic and Slovakia is slightly (Slovakia: 9.9%; Poland: 7.3%) or significantly lower (Czech Republic: 3.9%) compared to the EU (EU average: 10.6%). At the same time, the group of young people (aged 20-29) ready to take up a job, but unable to get it, in the three mentioned countries is at a higher level than measures covering the majority of working-age persons (aged 20-64 – Poland: 7.3%; Czech Republic: 3.9%; Slovakia: 9.9%) (Eurostat 2018).

Based on the academic literature, it can be assumed that students constitute a special subcategory of adult youth. Their situation is defined by the concept of structural 'abeyance': 1) between the social position of their parents and their own social position; 2) between the social position they aspire to and the social position they will manage to attain; 3) between higher positions in the society, which are to constitute a kind of gain on higher education, and the peripheral labour market, as a position resulting from failure to fulfil life aspirations. Furthermore, it can be stated that in many respects of their characteristics, academic youth fits the approach to the notion of precariat proposed by Standing. First, it is about experiencing deficits related to coping with the reality of work, which may cause significant negative consequences – a sense of anomie, fear, alienation (Standing 2011).

A Comparative Analysis of Work Experience of Polish, Czech And Slovak Academic Youth" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Based on work centrality and topicality of the problems related to it, the author carried out a study in 2018. Its aim was to determine to what extent the work experience of young people studying from Poland, the Czech Republic and Slovakia is marked by uncertainty and short-term nature. For comparative purposes, the research project covered representatives of selected centres from Poland (Upper Silesian Industrial District), the Czech Republic (Olomouc, Ostrava) and Slovakia (Nitra). Due to the limited space, this paper focuses only on a part of the broader issues raised in the study.

The aim of the paper is to describe the extent to which representatives of Polish, Czech and Slovak student employees are subject to the phenomenon of work precarisation. In the following sections, the subject matter of work precarisation will be defined and its operational aspects will be indicated. The obtained results will be presented broken down by national comparisons and lists of student employee groups. Finally, at the end of the paper, a model for classifying student employee groups broken down by their work experience will be proposed.

Literature Review

The latest scientific discourse about work includes various analyses from optimistic through balanced to fundamentally pessimistic. Among the comments of the first type, a special place is occupied by those which equate the post-industrial stage of economic development with an increase in creativity and innovation (Florida 2002). The academic literature also deals with many analytical viewpoints that, to an almost equal extent, perceive the potential of new dimensions of work, which indicates their possible shortcomings or refrain from clear assessment (Beck 1992; Castells 1996). Currently, voices stressing the negative aspects of the transformations of the work reality seem relatively broadly represented, i.e. less stability, increasing unemployment, degradation of the work ethic, ceasing to consider it as a factor shaping the permanent identity of individuals, breaking the linear relationship between the life trajectory and the career trajectory (Sennett 2000; Bauman 2005; Rifkin 1995; Klein 1999; Ford 2015).

In recent years, the status of probably the most important proposition to turn all negative social processes of labour transformation into one theoretical approach may be granted to Standing's concept of precariat. The above term – though rarely used since the 1980s by French and German researchers (Fink 2017) – gained prominence only in journalistic and scientific discussions on the social problems of societies affected by crisis. Standing, a British critic of globalization, successfully popularised this concept, demonstrating in his high-profile works that this term can be used to name a relatively recent and numerous category of people experiencing a number of deficits related to functioning in the real world of work. The title precariat is not allowed to gain permanent employment, social promotion, and professional identity. According to the author, this new class, existing in a state of permanent uncertainty, is a consequence of the post-industrial stage of social development – globalization, liberalization, greater flexibility of the labour market, and mainstreaming information technologies (Standing 2011). Although we should not take an entirely uncritical view of all his theses, the conceptual scope made popular by him is operationalised into an analytical framework (Szarfenberg 2016).

Precarious work can be defined as an activity devoid of social importance, which, although undertaken in order to satisfy someone's essential needs, does not lead to their fulfilment or allows their sufficient fulfilment for an individual. Precarious work does not allow an individual to permanently define their place in the social structure, nor are ethical norms and values applicable to it. Precarious work does not meet the needs in economic and cultural dimensions. On the one hand, it means low earnings forcing precarious worker to benefit from the support of others. On the other, precarious work has no prospects of self-development, training, or professionalism described by Richard Sennett (2000). The short-term, revolving nature of precarious work, on the other hand, excludes its determining function in working out individual's stand in society – building a permanent identification with a professional group and developing social promotion plans based on its performance. Life trajectories and work trajectories are independent of each other. Ultimately, work that takes a precarious form is devoid of an ethical dimension. This is due to its short duration and low compliance with the education of the people who perform it, which prompts them to consider such jobs as only something temporary – according to the 'no long term' principle.

Methodology

The empirical analysis presented in the paper is based on the author's own research, which was carried out between October 2017 and June 2018 in three out of four countries of the Visegrad Group. They were: Katowice, Poland (University of Silesia in Katowice, Silesian University of Technology, Medical University in Silesia, University of Economics in Katowice); Olomouc, the Czech Republic (Palacký University Olomouc); Ostrava, the Czech Republic (Technical University of Ostrava, University of Ostrava); Nitra, Slovakia (Slovak University of Agriculture in Nitra, Constantine the Philosopher University in Nitra).

In the project, the author used a questionnaire which was carried out in a form of a classroom survey among the academic youth completing their Bachelor and Master programmes in five main scientific disciplines: social sciences, humanities, economics, medical sciences and science. The questionnaire, consisting of several dozen of questions, was translated into Slovak and Czech, and then distributed by the researcher in the academic centres considered in the study. 313 questionnaires were completed in Poland, 304 in the Czech Republic, and 315 in Slovakia (932 in total).

Although the mentioned research tool consisted of four parts and dealt with the issues of objectified information about student work experience, its assessment, employee aspirations and socio-cultural capital, in this paper I will focus only on those questionnaire parameters that were directly subordinated to the problem of work precarisation. These were, in turn: 1) high assessment of job compliance with the field of study; 2) assessment of the job as a career stage; 3) high assessment of the social respect attributed to the job; 4) high assessment of job development; 5) high assessment of job prospects; 6) high assessment of job social importance; 7) assessment of job as too tiring.

Results

At least a temporary episode of work has been widespread among the respondents. Nine out of ten representatives of Czech (88.2%) and Slovak (90.2%) academic youth declared that in the last two years they had earned their living for a little while. In the case of Polish students, the experience of any work during the considered period was slightly less common, as it concerned eight out of ten respondents (79.2%). The relationship between nationality and the economic activation of students described here is confirmed by the statistical relationship test (V = 0,137).

There are similarities and differences in the number of individual occupational categories between the three compared national groups. The table below (Table 1) contains an original proposal of grouping the jobs performed by students, which loosely refers to the classification of professions recognised in sociology (EGP). I propose to describe the student professional structure as a configuration of six basic categories:

- Work based on specialist skills, i.e. intellectual qualifications acquired in the course of studies (e.g. teacher, tutor, researcher, programmer, logistician, quality controller, accountant);
- Office work, understood as less advanced intellectual jobs not necessarily related to the field of study (e.g. office assistant, call-centre consultant, customer service specialist, administrative employee);
- Work in catering sector (e.g. waiter, bartender, cafe service, fast-food service);
- Work in store sales (e.g. cashier, shop assistant);
- Work in services (e.g. guide, animator, receptionist, bank consultant);
- Work in manufacturing and manual jobs (e.g. production line worker, fitter, cleaner, merchandiser, security guard).

On the one hand, in the Polish, Czech and Slovak survey sample, the following categories had double-digit results: work in sales (Slovakia: 15.7%; Czech Republic: 20%; Poland: 24.6%), work in catering sector (Slovakia : 22%; Czech Republic: 21.6%; Poland: 17.4%;); work in manufacturing and manual jobs (Slovakia: 19.6%; Czech

Republic: 19.9%; Poland: 25.0%;) and work based on specialist skills (Slovakia: 23.6%; Czech Republic: 18%; Poland : 17.4%;). Thus, highly intellectually advanced jobs that derive from the 'hard' skills acquired in the course of studies are present in the experience of a minority group of students – 17 - 23 per cent of respondents depending on the country.

On the other hand, we can see that the percentages of the leading categories are not the same in the different national subgroups. The structure of students in Poland in relation to the other countries included is least marked by the profile of specialist jobs (Slovakia: 23.6%; Czech Republic: 18.0%; Poland: 17.4%), and they mostly occupy positions in sales (Slovakia: 15.7%; Czech Republic: 20.0%; Poland: 24.6%) and manufacturing (Slovakia: 19.6%; Czech Republic: 14.5%; Poland: 25.0%). Among Slovak youth studying relatively more often than among Czech or Polish students, we can find both specialist employees and those earning in catering sector. The Czech respondents, compared to their Polish and Slovak counterparts, have the highest percentage of service workers (Poland: 7.6%; Czech Republic: 17.6%; Slovakia: 9.1%), and the least numerous group of people earning in manufacturing and manual posts. The substantive discrepancy between the national order and the number of different employee groups is justified by the results of the chi square test (a comparison significant at $p < 0.05$) and the strength of the relationship between the variables (V = 0,175).

Students who belong to the identified employee categories consider their paid jobs differently – both in terms of their compliance with the educational path, coherence with the career vision, and the values pursued thanks to them. In order to summarise the most important results, a table has been prepared that contains the parameters of the previously developed simplified model of student precarious work (Table 2). The sub-items in the table below relate to the issue of work convergence with skills, the perception of its social usefulness and respect, and the assessment of development prospects. It turns out that within the mentioned aspects, representatives of specialist jobs clearly stand out positively in relation to the rest of the employee groups. Not only do the overwhelming majority of them highly assess their job compliance with the field of study (Slovakia: 76.7%; Czech Republic: 68.2%; Poland: 68.3%), but the vast majority of them also consider their work in terms of building a professional career (Slovakia: 70.0%; Czech Republic: 72.7%; Poland: 68.3%). What additionally distinguishes specialist employees is a significant percentage of declarations in favour of a high job assessment, both in terms of its perceived social importance (Slovakia: 51.7%; Czech Republic: 61.4%; Poland: 82.9%), social respect (Slovakia : 48.3%; Czech Republic: 61.4%; Poland: 56.1%), development (Slovakia: 71.7%; Czech Republic: 75.0%; Poland: 73.2%) and job prospects (Slovakia: 61.7%; Czech Republic: 60.5%; Poland: 58.5%;). There are certainly larger discrepancies between specialist employees from the three countries considered within some parameters. For example, Slovak specialists are a little less favourable towards social respect and the social importance of their job. Polish representatives of the category in question are characterised by a diametrically higher proportion of responses in relation to the job assessment as too tiring (Slovakia: 37.0%; Czech Republic: 38.5%; Poland: 70.3%;). However, the above discrepancies do not negate the general tendency, which indicates that, in almost all the analysed aspects, specialist employees stand out positively against the other categories.

Table 1: Classification of currently/recently performed jobs (by country and in %)

Country / Activity	Poland	Czech Republic	Slovakia
Specialist work	17.4	18.0	23.6
Office work	6.4	3.3	7.5
Work in catering sector	17.4	21.6	22.0
Work in sales	24.6	20.0	15.7
Work in services	7.6	17.6	9.1
Work in manufacturing and manual jobs	25.0	14.5	19.6

Source: Own studies; N respondents = 248 [PL]; 268 [CZ]; 284 [SK]. Measure of cross-correlation between variables are significant at $p < 0.05$; Cramer V = 0,175. Note: Data sum up in columns. The data do not add up to 100% due to the omission of the 'other professions' category.

In contrast, let us now look at the data characterising the work experience of those students who work in manufacturing and manual jobs. Not only do they rarely find a link between their paid occupation and the field of study (Slovakia: 12.0%; Czech Republic: 8.6%; Poland: 16.9%), but also rarely perceive their job as part of their professional career (Slovakia: 10 , 0%; Czech Republic: 11.4%; Poland: 15.3%). Furthermore, it was the group of students in manufacturing and manual jobs who relatively least frequently awarded high scores both in terms of the assumed social respect (Slovakia: 28.6%; Czech Republic: 22.9%; Poland: 27.1%) and social importance (Slovakia : 32.7%; Czech Republic: 23.5%; Poland: 27.1%), job prospects (Slovakia: 24.5%; Czech Republic: 22.9%; Poland: 13.6%) and its development value (Slovakia: 32.7%; Czech Republic: 34.8%; Poland: 23.7%).

The declarations of students employed in the catering sector show a similarly unattractive picture of employee experience. It turns out that the least frequently among all the groups covered, they perceive the link between their job and education (Poland: 2.4%; Czech Republic: 3.8%; Slovakia: 8.9%) and look at their job as a career stage (Poland: 4, 9%; Czech Republic: 13.2%; Slovakia: 12.5%). In Poland and the Czech Republic, a high percentage of them earn little (Poland: 26.8%; Czech Republic: 38.5%; Slovakia: 12.5%). In all three analysed countries, as many as six out of ten consider their job to be too tiring (Slovakia: 66.0%; Czech Republic: 59.6%; Poland: 67.6%). At the same time, however, it should be noted that catering employees have a more positive opinion on the parameter of social importance of their job than their colleagues working in manufacturing (Slovakia: 41.4%; Czech Republic: 41.5%; Poland: 31.7%).

Up to this point, three employee groups have been described, whose perception of earning experience sets two extreme limits of the model described here. There is a wide analytical space between the student specialist employees, who assess their job relatively best, and the students working in manufacturing, manual and catering jobs who have relatively the worst opinions about their work. This is a wide analytical space containing the other three employee segments identified in the study, namely: office workers, sales workers and service workers. While the contrasting properties of the first three reported groups allowed for their easy classification, the position of the other three categories is not so easy and clear to establish.

Office workers often see a link between their paid jobs and higher education (Slovakia: 21.1%; Czech Republic: 50.0%; Poland: 53.3%) and the chosen career path (Slovakia: 47.4%; Czech Republic: 75.0%; Poland: 53.3%). Compared to other groups of employees, a relatively low percentage of them say that their job is too tiring (Slovakia: 44.4%; Czech Republic: 33.3%; Poland: 14.3%) and are less enthusiastic than specialist employees when considering the parameters of social respect (Slovakia: 47.4%; Czech Republic: 37.5%; Poland: 46.7%) and the job importance (Slovakia: 52.6%; Czech Republic: 37.5%; Poland: 33.3%). A similar pattern also appears in the case of Czech and Slovak service workers. They often see the coherence of work with studies (Slovakia: 39.1%; Czech Republic: 40.5%) as well as career plans (Slovakia: 31.8%; Czech Republic: 41.5%). They rarely consider their job as too tiring (Slovakia: 17.4%; Czech Republic: 23.7%). However, less often than the previously described employee groups, they declare that they find social respect in their job (Slovakia: 21.7%; Czech Republic: 31.0%).

The last of the student professional categories that appears in the submitted model consists of sales employees. In terms of low assessment of links with studies (Slovakia: 7.5%; Czech Republic: 10.4%; Poland: 6.9%) and occupational plans (Slovakia: 17.5%; Czech Republic: 6.3%; Poland: 15 , 5%), these employees are close to the previously described representatives of the catering, manufacturing and manual work sectors. Sales workers are also characterised by a low perception of the social respect attributed to their jobs – in case of Czech and Slovak students it is the lowest percentage of responses (Slovakia: 15.0%; Czech Republic: 10.6%;), even lower than in the service or manufacturing sectors. However, what distinguishes the reported category of sales employees from the previous two groups (catering and manufacturing) is a clearly lower proportion of responses in relation to the assessment of job as too tiring (Slovakia: 44.4%; Czech Republic: 41.9%; Poland: 40.4%).

Table 2: The employee category and selected work parameters (by country and employee category, in %)

Employee category and country / Parameter	Specialist workers			Office workers			Workers in catering sector			Sales workers			Service workers			Manufacturing and manual workers		
	SK	CZ	PL	SK	CZ	PL	SK	CZ	PL	SK	CZ	PL	SK	CZ	PL	SK	CZ	PL
High assessment of compliance with the field of study	76.7	68.2	68.3	21.1	50.0	53.3	8.9	3.8	2.4	7.5	10.4	6.9	39.1	40.5	5.6	12.0	8.6	16.9
Work assessed as a career stage	70.0	72.7	68.3	47.4	75.0	53.3	12.5	13.2	4.9	17.5	6.3	15.5	31.8	41.5	11.1	10.0	11.4	15.3
High assessment of social respect	48.3	61.4	56.1	47.4	37.5	46.7	16.1	15.4	22.0	15.0	10.6	32.8	21.7	31.0	38.9	28.6	22.9	27.1
High assessment of development possibilities	71.7	75.0	73.2	36.8	75.0	60.0	23.2	34.0	34.1	40.0	21.3	27.6	47.8	54.8	55.6	32.7	34.8	23.7
High assessment of job prospects	61.7	60.5	58.5	36.8	62.5	53.3	16.1	17.3	14.6	20.0	19.1	19.0	52.2	35.7	16.7	24.5	22.9	13.6
High assessment of social importance	51.7	61.4	82.9	52.6	37.5	33.3	41.4	41.5	31.7	20.0	25.5	24.1	26.1	45.2	61.1	32.7	23.5	27.1
Assessment of job as too tiring	37.0	38.5	70.3	44.4	33.3	14.3	66.0	59.6	67.6	44.4	41.9	40.4	17.4	23.7	31.3	65.3	51.5	52.1

Source: Own studies; N respondents = 248 [PL]; 268 [CZ]; 284 [SK]. Cross-correlation measure between variables are significant at $p < 0.05$. Note: in the case of the 'high rating' parameters, the variants of the answers 'definitely' and 'rather' agree were combined. The 'other occupations' category was not included in the list.

Table 3: The strength of the relationship between the variables of employee affiliation and selected operating parameters (by country, in V Cramer)

Employee category / Country	High assessment of compliance with the field of study	Work assessed as a career stage	High assessment of social respect	High assessment of development possibilities	High assessment of job prospects	High assessment of social importance	Assessment of job as too tiring
SK	0,451	0,395	0,261	0,276	0,300	0,196	0,325
CZ	0,438	0,411	0,301	0,301	0,279	0,213	0,250
PL	0,425	0,430	0,241	0,306	0,308	0,370	0,348

Source: Own studies; N respondents = 248 [PL]; 268 [CZ]; 284 [SK]. Cross-correlation measure between variables are significant at p <0.05.

Virtually, all the previously described discrepancies in the experience of individual student professional groups is confirmed in mathematical tests (Table 3). The strength of the relationship, expressed by the Cramer V coefficient, turns out to be the highest in the comparison of the employee category variable, which is of interest to us, with the variable for assessing job compliance with the field of study (Slovakia: V = 451; Czech Republic: V = 0,438; Poland: V = 0,425) and the variable for assessing job as a career stage (Slovakia: V = 0,395; Czech Republic: V = 0,411; Poland: V = 0,430). Not the lowest statistics of relationship strength were also demonstrated for the perception of job development (Slovakia: V = 0,276; Czech Republic: V = 0,301; Poland: V = 0,241), job perspective (Slovakia: V = 0,300; Czech Republic: V = 0,279; Poland: V = 0,308) and social respect (Slovakia: V = 0,261; Czech Republic: V = 0,301; Poland: V = 0,241). All this would once again constitute the conclusion that placement within a student employee group is a factor that determines the nature of work experience more significantly than national origin.

Conclusions

Considering the empirical data broken down by nationality, it should be noted that students from Polish centres assessed their work a bit more critically than their Czech and Slovak peers. They were less likely to find values in the paid employment (e.g. remuneration, sense of satisfaction, stability) and more often reported irregularities in the conditions of its performance (such as: unfair treatment, excessive burdening with duties, waiting for work in conditions that did not meet the health and safety rules). Interestingly, these observations would largely coincide with the observations of other research projects that indicated a worse image of work in the minds of Polish workers than German workers (Czarzasty, Trappmann, Mrozowicki, Andrzejczuk 2018).

The obtained data also allow for the preparation of a model for the classification of student experience as employees. It is based on the relationship between job assessment and the degree of its precarisation among respondents from various earnings categories.

First, there is a combination in which the lower experience of work precarisation is accompanied by a high assessment of its value. Students who fall into this category are engaged in specialist and service work. Thus, such intuitive assumptions are confirmed, which would indicate employment in line with the field of the (specialist) education being acquired as potentially the most attractive for students. Providing not only the best qualitative working conditions, but also highly rated, the most prospective in the context of the future career path (for most students, their jobs are a stage of conscious shaping of the employee path), and seem to be closest to the structural position of the wage earners. In the three countries considered, representatives of the analysed category who would fit into this earnings profile are between 20 and 30 per cent. In the context of the previous results, however, the privileged ranking of service jobs – such as a guide, animator, receptionist or bank consultant – may be somewhat puzzling. Only sometimes they are coherent with the field of university education and thus the respondents rarely consider them as an important stage in their professional career. Despite this fact, students often admit that their jobs represent important values and relatively rarely report meeting precarised working conditions. This employment category covers over a dozen per cent of students included in the study (the highest proportion in the Czech centres).

The second segment of the model combines lower work precarisation with low assessment of its value. Such a paradox concerns only one small category of employees (about 5% of the respondents) – students who work the office employment sector (e.g. office help, administrative employee). The search for the reasons for such a state of affairs appears to be a valid premise for further research. Referring to the information obtained so far and remaining within the framework of preliminary guesses, some possible explanations could be indicated. Students who are office workers relatively often fall into in the casual employment profile (based the data obtained, it was over 45% of cases).

Within the third segment, there are several categories of employees, representing a total of approximately half of the surveyed student population. Work in sales, manufacturing, catering and simple manual jobs mean more exposure to precarious conditions and a lower assessment of the value of the paid job. Common features of all these jobs are: low association with higher education, not considering them as part of the planned employee path, and less frequent recognition of social respect and job importance.

Discussion

Identification of employee groups more exposed to precarious employment conditions is a valuable contribution to the discussion on the relationship between the education system and the employment market. In the academic literature, Poland is located closer to the liberal model of economic relations – with a small role of the state, the dominant role of general education and not very advanced vocational education. Such a state of affairs would not be harmful if it were complemented by high expenditure on research and development (Jasiecki 2013). The Czech Republic and Slovakia, on the other hand, are shown as those countries that have adapted to a greater extent the elements of the dual educational model – resulting in broader cooperation between the state and employers in education (e.g. through internship and work placement programmes). The results of own research presented in the paper would suggest that access to specialist education consistent with education – even during the studies – may be a deciding factor in shaping future employees' lives.

The current economic crisis opens up to new reflection on the results and conclusions presented in the paper. It is not yet certain what percentage of student jobs (both non-specialist and specialist) will be reduced in the face of a sharp economic slowdown or how working conditions will change in jobs that will be maintained. In the long-term perspective, hypotheses can be put forward regarding the deepening of the qualitative division between specialist and non-specialist student jobs, or even the permanent closure of the latter jobs within the precarious segment of the employment market. The answer to these issues will be found not until the years to come and in subsequent empirical research.

Abstract

Research on coping with a study load at civilian universities has confirmed that students choose both positive and negative coping strategies. However, an important factor that leads to achieving success in coping with the study load is the performance of an individual and his ability to remain in it – his achievement motivation. A standardized questionnaire tool has been developed to measure achievement motivation – the Achievement Motivation Inventory (AMI / the original German abbreviation is LMI), which has so far been used in the field of human resources rather than for the purposes of determining the prerequisites for coping with a study load. The article presents the results of the research into the structure and sources of motivation to perform professionally in the first-year students of the military type of study at military university in the economic and management focus obtained through this questionnaire. The results of each questionnaire were first processed manually in accordance with the standard evaluation procedure and then in Excel. Using a sample of 128 students, it has been proven that in probands, contrary to expectations, the sources of motivation, which are more related to the social conditions of the profession such as status orientation or dominance outweigh those, which are associated with the necessary personality traits to cope with the study load, such as perseverance, commitment, willingness to learn, independence, self-control and purposefulness. The results obtained are used by a military educational institution to tackle the problem of reducing prematurely terminated studies. At the same time, they are the first probe into the determination of motivation to perform in members of generation Z in tertiary education in the Czech Republic. The questionnaire can be recommended as one of the tools that suitably complements the set of diagnostic techniques for examining the student's ability to cope with the demands of the study and allows preventive measures against early school leaving to focus on more precisely. The findings are part of the solution of a specific research project entitled Experience of Foreign Military Universities wit Early Termination of Studies (SV19-FVL-K104-FED).

Keywords: motivation, development, study, achievement / performance, load.

Introduction

In today's society, graduation from university has become a necessary condition for the entry into a number of fields. Even if higher education in European and many non-European countries is far more accessible to a wide range of people than ever before, it has been facing the problem of a large number of prematurely terminated studies for a relatively long time. Just as civilian universities at home and abroad, Czech military higher education,

represented by a single university – the University of Defence in Brno – seeks to increase the number of successfully completed studies through a number of measures and thus satisfy the demanding requirements of military practice. We can conclude that the benefits associated with the military profession and studies at a state university are no longer strong enough reasons for members of the current young generation to complete their studies.

As the experience of civilian universities shows, the measures taken to reduce the dropout rate introduced by the school should have the desired effect on students. The school should examine the problem of unfinished studies comprehensively and in depth, in a planned and targeted manner using the knowledge and possibilities of individual approaches to the problem, i.e. administrative, sociological and psychological, or their effective combination (Fedorková, Nekvapilová, 2020). If the measures to reduce the dropout rate are to be effective, it is necessary to know not only the individual reasons, but especially their connections, which ultimately lead to the dropout, and also know how the student's attitude to school and study develops – all this not only in general parameters of the population, but especially in relation to a specific educational institution, field and a specific group (year) of students (Fedorková, Nekvapilová, 2020). *"Prematurely terminated studies are the result of specific aspects of an individual´s characteristics, his family, school and education system only if these aspects have influenced long-term negative attitudes towards school and study"* (Knotová et al., 2014).

To strengthen the socio-psychological approach to the investigation of prematurely terminated studies at the University of Defence, a specific research project entitled Experience of Foreign Military Universities with Early Termination of Studies (SV19-FVL-K104-FED) has been implemented since 2019. In connection with its solution, several partial studies have already been created. In these studies, the following problems were gradually examined: operationalization of the concept of unfinished study, the records of approaches to researching the problem in general and especially in military higher education, the study load and the coping strategies in the first-year military students (Fedorková, Nekvapilová, 2020). They also showed that, as in previous sub-researches (Vlašín, 2015) coping with a study load it requires, among other things, a certain degree of perseverance, increased effort and the ability to maintain it in the long term. These are the parameters that characterize an individual's performance. It is, therefore, possible to believe that the knowledge of his achievement motivation as a factor in coping with the study load should contribute to clarify his way of managing the demands of study, especially in the dimensions of direction, intensity and stability of motivation. It is precisely the motivation that decides whether the student will be active in the study, will devote time and energy to the pursuit of understanding the problems and the acquisition of skills, will strengthen his will to overcome the obstacles that the study load presents to him.

The aim of this article is to present the results of an achievement motivation research using standardized tools – the Achievement Motivation Inventory – LMI (Schuler, Prochaska, 2003), which were prepared in favour of already mentioned specific research in successful defended student´s work within the competition of student´s creative activities. The goal of this research was to find out whether the sources of motivation to perform professionally in the first-year students of the Faculty of Military Leadership at the University of Defence (UoD) in Brno outweigh those that are associated with the necessary personality traits to cope with the study load, such as perseverance, commitment, willingness to learn, independence, self-control, purposefulness or those related to the social conditions of the profession such as status orientation or dominance. The results obtained, together with the previous research, should primarily help predict the students' ability to cope with the demands of study and specify how to help; secondarily, they should identify how students are motivated to perform at work, which may affect the quality of other tasks, such as military duties and activities. In the conditions of the University of Defence, they can be used for all those who participate in education and training of military professionals, i.e. for teachers and mentors, commanders and personnel providing consultancy services.

Individual sources of coping with the study load and their measurement

The study load is usually defined by the number of teaching units and credits from the viewpoint of university, which are the same for all students in the field. According to numerous researches in the field of university study load, measuring the ability to master it simply by monitoring the number of completed credits and the length of time they have been acquired is proving to be completely insufficient. Measuring the ability to manage it simply by monitoring the number of credits completed and the length of time they have been earned is proving to be completely inadequate. Not only have they demonstrated a significant influence of institutional factors (Pospíšil et al., 2018) on managing the study load, but it is increasingly confirmed that a key element in the whole area is the

student with his natural individual abilities and characteristics, which inevitably manifest themselves in the management of the study load. The study load may has various intensity: from small deviations from the optimum, the equilibrium state, which are tackled by usual servomechanisms up to stress, which occurs only at a certain intensity of deviation from the optimum (Rumberger, Lim, 2008), and the management of which is often unpredictable due to individual personality traits. Each of the students, manages and experiences the demands of study differently. Precisely the research of individual factors of students, especially their personality traits, degree of resistance to stress, or strategies for coping with the study load, can provide the university with a lot of valuable information on whether and how its students are able to manage the demands of study.

Socio-psychological research on coping with the study demands also shows that the real ability to cope with the university study demands is significantly affected not only by the strategy of coping with the study load, but especially by the motivation of the individual and his approach to study as a certain type of achievement. Knowing the motivation (derived from the Latin word moveo, which means to move) allows an individual to find out what moves him, what leads him to certain activities. As the socio-psychological view of motivation shows: *"Motivation is an intrapsychically ongoing process, resulting in an internal state, a motive. A distinction must be made between the ultimate goal, which is again some kind of internal state, generally called satisfaction, and the means, by which that satisfaction is achieved"* (M. Nakonečný 2005), is the motivation a relatively complex construct, the individual elements of which and their mutual relations cannot be neglected in the measurement. This assumption is based on both foreign (Mahasneh, Alwan and Al-rawwad, 2020; Cokley, Bernard, Cunningham and Motoike, 2019; Mazumder, Dakeev, 2015), and national researches on the motivation to study looking for connections between study prerequisites and study abilities, character and academic motivation of university students (Vlk et al., 2017; Slezáčková, Bobková, 2014; Pavlas, 2015).

Motivation is significantly influenced by: a friendly environment, the approach of teachers, the composition of courses, relationships with classmates, awareness of career perspectives and many other circumstances (Fedorková, Nekvapilová, 2019). It is these conditions that can influence educational institutions without realizing their importance. On the other hand, the student himself must contribute to the institutional effort through his own education, willingness to change the aspects of motivation, learning strategies, his beliefs and approach. The process is based on knowledge – self-reflection of one's own behaviour in the sense of determining what needs to be changed and how to do it in the academic environment. Applying effective motivational strategies in learning is part of the process of improving one's academic behaviour and a path to graduation.

How the motives are realized, what the relationship between behaviour and its results is enables the research on performance to be understood. Performance means both behaviour and results. Behaviour comes or radiates from an executor and transforms performance from abstraction to action. Behaviour is not only a tool for achieving the results, but it is also a result in itself. It is a product of mental and physical effort used to perform tasks and can be assessed separately from the results (Sigmund, Kvintová, Šafář, 2014). Already H. A. Murray (2018) assigned the need for performance to the list of human needs. He explained this need as an urge to manipulate physical objects, people, or ideas; more specifically, to do something difficult, and if the result of this effort is positive, the individual has a sense of success. In the case of study, it is, e.g. learning for an exam, then the result is an excellent mark. Being successful and being recognized by others is the motivation of many people, but it is also associated with the fear of failure, which is sometimes frustrating. Thus, the strength of the performance motive is given by the relationship (Nakonečný, 1997) as follows:

$$\textit{strength of performance motive} = \frac{\textit{desire for success}}{\textit{fear of failure}}$$

This formula tells us that the greater the fear of failure, the smaller the motive to perform well. This is also related to the so-called level of aspiration, i.e. the level of demands that an individual lays on himself and that is associated with life success and failures. In order for an individual to perform successfully, he must be forced to overcome obstacles or to avoid them. He must be forced, especially in the realm of ambition (Murray, 2018). Achievement motivation continues to stem from a desire for success and a fear of failure. McClelland and Boyatzis (1982) distinguishes three basic needs, on which his theory is based. They are: the need for achievement, the need for affiliation and the need for power. The extent and the intensity measure of these needs occur differently in each person. For example, McClelland and Boyatzis found out that: *"successful managers have a high need for power and a lower need for the attainment of goals"* (Atkinson, Hilgard, 2000). Based on this, they concluded that the need for power also affected the degree of success. Researchers in the field of performance have come to the

conclusion that people who are very eager to satisfy the need for a successful performance are also characterized by the fact that the performance itself is authoritative for them, not just a reward that is conditioned by performance and is based on that performance. These people focus not only on the result (reward), but also on the path that leads to the result. Thus, their own performance becomes the main subject of their interest in the performance activity for these people, while people with a low need for a successful performance focus more on the reactions of their social environment and the end of result.

These findings are followed by the authors of the Questionnaire – (LMI) Achievement Motivation Inventory – H. Schuler and M. Prochaska (2003), which represents all relevant dimensions of the broad concept of achievement motivation or performance orientation related to the profession and also serves for the research of personality psychology. Achievement motivation is considered by the authors to be a global orientation of behaviour, in which various aspects of personality are involved. In their performance motivation research model, motives are sorted by model of achievement motivation research, including the ranking of motives according to the significance of their influence on the individual's final performance and on the area of activities that require his own initiative and activity (Schuler, Prochaska, 2003). They consider achievement motivation to be one of the most important signs for achieving professional success. Although the questionnaire has so far been used more by personnel officers in admission procedures or for individual consulting activities in the field of career development, it can be successfully used in other areas, as mentioned by the authors themselves (Schuler, Prochaska, 2003). It can be applied in the university environment as a useful tool to identify individual sources of coping with a study load, i.e. to determine the ability of an individual to manage the demands of study and to know his motivation to study as a certain type of performance.

The use of this questionnaire for research requires a more detailed explanation. The final version of the questionnaire consists of a total of 170 items that are assigned to 17 scales (dimensions). The total mean value of all 170 items is 4.55, with a minimum of 2.61 and a maximum of 6.32. The authors have included purposefulness and perseverance in central signs – the dimensions of achievement motivation, whereas **purposefulness** is characterized as a relationship to the future in terms of setting goals and high demands on what the individual wants to achieve and perform – personality development. **Perseverance** is understood as tenacity and the use of forces to handle tasks. People with high values are characterized by the fact that they work on their tasks with concentration, maintain a sufficient level of energy and are not distracted. The authors consider independence or status orientation to be marginal signs. **Independence** is a tendency towards autonomous behaviour and **status orientation** is described as an effort to achieve professional advancement, i.e. an important role in the social environment, hierarchy. Self-control and confidence in success are included in the theoretically related signs. **Self-control** refers to the way of organizing and performing tasks – not postponing duties, but concentrating on the task and discipline leading to the achievement of long-term goals. **Confidence in success** is associated with the overall self-confidence of the individual and describes the anticipation of the results of a certain behaviour with respect to the possibility of success, the use of abilities, skills and knowledge to achieve the goal.

The motivation model also contains the signs that can be integrated into the construct less easily: **Dominance** affects the tendency to exercise power, influence others and lead them. In cooperation, people with high values are strongly oriented towards others, take the initiative, convince with their actions and are willing to take full responsibility for others. **Commitment** thematizes the personal willingness to deliver performance, to expend the degree of effort and the amount of work done. Individuals with high values work a lot and the inactivity does them no good. **Flexibility** relates to the way we deal with new situations and challenges. It also means a willingness to change and the need for change. **Flow** indicates a tendency to deal with problems very intensively with the exclusion of all disturbing stimuli and with high concentration. **Fearlessness** describes the assumption of the result of the activity in a positive way with regard to the possibility of failure. People with high values are not afraid of failure or negative evaluation. They are powerful, they can work under time pressure, and they are emotionally stable and able to withstand stress. **Internality** is understood as an individual's belief in his own responsibility for the results of his activity. They feel responsibility for failure and poor performance. **Compensatory effort** is perceived as a personal effort to expend energy, resulting from a fear of failure. It is a constructive attitude that helps a person cope with failure; people with high values invest a lot of effort to avoid failure. **Pride in performance** is related to positive feelings associated with success. People with high values are satisfied if they deliver maximum performance or they increase it, however, they are easily controlled through their ambition and their self-esteem depends on performance. **Willingness to learn** refers to the effort to accept new knowledge – to expand one's knowledge. **Difficulty preference** means choosing the level of demands and risks in completing a

task. Individuals with high values prefer difficult questions and challenging tasks that require a high degree of dexterity. **Competitiveness** means a tendency to experience competition as an encouragement and motivation for professional performance.

A number of other foreign tools for diagnosing work motivation should be mentioned: Need Satisfaction Questionnaire (NSQ, 1961), Intrinsic Motivation Inventory (IMI, 1987), Basic Psychological Needs Scale (BPNS, 1996), Managing by Motivation Questionnaire (BPNS, 1996), MbM, 1996), Work Motivation Inventory (WMI, 2000), Management of Motiv Index (MII, 2000), Motivational Trait Questionnaire (MTQ, 2000), Motives, Values, Preferences Inventory (MVPI, 2001). A standardized *questionnaire of* achievement *motivation* (*D-M-V*, 1984) by T. Pardel, L. Maršalová and A. Hrabovská (Fedorková, Nekvapilová, 2019) has been used for measuring achievement *motivation, anxiety supporting achievement and anxiety inhibiting achievement*. In the Czech environment, self-constructed questionnaires (achievement motivation questionnaires) have also been used to research school achievement motivation of pupils and students, focused on e.g. the research of areas – the tendencies (efforts) to achieve successful performance and the tendencies to avoid failure (fears of failure).

Research of Achievement Motivation of University Students

Finding out the strength and structure of an individual's motivation to improve overall performance can help clarify the sources of achievement motivation for study, i.e. motivation to cope with the study demands, both in individuals and in study groups and then more accurately determine the circle of people and the way how to help them cope with the study load. This is the main starting point for implementing the research into achievement motivation in the first-year students of the University of Defence.

Research Methodology

The aim of the research is to find out whether the sources of motivation to perform professionally in the first-year students of the Faculty of Military Leadership at the University of Defence in Brno overweigh those that are associated with the necessary personality traits to cope with the study load, such as perseverance, commitment, willingness to learn, independence, self-control, purposefulness, or those that relate to the social conditions of the profession, such as status orientation or dominance. Respondents represent members of the Z generation. They are known to want to learn and develop their skills, but also to solve things their own way. It would therefore be possible to assume that their main sources of motivation are more internal – they are connected with personality qualities for coping with the study load - than external – connected with the social conditions of study. The main research question was based on this assumption: Do the sources of motivation that are associated with personality qualities for coping with the study load prevail over those that are related to social conditions?

For comprehensive finding of achievement motivation in the 1st year of study, a quantitative research design was chosen, aimed at determining the frequency of motivational factor occurrence in the year of study (raw scores). The research method used was a questioning method implemented through a standardized Achievement Motivation Inventory (Questionnaire) (LMI). The questionnaire was administered in groups according to particular platoons in compliance with the conditions of administration specified in the manual (Schuler, Prochaska, 2003).

The research sample consisted of the first-year students of the Faculty of Military Leadership at the University of Defence in the academic year 2018/2019, divided into eight platoons (groups). The questionnaire survey was launched in July 2019, in the summer semester, within the teaching of the subject Leadership. Out of the total number of 136 students, 128 respondents completed the questionnaire. The return was 94.1%. Due to the low representation of female students in the 1st year of study, no gender differences in motivation to perform were observed.

The evaluation of the questionnaires was carried out manually in accordance with the methodological instructions of the authors of the handbook (Schuler, Prochaska, 2003) and using evaluation templates for including statements in an appropriate scale, finding raw scores in the scales and the total raw motivation score. Respondents always answered separately and expressed the degree of agreement with each of the statements on the scale from 1 (I do not agree at all) to 7 (I completely agree). The answer on the numerical scale 1-7 represents the raw score of the item. The dominant dimensions of achievement motivation are determined based on the frequency of statements in individual dimensions. According to the established methodology, the numerical values of the test profile 8 and 9

express the dominant qualities (dimensions) of the student. Value 7 is an above-average value (characteristic), 4-6 are average values and 3-1 are below-average values.

Research Results

For practical use in pedagogical and counselling work with students, the results were compared according to particular platoons (groups). A partial finding is that the individual platoons in the 1st year of the Faculty of Military Leadership differ from one another in the main sources of motivation. In the case of the 1st platoon it is commitment, in the 2nd platoon the most significant dimension is purposefulness and in the 3rd platoon fearlessness prevails. The most significant dimension in the 4th platoon is purposefulness. In the 5th platoon, it is confidence in success, in the 6th platoon the same dimension dominates as in the 1st platoon and that is commitment. I n the 7th platoon the main source of motivation is competitiveness and in the 8th platoon it is strong purposefulness. An interesting finding is the results in the dimension of willingness to learn. In all platoons, this source of motivation had the lowest score. In the 1st and 3rd platoon, this dimension gained only 31 points. Immediately after the dimension of willingness to learn there is the dimension of flow, but it does not have as low score as the previous one.

Attention has also been paid to the individual frequencies of responses in all sources of motivation. The responses with the values of 4-6 points (average band) predominate in the dimension of perseverance – a total of 62 students range in this point limit. The values of 1-3 (below-average) and 4-6 for the dimension of dominance occur in 47 and 49 students; it can be said that the dominance in most students is at the average to the below-average level. In these students, the dimension of dominance does not predominate over other dimensions. The values for dominance are similar to the values for commitment. There is a surprising result for the dimension of confidence in success, where this characteristic is not significant in students, but rather achieves a below-average result. The flexibility dimension belongs to other dimensions that have the average and below-average level. The most significant negative result has been achieved by the dimension of willingness to learn; it is at a below-average level in 95 students. The dimension of willingness to learn is followed by the dimension of flow. The flow dimension does not achieve positive results and does not dominate in students. The results of fearlessness and internality dimensions are similar, the values range between 1-3 and 4-6. The level of compensatory effort dimension is average to below-average. As for the preferences of difficulty, independence and self-control, the results are almost identical, students are not significantly characterized by these abilities. In most students, status orientation prevails and the dimension of competitiveness is balanced. As for purposefulness, the result is almost similar as in competitiveness.

Figure 1 presents the global level of achievement motivation in a professional context. It illustrates, which three platoons dominate in the year. It is the 5th, 7th and 8th platoon. It can be assessed from the results that platoons with the values of 1-50 focus on the sources of motivation, which are related to social conditions – status orientation or dominance. In platoons with the values over 50, personality traits for coping with the study load prevail, i.e. perseverance, commitment, willingness to learn, independence, self-control and purposefulness. In this case, it is the 5th, 7th and 8th platoon, however, the differences are not too significant, when compared to the others.

Fig. 1: Total score in the 1st year

Conclusion

The aim of the study has been fulfilled by implementing the research into achievement motivation in the first-year students of the Faculty of Military Leadership and by finding out the answer to the main research question. The results of the research show that in the dimensions of status orientation and competitiveness, the students achieved above-average values. In the dimensions that are important for personal coping with the study load, such as willingness to learn, perseverance, commitment and flexibility, below-average or average values were found out. The answer to the main research question is negative and the hypothesis that the sources of motivation for performance are internal rather than external among the respondents was not confirmed by the research. The sources of motivation associated with personality traits for coping with the study load do not prevail over those associated with social conditions. In the dimensions of status orientation and competitiveness, the results are above-average, in contrast to those that are associated with personality traits, where the results are below-average.

Further, it has resulted from the research into achievement motivation that the two most often below-average dimensions are willingness to learn and flow. The staff of the Department of Leadership carrying out the research has recommended the Faculty management the tools to help students accelerate these dimensions. For willingness to learn, it is appropriate to use a point system as a tool; students would receive points for completing the tasks, which would be evaluated by the Faculty management at the end of the academic year as a reward – in the form of awards and honour boards. The points would be included in the overall assessment of the student achievement. Based on the number of points, students would be divided into individual fields – specializations within the Army of the Czech Republic. In the flow dimension, strengthening education is a good tool for improving student achievement such as presentations, or meetings of specialized staff with students for the purpose of explaining the importance and ability to focus on learning, not doing things at the last minute, but being productive in the long run.

A warning was the finding, that in 14 out of 17 dimensions, which lead to achievement motivation as a prerequisite for coping with the study load, students are below-average, in rare cases they are average. These are the dimensions of perseverance, dominance, commitment, flexibility, flow, fearlessness, internality, compensatory effort, willingness to learn, preference for difficulty, independence and self-control. In two cases, i.e. status orientation and competitiveness, above-average results prevail. In the last dimension, which is purposefulness, all four numerical groups are equal, so it can be stated that in this dimension there are individuals who are not purposeful, but also those who set their goals high. However, the question is whether they can attain these goals through their achievement motivation. As a recommendation, the tools can be chosen, e.g. interactive lessons, where the laws of personality dimensions of achievement motivation are explained to students, further, how it is possible to develop them and then to excel in these dimensions and deliver great achievements. One of the possible ways for reducing the academic failure of military students is the monitoring of personality prerequisites and achievement motivation to study at the beginning of university studies and based on that a differentiated approach to working with students in the field of self-knowledge and the systematic development of their necessary personality dispositions.

Acknowledgment

The study is an output of the preparatory phase of a specific university research project of the Specific Research of the Ministry of Education, Youth and Sports entitled – Experience of Foreign Military Universities with the Early Termination of Studies (SV19-FVL-K104-FED). In addition to the project, it is assumed that the results will be used to innovate the educational programs for the military study and the development of the dissertation thesis entitled – Specifics of Coping with the Study Load by the Students of the University of Defence.

Abstract

The article presents the role and function of technology in the industry and the results of authors' research on the impact of the technological potential of manufacturing processes on the competitiveness of the product. The research was done by applying the original BOST© method developed by Borkowski on the principles of Toyota management implementation (toyotarsim). The research survey was conducted to production workers of 10 heavy industry enterprises located in the Silesian Voivodeship using the BOST© questionnaire. The methodological part of the article presents the BOST method and data analysis techniques. The importance of factors analysed in the BOST method and their impact on the competitiveness of products were determined through a well-documented extensive statistical analysis using a spreadsheet application that is an integral part of the BOST method.

Keywords: Toyotarsim, BOST method, technology, competitiveness.

Introduction

P. Love (1999), in his works, presents an opinion that technology is crucial and significantly influences strategic decisions made in the course of industry development. Technology and its changes affect the production economy, energy consumption, education level, etc. There is a common opinion that technology is a "flywheel" of development. The economic power of Japan and East Asian countries was built thanks to the consistent use and development of technology. Maintaining technological competitiveness allows entering global markets and contributes to increasing employment in manufacturing sectors. The issues of technology may seem to concern only industrial engineers and managers, people with excellent knowledge of technology. However, more and more often technology management is performed as part of the activities of non-technical managers, who are required to be aware of what technology is and the knowledge of its place in the entire area of science. Therefore, it appeared reasonable to read the literature in terms of understanding the essence of technology.

The textbook definition of technology is as follows: "*Technology is a science whose subject is the use of natural processes or the knowledge of craftsmanship. (...) Technology includes physical and mental processes by which the transformation of inputs into outputs occurs.*" According to P.Love, the aim of technology is complementary to science: *"The goal of science is to obtain general and publishable knowledge. In economic terms, scientific achievements become a public good. Technology, on the other hand, focuses on occasions, special problems or groups of problems. Their solution often brings proprietary knowledge of considerable value. The owners of such intellectual property share it only on a commercial basis.* "The encyclopaedic definition of technology says that it is an area of technology dedicated to developing and conducting, under certain conditions, most favourable processes for the production or processing of raw materials, semi-finished or finished products. The technology significantly influences human, as well as animal's, ability to control and adapt to their natural environments. The Dictionary of Foreign

Expressions states that the term "*technology*" comes from the Greek words techne and logos (set, reason, etc.) and means "a method of transforming material goods into useful goods; also: knowledge about this process", the term is often confused with the name "*technique*". The same dictionary states that *technique* comes from the Greek word *techne* and means "*arts, crafts*" and "*all means and activities included in the scope of human activity related to the production of material goods*." Sometimes more attention is drawn to the fact that another, recently trendy English term "*know-how*" deserves the name "*technology*"; the dictionary explains it as "*the sum of technical and technological knowledge necessary to manufacture a specific product*".

The term "technology" may either be used generally or in specific areas; for example, construction technology, medical technology or information technology. There is a difficulty with the proper understanding of the term *technology* since it is often confused with the term *technique*, created by Stratton et al (2005). In German and other European languages (including Polish), there is a difference of meaning between "*technik*" and "*technologie*" which does not exist in English as both terms are usually translated as "*technology*". The French and German equivalents of "*technologie*" and "*gewerbekunde*" (literally: manufacturing science, craftsmanship) have similar origins. According to Schatzberg (2005), the English term "*technology*" not refers to the *science of technology* (i.e. technology), but to the *technique* itself. Terminological complexity gives unintentional ambiguity in translations as a result of the context and the person who uses the term. However, it is widely recognised that term *technology* describes a field of technical sciences dedicated to the study of production or processing methods.

Use of technology by human began by converting natural resources into simple tools. The prehistoric discovery of the fire control increased the availability of food sources; the invention of the wheel helped people to travel and monitor their environment. Technology affects society and its environment in many ways; has helped to develop a more advanced form of economies (including the globalisation of the economy) in many societies. Many technological processes generate undesirable by-products (pollutants) and lead to the depletion of natural resources with the detriment of the environment. Various implementations of technology influence society's value systems and new technologies often raise further ethical questions. The emergence of the concept of efficiency in terms of human performance is an excellent example of adoption a term initially only applied to machines. There are philosophical debates over the current and future use of technology in society, with disagreements over whether technology improves or worsens human life. Neo-luddism by Kirkpatrick and Spólny (2000), anarcho-primitivism of Jaworowski (2003) and similar movements criticise the omnipresence of technology in the modern world, believing that it harms the environment and distances people from themselves and nature.

Technology is one of the main factors determining the competitiveness of an organisation and the success of new production and service ventures, which makes it necessary to manage technology actively. The technological advantage of the enterprise, which is manifested in the development, implementation and application of new technologies for the production of innovative products, is the dominant factor in achieving a competitive advantage. The intensity of activities for the development of technology depends on the technological potential possessed by the organisation; the proficient use of which in everyday activities is conducive to technological progress (Łunarski, 2009).

Technology is strongly linked to competitiveness. The improvement of technology is dictated by the needs of the market and the pressures of competition - without improvement, one quickly loses the distance to the leaders. For these reasons, individual organisations launch unique motivational and organisational systems, the task of which is to increase the pace of improvement, its effectiveness, due to its particular usefulness for preventing natural destructive processes (wear, fatigue, corrosion, ageing, etc.) and the tendency to create chaos in systems without proper management.

Know-how improvements, new ideas for the use of available resources introduced in small steps (Kaizen) or milestones (innovations) almost directly translate into production efficiency, ergonomics of work in the process, and the competitiveness of the product itself. However, know-how is also management. It should be remembered that changes in management area are one of the most difficult, because they affect people, violate their habits, operating methods or cooperation systems. Therefore, it is necessary to continually introduce changes in the field of organisation, management, methods of motivation or problem-solving methods, as well as technology (Wiśniewska, 2014). According to Porter (2001), competitive advantage should be seen primarily in the ability to be innovative, to raise its level and thus obtain appropriate efficiency continually.

The World Bank and the International Monetary Fund emphasise that because of the ongoing trade liberalisation and "market opening", there is a positive and direct relationship between two variables, namely: competition and competitiveness. Meanwhile, in highly industrialised countries, literature is usually oriented towards gaining an advantage through lower prices and more efficient allocation. Competitiveness related to the freedom of trade is emphasised to a lesser extent, while the effects of antitrust policy on generating welfare are more strongly emphasised. However, whether in developed or developing countries, special attention is paid to the analysis of the relationship between competitiveness and innovation. Particular importance is attached to the importance of innovation in creating sustaining competitiveness. Technological competitiveness and the ability to compete in the distribution sphere are essential here. Currently, the ability to innovate has become an essential condition for achieving and maintaining sustainable competitiveness for every company and in every market, especially the global one (Wysokińska, 2013). One of the key factors increasing the competitiveness of an organisation is owning technology with the necessary features that competitors do not possess (Łunarski, 2009).

The Researched Companies

The research was conducted in a group of 10 companies from the metal industry operating in the Silesian Voivodeship; each company is identified in the article by using code name to preserve anonymity.

Enterprise M is a company operating mainly in the metal industry. Enterprise M can provide tooling facilities for manufacturing plants, which have press shops and use tooling up to 5000 kg. The company specialises in the production of tooling for plastic treatment. It produces wood and wood-based materials elements as part of its activity in the field of casting models.

The company M1 is a dynamically developing company in the fastener industry. The company provides solutions with the use of fasteners and fastening systems from leading domestic and foreign producers. The product range of the M1 company is used in many industries. The recipients are large industrial and commercial companies, as well as individual customers. The company is continuously working on expanding and improving its offer, putting the welfare and satisfaction of their customers first. The basic offer of the company includes fasteners manufactured according to domestic and foreign standards. Years of experience and professionalism in the field of fasteners are the advantages of the M1 company.

Enterprise M1 is a production, service and trade enterprise. It is one of the leading and recognised Polish companies producing steel screens from corrugated wires and meshes. The high position in the industry has been achieved through many years of experience in the field of steel screen production.

The M2 company provides complete service in the field of optimal product selection depending on the needs and taking into account individual requirements through production and offering the finished product. The high quality of our products, timely execution of orders and a short time of order execution are the advantages of M2 enterprise.

The priority is the continuous development of the company and individual products manufactured in it. The company cooperates with permanent suppliers to whom high requirements are set, by whom the company has no problems meeting the expectations of its customers. Competitiveness on the market also results from the reliability, honesty and integrity on which our company's operations are based.

For several years, the M3 company has been producing: screws, bolts for gutter clamps, double-threaded screws, metric pins, wall anchors, hooks, hex keys, rivets, screws and atypical fasteners for the construction, furniture and automotive industries. It also produces potting screws, bolts and pins made of all kinds of materials, including stainless, acid-resistant materials and in grades. It also performs galvanising of screw products and metal elements on pendants up to 3 meters long.

The M4 company offers processing of sheets, profiles and flat bars based on modern technologies. Operating both as a manufacturer and subcontractor, it increases the competitiveness and profitability of customers. It offers a comprehensive service from design, through production, to delivery logistics. It has a modern machine park and its own design office. Owing to the experienced staff, it guarantees short delivery times; serialisation adapted to the customer's needs and favourable prices combined with advantageous payment terms. The core competencies include the production of power cabinets, electrical and electronic enclosures, frames, frames, covers, cassettes, battery

shelves, containers, brackets and terminals - including component assembly. Concern for the environment is deeply embedded in the company. Based on partnership agreements, all standards for waste selection and waste disposal are fulfilled. 100% of the metal waste generated during production is recycled.

The M5 company is a producer of highly adjustable collars and metal containers for storage and transport. The company also manufactures many other metal products and structures according to entrusted or own documentation. The products are painted in various RAL colours and hot-dip galvanised at the customer's request. In order to meet the needs of the market, the company is constantly expanding its existing assortment while ensuring competitive prices and favourable sales conditions. The fundamental goal of the company is to satisfy customer requirements and to execute orders on time.

Enterprise M6 specialises at the production of fasteners, which is carried out with the use of modern technologies, the method of plastic working and machining with the use of numerically controlled machines (CNC). The company's primary goal is to offer a wide range of high-quality fasteners. Equipping the control department with a specialised measuring microscope, which allows accurate checking of the geometry of the thread outline, and with a testing machine connected to the IT system, they enable the generation of test reports.

The M7 company specialises in metalworking, including turning, gear milling, grinding and machining. It produces elements according to the documentation provided by the customer or a pattern made of regular steel, quality steel, non-ferrous metal alloys or plastics. According to the recipient's wishes, it produces elements and ready-made components from entrusted or own material. The M7 company has been adapting to the needs of a changing market for many years. Introducing optimal technological solutions translates into lower production costs. The employees are qualified and experienced staff with competences confirmed by the authorisations and certificates.

The M8 company has over 30 years of experience in the design and production of special tools made of tungsten carbide as well as quality steel. It is one of the leading suppliers of special tools for many companies and concerns. It employs qualified staff with many years of experience in this industry. The company's products are manufactured on high-class machines using the highest-quality semi-finished products. The M8 company is equipped with high-class measuring instruments, required for the production of dies and tools on the particular order. The machine park is modernised continuously; therefore, the products are made in the shortest possible time while maintaining high accuracy. The M8 company has extensive experience in electrical discharge machining. Wire EDM is performed on high-class Japanese numerically controlled machines.

The M9 enterprise was established in 1990 with the Polish-origin capital. From the very beginning, the company was focused on dynamic development, and it remains valid all the time. This strategy enabled it to become currently one of the largest Polish producer of perforated sheets, expanded metal, wire mesh welded from round and profiled wires, industrial screens as well as structures and products containing screens. It continually invests in the latest equipment, educates employees and develops the production base. These activities allow us to constantly expand our offer and produce products with better and better parameters at more competitive prices. The company have its own design office and a very well-equipped tool room and machining department are additional advantages.

Research Methodology

The research survey was conducted to production workers of 10 heavy industry enterprises located in the Silesian Voivodeship using the BOST questionnaire. The total number of respondents was 342. The proposed research approach is qualitative, based on the case study method (cases are specific companies in the metal industry). BOST is the legally protected name of research method developed by Borkowski S. (2012a) on the principles of Toyota management implementation. The acronym BOST was created from the first two letters of the author's surname and the first name. The framework of the BOST method is based on the identification of sets factors related to each of 14 Toyota management rules. The number of factors in each set depends on the scope of the particular rule, and it varies from 4 to 10. Sets of factors are called areas. Some policies are divided into two or three areas. Toyota's management policies are divided into four divisions. The BOST survey has two versions: an employee version and a supervisor version. The employee version includes a set of factors that describe the rules: 1; 2; 3; 4; 6; 7; 14 and elements of the Toyota's house roof (quality, costs, lead time, safety, crew morale). The supervisor version contains a set of factors describing all Toyota management principles and elements of Toyota's house roof. The presented questionnaire has a ranking scale. The respondents are expected to assess the importance of each factor by using a numerical scale. The

BOST survey is successfully used both in manufacturing companies and service institutions (including banks, hospitals, schools, shops). The BOST questionnaire and method are the primary instruments in toyotarism by Borkowski S. (2019).

The BOST survey provides two types of variables. The independent (explanatory) variables are characterising the respondents. The results obtained in the research are classified into dependent variables. The characteristics of the independent variable in the BOST method are presented in the form of an array (Table1).

Table 1: Characteristics of the respondents. General characteristics

Symbol	Designation of features and their characteristics					
	MK	**WE**	**WI**	**SC**	**MR**	**TR**
1	Man	<Secondary	< 25	< 5	1	Normal
2	Woman	Secondary	26 -35	6 to 15	2	Transfer
3		Higher I	36 - 45	16 to 25	3	Finances
4		Higher II	46 - 50	26 to 30	4	
5			51 - 55	31 to 35	5	
6			56 - 60	36 to 40	6	
7			61 - 65	41 to 45		
8			> 65	> 45		

Source: Borkowski (2016a)

The structure of the map described by the technological possibilities and the competitiveness of the product gives information about the purposefulness of producing a given product. The map in this literature is called a 3x3 matrix. In the case of testing the importance of significance, the technological potential and competitiveness of a product, the scale of evaluation is determined by the literature; it is "9" because it is required by the subjective matrix (3x3). The output for the 3x3 matrix is obtained from the BOST survey. For instance, it is area E4b, where the following request is addressed to respondents:

E4b. On a scale of 1 to 9, evaluate the competitiveness of the product and the technological potential of the manufacturing process.
1 – small, 9 – large

TK		Product competitiveness
TW		Technological potential

The version of the 3x3 matrix used in the BOST method is presented in Fig. 1. In the original by Love P. (1999), the X-axis is represented by technological capabilities and the Y-axis by market position. In the presented research, the Y-axis represents the competitiveness of a product. For substantive reasons, the matrix zones are numbered from 1 to 9, in the circular version and additionally, the axes are marked with letter symbols. It follows from the name of the matrix itself that the adopted rating scale must be divisible by 3.

Fig. 1: General characteristics of matrix 3x3.

Source: Borkowski 2016a

For the statistical evaluation of the evaluation sets, parameters were defined which in some way determine the "centre" of a given sample, i.e. central tendency measures. These include averages of various kinds, the mode and the median. The arithmetic mean ($\bar{x}$) is calculated by adding all the values of the feature and dividing the obtained result by the number of units tested (n) (Koronacki, Mielniczuk, 2001). The dominant (D - mode, the most frequent value) is the value that occurs most often in the sample. The median (M - median value) of a set of n numbers of ascending order is:

- for an odd number n, the middle term of the sequence,
- for an even number n, the arithmetic mean of the two middle terms of the sequence.

The median plays a special role among quartiles; it is the second quartile that divides the community into two equal parts. Quartiles are positional measures of location, which divide the community into 4 equal parts, including $^{1}/_{4}$, i.e. 25% of units (Bielecka A., 2011). The comparison of the dominant, median and arithmetic mean gives the basis for the assessment of the accuracy of the rating set (Pulaska-Turin B., 2008):

$\bar{x}$ = D = M – symmetric distribution (1)

$\bar{x}$ > D > M– right-hand asymmetry (2) $\bar{x}$ < D < M – left-hand asymmetry (3)

Differentiation of Average Ratings

The non-parametric *Mann-Whitney U test* (which is a non-parametric equivalent of the Student's t-test) by Rabiej M. (2012) is used to compare the mean assessments of the importance of factors, due to its greatest power among the tests used to compare two independent groups. This test is also used because the available data (answers) are of the ordinal type (i.e. they can be ordered) and come from a group of independent (unrelated) measurements. The null hypothesis in this test assumes that the distributions of the studied variable in the analysed populations do not differ significantly (median ratings in the sectors compared). Due to the availability of a large research sample (n> 20), the Z test statistic for this test will be calculated. This statistic is a function of the sum of ranks and the sample size of (Rabiej M., 2012). The applied test statistic Z has the form of Więckowska B. (2016) (formula 2.2):

$$Z = \frac{U - \frac{n_1 n_2}{2}}{\sqrt{\frac{n_1 n_2 (n_1+n_2+1)}{12} - \frac{n_1 n_2 \sum(t^3 - t)}{12(n_1+n_2)(n_1+n_2-1)}}} \quad (4)$$

where: U – test statistics for a small sample size, calculated according to the formula:

$$U = n_1 n_2 + \frac{n_1(n_1+1)}{2} - R_1 \quad (5)$$

n_1, n_2 - sample size, R_1 - sum of ranks for the first sample, t - number of cases included in the combined rank; this is the arithmetic mean calculated from the successive natural numbers proposed for these values; the associated ranks are assigned to the repeated values of the variable (Więckowska B.. 2016).

The paper presents an assessment of the similarity of average ratings in terms of preferences. For this purpose, the Borkowski (2016) range scale was used, which is equivalent to the one comparative scale Borkowski and Knop (2014), the limit of similarity was 8% (Borkowski, 2020).

Due to having two sets of numbers, mathematical statistics measures can be applied to them, determining the correlations between the independent characteristics of the respondents and the importance of a given factor. Correlation analysis aim is to establish the existence of relationships between the variables and assess the strength and direction of these relationships (Maksimowicz-Ajchel , 2007), (Podgórski, 2010). The statistic, which describes the strength of the linear relationship between two variables, is the sample correlation coefficient (r). It takes values from the closed interval <-1; 1>. A value -1 indicates there is a perfect negative correlation and a value of 1 indicates a perfect positive correlation. A value 0 means no linear correlation. Correlation analysis makes it possible to determine whether there is a relationship between the studied features and what is its strength and direction. The calculated correlation coefficient will be compared with the critical coefficients for three levels: a = 0.05, a = 0.10, and = 0.20, taking into account the number of freedom. This analysis aim will be an assessment of the strength and direction of the relationship between the variables (Goryl et al, 2000).

Presentation of the survey results in terms of the importance of factors describing the 3x3 matrix

A study using the BOST Borkowski (2016b) method provided results from enterprises. To facilitate the reading of the distribution of factor scores in the analysed communities, they are presented in the form of a map superimposed on a 3x3 matrix (Fig.2). The 3x3 matrix allows us to determine the competitiveness of the product depending on the technological potential of the production process and allows concluding as to the direction of product development in the context of the technological potential.

Fig. 2: Map of the number of pairs of ratings on 3x3 matrix, respectively for each company: a) M, b) M1, c) M2, d) M3, e) M4,f) M5, g) M6, h) M7, i) M8, j) M9.

Source: own study

Low ratings for a product's competitiveness can indicate poor production quality, as well as any other deficiencies, which indicate that the product is outdated in comparison to the products offered by competitors. Since production is carried out with the help of technology, it is possible to draw conclusions about the life stage of this technology based on this assessment. Well-known technology - widespread (in the peak phase of technology life) does not allow to produce a product "better" than the products of the competition. It is possible to achieve ratings of at most medium (4; 5; 6) or low (1; 2; 3). Achieving high marks (7; 8; 9) requires the use of a technology that is newer than the competition use. As production workers are rarely or not able to refer to marketing tools at all, their opinions can be the basis for management decisions.

The assessment of the technological potential of the manufacturing process relates to the technology owned by the enterprise, i.e. it covers the technology portfolio. Low portfolio scores mean that production is conducted with the use of standard technologies, and the need to manufacture some elements is outsourced to specialist companies. When assessing the average, the portfolio of technologies owned ensures that the requirements set by production are met,

and it keeps up with the competition. On the other hand, high marks prove that the company has such facilities that allow it to lead production in the latest technologies, outperforming the competition.

The data on Figure 2 show that the study involved: 31; 34; 29; 31; 35; 33; 35; 40; 35; 36 respondents from enterprises M, M1, M2, M3, M4, M5, M6, M7, M8, M9 respectively. The obtained assessments formed pairs of numbers which were distributed in all zones of the 3x3 matrix in one case (M8 enterprise), in eight - two enterprises (M1, M9), in seven - two enterprises (M, M2), in six - two enterprises (M4, M5), in four - three enterprises (M3, M6, M7). The characteristics of unused zones are as follows: zone A-D five times (enterprises: M3, M4, M5, M6, M7), zone B-D four times (enterprises: M2, M3, M6, M7), zone C-D eight times (M, M1, M2, M3, M4, M5, M6, M7), zone C-E four times (enterprises: M3, M4, M6, M7), zone C-F six times (M, M1, M2, M3, M4, M5, M6, M7). The comparison shows there were pairs of ratings in all ten cases in the zones A-E, A-F, B-E, B-F. These zones are characterised by high ratings of the importance of factors describing the axes of the 3x3 matrix. The consequence of the above list is the fact that four zones A-E, A-F, B-E, B-F determine the type of management decisions made regarding the technological potential and competitiveness of the product. Certainly, making a decision will help to determine the maximum number of pairs of ratings. It occurs in the following zones: A-F for four enterprises: M5, M6, M7, M8, B-F also for four enterprises: M1, M2, M3, M4, B-E for two enterprises: M and M9. It should be emphasised that the pairs of ratings from the A-F zone, the highest ones, indicate "Concentration of management activities on maintaining the existing state", there is actually use of the technological potential of the enterprise to obtain the highest competitiveness of the manufactured product. The location of the pairs of ratings in the B-F zone indicates the need to make management decisions in the enterprise in terms of greater use of technological potential. As it was shown in two enterprises, pairs of assessments were located in the central zone B - they were located in the central zone of the 3x3 matrix, forcing the enterprise to make decisions both in terms of improving the technological potential and increasing the competitiveness of the manufactured product, while it is supposed to "Look for opportunities" as to the order making decisions. The maximum number of pairs of ratings did not occur for zone A.

Statistical Analysis of The Obtained Evaluation Sets

Statistical analysis of the results from the BOST survey is based on comparison the value of the arithmetic mean with the dominant and the median to determine the skewness of the obtained sets of scores. The skewness assessment criterion is contained in the dependencies (1) - (3). The data for analysis are included in the figure. A comparison of the average ratings of the factors, characteristics of the dominants and medians will be presented first. The data on the left column of the figure indicates that in three enterprises (M, M8, M9) the average rating of the product competitiveness factor (TK) is lower than the average of the technological potential factor (TW). The lowest average score was the factor TK for enterprise M (5,39) and factor TW for enterprise M1 (5,79), while the highest for enterprise M7 (7,40) and enterprise M6 (6,89) corresponding to the factor TK, TW. Average scores were used to determine the zone on the 3x3 matrix. It was found that for the enterprises: M, M1, M2, M3, M4, M5, M6, M7, M8, M9, the zones are as follows: 9; 2; 2; 9; 2; 1; 1; 1; 9; 9 respectively. The compilation of this information shows there are three companies for which the arithmetic means are located in zone 1, the same amount in zone 2 and four in zone 9.

This chart differs from the 3x3 matrix zone chart according to the maximum number of votes. It is easy to notice that zone 2 has appeared, while zone 8 has disappeared, and the number of enterprises with zone 1 has decreased. The 3x3 matrix zone, based on the assessment of average factors describing its axes, may support the decision-making process in the enterprise. The analysis of the dominant value for the sets of assessments of the product competitiveness factor (TK) indicates that the rating 4 (M9) occurs only once, similarly the rating 5 (M), the rating 8 (M5) and the rating 9 (M6). In the remaining sets of ratings (six), the most common rating is 7. Regarding the median, the quantitative statement is as follows: one each has ratings: 5 (M), 6 (M9) and 8 (M5), in the remaining seven cases it is 7. As for the technological potential factor (TW), it should be noted that one time they occur as the dominant of the rating: 6 (M4), 8 (M7) and 9 (M8), three times the rating 7 (M1, M5, M6), in the remaining four cases, the score 5. Concerning the median, there are only two scores: 6 (in six cases) and 7 in the remaining four for the sets of enterprise scores (M5, M6, M7, M8). The analysis of the values: arithmetic mean, dominants, medians of the sets of factors assessments: product competitiveness (TK), technological potential (TW) present the following information:

- in three cases, the arithmetic mean of the sets of assessments for the product competitiveness factor (TK) is lower than the average of the sets of ratings for the technological potential factor (TW),

- the matrix zone determined on the basis of the arithmetic means of the TK and TW factors differ from the zones with the most scores,
- in the sets of assessments of the product competitiveness factor (TK), the most frequent assessment (dominant) is the grade 7 (the grades 5; 8; 9 are also dominant),
- the median of the sets of ratings for this factor is most often (seven times) described by the rating 7,
- the dominant feature of the set of ratings for the technological potential factor (TW) is usually (four times) the rating 5,
- assessment 6 of the set of assessments of the technological potential factor (TW) is the median in six cases,
- the dominant feature for the sets of product competitiveness assessments (TK) are the following assessments: 4; 5; 7; 8; 9 the median of 5; 6; 7; 8,
- while for the sets of assessments of the technological potential factor (TW) are the following ratings: 5; 6; 7; 8; 9 the median is only two ratings: 6; 7,
- the comparison of the above two statements shows that the number of ratings defining the dominant of the sets of ratings for both subjective factors is the same (the difference exists in the structure of ratings), in relation to the number determining the median, it is smaller in the case of the set of ratings for the factor technological potential (TW).

Returning to the skewness of the obtained sets of factor assessments, describing the 3x3 matrix, the following entries were obtained: $\bar{x}$ > D = M (2), $\bar{x}$ < D = M (6), $\bar{x}$ > D < M (1), $\bar{x}$ < D > M (1) in relation to the product competitiveness factor (TK). The summary of these dependencies for the sets of assessments of the technological potential factor (TW) indicates that the number of dependencies is as follows: : $\bar{x}$ < D = M (3), $\bar{x}$ > D < M (4), $\bar{x}$ < D > M (3). None of the entries corresponds to the formulas (1) - (3).

Fig. 3: Matrix 3x3-relationship analysis results for: $\bar{x}$; D; M.

Description: right column - skewness coefficients; left column- means, dominants, medians ($\bar{x}$; D; M) Fig. 3 sections applies respectively for each company: a), b) M, c), d) M1, e), f) M2, g), h) M3, i), j) M4, k), l) M5, m, n) M6, o), p) M7, r), s) M8, t), u) M9.

However, there is a certain similarity to the form of the mentioned formulas, namely: there are cases where the arithmetic mean is greater than the value of the dominant and cases, minorities - the dominant is equal to the median in both cases. In the case of the first statement, there is a reference to formula (2), the set of scores should have a right-hand skewness, while the second one refers to formula (3) and the set of scores should have a left-hand skewness. Verbal consultations with colleagues, working in statistics, confirmed the existence of other dependencies on the described formulas (1) - (3). In order to reliably determine skewness in such situations, the classic asymmetry coefficient should be calculated, which informs about the location of the obtained results relative to the average value (6):

$$W_A = \frac{\mu_3}{S^3(x)} \tag{6}$$

where:

W_a - classic asymmetry coefficient,

μ_3 - the third central moment calculated according to the formula (7):

$$\mu_3 = \frac{\sum_{i=1}^{n}(x_i - \bar{x})^3}{N} \tag{7}$$

Distributions can exhibit right (positive) skewness or left (negative) skewness. The strength of the asymmetry of the distribution can be determined on the basis of the skewness coefficient value as follows (Pulaska-Turyna. 2008):

- 0-0,4 - very weak asymmetry of the distribution,
- 0,4–0,8 - weak asymmetry of distribution,
- 0,8–1,2 - moderate asymmetry of the distribution,
- 1,2–1,6 - strong asymmetry of distribution,
- more than 1,6 - very strong asymmetry of distribution.

The results concerning the numerical value of the asymmetry coefficient (right column of the figure) indicate the existence of two right-skewed rating sets (M1, M9) and eight left-skewed rating sets for the product competitiveness factor (TK) rating sets. On the other hand, the sets of assessments of the factor technological potential (TW) have a right-hand skew in six cases, and left-hand skew in four cases. Descriptions of the histograms for the asymmetry coefficient indicate the strength of the asymmetry, and it falls into two groups: 0-0,4 and 0,4-0,8. The sets of assessments of the product competitiveness factor (TK) in six cases have weak distribution asymmetry, and the remaining four sets are characterised by very weak distribution asymmetry. Regarding the sets of assessments of the technological potential factor (TW), two cases of sets with a weak asymmetry of distribution were found (M5 and M7), the remaining eight sets are characterised by a very weak asymmetry of the distribution. Further analysis of the asymmetry factor indicates that there are four cases (M5, M7, M8, M9) for which the direction of the asymmetry of the evaluation sets is identical.

The evaluation values of average factors are compared: product competitiveness (TK), technological potential (TW), by answering the question, which factor's average is greater. The arithmetic means of the examined factors were used to define the zone of the 3x3 matrix. The sets of scores are used to determine the significance of the differentiation of

average scores and the correlation between them. Figure 4 shows the results, where the means differ significantly in 5 out of 10 cases, of which only 2 times (M1, M7) at the level of α = 0,05, also 2 times (M2, M4) at the level of α = 0,1 and once (M5) at the level of α = 0,2. The correlation between the assessments of the analysed factors occurs 6 times. At the level of α = 0,05 it occurs once (M), at the level of α = 0,1 the correlation appears 3 times (M1, M7, M9) and 2 times (M2, M8) at the level of α = 0,2. It should also be mentioned that in the case of M1, M2, M7 enterprises, the subjective factors have ratings and their means, showing statistically significant both relationships. However, for the data of enterprises: M3, M6, the mentioned relations are not found.

Fig. 4: Relations between the factors of the area E4b.Filled histogram - differentiation of means, empty histogram - correlation. Applicable companies: a) M, b) M1, c) M2, d) M3, e) M4, f) M5, g) M6, h) M7, i) M8, j) M9

Source: own study

Figure 5a shows the distribution of enterprises on the range axis for the product competitiveness factor (TK), while Figure 5b shows the structure of the distribution. The distribution on the range axis (Fig. 5a) of enterprises presents that there are two characteristic clusters of enterprises. In one of them, there are four enterprises (M3, M4, M1, M2), they are located in two zones of medium and high preferences. The product competitiveness factor (TK) in neighbouring enterprises is equally preferred because the distance between them is shorter than the criterion of 8% for 10 factors. More precisely, the interpretation of this cluster is as follows: the subjective TK factor in terms of preferences is similar to its preferences in both M3 and M1 enterprises. However, there is no similarity of this factor for M3 and M1 enterprises (the distance between them is 7,7 + 4 = 11,7 > 8). The product competitiveness factor (TK) in M1 is similarly preferred as in M4 and M2 instead. The second group of enterprises is in the highly preferred zone (80-100%).

Fig. 5: Comparison of preferences of TK and TW factors in the surveyed enterprises. The left column of figures - distribution of companies on the range scale, right column - structure of the range scale. It concerns the following factors: a), b) product competitiveness (TK), c), d) technological potential of the manufacturing process (TW)

Source: own study

The preference of the technological potential factor (TW) in the examined enterprises (Fig. 5c) also shows two characteristic clusters of them. In one of them (in the low preference zone 0-20%) there are five enterprises: M1, M9, M2, M4, M. The least TW factor is preferred in M1, the preference in it is similar to the reference in M9. On the other hand, the preference in the M9 enterprise is similar to the preferences in the mentioned enterprise M1 and the following enterprises: M2, M4, because the sum of the distances M9-M2 (4,5), M2-M4 (0,9) is 5,4 <8%. The second group, consisting of two enterprises: M3, M8, is in the average preference zone (40-60%), in the mentioned enterprises, the TW factor is similarly preferred. When analysing enterprises in which the following factors: TK, TW are extremely preferred, it should be stated that the TK factor is the least preferred in enterprise M, while in this enterprise the TW factor is more appreciated (on the scale it took place with a coordinate of 16,4%). The most preferred factor of TK is in the M7 enterprise; also the factor of TK is highly preferred in it (it is located with the coordinate 87,3% on the scale), which is located in the highly preferred zone. TW factor is the least preferred in company M1, this preference is similar to the preference in company M9. As shown in Fig. 4a, in M1, the TK factor is strongly preferred. The TW factor is most preferred in the M6 enterprise; the respondents also strongly prefer the TK factor.

The resultant value of the ratings of factors: product competitiveness (TK), technological potential (TW), is the distribution of their pairs on the 3x3 matrix, which results in the percentage of placing these pairs in its individual zones. Results in the field of preferences of the respondents in four zones: (A-F) - focus on the revealed opportunity ("1"), (A-E) - improve marketing ("2"), (B-F) - develop your technological capabilities ("8"), (B-E) - look for opportunities ("9"), are shown in Fig. 5. A characteristic feature of the preferences of pairs of factors in zone "1" is the clustering of six enterprises on the 16,3% section of the range scale. In these enterprises: M1, M, M9, M4, M2, M3 the pair of factors TK and TW is poorly preferred. There is a case of similarity in terms of preferences of the factors TK and TW in four enterprises: M, M9, M4, M2, because the distance between enterprise M and M2 is 4,5% of the scale <8%, in the aforementioned group. As shown in Figure 5c, the percentage share of a pair of factors: TK, TW in zone "2" of the matrix, there is a grouping of five enterprises on the 20% range of the range scale, located in the 53% -73% range of this scale. Therefore, the analysed factors are moderately or strongly preferred in these enterprises. There are six cases (the most) in which factors are similar in neighbouring enterprises: TK, TW in terms of preferences. The distribution of enterprises for the data from the zone "8" of the 3x3 matrix differs from the data for the other zones of this matrix (Fig. 5e). Enterprises in which the respondents prefer several factors: TK, TW the least or the most, do not show similarity to preferences in other enterprises, because the distance to the "neighbour" is not less than 26.5% of the scale.

Fig. 6: Comparison of the preferences of the distribution of factors: TK, TW in selected zones of the 3x3 matrix. The left column of figures - the distribution of enterprises on the range scale, the right column - the structure of the range scale. Applies to the following zones: a), b) "1", c), d) "2", e), f) "8", g), h) "9".
Source: own study

Eight enterprises are spread over 45,2% of the scale, in this grouping there are five cases in which the factors are similar in terms of preferences, this applies to enterprises: M8-M9, M5-M6, M3-M5, M4-M3, M7-M2. Figure 5g contains data of the distribution of enterprises in terms of the percentages of pairs of factors: TK, TW in zone "9", middle matrix 3x3. It presents that there are five enterprises at the beginning of this scale, and four at the end of the scale. Almost in the middle part of the scale (51,5%) there is enterprise M2, in which the pair of factors: TK, TW does not show similarities in terms of preferences in neighbouring enterprises. There were three cases (the least) in which there is a similarity in terms of factor preferences: TK, TW and it concerns pairs of enterprises: M8-M6, M-M4, M9-M.

Influence of respondents' characteristics on the assessment of analysed factors

Figure 7 shows the results of the correlation analysis, the influence of respondents' characteristics on the importance of factors describing the 3x3 matrix.

1; 2; 3 number of statistically significant coefficients. (+) positive correlation, (-) negative correlation

Fig. 7. Summary of the results of the correlation analysis to determine the influence of the respondents' characteristics on the importance of factors in the E4b area. Companies concerned: a) M, b) M1, c) M2, d) M3, e) M4, f) M5, g) M6, h) M7, i) M8, j) M9.

Source: own study

The independent variables were the respondents' characteristics: gender (MK), education (WE), age (WI), seniority (SC), mobility (MR), admission to work (TR). Dependent variables are the already mentioned coordinates of the 3x3 matrix, variable X - technological potential (TW), variable Y - product competitiveness (TK).

Out of a total of 60 cases of correlation (ten enterprises, six characteristics of the respondents), there was a correlation in 15 cases for the TK factor, and 13 for the TW factor. For the data of M3, no statistically significant correlation was found for the ratings of both factors at the level of $\alpha = 0,2$, while for the ratings of product competitiveness (TK) in the M6 company, and in the M7 company for the technological potential factor (TW). The maximum number of correlations occurs: for the product competitiveness factor (TK) for the enterprise data M4, there is a correlation based on gender (MK), education (WE), age (WI), and seniority (SC), (all only for $\alpha = 0,2$), for the technological potential

(TW) factor in the M6 enterprise, there is a correlation with age (WI), seniority (SC) of the respondents (for $\alpha = 0{,}05$) and their mode of admission to work (TR) (for $\alpha = 0, 1$). Regarding the activity of the influence of the respondents' characteristics on the level of assessments of the examined factors, the most active feature is the education of the respondents (WE) (6 cases), and the lowest mode of admission to work (TR) (3 cases).

Summary

The work concerns knowledge in the field of technology, competitiveness, innovation. While examining the scientific potential of knowledge in the field of technology, attention was paid to the importance of technology in the national economy. It has been shown that technology, which is one of the basic areas of creating positive value, is related to the competitiveness of a product. The innovative BOST research method is presented, allowing to determine the relationship between the technological potential of manufacturing processes (TK) and the competitiveness of products (TW) in 10 companies in the metal industry, the total number of respondents was 342. The research methodology uses the eastern approach to production management, based on the assumption that there is a sizeable creative potential in operational employees, enabling the identification of the importance of subjective factors (3x3 matrix).
The results of the BOST survey are presented in the form of the number of factor pairs: technological potential (TK), product competitiveness (TW) in individual zones of the 3x3 matrix, which made it possible to determine the number of respondents. It found that there is only one case of results appearing in all nine zones of the 3x3 matrix, while in three cases the results are only located in the following four zones: focus on the opportunity disclosed ("1"), improve marketing ("2"), develop your technological capabilities ("8"), look for opportunities ("9"). The maximum number of results is in one of the zones listed. The results in two cases, stay aloof ("5"), are characterised by severity ratings of up to 3 for both factors.
Statistical evaluation (skewness) of the obtained sets of scores was planned on the basis of the relationship between the arithmetic mean ($\bar{x}$), dominant (D) and median (M). These measures should show equality, minority, majority in relation to each other in the order listed. However, the following types of dependence occurred during the analysis $\bar{x} > D = M$, $\bar{x} < D = M$, $\bar{x} > D < M$, $\bar{x} < D > M$. The problem of unambiguous determination of skewness arose. The classical coefficient of variation was determined to explain the problem. It has been shown that in most cases (8) the sets of TK factors Left-hand skewness, while the sets of TW factor scores have half right-hand and half-left skew. As for the strength of the asymmetry, it is very weak or weak.

Summing the analysis of the range scale, it should be stated that the extreme positions on the range axis are taken by the following pairs of enterprises in the following zones: "1" - M1-M7: "2" - M9-M6; "8" - M-M1; "9" - M7-M9, the list does not include the following companies: M2, M3, M4, M5, M8. Further analysis of the set of pairs of enterprises shows the presence of enterprises twice. In M1, the factors: TK, TW are the least preferred in zone "1", while in zone "8" the most strongly, and in this case they do not show similarities to others in terms of preferences. In zone "9" of the matrix, subjective factors for a given enterprise are on average preferred. As for the preferences of factors: TK and TW, in zone "1" it is the most preferred in enterprise M7, in zone "2" this enterprise is near the middle of the scale and shows similarity to preferences in enterprise M1. The preference of the analysed pair of factors is the lowest in zone "9". The respondents revealed the lowest preferences of a pair of factors: TK and TW for zone "1" in company M9, while for zone "9" the preference is the strongest. The analysis shows that, depending on the zone of the 3x3 matrix, the subjective pair of factors is the least or the most preferred. Such a situation does not occur for the given enterprises: M and M6. It should be noted that these enterprises are in extreme positions on the scale of the range in terms of factor preferences: in company M, the factor TK is the least preferred, while the factor TW is the most preferred in company M6. The other two extreme positions are found in enterprises: M1 - the least preferred TW factor, M7 - the most preferred TK factor.

When making management decisions in terms of technological potential and product competitiveness, the data of the metalworking company (M7) for the TK factor, the manufacturer of fasteners (M6) for the TW factor should be used. However, in the case of a pair of these factors, to stay in the zone (A-F) - focus on the revealed opportunity ("1"), (A-E) - improve marketing ("2"), you should also use the experience of the mentioned companies. The signpost for the relocation of enterprises located in the following zones: (BF) - develop your technological capabilities ("8"), (BE) - look for opportunities ("9") to the previously mentioned zones of the 3x3 matrix are the data of the companies: manufacturer of screws, bolts (M1) and a manufacturer of perforated sheets and meshes (M9).

Total of 28 dependencies (15 for the TK factor) were found out of 120 possible as an result of the analysis of the influence of the respondents' characteristics. For the data of one enterprise, no statistically significant correlation was

found between the scores of the analysed factors and the characteristics of the respondents, in addition, no one case of the analysed relationship was found for both the TK and TW factors. The most active feature was the education of the respondents (WE) (6 cases out of 28 existing), and the least active (TR) (3 cases). Only for the data of one enterprise, there was a correlation dependence on four characteristics of the respondents.

Abstract

One of the main objectives of EU regional policy is to stimulate processes which enhance internal economic cohesion in individual regions. At the regional level, the purpose of cohesion may be perceived through the prism of the necessity to eliminate disparities between individual areas, i.e. districts (poviats), forming a given region, i.e. province (voivodeship). The aim of the study is to assess the impact of EU funds invested in individual Polish provinces on changing the level of diversity, and therefore the level of coherence of individual voivodeship in the area of social, economic, environmental and institutional and political governance. For this purpose were analyzed 208084 completed investment projects co-financing with Community funds amounted to PLN 433.5 billion, which were implemented in Poland in 2004-2018. The results of the conducted research clearly indicated areas in which there is a statistically significant relationship between the investments implemented with EU financial support and changes in the internal coherence of individual voivodships. This enables to issue recommendations regarding the way in which Community funds will be spent, which in the expected way affect the increase in internal cohesion of the regions.

Keywords: Economic Cohesion; Regional Policy; Economic Governance; Social Governance.

The importance of regional cohesion in European Union Regional Policy

The concept of EU regional policy has been defined in various ways. According to M. Rudnicki [Rudnicki 2000, p. 46], "EU regional policy is a thematically structured action introduced by the decision-making centre, which aims, through a set of legal and financial instruments, to remove disparities in the economic and social development of regions in the EU and to ensure sustainable growth of all its areas while maintaining its internal economic and social cohesion". European regional policy may also be understood as "a set of actions taken by the European Community's decision making centre to reduce disparities in economic, social and spatial development and to achieve cohesion between regions through the redistribution of financial resources in an integrated Europe" [Głąbicka 2003, p. 4]. However, the treaty provisions do not provide any formalised definition of regional policy. The term "regional policy" was not explicitly used in any of the three treaties establishing the European

Cite this Article as: Rafał CZYZYCKI, Rafał KLOSKA, Elżbieta OCIEPA-KICINSKA and Piotr SZKLARZ "Impact of European Union Funds on The Level of Cohesion of Regions in Poland" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Communities (Treaty establishing the European Coal and Steel Community; Treaty establishing the European Economic Community; Treaty establishing the European Atomic Energy Community), nor was it used in the Single European Act, the Treaty on European Union or the Treaty of Amsterdam. Nevertheless, already at the beginning of the integration process, regional disparities and their adverse consequences on the political, economic, social and cultural sphere were recognised [Leszkiewicz 2012, p. 228]. However, EU regional policy has been pursued practically since 1956, when the report of the International Committee, which prepared the Treaty of Rome, indicated the regional scope as one of the three main common courses of action for Member States. This report stressed the need to use the resources as much as possible to eliminate developmental delays in the regions of Member States, and accordingly the necessity to establish a special investment fund was reported [Pietrzyk 2000, p. 621]. The EEC's non-treaty document, which addressed regional problems, was the Programme of Community Action for 1962 1965. In 1968, the General Directorate for Regional Policy was established which, using the tools for controlling aid granted by individual countries for regional development, initiated the coordination of EU-wide activities under the regional policy.

The 2021-2027 cohesion policy framework takes greater account of action at local level – it supports the development of local growth strategies by municipal, local or other territorial authorities which should be responsible for or involved in the selection of EU funded projects. Regional co financing rates will be raised to pre-crisis levels which will increase responsibility for the projects implemented and encourage the improvement of their quality. The EU contribution will be set at a maximum of 40% to 70%. The new framework additionally facilitates the continuation of “community-led local development”, i.e. the development of local growth strategies by action groups involving local authorities, civil society and business partners [EU Budget 2018]. Cohesion policy will continue to invest in all regions and three categories of regions will still exist (less developed; transitional; more developed). The method of allocating funds continues to be largely based on GDP per capita, however new criteria (youth unemployment, low education level, climate change and immigrants reception and integration measures) will also be taken into account to better reflect the actual situation. The outermost regions will continue to benefit from specific EU support. Cohesion policy will continue to support bottom-up development strategies and strengthen the position of local authorities in managing the funds. The urban dimension of cohesion policy has been strengthened by earmarking 6% of ERDF funding for sustainable urban development and by establishing a new networking and capacity building programme for municipal authorities of the European Urban Initiative [Regional Development 2020].

The EU regional policy involves not only the elimination of divergence effects, but their prevention by stimulating the spread effects. It is therefore justified to selectively support regional development on a sectoral and territorial basis, adopting a holistic approach to avoid the adverse effects of divergence [Ziomek 2008, p. 149]. The EU and the most developed countries take a bottom up approach to development and, to this end, programmes are launched to identify and highlight the potential of local development activities. This trend supports local entrepreneurship, develops human capital, promotes innovation and establishes regional institutions and networks of related enterprises to achieve competitive advantage [Jałowiecki 1993, p. 59].

Evolution of regional policy in Poland

In the first years of Poland's transformation, the state's economic policy was dominated by macro-economic priorities aimed at introducing a new order after the central management system.

As a result, the changes occurring at the level of regional economy led to [Gruchman 2006, p. 147]:

1. Significant development of several of the largest urban agglomerations which additionally contributed to changes in the territorial facilities in their immediate vicinity. The Warsaw agglomeration has developed particularly dynamically, clearly exceeding the average rate of development of the rest of the country. The agglomeration concentrates the country's considerable potential in many areas (especially in respect of science and research).
2. Slow restructuring and, consequently, slow development of industrial districts, raw material processing and concentration of large plants. This concerned in particular the Upper Silesia, the Copper and Sulphur Basin as well as the Łódź Light Industry District.

3. The particularly difficult situation of regions in which agriculture prevails, especially those with state agricultural ownership (in the north and west of the country), which was reflected in very low development dynamics and high unemployment.

The processes of political transformation led to a rapid increase in regional disparities. This concerned mainly the four major processes: changes in the labour market (of which unemployment was the most important element), privatisation of the economy, foreign investment and development of a favourable business environment. The regional differentiation of these processes led to a strong polarisation of the country's regions into relatively few areas of success and successful transformation process (the so-called transformation leaders) and areas beset with problems of different nature [Kuciński 1997, p. 65]. Since 1 January 1999, the conditions for conducting regional policy have been amended in Poland. The public administration reform introduced three tiers of local government: commune [gmina], district [poviat] and province [voivodeship]. Under the new solutions, the self-governing province was assigned the responsibility for the implementation of development processes on its territory. The new legal situation has created a qualitatively different reality which was conducive to shaping the general policy of the state's territorial development and to following the local authorities' own regional development policy. As a result, regional policy could be pursued in both dimensions – inter-regional (government towards the regions) and intra-regional (local authorities within their regions).

Polish regional policy, based on a compensatory model of the EU economic cohesion, requires continuous improvement both in the forms of its implementation and with regard to its scale and set of instruments. It is currently based on the creation of social and economic space as well as the preparation of development programmes on the basis of strategic objectives and operational programmes. However, the main purpose of an intentional influence of the local government on production entities and consumers should be to initiate endogenous market processes resulting from entrepreneurship and to increase the added value of the whole area. Therefore, local authorities should create conditions for free and competitive economic activity, substantial investment in science-intensive and innovative sectors and improving the structure of the region's economy [Spychalski 2006, pp. 5-18].

Methodological aspects of measuring regional cohesion

As is the case with studies aimed at determining the level of socio-economic development of regions, the assessment of the cohesion level of the said regions entails the problem of the appropriate selection of diagnostic variables. The most common procedure involves a general identification of groups of factors and then the selection of appropriate diagnostic variables for each group. However, due to the lack of a universal and timeless, generally applicable system of appropriate indicators and explicit rules for the selection of diagnostic variables, the selection is primarily determined by the possibility of obtaining comparable data and the need to meet substantive and formal requirements (the spatial scope of the assessment, temporal and substantive scope, and above all its purpose) [Johann 2005, pp. 54-55; Słaby 1994, p. 39].

Considering the purpose of this study, the following measures were selected as the variables determining the level of development:

- in respect of social governance – rate of migration for permanent residence of persons at the working age per 10,000 people at the working age (X1), deaths of persons up to 65 years of age per 1,000 people at the working age (X2), average gross monthly remuneration (business entities over 9 persons) (X3), percentage of children in pre-school institutions per 1,000 children aged 3-5 (X4), percentage of the long-term unemployed (more than one year) in the total number of the registered unemployed (X5), registered unemployment rate (X6), number of out-patient clinics per 10,000 inhabitants (X7);
- in respect of economic governance – value of capital expenditure in enterprises (current prices in PLN; excluding business entities employing up to 9 persons) per 1 inhabitant at working age (X8), the number of national business entities recently entered in the National Register of Business Entities [REGON] per 10,000 people at working age (X9), number of natural persons conducting business activity per 100 people at working age (X10), number of national business entities entered in the National Register of Business Entities [REGON] per 1,000 people at working age (X11), length of local public roads per 100 sq km (X12);

- in respect of environmental governance – emission of carbon dioxide [tons/year] from plants with considerable environmental impact per 100 employees (X13), electricity consumption [kWh] per 1 inhabitant (X14), percentage of retained or neutralised pollutants in pollution reduction devices in plants with considerable environmental impact in the total pollution produced (X15), forestation rate (X16), percentage of green areas in total area (X17), amount of mixed municipal waste [kg] from households collected per year per 1 inhabitant (X18), percentage of municipal and industrial waste water treated in total waste water requiring treatment (X19), number of illegal landfills per 100 sq km of total area (X20);
- in terms of institutional and political governance – number of registered foundations, associations and social organisations per 10,000 inhabitants (X21), commune budget receipts [PLN] from maintenance fees per 1 inhabitant (X22), percentage of capital expenditures of communes and districts in total expenditures (X23).

Assuming, however, that the degree of cohesion of a given region may be equated with the degree of its internal differentiation, from a statistical perspective, the classic coefficient of variation Vs may be considered the basic measure of cohesion.

In order to determine the impact of EU funds invested in individual Polish provinces on the change in the level of differentiation, and thus the level of cohesion of individual provinces in terms of social governance, the following research procedure was conducted:

1. On the basis of data collected from the local database (https://bdl.stat.gov.pl), a ranking of provinces was compiled demonstrating the changes in the level of differentiation of individual diagnostic variables between 2004 (Poland's accession to the EU) and 2017 (completion of the majority of projects carried out under the EU financial perspective 2007-2013), assuming that the province with the greatest relative decrease in differentiation will be ranked highest.
2. On the basis of information provided at www.mapadotacji.gov.pl, a ranking of provinces has been compiled presenting the value of financial aid received per 1 inhabitant from the EU funds for the implementation of projects co-financed with the EU funds in a given province, broken down by specific investment areas.
3. By means of the Kendall's tau coefficient, the compliance evaluation was carried out on the rankings created in points 1 and 2, assuming that obtaining a statistically significant value of this coefficient indicates at the same time a considerable impact of the EU funds on the development of cohesion of regions in Poland (determining the significance level at p-value ≤ 0.05).

Study Results

Comparing the trends in the values adopted for the study of diagnostic variables in the districts comprising individual provinces in Poland in 2017 with the trends in 2004, it is difficult to clearly assess the actual impact of EU funds allocated in a given region on the change in the cohesion level of that region. The analysis of the changes in the coefficient of variation Vs in this period reveals that in terms of social governance, in the case of the rate of migration for permanent residence of people at working age per 10,000 people at this age (X1), in the vast majority of provinces a gap was reduced, ranging from 2.3% in the Warmińsko-Mazurskie province to over 93% in the Pomorskie province, while when analysing the number of deaths among people up to 65 years of age per 1,000 people at this age (X2), a reduction in the gap was recorded in half of the provinces (i.e. an increase in internal cohesion), and in the second half an increase, however, the change in the size of gap most often did not exceed 20%. In terms of average monthly gross wages and salaries (X3), practically in all provinces, a decrease in internal differentiation by approximately 20% was noted, an increase in this respect was recorded only in the Łódzkie (by 1.2%), Podkarpackie (by 14.8%) and Małopolskie province (by 18.5%). Among all diagnostic variables determining social governance, the greatest improvement in the internal cohesion of provinces concerned the percentage of children in pre-schools in the total number of children aged 3-5 (X4). The related differentiation decreased from 47.9% in the case of Opolskie province to 78.3% in Świętokrzyskie province.

In respect of economic governance, the only province which in the analysed period enhanced its cohesion in terms of all diagnostic variables, included in this area, was Podlaskie province. In 12 provinces an increase in cohesion was observed in terms of the number of natural persons conducting business activity per 100 people at working age (X10), in 10 – in terms of the number of national business entities recently entered in the REGON system per 10,000 people at working age (X9), in 9 – in terms of capital expenditure per 1 inhabitant (X8) and the length of

local public roads per 100 sq km (X12), while in the case of the total number of entities registered in the REGON system per 10,000 people at working age a decrease in internal differentiation was recorded only in 4 provinces. Generally, the decrease in the differentiation of regions in the analysed period was at the level of 10-20%.

In respect of environmental governance, 15 provinces saw a decrease in the internal differentiation in the amount of mixed municipal waste from households per 1 inhabitant (X_{18}) (on average, *Vs* decreased by approx. 50%). In 13 provinces cohesion improved in terms of the percentage of treated wastewater in the total amount of wastewater requiring treatment (X_{19}) (in 6 provinces the decrease in the variation coefficient exceeded 90%), in 11 provinces cohesion increased in respect of electricity consumption per 1 inhabitant (X_{14}) and 10 provinces experienced a decrease in the internal differentiation in the number of illegal landfills per 100 sq km of the province area (X_{20}).

In terms of institutional and political governance, the internal differentiation decreased in the number of registered foundations, associations and social organisations per 10,000 inhabitants (X_{21}) and occurred in 11 provinces (from 0.76% in the case of Mazowieckie province to over 41% in Lubuskie province), and in 12 provinces there was an increase in the internal cohesion in respect of the commune budget receipts from maintenance fees per 1 inhabitant (from 0.41% in Lubelskie province to 41% in Śląskie province), and in terms of the percentage of capital expenditure of communes and districts in the total expenditure a decrease in the differentiation within a given province was recorded in 8 regions (from 4% in Wielkopolskie province to 60% in Opolskie province (see Figure 1).

Figure 1: Change in variables depicting social, economic, environmental, institutional and political governance in individual Polish provinces in 2017, as compared to data from 2004, measured by means of the classic coefficient of variation Vs.

Source: own work

The analysis of the effects of projects carried out in individual provinces co-financed through EU funds on the change of internal cohesion of these provinces indicates that in terms of social governance:

1. as regards the rate of migration for permanent residence of persons at working age per 10,000 people (X1), there was a negative correlation between the change in the level of differentiation and the value of completed projects and the value of received EU aid for investments in the area of foreign cooperation. This entails a decrease in the internal cohesion of a given region as the value of such investment increases;
2. additionally, there was a negative correlation between the change in the level of internal differentiation of provinces in terms of the recorded number of deaths of people up to 65 years of age per 1,000 people at this age (X2) and the total value of investments co-financed from EU funds in respect of health care;
3. in terms of the average gross monthly salary (X3), the cohesion improved (decrease in internal differentiation) in the discussed regions, which saw a higher value of completed investment projects and a higher value of co-financing of those projects through Community funds, in the area related to supporting business development. Moreover, the value of all projects (completed as well as still in the implementation or settlement phase) had a significant, positive impact on international cooperation;
4. the internal differentiation in terms of the percentage of children in pre-schools in the total number of children aged 3-5 (X4) decreased in those provinces in which a higher value (per capita) of all "EU" projects categorised as "other" was reported.
5. as regards the percentage of the long-term unemployed in the total number of the unemployed (X5), the value of all projects in the category "work and social integration" had a negative impact on the internal cohesion of the region;
6. the internal differentiation of provinces additionally increased in the case of the general rate of registered unemployment (X6) as a result of an increase in the value of all projects and the value of EU funding for such projects, which were implemented in the area of international cooperation. The increase in the differentiation in this respect resulted also from the increase in the value of all investments carried out in the area related to power generation;
7. the cohesion of regions in terms of the number of out-patients clinics per 10,000 inhabitants (X7) was negatively affected by the value of EU funding for already completed projects related to power generation and regeneration (in this respect the overall value of such projects had a negative impact as well), while the overall value of completed projects in the area of research, development and innovation had a positive impact.

The table 1 presents information on the significance of the impact: the value of all projects (completed and settled, completed but not yet settled and in progress), the value of co-financing of the projects with EU funds, the value of completed projects only and the value of co-financing of completed projects (all values per 1 inhabitant of a given province), on the increase in internal cohesion of the province, where "+" means a significant, positive impact, "-" means a significant, yet negative impact, and "0" means no statistically significant impact. In respect of economic governance (cf. Table 1), there was a statistically significant impact of projects co-financed from Community funds in the area related to the generally understood business development on the increase in the internal differentiation of provinces in terms of the density of local public roads (X12), the impact of general value and the value of EU co-financing of projects concerning administration on the level of differentiation in terms of the level of capital expenditure in companies per capita (X8) and the amount of co-financing in respect of administration on the differentiation of provinces in terms of the percentage of natural persons conducting business activity was of similar nature (X10). A statistically significant positive impact on the cohesion of the regions in terms of economic governance was reported:

- between X8 variable and the total value and value of co-financing of completed investment projects in the area of power generation and the total value and the value of co-financing of all projects related to transport;
- in the case of variable X9 (number of entities recently registered in the REGON system per 100 people at working age) and the total value of all projects implemented by means of EU aid in the area related to science and education and the value of co-financing of completed projects in the area related to business development;
- between X10 variable and the value of co-financing of completed projects in the area of business development;
- X11 variable (total number of companies registered in the REGON system per 10,000 inhabitants) and the total value and value of co-financing of projects related to business development.

Table 1: Impact of projects co-financed by the European Union for the improvement of cohesion within Polish provinces in terms of economic governance in the years 2004-2017

Source: based on own research.

In the case of changes in regional cohesion in respect of environmental governance, the significant impact of projects co-financed by EU funds could be observed only in six cases:

- regardless of the settlement method, environmental protection projects had a significant, negative impact on the internal cohesion of provinces measured by forestation rate (X16);
- the differentiation of forestation rate in districts included in the same province decreased under the influence of the amount of co-financing of all projects related to business development;
- the cohesion of regions in this respect was additionally positively affected by the co-financing of completed projects related to telecommunications and e-services;
- a significant decrease in the internal differentiation of provinces in terms of the percentage of pollution with considerable environmental impact which has been treated (X15) as a result of an increase in the total value of project related to administration was observed;
- there has been an increase in the differentiation of electricity consumption per capita in the province along with an increase in the total value of completed projects related to research, development and innovation and an increase in the total value and value of co-financing of completed projects related to international cooperation;
- the cohesion of provinces improved in terms of the amount of mixed municipal household waste per capita due to the increase in the amount of co-financing of completed projects related to research, development and innovations.

In the last of the analysed areas, concerning institutional and political governance, only three determinants are considered in relation to the impact of EU funds on the cohesion of regions in Poland in 2004-2017: the number of registered foundations, associations and social organisations per 10,000 inhabitants (X_{21}), commune budget receipts from maintenance fees per capita (X_{22}) and the percentage of capital expenditure of communes and districts in total expenditure (X_{23}). The conducted research demonstrated a statistically significant increase in the internal diversity of provinces in terms of X_{21} variable, which was accompanied by the increase in co-financing of completed projects related to power generation and health protection. The total value of completed projects concerning health protection and the value of all projects in a given province related to power generation were positively correlated with an increase in the province cohesion in terms of the X_{22} variable, while the decrease in the level of internal

differentiation of provinces connected with X_{23} variable was accompanied by a simultaneous increase in the total value and amount of co-financing of completed projects related to health protection.

Conclusions

The analysis of the impact of EU funds allocated in particular regions of Poland on the change in the level of cohesion of these regions give rise to several reflections. First of all, to a certain extent it is possible to clearly demonstrate the existing, statistically significant relationship between projects carried out by means of EU financial aid in specific areas and changes in internal differentiation of individual provinces. However, while substantive justification of the majority of such interrelations does not pose any problems, some of them would require an additional, detailed analysis of individual projects and then drawing general conclusions about the given interrelation. Interrelations which are not "statistically significant" is a separate issue. The absence of such interrelation does not necessarily mean that certain projects do not contribute to the increase (or decrease) of the region's cohesion. The lack of "statistical" recognition of such interrelation may result from insufficient observations, a wide scope of influence of such projects which are too difficult to be "captured" by a single diagnostic variable, or the possibility of a synergy effect strengthening the impact on the cohesion of a given province of projects co-financed by the EU in other areas. Another issue is the mere study of cohesion (or differentiation) in a given area. Assuming that from the statistical point of view, the least controversial measure is the classic coefficient of variation Vs , it should be stressed, that the change in its value is a result of changes in two values – occurring in the standard deviation meter measuring the actual average variation of units (districts) in terms of the feature under consideration and the arithmetic mean value of that feature in those units present in the denominator. This means that a change in relative differentiation in a given province may result not only from an actual change in the average differentiation of individual districts, but also from a change in the observed, average level of a given phenomenon. In-depth studies conducted in this area indicate that in most of the recorded cases, the change in the internal cohesion of provinces measured by Vs resulted from changes in average values of variables, not their absolute differentiation.

Acknowledgment

The project is financed within the framework of the program of the Minister of Science and Higher Education under the name "Regional Excellence Initiative" in the years 2019 - 2022; project number 001/RID/2018/19; the amount of financing PLN 10,684,000.00.

Abstract

There is certain scientific interest in the field of process mining-based quality assessment and prediction models (using selected AI methods) that support faultless manufacturing. In the case of solving complex issues regarding such multidimensional problems it is advisable to search for new models that integrate several intelligent methods, e.g. linear regression for performing feature selection and Fully Connected Deep Neural Networks (FCDNN) for classifying business process instances. The purpose of this paper is to propose a quality assessment model based on Mixed Intelligent Methods (MIM) that can be used for manufacturing process mining. Theoretical considerations are illustrated with an example model implementation and results of computational experiments on industrial data. Conducting study on the use of MIM in process mining may be a development impulse for further research on quality assessment and prediction in Business Process Management (BPM) field as well as business and management study.

Keywords: AI methods in BPM, Process Mining, Quality Assessment Model, Recursive Feature Elimination, Regression, Deep Neural Network, Mixed Intelligent Methods.

Introduction

In conditions of high competition and global pressure, manufacturing companies should take advantage of market opportunities as well as build a strong competitive position on the global manufacturing industry market by offering products of appropriate quality and that have been manufactured in the shortest and constantly improved production cycles. Quality management in production processes is of key importance because poor quality of products obtained as outcomes of these processes may cause a decrease in competitive position and decrease in sales revenues. The results of the literature analysis in the field of Business Process Management (BPM) indicate that more than 60% of activities and projects related to quality improvement do not bring the expected results mainly due to the lack of predictive quality performance control and continuous monitoring of the occurrence of quality anomalies (Saab, Helms & Zoet, 2018).

There is an extensive literature describing the Manufacturing Execution System (MES) functioning as part of Enterprise Resource Planning (ERP) (Rozs & Ando, 2020). Existing MES and systems used by enterprises are often insufficient to ensure continuous processes improvement. Therefore, applications in this field of AI methods are developed, intelligent manufacturing systems are improved and even autonomous computer aided processes planning occur (Wei et al., 2019). Systems of this type are also enriched with Industrial Internet of Things technologies (associated with Industry 4.0 and cyber-physical systems), which enable the measurement of signals from connected sensors and various devices, as well as the collection and analysis of data and ensure achievement of specific economic benefits thanks to efficient management and improving the quality of production processes (Boyes, 2018).

GRZESZCZYK "Mixed Intelligent Methods for Quality Assessment in Manufacturing Process Mining" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Adopting assumptions about high quality processes and faultless production, in accordance with the Total Quality Management (TQM) concept, means the number of read signals from the sensors is increasing. The automation of production processes limits the role of people in controlling these processes and enterprises need to rely on developed process mining technologies. The quality of the final product often depends on so many features (measures, variables, attributes and dimensions) that it is necessary to reduce their number before conducting analysis. However, it is difficult to clearly prioritize them and manually limit the number thereof. As a result of the feature elimination (selection, filter), attributes that are overly correlated or statistically insignificant are omitted, which does not significantly worsen the results of the performed analysis.

A number of quality assessment and prediction models are known, which are based on selected AI methods and support faultless manufacturing. For example, among others, the following methods are used for modeling and optimization of manufacturing flotation process parameters: multilayer perceptron (Allahkarami, 2016), Bayesian network (Yan et al., 2020), fuzzy logic (Jahedsaravani et al., 2016), convolutional neural network (Zhang et al., 2020) and Support Vector Machines (SVM) (Chehreh Chelgani, Shahbazi & Hadavandi, 2018). Research results confirm that single AI methods often do not provide good results for massive data, which are additionally complicated and have high-dimensional and auto-correlated structures, although for experiments carried out with Deep Neural Networks (DNN) the results obtained are slightly better (Pu, Szmigiel & Apel, 2020). Gaining experience in this type of research is both essential and necessary. In the case of complex problems related to multidimensional quality assessment and prediction, it is worth considering the use of Mixed Intelligent Methods (MIM) in this field and developing research related to finding the answer to a research question: is there a need and a possibility to use MIM for quality assessment in manufacturing process mining? Combined (integrated, hybrid) use of various intelligent methods is generally known for its great suitability for solving complex problems by taking advantage of the benefits of each component in the hybrid (Hatzilygeroudis & Palade, 2018). In particular, MIM may include linear regression, which is used as a reference in Recursive Feature Elimination (RFE), and Fully Connected Deep Neural Networks (FCDNN) used for classifying business process instances - only when using selected features. The presented results of analysis regarding quality prediction in the manufacturing flotation process use both process data and operational data in accordance with modern principles of process mining.

Literature Review

According to the integrated and holistic view of BPM (with eliminates functional and disciplinary biases), several BP research topics can be distinguished, including traditional organizational functions (e.g. human resource management, marketing and sales), intra-organizational (e.g. TQM, performance assessment and knowledge management) as well as inter-organizational (e.g. Supply Chain Management and e-commerce) (Sidorova & Isik, 2010). The young research discipline, which is process mining, helps to solve problems in these fields by combining experience resulting from the development of BPM, Business Intelligence (BI), data mining, enterprise resource planning and workflow management. It is based on the integration of two types of analysis: one concerning model-oriented processes and the other focused on data. Process mining, like the previously known data mining, is associated with Machine Learning (ML) and AI methods. Similarly, process models can be built automatically as a result of applying learning algorithms using historical data saved in the form of event logs.

So far, many event log extraction approaches, methods, techniques and tools have been developed for process mining, which are specific or generic (Dakic, 2020). They can be divided into the following three types: process model discovery (various miner approaches, such as: heuristic, fuzzy, genetic, alpha, multi-phase, region-based and classical), conformance checking (used for process evaluation, repairing models, auditing analysis, arrangement of business processes and algorithm discovery) and model enhancement based on experiences from current and previously implemented processes (Ahmed, Faizan & Burney, 2019). Activities related to process discovery, conformance checking and enhancement are implemented in order to conduct analysis or optimization (van der Aalst, 2011). When using discovery methods, the initial process models are usually built based on event logs, which are compared with observed behavior to further improve on the basis of determined deviations between models and empirical event logs (van der Aalst, 2013).

The process mining achievements can be successfully used to tackle quality assessment in manufacturing problems. These achievements do not replace the previously known process improvement methods but can be a significant complement to them. Business Process Improvement, Corporate Performance Management, Continuous Process Improvement, Six Sigma, TQM and others can be assisted in accelerating the understanding of analyzed business

processes, integration, modeling and re-design (Garcia et al., 2019). Process mining methods and models also include those based on selected AI methods. Literature studies have shown relatively little interest in using artificial neural networks and SVM in this field (Maita et al., 2015). All the more, there is a lack of research on attempts to combine these methods and build hybrid (mixed) models. Due to the fact that single AI methods often do not provide good results for massive, complicated and high-dimensional data often with auto-correlated structures, experience from research on MIM and Mixed Intelligent Systems (MIS) should be derived (Grzeszczyk, 2018).

Due to the development of modern approaches to modeling, analyzing and improving the quality of production processes, the number of process monitoring signals read from various sensors is constantly increasing. The quality of final products is often dependent on so many features that it is necessary to strive to reduce their number in order to simplify calculations. It is difficult to intuitively limit their number and necessary to use appropriate methods to perform feature elimination, applied in such a way that it does not significantly deteriorate the results of calculations. Research results so far prove that the proper use of feature elimination allows to reduce the run-time of ML algorithms (taking into account the run-time of feature selection algorithms) and at the same time only allows a slight deterioration of the classification accuracy (Hinkka et al., 2018).

Despite significant development of process mining, in order to carry out process optimization, many enterprises are still mainly based on meetings of experts, mappings, traditional process documentation, manual documents, simple numerical statistics and visualizations (Wynn et al., 2017). The need for continuous optimization of business processes is a key challenge for enterprises and in times of digital transformation, turbulent internal and environmental changes as well as a constant increase in customer requirements, there is an urgent need to include AI instruments to improve and optimize internal manufacturing processes in organizations using AI and ML methods (Vrbka & Rowland, 2020). Literature research results indicate a growing scientific interest in the field of AI methodologies, which are increasingly proposed for use in processes management and modeling, improving organization strategies and eliminate failures (Fernandes et al., 2019).

Among the AI methods useful in research, the results of which are presented in this paper, the authors drew attention to regression and FCDNN. In the case of solving many practical business problems, non-traditional regression-based methods provide better results compared to classic statistical tools (Zurada, Levitan & Guan, 2011). Various regression-based analysis methods are frequently applied in RFE (Chai, Lei & Yin, 2019). In turn, in the scientific literature, one can find research results on the use of DNN and, in particular, FCDNN for solving predictive problems (Zerwas et al., 2019; Liu, Zhang & Song 2020).

Methodology

Research question - "Is there a need and possibility to use MIM for quality assessment in manufacturing process mining?" - is the basis for choosing the right research methods that enable the analysis of the available dataset containing historical data on iron ore manufacturing processes and quality assessment of iron ore pulps for use in flotation plants (Eduardo Magalhaes Oliveira, 2017). The following research methods and techniques were used in the presented research: critical literature research, computer simulation and experiments. Model building, its example implementation and experimental calculations were based on linear regression and FCDNN algorithms. The essence of the proposed quality assessment model based on MIM mainly consists in a serial combination of two intelligent methods used in the following way: linear regression is applied during RFE (the most important features describing production processes are selected) and FCDNN was used for classifying business process instances. FCDNN learning was only carried out using a selected set of features.

The presented results of analysis regarding quality prediction in the manufacturing flotation process use both process data and operational data in accordance with modern principles of process mining. Therefore, the research did not focus on discovery and conformance of built and improved process models but was implemented in accordance with modern trends in process mining. In the verification process of the proposed quality assessment model based on MIM, empirical data stored in the dataset that contains more than 736000 samples consisting of 24 features were used.

Fig. 1: Quality assessment in manufacturing process mining based on MIM
(source: own study)

In the current approaches of the manufacturing process often there are many measures analyzed for the quality assessment. The methodology proposed in the paper consists of two sequentially ordered intelligent methods (Figure 1). To facilitate the process of quality assessment RFE method was used at first for selecting most important measures with regard to the explained variable. The RFE used external model for estimating weights of features. As an external estimator the linear regression was used. RFE recursively used the linear regression model and checked its coefficients. After every repetition the least important features were deleted from the set of considered ones. The process was repeated until the desired number of features was reached. During experiments the number of selected features ranged from 1 to 21 (increasing by two at each of the experiment's step).

For each of the selected number of features the model was created, trained and evaluated. The more features, the more complicated the model containing more parameters to train is. The experiments were conducted using Python programming language, which is well known for its usefulness in data science (Porcu, 2018). The RFE method together with linear regression model were from Scikit-learn package (Scikit-learn user guide, 2020). Finally, FCDNN was implemented with the aid of Keras library with tensorflow backend (Abadi et al., 2016).

Results and Discussion

In the analyzed case based on a specific industrial dataset, the results of the application of MIM for quality assessment in process mining relate to quality prediction of raw materials that are delivered to production plants. Material purity is predicted using many features that have an impact on achieving satisfactory quality raw materials.

The measure for quality assessment which is the explained variable in the experiments is the percentage of silica in the iron ore concentrate (percentage of silica concentrate). Percentage of iron concentrate feature is highly correlated with percentage of silica concentrate and it would be highly desirable to measure the percentage of silica during iron ore mining process without using this feature. The date feature is irrelevant for measures, therefore both aforementioned features have been removed from the dataset resulting in 21 features (explanatory variables). Among selected features there are variables containing measures of the pulp before flotation process, air flows in flotation columns or pulp density etc. All variables were scaled to have mean 0 and standard deviation of 1 (standard normal distribution).

After the feature elimination process another intelligent method was used for estimating the percentage of silica in the iron ore concentrate. The variable in the dataset is continuous, therefore, it is a regression problem. For this task FCDNN was used. The model contains three hidden layers of 15-512, 512-256, 256-64 neurons respectively (each activated by ReLU function). Finally, the last layer contains only 1 neuron and has no activation (in this way regression task is achievable). Mean Squared Error (MSE) was chosen as a loss function and algorithm based on

Adaptive Moment Estimation (Adam optimizer) was used during training process. Finally, MSE and Mean Absolute Error (MAE) values were monitored for evaluating the model's ability to predict the percentage of silica.

Fig. 2: MSE over number of features

(source: own study)

As expected, MSE measures are decreasing for increasing number of features. However, as can be seen in Figure 2, above 11 features the decline of errors is decreasing much slower. The knowledge hidden in the deleted features is compensated by the trained model. After conducting the experiments with MIM the process managers can decide to omit some of the least important measures if the error in quality assessment is negligible and the costs of implementing those measures are too high. Therefore, the process of taking measures for quality assessment can be simplified thanks to the usage of MIM. Table 1 presents MSE and MSA values depending on the number of features.

Table 1: MSE and MSA depending on the number of features

Number of features	1	3	5	7	9	11	13	15	17	19	21
MSE	1.24	0.83	0.68	0.60	0.54	0.37	0.35	0.35	0.29	0.28	0.25
MSE Improvement	-	0.41	0.15	0.08	0.06	0.17	0.02	0	0.06	0.01	0.03
MAE	0.90	0.69	0.60	0.55	0.52	0.41	0.41	0.41	0.37	0.36	0.34
MAE Improvement	-	0.21	0.09	0.05	0.03	0.11	0	0	0.04	0.01	0.02

Source: own study

Obtained research results confirm that there is a need and possibility to use MIM for quality assessment in manufacturing process mining. As a result of using this type of solution, it was possible to shorten the learning time, reduce the number of measuring sensors used in production processes, and simplify the monitoring and prediction systems of raw materials. This is possible by reducing the relatively large number of features and eliminating the need for a series of unnecessary measurements, because relying on fewer measurement points provides satisfactory results. The obtained research results have practical values, e.g. for processing engineers, who, thanks to them, achieve productivity optimization as well as the possibility of objectifying and automating processing assessment and control of raw materials' quality.

Positive and negative aspects related to the use of FCDNN included in the currently proposed MIM result from the features and properties of neural networks. They are usually resistant to damage and errors occurring in learning sets. The possibility to obtain correct results even for incomplete and noisy data is important. On the one hand, neural networks are characterized by considerable application possibilities, on the other, however, they operate on the principle of a 'black box' and the justification for the results related to prediction is not clear and reliable. This disadvantage is also a kind of advantage since the inability to look into the 'black box' relieves production engineers from the need to determine the mathematical relationship between the explanatory (independent) variables and the explained (dependent) variable associated with the expected quality of raw materials. The

obtained calculation errors regarding prediction can sometimes be quite significant and their values depend to a large extent on the proper selection of the type of neural network and its architecture used. Therefore, the quality of the results obtained largely depends on the experience of the designers of the neural networks used for prediction of quality and processed material purities.

Conclusions

There have already been some studies in the field of process mining based quality assessment and prediction models that were based on selected AI methods introduced to support faultless manufacturing. In the case of solving complex issues regarding such multidimensional problems, it is advisable to search for new models that integrate several intelligent methods, e.g. linear regression for performing feature selection and FCDNN for classifying business process instances. This paper presents a proposal to use MIM to build a quality assessment model that can be used for manufacturing process mining. The proposed solutions constitute a significant contribution in the light of methodological theory and practice within the discipline of management and quality sciences.

The obtained results of theoretical and practical research allow for a positive answer to the research question posed regarding the existence of the need and the possibility of using MIM for quality assessment in manufacturing process mining. Theoretical considerations are illustrated by an example implementation of the model and results of computational experiments based on the dataset which contains historical data on iron ore manufacturing processes. The calculations carried out were based on regression and FCDNN algorithms. The essence of the proposed model lies in the serial combination of two intelligent methods that were used in the following way: linear regression is applied during RFE (the most important features describing production processes are selected), while FCDNN - for classifying business process instances, which only learns using selected features.

As a result of the application of MIM, not only was the improvement of the AI method used and the learning time shortened, but also the basis for simplifying the quality monitoring system of the examined production processes was created. The elimination of a relatively large number of features allows, for example, to remove unnecessary, time-consuming or expensive measurements, relying on a smaller number of measuring points provides reliable information on the quality of products obtained as a result of the implementation of the analyzed production processes. As a result of the analysis and calculations carried out, the production process was simplified, which made it more transparent and understandable.

There is too little research on MIM applications, in particular on quality assessment in manufacturing process mining, and therefore it is important to undertake research to bridge this gap. Conducting current research and planning similar ones in the future may be a development impulse for further research on quality assessment and prediction in the BPM field as well as progress within the theory and practice in the area of improving models and methods in management discipline. Continuation of this type of research may, for example, consist in improving selected methods that create MIM, as well as adding more AI methods. One of the methods that may be a significant complement to MIM can be one of the Neural Architecture Search (NAS) methods. Due to the fact that the presented quality assessment model includes the use of DNN, while developing and improving MIM, the authors of the paper may consider using existing experience related to unifying model in which techniques and methods for NAS problems could be explored and quantitatively compared (Malekhosseini, 2020). The introduction of this type of generation of the model can improve its performance.

Analysis of The Impact of Implementing Stricter Standards for Granting Mortgage Loans to The Mortgage Market in The Czech Republic

Ing. Linda Pudilová

Ing. Kamila Veselá
Ph.D., Czech University of Life Science Prague, Department of Economic Theories, Faculty of Economics and Management, Kamýcká 129, Praha 6 – Suchdol, Czech Republic, e-mail: veselakamila@pef.czu.cz

Abstract

In the last 20 years, the development of the economy and the need for own housing of the Czech population has been increasing, which is reflected in the increasing number of applications for housing loans. With the development of the economy, the overall indebtedness of economic entities is also increasing, confirming the trend of living on debt. Market developments have led to long-term interest rate cuts, with mortgage lending rates reaching a record low of 1.74% pa in 2016. As a result, even people with lower incomes were able to obtain a housing loan. Given that a similar situation preceded the past financial and mortgage crisis in the USA, the Czech National Bank has now tightened the criteria for granting mortgage loans.
The paper deals with the issue of these tightening criteria for the provision of mortgage loans, gradually implemented by the Czech National Bank since 2017. The main aim of the paper is to analyse the impact of introducing these stricter conditions on the mortgage market in the Czech Republic, on the average citizen and his/her ability to obtain a home loan, as well as the impact on the price of the loan, in particular the interest rate. In the paper are analysed housing loans in the form of mortgage loans and building savings loans. The paper seeks to quantify the impact of stricter criteria for granting mortgage loans on the creditworthiness of Czech citizens (i.e. their ability to raise and repay funds for their own property). Last but not least, the paper monitors the development of the housing market in the Czech Republic, the development of mortgage loans over time and interest rates on mortgage loans.

Keywords: Czech national bank, debt to income, debt service to income, mortgage loan, loan to value, interest, bank collateral

Introduction

The period 2017–2018 was a period of great changes in the mortgage market in the Czech Republic. In response to the development of previous years, when interest rates on mortgage loans reached their historical low (making mortgage loans more accessible even for people with lower income), the criteria for granting mortgage loans were tightened. Until then, banks granted loans at the risk limit, when they also granted mortgage loans to high-risk clients, who would probably not be able to repay their liabilities if the economic situation deteriorated, at record low interest rates (in 2016, for example, it was possible to obtain a mortgage loan at an interest rate of less than 2% pa) and with 100% financing (i.e. they lent an amount corresponding to 100% of the property value – LTV[1]). The measure of the Czech National Bank was the logical outcome of this development, as the Czech National Bank, fearing the emergence of another mortgage crisis, such as we witnessed in the USA in 2008–2009, took measures aimed at preventing over-indebtedness and granting of mortgage loans to people with lower income. The theoretical framework for this issue is defined by e.g. Mandel and Tomšík (13,14). For example, Revenda (16) points to the difference in the assistance of central banks to troubled banks in theory and in practice. According to

Cite this Article as: Linda Pudilová and Kamila Veselá " Analysis of The Impact of Implementing Stricter Standards for Granting Mortgage Loans to The Mortgage Market in The Czech Republic" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

him, assistance to insolvent banks is currently more and more affected by the criteria of the size of the troubled bank and its interconnections within the banking system (9, 15).

As already mentioned, it was possible to obtain a mortgage loan at record low interest rates in 2016, which even fell to 1.7% pa. In this period, despite the efforts of the Czech National Bank (low interest rates close to zero, devaluation of the koruna), the economy was in a situation close to deflation. The analysis for 2005–2015 confirmed the decline in the share of money in the economy (measured by the M1 and M2 monetary aggregates) on a monetary basis (11,12). The result is a claim that the central bank's monetary policy is ineffective in relation to the development of the amount of money in the economy (18). The issuance of money into the economy is linked to the granting of loans by commercial banks to non-banking entities (17).

The aim of the presented article is therefore primarily to define the impacts of the introduction of stricter standards for granting mortgage loans by the Czech National Bank. The impact analysis is carried out from two angles, from the point of view of the impact of these measures on the average citizen and his/her creditworthiness, and from the point of view of the impact on the entire mortgage market.

Methodology, Data Sources

The crucial source of information for the processing of this article and the research that the article presents are secondary data obtained from the Czech National Bank. They are subjected to a time series analysis from the ARAD system presented on the Czech National Bank's web portal[2]. The length of the analysed time series always depends on the length of the published data. To analyse the impact of the interest rate on the volume of housing loans and mortgage loans, the following time series are analysed:

- housing loan interest rates;
- mortgage loan interest rates;
- building savings loan interest rates.

These time series are presented for the period 31/01/2004 – 31/12/2018 with a monthly periodicity. The ARAD database of the Czech National Bank is also a source of information on the volume of loans granted by type of loan. In particular, the following are analysed:

- total volume of loans;
- total volume of housing loans granted;
- volume of mortgage loans granted;
- volume of building savings loans granted.

Data are available from 31/01/1997 to 31/12/2018, also with a monthly periodicity.

Growth rate and trend analysis were used in the time series analysis and the correlation between the amount of the interest rate and the amount of loans granted determined by means of the Pearson correlation coefficient were used to determine the dependence. Prior to the time series analysis itself, the time series were adjusted for the effect of calendar variations, i.e. recalculated to the unit time interval. These data are obtained according to the equation:

$$y_t = y_t * \frac{\overline{k_t}}{k_t} \tag{1}$$

where:

$\boldsymbol{y_t}$ *is the value of the adjusted indicator;*
$\boldsymbol{k_t}$*is the number of calendar days in a given period;*
$\overline{\boldsymbol{k_t}}$*is the average number of calendar days in a given period.*

The moving annual average method was used for trend analysis, which is calculated as the average of a constant number of consecutive periods (12 months). The moving average is plotted in the middle of the moving part of the

[2] www.cnb.cz/docs/ARADY/HTML/index.htm

observed *p* periods. The smoothing effect of the moving averages increases with the increasing length of the moving part. At the same time, the length of the unbalanced part at the beginning and end of the row increases, which makes *(p-1)/2* periods at each of the two ends of the row. In the case of an annual total, i.e. 12 months (*p* = even number), a centered moving average is calculated. The centered moving average is then calculated as the average of two adjacent uncentered moving averages.

$$\bar{y}_t = \frac{y_{t-m}+2y_{t-m+1}+\cdots.+2y_{t+m-1}+y_{t+m}}{12m} \tag{2}$$

where: $\bar{y}_t$ *is the moving average at time* t*;*
m *is a time series element.*

In the case of the time series of the number of housing loans granted, their dependence on the development of the interest rate is analysed. The Pearson correlation coefficient is used for this purpose. The Pearson correlation coefficient is conditioned by the probability distribution of a random vector. According to the set, the linear relationship of the quantities was evaluated and the Pearson correlation coefficient is calculated according to the equation:

$$r = \frac{\sum_{i=1}^{n}(x_i-\bar{x})(y_i-\bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i-\bar{x})^2\sum_{i=1}^{n}(y_i-\bar{y})^2}} = \frac{\sum_{i=1}^{n}x_iy_i-n\overline{\overline{xy}}}{(n-1)s_xs_y} \tag{3}$$

where: $\bar{x}$ *a* $\bar{y}$ *are sample averages;*
$s_x s_y$*are sample standard deviations;*

n *is the range of the set;*
r *is the correlation coefficient.*

Time series are evaluated both in absolute terms and in terms of differential indicators. The differential indicators were created as first-order differences according to the equation:

$$D1_t = y_t - y_{t-1} \text{ for t =2, ..., n.} \tag{4}$$

The growth rate of time series is determined by the equation:

$$k_t = \frac{y_t}{y_{t-1}} \tag{5}$$

and as percentage according to the relation:

$$k_t^{\%} = 100 * \left(\frac{y_t}{y_{t-1}} - 1\right) = 100 * (k_t - 1) \text{ for t=2,....,n [\%].} \tag{6}$$

Results and Discussion

With the growing quality of life of the population in the Czech Republic, both the number of housing loans granted and the number of mortgage loans, which dominate among housing loans, are growing. It is reflected in housing construction and housing quality indicators, where a clear trend is evident, with the exception of the financial crisis, which temporarily changed the trend after 2008 and housing construction declined. Later, however, the real estate market returned to a phase of growth. Another milestone is the year 2018, when the aforementioned stricter standards were met by the Czech National Bank, which again has a negative impact on the mortgage market. The following table compares individual loans that can be used to finance housing according to the qualitative criteria that are decisive for loan applicants.

Table 1: Comparison of loan criteria for housing financing

criterion	**Mortgage loan**	**BS loan + bridge loan**	**American mortgage**	**Consumer credit**
Loan maturity	5–25 years	about 8–20 years	about 5–15 years	about 1–10 years
Interest rate	about 2–4%	about 2–6%	about 3.5–6%	4–12%
Loan repayment	Very low (the ↑ the maturity, the ↓ the repayment)	Medium	Low	High
Loan purpose	for real estate	for own home	NO	NO
Collateral	real estate collateral	according to the loan amount (NOT real estate)	real estate collateral	according to the loan amount (NOT real estate)
State aid	for new housing (for older tax deductions)	part of savings, tax deductions	NO	NO

Source: own processing

The reason why the demand for housing loans has been growing for a long time must be sought in the development of society, the desire for a better way of life and the preference for one's own housing over rental housing, even among young people without obligations. At the same time, it can be stated that people prefer smaller but own housing, rather than larger but rental housing. E.g. the average number of persons per 1 permanently occupied flat, which was 3.35 persons in 1961, decreased to only 2.47 persons by 2011; another example is the indicator of the number of persons per 1 room, which decreased from 1.86 persons in 1961 to 0.73 persons in 2011 (10). The following chart shows the number of housing loans and mortgage loans granted for residential real estate.

Chart 1: Development of total housing loans granted, of which mortgage loans for residential real estate

Source: own processing; data: Czech national bank available online: www.cnb.cz [2020-08-30]

The total indebtedness of households is growing. The reasons can be found, for example, in the growing availability of credit products, the declining trend in the development of interest rates and also in the current lifestyle, which can be described as consumerist, highly consumer-oriented. If we compare household indebtedness, the total household indebtedness amounted to CZK 522,848 million in 2005 (data as of 31 December 2019, time series of ARAD by the Czech National Bank) and to CZK 1,712,990 million in 2018 (data as of 31 December 2018, ČNB). At the same time, the gap between the total household indebtedness and the indebtedness for housing purposes is narrowing, as the share of housing debts was 54% of the total household indebtedness in 2005, and 73% in 2018. However, this fact may already be affected, for example, by the desire of people for better and more expensive housing and rising real estate prices on the Czech market (12).The development of the number of housing loans granted was also subjected to an analysis based on the principle of moving annual totals, as shown in the following chart.

Chart 2: Development of the number of housing loans granted – moving annual total

Source: own processing; data: Czech national bank available online: www.cnb.cz [2020-08-30]

There was also a change in the structure of housing loans granted, especially in case of mortgage loans and building savings loans. While mortgage loans accounted for 47% of total housing loans in 2002 and building savings loans (and bridge loans from building savings) accounted for 36% of total housing loans, the market was fully dominated by mortgage loans in 2018, which amounted to 90 % of housing loans. The fact is caused both by a larger number of mortgage lenders than building savings loan lenders, and especially by differences in interest rates. For example, the interest rate on a mortgage loan was around 1.8% pa before 2018, while the interest rate on building savings loans was around 3% pa and more. The development of interest rates is confirmed by chart 3.

Chart 3: Development of housing loan interest rates

Source: own processing; data: Czech national bank available online: www.cnb.cz [2020-08-30]

The relationship between the development of interest rates and the number of mortgage loans granted was examined by means of correlation, or in this case, the Pearson correlation coefficient was used. It was analysed for the period 31/01/2004 – 31/12/2018 in monthly data. The correlation coefficient showed a value of -0.74 for total housing loans and -0.72 for mortgage loans, i.e. a strong correlation confirming that a decline in interest rates leads to an increase in loans granted. The time series of the volume of mortgage loans granted and mortgage loan interest rates in terms of differential indicators are shown in chart 4.

Chart 4: Development of the number of mortgage loans granted and of the mortgage loan interest rate

Source: own processing; data: Czech national bank available online: www.cnb.cz [2020-08-30]

Chart 4 presents the development of the volume of mortgage loans granted and the development of mortgage loan interest rates in terms of absolute differences. This approach clearly shows the milestones in the mortgage market. The extreme is the turn of 2008 and 2009, when there was a 22% increase in mortgage loans despite the increase in the mortgage loan percentage rate by 0.2%. The situation was caused by the entry into force of the amendment to the Building Savings Act and in the same period (i.e. from December 2008 to January 2009) there was a significant decrease in the volume of building savings loans granted from 705,000 newly concluded contracts in 2008 to 575,000 concluded contracts in 2009. Therefore, those interested in a housing loan at that time preferred mortgage loans over building savings loans.

When analysing and evaluating the time series of housing loans, it was possible to assess not only the impact of interest rates on the volume of loans granted, but also, for example, the impact of the mortgage crisis on the real estate market and the housing loan market (5) estimated that the financial crisis would have an impact on the economy in the following 10 years. At least as far as the mortgage market and real estate demand are concerned, this claim was not confirmed. The decline in demand for loans was reflected only in the following 2 years after the outbreak of the financial crisis (1, 6).

As already mentioned, in fear of the development of the economy and the mortgage market (as the example of the American mortgage crisis showed), when interest rates on mortgage loans attacked record lows in the Czech Republic as well, the national bank introduced stricter criteria for granting mortgage loans in 2017 (7). The measures were to focus in particular on how to better check the client and thus prevent the loan from being granted to persons without sufficient income. For this reason, not only did the CNB tighten the existing conditions (e.g. reduction in the LTV from 100% to 80% of the real estate value), but it also introduced completely new indicators (2). The following table clearly maps the conditions for granting mortgage loans before the introduction of stricter criteria and after their introduction.

Table 2: Overview of criteria for granting mortgage loans

Criterion:	**Conditions for granting mortgage loans**		
	General criteria		
age	18–65 (exceptionally 70 years old, working)		
income	Income confirmation, or 2 tax returns		
register	banking and non-banking register of debtors		
liabilities	according to the solvency margin		
residence	temporary for EU citizens, permanent for other foreigners		
	2016 and earlier	**2017**	**2018 and later**
income	- checking registers, - considering repayments of other loans	- checking registers, - considering repayments of other loans, - more detailed examination of structure of expenses	- checking registers, - considering repayments of other loans, - more detailed examination of structure of expenses
LTV	- 100% of the real estate price	- 80-90% of the real estate price	- 80% of the real estate price, exceptionally 90%
DTI	-	-	- total debt to annual income ratio (debt to income < 9x)
DSTI	-	-	- amount of all repayments to net income ratio (debt service to income < 45%)

Source: own processing

One of the most significant impacts of the introduction of stricter criteria on the average citizen was the limitation of loan to value (LTV), i.e. the fact that it is no longer possible to take out a loan at 100% of the real estate value, but it is necessary to have 20% of own resources. The criterion largely protects banks in the event that the client does not pay the loan and the bank is subsequently forced to sell the property. The new DTI and DSTI indicators then prevent a low-income client from reaching more expensive real estate even at a low interest rate, thus not getting into trouble in the event of a future increase in the interest rate. In the case of the DTI (debt to income) indicator, the applicant's total debt (i.e. the sum of all loans he/she has) must not exceed 9 times his/her annual income and the DSTI limits the applicant by the applicant's monthly mortgage loan repayment (and repayment of all other debts) not exceeding 45% of the applicant's net monthly income.

Conclusion

The CNB had rational reasons to tighten the conditions for granting mortgage loans. For many years, the mortgage market clearly adopted a trend of growing demand for own housing, i.e. growing demand for loans and a long-term decline in mortgage loan interest rates. Concerned about the emergence of the mortgage crisis (according to the example from the USA in 2008/2009) due to the granting of risk mortgage loans, the CNB decided to tighten the criteria (3, 8). The aim was first to protect banks from clients who do not pay (introduction of 80% LTV instead of the original 100%) and to thoroughly check clients and thus prevent over-indebtedness of Czech citizens (by introducing DTI and DSTI indicators).

It is logical that the main criterion of a person interested in a mortgage loan is the interest rate. A correlation between the development of mortgage loan interest rates and the volume of mortgage loans granted was also demonstrated. After the introduction of these criteria, the mortgage market thus expected the impacts, speculating

about an abysmal decline in the number of mortgage loans granted and an increase in the mortgage loan interest rates. However, 2019 showed that there was only a slight slowdown in the growth rate of mortgage loans and interest rates rose by an average of about 0.5% pa. It may seem that the CNB's measures were a step in the right direction, as they helped protect mortgage market participants and at the same time did not cause a sharp slowdown in the mortgage market that would lead to a slowdown in the economy.

The Development of An Instrument for Measuring Job Autonomy of Malaysian School Teachers: A Content Validity Study

Mohamad Noorman MASREK[1], Mohammad Fazli BAHARUDDIN[2],
Shamila MOHAMED SHUHIDAN[3]
[1, 2, 3]Faculty of Information Management, UiTM, MALAYSIA, mnoorman@uitm.edu.my

Abstract

Measuring job autonomy has always been a daunting task for not only researchers but also practitioners. Various ways and methods have been developed but self-reported measures remain the most popular for researchers. The extant literature provides ample self-reported instrument which can be used to gauge job autonomy. However, given that the degree and scope of job autonomy differs according to the type of job title, the available instruments cannot be conveniently adopted without going through the process of assessing the validity. This paper reports the findings of content validity exercise for self-reported job autonomy instrument for Malaysian school teachers. The chosen instrument was originally developed for a study involving students' perspective and due to that, an issue of validity could arise when the instrument is to be used by practicing teachers especially those with long years of experience. Using a pre-testing approach of questionnaire development, the chosen instrument was refined and extended from 13 items to 20 items measuring four dimensions of job autonomy. The results of the content validity index assessment suggest that the revised instrument is acceptably valid to be used by Malaysian school teachers or teachers from other developing countries that have similarities and resemblance in their job scopes.

Keywords: Job autonomy, Content validity, Instrument assessment, Malaysian school teacher.

Introduction

Job autonomy is important for organizations to enhance employee work performances. Job autonomy is concern with the freedom, independence and discretion given to employee in executing their work (Burcharth et al., 2017). Job autonomy is presence in almost any job titles (Li, 2018; Paradis et al., 2015; Spiegelaere et al., 2014). However, the degree and magnitude varies. For certain jobs a high degree of autonomy is required while other jobs the autonomy is relatively very little. The teaching profession is an example where job autonomy is highly required (Baharuddin, Masrek, & Shuhidan, 2020). Without job autonomy, teachers would not be able to execute their jobs effectively and efficiently (Friedman, 1999).

In order to understand job autonomy of the teaching profession, researchers have embarked on empirical research focusing on school teachers. Various models and framework have been developed which outlined various variables or elements of job autonomy (Awang-Hashim et al., 2017; Dhar, 2016; Spiegelaere et al., 2016; Friedman, 1999). The similarities in terms of the variables used or found in these studies, further highlights and emphasizes the significance of that particular variables. On the other hand, the differences in terms of newly discovered variables signifies an enrichment to our understanding about the topic. Along with these models or frameworks, researchers have also developed as assessment instrument which is either self-assessed or assessed by immediate superiors, known as headmasters, in the Malaysian school setting. Between the two, the later seem to outnumbered the later, probably due to convenient factor.

In the Malaysian setting, the schools are categorized in different ways. Government or private is the typical classification normally made. However, in each of these two categories, there is another layer of categorization, identified as either boarding or non-boarding (Othman, 2016) i.e. day school. Boarding schools requires the pupils or students to stay in the school hostels. In the Malaysian contexts, higher requirements are needed for admission to the government funded boarding schools. In other words, the students who are admitted to these schools are normally considered creams or excellent academically (Malaysia Education Blueprint, 2013). The education system

Cite this Article as: Mohamad Noorman MASREK, Mohammad Fazli BAHARUDDIN, Shamila MOHAMED SHUHIDAN "The Development of An Instrument for Measuring Job Autonomy of Malaysian School Teachers: A Content Validity Study" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

adopted in these boarding schools are also different to those used in the day schools. Given the differences that job nature, scope as well as performance indicators used in these schools are also quite different to teachers teaching in non-boarding schools. This distinction could suggest that the job autonomy would be also different. However, mining the literature indicates that studies addressing job autonomy has been focusing on non-boarding schools (Akbarpour-tehrani & Mansor, 2012; Awang-Hashim et al., 2017; Ismail, 2014). To this effect, it is not really known whether these dimensions are also applicable to boarding schools' teachers i.e. further examination is seen essential to validate the dimensions. On the basis of this background, the paper reports the findings of a study done to address this gap.

Literature Review

Table 1 showcases the different dimensions of job autonomy identified and used by previous studies. Depending on the research problem, objectives and scope, the researchers had dimensionalized job autonomy between three and six. Certain dimensions are being named differently, although the operational definitions are almost identical. For example, Spiegelaere et al (2012) and Dhar (2016) used the term 'organizing task' which is almost similar to 'teaching practice' used by Friedman (1999). However, upon further scrutiny on these studies, several themes or focus could be observed, namely freedom on performing jobs in terms of contents, delivery method and required training; freedom on the timing and location to perform jobs; freedom on making managerial decisions such as policy, finance and legal; and freedom on their professional behaviours. Out of these five themes, only the freedom on professional behaviours is considered relevant and appropriate for both boarding and non-boarding schools. In terms of jobs in terms of contents, delivery method as well as required training the Malaysian schools teachers do not seem to have much freedoms. In the same vein, limited autonomy is given in terms of work timing and place or location to execute their job.

Table 1: Dimensions of Job Autonomy

Authors	Dimension	Operational Definition
Dhar (2016); Spiegelaere et al. (2012)	1. Organizing Tasks	Freedom to perform jobs and activities.
	2. Learning Opportunities	Opportunities to develop my professional skills.
	3. Routine Work	Planning the routine tasks.
Spiegelaere et al. (2016)	1. Work Method	Sense of control over employees work and is likely to increase the overall work engagement of employees.
	2. Work Scheduling	Sense of control over the work and enables employees to react to different job demands by flexibly changing the sequencing of their tasks.
	3. Work Time	Discretion of employees on when to stop and start working.
	4. Place of Work	Freedom in deciding where to perform the job.
Verhoest et al. (2004)	1. Managerial autonomy	The decisions concerning managerial actions.
	2. Policy autonomy	The decisions concerning the structure and content of the primary production process, policy instruments and outputs, objectives and effects.
	3. Structural autonomy	Control by influencing the decisions through hierarchical and accountability lines.
	4. Financial autonomy	To the extent of which decision on funding or revenues for its financial resources.
	5. Legal autonomy	To the extent to which the legal status from altering the allocation of decision-making competencies or makes such changes.
	6. Interventional autonomy	The operations that require immediate intervention.
Friedman (1999)	1. Teaching	Decision on the school's pedagogical and social idiosyncrasy.

	practice	
	2. Achievement evaluation	Decision on means and procedures of evaluating student achievement.
	3. Parental involvement	Decision on parental collaboration modes.
	4. Staff development	Decision on the subjects for their in-service training in general, broad fields of interest.
	5. Extracurricular subjects	Decision on specific topics of enrichment activities for their students from existing programs.
	6. Curriculum change and development	Decision on developing unique teaching methods based on student needs.
Awang-Hashim et al. (2017)	1. Responsible	Attitude, dedication, and professionalism.
	2. Approachable	Flexible interpersonal teaching styles and friendliness.
	3. Shows respect	Gentle ways of dealing with students and colleagues.
	4. Conveys confidence	Ability to convey confidence to students and colleagues' capabilities.

Given that the objective of this study is to identify the dimensions used for assessing job autonomy in the context for boarding school teachers in Malaysia, the dimensions identified by Awang-Hashim et al. (2017) is considered the ideal option for further exploration. The four dimensions which are responsible, approachable, shows respect and convey confidence would be further validated as discussed in the methodology section of this paper. The fact that the study by Awang-Hashim et al. (2017) was done involving teachers in non-boarding schools, the need to empirically validate the dimensions and the corresponding scale is therefore very crucial. As stated in the preceding section, job nature, scope as well as performance indicators used in boarding schools differ to that non-boarding schools. To this effect simply adopting the dimensions together with the scales without undergoing validation process would raise the issue of validity and reliability.

Methodology

Instrument Development

As stated in the preceding section, the present study decided to further explore and validate the dimensions used by Awang-Hasim et al, (2017). The decision was made after reviewing the available literature on the topic. Using the four dimensions as the initial conceptual framework, the researchers embarked on a field study by interviewing the selected teachers from the boarding schools. The purpose of the interview was to understand the meaning of the four concepts (i.e. responsible, approachable shows respect and convey confidence) to them. Open ended questions revolving on "how" and "why" were put forwards. Each interview lasted for about 45 to 90 minutes. Appointment and arrangement was made earlier to make sure that the participants were totally free and they could fully commit and focus during the interview. For every responses given, the researchers tried to probe with follow-up questions so as to ensure that an in-depths responses could be collected. Using the thematic analysis of qualitative data analysis, the responses of the participants were mapped to the initial conceptual framework. The results of the analysis clearly showed that the four dimensions were also applicable in the context of the selected boarding school teachers.

Following the outcome of the interview, a follow up study was conducted to develop a self-reported assessment for measuring these four dimensions of job autonomy. The original instrument developed by Awang-Hasim et al, (2017) was assessed and evaluated by comparing with the responses obtained from the interviews. Several original items were removed while certain items were paraphrased. Several new items were also added and the final measurement is shown in Table 2. Given that the items employ perceptual measurement, each item is connected with a Likert Scale anchoring that gauge the extend to agreeableness or disagreeableness of the respondents. The anchoring used are 1: *Strongly Disagree*, 2: *Disagree*, 3: *Neutral*, 4: *Agree* and *5: Strongly Agree*.

Table 2: Items for Each Dimension

Responsible	
1	I display professionalism in my profession
2	I teach wholeheartedly using appropriate aids and activities
3	I give extra attention for all weak students
4	I don't mind providing extra classes for my students
5	I deal with students' issues responsibly
Approachable	
1	I understand and realize student's weaknesses
2	I am willing to listen to others problems
3	I am approachable by my student even outside of classroom
4	I am approachable by my colleagues even outside of school
5	I am approachable by parents of the students
Showing Respects	
1	I encourage everyone in school work in their own way
2	I speak gently with everyone in school
3	I acknowledge my colleagues' strength and weaknesses
4	I never humiliate anyone in school
5	I do not have favoritism among students
Conveys confidence	
1	I assign responsibility for school related tasks to the student
2	I conduct question and answer session in the class
3	I encouraged colleagues to work efficiently
4	I am generous with using encouraging words to students and colleagues
5	I always encourage students and colleagues to set high standards for achievement

Accordingly, a pre-test exercise was executed by following the steps suggested by Polit and Beck (2006). A form was created presenting the variables with the corresponding operational definitions and measurement items. The focus of the pre-testing is on the content validity, wordings, ordering of questions, instructions, layout, formatting, font, length and spelling. Lynn (1986) advised a minimum of three experts, but indicated that more than 10 were probably unnecessary. In the context of this study, a total of six participants as shown in Table 3 were engaged for the pre-testing exercise. Each of them was briefed to give their inputs on the aforementioned criteria.

Table 3: List of Panel Experts during the Questionnaire Pre-testing

No	Panel Experts	Organization
1	Associate Professor 1	Public University A
2	Associate Professor 2	Public University B
3	Teacher 1 (DG44)	School A
4	Teacher 2 (DG41)	School B
5	Teacher 3 (DG44)	School C
6	Education Officer (DG44)	State Education Department

For each item measuring the concept, a four-point ordinal rating was used: 1 = *No relevance at all*, 2 = *Item need some revision*, 3 = *Relevant but need minor revision*, and 4 = *Very relevant*. The experts were required to rate each item based on this scale. The content validity index for items (I-CVI) is computed as the number of experts giving a rating of either 3 or 4 (thus dichotomizing the ordinal scale into relevant and not relevant), divided by the total number of experts which is in this study involve 6 experts. Lynn (1986) suggested I-CVIs no lower than 0.83 if there are 6 experts in total. The other type of content validity performed was content validity index for scales (S-CVI) to measure the content validity of the overall scale which includes Universal Agreement (UA) and Ave (Average).

Findings

The results for the content validity assessment are shown in Table 4 until Table 7 while Table 8 summarizes the overall results. The I-CVI for all the items of the four dimensions ranged from 0.97 to 1.00. The S-CVI (Average) for responsible, approachable, and showing respect dimension of job autonomy were 0.97 (Table 5, Table 6 and Table 7) respectively. Meanwhile conveys confidence dimension of job autonomy was 1.00 (Table 8). The overall S-CVI for the 20-item scale was 0.98 which indicated high content validity of the items for the construct of job autonomy. All of the constructs are maintained as they have a relatively high value of agreement among experts. It can be concluded that the scores for pre-testing is above the recommended threshold and the constructs chosen for the research instrument are valid.

Table 4: I-CVI and S-CVI/Ave for Responsible (R)

Item	Expert 1	Expert 2	Expert 3	Expert 4	Expert 5	Expert 6	Number of Agreement	Item CVI
R1	1	1	1	1	1	1	6	1.00

Conclusion

The objective of this study is to identify the dimensions used for assessing job autonomy in the context for boarding school teachers for a developing country such as Malaysia. The literature review exercise had identified the appropriate dimensions and the corresponding. However, given that these dimensions were originally developed for non-boarding school teachers, further validation was conducted and the results showed that these dimensions, namely, responsible, approachable, showing respect and convey confidence were found to be relevant. In addition, the corresponding scales were also revised and the validation exercise showed that validity scores were highly reliable. Hence, researcher intending to examine job autonomy of boarding school teachers may consider adopting this scale.

While the study has successfully achieved its objective, it also suffers several limitations. The first and foremost is the dimensions chosen were purely based on a study done in the Malaysian context. Every country has its own schooling systems and due to that, care should be taken when adopting these dimensions and scales. Secondly, the chosen dimensions are also too narrow in terms of its scope, hence future research should consider extending by integrating other themes or category as highlighted in the literature review section.

Conclusion

The researcher would like extend our thanks to all respondents who participated in this study and also Universiti Teknologi MARA (UiTM) for providing all the necessary supports throughout the conduct of the study. The study is registered in UiTM as 600-IRMI/FRGS 5/3 (459/2019).

Abstract

The present study uses a proposed model to explore satisfaction and commitment of students in an online learning environment. First, it presents the key determinants of student satisfaction and their impact on student commitment. Second, it examines the significance impact of each of the three key determinants namely course structure, online tutorials flexibility and technology quality on both student satisfaction and commitment.

A sample of 410 students enrolled in an Egyptian higher education institution pursued an online questionnaire through Survey Monkey. This study uses structured equation model approach for data analysis that was gathered online. However, the only determinant namely course structure had insignificant effect on both student satisfaction and student commitment. Specifically, both key determinants namely online tutorial flexibility and technology quality had a significant influence on student satisfaction as well as student commitment. In addition, the mediating role of student satisfaction was tested and had positive influence between the key determinants and student commitment except with course structure.

The study highlights the issue of commitment as a behavior of students in an online learning environment and their satisfaction bonded with key determinants. The context is limited to one higher education institution in an online learning environment. Further research is needed to investigate the key determinants in other higher educational institutions in Egypt and could be extended to other countries if possible. This study will be useful for academics and educators interested in the behavior of students in e-learning through the digitalization era.

Keywords: satisfaction, commitment, online learning, course structure, online tutorial flexibility, technology quality

Introduction

Over the previous years, higher education institutions were offering courses online for students as one of their academic plan's components. Online courses are connecting a variety of tools such as social networking and curriculum available online through different e-learning platforms such as Moodle, Blackboard, etc. The active involvement of many students in these courses who participate individually according to their achieving goals, previous knowledge, and skills is a major factor for success. (McAuley et al., 2010). Education is one of the most dominant means of providing social equality as well as an accomplishing experience of an individual's life. The basic tools require computer screens connected to the internet so lectures could be delivered, the course content is visible for the students to read, audio devices are required to deliver the course content as well as interactions and discussions via video output. Many academic institutions used Zoom as their platform to deliver all course from video and audio tools as well as Moodle for the whole course content and syllabus from power points, pdf files, assignments, and quizzes.

E-learning is defined as the learning tool delivered via computers for the intention to develop education (Mayer, 2003), that has expanded quickly over last years with the upgrades in technology and the integration of it with educational curricula. (Smart and Cappel, 2006). E-learning is essential to develop good calibers well educated, as well as the rapid need of society for long term learning that is delivered in an appropriate form. Learning online

can take many forms from fully online, blended or web-assisted, no matter what the delivery technique of learning, however number of different tools are available at the students and faculty members' hands. (Alshehri, 2017). In fact, online learning is a tool that is globally used for learning with standards and it is not required from the learner or the student to attend the class physically and is suitable for students who are interested in studying while they have other commitments. (El-Ebiary et al., 2016).

E-learning now is not a strategy to overcome just learning from distance, it is now a way to adapt to learning as per personal schedule especially after the pandemic of COVID-19 2020. In this study, students used Moodle that allowed them to interact with the lecturers using audio and video, submit assignments and quizzes, upload and/or download files, have feedback on their grades and have access to the content anywhere anytime. Development of such platforms or applications made the online learning a more interactive way for students to learn at their preference. In recent years, interventions using technologies based on the Internet have allowed electronic learning as a major element in education (Aşkar and Halici, 2004). Online learning can provide academic institutions with a reduced cost, and adaptable tool to grow globally (Casey, 2008).

Students enjoyed this way of online delivery and sometimes it seemed to be more effective than face to face teaching. While students have an online meeting with their instructors, this screen sharing approach may helped the students to feel less exposed when asking for help compared to a physical class within groups. The students may prefer a quicker way to ask for help such as posting their questions on the online chat. This way of asking questions may allow the student to feel more comfort than raising up their hands in front of their colleagues in a computer lab. Similar recent studies have reported (Davison, 2020) that student interaction was motivated through the use of online chat functionality. (Dwivedi et al., 2020).

In light of the dramatic increase in the use of online courses, in higher education especially after the pandemic of COVID-19, the current study deals with identifying key determinants of student satisfaction in an online learning environment namely online tutorials flexibility, online tutorials quality and technology quality. It also investigates the impact of the student satisfaction on their commitment towards the institution and the learning process. Several studies tackled student satisfaction and its key determinants but one of the recent studies investigated factors that were relevant to the online learning environment students have experienced through the pandemic in Egypt. In the study of (Harsasi and Sutawijaya, 2018), it included four variables namely course structure, online tutorials flexibility, online tutorials quality and technology quality but online tutorials quality had less impact on student satisfaction. Therefore, the proposed model investigates three variables namely course structure, online tutorials flexibility and technology quality according to the pandemic period in Egypt.

This study sheds light on some of the determinants of students' satisfaction and the impact of students' satisfaction on their commitment online. This is to know which determinants are the most effective on the students' satisfaction in the online learning process and to explore the influence of their online satisfaction on their commitment towards their institution. Technology becomes a crucial part in our life. E-learning, internet and computers have been used extremely in the learning process during COVID-19 (Khan and Raad, 2020). This study may have a marked impact on online course satisfaction and commitment. Furthermore, this study may affect not only academic courses but have a paved a way for academic institutions and professional training centers to measure the behavior of students after COVID-19. Instructors and researchers can use this study and the preliminary model for the benefit of their research and instruction specially to understand and improve the behavior of students through the online learning process.

Literature Review

There are number of studies that have investigated student satisfaction and commitment in relation to e-learning. A study found that the less student satisfaction the more the failure of any e-learning implementation, and there are many determinants that affect student satisfaction in e-learning. Moreover, (Hermans et al., 2009) suggested that student satisfaction has a vital role to endorse higher education successfully. These authors tested the relationships among different factors that influence student satisfaction in an online learning environments. (Alshehri, 2017)

A definition for satisfaction and commitment need to be clarified. Student satisfaction is an indicator of whether learners or students are satisfied with their learning experience. (Li et al., 2016). In the academic context of higher education, student satisfaction plays an important role in universities' success (Firdaus, 2006), and the concept of satisfaction has been extended to evaluations of higher education services. (Elliott and Healy, 2001) state that the concept of students' satisfaction is a short-term behavior and a result of students' experiences with their educational services provided by their institution.

Previous research has found that organizational commitment which is defined as a person's commitment to the organization that they work in is related to their career commitment (Womack, 2016) , which means that a person's commitment to their organization is an indicator of their commitment to his or her career. The concept of organizational commitment is altered to state the commitment that the student feels towards his or her institution. (Womack, 2016)
Commitment can be viewed as future-oriented self-regulation where one set the goals based on their identity and then behave in a way to achieve the goals bounded by their identity. (Human-Vogel and Vogel, 2015).

A tool was developed to measure employee commitment based on a three-component model of affective, continuance and normative commitment. Affective commitment refers to the attachment and involvement to the organization, Continuance commitment refers to the costs assessed of leaving the organization and Normative commitment refers to the feeling of supporting the organization and remaining in it. (Wilson et al., 2016). The aim of a recent study was to explore factors that have an effect on student satisfaction in online learning environment based on previous research by (Sun et al., 2008) and (Eom et al., 2006).

The impact of course structure on student satisfaction

Course structure is viewed as an important variable that support the success of online learning. According to (Moore, 1991) the course structure
"expresses the rigidity or flexibility of the program's educational objectives, teaching strategies, and evaluation methods" and the course structure describes
"the extent to which an education program can accommodate or be responsive to each learner's individual needs."

Course structure has two parts which are course objectives and course infrastructure. Course objectives are concerned with the course curriculum that includes the topics to be learned, the assignments to be completed, the class participation online, group projects and so on. Those parts affect the student satisfaction level and their learning outcomes. According to (Eom et al., 2006), it was stated that course structure will be correlated to student satisfaction and perceived learning outcomes when the course material is organized in a logical sequence and that a clarified course objectives will lead to high student satisfaction levels. (Eom et al., 2006)

Hypothesis 1: Course structure has a significant impact on student satisfaction.

The impact of online tutorials flexibility on student satisfaction
Satisfaction and participation of students are facilitated because of the flexibility in time, location and methods found in online learning courses. (Arbaugh, 2002) (Arbaugh, 2000) (Berger, 1999). Moreover, the exclusion of any traditional classroom environment enables more interaction that promotes cooperative learning. Students can communicate online anytime anywhere with no limits. In addition, the virtuality available online reduces the discomfort of face to face communication that is available in traditional classrooms. Students have the freedom to express their opinions and ask questions through discussion groups without restraint. "The definition of e-Learning course flexibility is learners' perception of the efficient and effects of adopting e-Learning in their working, learning, and commuting hours". (Sun et al., 2008)

Hypothesis 2: Online tutorials flexibility has a significant impact on student satisfaction.

The impact of technology quality on student satisfaction

Several researchers suggest that the technology quality and Internet quality affect satisfaction in e-Learning (Piccoli et al., 2001) (Webster, 1997). Students will be willing to adopt an e-learning software or tool with few barriers and their satisfaction will be improved. (Amoroso and Cheney, 1991). Online learning may involve learning and discussion using tools such as video conferencing. Therefore, quality of the technology and the Internet are important factors in e-Learning (Piccoli et al., 2001) (Webster, 1997). In addition, a research conducted by (Webster, 1997) studied learning effects on the technology applied in a distance learning of 247 students and found that quality and reliability of technology influence learning effects. "The definition of technology quality is the learners' perceived quality of IT applied in e-Learning (such as microphones, earphones, electronic blackboards, and so on)". (Sun et al., 2008)

Hypothesis 3: Technology quality has a significant impact on student satisfaction.

The impact of student satisfaction on commitment

In an academic context, the knowledge about teachers' attitudes needs more attention as the universities' performance depends on their staff which must be satisfaction and commitment (Tsui and Cheng, 1999). In the same manner, students are other academic entities and their satisfaction and commitment require more attention. stated that an academic employee will feel more satisfied, more committed to his or her academic institution and will develop the output of their universities (Sami et al., 2012). Some research studies support the contention that satisfaction predicts commitment and that satisfaction is positively related with affective and normative commitment, but not with continuance commitment. (Bashir and Ganai, 2019)

Hypothesis 4: Student satisfaction has a significant impact on student commitment.

Research Hypotheses

The main aim of this study is to explore the impact of each of those variables on student satisfaction in an online learning environment and the mediating effect of student satisfaction between independent variables and student commitment.

Based on the previous study, this research adopted three variables that have influence on student satisfaction online. These variables are course structure, online tutorial flexibility and technology quality. To achieve the research objectives, the hypotheses developed as follows:

H1: Course structure has a significant impact on student satisfaction.
H2: Online tutorials flexibility has a significant impact on student satisfaction.
H3: Technology quality has a significant impact on student satisfaction.
H4: Student satisfaction has a significant impact on student commitment.

Figure 1: The proposed research model

Methodology

This research was based on the use of three independent variables (course structure, online tutorials flexibility and technology quality) and one mediating variable (student satisfaction). In addition, the dependent variable student commitment was used based on another previous study by (Wilson et al., 2016).

The observed data were collected using a survey methodology. The target population were students from higher education institutions and due to the pandemic of COVID-19, the sample size was 410 students inside one of the top accredited universities in Egypt. Participants of the study were students from different colleges inside the university. The students are those who pursued Second Semester 2020/2021 and who took the experiment of online courses through the pandemic of COVID-19.

A questionnaire was distributed to the students online through a link on SurveyMonkey. The responses to the questionnaire were 410 students from different colleges such as College of Management and Technology, College of International Transport & Logistics, College of Language & Communication, College of Computing & Information Technology and College of Engineering & Technology.

The survey instrument to explain the independent variables and the mediating variable that have been identified before were adopted from (Harsasi and Sutawijaya, 2018) while the dependent variable was adopted from (Wilson et al., 2016). Each variable's indicators are measured using 5 points Likert scale with the following scale:
1 = Strongly disagree
2 = Disagree
3 = Neither agree nor disagree
4 = Agree
5 = Strongly agree
Each variable has their own indicators as shown in Table 1.

Table 1: Indicators of each variable

Variable	Indicators	Code
Course Structure	1. Course material is presented in an organized structure	CS1
	2. The learning objectives in the online tutorial has been conveyed properly	CS2
	3. The material in the online tutorial has been understandable and arranged in a logical sequence	CS3
	4. The structure of the syllabus in the online tutorial already covers all the material I need to learn in one course	CS4
Online tutorial flexibility	1. Learning through online tutorial gave me the flexibility to adjust my learning time	OTF1
	2. Learning through online tutorial benefit me	OTF2
	3. Learning through online tutorial made me have the flexibility to divide the time between learning activities and other jobs	OTF3
	4. Learning through online tutorial has no disadvantage	OTF4
	5. Learning through online tutorial lets me manage my time more effectively	OTF5
	6. Learning through online tutorial makes me save time rather than having to attend class	OTF6
	7. Learning through online tutorial saved me from not missing the lecture as I can learn the material at any time	OTF7
Technology quality	1. I can access online learning anywhere	TQ1
	2. I do not experience any problems when learning online	TQ2
	3. I do not encounter any difficulty in responding to the discussion	TQ3

	4. I do not see any difficulty when uploading task, I feel that technology for online learning is:	TQ4
	Easy to use	TQ5
	Have useful functions	TQ6
	Very helpful for learning materials	TQ7
	Facilitate communication with tutors or other students	TQ8
Student Satisfaction	1. I am satisfied with the whole system of online learning	OSS1
	2. Overall, online learning system is already well	OSS2
	3. Overall, online learning has been successful	OSS3
	4. Learning through online learning system enable me to learn independently	OSS4
	5. I will keep learning through the online learning system in the future	OSS5
Student Commitment	1. I am happy being a student of AASTMT	SC1
	2. I enjoy discussing about AASTMT with the people outside it	SC2
	3. I really feel as if AASTMT's problems are mine	SC3
	4. I am deeply attached to AASTMT	SC4
	5. I am part of the family of AASTMT	SC5
	6. I feel emotionally attached to AASTMT	SC6
	7. AASMT has a great personal meaning for me	SC7
	8. I am afraid of what might happen if I quit my studies in AASMT without having another one lined up	SC8
	9. It would be very hard for me to leave my studies in AASMT right now, even if I wanted to	SC9
	10. Too much in my life would be disrupted if I decided to leave my studies in AASTMT now	SC10
	11. It would be too costly for me to leave AASTMT now	SC11
	12. Right now, staying on my studies in AASMT is a matter of necessity	SC12
	13. I think that people these days rarely move from a university to another	SC13
	14. I believe that a person must always be loyal to his or her AASMT	SC14
	15. Jumping from AASMT to another seems unethical to me	SC15
	16. One of the major reasons I continue to study in AASTMT is that I feel a sense of moral obligation to remain	SC16
	17. Even if I got another offer of a better university elsewhere, I would feel it is right to stay in AASTMT	SC17
	18. Things were better in the days when people stayed in one institution for most of their career	SC18

Results and Discussion

This section presents the data analysis part of the study. The analysis of this paper was done using the statistical package for social sciences (SPSS V26) for basic descriptive statistics, and (SmartPLS 3.2.7) for SEM-PLS modeling. It is divided into four sections respectively: Data preparation, measurement model for reliability and validity, several descriptive statistics and bivariate correlations are constructed and finally the structural model for hypothesis testing and mediation analysis.

Data preparation

This examination is important in any quantitative research and specifically when using SEM for data analysis (Hair Jr et al., 2017). The issue of missing data was inspected and found that some indicators have missing percent greater than 5%, so, according to (Hair Jr et al., 2017) the best scenario is the case-wise deletion. Considering outliers, there are no outliers detected in our dataset.

The data distribution is not an issue, since the SEM-PLS is non-parametric tool that does not assume normal data ((Hair Jr et al., 2017) (Garson, 2016). Structural equation modeling is an analysis approach that tests both the measurement model and path that helps to develop more realistic assumptions (Abdi, 2010) (Hair Jr et al., 2017). Hence, this study focuses on examining the prediction of the dependent variable, the mediation analysis, and the effect of independent variables, which make PLS method the most appropriate in this study.

Assessing the Measurement Model

The measurement models, which are also known as the outer models, describe the relationships between the constructs and their items. The assessment of the reflective measurement models in PLS-SEM requires evaluating the internal consistency reliability, convergent validity, and discriminant validity (Hair et al., 2011) (Nachtigall et al., 2003) (Xiong et al., 2015) (Garson, 2016). The internal consistency reliability examines whether all of the indicators associated with a construct are actually measuring it (Pallant and Manual, 2010). There are different ways to measure internal consistency. Cronbach's alpha is a statistical measure that is the most used for this purpose. The accepted value of Cronbach's alpha is 0.7, all values of Cronbach's alpha in the table (2) were above 0.7.

Table 2: Results of the Measurement Model

Latent Variable	Indicator	Loadings	AVE	CR	rho_A	Cronbach's Alpha	Discriminant Validity

Figure 2: Path Coefficints with Corresponding P-values

The AVE is a standard measure used to establish convergent validity. All of the constructs in Table (2) have AVE scores higher than 0.50. After establishing the convergent validity, it is time to examine the discriminant validity. Discriminant validity examines how much a construct differs from other constructs.

Descriptive Statistics and Multiple Correlations

Table (3) shows the descriptive statistics of the variables. It can be shown that course structure has mean and standard deviation as $(M = 3.67, SD = 0.943)$ with direct medium correlation to both online student satisfaction $(r = .683, P < 0.001)$, and student commitment $(r = .611, P < 0.001)$.

Table 3: Descriptive Statistics and Multiple Correlations

		CS	OTF	TQ	OSS	SC

	Kurtosis	0.271	-0.006	0.025	-0.088	0.152

***P<0.001

Online tutorial flexibility has mean and standard deviation as $(M = 3.65, SD = 0.979)$, with direct strong correlation to online student satisfaction $(r = .810, P < 0.001)$, and direct medium correlation to student commitment $(r = .579, P < 0.001)$. Technology quality has mean and standard deviation as $(M = 3.73, SD = 0.855)$, with direct strong correlation to online student satisfaction $(r = .837, P < 0.001)$, and direct medium correlation to student commitment $(r = .688, P < 0.001)$. Online student satisfaction with mean and standard deviation $(M = 3.58, SD = 1.01)$, and student commitment with mean and standard deviation $(M = 3.77, SD = 0.882)$ correlate to each other with direct medium correlation as $(r = .645, P < 0.001)$.

Assessing the Structural Model

Researchers provided guidelines for evaluating and reporting the structural model, including path coefficients, collinearity, coefficient of determination (R2), effect size (f^2), predictive relevance (Q2), and goodness of fit criteria, table (4) summarises those criteria.

Table 4: Criteria of Structural Model Assessment

Criteria	Guidelines	Reference
Path coefficients	Significance: $p \leq 0.05$	(Hair Jr et al., 2017)
Collinearity	VIF < 5	(Hair Jr et al., 2017)
Coefficient of determination (R^2)	Weak effect: $R^2 = 0.19$ Moderate effect: $R^2 = 0.33$ High effect: $R^2 = 0.67$	(Chin et al., 1998)
Effect Size (f^2)	f^2 between 0.02-0.14, small; f^2 between 0.15-0.34, moderate; $f^2 \geq 0.35$, High.	(Chen et al., 1998)
Cross-validated redundancy (Q^2)	Predictive Relevance Using blindfolding $Q^2 > 0$	(Chin et al., 1998)
Goodness of Fit (GoF)	GoF less than 0.1, no fit; GoF between 0.1 to 0.25, small; GoF between 0.25 to 0.36, medium; GoF between 0.25 to 0.36, large.	(Wetzels et al., 2009)

Path coefficients refer to the estimates of the relationships between the model's constructs. When assessing the PLS path, studies should report path coefficients beside the significance level, t-value, and p-value. According to (Hair Jr et al., 2017) , every significant coefficient eventually depends on the standard error, which is usually obtained by using bootstrapping. Moreover, the strength of path coefficients can be measured through direct and indirect effects. We are interested in some direct and indirect effects to test the hypothesis underlying this research.

The hypothesis testing has been done to understand the signs, size, and statistical significance of the estimated path coefficients between the constructs. Higher path coefficients suggest stronger effects between the predictor and predicted variables. The significance of the supposed relationships has been established by measuring the significance of the p-values for each path with threshold equalling p <0.05. The p-values and inference of hypotheses, as well as the confidence level for each estimate, are shown in Table 4. The findings of this study reveal that all hypotheses are accepted except H1 and H5.

The results show that online tutorials flexibility yeilded a significant effect on student satisfaction since ($\beta = 0.347, t = 4.798, P < 0.001, 95\%\ CI$ for $\beta = [0.208,0.493]$), so the 2nd hypothesis is accepted. Technology quality yeilded a significant effect on student satisfaction since ($\beta = 0.502, t = 6.858, P < 0.001, 95\%\ CI$ for $\beta = [0.351,0.637]$), so the 3rd hypothesis is accepted. Student satisfaction yeilded a significant effect on student commitment since ($\beta = 0.646, t = 15.87, P < 0.001, 95\%\ CI$ for $\beta = [0.561,0.724]$), so the 4th hypothesis is accepted. The mediation analyses showed that student satisfaction mediates the relationship between online tutorials flexibility and student commitment through the indirect effect ($\beta = 0.224, t = 4.759, P < 0.001, 95\%\ CI$ for $\beta = [0.135,0.32]$), so the 6th hypothesis is accepted. Student satisfaction also mediates the relationship between technology quality and student commitment through the indirect effect ($\beta = 0.325, t = 6.009, P < 0.001, 95\%\ CI$ for $\beta = [0.216,0.429]$), so the 7th hypothesis is accepted. The remaing hypotheses are not supported.

Table 6: Structural model assessment measures

	Student Satisfaction		Student Commitment	
	Effect size	**VIF**	**Effect size**	**VIF**
Course Structure	0.011 (No Effect)	2.344	-	
Online Tutorials Flexibility	0.154 (Moderate)	3.224	-	
Technology Quality	0.325 (Moderate)	3.2	-	
Student Satisfaction	-		0.717 (High)	1
Student Commitment	-		-	
R Square	0.758 (Strong)		0.417 (Moderate)	
R Square Adjusted	0.755 (Strong)		0.416 (Moderate)	
Q^2	0.584		0.26	

Coefficient of determination (R^2) refers to the effect of independent variables on the latent dependent variables (Hair et al., 2011),which is one of the quality measures of the structural model (Hair et al., 2014). Researchers have used a different cut-off of R^2 value. For example, (Hair et al., 2011) in marketing research described that R^2 values of 0.25, 0.50, or 0.75 are low, moderate, or high, respectively. In business research, (Chin et al., 1998) suggested that R^2 with 0.19, 0.33, or 0.67 are low, moderate, or high, respectively. The results of R Square are reported in the table (6), the R-Square of student satisfaction equals 76% which means that about 76% of the variations in student satisfaction are explained by the variations in the selected independent latent variables. Additionally, the R-Square of student commitment equals 42% which means that about 42% of the variations in student commitment are explained by the other latent variables.

The f^2 effect size is the measure of how much impact the endogenous construct will have if an exogenous construct was removed from the model. Table (4) shows the cut-off for the effect sizes. It can be noticed that course structure has no effect on student satisfaction, while both online tutorials flexibility and technology quality have moderate effect on student satisfaction. Finally, student satisfaction has high effect on student commitment. Q^2 value indicates the model's out-of-sample predictive power. When a model is said to have a predictive power or predictive relevance, it means that it can accurately predict data not used in the model estimation. The Q^2 value is calculated through running a blindfolding procedure. Before running this procedure, an omission distance (D) must be specified.

Researchers suggest specifying a D between 5 and 10 while being careful that the sample size divided by the selected D would not produce an integer. The omission distance indicates that while running the blindfolding procedure, every x data point of the items will be omitted and then predicted, with x being the specified D value (Hair et al., 2016). Based on the recommendation from the literature, an omission distance of 10 was selected to examine the predictive power of the model. Table (6) presents the Q^2 values obtained from the analysis. The values of Q^2 for both student satisfaction and student commitment are higher than 0, so it can be safely concluded that the model has a good predictive relevance.

(Tenenhaus et al., 2005), proposed the Goodness of Fit (GoF) as a global fit indicator, it is the geometric mean of both the average R^2 the average variance extracted of the endogenous variables. The GoF index can be calculated as follow:

$$GOF = \sqrt{\overline{R^2} \times \overline{AVE}} = \sqrt{0.5875 \times 0.7118} = 0.647.$$

The criteria of GoF for deciding whether GoF values are not acceptable, small, moderate, or high to be regarded as a globally appropriate PLS model have been given in table (3). According to these criteria and the value of the GOF (0.647), it can be safely concluded that the GoF model is large enough to considered sufficient valid global PLS model.

Conclusion

The present study used structure equation modeling to investigate the behavior of students' commitment towards e-learning during the pandemic of COVID-19 and the key determinants of student satisfaction in online learning environment. Few studies have developed to examine levels of satisfaction and commitment of students in the Egyptian higher education context through the digitization era.

Over the examination of a sample of 410 students enrolled in an Egyptian higher education institution, the study proved the validity of all the indicators of the variables in the proposed model. Moreover, all variables had a significant impact on student satisfaction except course structure, there was a positive correlation between student satisfaction and student commitment while course structure had an insignificant impact on student commitment. In addition, the majority of students' responses were from College of Management and Technology while other colleges were of same responses and this can justify that even disciplines can differ from one another in the satisfaction and commitment level. Therefore, based on the previous literature review, all variables had significant influence on both student satisfaction and commitment except the variable namely course structure.

Though the present study provides significant information for students and decision makers concerned with levels of student satisfaction and commitment in online learning environment, it was limited to be applied on a specific higher education institution inside Egypt. To address this limitation, the study should be expanded to other higher education institutions inside Egypt in different settings. It will be beneficial and useful for academics and decision makers to understand the behavior of students concerned with the commitment towards their institutions.

Future exploration and investigation might embrace testing the model on other higher education institutions to determine its validity in forecasting the satisfaction and commitment of students in an online learning environment. Some studies (Sun and Zhang, 2006) suggest that moderator variables such as age and gender add a great value in which they can be tested in the future (HASSAN et al.). Furthermore, more variables can be tested to explore their effect on both satisfaction and commitment.

Abstract

The task of the modern education system in a globalizing world is to exist competently in the digital sphere, connected with the emergence of new technologies, professions and changes in existing ones, digital transformation, the process of integrating digital technologies into various aspects of human activity, culture, operations and principles of creating new products and services. One of the main requirements for the European education system is the creation of adequate conditions for training citizens, employees, employers and entrepreneurs in digital literacy and mastering digital competence. The leading areas of digital transformation in EU education are: development of the nomenclature of digital competencies, information infrastructure, training, digital security and personal development.

Keywords: European Union, Education, Digital Transformation, Digital Technologies.

Introduction

Being competent in the digital sphere is a task for a person of the XXI century. Global trends of our time-changing habitual patterns of behavior and activity of people, the emergence of new technologies, new professions and changes in existing ones – are directly related to digital transformation (DT), the process of integrating digital technologies into business and other aspects of human activity, making fundamental changes in technology, culture, operations and the principles of creating new products and services, включая образование, например, преподавание латинского языка (Khabibullina, Ivanova, 2019).

Currently, the share of the digital economy in the US GDP is 10.9%, China-10%, the European Union (data for the UK, Germany, Italy, France and Sweden) - 8.2%, the Czech Republic and Poland-6.3%, Brazil-6.2%, India-5.5%, Russia (2015) - 3,9% (McKinsey, 2019).

The education system is a bridge that should ensure a confident transition to the digital age, associated with new types of work and a sharp increase in human creative capabilities and productivity.

The DST of education is caused by globalization, the development of continuing education, automation, training of transfessionals, total digitalization, leading to the blurring of borders within the organization of distance learning via the Internet (MOOC), the demand for specialists of the T-shape model, liberation from routine work, to life in the environment of digital traces, big data, (not)high-quality content, etc.

Centers have been established and programs have been developed to train people in digital technologies. Thus, a well-known center for research on digitalization is the canadian center for digital and media literacy "Mediasmarts" (Canadian's center for Digital and Media literature 'MediaSmarts') (Ottawa), created in 1994 under the auspices of the National Council of Canada for Cinematography (the original name of the "media Awareness Network") (MediaSmarts, 2019). In Russia, an educational program on digital transformation has been developed at the

KIRILLOV and Nadezhda SMIRNOVA "Modern European Education and Digital Transformation" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

SKOLKOVO innovation Center, the purpose of which is to prepare company teams to create a strategy for digital transformation of the enterprise with the construction of a financial model that justifies the profitability of this process in both the long and short term (Managing of digital transformation, 2020). In 2017, the Russian government approved the "Digital economy" program (order No. 1632-R of 28 July 2017) for the country's transition to "digital" rails by 2025, which includes five areas: information infrastructure, information security, personnel and education, regulatory regulation, and the formation of research competencies and technological reserves (The Program “Digital economy of the Russian Federation”, 2017). A basic competence model has been developed, including a List of key competencies of the digital economy (06.2019) (Development of a basic model of digital economy competencies, 2019). An Atlas of new professions has been published, including the following in the field of education: moderator, game master, mentor of startups, coordinator of an educational online platform, developer of educational technologies, ecopropedist, trainer in mind fitness, developer of tools for teaching States of consciousness, etc. The system of basic skills of a teacher of the near future will include the skills of system thinking, intersectoral communication, project management, programming / robotics / artificial intelligence, client orientation, multilingualism and multiculturalism, working with people, working in conditions of uncertainty, artistic creativity, environmental thinking (The Atlas of Emerging jobs, 2018).

Methodology

The main approach to studying the problem of digital technologies in European countries has become a theoretical approach, which implies analysis and synthesis, study of documents of the Council of Europe, pedagogical and methodological literature; analysis of the process of practical activity.

Research Results

A notable phenomenon in promoting the idea of DT was the guide "Digital transformation in learning: Microsoft white paper" (Transformation numérique dans l'enseignement: le livre blanc de Microsoft, 2020). In this white paper, Microsoft proves that digital and technological advances are transforming our society. As a major player in the digital revolution, Microsoft has released this guide with the goal of providing examples of positive practices and feedback that are intended to help in the transformation. For cities, departments, and regions, they are a lever of innovation, dynamism, and attractiveness. For teachers and educational institutions, these recommendations are a learning tool, and for students, a tool for mastering key (digital) competencies for future employment.

The concept of DT goes back to the term "digital literacy", introduced into scientific and wide public circulation by Paul Gilster, an American writer and journalist, Professor Paul Gilster of the University of Illinois (Chicago), an electronics engineer, author of the monograph "Digital literacy" (1997). The criteria for achieving digital literacy include: 1. criteria for achieving media literacy; 2. skills to find the necessary information and tools to work with it, the ability to quickly master these tools (information literacy); 3. communication skills with other users (communicative competence); 4. skills of producing information in its various forms and formats (creative competence).

Digital transformation is already taking place in education in various countries, but it is not just a technological breakthrough, but also a tool that promotes the involvement of various groups of citizens and all students (Khabibullina, Ivanova, 2020).

Digital technologies are now a priority for education systems and governments in Europe, European and international organizations. Training and skills are the basic levers for the development of society and the economy. Digital competence is becoming a key skill for lifelong learning, given that it is estimated that almost half of the world's traditional jobs – and 30 % of those in the European Union-will disappear in the next 25 years. There will be new professions that require advanced digital skills (9 out of 10 jobs will require digital skills in the near future). This requires a fundamental transformation of the education and training (E&T) system across Europe. In General, more and more European countries are investing in digital strategies to reform education and training. Understanding this imperative of education for the future has led to the search for ways to digitally transform education, create new trends and the most important supra-professional skills and abilities of future employees. This is an important part of the Europe 2020 agenda and its various flagship and policy initiatives in the field of education.

EC JRC (European Commission Joint Research Centre) research in this area began in 2005 and focuses on how to better use ICTs to rethink learning, to innovate in education and training, and to meet new skill requirements, especially digital competence, to ensure employment growth and social integration. More than 20 major studies have been conducted and more than 100 different publications have been published. The research of the joint research center of the European Commission is structured in three main areas: Skills and competencies of the XXI century, Innovation and modernization of education and training, open education. The key task of research and policy is to ensure that supply and demand for new skills and competencies are matched (Learning and Skills for the Digital Era, 2019).

A study of technical issues of digitalization of the European educational space conducted for the European Commission in 2013 (Le numérique, priorité pour l'éducation, 2018) showed that digital equipment in European Union (EU) schools does not meet expectations, since 63% of students do not have access to a "school with effective digital equipment" (i.e., with appropriate minimal equipment, broadband access and high internal "connectivity"). 70% of teachers in the EU recognize the importance of using digital tools in the classroom, but only 20-25% of them trust these digital tools and support their use. Most teachers use ICT primarily to prepare for learning, rather than to work with students during classes. It is stated with a certain degree of confidence that it is likely that parents and students have negative perceptions and/or fears related to digital technologies, and that they also prevent the use of digital tools for educational purposes.

The European Commission's survey of employed and non-employed persons with basic and higher digital skills (2014) found that Finland has the best indicators among 28 European countries (more than 80%). Luxembourg, Netherlands. Sweden, Denmark, the United Kingdom, Germany, Estonia show more than 75% (in descending order), France - 75%, Austria, Belgium, Malta, Slovakia, Slovenia, Lithuania, Spain, Latvia, Hungary and the Czech Republic - from 74 to 60%. Indicators for Portugal, Ireland, Greece, Italy, Poland and Cyprus range from 60 to 52%. Less than 50% of citizens with basic digital skills live in Croatia, Bulgaria, and Romania (Learning and Skills for the Digital Era, 2019).

The latest situation studies (2016-2018) show that currently 44% of the European Union population aged 16 to 74 do not have basic digital skills, and 19% of the EU population do not have any digital skills. The existing significant differences between EU member States, the digital skills gap among the population, especially between men and women, generations and different social groups, make it necessary to adopt a common European strategy. Without appropriate and targeted policies, older people and people with disabilities are likely to suffer from the digital transition. The issue of gender parity in the digital sector is open. For example, there are 3.1 times more men in the digital sector than women, who make up only 20% of science professionals, 27% of engineering graduates, and only 20% of computer science graduates. Only 19% of employees in the ICT sector are female managers, compared to 45% of employees in other sectors (Rapport sur l'éducation à l'ère numérique, 2018).

In addition, it is important to prepare educational institutions, teaching staff and staff to provide the appropriate skills to adapt to the challenges of the digital age. Access to and use of the Internet, technological and digital equipment have changed social behavior and communication, especially in younger segments of society. By 2025, all schools in the Union should have access to Internet connections with download speeds and an upward bandwidth of 1 GB of data per second.

At the same time, the EU is concerned that excessive use of technological and digital equipment, such as computers and tablets, can cause health and well-being problems, including sleep problems, lack of mobility (inactivity) and computer addiction. Therefore, it is necessary to take into account research on the harmful effects of digital technology on young children and on their brain development. Digital technologies should be an integral part of a student-centered and age-sensitive approach to education. New and innovative approaches to learning should not be an obstacle to personal contact between students and teachers. Each participant in the educational process must be a competent Internet user, trained and complying with the rules of digital hygiene, cybersecurity, data protection, making informed decisions and aware of Internet risks, such as online misinformation (fake), harassment, personal data violations, etc. The EU believes that the curricula of universities and vocational training institutions should contain curricula on cybersecurity, be complemented by innovative and high-quality digital training, interactive methods that complement traditional master's courses and provide platforms for collaboration and knowledge creation.

Thus, the European Commission points out that digital technologies are now fully integrated into society, so it is necessary to adapt to them. Citizens and educational entities are waiting for a special environment where digital skills can be optimally developed so that students can effectively fit into the professional sphere in the future (Khabibullina, 2019).

In this regard, in recent years, a legislative framework has been created, and a number of legal documents regulating the EU's activities in the field of digitalization have been adopted. Fundamental documents of a General nature include: - articles 165 and 166 of the Treaty on the functioning of the European Union (the FUE Treaty); - The Charter of fundamental rights of the European Union, in particular article 14; - article 2 of the Additional Protocol to the Council of Europe Convention on the protection of human rights and fundamental freedoms concerning the right to education»; - decision (EU) 2018/646 of the European Parliament and of the Council of 18 April 2018 on the General framework for the provision of better qualifications and certification services (Europass) and repeal of decision no.2241/2004 / EC. Conclusions, decisions, messages and advice on education in the EU are spelled out in the following documents: - resolution of 12 June 2018 "on the modernization of education in the European Union»; - resolution of 14 September 2017 "on a new competence strategy for Europe»; - resolution of January 19, 2016 "on the policy for the development of skills to combat youth unemployment»; - resolution of 9 September 2015 "on empowering girls through education in the European Union»; - resolution of September 8, 2015 " on promoting entrepreneurship among young people through education and training»; - Council recommendation of 22 may 2018 "on key skills for education and lifelong learning"; - Council conclusions of 22 may 2018 "Implementing the idea of a single European educational space"; - Council recommendation of 22 may 2017 "on the European certification system for lifelong learning»; - conclusions of the Council of may 30, 2016 "on the development of education in the media and critical thinking through education and training»; - Council recommendation of December 19, 2016 "on advanced training courses: new perspectives for adults"; - Council conclusions of may 20, 2014 "on effective education and training of teachers»; - Council resolution of 28 November 2011 "on the updated European agenda for adult education and training", etc.

A number of documents directly relate to digital training of various segments of the population and school children: - communication of the European Commission of 2 may 2012 "European strategy for the Internet adapted for children»; - resolution of April 15, 2014 "on new technologies and free educational resources»; - Council conclusions of 27 may 2015 "on the role of early childhood education and primary education in promoting creativity, innovation and digital skills»; - Commission report dated may 30, 2017 "school Development and best practices for a good start in life»; - Commission's communication dated January 17, 2018 "on the action Plan in the field of digital education»; - message of the Commission dated December 7, 2016 " Improvement and modernization of education»; - conclusion Of the Committee of regions of November 30, 2017 "on the modernization of school and higher education", etc.

The EU takes into account that the development of effective digitalization policies requires constant monitoring and evaluation of the level of digital skills, both in organizations and among the General population. Therefore, along with the problem of increasing the level of digital skills necessary for the professional and personal development of all European citizens, the issue of developing tools for determining the level of European competence in the field of digital technologies remains an urgent agenda of the European Union.

JRC's current research in this area covers the following projects: Digital competence for citizens (DigComp), Digital competence for consumers (DigCompConsumers), entrepreneurial competence (EntreComp), and the study of computational thinking, which can become as fundamental as numeracy and literacy (CompuThink) (Learning and Skills for the Digital Era, 2019).

Since the summer of 2015, Europass CV has included the online tool DigComp, which allows job seekers to independently assess their digital competence, describes and includes it in their curriculum Vitale (CV). on June 10, 2016, the Commission heard the report "New competence strategy for Europe", related to the launch of the European digital competence system DigComp 2.0.This is a tool for assessing, self-evaluating and improving the digital competence of citizens. DigComp 2.0 provides an updated list of 21 competencies (also called the conceptual reference model). Within this product, digital competence means that people must have competencies in five areas of DigComp: information literacy, communication and collaboration, digital content creation, cybersecurity, and problem solving in the digital environment. The European model of digital competencies for citizens (DIGCOMPEDU 2018) includes supra-professional digital competencies corresponding to the main sections (21):

- Viewing, searching and filtering data, information and digital content; evaluating data, information and digital content; managing data, information and digital content.
- Interaction through digital technologies; exchange through digital technologies; civic participation through digital technologies; collaboration using digital technologies; etiquette in the network, managing your digital identity.
- Creation and development of digital content; integration and processing of digital content; copyrights and licenses; programming.
- Device protection; personal data protection and privacy; health and well-being protection; environmental protection.
- Solving technical problems; identifying needs and technological solutions; creatively applying digital technologies; identifying gaps in digital competence.

The allocated digital competencies are aimed at improving the use of digital technologies in teaching and learning; developing skills necessary for digital transformation; and relying on data-based analysis and forecasting in education. The digital competence system can help to define the level of digital competence, clarify learning goals, identify learning opportunities, and facilitate job search (European Union "DigComp 2.1, 2017).

In the published strategic report "DigComp into action", "DigComp 2.1: the digital competence framework for citizens: With eight proficiency levels and examples of use", the user can get acquainted with the concept of Digital Competence and presented practical results and examples of using DigComp in case studies and tools throughout Europe. For example, the Basque Country in Spain has created a free online self-diagnosis tool to test its level of digital competence based on the DigComp platform. After a 15-minute online test, the results are available in a simple format to evaluate your skills and identify learning opportunities. More than 10,000 people have already been tested. The EU is currently planning to introduce a similar tool that will eventually be available to all citizens in their native languages (Being digitally competent – a task for the 21st century citizen, 2019).

The digital competence framework can help not only monitor citizens ' digital skills, but also support curriculum development. The DigComp platform can be used for planning and creating training offers. For example, the Spanish Ministry of education, culture and sports adapted DigComp for Spanish language teachers and used It as a strategic support document for further development of professional growth of teachers (Marco comun de Competencia Digital Docente 2.0, 2017).

Wallonia, or the Walloon region of Belgium, offers 5 priority areas of policy in the field of digital education in schools: initial and continuous training of teachers, digital infrastructure in schools, technical and logistical support, pedagogical support for initiatives, cooperation and exchange between educational entities (Le numérique, priorité pour l'éducation, 2018).

The pan-European digital economy and society indexing (DESI) offers an indicator for digital skills that also uses the DigComp framework. The "digital skills" indicator is one of many indicators for measuring human capital that are needed to explore the opportunities offered by a digital society.

JRC's current research focuses on digital competence organizations (DigCompOrg), digital competence of educators (DigCompEdu), policy reforms towards integrating digital technologies in education (Digedu), and learning Analytics (Learning and Skills for the Digital Era, 2019).

The TTC is the subject of annual discussion at meetings of the European Parliament. For example, the 2018 report of the Commission on culture and education (speaker – Yana Toom) "on learning in the age of digitalization" (Rapport sur l'éducation à l'ère numérique, 2018) discussed the challenges, opportunities and lessons to be learned in determining the Union's policy in this direction in the near future. The Resolution of the European Parliament made proposals in the following main areas:

- ***Developing A Nomenclature of Digital Competencies:***

the importance of assessing and monitoring changes in European digital skills; developing tools at the European level for both organizations (the digital skills system and the common European system for assessing key skills for education and lifelong learning) and individuals (self-assessment tools such as SELFIE) in all regional and minority

languages in the member States of the Union; the need to develop the Union's capabilities in areas such as artificial intelligence, big data, software development, quantum computing and web design, including the digital skills component of the digital Europe Program;

- ***Information Infrastructure:***

significant public investment to provide all schools with high-speed and high-performance networks, using existing Union programmes, including the interconnection mechanism in Europe, which can support the physical infrastructure of high-capacity networks and the WIFI4EU credit system, particularly in poor rural areas, remote areas and mountainous areas; close collaboration between all stakeholders, industry, local and regional authorities, communities and civil society for a successful transition to a more digitally based learning environment; adapting educational institutions to new technologies and innovative approaches to learning, providing the necessary support to educational institutions to improve digitization in the field of languages within the Union; support for pilot initiatives related to the European student card and "Erasmus without documents", with the new pilot project "Digital learning opportunities" within the Erasmus+ and Horizon 2020 programs; implementation of the digital education action plan, such as the European computer programming week, the Coalition for digital skills and jobs, or the Sofia call to action on digital skills and digital education; promoting synergy between programmes including Erasmus Mundus, Erasmus+, Horizon Europe, InvestEU and Digital Europe, reserving funds under these programmes and European structural and investment funds for the digitization of libraries, archives and museums in order to improve their use in the field of education and culture;

- ***Training:***

transforming the training system at all levels with a focus on the needs of society and the labour market in the future; teachers and trainers should be at the center of the digital transformation and should therefore receive initial training and continuing education;

- ***Digital Security and Personal Development:***

targeting and focusing strategies on the needs of different age groups and students; ensuring the right to personal development, the right balance between relevant digital skills and the skills of everyday life, sustainability, critical thinking and innovative potential of people; cultivating traditional and humanistic skills despite the crucial importance of improving basic and advanced digital skills of students; investing in interdisciplinary research on the various implications of digital technologies for education, linking education, pedagogy, psychology, sociology, neurology and computer technology, maximizing the benefits of using digital technologies in education and minimizing the risks associated with digital technologies; improving children's online safety and addressing cyber harassment, exposure to harmful and disruptive content, and other cybersecurity threats by developing and implementing prevention programs and awareness campaigns such as#SafeInternet4EU; addressing the special needs of all students by developing effective measures to promote digital skills, including among students with disabilities, minorities, migrant communities, school dropouts, the long-term unemployed, and the elderly; ensuring a gender-balanced approach to career development in the field of ICT and digital technologies, bridging the gender gap in digital technologies, etc.

Conclusions

The digital boom has affected a wide range of industries, with education taking a special place among them. This is the industry that modern Europe relies on. Digital transformation in European education should shape the readiness of European society for the challenges of the future. Ensuring this goal is the main goal of the European Union and the organizations responsible for this process. The data analyzed in the article shows that the EU leadership as a whole manages to achieve significant results in the process of digitalization. At the same time, the European Parliament has set ambitious goals that require the joint efforts of all EU member States.

Abstract
The article is devoted to a comparative analysis of digital educational technologies used in Russian educational institutions at different levels in the conditions of self-isolation caused by the coronavirus pandemic in the world. Based on the analysis of the results of the study, the authors conclude that the pandemic accelerated the transition to distance learning and at the same time exposed pedagogical, psychological and medical problems associated with the introduction of digital learning technologies. The positive results of digitalization of education are: the possibility of introducing new approaches, methods, models of teaching and upbringing in the educational process; the possibility of choosing an individual educational trajectory for students; increasing interest and more active involvement of schoolchildren and students in the process of obtaining and consolidation of knowledge; the ability to use a variety of mobile platforms, electronic textbooks, modern automated learning systems and augmented reality technologies that allow students to evaluate their knowledge and track their learning progress through a system of assessments and proposed test tasks.

Keywords: Digitalization of Education, Learning Technologies, Mental and Somatic Health, Coronavirus, Pandemic.

Introduction

The coronavirus pandemic around the world has pushed many sectors of the economy to digital transformation and transfer the work of employees to the online space. First of all, it affected the sphere of education. Thus, the educational institutions at all levels were transferred to distance learning in the first days after the announcement of the self-isolation regime in order to ensure the safety of life and health of students, professors, teachers and educators.

The transfer to online education, which was almost instantaneous, was facilitated by the creation of a passport for the priority project "Modern digital educational environment", developed in October 2016 by the Presidium of the presidential Council of the Russian Federation and the course adopted by the Government of the Russian Federation in 2019 on digitalization of the Russian economy (including education) and the signing of the corresponding national project. In addition, in recent years, one of the priority areas for improving secondary and higher education systems has been identified as the formation of an innovative educational environment based on information and communication technologies in order to improve the availability and quality of education. In order to solve this problem, the significant funds were allocated for technical and technological support of the educational process: for

Cite this Article as: Flera Ya. KHABIBULLINA, Iraida G. IVANOVA, Nikolaj A. KIRILLOV and Nadezhda SMIRNOVA "Features of the Use of Digital Educational Technologies During the COVID-19 Pandemic" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

the development of digital zones; automation of management activities; digital support for libraries; introduction of digital educational resources in the educational process; Informatization of educational and extracurricular activities, introduction of distance learning to improve the skills and retraining of teachers and employees.

In General, such an educational environment should provide graduates with competitive advantages when entering universities, and in the future it should help them achieve significant success in their professional activities throughout their life (Akbar, 2016; Collins, 2009; Lonka K., Cho V., 2015). At the same time, there are practically no studies aimed at studying the impact of digitalization in the educational system on the health indicators of participants in the process: teachers and pupils, students and professors.

This problem remains relevant for all countries of the world that have entered the path of digital transformation. For example, digital security is the subject of annual discussion at meetings of the European Parliament. For example, the report of the Commission on culture and education in 2018 (speaker – Yana Toom) "on learning in the era of digitalization "[13] considered the challenges, opportunities and lessons to be learned when determining the Union's policy in this direction in the near future. The resolution of the European Parliament, along with the development of the nomenclature of digital competencies, the development of information infrastructure, the transformation of the system of professional training of teachers, made proposals on digital security and personal development. They discussed investing in interdisciplinary research on the various effects of digital technologies on education, combining education, pedagogy, psychology, sociology, neurology and computer technology; minimizing the risks associated with digital technologies; improving the safety of children on the Internet and addressing the cyber impact of harmful and destructive content and other threats through the development and implementation of prevention programs and awareness campaigns, etc. (Khabibullina, 2019; Khabibullina, Ivanova, 2020).

Based on the above, the purpose of this study was to identify psychological, pedagogical and medical problems associated with the introduction of digital technologies in the educational process.

Material and Methods of Research

To collect primary information, we used: a method of analyzing documents related to the introduction of digital technologies, a questionnaire and a recitation of students, teachers, secondary and higher professional teachers to determine their attitude to the digitalization of education and assess the positive and negative consequences of the introduction of distance learning.

The object of the study was participants in the system of secondary and higher professional education: students, teachers, research and teaching staff, representatives of the administration of educational institutions.

The subject of the study was the parameters of changes in well-being and individual indications of mental and somatic health of participants in the educational process when implementing digital technologies and distance learning.

Research Results

The introduction of distance learning after the announcement of the self-isolation regime in Russia has affected the change in the role and place of the teacher in the new educational environment. As a result, in the new reality, the teacher gradually turns into a kind of a consultant or a mentor, whose main task is to teach students algorithmic thinking and work with big data, as well as the ability to independent setting and realizing goals and tasks, evaluating the quality of work performed and developing needs, and self-education skills.

In a very short period, the pandemic coronavirus resulted in a request for the creation of new digital educational resources (DER), innovative scientific-methodical base for preparation of new generation of specialists and retraining of the already employed, and for the upgrade of the existing logistics.

If at the initial stages of digitalization of education only the text documents and other educational materials necessary for the organization of the educational process were used as DER, then during the transition to distance learning, digital educational resources were supplemented with digitally presented photos, presentations, films and

video clips, static and dynamic models, virtual reality and interactive modeling objects, sound recordings and other visual materials (Sappey J. Dr, Relf St., 2010; Saykili, 2019; Tulinayo, Ssentume, Najjuma, 2018).

In General, the use of DER in the system of higher education made it possible to apply the full range of modern information and telecommunications technologies in the course of educational activities; to conduct objective diagnostics and assessment of students ' knowledge, skills and training level in accordance with the requirements of the state educational standard; to organize individual and independent educational activities, to form skills of self-study, self-development, self-improvement, self-education; to ensure constant and efficient communication between various participants in the educational process. It is interesting that the first and the most informative digital educational resources in Russia appeared and began to function successfully in non-state (commercial) universities and in regional branches of large universities. Therefore, they were the most prepared for the coronavirus pandemic and the complete transition to distance learning (Kirillov, 2018; Kirillov, 2019).

The analysis of the online format for organizing the educational process, conducted during the period of self-isolation in the regions of the Russian Federation (March-July), allows us to see not only positive aspects, but also significant problems and negative consequences of digitalization of education. Thus, the main positive role of digitalization was to increase the level of digital literacy or the ability to use modern information and telecommunications technologies by all participants in the process, both on the part of students and teachers, since today digital literacy is already a prerequisite for the possibility of obtaining additional knowledge, skills and self-education and self-development (Zaripova, Salekhova, Danilov, 2017; Klikunov, 2017; Maloshonok, 2016).

Among other positive aspects, we should highlight the opportunities provided by information technology. These are: the introduction of new approaches, methods, models of teaching and upbringing; the possibility of choosing an individual educational trajectory for students; more active involvement of schoolchildren and students in the educational process; the possibility of using mobile platforms, electronic textbooks, modern automated learning systems and augmented reality technologies. Thus, the introduction of distance learning in practice has shown that e-learning programs developed in a short period of time allow students to evaluate their knowledge and track their progress in learning through a system of assessments and proposed test tasks.

In particular, after the adoption of the Federal law of February 28, 2012 N 11-FZ "on amendments to the Law of the Russian Federation "on education" in terms of the use of e-learning, distance learning technologies", training of full-time and part-time students through interactive electronic means (Internet and local networks) has become an integral part of education at Mari State University. For example, French electronic resources were used to teach classical languages to foreign Francophone students (Khabibullina, Ivanova, 2019).Therefore, immediately after the announcement of the self-isolation regime, full-time students were able to continue classes with teachers according to a pre-arranged schedule in online mode.

Part-time students started distance learning later, according to the schedule of the educational process. In addition, they had the opportunity for self-study of educational materials (in any convenient place where there is Internet access) prepared in advance by the teacher and posted on the e-learning server of Mari state University, where a learning management system was formed in the form of a virtual learning environment.

For the use of the electronic educational and information system, students and teachers had only to register and get an individual user name and password. After authorization in the virtual environment, teachers were able to enter various educational materials in the form of texts and multimedia elements, view their training statistics, create tests to test their knowledge, and consult students remotely via video conference. At the same time, a student or a student of the courses held at the University could independently choose the appropriate form of training, as well as check the material they have mastered during the test tasks.

The educational electronic platform Moodle was used for conducting classes and self - study of disciplines at the University, and the Zoom platform was used for conducting lectures, practical and seminars, intermediate or repeated certification in the online mode.

In addition, students and teachers of Mari state University have 24/7 free access to educational literature, regulatory documents, multimedia materials in the electronic catalog of the MarSU library, the electronic library system "The student consultant", the electronic library system "YURAYT"; educational materials and fiction "LAN publishing

house", the publishing center "Academy", and "WILEY" publishing houses (onlinelibrary wiley.com), "AMERICAN MATHEMATICAL SOCIETY (ams.org/mathscinet)," ENVOY POLPRED.COM»; electronic library system "IPRBOOKS"; electronic medical library "The doctor's consultant".

All employees and students of Mari state University can view and download the resources available on the following platforms: "SPRINGER LINK" (https://rd.springer.com), "NATURE" (https://www.nature.com), as well as in the SPRINGER MATERIALS databases (http://materials.springer.com), "SPRINGER PROTOCOLS" (http://www.springerprotocols.com), "ZBMATH" (https://zbmath.org), "NANO" (http://nano.nature.com). Thanks to this, students and teachers can use free textbooks, workbooks, scientific and popular science literature in the field of higher medical and pharmaceutical education, agricultural sciences, natural science, as well as a basic set of textbooks for all specialties and training areas.

Thanks to the existing learning platforms, students can interact with teachers on an ongoing basis, have the opportunity to express their suggestions, complaints or feedback, which contributes to the improvement of existing and functioning e-learning platforms. In the course of this collaboration, existing digital learning platforms are adapted to the specific needs of students and their teachers. For example, students can join separate groups to complete their academic and scientific tasks, and share their results and knowledge with each other.

The negative consequences of digitalization of education, first of all, include the health deterioration of all participants in the educational process. First of all, this concerns school teachers and teachers of secondary and higher professional educational institutions, whose time in front of monitors has increased by at least two or even three times due to the introduction of distance learning. A survey which was conducted among 116 teachers and University professors of the Republic of Mari El and Chuvashia showed that visual acuity of the majority of respondents had been worsened significantly during the period of self-isolation, symptoms of existing chronic and exacerbation of some occupational diseases began to appear more severely. Moreover, in addition to somatic diseases, a significant number of respondents registered initial signs of mental disorders (sleep disorders, feelings of fear or anxiety, difficulties in clear thinking, pathological beliefs, memory impairment, inability to perform everyday functions, substance abuse) associated with the introduction of a self-isolation regime.

Students had even more health problems. Thus, digitalization has led to a significant decrease in interest in writing and the development of various types of creativity. In our opinion, this is due to the fact that writing involves parts of the brain which are responsible for sensory interpretation and for putting letters into words, as well as for recognizing them (Broca's center). Therefore, children lose the desire to read books, which is reflected not only in a decrease in the ability to recognize written texts, forgetting the rules of spelling, punctuation and grammar, but also in the appearance of problems associated with abstract thinking, the processes of imagination, perception, memorization and extraction of necessary information from memory.

It is also proven the fact of digital addiction during the prolonged use of gadgets, which causes depression, short temper and aggression in children. Isolation from peers and long time spent at computer monitors often replaces normal communication, which leads to the loss of social skills, the appearance of autism syndromes and reduced adaptive capabilities. Over time, for such people, the virtual world completely absorbs the real one, as in the case of severe forms of mental disability which are difficult to respond to today's available methods of mental influence or psychotherapy.

Even the very use of wireless Wi-Fi networks in schools and pre-school educational institutions can increase the risk of cancer, damage to hippocampal neurons, and negatively affect the blood-brain barrier.

Previously existing hygiene standards which were recommended by ophthalmologists prescribed sitting at a computer in the first class for no more than 10 minutes a day; in 2-4 grades -15 minutes; in grades 5-7 - 20 minutes; in grades 8-9 - 25 minutes and in grades 10-11 - 30 minutes, and when switching to distance learning, students were forced to stay with their parents at monitors for six or more hours. Therefore, the consequences of implementing distance learning in the future may not be quite rosy and beautiful. We have to evaluate them yet.

Many negative aspects of the introduction of digital technologies are noted by teachers and psychologists in the organization of the educational process. Thus, most researchers note that smartphones and gadgets distract children

from the educational process, negatively affect the development of children's communication skills and social interaction (Robotova, 2017; Shestakov, Adzhemov, Manonina, 2018).

Teachers are particularly concerned about the problem of objective assessment of the results of educational activities and, especially, when performing control works, passing tests and exams, defending term papers and final qualifying works. The main ways to" deceive " the teacher in this case are copying and using other people's works, buying a ready-made abstract, term papers and theses. In addition, the quality of sources on the Internet does not always meet the expectations of users, although many educational organizations for students have formed a list of electronic educational resources that they should use in the educational process in a short period of time. It was facilitated by the creation of the National open education platform in Russia in 2015, WHICH operates on the basis of the best Russian Universities (MSU, ITMO University, nust MISIS, MIPT, HSE, Urfu, St. Petersburg state University). More than three hundred online training courses in various fields of training are currently available at these Universities.

It should be noted that existing educational resources can be used by both students and teachers. They are freely available and contain both educational and reference material: electronic tests, interactive models, video and audio materials, illustrations, ready-made developments, and other educational and methodological materials intended for preparing and conducting interesting classes, homework, course and research projects.

The self-isolation regime in Russia has also exposed the problem of unequal access of students from different regions of the country to electronic technological resources. It turned out that not all students have a tablet or laptop with constant Internet access. Therefore, schools, colleges and universities were forced to allocate money for their purchase from their own resources or recommend students to use libraries or other places of access to the world wide web for distance learning.

This is not a complete list of negative factors and consequences of the introduction of digital education, although it should be recognized that, despite these and other significant "disadvantages" of digital education, modern information technologies provide new opportunities, methods of transfer and dissemination of knowledge, and also contribute to the formation of necessary competencies based on the acquired knowledge, skills and abilities. They significantly simplify the process of managing the educational process and to a certain extent they can provide equal access to information and building of necessary skills.

Conclusions

Digitalization of education today is one of the conditions for the transformation of higher education institutions, the process of which has been accelerated due to the developing covid-19 coronavirus pandemic in the world. As a result of the imposition of a state of emergency or self-isolation, educational organizations at all levels of education were forced to switch to distance learning, which continues in some of them to this day or is being re-introduced in the new academic year. But even after the abolition of self-isolation, many universities continue to conduct some types of classroom lessons (primarily lectures) online, which may indicate both the effectiveness of e-education and the desire of educational institutions to "optimize" the educational process by reducing classroom lessons and teaching staff.

In General, the forced transition to distance learning has revealed not only positive aspects of e-learning, but also pedagogical, psychological and medical problems associated with the introduction of digital technologies on the part of both students and teachers. Therefore, we consider it necessary to conduct long-term research on the comprehensive study of the influence of electronic technical training resources introduced into the educational process on the mental and somatic health of teachers and students, and the full transition to digital education is premature.

Expert Opinions as A Method of Diversification of Sources in Qualitative Research in Management Science

Abstract

The main problem of the article is a question: how to increase the credibility and variety of sources in qualitative research, especially in those areas of management science that cannot be directly verified by quantitative methods. The main aim is to assess the possibility of using business advisors (experts) as an objective source of research information. The background to the proposal is the area of making decisions in a crisis situation of an enterprise. In the empirical part, the method of systematic literature review was used. Furthermore, the paper presents recommendations for the use of various research tools enabling effective collection of information for research (based on authors' own experience).

Keywords: Experts, Research Information, Qualitative Research.

Introduction

The gap between theory and practice, considered in the context of the use of research results in business management, has been the subject of broad discourse in literature for a long time (Butler, 2008). It is often argued that management scientists focus on issues that are irrelevant to practitioners, and that most research results, due to their generalisations and the assumptions made, are devoid of application value (Bansal et al., 2012, Bullinger et al., 2015). Hence, conducting research in management sciences is generally considered as difficult and the results are inconclusive (Cohen, 2007). This approach is the reason for the widespread use of classical quantitative methods in research, which are the dominant research approach in most sciences (Klaes, 2012). This is due to the fact that quantitative research has traditionally been (and still is) associated with representativeness, care for data collection with objectivity and the development of systematic and standardised procedures. Studies conducted using qualitative methods, on the other hand, are often seen as related to that which is detailed, which condemns their results to remain at the 'pre-scientific' stage (Kelemen & Rumens, 2012). It is therefore not surprising that the alternative to the quantitative approach, i.e. the use of qualitative and unrepresentative methods, is subject to frequent criticism (cf. Sarma, 2015). At the same time, however, there are more and more demands in the research community to defend the qualitative methods. Many of the earlier critical arguments are being denied, and earlier criticism motivates the development of better tools and standards of their application. This allows for a better description of economic reality (cf. Czakon 2009, Sułkowski 2014; Bluhm, Harman, Lee & Mitchell 2011). At the same time, taking into account many non-measurable or difficult to measure factors results in a lower level of universalism of conclusions and sustainability of laws of science (Matejun 2011, p. 93).

One of the more difficult research areas of management science, where qualitative research is gaining ground, is strategic management and managerial decisions, particularly important in times of instability and crisis. Researchers are looking for the right models to describe the reality and practice of entrepreneurial choices, but they are aware of the enormous subjectivity of the conclusions drawn and the distortions that arise during the gathering of data. This creates a certain disparity between the desire for reproducible and universal conclusions and the awareness of the impact of many non-measurable factors on reality although many authors tend to prefer a qualitative approach to problems of a strategic nature (Greckhamer, V. Misangyi, H. Elms, R. Lacey 2008; Cornelissen 2017; Gaya & Smith 2016). One of the reasons for this trend is the problem of getting to the right sources as practice usually verifies all strategic plans and the process of strategic management itself becomes very dynamic and not always

formalised. In such conditions, it is not only the lack of documentary sources but also the distortions of opinion that occur during the time that make it difficult to systematise the researcher's tools.

The problem to be defined is therefore related to how to increase the credibility and variety of sources in qualitative research, especially in those areas of management science that cannot be directly verified by quantitative methods. On the one hand, the authors of the paper are in favour of accepting a wide range of qualitative methods but also, on the other hand, of the necessity to maintain the rigour of the stages of research proceedings. In the course of this discussion, they want to draw particular attention to the sources of information used by researchers applying the qualitative methods. The main aim of the paper is to assess the possibility of using business advisors (experts) as an objective source of research information. The background to the proposal is the area of making strategic decisions in a crisis situation of an enterprise. The paper justifies the choice of such an area (taken because of the particular difficulties in obtaining information from companies in a crisis and the risk of significant data distortion).

In the empirical part, the method of systematic literature review was used, which allowed for a formalised and objective synthesis of the scientific achievements to date, as well as for the evaluation of the research to date (Columb and Lalkhen, 2005). The research procedure included the analysis of 4,385 articles and 34 publications marked as conference materials in the database. Furthermore, the paper presents recommendations for the use of various research tools enabling effective collection of information for research.

Decision-Making in A Crisis – A Literature Review

Classical sciences with a much longer history than economics or management have set some standards that are difficult to match, especially in terms of universality and repeatability of the statements and truths they produce. In mathematics, commonly regarded as the 'queen of the sciences', it is difficult to talk about the variability of the issues being studied, although already in biology, for example, long-term evolution and variability of objects and phenomena are observed. In social sciences, these changes take place much faster, and the diversity of objects and phenomena being studied is connected not only with time or area but also with very individual features of each organisation and its every member. However, while e.g. in natural sciences, the existence of the so-called 'butterfly effect' does not exempt researchers from striving to build better and better mathematical models describing the reality (in fact, weather forecasts have improved significantly since the times of E. Lorenz), in social sciences much deeper questions are raised. Many authors point out that in the case of management problems it is impossible to determine the relation between the solutions applied and the economic effects of those solutions (Kaleta 2006, p. 43). The assumption of ceteris paribus (Latin phrase indicating the lack of influence of other factors), which is made in many theories, encourages the formulation of economic statements but it is too simplistic for the search for regularities in management problems, especially those of a strategic dimension.

At the same time, since the crisis of 2008, many authors have drawn attention to the need to search for a new model of economics (Jancar-Webster, 2016) that would be acceptable to companies and their decision-makers (Waterman, 2016). The contemporary consideration of social and environmental problems and related globalisation affects individual companies, even those operating on a local scale. This necessitates changes in research methods, especially taking into account the socio-economic context (Vlados, C., Deniozos, N., Chatzinikolaou, D., & Demertzis, M. (2018), the importance of which increases with the growing popularity of behavioural economics (cf. Thaler, & Ganser 2015, p. 77; Wilkinson & Klaes, 2017).

This need also applies to the very process of implementing changes and restructuring, especially as many of the problems related to crisis responses or restructuring measures are non-linear (cf. Datta, Guthrie, Basuil, Pandey, 2010, p. 339), which means that using the same tools can have different effects, and strengthening the tools will not always enhance the effect. It should be remembered that making managerial decisions in a crisis situation is a challenge as it is burdened with the need for a relatively quick response, most often under stress (Vargo & Seville, 2011). Moreover, during a crisis, people are affected by emotional factors that undoubtedly influence the decision-making process (Janka et al., 2015), which hinders the research process aimed at formulating generalisations. Thus, the result of a test conducted by an investigator on one sample need not be repeated on another one. This is one of the most important limitations of modern economics: it cannot formulate final decisions or any absolute truths (Mączyńska 2012, p. 11).

The use of mathematical methods in such conditions, however correct, cannot therefore do without qualitative research. The above-mentioned differences in the results obtained by various researchers for the study of management and strategic (including restructuring) problems, encourage the use of the descriptive approach describing real choices rather than the normative approach characterising hypothetical rational choices (cf. Stańczyk, Sus 2013, p. 8; Bunger, A. C, Powell, B. J., Robertson, H. A., MacDowell, H., Birken, S. A., & Shea, C. 2017; Gaya, H. J., & Smith, E. E. (2016)). Studies of literature (cf. Bakonyi, 2018; Higgins-Freedman, 2013; Parnell, 2015) allow to point out several reasons for using qualitative methods in the research of decision making, especially in a crisis situation. Firstly, this enables researchers to create multi-faceted analyses relating to complex social relations in organisations (Selmier et al., 2015). Secondly, it allows existing theories to be extended with new examples and observations (Eisenhardt & Graebner, 2007). Thirdly, qualitative research allows for a broader analysis of personal interpretations of a given situation, which in a crisis can provide important support for decision making (Bakonyi, 2018). It is also worth to refer at this point to Popper's diamond model (Popper, 2008) which illustrates research methods aimed at making scenario-based decisions. When analysing the said model, it is clear that qualitative methods such as interviews, literature review, morphological analysis, interaction trees, scenarios and SWOT analysis all make an integral part of the model.

Indeed, in many management areas, a growing share or even dominance of qualitative methods can be observed. For instance, they are more popular in the area of marketing research or general management issues (cf. Kan, Adegbite, Omari, & Abdellatif, 2016 although the study indicated a specific qualitative method, namely comparative analysis).

It is also worth noting the growing (predominant) share of case studies (Piekkari, Welch, 2018); among the individual research techniques, the methods of interviewing, examining documents, observations, and, less frequently, questionnaire research are mentioned (Matejun 2011, p. 93; Gummesson, E. (2017)).

At the same time, however, there are areas where these trends are reversed: authors who verify the way in which the area of public administration is examined noted, after analysing (in 2001-2010) over 1,600 papers from 4 leading journals, the domination of qualitative methods (56%); however, it is the share of quantitative methods that is growing significantly over time (Groeneveld, Tummers, Bronkhorst, Ashikali, Van Thiel, 2015). Likewise, some authors draw attention to some regional differences, e.g. a greater share of quantitative methods in American journals compared with European ones (cf. Cassell, C., 2017) although the conclusion drawn by these authors contains an assumption, adopted also in this paper, concerning the necessity of methodological improvement of qualitative methods and promotion of methodological diversity.

In view of the above, the next part verifies the research methods used based on our own research. However, referring to the earlier justification, the literature related to the subject of decision-making and strategic choices in a crisis situation was analysed.

Research methods – an analysis of the practice

In order to verify the distribution of methods, an analysis of scientific literature from the period 2012-2019 was used to search for information about the way the research was conducted, both in abstracts and full texts. The procedure was conducted taking into account indications of the Systematic and Reproducible Process for Identifying Journals, Articles, and Content to Include in a Literature Review Study (Aguinis, Ramani & Alabduljader 2018, p. 89). The search was carried out in the EBSCO database (the selection criterion was based on the availability of the database and its content) in the period 2012-2019. In order to narrow potential results to the area of management and quality sciences, the following databases were selected from among the available ones: EconLit with Full Text, Business Source Ultimate, Academic Search Ultimate, MasterFILE Premier, ERIC and MasterFILE Reference eBook Collection. The main role of the study was to obtain a picture of the popularity of the methods used, and not a direct evaluation of the results obtained, so the selection was not limited to high-indexed journals. The search process was based on 3 key concepts, i.e. decision making, crisis and strategy, which were the search criteria, while the types of sources were limited to papers and conference materials from scientific journals published in 2012-2019 (with online access to the full text). In the first stage of the search, the keywords were to be part of the headline or subheading. Unfortunately, due to the fact that only few publications fitted these narrow criteria (5 papers), modifications were made. The previously indicated terms were divided as follows: the concept of the topic was narrowed down to 'decision making' and the words 'crisis' and 'strategy' had to appear in the

content of the publication. The modification of the criteria made it possible to find 4,385 articles and 34 publications marked as conference materials in the database.

Table 1: Number of publications in the sample studied

Number of publications published in each year	Scientific journals	Conference materials
2019	174	0
2018	583	4
2017	603	2
2016	579	5
2015	639	12
2014	646	7
2013	618	2
2012	543	2
TOTAL	**4,385**	**34**

In the group of the papers identified, an attempt was made to find a way of conducting research by looking for appropriate wording in abstracts and full texts. The table 2 presents the results, where the results were aggregated combining different definitions of quantitative and qualitative research; the research techniques indicated are specified separately. It should not come as a surprise that qualitative methods prevail (the keywords sought were related to issues of strategy, and not e.g. finance). Noteworthy, however, is the frequency of the use of case study and interview techniques by the authors although this result is consistent with the theses put forward by the above-mentioned authors.

Table 2: Structure of the research methods applied in the sample studied

Type of research *(number of appearances)*	**Abstract**	**Full text**	**%** *(number of appearances/ Total*
Qualitative interviews, study, survey (…)	1,009	189	27.1%
Quantitative analysis, survey (…)	518	32	12.4%
Brainstorming	86	2	2.0%
Case study	1,945	324	51.3%
Experiment	1,196	135	30.1%
Interview	1,633	380	45.6%
Expert	**1,936**	**184**	**48.0%**
TOTAL *(one publication can have multiple types of research)*	**4,419**		

At the same time, it should be pointed out that the use of case studies and interviews is associated with the risk of one-sided opinions and the lack of a complete picture of the issue or case. Of course, the use of other methods, financial analyses or documentation reviews may affect the correctness of conclusions, but it will not be possible to resolve the issue of the decision-making cycle (especially in crisis situations) based on them. In the opinion of the authors, the answer to this may be the application of the knowledge of experts, i.e. external advisors to companies who actively participate in the processes of changes, restructuring and strategic decisions.

In the literature review carried out, the use of expert knowledge was additionally verified. In the available full-text literature, reference to expert knowledge was found in 184 items, which were subjected to detailed verification. In the course of further investigation it was established that the direct use of expert knowledge was referred to in 30 publications (out of 184).

Among the studies examined, as many as 22 directly concerned the process of making decisions in a crisis, including the way of communication, factors influencing the decisions (including the problem of information quality), the role of managers in decision-making, the identification of conflicts, the use of decision-supporting systems, and the study of the decision-making process in various types of companies (in the face of a crisis). The others addressed the issues of strategic choices and reasons for these choices in relation to the entire entities. Individual publications raised the issue of conflicts or human capital.

Experts as a response to the challenges of qualitative research methods – discussion

The application of expertise to qualitative research, in particular interviews and case studies, may affect the results of the research, but also the research process itself. In particular, there are many problems and distortions in the investigation of restructuring processes or crisis situations, including:

1. Problems related to the acquisition managers' (decision makers') knowledge:

    a. The impact of restructuring (crisis) on managers themselves, particularly in relation to perception and the reality of the increasing job insecurity and career insecurity (Foster, W. M., Hassard, J. S., Morris, J., & Wolfram Cox, J. (2019);
    b. The difficulty (often mitigated by e.g. participatory observation) in identifying the soft sphere, i.e. the effect of feelings or emotions on decisions made by managers (Z. Mikołajczyk (2014, pp. 158-159);
    c. Tendencies towards making distortions by the participants of the change processes, which includes exaggerating their own share in successes, omitting failures and changing their own evaluations ex post facto, which, in turn, makes it difficult to learn the actual reasons for decisions or the course of action;
    d. Difficulty in identifying determinants resulting from the organisational culture, informal solutions or the role of intuition;
    e. There also appears a practical difficulty in reaching the decision makers: on the one hand, they are the busiest people but on the other hand, they want to keep a lot of valuable information secret. Many researchers are familiar with the problems of mistrust, avoidance of meetings, time constraints or being sent to subordinates.
2. Problems associated with obtaining a broader picture of case studies, including the following:

    a. Low representativeness;
    b. High costs and time consuming research;
    c. Risk of intuitiveness and influence of the researcher's projections;
    d. Low access to measurable data;
    e. Excessive simplicity or the risk of generalisations.

There is no doubt that quantitative research makes it possible to reduce or bypass the aforementioned problems but it will not make it possible to learn about decision-making processes or their specific determinants.

In the opinion of the authors, the solution to this problem may be to use expert sources, not so much in terms of data interpretation, however, as in terms of the participation of experts in the processes described in the research. The advantages of this solution are shown by the situation of crisis, changes in organisation and restructuring:

1. External advisers (of different specialisations) usually have direct contact with decision-makers (and support them with their knowledge) so they can know both the conditions in which decisions are made and the decision-makers themselves (and their intentions).
2. They are not burdened with relationships with members of the organisation or other behavioural distortions.
3. They know the people, the organisation and the business parameters of the companies; in particular, they have detailed knowledge of their specialisation (which is necessary to provide consulting services).
4. They have much more experience in their field than the managers themselves.
5. In their work they use a professional language, largely consistent with the language used by researchers.
6. They can interpret events taking into account their other experiences (from other companies or situations).

Using the knowledge of professional and external participants in processes of changes and decision-making in companies also allows to reduce information asymmetry and to learn about management from perspectives other than the classic ones. This approach offers the opportunity to expand already established knowledge and develop generalisations (which can be further confirmed by quantitative studies) (cf. Bergh, Ketchen, Orlandi, Heugens, Boyd, 2019; Chakon, 2006).

Experts in Research Practice – Recommendations

Taking advantage of the authors' own experience in implementing research with the use of expert knowledge (Wojtkowiak 2019, Gołembski 2019), the group studied and the possible way of selecting experts as well as the way of acquiring and using data are indicated below. Attention is also drawn to certain practical aspects of the researcher's work.

When indicating experts as the source of research, it is worth specifying the group itself. Depending on the subject of the research, these may include auditors (of various specialisations, especially financial auditors), lawyers, industry specialists, different advisors (e.g. in the field of investments, finance, human resources, management, etc.).

Their selection, depending on the method of conducting the research, may be purposeful, where the criterion will be related to the area (selection of experts of a particular specialisation) or to the subject of the research (selection of experts related to a particular industry or company), but it may also be based on the criterion of availability. The role of the researcher is to:

- verify the expert's knowledge in the field under examination;
- agree on the scope of information and data to be used; this includes verification of the consistency of terminology and the correct interpretation of questions and issues (especially when using survey techniques);
- verify the expert's impartiality or take their bias into account (e.g. due to representing the client's interest) in the research results;
- maintain appropriate measures to guarantee the confidentiality of both the expert and the companies or persons presented by them.

Experts as a source of research are used in the Delphi method. Using these long-standing practices of this method, a wide range of information gathering techniques can be used to collect information from experts, i.e. experiments, expert panels, focus groups, surveys and direct interviews.

Specialists in various fields can be a source of knowledge about particular companies, situations, or other objects and subjects studied. It is worth noting, however, that their knowledge can also be used at further stages of research work, i.e. for commenting and critical analysis of the results obtained, testing models developed in the course of the research or forecasting future situations.

Reaching out to specialists and advisors may be a sort of challenge for researchers. In the authors' work, some effective ways of attracting interest in their knowledge were mutual recommendations, their own experience of expert work, contacts with managers (employing experts) and participation in industry conferences. On many occasions collaboration was encouraged through the sharing of the results obtained as well as presenting the practicality of the earlier results.

This systematisation is summarised below is a graph presenting a suggested procedure of using expert knowledge.

Figure: Procedure for the use of expertise

However, the use of experts as a source of information in research is not without its shortcomings. These include e.g. the risk of excessive specialisation, the risk of errors in interpretation and of the ever-changing perception of one's own role in the events examined (as in the case of managers), and the risk of incomplete image (incomplete expert knowledge). One should also bear in mind the fact that such studies are costly and time-consuming and may involve problems with reaching the experts themselves.

Yet, the risks listed above do not change the conclusion that in the era of the development of humanities and interdisciplinarity (cf. Prawelska-Skrzypek, Lenartowicz, 2013), diversification of research sources or stages, with the participation of professional experts, may enrich the description of reality. The examples of research by other authors referred to and the own research presented here show that there is a management area in which the participation of qualitative methods is significant and growing. Nonetheless, the use of expert knowledge is still rare, although there are areas, such as decision making in crisis situations, where research using expert knowledge is conducted by a larger group of authors.

Conclusions / Discussion

Management sciences have for many years been pointing to the need for methodological pluralism and holism combining methodological perspectives in order to gain a richer insight and better understanding of social phenomena (cf. Dainty, 2008, p.11; Groeneveld, Tummers, Bronkhorst, Ashikali, Van Thiel, 2015; Sułkowski 2005; Barker, Nancarrow, Spackman, 2001). Thus, it is worthwhile to combine both well-established quantitative research methods and to develop the methodology of the qualitative tools. It is possible to expand the sources of research and to improve the tools used, not only in order to search for permanent paradigms, but also to help understand such heterogeneous science as economics.

Management sciences are expected to provide the function of usability. On the one hand, they must build knowledge that meets the paradigms of coherence or impartiality; and on the other hand, they are expected to support decisions, effective prediction and the indication of possible choices. However, there is a paradox associated with management knowledge, which is linked to the volatility not only of the environment, but of both

the subjects of management and the managers themselves. Researchers must therefore use pragmatic, empirical methods that describe reality based on experience.

While scientists claim the right to describe, analyse and structure these experiences, it is the experts who are the best carriers of this knowledge; it is entrepreneurs who use their knowledge and thus become participants (and critics) of best management practices. From the considerations presented in this paper, an important premise emerges for further research on the possibility of using expert knowledge in conducting qualitative research. It is so that there appears a need for a more detailed verification of the publications selected in the course of the research procedure, in terms of the effects of using expert knowledge. In the opinion of the authors, this will allow for a broader exploration of the potential of qualitative methods for building the value of research conducted, for both the theory and practice of management.

Abstract

Malaysian Construction industry is facing such as a huge challenge starting from the new technologies that is placed as a trend for construction industry arising, productivity output and efficiency which focusing on the quality and value of any construction projects. Construction projects plays as an economic concern for the nationwide and construction work with its effort required such an implementation and installation for its handling of materials during that installation. This review paper contains a review for the current mitigation measures that are implemented for reducing from the construction waste among Malaysian practice in the side of automation technology such as the concept of 3R approach, IBS, BIM, GBI and Internet of Things (IoT) involvement that act as tracking for the materials during the placement which play as a remote operation for managing both human and materials resources. This paper presents a review of existing literature on construction waste and its mitigations measures in the Malaysian practices that have been implemented in the construction industry that substantially contributes to existing knowledge using solid foundation for further research in the application of IoT that connect to Automation technologies in construction in the aspect of materials management and the pattern of this review is to shows the important of technologies adoptions as existing strategies in construction industry in terms of reduce from the materials waste and the method of the placing information is focused on the current practice of construction waste practices during construction stage toward sustainable project in the Malaysian construction industry.

Keyword: Technology Automation, IoT, Mitigation measures, Materials Waste Reduction.

Introduction

Mahmud, Assan, & Islam (2018) identified in their research that IoT is a man-made technology conceptualized through intelligent virtual objects that can understand everything and allow the surrounding devices to interact automatically without manual control. Every year, the use of IoT devices is increasing exponentially. It is estimated that as many as 75.44 billion devices will be connected to the IoT network. With the expansion of the Internet of Things network, the construction industry should be considered, otherwise the construction industry will be left behind by other industries. This is because the construction industry should use the applications provided by the Internet of Things to ensure the stability of the construction industry in the project. Nowadays, the world is moving towards a new revolution, namely Industrial Revolution 4.0, in which the Internet of Things is the foundation of this new industrial revolution. The Internet

of Things (IoT) method defines 370 global network structures based on standards and 371 communication protocol sets, including physical and virtual devices (Isikdag, 2015).

Yusof *et al.* (2017) stated that the relationship between Environmental Practice (EP) in construction projects and the environmental and economic performance in construction firms due to (EP) in construction management includes project management system through policies and procedures with conducts ongoing process improvement as the current knowledge. The relationship between construction companies has increased for their benefit by helping and clarifying these relationships. It is useful to help policy makers and construction companies to ensure a wide range of EP in the construction sector. According to research by (Pedro *et al.,* 2018), the main reason for environmental impact is discovered by consumption new materials resources to speed up the work during construction process with an accelerate destruction to make excellent functions performance for the projects, while there are side effects of sustainable materials that can be used significantly for wastes recycling elements with a consideration to the quality and their usefulness in terms of suitable dimension's materials that occupy a new position in the construction industry. Malaysia is realizing the vision of a smart city after the integration of smart city plans in the 11th Malaysia plan, the government has stimulated various plans to adopt IoT in the construction industry as in the smart city project (Bernama, 2018).

Construction waste has raised since last decades which caused serious environmental problems in Malaysian construction industry which generated approximately 8 million tons of construction waste per year realized by (GDP). That amount of wastes contribute an impact to the development of social and economic infrastructure such buildings, architectural, tunnels, road works, bridges and airports. Construction industry often referred to as friendly environment but with increasing of construction waste due to construction activities gradually increasing (Saadi *et al.,* 2016). There are many advantages to use Internet of Things in the construction industry that include better execution in the perspective of monitoring and control the necessary action and services that required for the construction project with better quality, cost and time savings. Due to its availability, it has also been extended for quick decision making, real-time data analysis with an improving for the crisis management of materials and emergency response that introduce an effective monitoring for the materials tracking and safety (Gamil Y *et al,* 2020).

In construction industry, there are such a crucial part which plays such an important factor with rapid effect in most countries toward the economy growth. Besides "Building Information Modeling" BIM technologies that played as automation technology application in the construction industry with major roles toward improving construction management setting. BIM implementation in construction industry helps to reduce from waste and the potential litigation. Rajendran *et al.* (2014) declared that construction industry is well-thought-out as one of the major contributions with negatively enhancing to the development of construction industry by outlay a lot of money for construction projects with reflection to the wasting of materials that act as challenge causing delay to the project among the estimated time then expenditure exceeding the budget of project.

Literature Review

Automation Technologies using in the Construction Industry

Rapidity in the construction growth among many projects in Kuala Lumpur as investiture resulted in increasing construction wasting problems as mentioned by Mohd *et al.,* (2016) earlier that for waste index method. Another study by Umar *et al.* (2018) stated that the weight index for construction waste among the construction implementation defined as the amount for the unit of volume or other description. It is defined as the weight of construction waste that is generated per the meter squared for the Gross Floor Area (GFA) or the area of the current activity for the actual stage or phase. Waste index computations had been predicted by Umar *et al.* (2018) as the amount of waste that arise for the life-cycles of any construction projects. In Malaysia, however, there is such a shortage among the available information regarding to the waste during project life-Sycle. Automation in construction is a term which focuses on the application of computer-controlled processes and mechanization concepts. It involves the application of the latest automation technologies, which may perform unfinished, undesirable or unsafe human construction tasks in the construction department (Xu & Lu, 2018). Therefore, the quantification method of waste mitigation measures in Malaysian construction industry had been modified to be comport with the point of data limitations for the quality whereas the incorporate for the effects among past research that conducted

in the perception of contractor's performance which CIDB classified as grade five, six, and seven had selected by (Umar *et al.,* 2018).

Figure 1: waste generated from high rise buildings, bungalow and terrace by

(Umar et al.,2018)

During the past studies among Malaysian construction industry, the surrounding terrace and bungalow projects had established awareness for the waste reduction and alleviation measures and that were for the building up to appropriate planning for the resources and environmental management during all phases of a construction project to ensure the quality of the project figure1. However, there are numerous authors who have given their own definition for the construction industry depending on their point of view (Saadi *et al.,* 2016). In general, the construction activities refer to many activities such as building works, tunneling, road works, bridges and airfield (Nagapan *et al.,* 2012), whereas construction projects are important in providing the necessary infrastructure towards the development of the country. Furthermore, construction wastes are also associated with serious environmental issues in Malaysia (Saadi *et al.,* 2016). Apart from that, Malaysia generates 25,600 tonnes of municipal solid wastes daily. The generation of Municipal Solid Waste (MSW) in one of the districts in the state of Johor, Southern Malaysia has increased up to 3000 tonnes per day (Begum *et al.,* 2009). On that notes, the Malaysian government needs to tackle this problem by revising the existing strategies in implementing construction waste minimisation initiatives.

Umar *et al.* (2018) estimated that the generated waste ranked among high rise buildings with accumulate 41% of all projects, while terrace and bungalow projects represent 51% and 8%, respectively which shows that the most of these projects were located in Selangor by the percentage of (25%) and Johor Bahru (15%); while the remaining 60% were found across the 12 states in Malaysia that became an important issue for the high densely populated cities in Malaysia. It is well known that several sources causing an impact for the environmental pollution as air emissions from the buildings which are considered as one of the major factors that contribute with compounds amount increasingly. Construction is a diligence field that generates a lot of waste, and the top of that is site waste due to construction work that performed during the site activities which direct of waste to a mixture, whether it is construction, site clearance, renovation or excavation.

Mitigation Measures using BIM Application

Building Information Modeling (BIM) application is considered as specific of the innovative technologies that need to be organized in the planning and design. Musa et al., (2018) mentioned that in construction as imperative features of BIM used to come up with an object oriented record composed which call intelligent objects that show the project in a 3D Dimensions that illustration of integrated information, and an interrelated relational record. The use of BIM as a technological innovation can be seen as one of the potential solutions to emerging problems and can make the industry more efficient, effective, flexible and innovative, while increasing from construction productivity to contribute to the

economic growth, although the implementation of BIM can overcome from constructive issues (Musa *et al.,* 2018). Construction workers need to understand the advantages of BIM and its future challenges for helping them to improve from the implementation of construction activities and processes. BIM is usually applied at all stages of project starting from the beginning to the delivery. BIM can covers the entire needs of construction community's and assessment of the terms of development, management, and the legal compliance during the equipment and materials lifecycle (Dein, 2013).

Encountered challenges start from the productivities among the communities to the consideration of quality and value output in construction project as mentioned by Bin Zakaria *et al.,* (2013). For Malaysian projects, the study that played as the most problematic issues among construction industry project is still critical in such as delay of projects, the production with low quality product and intensive labor when using old technology. BIM is used for model analysis, conflict detection, product selection and conceptualization of the entire project to improve the performance and quality of construction projects (Abrishami *et al.,* 2014 ; Mohd Nor & Grant, 2014).

The development rise by BIM implementation as diverse needs as its visualization look especially in 3D dimensions earlier and its analysis for the cost estimation, facility of manpower and duration. It involves as genuine innovations within the construction industry and its compliant from the perspective of "Building Research Establishment" (BRE) that developed a specification and huge database which named "Integrated Materials Profile And Costing Tools" (IMPACT) as overall for the aim of integrating" "Life Cycle Assessment" (LCA), "life cycle Cost" (LCC) and BIM (Akanbi *et al.,* 2018).

Mitigation Measures Using 3R and 4R Approach

Nasaruddin *et al.* (2008) & Umar *et al.* (2018) in there research developed the Malaysian waste management namely as disposal and sorting forms an integral part of the local authority administration. However, the increasing amount of disposal for the material was that it leads to emergent dumping with illegal large amount that is produced during construction implementing by major infrastructure projects. As a consequent, commercial building and housing development projects in Malaysian projects cause such significant impact to the environment as stated by Nasaruddin *et al.* (2008). This results in non-proper system to manage waste and one of the possible ways is to reduce, reuse and recycle construction waste whereas these issues have caught an attention for the government as the increased public concerns and local community needs.

Kazerooni Sadi *et al.* (2012) identified that 4R term for Reduce, Reuse, Recycle and Recovery approaches for reducing the waste in construction in the local construction industry which adds such recovery key as knowledge to reduce the waste by management progressions during the implementation while still far from satisfying. However, 3Rs principle, also known as the 3R approaches in WM 3Rs, which classify WM Waste Management strategies that still shortage for waste reduction which can be generally summarized into five categories encompassing such as "reducing waste through government legislation", "reducing waste by design", "developing an effective Waste Management System" (WMS), furthering "use of low waste technologies" and "improving practitioners' attitudes toward waste reduction". However, the 4R concept is still not fully functioning, which may lead to increase for the costs of wasted components because it hinders the setting of more formal practices and efficiency for management. Coordination between these three main impact minimization strategies in the demolition, design and construction processes is fundamental, and is a basic principle of waste management. Therefore, waste reduction is considered the most effective waste impact minimization strategy. However, it is inevitable that some C & D waste will be generated, and reuse and recycling strategies are a practical way to reduce the amount of C&D waste sent to landfills. "Reuse" usually means using the same material multiple times in a building, including reusing the material for different functions, such as structural steel, wooden shutters, and doors (Park & Tucker, 2017).

The economic downturn has also affected the local construction industry, and can use any low-cost waste management method to prevent the costs. For the differences amongst the technologies, waste recycling stands obtainable from the added three technologies according to the result that conclude among the local practitioners that have always been chosen as a method which is beneficial to them. Reducing waste in construction can be considered as a conceptual as it comprises an extensive planning for the different stages of project Kazerooni Sadi *et al.* (2012). Meanwhile, waste recycling

deliberates as a standard form for material handling, it can be seen that undamaged materials can be used for other purposes before they are completely damaged or recycled to be used again.

Mitigation Measures Using Industrial Building System IBS

IBS in construction is widely used by researchers, and governments which represents such an industrialization in the architecture. However, it covers wide range, including application and act as systems that properly not familiar with traditional practices. IBS became a term representing those construction industry based materials management and protection. In the Malaysian construction industry, IBS implementations has been such a good application that reduces from construction waste. Building System (IBS) is a method of using industrialized building materials for construction in manufacturing plants. This method can replace conventional methods and can reduce the number of foreign workers, improve construction quality, reduce costs, and reduce construction time (Nawi *et al.,* 2015).

The classifications provided by CIDB have also been misunderstood in place of systems with limitation to construction industry, and IBS is interpreted as a method or process for making buildings requiring less labor-oriented with faster progress which meets the quality requirements. The broad view of IBS is to change traditional concepts, redesign for the capital development with better cooperation that promotes transparency (Anuar *et al.,* 2011). However, it has been agreed that moving towards the industrialization of the construction industry is a global initiative, not a partial or isolated initiative. Definitions and classifications need to be developed, incorporating global perspectives and understandings. Therefore, the definition and classification of off-site, prefabricated, off-site construction, modern construction methods, off-site production, off-site manufacturing and pre-assembly need to be checked (Anuar *et al.,* 2011).

According to study by Ali *et al.* (2018), only about 70% of private projects and 42% of public projects in Malaysia use modern IBS technology. In addition, when the IBS roadmap 2011-2015 aims to score 70 or higher for all public projects in the perspective of using IBS, the use of IBS in public projects is lower than expected, with only 24% for the public projects which indicated value above RM10 million and it equal to 70 or higher. To date, as of May 2016, Datuk Fadillah Yusof, Minister of Works, said that according to a 2014 study by (CIDB), the private sector implementation rate as low, only about 14%, while 69% of government projects using IBS (Ali *et al.,* 2018).

Mitigation Measures Using Green Building Index GBI

Construction projects received GBI in Malaysia with ratings based on the six criteria such as “energy efficiency”, “indoor environmental quality”, “sustainable site planning”, “management materials and resources”, “water efficiency” and “innovation”. Meeting green technologies in construction industry which plays such a friendly environment quality, Key practice is a technology that has proven through experience and research to reliably produce the desired result (Aghili, 2018). Implementing the green principles as mitigation measure for project management is considered as significant for cost savings to be achieve over time more to the quality project life-cycle.

The main purpose of GBI is to reduce from the impact of wasting materials to the environment in order to achieve sustainable development. Green buildings system GBI have improved the environment in many ways which can protect the natural environment, promote a healthy life, and reduce from the negative impact on environment. Key practices of green building management affect positively the environmental assist as well as economic aspects. Similarly, environmental protection through sustainable projects can reduce project operating costs, increase the value of buildings, and increase return on investment (Vyas *et al.,* 2019). In recent years, the ideology of environmentally sustainable development and the new paradigm of "sustainable human development" has spread in the Malaysian construction to increase the industry's consciousness of viable development (the Malaysian government has launched the 11th Malaysia Plan). In 2016, The Construction Industry Development Board of Malaysia (CIDB) has developed a new construction plan that is the Construction Industry Transformation Plan (CITP) as one of the main goals of CITP to integrate from the environmental sustainability into the construction process (CITP, 2017).

There are many foundations to inspire the execution of GBI. For example, any green building project requires systematic management and appropriate operating activities. There is also a need to work with many experts to drive the success of green building projects.

Mitigation Practice using Internet of Thing IoT in Construction Industry

Isikdag (2015) stated that the use of IoT in construction industry is to generate early warnings and alarms as dynamical safety barriers for hazard energy on underground construction sites. In order to ensure the performance of the proposed system, the hazardous energy and its coupling mechanism are analyzed to provide safety barrier strategies and solutions to avoid unsafe behaviors and unsafe conditions of construction equipment and worker environments (Zhou & Ding, 2017).

Figure 2: the connectivity of IoT sensors and storage (MIMOS Berhad, 2015)

According to the Malaysian National Internet of Things (IoT) summary by MIMOS Berhad (2015) reported that the (IoT) is such a convergence that includes smart devices that have the ability to generate the data through the sensors for storing the knowledge and information to increase from the human productivity that give such an enhancement for the quality of life. As in the Figure 2, there three main components that are connected namely "connected things" as dynamic and static with embedded sensors. The second is the "connectivity infrastructure" and the third as an important one is the "analytics application". They are respectively connected as a network for sorting and storing the data, knowledge and collaborate the information for the actual work and act as protection for the data with the workers and machinery information.

IoT in for Construction Industry

Internet of Things (IoT) is a human-designed technology conceptualized by a smart virtual object that can understand all substances and allow the surrounding devices to interact automatically without manual control. In simple words, IoT is a network of sensors, appliances and devices competent of sending and receiving data about changes to their current physical situation and environment nearby them over the internet (Maru & Raval, 2020). The Internet of Things technology has been developed in the three-layer network architecture, such as RFID-based instrument-level positioning and tracking technology, centimeter-level ultrasonic detection technology and infrared access technology, etc., to help workers change their dangerous behaviors and avoid changing Accident at the construction site (Zhou & Ding, 2017).

The Internet of Things (IoT) is dedicated to achieving communication between all the three devices, which are things that exist in real life or 4 are virtual. Being a real thing or a virtual thing is not the five key points of the IoT approach. As mentioned before Cheng & Cheah (2020) that IERC- The European Internet of Things Research Cluster stated that the Internet of Things is “a dynamic global network infrastructure with self-configuring functions based on standards and interoperable communication protocols, in which physical and virtual “things” have identities, physical attributes and virtual personalities. Use smart interfaces and seamlessly integrate into the information network. Figure 3 provides the simplest understanding of IoT because it is superior to all types of interactions, such as machine-to-machine, machine-to-environment, human-to-human, human-to-machine, machine-to-human, machine-to-environment, and physical systems.

Figure 3: function of IoT toward the environment (Maru & Raval, 2020)

Using these advanced technologies, other industries are growing rapidly. The construction industry should emphasize the use of this IoT application because the construction industry will become more and more complex in the future. If there is no application that can promote related work, then the construction industry will be left behind by the development of other industries (Maru & Raval, 2020).

According to Cheng & Cheah (2020), Internet of Things applications can be divided into 3 major areas and various types of applications, namely the industrial domain, the smart city domain and the health welfare domain. "Smart" is usually marked with the realization of the Internet of Things such as smart homes and smart countries. "Things" in the environment can be sent through the Internet for analysis. There are many technologies or devices that can realize the invention of IoT, such as "sensors, network computing devices, web storage, data processing, and IoT applications".

The sensor is the first enabler of the Internet of Things. It collects data from the environment and sends it to the connected data processing, also known as the actuator. Sensors have been continuously developed with the development of microprocessors, even a mobile phone includes 14 sensors, such as cameras, motion sensors, GPS, etc. Wi-Fi and Bluetooth are also usually embedded in the Smart Lock system, and then this IoT lock will use this network to communicate with applications developed in mobile devices (Almosawi, 2018).

The Internet of Things is a huge prejudice. A large number of sensors and devices will connect to the Internet and interact with the cloud. The Internet of Things (IoT) is a system of mutually compatible computing devices that can transmit data through the network without human-computer interaction with people or people (Yacob *et al.,* 2020) Can withstand different business applications, such as vehicles, houses, buildings, machines, environmental sensors, etc. The Internet of Things is developing rapidly and is expected to include 18 billion connected devices by 2022 (Almosawi, 2018).

Table: some focuses of IoT in construction ((Arslan, Ulubeyli, & Kazaz, 2019)

Approach and Focuses	Author and Date
The research appointed on the smart objects	Kortuem et al. (2010)
On the smart homes	Park et al. (2017)
On the BIM integration	Teizer et al. (2017) Zhong et al. (2017) (Ding et al., 2018)
On the safety and health	(Park & Tucker, 2017) Mehata, et al. 2019) (Zhou & Ding, 2017)
Prefabricated materials in construction	(Xu & Lu, 2018)

According to Mehata *et al.* (2019), almost 48000 of workers dies accidently by such a fault or incident every year due to the accidents in the workplace of construction which the top of the recorded number were on the site as the list of dies reached 24.20 percent among the total accidents. However, most of the deaths that occurred were preventable.

Waste Management in Malaysian Construction Industry

Project's materials and waste management in construction are highlighted valuable and accounted substitute to the percentage of total cost of the project in the perspective of project economy. According to the analytical study by (Najafy, 2014), the interest trend currently in the arena of waste managing in the construction which has been upwards toward the contribution project benefit in cost saving as economic perspective. However, the two main developing countries, namely Malaysia and China, have shown increasing interest in waste management. For example, there is a lack of coordination in waste management and minimization in construction. This has become quite big problem if the work does not contain prefabricated components and components that minimize from the waste. So, this is a missed opportunity because using prefabrication can significantly reduce construction and demolition waste by as much as 52% compared to traditional construction techniques. In addition, it is reported that the interaction between the designer and the material supplier is minimal, while the other guiding role between the supplier and the contractor is minimal. This interaction between project partners is considered to be in the procurement process an important reason for continuing to over-order materials required for the project. Implementation of the elements and continuous waste throughout the supply chain (Najafy, 2014).

Aliferova *et al.* (2017) statement pointed out that all construction waste is caused by human activities and can cause environmental problems, such as construction waste, rubble, disasters, construction materials and site cleaning during construction and any waste in construction projects. In addition, previous studies have mentioned that construction waste is a useful, unnecessary or discarded material generated by human activities and is not free-flowing. However, appropriate waste is needed to avoid, reduce and reuse waste generated by human activities. In addition, the average number of buildings in 2015 was 28.6 tons of waste generated per day.

Implication of Material Waste in Malaysian Construction Industry

According to study by Tran (Tran, 2017), excessive materials are the main cause of construction waste, indicating that the largest source of material waste in commercial buildings is concrete waste (43.5%), followed by timber formwork (18.7%), steel bars (9.8%), and bricks (8.4%). %), mortar (8.4%) and tiles (1.2%). The waste rate is significant. According to the research results, another key factor that may have a significant impact on construction waste is the lack of commitment and support. Management and construction stakeholders cannot reduce waste to a minimum. Ismam & Ismail (2014) mentioned that several environmental problems that continue to plague the land and endanger the production of

natural resources. In addition, they added that if no effort is made to reduce carbon dioxide emissions, the greenhouse gas effect caused by carbon dioxide emissions is expected to increase to 40 billion tons by 2030. In addition, the construction industry has a huge impact on the environment, and the consideration of sustainable development has become the top agenda at the global level (Tunji *et al.,* 2018). A review by (Ding *et al.,* 2018) concentrated on the construction process in purpose of avoiding waste generation by waste's reuse and taking over the implementation of effective waste management among construction stages to reduce from CW generation and play such an important action of waste management during the implementation of materials. Basically, construction project has three foremost waste minimization practices that are placed to avoid materials wastage such as reduce, reusing and recycling of material waste in construction industry. In addition, to avoid waste in construction work the principal is relay on the shortage from the waste at from the sources followed by reusing the unwanted materials by recycling, whereby reducing the volume of waste material to be disposed and discharged (Ahmad *et al.,* 2014).

Ashraf (2018) mentioned in his study that practitioners in the waste during construction activities considered as sustainable practice for saving the cost of project and protect the environment from pollution when reuse the extra materials or disposal unwanted materials which the process of reuse as waste minimise and reduce be in the site work as the action of reuse after recycling indicated by information from the previous waste management as report by Ashraf (2018) that the solid waste is expected to be increase by 70% between 2010 and 2025, which equal more than 3.5Mt to 6Mt per day. The concept of sustainable development is seen as meeting to improve social and economic development practices without affecting the ability of the coming generations as evidence of research toward the sustainability for the developing countries compared to the developed countries currently in order to integrate from sustainability into new technologies and policies in construction industries for developing countries. According to Aliferova *et al.* (2017), the value of new projected construction work estimated in Malaysia as reported by CIDB in 2017 has been showed as RM 138 Billion for construction projects compared with RM131 billion in 2016. The forecast and development of the construction project in Malaysia shows a huge amount in structural projects with good investments in Malaysian construction industry. From the above discussion, the increase in demand for new development and renovation projects is important for increasing the development and renovation projects toward the new technology in construction by using the new renovation and technology especially in the construction projects, the development of infrastructure has contributed to environmental problems. Consequently, in construction industry among the minimization of waste materials which is the highest priority should be given to waste reduction strategies, because conceptually speaking, avoiding or reducing waste generation is more meaningful than developing a comprehensive waste treatment plan (Ashraf, 2018). In addition, reuse and recycling strategies can also enable the effective use of waste. However, although reuse and recycling can reduce the final disposal and treatment of waste, it cannot avoid waste generation. The significance of minimizing waste is that when materials are controlled and reused during construction to avoid waste generation, economic projects are used to ensure high quality of life, environmental cleanliness, health and safety, and sustainable construction.

Conclusion

Automation technologies in construction are such an emergent technology with keen move for its applicability and in the current technologies for construction has been criticized by some researchers. This review is an important collection that identifies such a review for the automation technologies uses in construction industry with an invest more on the implementing of IoT approach for the management of construction materials. IoT adoption in construction projects is unlikely to replace the human usage in workplace. Instead, it alter from the business efficiency in the industry when it reduces from the expensive errors on the worksite as it reduces from the injuries by the use of robotics and devices which makes the operations goes smoothly. The most likely approach in the Malaysian instructions using the 3R approach with BIM beside IBS practices that has the ability to bring up and introduce the technology with prioritized investment where IoT can have the immediate impact with its unique needs.

Acknowledgement

The authors would like to express their greatest appreciation and gratitude to the main supervisor Prof. Madya Ir. Ts. Dr. Riduan Bin Yunus and Univerisiti Tun Hussein Onn Malaysia (UTHM) for all their supports in making this study toward success. Lastly this research still ongoing.

Abstract

Initiatives concern in construction industry is one of the important terms that have dealt with management of construction materials with a huge concern to the social and monetary of the nationwide with a positive generation for the wealth and development. The inadequate deal with waste management administration among the construction players and practitioners rehearses has prompted such as fruitless outcome in diminishing of ecological effects and unlawful dumping for construction waste materials either during construction and build or demolition. This paper presents such a review on the construction waste management in Malaysian construction industry with the use of initiatives management toward the development that have been actualized in the Malaysian government and construction industry practice as far as to meet the development and technology involve toward construction waste management that apparently used in the current materials management in construction this paper fills in the gaps with effective way that enhance from the existing practices toward an effective construction waste management.

Keywords: Construction Waste, Initiatives for Managing Construction Waste.

Introduction

As stated by Veerasanai & Alias (2020), the development of any nation is strongly affected by the monetary development aside from the daily lives of citizen that serve the development of any country; the business' action fills in as a basic contribution for the exhibition of different segments in the nation. Manoharan *et al.* (2020) declared that the development for construction projects are hugely in conjunction with Malaysian plan 2020 according to the roles that have become much vital toward the growth. These roles played increasingly with a crucial enhancement for the status of development that battled to accomplish the target that has been planned initially to be accomplished in the year 2020. The development in construction industry is imperative increase with a vital improvement in the side of economic development which still in expand with both infrastructure and construction industry demand that are seeking a development and improvement as essential to the environments and sustainability as well as to the human life concern on the earth.

Zhang *et al.* (2014) stated that the pressure environmental change among the human change, land use, and economic growth movement. Development in construction aspects are in the demand for more improvement which blasting in a

Abdullah, Riduan Yunus and Ahmed Saleh Ahmed Saif AL-SHAMERI "Construction Waste and Its Initiatives Managing Among Malaysian's Practice (Review)" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

numerous nation's thought and priority. Construction industry act as a role for the socio-economic development for any country. Nowadays, Construction industry is rapidly increasing and growing according to the standard of living and the demands of infrastructure project's needs, changes in the consumption habits, as well as the natural increase in the population of citizens (Nagapan *et al.,* 2012) .

Hasmori *et al.* (2020) Expressed that the unused components of construction materials that come as a result for the construction activities either during the pre-construction or construction stage even post construction, despite such commitments and contributions with rapid development, are considered as a serious issue that is faced within the increase of the materials waste. The Public Cleansing Management Corporation of Malaysia reported that about 8 million tones' of construction waste generated from the construction projects every year.

The existing body of knowledge among the previous researcher's review could be explored and distinguished with such affective implementation in the term of waste minimization by the implementation of initiatives of waste minimization in construction industry among the initiatives managing and formulated use in the developed countries. Nurzalikha *et al.,* (2015) underscore that numerous nations are additionally considering the appropriate site management and location that utilize reusing and recycling for the generated waste that produced during construction activities with any condition have to be recycled and reused within any guidelines to secure the materials losses according to the environmental regulation and safety practice. The reason why construction waste is not systematic is that the construction party lacks awareness of construction waste management which can be seen from the statement that Malaysia needs systematic waste management to reduce from the amount of waste by 2020. Due to the expansion of lifestyle standards and development, the increase in construction demand and the increase in the amount of construction materials, the Malaysian construction industry has developed rapidly. The population has made a positive contribution to the increase in the numbers of generated waste (Mohd Hilmi & Narimah Kasim, 2017).

Overview of Construction Waste Management and its Initiatives Practice in Malaysia

Many of Malaysian organizations engaged with the development sector in the construction perspectives provide an economic strength that is connected to the development of infrastructure development that keeps moving for the nation development. Construction industry is one of the most challenging industries because it is risky and one of the most prosperous industries in the world. According to data reported by Kanimoli *et al.,* (2020), Department of Statistics Malaysia(2019) reported that the value of construction work that completed by the Malaysian Construction Department in the fourth quarter of 2018 was RM36.5 billion. In addition, from the overall economic performance of Malaysia in 2018, civil engineering and professional construction industries contributed 4.8% of Gross Domestic Product GDP. According to data from Trading Economics, by the end of the last quarter of 2019, global macro models and analysis expectations show that the Gross Domestic Product of the Malaysian construction industry is estimated to be 14.727 billion RM. In addition, the construction industry is one of the top five industries in Malaysia that directly contributes to Malaysia's economic performance (Kanimoli *et al.,* 2020).

CIDB educates key players in the industry through a series of training courses, workshops and awareness-raising activities that support national policies. However, according to the feedback from CIDB that align with what Ikau & Joseph, (2020) Malaysian industry participant's still lack knowledge about sustainable construction. Another initiative is to formulate with the National Green Technology Policy launched in 2009 which shows that green practices are used as the basis for Malaysian government to guide the sustainable practice in construction industry. In addition, the policy also indicates that the government is committed to solving all relevant green issues in the country, thereby complementing the global vision for sustainable development (Ismail *et al.,* 2012).

Construction industry is a major consumer for the natural resources worldwide, and almost 60% from the natural resources consumed by construction industry which caused many of the environmental impacts. These impacts include the destruction of water sources, changes in biological and ecosystems, and the destruction of the food supply chain between the biological factors. Several laws and regulations have been implemented in countries around the world. In addition, waste management technology is developed by government agencies, and researchers all over the world are working hard

to reduce from the waste generation. Various technologies such as recycling and recovery technologies are emphasized, which are very effective in reducing the rate of waste accumulation (Manoharan *et al.,* 2020).

The increase in the number of construction projects is attributed to the population needs, which has a harmful and negative impact on the waste ecosystem. In recent years, the management of construction waste, especially in the Malaysian construction industry, has become a major environmental issue that has been discussed in the media. There are still few shortage due to the minimization of construction waste that is daily generated and disposed to the landfill as most common disposal methods in the construction industry in Malaysia. At all stages of the construction industry, increasing pressures require the implementation of useful work strategies to minimize from the waste materials. Despite many government policies among the initiatives management that address this issue, on-site sustainable waste management is still not in a priority for most contractors. According to Jereme *et al.,* (2019), in 2020 the targeting goal is to recycle 20% of the total waste that generated while 15% of the intermediate treatment and the remaining 65% of the waste in the disposal of various landfills. The environmental performance of the built environment can be implemented by Waste minimization strategy to enhance. Waste reduction is one of the initiatives to advance the country's sustainable development agenda (Ikau & Joseph, 2020). According to Bidin (2020), many measures have been taken to ensure that the problems related to environmental degradation can be minimized. The introduction of green procurement is one of the strategies that help solve environmental problems when implementing construction projects in the Malaysian construction industry.

Construction Industry

Construction industry or as some researchers named the term as Engineering and Construction (EC) regard to the traditional and respond of change (Omar, 2017). Construction as a routine of staying and place for humankind purposes is considered as the one of the first action among businesses which human developed as a simple daily lives according to the requirement of living with a unique ways (Forum, 2016). Construction industry relays on the other industries in the perspective of business as it provides and maintains the accommodations and plants of infrastructure with a determination of where everyone lives, work and entertains. Construction is the decisive factor in where and how almost everyone lives and work. The construction industry is important for economic growth. However, Malaysia's growing for the development has led to environmental damage. That becomes a major problem (Nagapan *et al.,* 2013). In conjunction with Jain *et al.* (2020), the construction industry produced such a large amount of waste. On the other hand, it is recognized that construction activities and work throughout the renovation or demolition as well as it generates inert and non-inert materials, which are generally addressed as construction waste. For almost the entire population of the world, the built environment will seriously affect the quality of life. The annual revenue of the construction industry is nearly 10 trillion US dollars, and the added value is 3.6 trillion US dollars, accounting for about 6% out of global GDP (Mahidin *et al.,* 2020). However, by the most of states, it can be clearly seen by the immense contribution of construction industry in Malaysia economy in 2016 as shown in Table 1. It also illustrates, besides the entire Malaysia, there is ten states including; Johor, Kedah, Kelantan, Melaka, Sembilan, Pahang, Penang, Perak, Perlis, and Kuala Lumpur whose construction industry growth is bigger than their Gross Domestic Product growth. While only four states incorporating; Selangor, Terengganu, Sabah, and Sarawak whose GDP growth conquered the construction industry growth in this regard.

Table 1: the contribution of construction's growth to Malaysian economy by states 2016 Department Of Statistics Malaysia (DOSM,2017)

Region	**Construction (%)**	**(GDP) (%)**
Malaysia	7.4	4.2
Johor	24	5.7
Kedah	15.9	3.2
Kelantan	29.6	4.8
Melaka	5.6	4.5

Negeri Sembilan	9.8	3.5
Pahang	29.7	2
Penang	10.4	5.6
Perak	8.3	4.1
Perlis	9.8	3.9
Selangor	-2	4.8
Terengganu	2.0	3.1
Sabah	-3.2	4.7
Sarawak	-5.1	2.3
Kuala Lumpur	12.8	5.9
WP Labuan	-18.6	7.2

Table 2: The share and growth of the construction industry (DOSM, 2020).

Domain	**Share**			**Growth**		
	2019	**2020A**	**2020B**	**2019**	**2020A**	**2020B**
Non-Residential Buildings	25.1%	25.9%	29.4%	-10.3%	-11.0%	-36.2%
Special traders	4.9%	5.0%	7.0%	3.8%%	-8.6%	-28.7%
Residential Buildings	24.5%	24.1%	27.3%	2.7%	-7.6%	-38.7%
Civil Engineering	45.4%	44.9%	36.4%	7.9%	-2.3%	-55.2%

According to the Malaysian quarterly construction statistics, the value of construction work done has been decreasing from the fourth quarter of 2019 till the recent presented information in the second quarter of 2020 (that is RM37.0 Billion in 4th quarter 2019, RM35 Billion 1st quarter 2020, and RM19.8 Billion in the 2nd quarter of 2020). Based on the table, all the activities in the construction industry has slowed down in the first and second quarters of 2020. This slowdown was a result of the closing of construction activities due to the impact of Covid19 because they companies had to follow Movement Control Oder (MCO). Comparing the data in the table, it can be clear that the decrease was caused by Civil engineering, Residential buildings, Non-residential buildings and Special trade's activities. The highest decline, for example, was in the civil engineering which declines from 7.9% in 2019 and reached to -55.2% in the second quarter of 2020.

Furthermore, the Civil Engineering sub-sector is the main contributor to the value of the construction work although it has been decreasing through the tree quarters (45.4% in the fourth quarter of 2019, 44.9% in the first quarter of 2020, and 36.4% in the second quarter of 2020).

As a result of the increasing competition from entrants in the domestic and international markets, especially in the construction sector which has proven to contribute immensely to the growth of the Malaysian economy. Malaysian industries are urged and advised to make greater efforts to achieve performance effectiveness through better management and organizational strategies in the construction sector. In conclusion, it can be seen clearly that the construction industry has substantial value for Malaysian economy and considered as one of the biggest supporting sectors for Malaysian development. More precisely, it accounts for about 5% of GDP in the developed countries, while in the developing countries, it often accounts for more than 8% of GDP (Veerasanai & Alias, 2020). Construction industry is anticipated to

grow substantially in the next few years, with an estimated revenue of $15 trillion US dollar by 2025 (Forum, 2016 ; Omar, 2017) and they added that today there are more than 100 million people currently involved in the construction industry works worldwide.

Initiative among Construction Industry Practice

The current growth of industrial civilization with the rapid development of urban economy have brought increasing pressure to the natural environment change. Today, construction projects are very difficult and complicated to be understood as involving such a multiple interwoven processes as well several activities (Olawumi & Chan, 2019). Smart and innovative system and practice with the current technologies that implemented for construction project throughout the use of BIM, IBS and green sustainability and technology for managing the materials implementation during the activities of project showed such a positive output for construction project nationwide. The construction industry plays a role in the national welfare of a country by developing housing and office buildings, education and health centers, transportation infrastructure, industrial plants, and the restoration of national infrastructure and other public facilities (Subani et al., 2010).

Aliferova et al. (2017) pointed out that all construction waste is caused by human activities and which caused an environmental problems, such as construction waste, ruins, construction materials losses and construction site cleaning process and any waste in construction projects that the researchers has mentioned that such as unwanted materials and waste that produced during construction stages as unwanted which required an discarded. However, appropriate waste recycling and reuse by waste management and initiatives practice in construction projects generally have to mitigate and reduce to maintain the natural resources (Manoharan *et al.,* 2020). In addition, the average number of waste that produced from the construction industry which exactly was from the buildings in 2015 was reported as 28.6 tons daily.

As the review shows, the amount of construction waste that is generated is increasing, and illegal dumping and the reviews decleaed that the amount of construction waste since 2004 to 2013 as a sample among some studies were conducted in Penang, Johor, Malacca and Selangor. The current are soulotions as a potential for the problems for the existing practice in the construction industry onducted mong the contractors often incentivized by their suppliers to purchase a large quantities of materials. In this way, contractors can obtain greater discount rates from merchants and suppliers. In turn, this encourages contractors to use materials with ignoring the recycling for the waste that generaed as the new materials are cheaper than the recycling and its process for reusing Aliferova *et al.,* (2017) & Najafy (Najafy, 2014).

According to Adeleke *et al.,*(2019) construction is the foundation of all major economic drivers and has made a huge contribution to a country's economy, especially in the era of globalization. In order to keep the environment and ensure sustainable development, many environmental regulations and initiatives have been formulated. Most of these efforts are aimed at preventing the production of C&D waste and/or reducing it as much as possible. The summary of the Initiative among Construction Industry Practice is summarized in table 3.

Table 3: Summary for the previous researchers' gaps among construction waste in Malaysian practice

Previous research among waste minimization in construction industry	Gaps of their research	Authors /years
Construction waste minimizes as solid waste practice to minimize construction waste as barriers for reducing the hazards that come from construction activities.	The concern that the research focused in the final finding that the barriers of waste minimization practice in Malaysian industry was undergoing toward possible waste recycling using the current practice for prevent the environmental impact and moving toward green materials practice.	(Mallak et al.,2014)

Construction solid waste minimization practice among Malaysian construction by the evaluation of contractors in construction sites.	Focusses of this study on the types of construction's solid as a products with further discussed to minimization waste.	(Ahmad, et al.,2014)
-Quantification among local construction players for solid waste reduction among the current practice for waste in construction case study Klang Valley.	The research focused on the classifications of the waste on site. Generation of waste produced a negative impact to the environment.	(Nor et al., 2013)
Initial findings on the perspectives of local contractor's evaluation on waste Minimization and barriers as incentives on construction sites.	Identify the relative of importance factors that influencing waste minimization barriers and incentives on the construction sites location Kuching, Sarawak.	(Ikau et al., 2013)
The research identifying the causes for construction waste: case study on central region in the area of peninsula Malaysia.	The gape was focusing on the factors that causing construction waste in Malaysia.	(Nagapan, Abdul Rahman, & Asmi, 2012)
Municipal waste solid management for Malaysian construction among the current practices, challenges.	The focusses of this research restricted to the current practice and challenges for municipal solid waste management in Malaysia	(Dinie,et al., 2013)
Study on the waste minimization as sustainable, management strategy for Malaysian industries.	The gap of this research restricted to the Peninsular Malaysia which approximately 95-97% of solid wastes are transferred to the landfill as disposal and 3-5% of the generated wastes are recycled.	(Mallak et al., 2018)
Sustainable practice for construction waste management in Malaysia among contractor's perspective.	Research focusing on the current status of waste management practices the Malaysian construction sector.	(Effie et al., 2011)
Review on the construction waste management and initiatives in Malaysia	construction waste and Initiatives the initiatives practice in the construction industry reveals the current situation that exist in waste management in Malaysia but not all initiatives are implemented by stakeholders.	(Saadi et al., 2016)
Construction waste management among projects in Penang Malaysian	Relationship between the formalization and construction waste management the study conducted on Penang projects Malaysia.	(Kanimoli et al., 2020)

Initiatives Management among Circular Economy

Recent international and national policy for the initiatives management in construction industry promulgates the involvement of Circular Economy (CE) in construction as the new central pathway towards sustainability of construction project which the concept of Circular Economy (CE) has recently recaptured its momentum and even reached the mainstream discourses, in particular through the new policy of initiatives practice for construction waste (Hild, Schulz, & Edda, 2019). Although this method has successfully sparked such a discussions about the criticize approach for the

design of materials with longevity, reparability as a choice for the shared goods and services with critics criticizing this method. Criticism focuses purely on the technological fixation of circular economy approach and its ecological modernist ideas, that, gradually adapting as current system to the constraints of material resources, while leaving aside the sociopolitical aspects of consumption and the possibility of a self-sufficient lifestyle demand (Hild *et al.,* 2019).

Strategies toward CE Initiatives in Malaysia

Reuse and recycle waste as a prior remanufacturing or refurbishing for the other uses, the CE concept emphasizes the environmental protection by reducing the environmental impact which intends to create such a new opportunities to the transform of natural resources and renewable resources for the application of energy, saving and materials conserving (Lin *et al.,* 2019). It has been widely adopted in the developed countries, particularly on European nations and America that received significantly less attention than the developing country that still shortage for the understanding of the synergy that can be created in the improvement of CE approach for the sustainability in construction industry, meanwhile, the developing countries especially those who suffer from the low-income consequence, are facing such as growing in the waste disaster (Wilson, 2015).

Figure 1 : Comparison between CE , Green Economy GE and Bio-Economy BE (Lin *et al.,* 2019).

Since CE is a relatively new term in the developing countries which is often used as alternate with the other mainstream of sustainable development approaches, green economy (GE) and bio-economy (BE) have three concepts with certain similarities in the promoting of economic, environmental and social sustainable keys of development. There are still some differences that cannot be ignored as figure 1. illustrates the comparisons between these three approaches since 2008 - 2018 for Malaysian practice CE marked as the first among GE and BE that helps Malaysian construction industries , stakeholders and construction players to choose the best operating and strategy on the road of sustainable development (Lin *et al.,* 2019).

According to a study by Aliferova *et al.* (2017), they reported that as a continuations action that the development of the construction industry took the place in Malaysia, more impact resulting as output for the generated waste out of construction activities. In addition, construction waste generated by construction projects has an adverse impact on the environment, especially in illegal dumping for the generated waste. The increasing number of illegal dumping activities in construction projects in Malaysia shows that construction waste management in Malaysia needs to be taken seriously by stakeholders and participants in the construction industry (Jain *et al.,* 2020). Therefore, Circular Economy CE showed such a treat for cutting the edge of recycled, repaired or reused materials instead of consume the natural materials or disposal regarded as "waste" has become one of the frontier strategies for the environment issues.

According to Hild, Schulz, & Edda (2019), to explain that the CE represents the boundary of the environmental sustainability and development by commodity the awareness, thereby establishing an effective relationship between the environmental protection and economic development, and as it realizing the prevention of materials losing which can be achieved through the long-term of economic concern and innovation especially with the current crisis upon COVID-19 pandemic that brought the global to fluctuations focus on construction waste and it's management with the response of policymakers (Bhakta *et al.,* 2020). Based on the redesign of the income stream to achieve an interaction between the designer and material supplier which still in lack, the other guidance between the supplier and the contractor is in need for attention as well. This interaction between the project partners is considered as procurement process and important reason for continuing to over-order materials that not required for the project and request the required materials to avoid waste for the components throughout the supply chain Najafy (Najafy, 2014).

Using BIM as Circular Economy

Based on Whole Life Performance Estimator (BWPE) the study by Akanbi *et al.* (2018), they mentioned that the development of building materials and project performance from their point of view, and the research that conducted using the BIM approach showed that the structural components have good performance, which affected the building molding at the design stage, and the results determined the factors that affect the performance of the structural components using the estimation of modeling methods to evaluate the building during design stage by BWPE for the factors of Weibull reliability distribution for in manufacturing products (Akanbi *et al.,* 2018) .

The rise development in construction industry by Building Information Modelling BIM implement such a diverse needs for the visualization look especially in 3D dimensions earlier as developed by (Akanbi *et al*., 2018) and its analysis for the cost estimation among facilities, manpower and duration that involves as genuine innovation within the construction of industry and its compliant as a perspective of "Building Research Establishment" (BRE) that developed with a specification and huge database which is named "Integrated Materials Profile And Costing Tools" (IMPACT) as overall for the aim of integrating of Life Cycle Assessment (LCA) and life cycle cost (LCC) with the involvement of BIM in the development of construction had a great offer for the solutions of many inefficiencies and systemic failures that inherent in the construction industry with several solving for problems that occur as design conflicts during the process and implementation (Sacks & Pikas, 2013)

Circular Economy (CE) concept and sustainability for construction projects had evolved that is increasingly appeared in the perspective of construction and come out with decision makers, and strives to establish such a conceptual relationship between the (CE) and construction sustainability as stated (Akanbi *et al.,* 2018).

Figure 2 : A conceptual diagram for circular economy as sustainability economy (Wautelet, 2017)

The circular economy CE has recently been valued. It has created opportunities through the arising for CE principles as a set that brought such a rise to most global companies in the perspective of the economic forum and that opportunity based on the principals of CE (Wautelet, 2017). Circularity in economic indicates a durable use for the materials components on the behave of sustainability and giving some solutions in the materials loops which proposed the reuse and recycling with an upgrade and remanufacture by the term of materials resources with efficient profit that enable the materials loops to energy saving and renewable decrease in the materials system resilience figure 2. The concept of CE is rooted in the review as a living systems that starting with the use of materials from the design stage to reduce material waste, and puncturing the materials during construction and then distributing them. These can be consumed by the project, and the excess products. It can be used and repaired and transferred to recycling to prevent the final waste of materials, optimize from the cycle decomposition, and reuse the economic notice of the transfer of economic value to economic value to save the product through the implementation of the notice. The most extensive definition of sustainable development in the current compromise program is to meet the needs of future generations as future capabilities in minimizing materials resources with an input for waste mitigation and energy saving during the activities and supply replenishment of materials. This feature provides a mechanism to extend the collaboration between designers, engineers, constructors, and facility managers throughout the project's life cycle. Another aspect of BIM is that the information once created can be reused. Time, reduce errors improved consistency, clarity, accuracy, and clear author responsibility with the use of technology indicated 20-30% for the increase of construction productivity (Kivits & Furneaux, 2013).

Conclusion

This ongoing research is still in its early stages. Therefore, the information provided in this article is mainly based on a comprehensive review of the initiatives practice of Malaysian construction industry. An overview of construction waste and initiatives reveals the current status of construction waste management, and it elaborate some of circular Economy CE uses and approaches. Not all initiatives are implemented by construction stakeholders, so there are more comprehensive approaches needed to ensure that economic, social and environmental aspects can be protected. At the end, a strong support among Malaysian government is needed to provide such more effective toward construction waste management practice and policies. Otherwise, sustainability and environmental issues will not be effectively resolved.

Acknowledgement

The authors would like to express their greatest appreciation and gratitude to the main supervisor Prof. Madya Ir. Ts. Dr. Riduan Bin Yunus and Univerisiti Tun Hussein Onn Malaysia (UTHM) for all their supports in making this study toward success. Lastly this research still ongoing.

Information Security Management as A Determinant of The Functioning of Organisations

Klaudia SKELNIK

WSB University in Gdańsk
kskelnik@wsb.gda.pl

Summary

The aim of the article is to present and analyse potential threats posed by underestimating the influence of information security on the functioning of organisations. The immense influence of information security on organisations should not be ignored, as even the smallest decision in an organisation is based on the flow of information. Taking this into account the author deems information to be the most important factor which determines the functioning of an organisation. Such a formulation requires a description of the influence of information security management on proper and efficient functioning of organisations. The term information is becoming a key category, a central point of consideration which is a common set for research conducted at an intersection of various fields and scientific disciplines. When discussing organisations, their activities and functioning, it is necessary to include the role of information. Based on collected information and source literature the author intends to introduce the complexity of the term information, information security and its influence of shaping organisations. Based on the collected observations and literature analysis, the author wishes to present the complexity of the notion of information, information security, and its impact on the shaping of organisations. The author believes that most studies focus on technical threats connected with processing information, and do not devote enough attention to the significance of information, its value or the threats connected with this. The author wishes to highlight that numerous studies and participant observation show that many organisations underestimate information security. In fact, the top management and employees of many organisations show a lack of competence in the scope of the role and significance of information in organisations.

Keywords: Information, Organisation, Information Security.

Information and Its Significance

When trying to define the term information we need to stress that it is both difficult and frequently defined. As a result source literature provides numerous diverse perspectives representing different fields and scientific disciplines.

Information, depending on content and the accepted frame of reference, can be interpreted in a broader or narrower sense. In a broader sense it can be understood as "content taken from the outside world within our process of adjusting to it and adapting our senses to it" [Fischer B., Świerczyńska – Głownia W., 2006]. In a narrow sense information refers to a message "acquired by human beings through observation or mental activity, which is transferred in a transmission (from person) – reception (to person) system" [Groniewska H.,1990].

Information was also defined in an academic coursebook by J. Seidler titled *Nauka o informacji* (1983). According to the author: "Information is knowledge acquired through the reception of messages, which enables the recipient to carry out or improve activities. This means that information is restricted to those sensations which inspire the human mind and imagination. Its existence is relatively tied to the existence of human beings and their minds" (TN: own translation).

According to E. Niedzielska, a Polish specialist in the field of information technology, information is "a specific, immaterial good, which assumes growing significance with economic development and with the development of means and forms of social communication, thus changing the face of many traditionally organized economies of the world".

An interesting view on information is presented by Werner Gitt, professor of engineering, in his book *In the Beginning was Information*. The author provides a precise definition of information presenting five various aspects of it (Gitt W., 2005):

1. Statistics – information is distinguished by a specific alignment of its components.
2. Syntax – information is provided in a logical system which can be read – e.g. Morse code
3. Semantics – information has a logical meaning as a transmission of content – e.g. the train form Wrocław departs at 1:00 pm from platform 1.
4. Pragmatics – information can be applied in a practical manner, e.g. in actions and processes in physical and biological systems.
5. Apobetics – using information in processes results in achieving a logical aim.

In Poland one of the first authors who provided a scientific definition of information was J. Ratajewski. He distinguishes between subjective and objective sense, which resulted in the emergence of two separate explanations. Information in an objective sense, i.e. perceived as a message, is "a mutual relationship between at least two objects (organisms), consisting of meaning (content) and a physical carrier (form), the purpose of which is to transmit signals from one object (organism) to another object (organism)". In a subjective sense, i.e. as action, information is "a set of specific activities (actions) for the purpose of producing, processing, storing, searching, sharing and receiving messages (content, meaning) regarding a specific object" [Ratajewski J., 2013].

Elżbieta Kałuszyńska states: "limiting information to consciously received and transmitted signals in my view also delineates the scope of this term too narrowly". According to W. Falkiewicz information is messages or combinations of messages which enable real or potential users to satisfy their needs regarding information, thus decreasing the level of ignorance concerning a studied phenomenon, and improve their knowledge of the environment as well as allow them to perform purposeful activities more efficiently [Kałuszyńska E., 2005].

We are dealing with numerous diverse perspectives which represent various fields and scientific disciplines. As demonstrated, information refers to a number of intuitive understandings of the term and it can be said that it lies at the beginning of everything. For the purpose of the author's considerations it is important to state that information is knowledge acquired through the reception of messages, which allows the recipient to carry out or improve activity, and its existence is relatively tied to the existence of human beings and their minds.

Analysis of the above statements does not justify rejecting any of them and accepting one as the "only right" option. On the contrary, it should be said that these are complimentary, mutually supportive opinions, which describe information from various points of view and in various contexts. Neither one of them can be treated as a complete interpretation of the term and each focuses only on a particular issue. What these statements also have in common is that they show information as something which exists, however, they do not operationalise it, i.e. they do not give instructions on how to analyse it, how to organise its processing, how to register it or how to carry out other relevant operations.

Marian Mazur, as a cyberneticist, placed his inquiries regarding information in the guiding environment, which is logical and fully justified in his case. Mere perception of information as an element of decision procedures means that inquiries on this regard should be placed in a somewhat broader context, selecting not merely the phenomenon of guiding but also that of influencing, the denotation of which takes a significantly larger set of designates into account than guiding, as an object of study. Influencing includes all influence exerted on all references through all sources of influence. In this space the dominant semi-spaces in which, according to Mazur, one can find answers to the fundamental problem question regarding identification of semantic content symbolised by the term information, seem to constitute designates which reflect thought perspectives on important characteristics of objects and phenomena, ascribed semantically to the terms: guiding, experiencing, cognising and communicating, connoted by influence. These terms do not delineate space connected only with information. They do not include all phenomena. However, they delineate a sufficiently large semantic space which includes content that many people refer to as information.

Other authors indicate difficulties in characterising the term, stating that information is "a basic term which is not fully defined because of its primary, elementary character. All past attempts at defining it are generally deemed

unsatisfactory or at best limited to showcasing certain aspects (…). A message (data, signal) analysed and processed to a form understandable to the recipient, which notifies him or her of a situation and has value for him or her in the decision-making process".
To sum up, the perspective of Sandra Braman on the multifaceted character of information seems accurate. The author orders information into four primary interpretational groups [Braman S., 2004]:

- Information as an asset – information, its creators, transformers and users are perceived as individual and distinct subjects. Information is fragmented, fluid and unconnected in a knowledge structure in which it could be organised
- Information as a commodity – this term includes a market element, it entails exchange and use of information by and among people. This exchange may have the character of a commercial transaction, thus the information has an economic value.
- Information as a perception of patterns – in this case information is seen in a broader perspective because it has a past and a future, depends on motivation as well as other environmental or random factors. What is more, it brings certain results. Such a broad understanding implies the possibility of using it with regard to social structures. Information also holds a certain value, though this value is usually limited to decreasing uncertainty regarding one specific area.
- Information as a constitutive force in a society – information plays an important role in shaping social context. It is not merely a force which influences the outside environment – it is also a subject to influence. Definitions in this stream refer to a very broad sphere of phenomena and processes, including those fundamentally based on information which is significant in creating social reality.

Additionally, the current development of information or the revolution in its transmission, creates new conditions for the functioning of organisations, which are characterised by an intensity of certain areas of activity. The environment of information provides people with numerous inaccurate, uncertain, incomplete and out-of-date, and thus useless and unreliable information. In this situation the quality of information becomes a key issue. As a result of the flood of information people cannot comprehend it and increasingly stop valuing, appreciating and noticing its influence.

The problems of modern information are related to its currentness, completeness, digestibility, clarity and credibility. Informational asymmetry is defined as a situation in which one party to the transaction possesses more information regarding the conditions and circumstances of the transaction than the other party. This phenomenon consists in an unequal distribution of information important for the parties to an agreement. The side which possesses an informational advantage may use it to increase its benefits at the expense of the side which less well informed. In this situation the allocation of resources will be less effective. The problem of informational asymmetry is connected with the problem of the so called imperfect information, which refers to a situation when an economic subject does not have full knowledge about a given phenomenon. Imperfect information may occur for just one subject while informational asymmetry requires at least two subjects between which certain relations occur.

An important characteristic of information is its substitutability and complementarity. Full complementarity of information is a much more frequent phenomenon than the complementarity of other commodities. We frequently encounter a situation when one information has zero value without another complementary information. An example of this is software, which is useless without passwords or codes connected with buying only the original version. Another example is the popular story of the half of the map leading to a treasure, which is useless without the other half [Forlicz, 1996].

The author believes that the answer to the question regarding information is also to be sought in spaces where it is used. One can highlight the role of information in decision-making processes or in economic activity. However, a human being is a personality which needs to be considered in various dimensions – professional, social, psychological, cultural and historical. In every such dimension information is always needed and assumes various and important roles.

Information as a Factor Shaping Action

According to James Gleick information is everywhere. The author also adds that information is "blood and fuel, the vital principle that runs our world". Tomasz Goban-Klas states that "without matter there is nothing, without energy there is no motion, without information there is chaos".

In all of research no one knows all the functions of information influence because these functions manifest themselves everywhere. All functions come to the fore in various statements and messages in varying degrees.
Wiesław Babik lists an expanded categorisation of information functions. Among the most important of these he mentions: informative, knowledge-creating, communicational, integrational, recreational, culture-creating, innovative, educational, decisional, guiding, motivational, capital, opinion-forming and resource. This catalogue is not a not list, nor is it a decisive one, for the same sequence of signals reaching many various recipients would cause various effects which would derive from the functions performed by given information [Babik W., 2002].

The informative function, particularly in advanced economies, becomes dominant as an integral part of an organisation's system of information. Without it an organisation cannot function effectively. Information provided in a proper manner in crucial and used in a broad scope. Among other things it constitutes a basis for determining the scope of activities of an organisation and its particular cells. This assessment is founded on information regarding the course of specific processes and their effects. After the information is subjected to proper analysis it constitutes an important basis for making operative (current) as well as strategic decisions which look into the future and are meant to result in better, more effective administration [Messner, 1944].

In modern economy we are dealing with two primary roles of information. The first is being factor in production and the second is connected with communication between an entrepreneur and the environment in a marketing perspective. Without information on consumer needs which collected through market research it would not be possible to create an offer which would satisfy their requirements [Medlik, 1995]. In fact adequate information about a product is often more important than production itself as a factor creating a consumer market. Information is undoubtedly the most important element of promotion. Provided adequately, on time and directed at the right group it is a tool for achieving competitive advantage [Medlik, 1995].

For an organisation information, its quality and currentness are important factors with regard to competitiveness, because in modern times success in the economy is measured not only by market share, the volume of consumer assets or market size, but also by success in managing knowledge and the ability to use the company's intellectual capital [Koźmiński, 2002].

Also of importance is the fact that information constitutes a necessary element of the decision-making process. That is why some believe that decision itself is a form of information for it frequently influences its content. Information also constitutes a tool for shaping human personality. Reception of information forces each of us to analyse it and results in a specific reaction: it forces us to choose an objective of our actions or the means of achieving that objective. The opinion-creating function is expressed by the fact that information also allows us to shape our opinion regarding other people and events. It can also be used for shaping individual outlook as well as building and structuring a value system. The guiding function consists in the fact that the sender aims at a specific reaction of the recipient and at influencing his or her behavior, opinion or position. This function is also related to a decision making process because an individual who gets information from the outside environment is initially faced with a decision dilemma and at a later stage takes specific action as a result of this information. The motivational function, which plays out in relation to relating response to an individual concerning a direction he or she has taken, may also serve as a stimulus to increase effort.

Glynn Harmon (1984) adopts a view that information is a type of meta-energy, which moves larger quantities of energy and decides on the intensity of the activities undertaken by human beings.

In order to illustrate the problem one should remember that transmission of information is communication. Most authors believe that communication is composed in such a way as to influence the recipient to act in a way as to reach an intended objective[1]. Moreover, some researchers understand "influencing" as all processes of the pre-informative and informative phase [Aleksandrowicz T., 2013]. Thus "influencing" is related to all processes connected with communicating content which is received through information channels. In this meaning the term "influencing" encompasses all phases connected with communication: sending → transmitting → receiving. It should be added that the widespread term "communication" also has many meanings.

When speaking of functions of information influencing in an organisation we take into account the role of internal management and the accepted communicational style.

An interesting classification of functions for the Polish theory of communication was implemented by Antonina Kłoskowska. The author of *Socjologia Kultury* accepts the structure of the communication process as the main criterion of the division of functions. Each message which is part of communication consists of five main elements: sender, recipient, designate (content of the message), code and a specific type of social contact. Antonina Kłoskowska focuses her attention on each of these elements and highlights the following functions of communication [Kłoskowska A., 1981]:

1) the emotive function (connected with the sender), also called the expressive function, which is manifested by expressing the state, emotions or thoughts of the sender;
2) the connotative function (recipient), also called the appellative function, used by groups of people for communication;
3) the referential function (designate), also called the cognitive function, which is directed at communicating information and descriptions of facts and phenomena;
4) the metalanguage function (code), which facilitates learning the rules of a given language and, by extension, a given communication system;
5) the phatic function (type of contact), which is meant to maintain social contact[1].

According to Kłoskowska the referential function is the most important from the point of view of communicating because it is the objective of all messages. She believes that the same message can have several functions at the same time. There are also messages which are dominated by only one function.

Taking all of this into consideration we can state that the impact of information in a given organisation can be reduced to the following issues:

1. The way in which communication takes place largely determines the content, structure and dynamics of changes occurring in organisations, which in turn impacts the process of communication and achieving objectives.
2. Communication influences the attitude of society, determining the reaction of employees on the content of the information and their behaviour in the sphere of human relations.
3. Communication influences the value system. Positive and negative changes occur in the recipients' value systems.

The list above is comprised only of the most important functions. It is certainly not complete. Confirmation of these functions and possible indication of new ones probably depends on experience and practice.

One could certainly put forward a thesis that one who has information has power. Agnieszka Szewczyk, invoking Andrzej Targowski, writes: "the one in power is not the one who is in power but the one who has the right bits of information in the right memory, accessible at the right time" (TN: own translation).
It seems that a broad research front should have ended the theoretical struggle over information long ago. However, the opposite of this is true. Research on information is so dispersed and specialised that it is very difficult to distinguish particular dimensions of information, and even more difficult to comprehend it in its entirety. The struggle continues and with it a discussion which involves representatives of various sciences.

More and more frequently the term information becomes a key category, a central point of consideration which constitutes a set common for research carried out at an intersection of various areas and scientific disciplines. The interpretations of the term information presented in the article are often inter- or transdisciplinary, for, as a result of globalisation, technological changes and convergence, it is becoming increasingly difficult to precisely separate the scientific areas and grounding them in one discipline.

In indicating the value of information the author wishes to emphasise its influence on the management of organisations. Thus it vital for every organisation to manage information security, as a determining factor for the functioning of organisations.

Information security and the operating of organisations

Entrepreneurship is inextricably tied with processing vast amounts of information. Some are strategic for the implementation of the organisation's aims, others are less significant. However, it is undeniable that information

should be one of the most important assets in an organisation, which requires proper security against a wide range of threats. Thus, the problem of information security concerns every business enterprise regardless of its size, organisation, industry or degree of development.
In defining the term 'information security' it is necessary to refer to the ISO/IEC 27001:2007 and ISO/IEC 17799:2007 norms, which use the term information security as retaining confidentiality, integrity and access to information. We can also include other properties, such as authenticity, accountability, incontrovertibility and reliability. The ISO/IEC 17799 norm refers to information security in a complex manner, and provides solutions which allow the elimination of the most frequently marginalised issues in creating safety procedures. Local regulations of all countries use the document as a type of reference.

The statement that information security is one of the most important area which should be secured by organs managing an organisation is trivial in the present times. Information security is nothing more than "guarding information which consists in preventing and impeding access to data on the physical character of the current and planned state of affairs and phenomena in one's own functioning space, making it difficult to lead to the knowledge of information entropy and to physically destroy storage devices [Kwieciński M., 2010]" (TN: own translation).

The term information security should be explained in more detail, beginning with the identification of the following risk areas [Biłaś, A. 2017]:

- traditional information threats – espionage, subversion, sabotage (aimed at gathering information, offensive disinformation conducted by other people, bodies, organisations),
- chance events – all natural disasters, catastrophes, accidents which influence information security in an organisation (e.g. fire in a building in which information is stored),
- technological threats – threats connected with gathering, storing, processing and transmitting information through ICT (cybercrime, cyberterrorism, information warfare),
- threats resulting from insufficient organisational and structural solutions

At each level of information security management the main objective is to prevent the disclosure of information. It should be highlighted that an excessively broad understanding of security may hinder the flow of information in a state, organisation etc.

K. Liderman characterises information security as justified confidence on the part of a subject with the quality and accessibility of collected and used information, thus the term information security relates to the subject (person, organisation), who is at risk of losing information assets or receiving information of insufficient quality (Liderman K., 2012). According to Liderman, information security has still not been unambiguously interpreted and along with the related term "security of information" is used in various contexts, encapsulating all forms – including verbal ones – of exchange, storage and processing of information.

The complexity of modern information influence requires a broad, multidisciplinary perspective. Selected threats to information security, for the purpose of this article, are listed below. P. Bączek classifies threats to information security into (Bączek 2006, p. 72-73):

- chance events;
- traditional information threats;
- technological threats;
- threats referring to civil rights of individuals or social groups.

Information security is understood in various ways, depending on the situation and requirements. However, irrespective of the participants and their level of involvement, all those who take part in exchanging information want to make certain that particular requirements regarding its security are met.

These requirements include: privacy or confidentiality, data integrity, authentication or identification, authentication of the message, signature, authorisation, attestation, access control, certification, timecode, evidence, receipt, clearance, ownership, anonymity, incontrovertibility or revocation.

Information security is also described in source literature as a state in which the risk of threats connected with the proper functioning of information assets is limited to an acceptable level (M. Wrzosek, 2010).

The author tries to highlight the fact that an increase in threats related to information security is connected with effective functioning of organisations. Risk and threats are something we became used to once we realised that "progress" is not necessarily a blessing. Each rise in the production of "goods" entails an increase in the production of "bads" (Beck 1992). Analysis of source literature on the development of the information society allows us to conclude that there are numerous studies containing information on the positive and negative aspects of this issue. Additionally, a separate problem is posed by information security. The lack of sustainability between the development of the information society and its knowledge on threats to information security is the most important threat. Security and threats to it are inextricably tied. They constitute two points through which we perceive social phenomena, because our sense of security is dependent on the magnitude of the threat – the greater it is the lower the sense of security becomes and vice versa.

The complexity of the modern information influence requires a broad multi-disciplinary perspective. For the purpose of the author's approach, in order to conduct an analysis, after defining information and information security it is necessary to present threats to information security in organisations. Information is sometimes knowledge gathered through receiving messages, which helps the recipient analyse and improve his or her actions, while its existence is relatively linked to the existence of humans and their minds. The method of observation through an analysis of events in the professional environment adopted by the author allows one to compare facts with studies, and to draw relatively broad conclusions, though not entirely detailed due to the character of the publication, the introduction of sources of threats in the sphere of information security in an organisation, as presented by the following figure.

Fig. 1: Threats to information security in organisations

Source: own compilation

The author indicates selected threats to information in an organisation dependent on ensuring information security. The threats indicate how complex and information-based the process of functioning of organisations is. In organisations information plays a very important if not primary role. Moreover, the author believes that attention also needs to be devoted to the decision-making role of information as a crucial element of operation within organisations. Taking the above into account information was regarded as a deciding factor which determines effective functioning of organisations.
It should be stressed that in the aspect of information organisations should rely on the following premises:

1) increasing the security of information systems,
2) constant assessment of vulnerabilities of information systems which determne the operations and functioning of organisations,
3) development of methods to estimate the sustained and/or inflicted damage (information loss).

Ensuring information security, i.e. consequently aspiring to make certain that accuracy, reliability, accessibility, currentness and timeliness, amount of information, significance of information, responsibility and usefulness were adequate to the understanding and accurate assessment of risk connected with threats to security, should be the determining factor in organisations.

Living and operating in the modern world entails using information. This phrase encompasses the sense of social, economic, political and educational transformations. People entangled in various social processes, playing specific social roles is, from an early age, subjected to a stream of various information (Goban-Klas et al.). Effective functioning of organisations without at least a basic information infrastructure is impossible. Society perceives information security as a state of individual, group and societal confidence regarding the accessibility and quality of obtained, stored, used and transmitted information. However, this seems much more complicated.

Group activity is the basic type of activity. Each group activity requires guidance. According to J. Zieleniewski: “By guidance, in a general sense, we mean activity aimed at making other things function according to the objective of the person doing the guiding”. “In a narrower sense, i.e. <directing people> we understand […] such action which is aimed at making other people act according to the aim of the director”. In other words it can be said that guidance is to make a group or individual people function according to the assumptions of the organisation [Zieleniewski J., 1981].

All known and used terms such as managing, ruling, administrating or commanding are special cases of guiding. These activities assume a constant process of exchanging information realized horizontally (inside an autonomous information system and inside cooperating peripheral systems) and vertically (these are tasks assigned to subordinates by their superiors, as well as regular and ad hoc reports submitted by subordinates to superiors).

As stated earlier between every two objects (systems), where one is a sender and the other a receiver, there occurs information influence connected with the emergence of a specific informational (communicational) situation, which takes place through an information channel. It should be highlighted that informational influence in the guiding process is based on messages. However, it should be said that the element of evaluation will always generate separation between persuasive, informational and manipulative influence, which is heavily influenced by information security management.

To sum up, in the era of information, along with its greater accessibility and flow, information assumes greater significance in the everyday functioning of organisations. The subjectivity of information results in the fact that its value differs depending on recipient. This causes problems in the evaluation of the usefulness and value of information. Information, which is an intermediary in the creation of knowledge, is essential for making decisions. However, it is frequently the case that separating vital information from “noise” constitutes a major issue. Extraction of important, accurate information in time to make decisions will be the most important skill.

An individual needs information, because it enables him or her to build and expand the world they live in. Information needs lead to information behaviours, which in turn influence actions and decision processes in organisations. Thus, as indicated in the title, information determines the functioning of organisations.

Conclusion

Field work and the author's observations indicate that we can list situations, which indicate that every activity of every organisation is focused on determining which information and to what extent is at risk of being lost and thus may be of interest to competition. The aim of these activities is to indicate which information needs special protection. Thus it is necessary to constantly analyse the information at one's disposal and their value. This indicates the need for information security management. However, one should not contribute to the creation of barriers between a given organisation and its environment, for the exchange of information takes place in the form of feedback, giving subjects opportunity for development.

One should also remember that regardless of an organisation's size and scope of operation, each should introduce a security policy, which constitutes a set of principles connected with all aspects of security. A security policy, or a security strategy, is also a set of principles, methods and tools of information protection and supervision. It should encapsulate the following elements:

- information policy,
- information security,
- ICT security policy,
- the scope of protection of trade secrets,
- rules for preventing crimes against organisations.

The main aim of the article was to conduct an analysis of the scientific literature and the current standards, as well as to determine the significance of understanding the notion of information and security for the functioning of organisations.

When we observe the everyday practice of economic reality we become witnesses and often participants of events which testify to the fact that the threat to information security is real and that loss on information can damage the essential interests of an organization, and put the personal safety and basic values of social life in jeopardy. Modern entrepreneurs who play an active role on the business plane in a market environment cannot underestimate information security, nor can they afford not ensuring it. When we look at a business enterprise from the point of view of its internal processes, we can state that one of the most important of these is connected with gathering, processing and communicating information. That is because they constitute a basic element of all decisions made by the management. As a result, information assets can be considered the most important factor in achieving the goals of each economic subject. That is, if we assume that intentional information-decision processes form the content of all management functions. The essence of these processes lies in acquiring, processing and transmitting information, making and communicating decisions, as well as communicating with other subjects and with the environment. The significance of information is well highlighted by the statement that management is the art of using information.

Abstract

Possessing a professional accounting qualification means one is halfway through becoming a chartered accountant (CA) in Malaysia. However, due to the challenging nature of professional accounting examinations, candidates are struggling to complete the course timely, hence deterring the process of becoming a CA. Therefore, this paper focuses on three strategies - learning approach, study skills and learning pedagogy as a means for students to pass their professional accounting examination successfully. Review of relevant literature revealed that by adopting a deep approach to learning, frequent self-testing using past examination questions and applicating a teacher-centred pedagogy as part of the learning process could elevate students' performance. These findings may offer groundwork for empirical research to be conducted that may be beneficial to all students, tuition providers and the professional bodies.

Keywords: Professional qualifications; Academic performance; study skills.

Introduction

The dynamic and shifting business landscape demands a more significant role of an accountant to contribute towards nation-building and economic growth (Owusu, Obeng, Ofori, Ossei Kwakye, & Bekoe, 2018). The Malaysia Institute of Accountant (MIA) argues that to raise an accountant's quality and competency is by becoming a CA (Oh, 2014). Therefore, one of the agenda under the Malaysia Economic Transformation Programme's is to

Cite this Article as: Adibah Jamaluddin, Melissa Mam Yudi, Siti Syaqilah Hambali, Nazreen Sahol Hamid and Siti Aisyah Kamaruzaman "Enhancing Students' Performance in Professional Accounting Examination" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

increase 60,000 CA by 2030 as the main engine to drive Malaysia's National Transformation Programme (MIA, 2018,2019).

One way of becoming a CA in Malaysia is to be a member of a recognised professional accounting body such as ACCA, MICPA, CIMA, CPA and ICAEW(MIA, 1967). This call for candidates to possess a professional accounting qualification with three years of working experience in the related field. The establishment of the Committee to Strengthen the Accountancy Profession in Malaysia (CSAP) further necessitate the completion of a professional accounting qualification (Lee, 2018). As a result, there is an increasing trend in the enrolment for professional accountancy programmes (Nor, Zaini, & Zahid, 2013;Vien, 2015;Lee, 2018).

Despite the spike in enrolment, achieving the targeted 60,000 CA seems to be a far stretch ambition. As of September 2020, the number of CA in Malaysia is only 36,976. To produce almost 23,000 CA in ten years, demand not only MIA but all accounting firms, professional bodies and tuition providers to shoulder the responsibility. In this context, since obtaining professional accounting qualification means candidates are halfway through becoming a CA, producing more accounting graduates with professional qualification can be seen as a means to fill the gap. Therefore, identifying challenges or obstacles in generating accounting graduates with a professional qualification is vital.

According to Roos (2009) and Mustapha and Abu Hassan (2012), one of the main obstacles is the professional accounting examination is too challenging to pass, thereby takes a longer time to obtain the qualification. For example, the average passing rate for ACCA papers at the Strategic Professional level from September 2018 to March 2020 is only about 40% (ACCA, 2020), while the average passing rates for CIMA case study exams as at September 2020 is about 52% (CIMA, 2020). Thus, the statistics indicate that obtaining a professional accounting qualification is not an easy task.

Meanwhile, Bahari, Tahir, & Mat Rahim (2014) argued that professional accounting programmes are more complicated than regular diploma programmes. The plausible reasons are threefold (Masters, 2015). First, the breadth of professional accounting syllabus demands a practical application of knowledge in a real-world business environment. Second, total reliance on final examination under extremely time-pressured settings means the student has to perform their best on the examination day for there are no continuous assessments. Finally, the separation between examining team who develop the examination questions with the lecturer who teach the courses also contributes towards posing an obstacle to passing the professional accounting examinations as "lecturer will have no idea what will appear in the exam" (Masters, 2015, p.2) Hence, overcoming these challenges deemed imperatives in crystallising the national agenda.

The objective of this conceptual paper is to analyse the current research finding to deliberate on the strategies to enhance student's performance in professional accounting examination. On the one hand, existing and potential students will have an overview of what is expected from them upon taking the professional qualification journey, thereby are more confident and prepared to face the challenges. On the other hand, the tuition providers will be able to devise suitable approaches to facilitate students in producing more accounting graduates with professional accounting qualification to materialise the nation's agenda.

Learning Approach

A professional accounting student is deemed to possess the expected competency and proficiency to be an accountant by having passed the professional accounting examinations (CIMA, 2019). This call for a suitable learning approach as the student's intention when studying and the way they process the information can influence academic performance (Siew, Basit, & Hassan, 2017; Ferriman, 2013; Salleh, Johan, & Saruji, 2019). Houghton (2004) distinguish between a deep and surface approach to learning. While the former refers to how a student "examines new facts and ideas critically, tying them into existing cognitive structures and making numerous connections between these facts and ideas", the latter is where a student merely "accept new facts and ideas and store them as isolated and unconnected items". This paper contends that a deep approach to learning helps to increase the chances to pass professional examinations based on the following arguments.

First, the question tested in professional accounting examination, especially at the strategic professional level, is mostly a scenario-based question that mimics a real business setting requiring the application and not a simple reproduction of knowledge (ACCA, 2013;CIMA, 2019). For example, one of the learning outcomes for ACCA's Performance Management paper is the ability to apply management accounting techniques and assessing the performance of the organisation. However, using an appropriate accounting technique in a newly set up business is very different than those that are well-established. Likewise, interpreting whether a company is performing well in a normal economic environment than those operating under a global financial crisis demands a student to demonstrate their ability to understand both the knowledge and the context of the question. Since a student who adopts a deep approach looks for meaning intending to understand rather than merely rote learning (Enwistle, 1987), they can develop a firm understanding of the key concepts and the logic behind it in relating and applying it to the scenario (Jackson, 2012).This has been proved to positively affect student's performance, particularly on complex examination questions (Davidson, 2002).

Second, the examination demands a higher level of cognitive processing ability as the question can be asked across the whole breadth of the syllabus, including prior or assumed knowledge. For example, to be able to perform well in ACCA's Strategic Business Leadership paper, a student should be able to link between those covered at the strategic and fundamental level. Similarly, CIMA's Strategic Case Study requires the student to integrate knowledge learned from at least paper E3 (Strategic Management), F3 (Financial Strategy) and P3 (Risk Management). Adopting a deep approach allows a student to relate new ideas to prior knowledge and to make sense of the experience to derive at a conclusion in solving a problem (Enwistle, 1987). This could explain why professional accounting students preferred to adopt a deep approach (Ahmad, Farizal Mohammed, Yatim, & Ismail, 2017) as it enhances their analytical and critical thinking. As argued by Hassall and Joyce (2001) and Flood and Wilson (2008), professional accounting bodies desire the student to be deep learners as the approach develops a life-long learning skill that is imperative when they build their careers.

In summary, the professional accounting qualification is designed to mould a student that is capable of displaying the desired competency and qualities to be an accountant demanded by the employers. To achieve that, a student must first pass the examination by adopting a deep approach to learning.

Study Skills

Academic progress and success have always been associated with good practice of study skills or habits – which are known as academic enablers or critical tools for learning (Gettinger & Seibert, 2002). Given the breadth of syllabus and the volume of materials that students would need to utilise in pursuing a professional qualification, taking a strategic approach on studying from the start is crucial for a rewarding outcome (Masters, 2015; ACCA, 2013). According to Nonis and Hudson (2010), those who practice good study habits can make study time effective rather than spending a large amount of time just studying without the proper approach. This paper suggests self-testing and familiarisation with past examination questions as the essential study skills or habits to pass professional accounting examination.

Darwin (2011)revealed that study habits have a high correlation with accounting grade. In particular, self-testing such as practice questions or practise quiz at the end of a chapter or topic and knowledge diagnostic checkboxes contributes towards the performance of the majority of undergraduate students to obtain high GPA score (Hartwig and Dunlosky, 2012). The reason is it allows students to monitor their learning progress; thereby increases the likelihood of information retrieval from memory (Kornell and Bjork, 2007). Therefore, frequent practice force students to stay current with the course allowing them to perform better in the exam (Roediger and Butler, 2011).

While self-testing contributes in gauging their progress in the course, familiarisation with past examination questions helps students to apply their technical knowledge and improve their exam technique (ACCA, 2013). As argued by Mam Yudi, Ahmad, Sahol Hamid, Yatim, and Abdullah (2018), working through the past examinations' papers reduce test anxiety as a student are more familiar with the examiner's question requirements, allowing them to retrieve and utilise materials they have learned successfully. More importantly, attempting the past examinations questions under the same time pressure and conditions as actual examinations increase the likelihood of passing the ACCA paper (Masters, 2015). This is consistent with Landauer and Bjork (1978), where the more difficult the process of memory retrieval, the better the retention of information.

In conclusion, self-testing and familiarisation with past examinations questions are a complement. With no continuous assessment, the frequency of self-testing using past examination questions will increase the probability to pass and obtain a professional accounting qualification for a student are more accustomed to the examiner's requirements and pressures of the actual examination day.

Learning Pedagogy

Each student is unique – they have different attitudes, learning pace and even different learning styles. Bahari et al. (2014) suggest that students who viewed themselves as more committed, determined and disciplined can pass the professional accounting examination better than those who did not. The reason is the nature of professional accounting examinations that is exam-oriented, i.e. pass or fail depends entirely on student's performance on the examination day (ACCA, 2013). Nevertheless, relying merely on self-determination is insufficient to pass the professional accounting examination as it depends on the process of imparting the knowledge, i.e. pedagogical approach too (Mohammed and Abdullah, 2018). This paper compares and contrasts between the student-centred and teacher-centred learning pedagogy to suggest that the latter is more suited for students to perform well in professional accounting examinations.

According to Batchelor & Di Napoli (2006), student-centred learning is when the students are in charge of their learning process. It focuses on flexibility in the learning atmosphere and providing greater access to learning resources (Jaijairam, 2011), accordingly shifts the responsibility of learning from the teachers to the students, for example, learning through group discussion and presentation and other interactive activities with the aid of technology. Greater engagement in the learning process increases their academic performance as students internalise the teacher's feedback and constructive comment to understand the subject matter (Dopper and Sjoer, 2004; Jaijairam, 2011). However, this may not be the case for professional accounting examinations where the professional bodies govern the syllabus (Mohammed & Abdullah, 2018). A deep understanding of theoretical knowledge and practices of the accounting principle is required (Qhosola, 2015) to match not only the heavy requirements of the professional bodies but also the comprehensiveness of the syllabus, thereby, offers a little or no time for student-centred activities (Coetzee & Schmulian, 2012).

Meanwhile, the traditional teacher-centred pedagogy is generally known as a style in which the teacher assumes primary responsibility for conveying the knowledge to students (Mascolo, 2009). The teacher delivers facts by connecting it to his expertise and experience where students simply accept the facts passively (Mohammed, Kassim, & Ismail, 2020; Mascolo, 2009). Consequently, the pedagogy was widely criticised for producing students with a strong theoretical base but not necessarily ready to face the challenges in a dynamic working environment (Mohammed & Abdullah, 2018).

Surprisingly, despite the criticism, Mohammed et al., (2020) prove that professional accounting programs' students favoured the pedagogy as they need the teacher's guidance in understanding and applying the accounting principle in solving the real-world scenario questions. This tends to lend support to Mohammed and Abdullah (2018)'s contention that a teacher-centred learning is more effective in increasing the chances to pass the professional accounting examinations. The reason is one of the roles of the teacher is to demonstrate how to apply the knowledge - explain why in certain scenarios, the answer can be different, but in certain contexts, the answer can be similar. For example, in devising a strategy to expand a business, although the decision to acquire a small business can be applied in scenario A, this may not be applicable in scenario B where there is no expert in the acquisition process and limited financial resources which is available in scenario A. However, some of the decision in scenario B can be applied in scenario C which operates under a global financial crisis setting. As suggested by Salleh, Johan, Artiqah, & Saad (2020) teachers should play a greater role in imparting the knowledge process as it contributes towards the success rates in the professional accounting examinations.

Interestingly, Pogacnik et al. (2004) claimed that the number of contact hours in class is associated with student's exam grade. The authors further explained that students who attend few lectures tend to study less and waste their extra available time. Impliedly, the findings of the study support a teacher-centred pedagogy (p.259), as the more contact hours that a student has with the teachers will encourage them to internalise their learning process, which positively affects their exam performance. In fact, Raghunandan, Read and Brown (2003) argue that a minimum 150-hours requirement as opposed to the prior 120 hours contributes towards higher success rates in the

professional accounting examinations. Therefore, this further supports the argument that adopting a teacher-centred learning pedagogy has exceptional benefits for those undertaking professional accounting examinations.

In a nutshell, one of the ways to pass a professional accounting examination is to rely more on the teachers who have expertise and experience to address the requirements of the syllabus and professional bodies as reflected in the examination's question requirements. Hence, a teacher-centred learning pedagogy is more suitable to guarantee a higher success rate.

Conclusion

Masters (2015) claims that "many students embark on this (professional accounting qualification) journey without really understanding what they are getting into" (p.1). Potentially, this explains why the examination pass rates for the professional accounting examination range between 30-50%. In this paper, first, we identify the challenges that pose as obstacles to pass in professional accounting examinations, that is, (1) the comprehensive syllabus that is governed by the strict requirement of the professional bodies; (2) the exam-oriented style that depends entirely on the student's performance on the examination day; and (3) the independency between the teaching team and the examiners that make the examination's requirements to be unpredictable and challenging.

We then focus on three strategies - learning approach, study skills and learning pedagogy to help address those challenges. We argue that adopting a deep approach to learning can shape a student to possess the desired skills and competency demanded from an accountant. This is achievable by having passed professional accounting examinations that calls for self-testing and familiarisation with past examinations questions. Having an expert and experienced lecturer to guide the learning process i.e. adopting a teacher-centred learning process further contribute towards enhancing the student's performance in the professional accounting examinations. This is vital because having passed the examinations means obtaining the professional accounting qualification as a feeder towards crystallising the national agenda in producing more CA. While the findings help to prepare the students in overcoming the challenges, it also allows the tuition provider to provide the necessary assistance in improving the passing rates and the professional bodies in finding ways to attract new members. More importantly, the findings offer a groundwork for empirical research to be conducted that may be beneficial to all students, tuition providers and the professional bodies.

Abstract

The paper examines the problem of assessing the level of Russian regions power systems energy security from the perspective of economic and managerial threats to consumers reliable power supply. A method for determining the economically justified level of energy security of regions in the conditions of market liberalization in the power industry is proposed. The method is based on an optimization criterion for ensuring a balance of interests of territorial government bodies and regional generating companies in the formation of regional energy systems development strategy.

Keywords: Energy security, regional power systems, territorial public administration, regional energy companies, energy markets, economic accessibility, optimization criterion

Introduction

Ensuring energy security is one of the priorities of the state's economic activity. At the same time, the state's activity in the energy sector is traditionally included in its economic functions and is understood rather narrowly as the regulation of natural monopolies in the energy sector, which is a clear underestimation of the role that energy plays in the economy (Bompard et. al, 2017; Chernyaev et al., 2018; Isaeva et al., 2018; García-Gusano et al., 2017; Lisin et al., 2018a).

The state's activity in the energy sector, first of all, should be aimed at ensuring reliable and continuous energy systems operation at various organizational levels, the sustainable development of which in the face of energy security modern problems and challenges will be a guarantee of energy security of the country and its regions. In this case, the economic relations regulation arising in the process of regional energy systems functioning and development will be the key mechanism of state management at the territorial level in market conditions. This representation of the state's activity allows us to distinguish its energy function as a set of economic activity directions aimed at ensuring the reliable operation and sustainable development of the energy system of the country and its regions, the formation of energy resources and products markets, and the regulation of legal relations between their participants.

The market model of energy sector management adopted in Russia requires coordination of development strategies for its facilities from the energy companies that manage them and territorial government bodies, in order to ensure the necessary level of energy security of the regions to respond to external and internal challenges to the reliability and efficiency of local consumers integrated energy supply.

The conflict of interests generated by the market, which is shown in the difference in ideas about the efficiency of the energy sector at different levels of management of its facilities (region and energy enterprises), leads to a mismatch of the territorial energy management system. While the state's criterion for the efficiency of the energy sector is effective operation of power systems while ensuring a given level of reliability, the criterion for energy

enterprises is profitability, that is, the compliance of economic facilities with a competitive technological infrastructure that allows to earn profits in the various trading sectors of energy markets (Lisin et al., 2018a; Lisin et al., 2018b; Melas et al., 2017).

Failure to take this factor into account in the formation of regional energy policy leads to conditions under which energy enterprises are not able to meet the state requirements for the energy sector. Thus, the energy strategy of the region is deprived of the ability to carry out managerial functions, turning into a framework document. Preconditions are created not only for deviating the development of the energy economy from the science-based directions laid down in the strategy, but also for the formation of completely different vectors of its evolution, caused by unexplored causal relationships, which increases the uncertainty and, consequently, the probability of realization of threats to energy security.

Literature Review

The key documents defining the conceptual apparatus and the main indicators of energy security of Russian regions are (Senderov et al., 2018; Proskuryakova, 2017; Alekseev et al., 2019; 35-FZ; 190-FZ; 256-FZ; Bogoviz et al., 2018):

- Energy Strategies of Russia until 2030 and 2035 (2009, 2014)
- General layout of power facilities until 2030 and 2035 (2010, 2017)
- Federal Laws “On the Electric Power Industry” (2010), “On Heat Supply” (2010), “On the Safety of Fuel and Energy Complex” (2011)
- Energy Security Doctrine (2012)

According to these documents, energy security, expressing the energy aspects of national security, determines the state of the country's defense against threats to reliable fuel and energy supply, the provision of which is one of the priority tasks of the state.

The conceptual apparatus of energy security is based on the concepts of national security and reliability (Lisin et al., 2018a; Bogoviz et al., 2018; Proskuryakova, 2018).

From the standpoint of the concept of national security, energy security expresses its energy aspects and reflects the contribution of energy to its provision. In fact, energy security is a part of economic security that characterizes the security of economic relations. It is implemented through economic mechanisms and stands out in a separate category due to the decisive influence of energy on the development of the national economy (Lisin et al., 2018a; Bogoviz et al., 2018; Khrushcheva et al., 2016).

From the standpoint of reliability concept, energy security characterizes the continuity of the process of energy supply to consumers. At the same time, if reliability is a property of the regional power system, then energy security characterizes the state of the power system, achieved by ensuring (Bogoviz et al., 2018; Khorol’skii et al., 2017; Postnikov et al., 2017):

- a deficit-free supply of resources in the region,
- the economic availability of energy products for local consumers,
- the availability of technologies that make it possible to organize reliable and efficient operation of the power system under existing environmental restrictions.

Hence, energy security is characterized by such categories as resource sufficiency, economic accessibility and technological feasibility.

Background

Modern sources and threats to energy security

The main sources and nature of modern threats to energy security are enshrined in the Energy Security Doctrine of Russia. It identifies the following types of threats to energy security:

- internal economic threats,
