Practitioner Implications

One of the recent studies established the trust level of online news, mainly social media and search engines, and concludes that trust levels on traditional news media are higher than social media (Park, Fisher, Flew, and Dulleck, 2020). In like manner, Llewellyn (2020) raised some warning signals as an antecedent of social media message trust. Besides, other authors have raised their concern on rumors amplification, information dissemination timeliness, location, behaviour, fear, and stigma as the source of social media information misinformation, misconception, and misperception (Cinelli et al. 2020; La et al. 2020; Huynh (2020; Depoux et al. 2020; Lin 2020; McPhetres, Zhang, Lu, and Rand 2020). With arguments and proposition from the earlier studies, it became apparent that multiple

uncensored sources of information through social media is a challenge that needs quick intervention. Social media are confused about whom to trust, public or government. If it is possible to tread the line of authority and specialization, WHO information should be more reliable for the public and preferable to the public information. This study answers the research question of *the difference between public and WHO information spreading patterns via Tweets* (RQ1).

Fig 4.8: Topic Modelling graphs for WHO tweets

The study shows a close similarity of tweets between the public and the WHO, but in terms of the worth and weight, WHO's tweet value, surpasses the public tweet. To go by this result, people still perceived the WHO information dissemination through tweets to be reliable and dependable despite the bias and sentiment of misinformation. Another question that prompts this finding is why WHO information on traditional media has the same equal weight with social media through the same content but a different channel. The earlier studies mentioned above show an imbalance of social media messages.

Table 4.2: Table showing 5 topic model for WHO tweet

Topic 1	Topic 1 weight	Topic 2	Topic 2 weight	Topic 3	Topic 3 weight	Topic 4	Topic 4 weight	Topic 5	Topic 5 weight
country	0.028	person	0.042	right	0.027	people	0.037	free	0.040
health	0.028	coronavirus	0.039	need	0.025	ill	0.026	coronavirus	0.029
system	0.023	use	0.031	people	0.025	vulnerable	0.026	maintain	0.022
vital	0.020	home	0.030	prepare	0.024	household	0.026	course	0.019
patient	0.019	confirm	0.028	service	0.018	amp	0.025	language	0.019
shortage	0.017	suspect	0.028	world	0.016	coronavirus	0.021	product	0.019
coronavirus	0.014	mask	0.022	coronavirus	0.014	country	0.021	work	0.018
mask	0.013	refugee	0.021	global	0.014	work	0.018	join	0.014
incl	0.013	people	0.021	support	0.013	water	0.015	area	0.012
improve	0.012	cough	0.019	government	0.013	soap	0.015	demand	0.012

It is a combination of fake and genuine news with mixed reactions. The study also answers the question of *how to strike a balance between sparsely and densely tweets during the ongoing COVID-19* (RQ2). This study established COVID-19 sparsely and densely tweets.

Fig 4.9: Topic Modelling graphs for Public and WHO tweets

This comparison indicates that the similar tweets clustered together and densely populated while the unfamiliar tweets lightly clustered together and sparsely recognized and indicate different opinions. The dense tweets show that COVID-19 tweets of highly connected opinions are more equally linked together, which might be advantageous for policymakers' information processing. The revealed dense networks can give COVID-19 managers new ideas about the COVID-19 message's sentiments and how COVID-19 spread in an increasingly interconnected society, and how this affects the increasingly connected society. This insight helps the manager's position their strategy on transferring information in a very transparent manner and positively influencing the societal decision. This study recommends that the managers will strike a balance between sparsely and densely tweets when leveraging on it for decision making.

Conclusion

In addition to what earlier studies emphasized, social media's importance and danger in information dissemination is escalating, especially during the ongoing COVID-19. This study contributes to the social media literature by understanding the similarity and divergence of COVID-19 tweets of the public and the health agency such as WHO. The study also sheds more light on the COVID-19 sparse and densely text network and their implications for the policymakers. Despite the contribution of this study, it is limited by time-series data of COVID-19. As COVID-19 prediction is curvilinear, its dataset is changing. Future studies should collect more COVID-19 tweet data and embark on a comparison study to give meaning to the past and current data.

Abstract

Quality control and improvement is a crucial process development of any institution that craves growth. One part of the SPC approach is to aid the constant improvement of performance by further reducing unexplained variability. Another aspect of Statistical Process Control (SPC) is that planned and unplanned changes signaled as fast as considering the natural process variability. This paper aimed to determine whether students' performance is significantly distributed according to academic patterns using the quality control procedure. This study found that one of the notable Nigerian Private University student academic performances drawn from three engineering departments based on the mean chart is in control and out of control, indicating excellent, intermediate, and lower results. The study also shows upper, average, and lower results with a close margin. This insight is an interdepartmental issue. The school managers need to formulate a holistic policy that will improve the existing academic performance to move the outlier students from worst to better and from better to best.

Keywords: Academic performance, Statistical Process Control, Control Chart, Assignable cause, GPA

Introduction

Quality control and improvement is a crucial process development of any institution that craves growth. Aslam, Saghir, and Ahmad (2020) categorize quality improvement as an intention for rigorous competition and a desire for profit maximization. People believe that statistical process control (SPC) is peculiar to the manufacturing processes. It is still a growing process in health, education, government services, Internet traffic monitoring, and environment protection (Qiu, 2019). There is a caution by earlier study not to tamper with the existing process until it is statistically proving that the process is misbehaving (Aslam et al. 2020). More initial research by Elepo and Balogun (2016) has established a misbehaving process in Nigerian University student academic performance, hence calls for this follow-up study.

Statistical Process Control (SPC) is a structure of thoughts (Wheeler and Chambers, 1992) and a collection of problem-solving tools useful in accomplishing process stability through reduced variability (Quesenberry, 1997; Mitra, 1998; Montgomery, 2009). One part of the SPC approach is to aid the constant improvement of performance by further reducing unexplained variability. Another aspect of SPC is planned and unplanned changes that signal as fast as considering the natural process variability (De Vries and Reneau, 2010). Statistical Process control began in

the manufacturing industries during the 1920s, yet there are presently bounteous applications in health care and disease transmission (Woodall, 2006; Thor et al. 2007).

According to Carey and Stake (2003), "Statistical Process Control (SPC) is a theory, technique, and collection of approaches for the continuous improvement of systems, procedures, and outcomes. The SPC methodology is based on data learning and focused on the principle of variance (understanding common and special causes). The SPC strategy combines analytical; process thought, avoidance, stratification, stability, capacity, and prediction. SPC involves estimation, data collection techniques, and expected research. Graphical techniques, such as Shewhart charts (more generally referred to as 'control charts'), run maps, frequency graphs, histograms, Pareto analysis, scatter diagrams, and flow diagrams, are the key instruments used in SPCs." The control chart is one of the critical instruments of the SPC. A control chart is a statistical tool used for observations plotted after some time to see if the mechanism is working, as it should (De Vries and Reneau, 2010).

Morales (2013) also defined control charts as apparatuses of Statistical Process Control (SPC) that monitor a production process's condition, identifying when a product change's quality characteristics. The concept of 'control' relates to the quality feature within limits set (control limits) to ensure output and quality efficiency. If the attribute (i.e., weight, length, and dimensions) is not within these limits, then the process is in an "out-of-control" state. In such a case, it is essential to discover and address the assignable cause that originated this state (failure).

This paper aims to determine whether or not students' performance is significantly distributed according to academic patterns using the quality control procedure, detecting any statistically significant positive or negative shift in a student's GPA from the desired target level using quality control charts.

This study will facilitate proper monitoring of student performance in the university so that "non-conforming" scores are identified quickly so that such students could properly and adequately be advised to forestall poor outcomes shortly.

Recent studies examine the strength of academic performance agreement as a counseling guide for the University (Balogun, Moshin and Olaleye, 2020). Other studies also applied SPC to monitor mechanized sugarcane harvesting (Paixão et al., 2020) and the monitoring of anatomical changes of individual patients during the head-and-neck radiotherapy process (Lowther et al. 2019). Integrated production maintains a policy for unreliable manufacturing systems (Bahria, Chelbi, Bouchriha, and Dridi, 2019). The proposal of an intelligent SPC method based on feature learning (Zan et al. 2020) and Qiu (2019) highlights some recent literature that showcases nonparametric SPC, control charts for monitoring Spatio-temporal and dynamic processes. These studies portray the vast research domain of SPC. This study divides into six sections. The first section captures the introduction, the second section with literature, the third section with methodology, the fourth section with results, the fifth section with discussion, and the last section concludes the study.

Literature Review

Predicting Student's Academic Performance

Predicting students' academic performance is a crucial part of institutions of higher learning. A better appreciation of the factors that influence students' academic performance is a challenging research exercise because of many diverse aspects such as previous academic performance, interaction with teachers, cultural, and social (Romero and Ventura, 2013). Numerous studies have been carried out on these factors, and they had brought about concrete results. Some works have been done on how socioeconomic status affects students' academic performance (Goddard, Sweetland, and Hoy, 2000). Some other researchers studied the relationship between student's academic performance and the behaviors of their parents (Attaway and Bry, 2004) while others focused on the efficiency of the teacher to improve student's academic performance (Bassam, Ahmed, Mohammad, Mohammad, 2014; Gerber and Fin, 2001). Romero and Ventura (2013) suggest that studies conducted on EDM have been applied to web-based education due to the Learning Management System (LMS) (e.g., WebCT Blackboard and Moodle). Providing information about students' academic assessments and the number of times students access teaching resources. This step is very relevant information to predict students' academic performance and discover course weaknesses (Romero, López, Luna, and Ventura, 2013). Prediction and analysis of students' academic performance are essential for student academic progress (Baker, Corbett, and Koedinger, 2004; Romero and Ventura, 2013).

The objective of predicting student academic performance is to estimate the unknown value that describes the student. In education, the values usually predicted are performance, knowledge, score, or mark. The value of a student's

academic performance is either continuous/numerical (regression- Draper and Smith, 1998) value or discrete/categorical (classification-Espejo, Ventura, Herrera, 2010) value. Prediction of a student's academic performance remains an old and widespread application of data mining in education. Different techniques and models, such as neural networks, correlation analysis, rule-based systems, regression, and Bayesian networks, have been applied.

Intelligent Tutoring Systems

Intelligent Tutoring Systems (Hämäläinen and Vinni, 2006) is a machine learning method employed to student's academic performance to predict either fail or pass in a course. A similar algorithm, such as Moodle usage data, is utilized to predict students' final marks (Romero, Ventura, Hervás, Gonzales, 2008). The Moodle usage data algorithm is used to predict students' academic final grade dependent on features extracted from logged data (Minaei-Bidgoli, Kashy, Kortmeyer, Punch, 2003) and to predict University students' academic performance (Ibrahim and Rusli, 2007).

Neural Network

Different types of neural network models have been used to predict the performance of a candidate being considered for admission into the university (Oladokun, Adebanjo, Charles-owaba, 2008); predict final student grades (Gedeon and Turner, 1993); performance from test scores

(Fausett and Elwasif, 1994); predict the number of errors a student will make (Want and Mitrovic, 2002); and predict students' marks from Moodle logs (Delgado, Gibaja, Pegalajar, Pérez, 2006). The application of Bayesian networks is seen in the prediction of student's academic performance within a tutoring system (Pardos, Heffernan, Anderson, Heffernan, 2007); student-applicant performance (Haddawy, Thi, Hien, 2007); to predict a future graduate's Cumulative Grade Point Average (CGPA) based on the background of the applicant at the time of admission (Hien and Haddawy, 2007).

Rule-Based Systems

Different types of rule-based systems have been used in the prediction of student's academic performance in terms of predicting the marks in an e-learning environment through the application of fuzzy association rules (Nebot, Castro, Vellido, Mugica, 2006); to predict, monitor, and evaluate student's academic performance by applying rule induction (Ogor, 2007). Rule-based systems can predict students' academic learner performance based on the learning portfolios compiled using key formative assessment rules (Chen, c., Chen, Li, 2007). Rule-based systems can predict student grades in LMSs, using grammar guided genetic programming (Zafra and Ventura, 2009). Using decision tree rule-based systems can be applied in predicting students' academic performance and providing well-timed lessons in web-based eLearning systems (Chan, 2007).

Regression Techniques

Several regression techniques, such as locally weighted linear regression, neural networks, support vector machines, model trees, and linear regression, have been applied to predict students' marks in an open university (Kotsiantis and Pintelas, 2005). Linear regression prediction models can predict end-of-year accountability assessment scores (Anozie and Junker, 2006). In predicting students' performance from the log and test scores in web-based instruction, a multivariable regression model technique has been employed (Yu, Jannasch-pennell, Digangi, Wasson, 1999). Similarly, stepwise linear regression can predict students' academic performance (Golding, Donalson, 2006). Using multiple regression factors that have the probability of predicting student's academic success in courses run in colleges can be identified (Martinez, 2001), while linear regression can be used to predict student's examination results in courses taught in distance education (Myller, Suhonen, Sutinen, 2002). Again, using a robust Ridge regression algorithm, the linear regression technique is often applied in predicting the probability a student has of producing the right answer to a problem in an ITS (Cetintas, Xin, Hord, 2009). To predict end-of-year accountability assessment scores (Anozie & Junker, 2006) and indicate a student's academic performance test score (Feng, Heffernan, Koedinger, 2005).

Bayesian Networks

Bayesian networks predict student knowledge through cognitive tutors (Baker, Corbett, Aleven, 2008). Bayesian networks have been used to detect students' academic learning styles in a web-based education system (Garcia,

Amandi, Schiaffino, Campo, 2007). To correctly predict whether a student will answer a problem correctly, Bayesian networks can be applied (Jonsson, Hasmik, Johns, Mehranian, Arroyo, Woolf, Barto, Fisher, Mahadevan, 2005). Bayesian networks can be used to model a student's changing state of knowledge within the period of skill acquisition in ITS (Chang, Beck, Mostow, Corbett, 2006). Bayesian networks are used to infer intangible learning variables from students' academic performance help-seeking behavior, particularly in a web-based tutoring system (Arroyo, Murray, Woolf, 2004) and for knowledge tracing to authenticate the impact of self-discipline on students' academic knowledge and learning (Gong, Rai, Beck, Heffernan, 2009).

Methodology

Data for this study were collected from students' academic records in the Department of Information and Communication Engineering, Mechanical Engineering and Petroleum Engineering, Covenant University, Ota, Ogun State, Nigeria from 2004/2005, 2005/2006, 2006/2007, 2007/2008, 2008/2009, and 2009/2010 academic sessions. Thus, this study's data is secondary data of 195, 166, and 195 observations on students' G.P.A. for six academic sessions. In this work, we will be using a control chart to monitor the mean and the variability of the process (students' academic performance). The analysis is carried out on IBM SPSS version 25.

Derivation of $\bar{x}$ and s formula

According to Montgomery (2009) setting up and operating $\bar{x}$ *and* s control charts require a similar sequence of steps as that of $\bar{x}$ *and* R chart, except that for each of the sample we calculate the sample mean $\bar{x}$ and sample standard deviation s. If the σ^2 defined as the unknown variance of the probability distribution, then the unbiased estimator of σ^2 is as follows:

$$\sigma^2 = \frac{\sum_{i=1}^{n}(x_i - \bar{x})^2}{n-1}$$

However, the sample standard deviations is not an unbiased estimator of σ. If the underlying distribution is normal, s estimates $c_4\sigma$, where c_4 is a constant which depends on the sample size n. Furthermore, the standard deviation of s is $\sigma\sqrt{1-c_4}$. The information so far is used to establish the control chart of $\bar{x}$ *and* s. Considering the case where the standard value is given for σ. Since $E(s) = c_4\sigma$, the center line for the control chart is $c_4\sigma$. Using the three sigma control limits for s are then

$$UCL = c_4\sigma + 3\sigma\sqrt{1-c_4^2}$$

$$LCL = c_4\sigma - 3\sigma\sqrt{1-c_4^2}$$

It is therefore customary to define the two constants as:

$$B_5 = c_4 - 3\sqrt{1-c_4^2} \quad and$$

$$B_6 = c_4 + 3\sqrt{1-c_4^2}$$

Consequently, the parameters of the s chart with a standard value for σ is given as:

$$UCL = B_6\sigma, \qquad CL = c_4\sigma, \qquad LCL = B_5\sigma$$

The values of B_5 and B_6 are from the table with various sample sizes. The statistic $\frac{\bar{s}}{c_4}$ is an unbiased estimator of σ. Therefore, the parameters of the S chart would be

$$UCL = \bar{s} + 3\frac{\bar{s}}{c_4}\sqrt{1-c_4}$$

$$Center\ line(CL) = \bar{s}$$

$$LCL = \bar{s} - 3\frac{\bar{s}}{c_4}\sqrt{1-c_4}$$

The constants are defined as

$$B_3 = 1 - \frac{3}{c_4}\sqrt{1-c_4^2} \quad and$$

$$B_4 = 1 + \frac{3}{c_4}\sqrt{1-c_4^2}$$

Consequently, the parameters of the s chart are written as:

$$UCL = B_4\bar{s}, \quad Center\ line\ (CL) = \bar{s}, \quad LCL = B_3\bar{s}$$

Note that $B_4 = \frac{B_6}{c_4}$ and $B_3 = \frac{B_5}{c_4}$. When $\frac{\bar{s}}{c_4}$ is used to estimate σ, the control limits on the corresponding $\bar{x}$ chart is defined as:

$$UCL = \bar{\bar{x}} + \frac{3\bar{s}}{c_4\sqrt{n}}$$
$$Center\ line\ (CL) = \bar{\bar{x}}$$
$$LCL = \bar{\bar{x}} - \frac{3\bar{s}}{c_4\sqrt{n}}$$

Assume the constants $A_3 = \frac{3}{c_4\sqrt{n}}$. Then the $\bar{x}$ chart parameter becomes:

$$UCL = \bar{\bar{x}} + A_3\bar{s}, \qquad Center\ line\ (CL) = \bar{\bar{x}},\ \ LCL = \bar{\bar{x}} - A_3\bar{s}$$

Definition of symbols used

According to Akinrefon and Balogun (2015) the symbols used for $\bar{x}$ *and* s are defined as follows:

$\bar{\bar{x}}$ = Average of the subgroup average
$\bar{x}$ = Average of subgroup
n = Number of subgroups
σ = Population standard deviation of the subgroup average
s = Sample standard deviation of the subgroup average
$\bar{s}$ = Average of the standard deviation of the subgroup
UCL = Upper Control Limits
LCL = Lower Control Limits
B_4 = Approximation factor used to calculate within subgroup standard deviation chart control limit
B_3 = Approximation factor used to calculate within subgroup standard deviation chart control limit
A_3 = Approximation factor used to calculate control limit
c_4 = Approximation factor used to calculate within subgroup standard deviation

Results

This section interprets the results from mean and standard deviation control charts from three departments, namely: Petroleum Engineering, Chemical Engineering, Information, and Communication Engineering department.
Petroleum Engineering Department

Fig. 1: Xbar and S chart for Petroleum Engineering department

Interpretation of the control chart

For mean chart: $UCL = \bar{\bar{x}} + A_3\bar{s} = 4.141, CL = \bar{\bar{x}} = 3.534\ and\ \ LCL = \bar{\bar{x}} - A_3\bar{s} = 2.926$. The mean chart of the student's GPA from the Petroleum Engineering department shows that not all the points are within the control limits. Thus, the student's performance is out of control, meaning that there is some assignable cause of variation in the

student's performance, which should be observed and corrected. This study emphasizes points that fall below the control limit, i.e., students with poor results. From Fig. 1, the upper limit is 4.14, which means that students whose GPA falls on and above the upper control limits are extremely good since those students would graduate with second-class upper and first-class from the department. The department's average student performance is 3.53, which corresponds to the second grade, which means that the average student in the department will graduate with the second-class grade. The lower limit is 2.93, which implies acceptable performance and is thus considered the lower bound for students' academic performance from the department. A GPA, which drops below the limit, is considered out of control. The Students whose GPA falls below the lower limits will be graduating with a second-class, a third class, or a pass. Generally, the results of students graduating from the department are strong, except for a few students whose performance is poor as they graduated in the third grade. This result is due to the facilities available to students and lecturers, the academic program's quality, and the lecturers' attitude. This success is evident in private universities in Nigeria. From standard deviation chart: $UCL = B_4\bar{s} = 0.889, CL = \bar{s} = 0.426\ and\ \ LCL = B_3\bar{s} = 0$. The standard deviation chart of students' GPA from the Petroleum Engineering Department indicates that two-point is outside the control limits. As such, the process is out of control due to an assignable cause of variation in student results. Students whose GPA falls below the lower control limit will graduate with an average or unsatisfactory result. In contrast, those who fall above the upper control limit will graduate with an outstanding result.

Chemical Engineering

Fig. 2: Xbar and S chart for Chemical Engineering department

Interpretation of the control chart

For mean chart: $UCL = \bar{\bar{x}} + A_3\bar{s} = 4.225, CL = \bar{\bar{x}} = 3.553\ and\ \ LCL = \bar{\bar{x}} - A_3\bar{s} = 2.881$. The mean chart of students' GPA from the Chemical Engineering Department indicates that not all points fall within the control limits. Thus, the student's performance is out of control, meaning that there is some assignable cause of variation in the student's performance, which should be detected and corrected. This study emphasizes points that fall below the control limit, i.e., students with poor results. Fig. 2 shows the upper limits are 4.23, indicating students whose GPA falls above the upper control limits are considered extremely good. Such students would be graduating with second-class upper and first-class grades from the department. The department's average student performance is 3.55, which corresponds to the second grade, which means that the average student in the department will graduate with the second grade. The lower limit is 2.88, which implies acceptable performance and is thus considered the lower bound for students' academic performance from the department. The GPA, which falls below the limit, is considered out of control. Students' GPA falls on the lower limits would be awarded a second class, a third class, or a pass. Generally, the results of students graduating from the department are good, except for a few students whose performance is bad as they graduated from the Third-Class grade.

From standard deviation chart: $UCL = B_4\bar{s} = 0.984, CL = \bar{s} = 0.471\ and\ \ LCL = B_3\bar{s} = 0$. The standard deviation chart of students' GPA from the Department of Mechanical Engineering indicates that one point is outside the control limits. As such, the process is out of control due to an assignable cause of variation in student results. The point that falls below the lower control limit is that students will graduate with an average or poor result. In contrast, the students who fall above the upper control limit will graduate with an outstanding result.

Information and Communication Engineering

Fig. 3: Xbar and S chart for information and Communication Engineering department

Interpretation of the control chart

For mean chart: $UCL = \bar{\bar{x}} + A_3\bar{s} = 4.071, CL = \bar{\bar{x}} = 3.471\ and\ \ LCL = \bar{\bar{x}} - A_3\bar{s} = 2.871$. The mean chart of the students' GPA from the Information and Communication Engineering Department indicates that not all points are within the control limits. Thus, the student's performance is out of control, meaning that there is some assignable cause of variation in the student's performance, which should be detected and corrected. This study emphasizes points that fall below the control limit, i.e., students with poor results. Fig. 3 shows the upper limit is 4.07, implying that students whose GPA falls below and above the upper control limits are extremely good since those students would graduate with a second-class upper and first-class grade from the department. The average students' performance in the department is 3.47, which corresponds to the lower grade second class, which means that the average student in the department will graduate with a second-class lower grade. The lower limit is 2.87, which implies acceptable performance and is thus considered the lower bound for students' academic performance. A GPA, which falls below the limit, is considered out of control. Students' GPA falls within the lower limits will be graduating with a second-class lower grade, a third class, or a pass. The results of students graduating from the department are good, except for a few students whose performance is poor as they graduated from the Third-Class grade. From standard deviation chart: $UCL = B_4\bar{s} = 0.878, CL = \bar{s} = 0.420\ and\ \ LCL = B_3\bar{s} = 0$. The standard deviation chart of students' GPA from the Information and Communication Engineering Department indicates that one point is outside the control limits. As such, the process is out of control due to an assignable cause of variation in student results. The point that falls below the lower control limit is that students will graduate with an average or poor result. In contrast, those who fall above the upper control limit will graduate with an outstanding result.

Discussion

This study found that one of the notable Nigerian Private University student academic performances drawn from three engineering departments based on the mean chart is in control and out of control, indicating excellent, intermediate, and lower results. The study also shows upper, average, and lower results with a close margin. The clustering of ideal, middle, and lower points is distinct but only requires the student to get 0.62 to cross from lower to average and 0.59 from average to the upper level in the GPA SPC chart. Comparatively, the Petroleum Engineering department emerged in the upper point, became second in average point, and first in a lower point. Chemical Engineering attained second in upper point, first in average point, and second in lower point while Information and Communication Engineering came third in upper, average, and lower points. Petroleum Engineering and Chemical Engineering department undulate while Information and Communication Engineering maintain a steady rank in all the applied metric system. This study's result is similar to Haddawy, Thi, and Hien (2007), which predicted the future graduate's Cumulative Grade Point Average (CGPA) with the Neural Network data analysis technique. However, the difference between the upper, average, and lower points of each engineering department in a private setting is not conspicuous. Additional research is needed to determine how students who fall into the lower category can improve and become average students and, likewise, for intermediate students to become upper students. Excellent results in the private university will enhance public relations and boost students' chances of getting hired after their studies. Producing exceptional students in a Private University may also be an extension of reputation management, competitive advantage, and indirectly for-profit maximization (Olaleye, Sanusi, and Salo, 2018; Aslam, Saghir, and Ahmad, 2020).

Conclusion

This study found a considerable variation in the students' academic performance, especially the out of control groups. This insight is an interdepartmental issue. The school managers need to formulate a holistic policy that will improve the existing academic performance to move the outlier students from worst to better and from better to best. This policy will pave the way for continuous student academic improvement. This study is significant because it is foremost to apply SPC to determine private university students' academic performance. Despite this study's impact, it is limited to only three departments, which may not represent the entire private university's programs. It will be interesting if future studies can study the whole departments established in a private university concerning students' academic performance. Future studies also can compare private and public universities' student academic performance in emerging countries.

Abstract

In coping with the vision that Malaysia will become a developing country by 2020, the Malaysian government encourages to improve higher growth in Gross Domestic Product (GDP) while increasing the number of entrepreneurs in various sectors. Growing the number of women entrepreneurs is one of the government's current initiatives in realizing the vision of being a well-developed country with a competitive economy, sustainable revenue, and stable social structure as a multiracial country. Several researchers have conducted studies on the relationships between Entrepreneurial Competencies (EC) and Entrepreneurial Orientation (EO) dimensions towards women-owned SMEs business performance and overlooked the measurement of criteria and sub-criteria ranking, which is the most important factor in contributing their performance and becoming a crucial gap to be further investigated. Hence, this study evaluates the effective criteria that contribute most towards women-owned SMEs' performance by using Analytical Hierarchy Process employing Super Decision software. The survey questionnaires were distributed among 140 respondents in Batu Pahat, district of Johor state. However, only 128 sets of questionnaires were usable for data analysis, with a 91.43% response rate. The findings indicate that EC and EO ranking criteria are equally important to the women-owned SMEs' performance. In contrast, the consistency ratio (CR) was found to be equal to zero. Consequently, CR will give value if the paired comparison is more than two criteria, and the consistency applies only to the pairwise comparison matrices.

Keywords*:* Entrepreneurial competency, Entrepreneurial orientation, Women-owned SMEs, Business Performance, Analytical Hierarchy Process.

Introduction

Small and medium-sized enterprises (SMEs) have played a critical role in growing Malaysia's economy since the late 1990s (Chin & Lim, 2018), as well as being drivers of economic development, generating job opportunities, and promoting innovation (Haider, Asad & Fatima, 2017). Despite this phenomenon, they recognize that male entrepreneurship is being explored, but previous studies have emphasized the emergence of female entrepreneurs and their contribution to the economy and social well-being (Sucheta Agarwal, 2018; Lenka & Agarwal, 2017; Yadav & Unni, 2016). Day by day, women entrepreneurs' involvement has increased dramatically worldwide (Sucheta Agarwal, 2018). It has been nominated as the new engine for economic growth, bringing prosperity and welfare in developing nations. As reported by Economic Census 2016 by the Department of Statistics Malaysia (DOSM) (2017), SMEs constitute 98.5% or 907,065 of business establishments in Malaysia, and 20.6% of them are wholly owned by women entrepreneurs with an annual growth rate of 8% (DOSM, 2017). Hence, women-controlled and women-owned businesses are now regarded as essential functional components of society and economy, comprising around 25.8% to 28.1% of the total entrepreneurs worldwide (Kumari Amrita, Chandra Prakash Garg, 2018). In Malaysia, women-owned SMEs are most probably underperformed by a lack of intangible resources, different behavior, or women entrepreneurs' characteristics compared to their male counterparts (Teoh & Chong, 2007). According to Ali Jafri & Khurram (2019), the difference in male and female entrepreneurs' business performance is due to their intrinsic and discrete patterns of socialization and approach to their businesses.

Despite the number of women entrepreneurs, entrepreneurial competencies (EC) is one of the significant factors when it comes to performance (Chimucheka, 2018). The previous research was revealed that EC is the vital criteria for the success of an enterprise and several training programs primarily on enhancing the level of competencies among the small businesses in an attempt to broaden the competitive advantage and market performance (Ramadani, Gërguri, Dana, & Tašaminova, 2013; Chimucheka, 2018).

Besides EC is considered the crucial criterion to focus on, the other EC criteria, which is the entrepreneurial orientation (EO), also the criteria stated as the key contributor to the women-owned SMEs (Rashid, 2017). In line with Ali Yassin (2013), EO criteria have fascinated increasing interest, yet most of the studies were conducted among men businesses as the criteria that affected the firms' growth (Eggers, Kraus, Hughes, Laraway & Snycerski, 2013; Rashid, 2017). EO plays a vital role in the entrepreneur's success in the growth of businesses and economic development (Arshad, Rasli, Arshad, & Zain, 2014).

Thus, in general, the previous studies have been conducted to look at EC and EO's relationships towards women-owned SMEs' business performance using SPSS (Mitchelmore & Rowley, 2013; Ali Yassin Sheikh Ali, 2014; Almubarak, 2016; Rashid, 2017). Nevertheless, the studies' findings only proved the significance of the relationship and overlooked the measurement of ranking the most effective criteria that contributed to their performance. Therefore, this study looks at the measurement using an absolute scale by implementing AHP through several criteria and sub-criteria.

Literature Review

Women-owned SMEs

In this paper, women-owned SMEs defined as a female who is an owner-manager of a business (Mckay, 2001; Subramaniam, P., & Islam, 2014), or a woman or group of women, who initiate, organize and operate a business enterprise (Suganthi, 2009; Thayammal, 2011). As cited by Bakar et al. (2015), owner-managers become the subject because they are key informants of business, and they are involved in the overall running of the firms.

Entrepreneurial Competencies (EC)

According to Kaur A. (2013), entrepreneurial competency is defined as the individual characteristics that underlying possess by a person which result in new ventures creation, survival, and growth with primary characteristics such as basic and specific knowledge, motivates, traits, self-image, roles and skills (Bird, 1995). In line with Man et al. (2002), EC well-defined as the entrepreneur's entire capabilities to execute the job role fruitfully consists of six major areas: an opportunity, organizing, strategic, relationship, commitment, and conceptual competencies.

Opportunity Recognition Competency

According to Man et al. (2002), this competency to the ability to recognize the opportunities in the market through various means; and is operationalized by measuring various behaviors such as identifying the services or products needed by the customers, perceiving unmet needs of the customers, looking for beneficial product and services for the customers, and availing the best opportunities. Parallel with Man et al. 2002 and Tang et al. (2012), an entrepreneur must be mindful of any chance and assets accessible that empower them to perceive the holes and ought to have coordinated the chance or assets that they have.

Relationship Competency

According to Man et al. (2002), this perspective of building participation and trust utilizes associations, influential correspondence and correspondence, and relational aptitudes. While referred to Rowley (2013), individual and relationship competencies refer to the ability to haggle with others and maintain a good personal network of work contacts, developing long-term trusting and loyal relationships with others.

Conceptual Competency

Conceptual competency refers to the conceptual abilities reflected in the entrepreneurs' behavior in making the decision for market opportunities and understanding the complex information to improve the businesses by using an alternative solution (Man & Lau, 2000; Mamun et al., 2019).

Organizing Competency

Organizing competency includes the organization of internal and external resources such as budget, materials, human resources, work schedule, and programs (Snell, Lau, Snell, & Lau, 1994; Man et al., 2002; Kaur A., 2013; Mamun et al., 2019) through team-building, managing employees, training, and controlling for better performance (Man & Lau, 2000; Bae & Rowley, 2004).

Strategic Competency

Strategic competency involves an entrepreneur's ability to develop a business vision in mind, which is consistent with the literature of entrepreneurial competency (Snell et al., 1994; Thompson et al., 1996; Mamun et al., 2019) by setting, evaluating and implementing the strategies of the firm (Man et al., 2002).

Commitment Competency

Commitment competency refers to the driver of an entrepreneur to continue business (Mamun et al., 2019), who strive to achieve a long-term goal with strong devotion (Man & Lau, 2000), and also will define as an effort or hard work that required by entrepreneurs to manage their business (Sambasivan et al., 2010).

Entrepreneurial Orientation (EO)

EO is defined as a firm-level strategic orientation that captures an organization's strategy-making practices, managerial philosophies, and firm behaviors that are entrepreneurial (Doris, 2016). As indicated by Green, Covin, & Slevin (2008), entrepreneurial orientation is building strategic domain concepts including the specific firm-level outcomes and priorities related to management, beliefs, and behaviors that expressed between senior managers of a firm (Green, Covin & Slevin, 2008) and EO determines as specific strategic decisions and resource allocations in organizations (Edmon & Wiklund 2010). In this study, EO is recognized by three-dimensional conceptualization, namely, innovativeness, proactiveness, and risk-taking (Miller, 1983).

Risk Taking

Risk-taking is known as a tendency to take bold actions such as venturing into unknown new markets, committing a large portion of resources to ventures with uncertain outcomes, and/or borrowing heavily (Dess & Lumpkin, 2001).

Innovativeness

The concept of innovativeness is described as a willingness to support creativity and experimentation in introducing new products/services, and novelty, technological leadership, and research development (R&D) in developing new processes (Dess & Lumpkin, 2001).

Proactiveness

Proactiveness is the pursuit of opportunities and competitive rivalry in anticipation of future demand by introducing new products or services to create change and shape the business environment (Dess & Lumpkin, 2001).

Methodology

Comparison of Multi-Objective Decision Making (MODM) and Multi-Attribute (MADM) Approaches

Previous research highlighted that the multi-criteria decision-making method (MCDM) effectively deals with the intrinsic multidimensionality, complexity, and subjectivity in the research area (Merad et al., 2013; Wang, 2015; Calabrese et al., 2019). The main attribute of MCDM is its emphasis on the judgment of group decision making, determining the objectives (goals) and criteria, estimating the weighted relative importance, and assessing the contributions of each option for each criterion (DCLG, 2009). Hence, the MCDM problems can be categorized into two groups, which are Multi-Objective Decision Making (MODM) and Multi-Attribute Decision Making (MADM) (Lu, Zhang, Ruan, & Wu, 2007).

Table 1: Comparison of MODM and MADM Approaches

	MODM	MADM
Criteria	Objectives	Attribute
Number of alternatives	Infinite (Large number)	Finite (Limited number)
Decision maker's control	Significant	Limited
Relevant to:	Design/Search	Evaluation/Choice
Relevant of geographic data structure	Vector-based GIS	Raster-based GIS

Source: Adapted from: (Malczewski, 1991)

As the continuous type of MCDM, MODM is the method that considered the values of decision variables that are many available alternatives, for example, Goal Programming (GP). As claimed by Vyas and Misal (2013), MADM methods are discrete with a limited number of predetermined alternatives. The MADM methods include Multi-Attribute Utility Theory (MAUT), Analytical Hierarchy Process (AHP), and Technique for Order Preferences by Similarity to Ideal Solutions (TOPSIS) and Analytical Network Process (ANP). Based on the table below show the strength and weakness of MADM methods.

Table 2: Strength and Weakness of MADM methods

Method	Strengths	Weaknesses
AHP	•Easy to use •Scalable •Hierarchy structure can easily adjust to fit many sized problems •Not data intensive	•Problems due to interdependence between criteria and alternatives •Can lead to inconsistencies between judgement and ranking criteria •Rank reversal
ANP	•Allow accessing the consistency of judgements •Facilitates the process of assigning weights because splits up the problem into smaller parts	•Requires filling in a lot of questionnaires

SAW	•Ability to compensate among criteria •Intuitive to decision makes •Calculation is simple does not require complex computer programs	•Estimates revealed do not always reflect the real situation •Result obtained may not be logical
MAUT	•Takes uncertainty into account •Can incorporate preferences	•Need a lot of input •Preference need to be precise
SMART	•Simple •Allows for any type of weight assignment techniques •Less effort by decision makers	•Produce may not be convenient considering the framework
TOPSIS	•Has a simple process •Easy to use and program •The number of steps remains the same regardless of the number of attributes	•Its use a Euclidean Distance does not consider the correlation of attributes •Difficult to weight and keep consistency of judgement
ELECTRE	•Takes uncertainty and vagueness into account	•Its process and outcome can be difficult to explain I layman's terms •Outranking causes the strength and weakness of the alternatives to not be directly identified
PROMETHEE	•Easy to use •Does not require assumption that criteria are proportionate	•Does not provide a clear method by which to assign weights

(Source: (Lesmes, Castillo, & Zarama, 2009; Velasquez & T.Hester, 2013)

In particular, AHP is a simple decision-making tool to deal with complex, unstructured, and multi-attributed problems established by (Saaty 1980; Esra Albayrak, 2004), and is widely used by the decision-maker and researcher (Russo & Camanho, 2015). As supported by Tseng, Wu, Ma, Kuo, & Sai (2017), AHP is a practical method that assists in decision making using structural hierarchy with various criteria weighted by pairwise comparison. Hence, to gauge the individual's preference and needs is a critical part of the different decision-making levels. Due to the numerous attributes of women-owned SMEs' criteria, this may lead to difficulties in selecting the most effective criteria that affect the performance. Therefore, AHP, as an MCDM, will prescribing an accurate decision and helps the decision-makers find the one that best suits their needs and their understanding of the problem (Yang & Li, 2010).

Judgment Matrix and Consistency Test

In this paper, Super Decisions of AHP is a software package developed for the analysis, synthesis, and justification of complex decisions, with dependence feedback based on the analytic hierarchy process (AHP) methodology (Sharma *et al.*, 2018). The scale method of grade 1-9 was used to determine the relative merits of the elements. The figure 3.1 shows Super Decision model and figure 3.2 shows the comparison between parameters as questionnaires survey form of women-owned SMEs using the absolute scale method 1-9 based on the principle and judgement matrix of AHP.

Figure 1: Super Decision Model showing Clusters and Node

Figure 2: Super Decision Model showing pairwise comparison between parameters as Questionnaires Survey Form

Process of Methodology

Figure 3 presents a two-stage process of methodology. Initially, the process was conducted to identify the criteria and sub-criteria of women-owned SMEs' performance based on EC and EO. The systematics of the literature review has been conducted from the previous existing research. By reviewing the literature, the researcher has conducted a preliminary study to finalize women-owned SMEs' critical criteria. The criteria of EC and EO have contributed to women-owned SMEs.

After conducting a preliminary study, the questionnaire surveys were designed and distributed to the selected respondents. The questionnaire consists of three sections: the demographic profile, criteria of women-owned SMEs, and sub-criteria of women SMEs. The demographic will be analyzed using the Statistical Package for Social Science (SPSS) version 23. The next step was completed by applying the Super Decision software AHP method to calculate the weights of criteria and sub-criteria using an absolute value scale. Therefore, the ranking and assessment of the criteria and sub-criteria were analyzed after checking the comparison consistency. Based on the ranking results of AHP, the discussion and conclusion have been summarized.

Figure 3: The Process of Methodology

Results and Findings

Profile of Respondents

The demographic profile responses of the 128 survey respondents are illustrated in Table 4.1. The respondents are capable of evaluating the critical criteria of women-owned SMEs in Batu Pahat, Johor.

The current age category for the respondents was analyzed to ensure the involvement of all age spans. Women-owned SMEs ranging from 31 to 35 years old were recorded as the highest score of 26.6 percent (n=34) and followed by 36 to 40, which contributes 24.2 percent (n=31).

The current age of women-owned SMEs in the range below 25 years old has the lowest percentages, 3.9 percent (n=5), due to a lack of business confidence. The current age between 26 to 30 years old respondents just about to set up their business, which also contributes to low percentages which are only 7 percent (n=9). Next, the current age of respondents in the range from 41 to 45 years, 46 to 50 years, and above 50 years old, accordingly contributes 14.1 percent (n=18), 13.30%(n=17), and 10.9 percent (n=14).

The next section of demographic analysis presents the respondents' age when they have started to own or manage their businesses. The majority of them have started their businesses below 25 years old, with a total percentage of 37.6 percent (n=47). Women owner-managers ranging from 26 to 30 years old account for 18.6 percent (n=24), followed by 16.4 percent (n=21) for those aged 36 to 40. The range of age between 31 until 35 contributed 15.6 percent (n=20) and then dropped to 10.2 percent (n=13) for those in the range of 41 to 45 years old, and gradually only 2.3 percent (n=3) of those over 50 years old.

In terms of marital status, three options were given in the survey: single, married, or widow. According to overall respondents, the majority of them with 79.7 percent (n=102) stated that they are married, while the percentages of those who are single or widowed stated 9.4 percent (n=12) and 10.90% n=14).

Concerning race, most of the respondents are Malay, representing 76.6 percent (n=98) of the population sample,22 Chinese (17.2 percent), and 14 Indians (6.3 percent). The next section of the descriptive analysis of respondents will explain the number of children. The number of children for respondents between 1 to 3 accounted for the highest percentage, 43 percent (n=55), and followed by 4 to 6 children, which accounted for 29.7 percent (n=38). Despite that, 22.7 percent (n=29) of the respondents have less than one child, and 4.7 percent (n=6) has more than six children.

Concerning educational background, respondents who finished their secondary school accounted for 57.8 percent (n=74), while those who obtained their diploma accounted for 28.9 percent (n=37) and first degree accounted for 10.2 percent (n=13). The lowest education level was primary school, which accounted for 3.1 percent (n=4).

In terms of working experience, most of the respondents have a total working experience between 1 to 5 years, which accounted for 30.5 percent (n=39), followed by 27.3 percent (n=35) of those with working experience 6-10 years. A percentage of 22.7 percent (n=29) have 11 to 15 working experience,10.2 percent (n=13) has more than 20 years working experience, and 4.7 percent (n=6) for those with working experience less than one year and 16 to 20 years.

Table 3 shows the years of experience with the firm. A percentage of 45.3 percent (n=58) has been with the firm between 1 to 5 years, 28.1 percent (n=36) has been with the firm between 6 to 10 years, 13.3 percent (n=17) has been with the firm between 11 to 15 years, 6.3 percent (n=8) have been less than one year, 3.1 percent (n=4) have been the firm between 16 to 20 years and 3.9 percent (n=5) for more than 20 years.

Results of Decision AHP

The criteria and sub-criteria of women-owned SMEs were analyzed using the Super Decision V3 software of AHP. These comparisons were used to obtain the weights of importance for the decision criteria. The results obtained were used to rank the most important criteria for women-owned SMEs for better performance.Meanwhile, Table 4 until Table 6 shows the theoretical matrix representing the questionnaire survey form for criteria and sub-criteria of women owner-managers and based on the pairwise comparison. Based on the results, the ranking of important criteria and sub-criteria are recorded in Table 7 below.

Table 4: Theoretical Matrix representation of Questionnaire Survey Form for Criteria of Women-SMEs Performance

Pair Comparison	Entrepreneurial Competencies	Entrepreneurial Orientation	Eigen Vector	Performance (%)
Entrepreneurial Competencies	1	1	0.50	50.00
Entrepreneurial Orientation	1	1	0.50	50.00
	CR=0		**1.0000**	**100%**

Based on the findings that the researcher had analyzed for the 128 respondents, the Consistency Ratio (CR) for women-owned SMEs' criteria is equal to zero. CR will give value if the paired comparison is more than two criteria, and the consistency applies only to the pairwise comparison matrices. For the Eigen Vector, the value for EC and EO are evaluated as equally important, which 50 percent of both criteria women-owned SMEs performances. After comparing the main criteria, each sub-criteria have also been compared for their groups.

Table 5: Theoretical Matrix representation of Questionnaire Survey Form for Sub-Criteria (EC) of Women-SMEs Performance

Pair Comparison	Opportunity Recognition	Relationship	Conceptual	Organizing	Strategic	Commitment	Eigen Vector	Performance (%)
Opportunity Recognition	1	1/2	1	2	1	1	0.157348	15.73
Relationship	2	1	1/2	3	1	1/4	0.1678965	16.79
Conceptual	1	2	1	2	1	1/2	0.0992844	9.93
Organizing	1/2	1/3	1/2	1	1	1/4	0.1162039	11.62
Strategic	1	1	1	1	1	1	0.3196311	31.96
Commitment	1	4	2	4	1	1	0.139636	13.97
	CR= 0.08682						**1.0000**	**100%**

Table 5 reports the comparison matrices between EC's sub-criteria for overall respondents with the CR=0.08682 < 0.1. The evaluation of the important criteria of women-owned SMEs' performance is being considered as acceptable. The paired comparison for strategic has contributed the highest percentage with 31.96 percent for women-owned SMEs for 128 respondents in Batu Pahat. It means the women owner-managers in Batu Pahat have concluded that strategy is one of the most important sub-criteria in improving their business performance. Meanwhile, the percentage that has contributed as important gives 16.79 percent, followed by opportunity recognition 15.73 percent, commitment 13.97 percent, and 11.62 percent for organizing. The lowest percentage of the sub-criteria of EC is conceptual, with 9.93 percent.

Table 6: Theoretical Matrix representation of Questionnaire Survey Form for Sub-Criteria (EO) of Women-owned SMEs Performance

Pair Comparison	Risk Taking	Innovativeness	Proactiveness	Eigen Vector	Performance (%)
Risk Taking	1	2	1/3	0.2809364	28.09
Innovativeness	1/2	1	1/9	0.2552477	25.53
Proactiveness	3	9	1	0.4638159	46.38
	CR= 0.35331			**1.0000**	**100%**

Table 6 reports that the pair comparison matrices between the sub-criteria of EO with CR=0.35331, > 0.1. The consistency is desirable to be less than 0.10 or 10%. Each of the respondents was looked at, and the consistency was tried to improve if it was above 0.10. However, it has limitations while doing the way to improve it, and it should be convincing. Due to limited knowledge and unaware of others, this will make the results inconsistent (Natee et al., 2016). To summarize the results, the percentage of proactiveness has contributed 46.38 percent and followed by risk-taking with 28.09 percent and innovativeness 25.53 percent.

Table 7: Rank of Importance Criteria and Sub-criteria of Women-owned SMEs

Main Criteria	Rank	Sub-criteria	Rank
Entrepreneurial Competencies	**1**	Opportunity Recognition	**3**
		Relationship	**2**
		Conceptual	**6**
		Organizing	**5**
		Strategic	**1**
		Commitment	**4**
Entrepreneurial Orientation	**1**	Risk Taking	**2**
		Innovativeness	**3**
		Proactiveness	**1**

After the pairwise comparison matrix is formed, the measurement's priority vector and consistency are being calculated based on the method explained. The data were obtained from the respondent in Batu Pahat. Based on the overall result for the 128 respondents, the ranking of important criteria and sub-criteria of women owner-managers that were recorded, which contribute to the average result of EC and EO. However, based on EC's sub-criteria, the most important sub-criteria is strategically categorized in the first ranked, followed by relationship, opportunity recognition, commitment, organizing, and the last is conceptual. Then, for EO's sub-criteria, proactiveness is recorded as the first rank and followed by risk-taking and innovativeness.

Discussion and Conclusion

This study aims to identify the criteria of women-owned SMEs' performance, EC and EO, using the Super Decision of AHP method. The findings indicate that EC and EO's ranking criteria are equal in important for women-owned SMEs performance. While the consistency ratio (CR), was found important too. Consequently, SMEs' will give value if the pair comparison is more than two criteria, and the consistency applies only to the pairwise comparison matrices. Based on the previous research, EO and EC were significantly related to women-owned SMEs' business performance (Rashid, 2017; Zainol, 2018). However, previous studies only focused on the relationship between SMEs' and EC of women-owned SMEs towards performance and overlooked the ranking of performance that important to be studied in this paper. Thus, this study is important for women entrepreneurs as their guideline to improve their skills, knowledge and entrepreneurial elements in order to make their business more successful. This research revealed that are broadened and deepened in this study contribute to the existing body of knowledge in women entrepreneurs' study and entrepreneurship literature towards improving the SMEs' performance. The theoretical contributions and practical implications will contribute to the better findings for women owners/managers of SMEs and women entrepreneurial development in Malaysia. Finally, it is further hoped for better results that will help boost the growth of women-owned SMEs, which are crucial to developing the economy.

Limitation and Recommendation

This paper encounters a few limitations, which is first based on the criteria of EO. Therefore, the data collected may suffer from CR because the consistency is above 0.10. Even though the CR has been tested and was found acceptable in this research, it may invariably affect the results' accuracy. Therefore, the current study recommends the combination method with a qualitative methodology, such as the Delphi method, to complement the pairwise comparisons in future research. Secondly, the findings and conclusions drawn from this research might not be limited to one state only, including other states in Malaysia. As for that, the results may not be applicable since it only focused on a limited area. Thus, the results could be broader, and it can be compared to the other states to examine generalisability. Finally, while these findings of the research allude to the importance of criteria for women-owned SMEs, the critical criteria of women-owned SMEs' performance are not examined. Therefore, future research can be considered to examine these effects. This will draw superior implications and maximize their business performance by focusing on the criteria that yield countless impacts on SMEs' business performance.

Abstract

The presented article presents a multi-criteria fuzzy model of nursing care quality evaluation based on the evaluation criteria given in the proprietary BOHIPSZO procedure. A multi-criteria model was created on the set of criteria and sub-criteria. For each sub-criterion, a score of 0-10 points was assumed, which provided a broader picture of nursing care standards' fulfillment. The assessment is made by randomly selected patients - because each of the eight essential criteria consists of several factors. The possibility of representing the patient's uncertainty about the assessment was taken into account by the prospect of giving a score range in case of doubt.
Additionally, it was proposed that the commissioning team could define the importance of particular criteria if this team places greater emphasis on specific standards of nursing care. Based on the patients' assessments, each patient's final judgments are calculated, taking into account the (optional) importance of the criteria and sub-criteria. In the final phase, the final assessment of the health unit is determined.

Keywords: Quality of Nursing Care, Fuzzy Model, Fuzzy Numbers, Multi-Criteria Programming, Management Of Health Care Facilities

Introduction

Nowadays, quality in health care is one of the most critical problems in managing health care facilities. In the health care system, the quality of services provided is of particular importance because it concerns human health and life. The quality of medical services is most often the essential criterion for choosing a health center by a patient, which in turn has an impact on the constantly growing expectations of patients, and in health centers require continuous work for the quality of services offered to achieve or maintain a high position on the market of medical service providers, including nursing.

The initial stage is to define the current standard of nursing services offered, to identify strengths and weaknesses. To this end, the health unit should be assessed based on the measures that determine the potential patient's expectations. The first step is to adopt criteria for evaluating nursing services. There are various methods in the literature to measure and assess the quality of nursing care. The best known are the Nursing audit, Monitor, Qualpacs, and BOHIPSZO. This study aims to define an optimal nursing care assessment model that can be supported by units managing a given health care unit. In this smaller paper, the basis for developing a multi-criteria model of nursing care assessment is the BOHIPSZO procedure (the procedure discussed in point 3 of the article) by Lenartowicz (1998). In addition to adopting the criteria structure described in this procedure, a different scoring method has been introduced, taking into account the patient's uncertainty regarding the nursing care assessments.

Representation of uncertain information - *LR* type numbers

Because the model assumes the possibility of taking into account the uncertainty as to the number of points awarded under individual sub-criteria, the use of fuzzy numbers of the LR type was adopted as a representation of the variables describing the number of points awarded in the form of ranges - as an expression of uncertainty as well as a specific value in the case of confidence in the assessment by Piegat (1999). Three parameters where characterize these numbers:

- parameter m is a real number called the average or most probable value,
- parameter α is the left-hand "spread" (the difference between the value of the parameter m and the value of the minimum rating)
- parameter β is the right-hand "spread" (the difference between the maximum amount of the assessment and the value of the m parameter)

In this study, a triangular membership function was used, which considers the evaluation's minimum and maximum values and the most probable one. The following formula describes this function:

$$\mu_A(x) = \begin{cases} L\left(\dfrac{m-x}{\alpha}\right) & dla \quad x < m \\ 1 & dla \quad x = m \\ R\left(\dfrac{x-m}{\beta}\right) & dla \quad x > m \end{cases} . \tag{1}$$

However, the L and R functions are functions defined by the formula:

$$L(x) = R(x) = \begin{cases} 0 & dla \quad x < m-\alpha \\ 1-|x| & dla \quad m-\alpha \le x \le m+\beta \\ 0 & dla \quad x > m+\beta \end{cases} . \tag{2}$$

Value$m$ is the determining value - the most expected or, if not specified, it is calculated according to the formula:

$$m = \frac{m-\alpha+m+\beta}{2}. \tag{3}$$

Nursing care assessment quality assessments are presented in the form of point intervals ([m-α, m] and [m, m + β]), which take into account the uncertainty to the most probable value of m. The evaluation is based on mathematical operations on these three parameters m, α, β(by Piegat (1999)).

Multi-criteria model of nursing care quality assessment

Nursing care assessment should include documentation analysis, interviews, and observation. The assessor (team) should review the patient's medical history and care, diagnosis, patient problems, and care plan. The presented model is based on the nursing care quality assessment procedure criteria by H. Lenartowicz – BOHIPSZO by Lenartowicz (1998). This procedure covers 71 sub-criteria divided into eight groups. The individual criteria (*Level 1*) with sub-criteria (*Level 2*) are presented below, taking into account the assumed variable representation as *LR* fuzzy numbers:

1. Safety (*theLevel 1* criterion) is described by a fuzzy variable $S_i(m_{S_i}, \alpha_{S_i}, \beta_{S_i})$ consisting of the following sub-criteria (*theLevel 2 criteria*):

1.1. Electrical, gas, and oxygen installations, apparatus does not endanger the patient, the patient is instructed on safe behavior, warning notices are posted $S_{i-1}(m_{S_{i-1}}, \alpha_{S_{i-1}}, \beta_{S_{i-1}})$

1.2. The rooms (patient room, treatment room, corridor, and others) are: tidy, adequately lit at night, dry floors, proper cleaning, beds secured with sidewalls or other means, windows and doors secured, if necessary $S_{i-2}(m_{S_{i-2}}, \alpha_{S_{i-2}}, \beta_{S_{i-2}})$

1.3. Efficient signaling is within reach of the patient in the room, bathroom, toilet, appropriate handles, and handrails are attached, the trolley and the bed have efficient brakes $S_{i-3}(m_{S_{i-3}}, \alpha_{S_{i-3}}, \beta_{S_{i-3}})$

1.4. The ward first aid kit is not accessible to unauthorized persons. Medicines and infusion fluids are stored in their original packaging and a designated place. Disinfectants and other chemicals are not available to patients $S_{i-4}(m_{S_{i-4}}, \alpha_{S_{i-4}}, \beta_{S_{i-4}})$

1.5. Standards for calling a resuscitation team and managing an emergency are developed and known to nurses. Appropriate equipment and pharmacological agents are prepared $S_{i-5}(m_{S_{i-5}}, \alpha_{S_{i-5}}, \beta_{S_{i-5}})$

1.6. The course of action in the event of a fire and the method of evacuating the sick are known to nurses and auxiliary staff. Fire fighting equipment is in place $S_{i-6}(m_{S_{i-6}}, \alpha_{S_{i-6}}, \beta_{S_{i-6}})$

1.7. The patient is wearing an identification bracelet. On the front of his nursing record, he is allergic to what drugs. His name and surname are written on the Bed $S_{i-7}(m_{S_{i-7}}, \alpha_{S_{i-7}}, \beta_{S_{i-7}})$

2. Protection against infection (*Level 1* criterion) is described by a fuzzy variable $PAI_i(m_{PAI_i}, \alpha_{PAi_i}, \beta_{PAI_i})$ consisting of the following sub-criteria (*Level 2*criteria):

2.1. The nurse acts aseptically in performing or assisting in all procedures requiring sterility $PAI_{i-1}(m_{PAI_{i-1}}, \alpha_{PAI_{i-1}}, \beta_{PAI_{i-1}})$

2.2. Tools are disposable or sterilized according to the rules. Sterility is checked regularly, and validity periods are adhered to $PAI_{i-2}(m_{PAI_{i-2}}, \alpha_{PAI_{i-2}}, \beta_{PAI_{i-2}})$

2.3. Disinfected by established rules are: medical equipment, e.g., incubators, respirators, oxygen masks, etc., sanitary equipment, e.g., swimming pools, ducks, bowls, IV stands, heating booths, furniture, beds with mattresses, cabinets $PAI_{i-3}(m_{PAI_{i-3}}, \alpha_{PAI_{i-3}}, \beta_{PAI_{i-3}})$

2.4. Handling of clean and dirty underwear, dishes, kitchen waste, used dressing material and disposable equipment, etc. $PAI_{i-4}(m_{PAI_{i-4}}, \alpha_{PAI_{i-4}}, \beta_{PAI_{i-4}})$

2.5. The ward rooms are disinfected according to the rules, and often Aires $PAI_{i-5}(m_{PAI_{i-5}}, \alpha_{PAI_{i-5}}, \beta_{PAI_{i-5}})$

2.6. A potentially infected and contagious patient is isolated by a sanitary regime. The used equipment, underwear, other material is destroyed correctly, moved, disinfected, and sterilized $PAI_{i-6}(m_{PAI_{i-6}}, \alpha_{6PAI_{i-6}}, \beta_{PAI_{i-6}})$

2.7. Nurses and their staff: wash their hands after each activity, use different protective equipment (gloves, gowns ...) adequately to the situation $PAI_{i-7}(m_{PAI_{i-7}}, \alpha_{PAI_{i-7}}, \beta_{PAI_{i-7}})$

2.8. All nurses and auxiliary staff have up-to-date health records. The Nursing Infection Committee represents nursing. Nurses know the infection rate inside the hospital where they work $PAI_{i-8}(m_{PAI_{i-8}}, \alpha_{PAI_{i-8}}, \beta_{PAI_{i-8}})$

3. Hotel services and satisfaction of needs (*Level 1* criterion) are described by a fuzzy variable $HSMN_i(m_{HSMN_i}, \alpha_{HSMN_i}, \beta_{HSMN_i})$ and consists of the following sub-criteria (*Level 2*criteria):

3.1. The patient's room is adequately spacious and furnished. The patient was helped to maintain body temperature (heating/cooling). The bathroom and toilet are clean $HSMN_{i-1}(m_{HSMN_{i-1}}, \alpha_{HSMN_{i-1}}, \beta_{HSMN_{i-1}})$

3.2. The bed is comfortable and clean. The bedside cabinet, screen, curtains, floor are clean $HSMN_{i-2}(m_{HSMN_{i-2}}, \alpha_{HSMN_{i-2}}, \beta_{HSMN_{i-2}})$

3.3. The patient's body (skin, mucosa, teeth, hair, nails) is clean. Underwear, bed linen, towels are clean. The male patient is shaven; the female patient is combed. Personal hygiene products such as soap, toothpaste, comb, and slippers are provided by the ward when needed $HSMN_{i-3}(m_{HSMN_{i-3}}, \alpha_{HSMN_{i-3}}, \beta_{HSMN_{i-3}})$

3.4. The patient is allowed to use his clothes, as long as there are no clear contraindications $HSMN_{i-4}(m_{HSMN_{i-4}}, \alpha_{HSMN_{i-4}}, \beta_{HSMN_{i-4}})$

3.5. The patient is provided with a comfortable and proper position and peace and quiet, conducive to rest during the day and night. The patient is not woken up in the morning to wash, take temperature, and other procedures $HSMN_{i-5}(m_{HSMN_{i-5}}, \alpha_{HSMN_{i-5}}, \beta_{HSMN_{i-5}})$

3.6. A lying patient can regulate the radio, TV, and bedside lighting. The locker, bedside table, and other personal equipment are within easy reach of the patient $HSMN_{i-6}(m_{HSMN_{i-6}}, \alpha_{HSMN_{i-6}}, \beta_{HSMN_{i-6}})$

3.7. The patient was assisted in starting or limiting his movement. The patient can use a cane, stroller support, stroller. The recommended exercises are performed frequently enough by the patient himself. Activities performed with the help of a nurse $HSMN_{i-7}(m_{HSMN_{i-7}}, \alpha_{HSMN_{i-7}}, \beta_{HSMN_{i-7}})$

3.8. The patient receives meals according to the ordered diet, at the right temperature. Meals served at the right time. Dishes and cutlery are aesthetic, clean, and properly stored $HSMN_{i-8}(m_{HSMN_{i-8}}, \alpha_{HSMN_{i-8}}, \beta_{HSMN_{i-8}})$

3.9. The patient is watered and fed by the nurse without rush, in a calm atmosphere $HSMN_{i-9}(m_{HSMN_{i-9}}, \alpha_{HSMN_{i-9}}, \beta_{HSMN_{i-9}})$

3.10. The patient was encouraged to consume or limit fluids and food. The patient received help with nausea and vomiting $HSMN_{i-10}(m_{HSMN_{i-10}}, \alpha_{HSMN_{i-10}}, \beta_{HSMN_{i-10}})$

3.11. The following are properly stored: - private, valuable things, food of the patient $HSMN_{i-11}(m_{HSMN_{i-11}}, \alpha_{HSMN_{i-11}}, \beta_{HSMN_{i-11}})$

3.12. The patient was given a pool/duck as soon as he asked. The dish was picked up without being asked to retake it. Bowel movements and urination are recorded and regulated $HSMN_{i-12}(m_{HSMN_{i-12}}, \alpha_{HSMN_{i-12}}, \beta_{HSMN_{i-12}})$

4. Information (*Level 1* criterion) is described as a fuzzy variable $I_i(m_{I_i}, \alpha_{I_i}, \beta_{I_i})$ and consists of the following sub-criteria (*Level 2*criteria):

4.1. The patient has access to information about the types, scope, and conditions of care provided by the hospital/institution. He is informed of all his rights. Familiar with the course of submitting complaints and information. An information booklet and a written set of his rights are available $I_{i-1}(m_{I_{i-1}}, \alpha_{I_{i-1}}, \beta_{I_{i-1}})$

4.2. The patient was familiarized with: - the layout of rooms in the ward, facilities for patients in the community and the hospital, - customs, daily schedule, with patients from the same room $I_{i-2}(m_{I_{i-2}}, \alpha_{I_{i-2}}, \beta_{I_{i-2}})$

4.3. The patient knows the name and surname of the treating physician, ward nurse, and nurse responsible for his care. It is customary in the ward to introduce themselves to the sick, giving their functions $I_{i-3}(m_{I_{i-3}}, \alpha_{I_{i-3}}, \beta_{I_{i31}})$

4.4. The patient is acquainted with the state of health - diseases that determine the scope of nursing - in an accessible way. He receives real-time information about everything that has to be done and why. Has access to the nursing documentation, demands that it be supplemented if it is incomplete or corrected if it is inaccurate $I_{i-4}(m_{I_{i-4}}, \alpha_{I_{i-4}}, \beta_{I_{i-4}})$

4.5. The confidentiality of the information obtained during the patient-nurse contacts and obtained from other sources is maintained $I_{i-5}(m_{I_{i-5}}, \alpha_{I_{i-5}}, \beta_{I_{i-5}})$

5. The subjectivity of the patient (*Level 1* criterion) is described by a fuzzy variable $SP_i(m_{SP_i}, \alpha_{SP_i}, \beta_{SP_i})$ and consists of the following sub-criteria (*Level 2* criteria):

5.1. After informing about the goals, course, expected results, and consequences, the nurse asks the patient for consent to the proposed treatment and nursing procedures, demonstration for educational purposes and the presence of students, visits of people not related to the patient, and not taking part in care, participation in surveys and research scientific $SP_{i-1}(m_{SP_{i-1}}, \alpha_{SP_{i-1}}, \beta_{SP_{i-1}})$

5.2. The patient or a close person takes part in the care planning, co-decides on the method of nursing and the duration of the procedure, if there are different methods and different times are possible. It is included in the course of a medical visit. It is included in the duration of a nursing visit $SP_{i-2}(m_{SP_{i-2}}, \alpha_{SP_{i-2}}, \beta_{SP_{i-2}})$

5.3. The nurse respects the patient's moral and cultural values, beliefs, and beliefs. He does not comment; he does not judge. Religious needs are respected $SP_{i-3}(m_{SP_{i-3}}, \alpha_{SP_{i-3}}, \beta_{SP_{i-3}})$

5.4. The nurse: - addresses the patient with his favorite phrase with courtesy and kindness, - listens to the patient carefully, - encourages to express thoughts and feelings - related to his health - illness, especially about anxiety, fear, - talks to the patient during exercise activities, - sitting and talking to the patient, regardless of performing instrumental procedures, - greets the patient and his relatives according to the custom in the ward $SP_{i-4}(m_{SP_{i-4}}, \alpha_{SP_{i-4}}, \beta_{SP_{i-4}})$

5.5. The patient's intimacy and personal dignity are respected. The nurse interviews the patient in a secluded place in a cultural and discreet atmosphere. Performs treatments with closed doors, curtains/screens closed, without the presence of bystanders $SP_{i-5}(m_{SP_{i-5}}, \alpha_{SP_{i-5}}, \beta_{SP_{i-5}})$

5.6. The nurse reacts immediately to the evoking light or sound signals; the patient does not have to repeat the request for the service $SP_{i-6}(m_{SP_{i-6}}, \alpha_{SP_{i-6}}, \beta_{SP_{i-6}})$

5.7. The means of communication between the patient and the external environment are provided: - the patient is visited according to his / her wishes, - access to a telephone enabling privacy of conversations is easy, - the patient can use the hospital's book collection, - the patient can use the daily press, correspondence contacts are facilitated $SP_{i-7}(m_{SP_{i-7}}, \alpha_{SP_{i-7}}, \beta_{SP_{i-7}})$

5.8. The nurse organizes the patient's free time: - reads to the patient, writes on his / her behalf, - initiates group games, encourages new interests, and Hobbes $SP_{i-8}(m_{SP_{i-8}}, \alpha_{SP_{i-8}}, \beta_{SP_{i-8}})$

5.9. A nurse helps an injured patient to maintain his physical appearance as desired. It gives evidence that it is not rejected $SP_{i-9}(m_{SP_{i-9}}, \alpha_{SP_{i-9}}, \beta_{SP_{i-9}})$

5.10. A dying patient hates physical pain. He is not alone; nurturing continues. The nurse is present, maintains contacts until the end, touches him, holds his hands, the seriousness of death is preserved. The family was shown to help ease their pain $SP_{i-10}(m_{SP_{i-10}}, \alpha_{SP_{i-10}}, \beta_{SP_{i-10}})$

6. Self-care (*Level 1* criterion) is described as a fuzzy variable $SC_i(m_{SC_i}, \alpha_{SC_i}, \beta_{SC_i})$ and consists of the following sub-criteria (*Level 2*criteria):

6.1. Teaching the patient/relatives are included in the plan $SC_{i-1}(m_{SC_{i-1}}, \alpha_{SC_{i-1}}, \beta_{SC_{i-1}})$

6.2. The patient (relatives) was provided with information on a healthy lifestyle: improving breathing, quantitative and qualitative needs of the body, caloric content and methods of preparing meals, fluid balance, personal hygiene, means and methods of regulating excretion, regulating temperature, heating and cooling the body, functioning of the system sexual maturity, emotional, moral, bodily, sexual maturity, human values of sex life, contraception, physical activity, sleep, rest, ways of maintaining physical fitness, self-acceptance, emotional balance and self-confidence, the satisfaction of mental needs, participation in cultural life, maturity and social sensitivity of family, social and social life, biological and environmental threats, specific risk factors and disease prevention $SC_{i-2}(m_{SC_{i-2}}, \alpha_{SC_{i-2}}, \beta_{SC_{i-2}})$

6.3. The patient/family was taught self-monitoring of a health condition: measuring body temperature, pulse, blood pressure, body weight, and breast examination (women). The patient is aware of the values accepted as normal $SC_{i-3}(m_{SC_{i-3}}, \alpha_{SC_{i-3}}, \beta_{SC_{i-3}})$

6.4. The patient is encouraged, convinced, and motivated to lead a healthy lifestyle $SC_{i-4}(m_{SC_{i-4}}, \alpha_{SC_{i-4}}, \beta_{SC_{i-4}})$

6.5. Patient: understands the essence of his disease, its causes, symptoms, dietary and surgical treatment, type of surgery and consequences, pharmacological, names, doses and effects of drugs, rehabilitation, and the perspective of health/limitations. Patient: knows how to perform appropriate nursing, treatment, and rehabilitation activities, e.g., urine tests, injections, has received a written set of recommendations and descriptions of medicines at home, knows how to notice changes in health, knows what symptoms he cannot ignore, knows how to proceed, where and when to get checked $SC_{i-5}(m_{SC_{i-5}}, \alpha_{SC_{i-5}}, \beta_{SC_{i-5}})$

6.6. The patient knows how to eliminate harmful factors in his lifestyle and environment related to his health – disease $SC_{i-6}(m_{SC_{i-6}}, \alpha_{SC_{i-6}}, \beta_{SC_{i-6}})$

7. Treatment and care treatments (*Level 1* criterion) is described by a fuzzy variable $T_i(m_{T_i}, \alpha_{T_i}, \beta_{T_i})$ and consists of the following sub-criteria (*Level 2* criteria):

7.1. Basic and patient-specific health parameters - diseases are measured, observed, recorded $T_{i-1}(m_{T_{i-1}}, \alpha_{T_{i-1}}, \beta_{T_{i-1}})$

7.2. Material samples for testing were collected: after the patient was prepared, on the agreed day and time, in the right way $T_{i-2}(m_{T_{i-2}}, \alpha_{T_{i-2}}, \beta_{T_{i-2}})$

7.3. Other diagnostic procedures were performed: after preparing the patient on time, using the right technique

7.4. The patient is given medication: in the right dose, often enough to eliminate the pain $T_{i-4}(m_{T_{i-4}}, \alpha_{T_{i-4}}, \beta_{T_{i-4}})$

7.5. The nurse changed position, used other measures to relieve pain $T_{i-5}(m_{T_{i-5}}, \alpha_{T_{i-5}}, \beta_{T_{i-5}})$

7.6. Care of: skin exposed to pressure, wounds, bedsores, fistulas according to $T_{i-6}(m_{T_{i-6}}, \alpha_{T_{i-6}}, \beta_{T_{i-6}})$

7.7. The patient received the prescribed medications: in the right dose, at the right time, the right way and technique, by authorized persons, the principle of one-person responsibility for the administered medication is applied $T_{i-7}(m_{T_{i-7}}, \alpha_{T_{i-7}}, \beta_{T_{i-7}})$

7.8. Supplemental oxygen is properly administered (amount, hydration, tubing/mask fixation) $T_{i-8}(m_{T_{i-8}}, \alpha_{T_{i-8}}, \beta_{T_{i-8}})$

7.9. Catheter drainage: aseptic drains and pouches, their placement facilitates drainage, closed drainage (protection against dust), perineal toilet performer $T_{i-9}(m_{T_{i-9}}, \alpha_{T_{i-9}}, \beta_{T_{i-9}})$

7.10. Anti-inflammatory treatments performed: punctually, by the established rules, by an employee with sufficient qualifications $T_{i-10}(m_{T_{i-10}}, \alpha_{T_{i-10}}, \beta_{T_{i-10}})$

7.11. Other treatments performed: after preparing the patient on time, using the right technique $T_{i-11}(m_{T_{i-11}}, \alpha_{T_{i-11}}, \beta_{T_{i-11}})$

7.12. Rehabilitation procedures are performed: after preparing the patient, often enough, with the correct technique $T_{i-12}(m_{T_{i-12}}, \alpha_{T_{i-12}}, \beta_{T_{i-12}})$

7.13. Procedures do not unnecessarily limit the patient's independence (e.g., needles, drips, drains, dressings, pouches are carefully applied, the patient can move/walk) $T_{i-13}(m_{T_{i-13}}, \alpha_{T_{i-13}}, \beta_{T_{i-13}})$

8. Organization and documentation (*Level 1* criterion) are described as a fuzzy variable $OD_i(m_{OD_i}, \alpha_{OD_i}, \beta_{OD_i})$ and consists of the following sub-criteria (*Level 2* criteria):

8.1. The nursing practice in the ward is theory-based. The department (nurses) has a formulated mission $OD_{i-1}(m_{OD_{i-i}}, \alpha_{OD_{i-1}}, \beta_{OD_{i-1}})$

8.2. Each patient has an assigned nurse responsible for his care and stay in the institution; the patient knows about it and experiences her role $OD_{i-2}(m_{OD_{i-2}}, \alpha_{OD_{i-2}}, \beta_{OD_{i-2}})$

8.3. The patient's condition was diagnosed on admission: physically, emotionally, mentally, and socially. The collected data and the results of the performed measurements are recorded in the documentation $OD_{i-3}(m_{OD_{i-3}}, \alpha_{OD_{i-3}}, \beta_{OD_{i-3}})$

8.4. The patient's nursing problems are recognized and recorded in the documentation $OD_{i-4}(m_{OD_{i-4}}, \alpha_{OD_{i-4}}, \beta_{OD_{i-4}})$

8.5. Care plan (goals, activities, methods, resources, deadlines, frequency of activities performed independently by the patient and by the nurse): is developed by the nurses, is developed together with the patient (family), is updated, has a written form accessible to the patient and not available for bystanders $OD_{i-5}(m_{OD_{i-5}}, \alpha_{OD_{i-5}}, \beta_{OD_{i-5}})$

8.6. The patient/family is involved in the care. Delivery of care, response to therapy, progress, and results are recorded $OD_{i-6}(m_{OD_{i-6}}, \alpha_{OD_{i-6}}, \beta_{OD_{i-6}})$

8.7. Cards: feverish, fluid balance, additional observational - carefully carried out. Reports: are carefully and accurately kept $OD_{i-7}(m_{OD_{i-7}}, \alpha_{OD_{i-7}}, \beta_{OD_{i-7}})$

8.8. Between each shift of duty: there is a report, a nursing round of the staffing of both changes, regular conferences in the ward on the quality of nursing $OD_{i-8}(m_{OD_{i-8}}, \alpha_{OD_{i-8}}, \beta_{OD_{i-8}})$

8.9. The patient's discharge is planned together (with him or his family). Adequate persons and institutions notified to ensure continuity of care $OD_{i-9}(m_{OD_{i-9}}, \alpha_{OD_{i-9}}, \beta_{OD_{i-9}})$

8.10. The nurse responsible for patient care cooperates with the treating physician, rehabilitator, and other specialists in the field of care for "his patient." $OD_{i-10}(m_{OD_{i-10}}, \alpha_{OD_{i-10}}, \beta_{OD_{i-10}})$

There are eight criteria in the presented model. Descriptive sub-criteria were assigned to each standard. To assess the quality, you can choose criteria and sub-criteria based on which the quality of the examined health center's nursing services will be evaluated. Randomly selected patients assess care. In the BOHIPSZO procedure, three variants of the assessment were adopted: YES, NO, NO REQUIREMENT. Individual criteria were estimated on a multi-point scale. The sum of all requirements was 240 points (100%). In the final stage, the overall nursing care factor is calculated, making it possible to compare the state of care provided to the level of care that the patient should receive. In the model presented in this article, it is assumed that a scale of 0 to 10 is used to assess nursing care in a health center, which enables a broader assessment taking into account the degree of meeting a given criterion. Because each sub-criterion consists of several factors presented in a descriptive form, the possibility of a range assessment expressing the assessment's uncertainty were taken into account [min; max]. In the proposed model, the possibility of taking into account the importance of individual criteria and sub-criteria is also used, if the person (team, institution) ordering the assessment differentiates the weight of unique criteria.

Once the scores against the selected criteria have been determined, the next step is to calculate each patient's final nursing care score. Depending on the purpose of the assessment, two (or more) health centers can be compared in

terms of nursing care - in the case of comparative analysis, or the level of care offered to the level of care that the patient should receive - achieving the maximum number of points for each of the sub-criteria adopted. On this basis, it will be possible to determine the strengths and weaknesses of the health center and deficiencies in the implementation of individual areas of nursing care. In the final stage of the assessment, a global evaluation of the quality of care is determined for the entire surveyed health center (or its unit).

Multi-criteria fuzzy model of nursing care quality assessment

In the presented model, it is assumed that *N* patients are involved in determining the ratings. The set of patients *P* is determined:

$$P = \{P_1, P_2, ..., P_i, ..., P_N\} \qquad i = 1, ..., N \tag{4}$$

The importance of groups of criteria (*Level 1* criteria) is given in the variable W_k (*k-Level 1* criteria). It is assumed that the importance of the requirements are set on the interval [0,1], which is related to the condition that the sum of the weights of the criteria expressed by the decision-maker must be 1.

$$\sum_{k=1}^{8} W_k = 1. \tag{5}$$

The Level 2 criteria' validity - *Level 1* sub-criteria is described by a variable W_{kj} (*k-Level 1* criterion, *j-Level 2* criterion). As in the *Level 1* criteria, the importance of the requirements is set at [0,1], and the sum of the weights of the criteria must be 1.

$$\sum_{j=1}^{J} W_{kj} = 1. \tag{6}$$

Below are the general rules for describing the assessment of the quality of care to individual sub-criteria using the fuzzy number of the *LR* type O_{ikj}, defined characteristic three $(m_{O_{ikj}}, \alpha_{O_{ikj}}, \beta_{O_{ikj}})$, where $\alpha_{O_{ikj}}, \beta_{O_{ikj}} > 0$ are fixed left and right scatter (range expressing uncertainty as to the precision of this term), $m_{O_{ikj}}$ is the determining value - the most expected or average calculated according to the formula:

$$o_{ikj}^{\text{mod}} = \frac{o_{ikj}^{\min} + o_{ikj}^{\max}}{2} \tag{7}$$

The *L* and *R* functions are fixed base functions described by the formula (2). Assessments o_{ikj} are treated as "around o_{ikj}^{mod}, "and the uncertainty as to the precise determination is expressed in the form of the limits of the range [$o_{ikj}^{\min}$, $o_{ikj}^{\max}$]:

$$L(o_{ikj}) = R(o_{ikj}) = \begin{cases} 0 & dla \quad o_{ikj} < m_{ikj} - \alpha_{O_{ikj}} \\ 1 - |o_{ikj}| & dla \quad m_{O_i kj} + \beta_{O_i kj} \geq o_{ikj} \geq m_{O_{ikj}} - \alpha_{O_i kj}, \\ 0 & dla \quad o_{ikj} > m_{O_{ikj}} + \beta_{O_{ikj}} \end{cases} \tag{8}$$

Because the value of qualitative assessments o_{ikj} is treated as the degree of care fulfillment for the *i*-th patient of a particular ideal state in the light of a given criterion, the value of these assessments should be normalized.

$$\hat{\alpha}_{O_{ikj}} = \frac{\alpha_{O_{ikj}}}{\max\ (m_{kj} + \beta_{kj})}, \tag{9}$$

$$\hat{m}_{O_{kji}} = \frac{m_{O_{ikj}}}{\max\ (m_{kj} + \beta_{kj})}, \tag{10}$$

$$\hat{\beta}_{O_{ikj}} = \frac{\beta_{O_{ikj}}}{\max\ (m_{kj} + \beta_{kj})}, \tag{11}$$

where $\max(o_{kj}^{\max})$ is the highest value among the lawful limits of patient care ratings for a given criterion $(m_{O_{kj}} + \beta_{O_{kj}})$. After normalization, the variables $\hat{\alpha}_{O_{ikj}}$ $\hat{m}_{O_{ikj}}$ i $\hat{\beta}_{O_{ikj}}$ are the new valid variables $m_{O_{ikj}}, \alpha_{O_{ikj}}, \beta_{O_{ikj}}$. The membership function of the care assessment *i* –patient concerning a given standard is as follows:

$$\mu_{O_{ikj}}(o_i) = \begin{cases} L\left(\dfrac{m_{O_{ikj}} - o_{ikj}}{\alpha_{O_i}}\right) & dla \quad o_{ikj} < m_{O_{ikj}} \\ 1 \quad dla \quad o_{ikj} = m_{O_{ikj}} & \\ R\left(\dfrac{o_{ikj} - m_{O_{jkj}}}{\beta_{O_{ikj}}}\right) & dla \quad o_{ikj} > m_{O_{ikj}} \end{cases}. \tag{12}$$

When normalized scores against *the Level 2* criteria are defined, care scores against the higher tier criterion (*Level 1*) can be defined as the sum of scores for each standard within a given group (if you include criteria weights, define a weighted assessment of patient care within each group).

Assuming that O_{igj} it is the assessment of care against *the Level 2* criterion, determined by the characteristic three $(m_{O_{ikj}}, \alpha_{O_{igj}}, \beta_{O_{igj}})$, the final assessment against *the Level 1* criterion O_{ik} is as follows:

$$O_{ik} = \frac{\sum_{j=1}^{J} W_{kj} \cdot O_{ikj}}{\sum_{j=1}^{J} W_{kj}}. \tag{13}$$

Since O_{ik} it is an assessment of care against *the Level 1* criterion, the defined characteristic Tyree $(m_{O_{ik}}, \alpha_{O_{ik}}, \beta_{O_{ik}})$, the final evaluation of respect for the *i*-th patient against the global standard O_i is as follows:

$$O_i = \frac{\sum_{k=1}^{K} W_k \cdot O_{ik}}{\sum_{k=1}^{K} W_k}. \tag{14}$$

This operation assigns each patient in the *P* set a fuzzy score against the worldwide criterion. The next step of the algorithm is defuzzification, i.e., determining the fuzzy evaluation's real number. This paper proposes the center of gravity method:

$$O_i = \frac{3 \cdot m_i - \alpha_i + \beta_i}{3}. \tag{15}$$

At this stage, the strengths and weaknesses of nursing care can be identified in detail.Based on the received nursing care ratings for individual patients, the overall nursing care rating for a given unit of a health facility can be determined according to the formula:

$$O = \frac{\sum_{i=1}^{N} O_i}{N}. \tag{16}$$

Based on the received assessment of a given health center's care, a comparative analysis of the obtained results of various units can be made. The higher the rating value, the higher the positive opinion a given center receives.

Assuming the above general model and the designation of fuzzy variables representing the assessments of nursing care by individual patients, we proceed to the first step, i.e., the membership function's determination for the reviews against *the Level 2* criterion. For example, for *the Level 2* criterion –"Electrical, gas, and oxygen installations, apparatus does not endanger the patient, the patient is instructed on safe behavior, warning notices are placed"described the formula describes fuzzy variable membership function:

$$\mu_{S_{ikj}}(s_i) = \begin{cases} L\left(\dfrac{m_{S_{ikj}} - s_{ikj}}{\alpha_{s_i}}\right) & dla \quad s_{ikj} < m_{s_{ikj}} \\ 1 \quad dla \quad s_{ikj} = m_{S_{ikj}} & \\ R\left(\dfrac{s_{ikj} - m_{S_{jkj}}}{\beta_{S_{ikj}}}\right) & dla \quad s_{ikj} > m_{S_{ikj}} \end{cases}. \tag{17}$$

Similarly, we define the membership function for the grades against the subsequent *Level 2* criteria.

The next step is to normalize the assessments determined by patients based on*the Level 2* criteria. For example, for *the Level 1* criterion - "Safety"and the first sub-criterion " Electrical, gas, and oxygen installations, devices do not pose a threat to the patient, the patient has been instructed on safe behavior, warning notices are placed"the described variable $S_{i-1}(m_{S_{i-1}}, \alpha_{S_{i-1}}, \beta_{S_{i-1}})$ normalization is as follows:

$$\hat{\alpha}_{S_{i-1}} = \frac{\alpha_{S_{i-1}}}{\max(m_{S_{k1}} + \beta_{S_{k1}})}, \tag{18}$$

$$\hat{m}_{S_{i-1}} = \frac{m_{S_{i-1}}}{\max(m_{S_{k1}} + \beta_{S_{k1}})}, \tag{19}$$

$$\hat{\beta}_{S_{i-1}} = \frac{\beta_{S_{i-1}}}{\max(m_{S_{k1}} + \beta_{S_{k1}})}, \tag{20}$$

where $\max(m_{S_{k1}} + \beta_{S_{k1}})$ is the highest value among the lawful limits of patient care ratings under the criterion specified in 1.1.: $(m_{S_{k1}} + \beta_{S_{k1}})$. After normalizing, the variables $\hat{\alpha}_{S_{i-1,k1}}$, $\hat{m}_{S_{i-1,k1}}$ i $\hat{\beta}_{S_{i-1,k1}}$ are the new valid variables $m_{S_{i-1,k1}}, \alpha_{S_{i-1,k1}}, \beta_{S_{i-1,k1}}$. We formalize the grades in the same way against all *Level 2* criteria.

When normalized scores against *Level 2* criteria are defined, care scores against a higher tier criterion (*Level 1*) can be defined as the sum of scores for each standard within a given group (if you include criteria weights, define a weighted assessment of patient care within each group). And so, the judgments against *the Level 1* criteria are as follows:

1. Safety

$$S_i = \frac{W_{1,1} \cdot S_{i-1} + W_{1,2} \cdot S_{i-2} + W_{1,2} \cdot S_{i-3} + W_{1,4} \cdot S_{i-4} + W_{1,5} \cdot S_{i-5} + W_{1,6} \cdot S_{i-6} + W_{1,7} \cdot S_7}{\sum_{j=1}^{7} W_{1j}}. \tag{21}$$

2. Protection against infections

$$PAI_i = \frac{W_{2,1} \cdot PAI_{i-1} + W_{2,2} \cdot PAI_{i-2} + W_{2,2} \cdot PAI_{i-3} + W_{2,4} \cdot PAI_{i-4} + W_{2,5} \cdot PAI_{i-5}}{\sum_{j=1}^{8} W_{2j}} +$$

$$+ \frac{+ W_{2,6} \cdot PAI_{i-6} + W_{2,7} \cdot PAI_{i-7} + W_{2,8} \cdot PAI_{i-8}}{\sum_{j=1}^{8} W_{2j}}. \tag{22}$$

3. Hotel services and meeting your needs

$$HSMN_i = \frac{W_{3,1} \cdot HSMN_{i-1} + W_{3,2} \cdot HSMN_{i-2} + W_{3,2} \cdot HSMN_{i-3} + W_{3,4} \cdot HSMN_{i-4} + W_{3,5} \cdot HSMN_{i-5} + W_{3,6} \cdot HSMN_{i-6}}{\sum_{j=1}^{12} W_{3j}} +$$

$$+ \frac{W_{3,7} \cdot HSMN_{i-7} + W_{3,8} \cdot HSMN_{i-8} + W_{3,9} \cdot HSMN_{i-9} + W_{3,10} \cdot HSMN_{i-10} + W_{3,11} \cdot HSMN_{i-11} + W_{3,12} \cdot HSMN_{i-12}}{\sum_{j=1}^{12} W_{3j}} \tag{23}$$

4. Information

$$I_i = \frac{W_{4,1} \cdot I_{i-1} + W_{4,2} \cdot I_{i-2} + W_{4,2} \cdot I_{i-3} + W_{4,4} \cdot I_{i-4} + W_{4,5} \cdot I_{i-5}}{\sum_{j=1}^{5} W_{4j}}. \tag{24}$$

5. The subjectivity of the patient

$$SP_i = \frac{W_{5,1} \cdot SP_{i-1} + W_{5,2} \cdot SP_{i-2} + W_{5,2} \cdot SP_{i-3} + W_{5,4} \cdot SP_{i-4} + W_{5,5} \cdot SP_{i-5}}{\sum_{j=1}^{10} W_{5j}} +$$

$$+ \frac{W_{5,1} \cdot SP_{i-6} + W_{5,1} \cdot SP_{i-7} + W_{5,1} \cdot SP_{i-8} + W_{5,1} \cdot SP_{i-9} + W_{5,1} \cdot SP_{i-10}}{\sum_{j=1}^{10} W_{5j}} \tag{25}$$

6. Self-care

$$SC_i = \frac{W_{6,1} \cdot SC_{i-1} + W_{6,2} \cdot SC_{i-2} + W_{6,2} \cdot SC_{i-3} + W_{6,4} \cdot SC_{i-4} + W_{6,5} \cdot SC_{i-5} + W_{6,6} \cdot SC_{i-6}}{\sum_{j=1}^{6} W_{6j}}. \tag{26}$$

7. Healing and beauty treatments

$$T_i = \frac{W_{7,1} \cdot T_{i-1} + W_{7,2} \cdot T_{i-2} + W_{7,2} \cdot T_{i-3} + W_{7,4} \cdot T_{i-4} + W_{7,5} \cdot T_{i-5} + W_{7,6} \cdot T_{i-6}}{\sum_{j=1}^{13} W_{7j}} +$$

$$+ \frac{W_{7,7} \cdot T_{i-7} + W_{7,8} \cdot T_{i-8} + W_{7,9} \cdot T_{i-9} + W_{7,10} \cdot T_{i-10} + W_{7,11} \cdot T_{i-11} + W_{7,12} \cdot T_{i-12} + W_{7,13} \cdot T_{i-13}}{\sum_{j=1}^{13} W_{7j}} \tag{27}$$

8. Organization and documentation

$$T_i = \frac{W_{8,1} \cdot T_{i-1} + W_{8,2} \cdot T_{i-2} + W_{8,2} \cdot T_{i-3} + W_{8,4} \cdot T_{i-4} + W_{8,5} \cdot T_{i-5}}{\sum_{j=1}^{10} W_{8j}} +$$

$$+ \frac{W_{8,6} \cdot T_{i-7} + W_{8,6} \cdot T_{i-8} + W_{8,8} \cdot T_{i-9} + W_{8,9} \cdot T_{i-10} + W_{8,10} \cdot T_{i-10}}{\sum_{j=1}^{10} W_{8j}} \quad (28)$$

Since the quality of care ratings o_{ik} are treated as the degree of fulfillment of care for the *i*-th patient of a specific ideal condition in light of a given criterion, these ratings' values should be normalized. For example, for *the Level 1* criterion - "Safety," standardization is carried out according to the following formulas:

$$\hat{\alpha}_{S_i} = \frac{\alpha_{S_i}}{\max(m_S + \beta_S)}, \quad (29)$$

$$\hat{m}_{S_i} = \frac{m_{S_i}}{\max(m_S + \beta_S)}, \quad (30)$$

$$\hat{\beta}_{S_i} = \frac{\beta_{S_i}}{\max(m_S + \beta_S)}, \quad (31)$$

where $\max(m_S + \beta_S)$ is the highest value among the legal limits of patient care ratings under the "Safety" criterion $(m_S + \beta_S)$. After normalization, thevariables $\hat{\alpha}_{S_i}$ $\hat{m}_{S_i}$ i $\hat{\beta}_{S_i}$ are the new valid variables $m_{S_i}, \alpha_{S_i}, \beta_{S_i}$ In the same way, we normalize the scores against all *Level 1* criteria.

After normalizing the scores against *the Level 1* criteria, you can define the care scores against the global standard as the sum of scores for each measure (if you include the criteria weights, specify a weighted score for patient care). Because O_{ik} is the assessment of care against *the Level 1* criterion,criterion, the determined characteristic three $(m_{O_{ik}}, \alpha_{O_{ik}}, \beta_{O_{ik}})$, the final evaluation of respect for the *i*-th patient against the global standard O_i is as follows:

$$O_i = \frac{W_1 \cdot S_i + W_2 \cdot PAI_i + W_3 \cdot HSMN_i + W_4 \cdot I_i + W_5 \cdot SP_i + W_6 \cdot SC_i + W_7 \cdot T_i + W_8 \cdot OD_i +}{\sum_{k=1}^{8} W_k}. \quad (32)$$

The above action assigns each patient in the *P* set a fuzzy nursing care score against the global criterion. The next step in the evaluation procedure is defuzzification, determining the actual number of fuzzy evaluation. In this study, the center of gravity method described by the formula was adopted:

$$O_i = \frac{3 \cdot m_i - \alpha_i + \beta_i}{3}. \quad (33)$$

At this stage, the strengths and weaknesses of nursing care can be identified in detail. It is critical information for the managers of a given health unit.

Based on the nursing care ratings received for individual patients, the overall nursing care rating for a given unit of a health facility can be determined according to the formula:

$$O = \frac{\sum_{i=1}^{N} O_i}{N}. \quad (34)$$

Based on the received assessment of a given health center's care, a comparative analysis of the obtained results of various units can be made. The higher the rating value, the higher the positive opinion a given center receives.

Summary

It seems justified to create quality teams as an indispensable element of ensuring the changes introduced in providing high-quality nursing care. High quality affects the competitiveness of a given health center and its excellent image. It is a testimony to the high level of a given unit among other medical service providers. Each health care unit should strive to obtain the highest possible level of quality of services provided. Systematic estimation of the quality of nursing care provided is an indispensable element. Its deficiencies should be the basis for developing a corrective plan and introducing changes and improvements to improve nursing care quality.

Abstract

The lack of women's participation in top management positions is illustrated by the level of involvement that has eroded and the increase in jobs (Huang, Krivkovich, Starikova, Yee, and Zanoschi, 2019). The participation of women at higher levels or strategic positions in the company becomes essential because of the benefits it brings; in terms of social, political, and economics. Researchers want to explore how the Broken Rung phenomenon participates as a cause of Female Leadership Deficit in Indonesia. This study used a qualitative method with the Phenomenology approach. Retrieval of research data by conducting semi-structured in-depth interviews. Research analysis consists of four stages of coding, including open coding, axial coding, selective coding, and process coding. This research concludes that the Broken Rung is not found in Indonesia because before its system was unfair to females, there were already a few females in specific industries. The findings show that it happens due to job/industry stereotyping and self-discrimination by female itself.

Keywords: Broken Rung, Female Leader, Leadership, Gender Equality

Introduction

Based on data from Worldometers (2020), the difference between male and female population is only 0.8%, which means the number of the female population is not much different from the number of the male population. However, in terms of the involvement of women in various productive sectors in the world, women then become a minority, resulting in a significant gap when compared to the participation of men in the same industry. In Indonesia, male labor force participation is 83.9%, and female labor force participation is 54.3% (World Economic Forum, 2019). While the participation rate of women at work continues to increase, the quality of women's involvement in work also needs to be improved. Indonesia ranks 115 out of 152 countries in the category of the labor force participation rate and 112 of 152 in the professional and technical workers category (World Economic Forum, 2019).

The lack of women's participation in top management positions is illustrated by the level of involvement that has eroded and the increasing level of jobs. According to data from Huang et al. (2019), women comprise 48% of entry-level professional staff, and the number decreases with middle and high management positions. Women occupy only 38% of middle-level management positions, and then only 21% enter leadership-level (c-level). The involvement of women in strategic positions is one of the targets to be achieved globally through The Sustainable Development Goals (SDGs) or commonly known as Global Goals in 2015. This target reads:

"Ensure women's **full and effective participation and equal opportunities for leadership at all levels of decision-making** in political, economic, and public life" (Nations, 2015).

According to Desvaux, Devillard, Labaye, Sancier-Sultan, Kossoff, de Zelicourt, and Barton (2017), if every country in the world can close the gender gap, global GDP growth in 2025 may increase to $12 trillion. Indonesia also can

increase GDP to $135 billion if more women are involved in the productive sector. Research from Powell and Butterfield (2015) shows the importance of having women in strategic positions so that women at lower levels can successfully overcome challenges in their careers. Research from Moreno-Gómez, Lafuente, & Vaillant (2018) said that the representation of women in top management positively affects the company's Return on Assets and Return on Equity.

Gender diversity initiatives have been echoed by leading companies, and not a few female employees have been given opportunities in middle and top-level management. However, women still cannot make it to the top of their careers. There is an opinion that says that the phenomenon of Female Leadership Deficit is rooted in the lack of promotion systems in the company, known as "Broken Rung." This study wants to explore how Broken Rung participates in the Female Leadership Deficit, what factors play a role and how to overcome this phenomenon so that Indonesia can utilize the benefits and maximize the potential that exists from the presence of more female leaders in the company's strategic position (Huang et al., 2019).

Literature Review

Female Leadership and Distributive Justice Theory

Leadership is identified and classified in personal, organizational, and cultural contexts (Howell & Costley, 2006). The definition of leadership varies according to place, social background, work environment, type of industry, and gender (Muna, 2011; Wang, Oh, Courtright, and Colbert, 2011). In the context of gender, psychologists argue that the differentiation of gender roles in human society is based on traits that can be inherited genetically (Buss & Schmitt, 2011). Social role theory (Eagly, 1987) argues that since infancy, boys and girls are subject to different rewards and sanctions. So that women and men in leadership are two different things. The natural state of women, which allows them to conceive, is a limitation on the contribution of women in economic terms compared to men (Wood & Eagly, 2002). Gender is a cultural reference that helps people build and maintain relationships with others. The status of men and women develops into a hierarchy where men are considered more suitable to be leaders.

Women are often categorized as having a transformational leadership style. Some authors even refer to it as "the feminine leadership style" (Chao, 2011; Carless, 1998). Ridgeway (2011) shows that women tend not to be leaders in an environment that consist of a mixture of men and women (Eagly & Karau, 1991), face the problem of legitimacy (Ritter & Yoder, 2004) and get a rougher evaluation when their effectiveness is being questioned (Eagly, Makhijani, and Klonsky, 1992).

Leadership in the gender context illustrates that there are differences between leadership carried out by men and women. The difference in question is how a woman who leads is assessed, treated, and considered different from men, so that in the future, the opportunities that are obtained, the access they have, and the outcome/output produced will also be different (Ridgeway, 2011). This inequality refers to the theory of distributive justice. Distributive justice refers to individual perceptions of whether resource allocation is fair (Greenberg, 1990). Equity theory posits that individuals compare their output/input ratios (Adams, 1963). The output comprises the factors that individuals receive in exchange for investing themselves in their work. Input, on the other hand, refers to situations in which individuals invest themselves. The ideal situation is for individuals to perceive that their ratio is identical to that of others. The differences between gender often reflect injustice and inequity, which, in this context, leads to gender inequality.

The most basic demand for justice is equal treatment of all people in the same situation. Women in leadership positions in companies have fought to achieve gender equality. The United Nations Sexual and Reproductive Health Agency (UNFPA) describes gender equality as the same pleasure/benefit received by women and men for goods, opportunities, resources, and awards. Gender equality does not mean that women are equal to men, but that access to opportunities and changes in life does not depend on or limited by gender. With the explanation above, gender equality needs to be achieved. From the research, there are still inequalities in the enjoyment/benefit of women and men for goods, opportunities, resources, and awards received.

Broken Rung

The initial theory to understand how women develop to achieve leadership positions is explained by Ragins and Sundstrom (1989), they differentiate factors at four levels of analysis, namely social, organizational, interpersonal, and individual. At the individual level, women must have many skills and abilities to become leaders. They must also have a good relationship with their subordinates and co-workers (interpersonal level). Not only that, although women may have good skills and relationships with subordinates, they may face challenges in selection and promotion

(organizational level). Lastly, the social level concentrates on factors such as how people stereotype women's roles (Peus et al., 2015).

At the organizational level, women face recruitment and promotion challenges. This is what the study starts with. The term Broken Rung was first used by Huang et al. (2019) in a report titled "Women in The Workplace 2019" by LeanIn.org & McKinsey & Company. The Broken Rung is said to be the initial cause of a woman's obstacle to occupy a strategic position in the company. The barriers that come from the company promotion system or "Corporate Ladder" are not friendly with female employees' ability to rise to a higher position in the company. Out of every 100 men promoted and employed as managers, only 72 women are promoted and employed as managers (Huang et al., 2019).

The Broken Rung then produces more women who are trapped at the initial managerial level, and fewer women become managers. Therefore, it is not surprising that men end up holding 62% of manager-level positions, while women only hold 38% of positions at the same level (Huang et al., 2019). Because there are far more men than women at the managerial level, fewer women will be employed or promoted to senior managers. The number of women decreases at each subsequent level (Lange, Wodon, and Carey, 2018).

The initial allegation of many women not being in the top position of the company is due to the "opt-out" phenomenon. That is a situation when many women leave the company because they prefer to take care of other things that are considered critical, such as household affairs. Women do not leave companies with higher rates than men. Only less than 2% of female employees plan to leave the workforce to focus on the family; the rest leave to work elsewhere (Huang et al., 2019).

Another problem with this obstacle is that there are only a few companies that are aware of The Broken Rung barriers. This is indicated by the low awareness of the company's HR to provide support for female employees to pursue their careers (Huang et al., 2019).

The Broken Rung focuses more on the causes of problems that are in the company's promotion system. This is because the companies are not aware of the importance of women's representation at the initial managerial level. Companies are satisfied with the number of representations of their female employees at the initial managerial level (Huang et al., 2019). Karam and Afiouni (2014) argue that the roots of individual gendered behaviors and actions lie not only within organizations but also in societies and institutional mechanisms outside of organizations. Hence we try to explore the cause of the female leadership deficit in Indonesia through the organization dimension (particularly, Human Resource Management) as a start point.

Research Method

This study uses a qualitative approach with consideration of topics and research objectives. This qualitative research uses the Phenomenology approach. That is an approach where researchers focus on finding meaning from individual life experiences related to a phenomenon. Then the researchers interpret individual social actions as something that has meaning and has something to do with the phenomenon being studied (Creswell, 2009). The method used in this approach is an in-depth-semi-structured interview. A semi-structured interview itself is an interview where the question and answer session are conducted more flexibly and openly. In choosing research subjects, researchers use a purposive and snowball sampling. The number of research subjects on the purposive and snowball methods is often determined based on theoretical saturation, which is a point where the information obtained no longer provides additional information on the research question. Data on the study did not provide additional information/saturated to the 24th respondent. Twenty-four interviews were conducted with female leaders in their company and human resource managers (Table I). Respondents came from diverse industries.

In analyzing qualitative research, there are at least four stages that can be done to get the results of the research. These stages are open coding, axial coding, selective coding, and process coding (Corbin and Strauss, 2014). These four stages are not rigid and linear, but rather a stage that can be worked on repeatedly.

Before conducting interviews with respondents, a pilot test was conducted with fellow researchers. To guarantee the Internal Validity of this study, researchers used the source triangulation and investigator triangulation. These triangulations are used by using research sources from various reference journals and researches evaluated by external parties. To strengthen the data, researchers provide what is often referred to as "thick description." The thick description (Davis, 1991) is a comprehensive explanation related to the questions that will be asked to the research subject to be understood thoroughly by the research subjects. Reliability of research can be guaranteed using the audit trail, where an auditor checks the information obtained and the methods used in the study (Lincoln and Guba, 1985).

Conformability of the research refers to how much the research results can be confirmed and corroborated by other parties so that this study presents pieces of interview transcripts that are relevant to the topic being discussed (Wahyuni, 2016).

Respondent Profile

The results of this study were taken from 24 respondents who had different backgrounds, industries, and company scopes. In the findings and analysis section, the respondents are divided into high-level employees (female leaders) and middle-level employees. The status of female employees is also divided into single, married and having children, married and not having children, and divorced. The industries of the respondents in this study are not limited, so that from the data above, it can be seen that the existing industries are very diverse. Overall, four respondents are in the technology industry in various fields, for example, finance, textiles, education, to health. In addition to the technology industry, the fast-moving consumer goods (FMCG) industry was also filled by four respondents in this study. Furthermore, the industries, each of which has three respondents, include social and creative media. Meanwhile, there are two respondents each, including mining and island tourism (diving). The rest are diverse industries, and there is only one respondent's representative, namely conventional finance, oil and gas, insurance, mental health, skin health, and transportation. The respondents' length of work experience ranged from 3-27 years. This is understandable because most of the respondents have occupied upper managerial positions, which require much time. Finally, the scope of the company is divided into national and multinational companies. In the findings and analysis, there is no difference between the two company scopes. In both national and multinational companies, women experience obstacles in their respective organizations, which hinders their career advancement in each industry. As for the explanation of the respondent's profile is summarized in the following table:

Table 1: Respondent's Profiles

R	Age (years)	Status	Position	Industry	MNC/National Company	Experience (years)
R1	38	Married, two kids	CEO	Technology	National Company	19
R2	30	Single	Dive Center Manager	Tourism	National Company	6
R3	27	Married	Professional Health and Hygiene Coordinator	Mine	National Company	7
R4	36	Single	Branch Manager	Beauty	National Company	13
R5	30	Single	Executive Editor	Media	MNC	10
R6	24	Single	Founder & CEO	Mental Health	National Company	4
R7	30	Single	Program coordinator	Social	National Company	5
R8	24	Single	CEO and Founder	Garment Technology	National Company	4
R9	29	Single	Operational Head	Basic Needs	National Company	10
R10	38	Married, one kid	General Manager	Digital Agency	National Company	17
R11	43	Married	VP of Strategic Planning & Corporate Management	Oil and Gas	National Company	20
R12	37	Single	Construction Director	Public Transportati on	National Company	12
R13	51	Married	HR Lead	Food	MNC	25

R	Age (years)	Status	Position	Industry	MNC/National Company	Experience (years)
R14	28	Single	Assistant Manager	Tourism	National Company	6
R15	29	Single	Head of Digital	Media	National Company	7
R16	45	Married, four kids	Executive Director	Social	MNC	22
R17	45	Divorce, two kids	Head of Human Capital Policy	Mine	National Company	20
R18	47	Single	Executive Director	Business Coalition	National Company	27
R19	41	Married	Director of Fundraising	Social	MNC	17
R20	26	Single	Business Development	Micro Finance	MNC	8
R21	29	Married	HR Manager	FMCG	MNC	6
R22	32	Married, one kid	HR Leader	Fintech	National Company	10
R23	26	Single	HR Executive	Insurance	National Company	3
R24	30	Single	HR Business Partner	FMCG	MNC	7

Research Result

From the interview, the respondents gave positive responses to the female leader. Not only assuming that women can be good leaders, but most respondents (14 out of 24 respondents) also say women can be good leaders because women have specific characteristics not possessed by men, such as being mothers to create particular abilities.

> In some aspects, women are better than men because we have differences. We are a better listener, we have better intuitive, we are more perseverant, we are more patient, so sometimes we can be better leaders in inspiring other people. Women can be good leaders because women have characteristics that may not be owned by men (Respondent 12)

> Precisely one of the advantages of women is multitasking because we have been trained since childhood. For example, we have to take care of the family and the company, and it is parallel (Respondent 11).

On the question "how can one be a good leader" and its description, researchers refer to several theories of the division of the nature of leaders divided into feminine and masculine (Williams and Best, 1990). The result is that the respondents mention the feminine nature of being able to listen, to have empathy, to protect their subordinates, and to have a service nature. Respondents also mentioned masculine characteristics such as being responsible, providing clear direction to their subordinates, and having good time management skills.

However, respondents mentioned that the nature of leadership is neutral (apart from the feminine and masculine nature), including being able to give an example to subordinates, can create other leaders, be able to move others to achieve common goals, and have an influence where they are on. The neutral attitude shown by the respondents is reflected when answering the question "can a woman be a good leader?" respondents have the view that good leaders do not have a relationship with their gender.

> I do not see any difference. Leadership is not a sex linkage. Other factors are about our character, our knowledge, our competence (Respondent 1)

A total of 11 respondents in this study determined the figure of women as leaders who had lots of personal influences on them. A total of 6 of respondents set the figure of a mother as a true leader who became a role model and gave many lessons:

> My mom works and takes care of the household. We do not have helpers. My mom told me that women must be able to work to have our own income, and we are not being underestimated (Respondent 4).

The figure of a man also becomes a leader and role model that influences the respondents. Six respondents mentioned men as leaders who gave personal influence; 3 of them mentioned the figure of fathers as true leaders:

> ... from my father, because my mom is just a housewife, so automatically I see the leader as my father. It is also because I am close to my father. Mostly if you talk about work, usually we want to tell the story to the person who also works (Respondent 9)

Although the views on women leaders are progressive, some views are still obstacles for women leaders, one of which is the view that leaders should not be women. In certain places or contexts of society, the views of women leaders cannot be separated from the role of women as a mother or a wife.

> Because people still think men should lead. You are a woman, and you want to lead, what's the proof? What have you done? So, we have to show and give proof that we are right. Because it is not enough for men, we have to be more than that. Because even our efforts will be considered less, so it must be more so that it can be seen as equal (Respondent 9).

> There is a double standard for women. It is assumed that women will be successful if the household life is successful (Respondent 12).

Female leaders will also be considered flawed if it is proven to fail to separate their personal and professional affairs, where the female leader, in this case, does have a dual role as a leader and also a wife/mother. The female leader will also be judged poor because of the system she passed as a leader so that when her performance is low, the system/rules will be criticized.

> The bad thing is that, what is forced, leaders must be female because this is the share of females, only for diversity, so there must be females without even seeing their competencies. Right now, some companies must have at least several females, so they were accepted just for the sake because they are females and it does not fair. She got the position, there is a privilege for female (Respondent 1).

Broken Rung

Broken Rung focuses on how companies realize the importance of gender equality in middle and upper-level managerial positions. In addition to awareness, the company's satisfaction with its performance to achieve gender equality can also be seen from the statements of the respondents.

In mid-level managerial positions, 11 companies are dominated by female employees and 7 companies that are dominated by men. Whereas at the top managerial position, 8 companies are dominated by women, and 12 companies are dominated by men. The rests of the gender proportion at each level are equal.

Awareness of the importance of gender equality is one of the keys to achieve gender equality itself. At the middle level, as many as 13 companies said they were aware of the importance of gender equality, however this was not / had not been achieved due to other factors beyond the respondents' control.

> in my opinion, there are still many men (in this company). Because back to the island culture, men are the ones who work, women stay at home. This industry is also specific (tourism, diving), so it cannot be equated with banking, for example (Respondent 3).

Because there are factors beyond the control of the respondent that cause the absence of gender equality in middle-level managerial positions (especially in certain industries), so that makes the respondent feel "satisfied" or surrender to the conditions that exist in the field:

> My work is indeed a male-dominated world. Not many women want to study geology or metallurgy, how many women studies engineering? Well, if only a few women studied so what is in the world of work? So, to enlarge the ratio, it must be from an early age, from the STEM, from the beginning it has been taught that it is not gendered biased (Respondent 17).

Meanwhile, there are still companies whose mid-level are dominated by men, and do not make gender equality something that needs to be considered:

> I think it's normal (middle-level proportions dominated by men) because in my company alone it doesn't feel like, "oh the manager must be a man, oh the manager must be a woman". still reasonable because in my opinion, if you want to be a leader then you try (Respondent 22).

Companies that are not sensitive to gender equality, especially at the middle managerial level, stated that other factors cause the least participation of women:

> As a company, there are no gender-related policies, evenly. Usually, those who are intimidated are women, there are those who don't want to get promoted because for example, they cannot share time with family, when they are needed, they cannot fulfill that. So, the limitation is indeed on the person, not on the system (Respondent 11).

In top managerial positions, 12 companies have realized the importance of gender equality. A total of 7 of them are companies with a top-level dominated by women. As for the causes of not achieving gender equality at the top managerial level because there are other factors beyond the control of the respondent/company:

> It is not because I set the companies to have more women, but rather the fields of companies are related to mental health, and maybe because there is a stigma that mental health is more feminine, so it attracts those who have a feminine side (Respondent 6).

According to some respondents, this is because from the beginning the availability of female human resources was not much, especially in certain industries:

> Actually, at that time, because there were not many women who could fulfill the position. Because the mining industry has more operations which are clearly for men, so it goes down more and more ... the portion is a lot of work for men (Respondent 2)

Unconsciousness of the importance of gender equality in managerial positions over those dominated by men is also caused by social views of men and women themselves:

> If that proportion is true, I think it's still reasonable because it goes back to stigma and, and maybe yes I'm not saying that, for example, a woman has poor education, no, but as a man they already has a faith: "you should be able to advance yourself, you have to be successful", that's what happens in Indonesian society, right? Like as a man, "you have to be more advanced" (Respondent 22)

One respondent whose company has achieved gender equality in a mid-level managerial position stated the challenges faced by the company to achieve gender equality as a whole:

> Almost every company is around that (gender equality) because that's the standard now. At the engineer-level, we already have 47% female. At the entry-level, it's already 50:50. The next challenge is how we can retain them, so it is about grooming, developing them from the start. Therefore, they can go up the positions fairly. The company can provide that, but at the same time, if they still have a problem with their family, where they have to prioritize certain aspects it might be something that we might not be able to help that much, because it's their choices (Respondent 12).

Discussion

The researchers discuss how the findings above contribute to the phenomenon of Female Leadership Deficit, what factors play a role and how to overcome the phenomenon. A report entitled "Women in The Workplace 2019" by LeanIn.org and McKinsey & Company states that Broken Rung is the initial cause of a woman's obstacle to being able to occupy a strategic position in her company. The main problem is the employee promotion system in companies that are not friendly to the career advancement of a female employee so that there are only a few and there will be fewer women who occupy top-level positions. Broken Rung is illustrated by the low awareness of the company about the importance of gender equality at every career level. Companies that are not aware of the importance of gender equality are also easily satisfied with women's representation at every career level even though the numbers have not been equal.

The findings in this study indicate another matter. More than half of the respondents' companies have realized the importance of gender equality at every career level. However, from 24 companies, there are only 4 companies that have achieved gender equality at each managerial level. Companies that have not yet achieved gender equality but are aware of the importance of the matter stated that this happened because of stereotypes in certain industries. In the companies with a majority of women employees, the industry is considered to be a feminine industry, such as the beauty and mental health industries while the majority of male companies are companies in industries that are closely related to masculinity such as oil and gas, technology, and remote island tourism. This is supported by the findings of Tomoko Adachi (2013) that the ratio of jobholders is strongly associated with gender stereotypes of work. The results of Tomoko Adachi (2013) then support the findings of Gottfredson (1981) that job drawings tend to reflect the actual work and that the sex of the worker is the most prominent work attribute in shaping the job description. The results also coincide with findings from Glick, Wilk, and Perreault (1995) who found the gender ratio is one important component of the sex factors, and findings from Kulik (1999), who reported that the sex of the job was based on perceptions of distribution of man and woman employees in each occupation. This shows that the formation of job gender stereotypes is based on the perceived ratio between men and women in certain jobs.

In the study which examined bias in determining candidacy for leadership positions, Garcia-Retamero and López-Zafra (2006) found that when the candidate is female, and the industry is not congruent with her gender role, decision-makers manifest prejudice in selection. Mulvaney, O'neill, Cleveland, and Crouter (2007) argue that the contradictions between typical female role (i.e. staying at home and taking care of others) and typical employee role (i.e. spending time outside the home) may adversely affect women's career advancement. It's finally resulting only few female in certain industry (male dominated industry).

Not only are there a small number of women in the masculine industry, but a small number of men in the feminine industry are also caused by gender stereotypes of the job itself. If it focuses on the lack of female leaders, then the cause is the number of female workers in industries that are considered to be masculine is still very small. The discrimination that often occurs in respondents in this study is "self-discrimination" when entering and in jobs where women "choose" certain jobs. Women often decide not to apply for certain positions because they anticipate discrimination or they are socialized to believe that the traditional division of labor is true. This also happens in the education field, where women often discriminate themselves with several majors that are not under their gender stereotypes, engineering majors, for example. Whereas forms of direct discrimination tend to benefit men in recruitment, provision of training, promotions, types of contracts, and wage rates.

Therefore, one of the causes of the small number of women leaders is that the number of female workers is still small. This often happens in industries with masculine stereotypes. Evidently, according to the presentation from Debbie Chastity, Vice President and General Counsel of PT Chevron Pacific, based on statistics, Chevron has a total workforce of 3,500 people, but they only have 11% of women. This is why even though the company has realized the importance of gender equality by having rules and facilities for gender equality in its system, gender equality will not be achieved because the number of women since entry-level alone is not the same as the number of men.

There are complicated reasons why women seem not to "break the ceiling" or seem to accept obstacles that prevent them from getting those promotions. This attitude can also result from self-discrimination in order to avoid deeply rooted social discrimination (Anker, Richard Melkas, & Helina Korten, 2003). This creates women to be more reluctant to enter the industry which they consider to be masculine. This then creates only a small number of female workers in industries that are considered to be masculine/male dominated industries.

According to Bola Adesola, CEO of Standard Chartered Bank Nigeria (Desvaux et al., 2017), often it is the thoughts that exist in women themselves that prevent them from doing more in their careers. This may be formed due to the influence of "reality" or external factors experienced by women themselves, but unfortunately, women seem to "accept" all the reality or assumptions that exist in the socio-cultural community (Desvaux et al., 2017). Therefore, the most important way that must be done to overcome this phenomenon is to reset what is in the women's mindset. Women must be confident that they have the same abilities and opportunities as men. This has been proven by the respondents who managed to be in the top managerial positions. They recognize that internal obstacles become challenges in their careers, but they have a strong mindset that women are the same as men, have the same abilities and opportunities, as long as they also have strong ambition and motivation.

Conclusion

Female and its many potentials and advantages are still facing the obstacle to get to the top position. It is because there are only a few female leaders in organizations responsible for strategic and decision-making roles. Like a domino effect, this situation will make females, especially in male dominated-worlds, not being represented in which

their needs and voices are seldom to be heard, and it will not be changed if there are still few females in top positions. Broken Rung which is mentioned as one of the causes of this phenomenon is not found in the findings.

The respondents' companies were already aware of the importance of gender equality. The broken rung is not founded because before the companies had a promotion system that was unfriendly to the female employees, the females themselves were indeed not available in certain industries, which resulted in the company inevitably having only a few females occupying the top managerial position in the male-dominated industry. The most basic internal factor is the result of self-discrimination by females, a mindset that follows what is in reality namely social discrimination. Females who have discriminated themselves will then limit themselves in doing things or making decisions.

It is in line with the statement from Ragins and Sundstrom (1989) that the dimensions faced by women in achieving leadership positions are individual, interpersonal, organizational, and social. But from this study, it turns out that before the organizational dimension inhibits women's career advancement, there is an individual dimension that is symbolized by self-discrimination and a social dimension with gender stereotypes in certain industries that prove that broken rung has not been found in this study.

The initial solution from this problem is a whole changing mindset with strong beliefs and motivations from the female. Because it will not affect much if the company has a good promotion system for a female employee and if the female employee itself didn't match with the number of male employees available to be promoted. From these findings we knew that the root cause of the Female Leadership Deficit in Indonesia is not from the promotion system which is not friendly to female employees, yet, there's another factor that cannot be controlled even by the company whereas this factor supports female workers availability in a certain industry.

Implication

Managerial Implication

These findings can provide information for individuals, professionals, organizations, and decision-makers about the initial problem of the phenomenon of Female Leadership Deficit. By knowing that there are stereotypes in certain jobs/industries, companies can implement strategies that are on target if they want to achieve gender equality. Because without knowing that actually, broken rung does not occur in Indonesia, the company will be considered a party that does not provide opportunities for female employees to be promoted. Meanwhile, it turns out that the number of female employees is not the same as the number of male employees from the entry-level.

If the company commits to gender equality, there have to be some ways to deal with stereotypes in the industry/work. Companies can carry out gender equality campaigns by showing the seriousness of the company related to gender equality in industries that have gender stereotypes. This can be done by creating empowerment programs for minority employees in the industry. For example, in the male-dominated industry, a female employee empowerment program is held by giving training and development programs so that the capabilities and competencies possessed can be equal to those of male employees. Women are vulnerable to social discrimination and self-discrimination, companies can deal with this problem by providing support in the form of motivational training programs, support groups, and also creating a supportive and fair corporate culture.

In addition to empowerment programs, in a male-dominated industry, companies must be able to guarantee a supportive and safe environment for female employees. In addition to the fairness and objectivity of the company in evaluating employee performance, companies need to realize that a healthy and supportive environment is very important to keep female employees to avoid opt-out/turnover. Female employees still feel discrimination because it is considered not suitable to lead, so it is very vulnerable to eventually leave the company. This causes fewer female employees to be available.

Suggestion for the next research

- In this research, researchers had not anticipate that there are industries with the characteristics of male-dominated industries and also female-dominated industries. Therefore, this research using the assumption on general industries that all industries are the same.
- The facts that there are different nature from the female-dominated industries to male-dominated industries. Therefore, researcher must understand that there are female-dominated and male-dominated industries. Researcher cannot assume that the nature of the industry is the same with other industry.

- Because of the differences in nature, researcher must assume that this factor might play role in understanding the phenomenon of female leadership deficit in male-dominated industry versus female-dominated industry and be able to make comparison between those two industries respectively.

stepan.kavan@email.cz

Abstract

The Smart Region/City concept aims to reach sustainable growth and a balanced relationship within and between cities and the countryside, it continuously improves the quality of infrastructure and services in many areas ranging from energy industry, transport, health care, social services and education to security. The Smart concept is unique because it involves cooperation among many different fields which are different at first sight and which should be integrated into one complex whole within the Smart Region or Smart City concept. The goal of this analysis is to map the current state and the degree to which the South Bohemian Region is involved in the Smart City/Smart Region concept, to map the level of this Smart concept implementation process and the opinion of the need for its support, and subsequently to find appropriate measures to increase the involvement in the concept. An integral part of this analysis will be to determine the development and limiting factors of the Smart City/Smart Region concept.

Keywords: Developing factors, Limiting factors, SMART City, SMART Region.

Introduction

These days, the world is full of "smart cities" and "smart regions". They proliferate rapidly as new digital technologies are applied to enhance daily life. Smartness is "in", it is "cool", and the labels proliferate. Yet, this labelling often masks the real challenges of smart regions and smart citizens living in smart societies. How can we make so-called smart regions smarter? What do residents need to be able to survive, and thrive, in smart regions? What is the nature of smartness? (Markkula, Kune, 2015).

Smart City or Smart Region are one of the concepts of applying the principles of sustainable development to the organization of a city/region using modern technology in order to improve the quality of life and make governance more effective. This concept is most widely used in the fields of energetics and transport, both of which can be dealt with more effectively by using appropriate information and communication technologies. However, the Smart City/Region concept does not only cover the above-mentioned areas, it can also be applied e.g. to water management, safety, public lighting, waste management, e-government or crisis management.

The Smart City concept is a program change driven by the political representation of the city and it is a gradual process, not a state. In contrast to conventional planning and operation of urban agendas, Smart City simplifies the process of engaging the professional and general public by using electronic tools (e.g. communication platforms or social networks). It enables the city's strategies to be made up not only by a professionally competent contractor in cooperation with the relevant department of the city, but also by work groups made up of experts from various institutions, local entrepreneurs and interest groups that are effectively coordinated by the city using electronic media. The resulting strategies can be submitted for comments in electronic public forums and then discussed with the public at open meetings so that the introduction of their final form is generally accepted by the citizens and reflects as many notions and ideas as possible at the same time. This approach also anticipates prudent investment in new technologies

Cite this Article as: Jiri DUSEK and Stepan KAVAN“ SMART Cities, SMART Regions, SMART Solutions in Regional Innovation Ecosystems of a Selected Model Area of the South Bohemian Region” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

that will support these new programs. This has an impact on the investment costs but above all on the operating costs associated with the technology (Bárta, et al., 2015). There is an equivalent of the Smart City concept on a regional scale, on the level of self-governing lower units and it is called the Smart Region concept.

Smart City/Region Concept

In Europe, the Smart City/Region concept is a response to considerable urbanization and, to a large extent, a further step in the development of the EU's regional policy, which has so far focused on supporting larger regions. However, the ongoing concentration of economic power requires a special approach to tackling the problems of small regions, cities and municipalities, which are being pushed by citizens' demands for environmental improvements while maintaining economic performance that largely ensures quality of life. Massive investments to improve urban conditions are becoming increasingly complicated and the tight budgets of smaller regions or municipalities are not prepared to carry out such activities without an external impulse (the state, the European Union). Smart City/Region involves industry, universities and not just the capacities of the city or region (human, financial) to improve conditions. In this partnership the city/region in fact creates conditions for pilot projects aimed at finding solutions that are beneficial to citizens, while looking for innovative economic models to finance further expansion of the system. It is an interconnection of existing processes towards seeking synergies for their higher efficiency (Král, et al., 2017).

The Smart City/Region concept is not yet clearly defined in literature, but there are some common features of Smart City/Region that are common for most scholarly and conceptual documents on this subject. They include particularly the following attributes (Caragliu, Del Bo, Nijkamp, 2009):

- High-quality network infrastructure in the city and its effective use to meet the economic, social and other needs of the city's inhabitants.
- Urban development of the city which is friendly to business and innovation.
- Cities have an efficient public service apparatus that enables economic growth while ensuring social inclusion.
- Emphasis on the development of creative, innovative and high-tech sectors, including the development of qualified work infrastructure and appropriate infrastructure.
- Emphasis on environmental and energy sustainability of urban development.

The following definition of Smart City suitably summarizes the above-mentioned basic attributes (Hollands, 2008). In this definition, Smart City is understood as a modern urban concept, the basic vision of which is to achieve interconnection of highly developed urban infrastructure (energy, telecommunications, transport, environmental), business and education and educational institutions in the city into one effective whole with maximum functionality.

Smart City works with other “intelligent” technology concepts, especially Smart Grid, smart buildings and clean mobility. The emphasis on a comprehensive approach is also reflected in the European project of the University of Vienna, which has defined the basic dimensions of Smart City development as follows (Giffinger, et al., 2007): Smart Economy, Smart People, Smart Governance, Smart Mobility, Smart Environment, Smart Living.

It is important to point out that Smart City is not a purely technical field. It involves interconnection of a wide range of different professions, and even though state-of-the-art technologies are its integral part, they only act as one of the tools to ensure a high-quality life for the city's inhabitants and make energy and services more efficient. Just because a city has smart and energy-efficient street lighting doesn't mean it's Smart at the same time. Terminal devices, in most cases sensors, are the basic technical element of smart cities. Sensors are basically very simple devices that can measure a certain physical or technical quantity. Sensors are further integrated into sensor networks, which can generate a large amount of information on various changes in the environment. An important feature within a smart city is sharing collected information among different systems. To improve the interoperability of individual components, we need to share information with users and provide data among systems, ideally in real time. What makes the whole Smart City concept really smart is analysing a huge amount of data (the so-called Big Data) and then performing defined actions. Interconnection of products, services and people into one unit through the so-called Internet of Things (IoT) was made possible mainly by the following factors (Bláha, 2016): new technologies and cheap internet connection, availability of sensors and necessary hardware, massive use of smartphones, availability and speed of the Internet.

However, this very fast and almost uncontrolled development and technological complexity of integrating existing infrastructures with relatively young internet technologies, such as cloud services, smartphones and mobile applications, wearables, wireless technologies (Wi-Fi, RFID, NFC), etc., open doors to potential cyber threats.
This implies that the Smart City concept is relatively flexible and can be adapted to the level of development and to the needs of a particular city. For example, the initiative called Smart Cities and Communities supported by the European Commission (European Union, 2019) and the related mayor initiative Covenant of Mayors (2008) focus primarily on 3 dimensions out of these 6 dimensions, namely on smart mobility, smart environment and smart housing (especially with regard to energy savings in buildings and networks). On the other hand, for example Amsterdam chose to focus primarily on innovation and entrepreneurship in its Smart City concept – see more Amsterdam City (2019), i.e. on the dimensions of smart economy and smart people.

Methods

The aim of this analysis is to map the current status and the degree of involvement of the South Bohemian Region in the Smart City/Smart Region concept, to map the level of this Smart concept implementation and opinions on the need for its support and to propose appropriate measures of how to increase involvement in this concept accordingly. Using the SWOT analysis to determine the development and limiting factors of the Smart City/Smart Region concept forms an integral part of this analysis. The paper also contains data from the research of regional development of municipalities in the South Bohemian Region which was carried out by the authors in 2007-2015 on a basic set of 623 municipalities in the South Bohemian Region.

Research Results

Implementation of Smart concept in EU and Czech Republic

On the European level the concept of Smart Cities started to be used and developed mainly from the initiative of industry. In 2011, the *Smart Cities and Communities* industrial activity was established, involving the link between transport and energetics and aimed at reducing their environmental demands. A year later, the European Innovation Partnership on Smart Cities and Communities (EIP-SCC) was launched, including information and communication technologies and giving the Smart Cities concept a basic structure. However, this does not mean that the term "smart" did not exist in the context of the deployment of various smart technologies in cities or regions before 2011. This is evidenced by the Czech Smart Region Vrchlabí, which was launched as a pilot project of smart energy networks in the Czech Republic and a part of the transnational Grid4EU project in 2010. The activities of the city of Písek, whose strategic document *Blue and Yellow Book Smart Písek* was created in 2015, can be considered the first comprehensive strategic approach to the Smart Cities concept. Since then, according to Collective of Authors (2018) many other smart cities have been developing in the Czech Republic, more or less based on the *Methodology of the Smart Cities Concept*.

Sustainable mobility and the area of information and communication technology and effective territorial management are the dominant target areas for the implementation of the Smart concept in the Czech Republic. These areas are among the most frequently mentioned when identifying successfully implemented projects. In this category, projects in the field of ICT and effective territorial management account for 45% of the total number of projects already implemented and projects in the field of sustainable mobility make up 31% of the projects. Among the Smart Concept projects currently underway, projects for the ICT target area and effective territorial management account for 28% of the total number of projects which are currently being implemented, while the projects currently underway in the area of sustainable mobility account for 44%. These two target areas maintain a dominant position among the projects under preparation, where approximately one third of the intended Smart concept projects are directed into each of these areas. In the *Analysis of the Current Level of Involvement of the Czech Republic in the Smart City and Smart Region Concept in Relation to New Trends* the biggest obstacles to the implementation and the development of the Smart City/Region concept were identified to be: lack of financial resources, legislative obstacles, insufficient communication of ministries relevant to the implementation of the Smart City/Region concept, insufficient political will, overwhelming by devolved state administration and administrative demands – for details see Greg, et al. (2018). These findings also correspond to a number of other domestic and foreign researches – whether they are specifically focused on Smart City and Smart Region (see, for example, Růžička, 2018, or Dolejš, 2018) or generally targeted to the barriers of regional development as such. According to Schnabel (2012) unfavourable framework political

conditions and narrow profiles of all available resources are among the biggest problems in Germany. Local "selfishness" and the diversity of interests of individual participants are also a significant barrier. Other obstacles are perceived to be less significant by the respondents. The unfavourable framework political conditions mainly reflect the complexity of the German local and regional public administration.

In the Czech Republic, a number of development problems arise from the size structure of municipalities and that is why the lack of financial resources is the most frequently mentioned barrier (and also an incentive) to regional development. This was confirmed by the *Questionnaire Survey Focused on the Analysis of Selected Issues of Municipalities and Towns in the South Bohemian Region* which was carried out by the authors in 2004 and 2014. In this survey, the "lack of financial resources" is seen an obstacle to regional development by up to 80.4% of municipalities. However, after accession to the EU, the situation improved noticeably, the figure being only 56.7%, which is a decrease by approximately one quarter. The 80% perception of the lack of financial resources as a serious barrier to development corresponds to similar results of research carried out, for example, by the Centre for Regional Development Research, University of West Bohemia in Pilsen. As regards barriers for regional development, considerable % growth during the programming period of 2007-2013 was recorded by the time and administrative demands of this cooperation and project implementation. The assessment of answers shows that respondents point to complicated and rapidly changing legislation, not fully prepared programming period, involvement of other partners, etc. It is therefore not surprising that almost 20% of Czech municipalities do not make use of the possibilities offered by the European funds or grant schemes of the state or regions.

Although the implementation of the Smart City/Region concept has been well advanced in recent years and today almost every major city has its concept or strategy, we are still encountering limits that prevent the concept from spreading more massively. Although technology is developing very quickly, in some areas it is clear that current opportunities are still lagging behind expectations. In contrast, the initial optimistic forecasts were not fulfilled in other respects and other solutions are being sought. However, technology itself is probably the smallest problem today. In many cases, the financial aspect is particularly limiting, because not all Smart projects are savings-oriented. They often consist in improving services, which costs something. Another major limitation is the lack of awareness of what Smart concepts really mean, what practical solutions they can bring and how they can improve citizens' lives. What must not forgotten either is a significant complication (especially when working with data) in the form of legislation or historical contractual relations still in progress. In some cases, these relationships may make it impossible to use existing datasets efficiently. However, it can be assumed that the above problems and barriers will gradually find solutions and new technologies will be able to penetrate all municipalities and regions in a better way, not only in Czechia but also in other EU countries (Kožený, 2019).

Fig. 1: Obstacles to regional development in the South Bohemian Region

Source: Authors' own research – within the *Questionnaire Survey Focused on the Analysis of Selected Issues of Municipalities and Towns in the South Bohemian Region* (2004, 2014).

Results from analyse made in South Bohemia Region

If we focus on the involvement of cities, municipalities and regions of the South Bohemian Region in the Smart concept, only 12 municipalities involved can be identified (see also PricewaterhouseCoopers, 2019, authors' own research), of which 7 with a strategic document or analysis:

- České Budějovice - document entitled *Smart Cities Potential Analysis* (* 2018),
- Český Krumlov - analysis entitled *Smart City Maturity Scape* (* 2018),
- Milevsko - strategy document entitled *Live Milevsko* (* 2017),
- Písek - "ideological" document *Blue & Yellow Book Smart Písek* (* 2015),
- Předmíř - strategic document *Our Smart Předmíř* (* 2018),
- Strmilov - strategic document *Smart Village Strmilov - Smart Solutions for Small Towns* (* 2019),
- Tábor - strategic document *Smart City with a Face* (*2018),
- Bechyně - without a strategic document, implementation of a Smart project Charging Infrastructure for Electromobility (* 2019),
- Blatná - without a strategic document, implementation of a Smart project Capa Sitty Solar Benches (* 2017),
- Jindřichův Hradec - without a strategic document, implementation of projects Parking System and Smart Tourism (* 2018),
- Prachatice - without a strategic document, implementation of smart waste sorting, smart benches and systematic care for the elderly (* 2018),
- Strakonice - without a strategic document, implementation of monitoring how full the waste containers are (* 2019).

Out of the 17 municipalities with extended powers in the South Bohemian Region, 9 municipalities (i.e. 52.9%) participate in Smart concepts and as regards former district towns, 6 out of 7 towns participate (i.e. 85.7%). Only Český Krumlov is not involved, where guidance boards for parking lots have been in operation since 2003, but it is not a fully-fledged Smart technology. Among municipalities with extended powers, Dačice, Kaplice, Soběslav, Trhové Sviny, Třeboň, Týn nad Vltavou, Vimperk and Vodňany do not participate. On the sample of municipalities involved we can clearly demonstrate that so far the Smart concept has been the privilege of large, economically and politically strong municipalities, with the 7 largest cities in the South Bohemian Region involved in the Smart concept. On the contrary, except for Milevsko, 8 out of the 9 smallest municipalities with extended powers do not participate. Small towns and municipalities - Bechyně (5,097 inhabitants), Strmilov (1,425 inhabitants) and Předmíř (332 inhabitants) - are a positive exception among large municipalities. The collected data/results can be generalized by saying that the differences regarding the involvement in the Smart City or Smart Region concept increase with the degree of disaggregation (i.e. the involvement is higher at the level of large cities, former districts and lower units, such as administrative districts of municipalities with extended powers, than in smaller regions and municipalities of the South Bohemian Region).

Table 1: SWOT analysis of the Smart City/Region concept in the South Bohemian Region

Strong points	**Weak points**
➢ mobility is the Smart topic which is discussed most (parking, entry of cars in the centre, speed measuring) ➢ pilot projects in the fields of mobility, eGoverment and digitalization, energetics, environment, social and health services, effective territorial and innovation management ➢ development of electromobility ➢ initiation of activities is based on the interest of the public and commercial sphere ➢ inspiring examples of good practice from abroad ➢ regional subsidy program to support Smart projects ➢ existence and sharing of large amounts of data concerning the city administration ➢ high readiness of technological tools already implemented ➢ existing infrastructure providing information ➢ strong background in scientific and research environment ➢ working groups dealing with Smart issues at the level of regions and selected cities ➢ support of the Smart concept in strategic concepts ➢ strengthening the innovation structure of the South Bohemian Region ➢ interest in developing the digital region and implementing innovative solutions ➢ creation of the Smart Region of South Bohemia Commission	➢ not much emphasis is put on dealing with certain topics ➢ no network infrastructure ➢ large area with low population ➢ problems with the implementation of eGovernment ➢ lack of data for effective work with certain agendas (e.g. in the field of transport) ➢ low level of knowledge and ability to work with data ➢ incompatible formats of historical data ➢ problems with data storage and backup ➢ low extraction of information from the collected data ➢ fragmentation and confusion of data sources ➢ data duplicity ➢ weak interconnection of stakeholders in the course of the region's development ➢ low awareness, communication and information about Smart activities ➢ financial, technical and human resources used in an inefficient way ➢ bureaucracy and administrative complexity of Smart projects ➢ the return of the investment is longer than the election period ➢ lack of interest in Smart issues and implementation of Smart projects ➢ demographic changes ➢ lack of technically educated persons ➢ poor commercialization of science, research and innovation results ➢ a short period of time to implement projects from the Smart City subsidy program, low program allocation
Opportunities	**Threats**

➢ implementation of new innovative Smart projects ➢ building a nationwide network of electrical charging stations ➢ centralization of data and unification of subjects' awareness ➢ public education on working with data and using the Smart City / Region concept ➢ access to open data ➢ sharing data with entities of the same nature ➢ analysis of the existing data and its availability in the region ➢ data aggregation using analytical tools and learning how to work with available data across disciplines ➢ possibility of cooperation on the development of ICT with technological and research institutions ➢ elaboration of other strategies that will contribute to the development of the region ➢ creation of a communication platform to share knowledge and popularize the Smart concept ➢ development of eGovernment ➢ modernization and expansion of network infrastructure ➢ utilization of technological trends (e.g. 5G network, IoT, etc.) ➢ utilization of the growing potential in science and research institutions ➢ increasing the number of projects implementing smart approaches and solutions ➢ bringing together experts from different fields and disciplines to target projects in a better way ➢ establishing long-term cooperation with foreign entities ➢ applying the Smart Village concept to small villages and towns ➢ communication platform with all stakeholders in the territory, which will be connected with the region and cities ➢ knowledge transfer using previous knowledge from projects implemented for other regions ➢ significant support for technology transfer and support for the commercialization of research results ➢ support of towns, municipalities and regions in mutual cooperation	➢ suburbanization across a region with unsolved infrastructure ➢ failure to create an ecosystem of cooperation between entities ➢ Smart topics will be developed separately and non-systemically ➢ discontinuation of cooperation with stakeholders ➢ implementation of projects due to a large number of stakeholders ➢ vendor lock / blocked data ➢ failure to find professionals working with data ➢ security threat / abuse / disclosure of sensitive data from the GDPR perspective ➢ restrictions on working with data owned by other entities ➢ no link between information and data from the systems ➢ data is not shared to GIS and GEO portal ➢ lack of interest in working with digitized eGovernment services ➢ low usability of communication services ➢ security threat and unsecured data ➢ non-systemic changes in legislation ➢ subsidy programs for the implementation of projects will be cancelled ➢ no subsidy program for the next programming period 2021-2027 ➢ unwillingness to accept proposed solutions ➢ low amount of financial resources for the implementation of Smart solutions ➢ loss of support when political representation changes ➢ introduction of GDPR in other waves ➢ failure to provide citizens with information ➢ low cooperation with stakeholders ➢ the knowledge platform will be closed for sharing knowledge and experience ➢ the existence of barriers which will hinder the cooperating ecosystem ➢ cancellation of the Smart Region of South Bohemia Commission

Source: Own processing based on strategic documents of towns, municipalities and the South Bohemian Region (2019).

Conclusions

There is a paradox in the regions, cities and municipalities - the speed of building infrastructure is insufficient as regards the pace of development, there are inadequacies in public transport or on roads, but residents demand constantly improving quality of life. The problem cannot often be solved by expanding cities or parts of cities, so the latest smart technologies that transform existing infrastructure come into play. The Smart City/Region concept can integrate intelligent solutions into the infrastructure of cities and municipalities, successfully enhancing the efficiency of buildings, transport and energy systems. These steps lead to improving the quality of life of the inhabitants of cities and municipalities. Thanks to the utilization of the latest technologies, efficiency, safety and economic competitiveness is increased and pleasant and healthy living environment is created. Digitization and automation are fundamentally changing the entire infrastructure. By using intelligent algorithms that process data and start processes immediately, it is possible to optimize performance, efficiency, and improve the quality of life of the inhabitants of cities and municipalities (Siemens, 2019).

The analysis of strong points and weak points was prepared with regard to the forthcoming Strategic Development Plan of the Smart Region of the South Bohemian Region. Both the internal environment and external factors were analysed. The analysis of the internal environment consisted mainly in analysing the current state of implementation of measures in the areas of mobility, eGovernment and digitization, energetics, environment, social and health services, effective territorial and innovation management. The analysis also dealt with the level of utilization of information and communication technologies and a partial risk analysis was performed. The analysis of the external environment consisted in analysing higher strategic documents, relevant global and technological trends and also an analysis of key participants was performed. The results of the individual partial analyses have been generalized and

they are included in the above SWOT analysis. Based on the performed analyses incl. the SWOT analysis, the initial general assumptions were identified and confirmed - i.e. the main positives and negatives/problems the Smart City/Region concept is currently facing in the South Bohemian Region (possible suggestions and solutions are listed in the SWOT analysis - opportunities):

+ introducing innovative technologies for citizens,
+ using the Smart concept in a number of different sectors,
+ a number of pilot projects in different areas,
+ improving the quality of life in cities and municipalities,

– financial limitations of cities, municipalities and regions,
– involvement only in large municipalities of the region,
– insufficient awareness of the Smart City/Region concept
– legislative obstacles.

Abstract

The article considers the assessment of the digital maturity of the enterprise as one of the important precondition for its digital transformation. The concept of digital maturity of the enterprise is analyzed and its essence is determined. Existing models of estimation of the enterprise's digital maturity, developed by foreign scientists and consulting companies, are characterized. It is established that the given models of assessment of digital maturity have a structure that corresponds to the standard model of the CMMI and provides the possibility of finding bottlenecks of the enterprise for carrying out digital transformation. It is proved that the existing models also have certain features that make them ineffective for localization of problems and construction of the enterprise development plan, and the disadvantages of these models are not adapted to the reality of the environment in which Ukrainian enterprises operate. Therefore, an author's model for assessing the digital maturity of an enterprise has been developed that provides a structured approach to assessing digital maturity and is complete enough to cover all aspects of the digital transformation of the enterprise. On the basis of the conducted research, a method of enterprise's digital maturity assessment was developed which provides for determining the level of digital maturity in 6 directions of activity of the enterprise: strategy, personnel, structure, technologies, marketing, organizational culture. It is concluded that the assessment of the digital maturity of the enterprise enables the enterprise to obtain certain advantages: the opportunity to form a holistic view of the real level of digital maturity and the desired state; making recommendations based on the conditions and features of a particular enterprise; identifying the hidden digital potential of the enterprise; familiarization with the opportunities provided by digital technologies.

Keywords: Digital Maturity, Enterprise, Digital Transformation, Digitization, Digital Maturity Assessment Algorithm

Introduction

The world is constantly changing, and one of the main modern drivers of development is the digital economy. Digital technologies open up unique opportunities for the progress of the national economies as in the whole as in individual enterprise. In order to achieve the maximum efficiency of digital transformations in the enterprise, it is firstly necessary to understand the current situation in this area. Otherwise, valuable time and resources may be wasted and may not bring the desired effect to the company.

The digital transformation of an enterprise take place through various processes, some of which are evolutionary, some of which are revolutionary. It all depends, first of all, on the current digital maturity of the organization. That is why understanding of organizational digital maturity is the first logical step towards digitalization.

Assessing and increasing the digital maturity of the company allow achieving better results and a stable position compared to competitors. This is especially relevant in an era when the digital environment is tending to constant

Cite this Article as: Alla POLYANSKA, Svitlana SAVCHUK and Yevhen REVTIUK " Assessment of Digital Maturity of Enterprise as a Precondition of Digital Transformation" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

unpredictable changes. The benefits of digitalization are obvious, but relatively few domestic enterprises are fully realizing their digital potential, losing many opportunities and competitive advantages. This is often happened due to the complexity of the digital transformation process itself, as the company cannot assess its current capabilities and choose the most effective way to implement necessary changes. This determines the relevance of the chosen research topic. Thus, the assessment of an enterprise's digital maturity as the subject of the proposed paper is the question that deserves attention.

Taking into account noted above, the goal of this article is to work out the methodical approach to the assessment of an enterprise's digital maturity on the base of the characteristic of existing models and to implement it on the enterprise to summarise its practicalness and valueness as preconditions of digital transformation. To atchiev this goal, the structura of the article include:

- to work out the algorithm of assessment of the digital maturity of the enterprise;
- to acknowledge the general characteristics of existing models for assessing the digital maturity of the enterprise;
- to point out the characteristics of digital maturity of a specific enterprise;
- to make the assessment of the digital maturity of the enterprise;
- to summarise the getting result.

Fig. 1: The algorithm of the digital maturity assessment

Methodology

The European Center for Information Systems Research (ERSIC) [1] identifies three steps that an enterprise must take to create the necessary conditions for digital transformation, namely:

- assessment of the current level of digital maturity and existing development skills in this area;
- determining the level of current and desired digital maturity of the business;
- defining the action plan that is needed to achieve the desired level of digital maturity.

Digital maturity assessment is used as a standardized structure to determine the overall capabilities and ambitions of the company. It helps to prioritize those areas that have the greatest impact on business and can provide maximum effect in the digitalization. And each enterprise can organize the assessment of digital maturity by taking into account the enterprise's needs and world tendencies of digitalization.

Implementing mentioned above three important steps to digital transformation, we worked out the method of digital maturity assessment (Fig.1) that can help the enterprise to identify its level of maturity as in specific areas as in the whole.

Results

At this stage of the investigation, we propose to apply the formed algorithm of the digital maturity assessment into practice and sequintly consider each of the levels of digital maturity assessment.

1. Determining the purpose of digital transformation based on development trends or needs of the enterprise.

We tend to use the meaning of digital maturity that is defined as the level at which an organization is able to optimize its online presence, with using analysis to improve digital performance and anticipate future customer needs [2]. However, in this definition, digital maturity is limited by the usage of the technology in marketing area. But the definition of digital maturity concept itself is much broader, because the maturity of the enterprise determines not only the level of implementation of digital technologies in various areas of the enterprise (personnel management, production, communications), but also the effectiveness of digital strategy. In a study by Capgemini and the MIT Digital Business Center [3], digital maturity is considered as a function of two dimensions:

- digital intensity - the amount of investment in digitalization; measured by coordinated areas of digital transformation (digital project portfolio);
- the intensity of digital transformation management or digital enterprise support, as measured by the availability of digital vision, the effectiveness of digital strategy, etc.

So, due to the studies of digital maturity we can conclude that the perpose of digitalization is to support or divelop useful for enterprise areas.

2. Acquaintance with the experience of digital transformation at domestic and foreign enterprises

In order to implement digitalization initiatives, it is necessary to assess the digital maturity of the enterprise. To obtain an objective assessment, foreign scientists and consulting companies have developed various models for assessing the digita maturity of the enterprise. Table 1 lists and summarizes some of the most famous models.

- Some models don't concider enough indicators of insufficient for the assessment to be able to assess a large enterprise that has different activities;
- The models are somewhat superficial in the coverage of specific c issues, as they are designed as universal and suitable for companies in various industries;
- Models are not adapted to the reality of the environment in which Ukrainian enterprises operate;
- Models of the enterprise digital maturity don't offer ways to improve enterprise management due to the general nature.

Based on the analysis of existing models for digital maturity assessing, there is a demand to develop a model of digital maturity that will meet the following requirements:

- The model provides a structured approach to the evaluation of digital transformations and is complete enough to cover all aspects of digital transformation;
- The model is detailed in accordance with the peculiarities of enterprise management in the framework of digitalization;
- The model is independent of how the production processes of the enterprise are organized;
- The model doesn't contradict the existing models for assessing the digital maturity of the enterprise.

Table 1: The General characteristic of existing models for assessing the digital maturity of the enterprise

№	Model name	Characteristic
1	*Center for Digital Business*) i Capgemini Consulting	According to the results of the analysis of more than 400 large companies from different industries, three key areas of digital transformation were identified: customer experience (Transforming Customer Experience), operational processes (Transforming Operational Processes) and business models (Transforming Business Models) [4]. Within each of the selected areas there are three complementary elements, and these elements form a set of building blocks of digital conversion. However, no company completely transforms all elements at once. Different companies are moving towards digital transformation at different rates and achieving different levels of success
2	Digital Maturity Model of Deloitte company [5]	Digital capabilities are assessed in 5 key areas: consumers, strategy, technology, manufacturing, structure and culture. tour of the organization (Customer, Strategy, Technology, Operations, Organization & Culture). The five main dimensions are divided into 28 sub-dimensions, which, in turn, are divided into 179 indicators, according to which digital maturity get assessed. The emphasis is made on the business strategy. Consecutive steps of the strategy concretization are to define a business model and an operating model.
3	*Digital Transformation Index*, developed by analytical agency *Arthur D. Little* [6]	Has a larger number of consolidated areas of evaluation: a) strategy and leadership (Strategy & Governance); b) products & services; c) customer management; d) operations and supply chains (Operations & SupplyChain); e) corporate services and control; f) information technology (InformationTechnology); g) workplace and culture (Workplace & Culture). For each company, the evaluation results are presented in the form of a radar, which, taking into account industry specifics, as well as marks of the level of "virtual stars" (Virtual Star) and the average industry level (Average).
4	(*Digital Business Aptitude - DBA*) company *KPMG* [7]	It combines 5 areas of evaluation: vision and strategy (Vision & Strategy), digital talents (Digital Talent), key digital processes (Digital FirstProcesses), flexible sources and technologies (Agile Sourcing & Technology), leadership (Governance). As in the previous two models, each of the selected areas includes several components. The evaluation results are presented in the form of radar, each evaluation sector has its own color. A feature and advantage of this model is a diagnostic tool for self-assessment, which is freely available. On a radar on each direction of an estimation 2 levels are allocated: for the given enterprise and average on all enterprises which have passed an estimation. Thus, a basis for comparative evaluation is formed, which is very important for decision-making in the field of strategy selection and priority areas of digital transformation.

5	Dgitization Piano, developed at the initiative of companies IMD i Cisco (Global Center for Digital Business Transformation) [8].	Similar to the 7 notes, there are 7 Transformation Categories, which are the most important elements of the value chain of the organization: business model (Business Model), organizational structure (Structure), employees (People), processes (Processes), IT capabilities (IT Capability), proposals (Offerings), model of interaction (Engagement Model). A list of guiding questions has been developed for each of them, the answers to which can help to make a plan of transformations. A feature of this model is to determine the gap between the current and desired levels in each direction. Thus for reception of effect simultaneous transformation of several elements and technologies - creation of musical chords is recommended.
6	Evaluation by company method *Ionology*[5].	Company Ionology identifies 5 blocks of digital transformation: Strategy & Culture, Staff & Customer, Process & Innovation, Technology, Data & Analytics.
7	Industry Maturity Index 4.0 Acatech [9]	Developed on the basis of research that was conducted by the National Academy of Sciences and Technology of Germany. There are four key areas of digital transformation: resources, information systems, culture and organizational structure. The evaluation methodology is somewhat more complex than described above. The index is formed simultaneously in several areas. The selected areas are evaluated in accordance with the stages of development of Industry 4.0 (informatization, connectivity, clarity, transparency, predictability, self-correction). In addition, corporate processes are analyzed in terms of five functional areas (development, production, logistics, service, marketing and sales). Particular attention is paid to the transformation of organizational structure and culture. The main goal is to create a flexible company that is constantly evolving.

These models for digital maturity assessing have a structure that corresponds to the standard model CMMI (Capability Maturity Model Integratio) and provides the ability to find bottlenecks in the enterprise for digital transformation. But they also have certain features that make them ineffective enough to localize problems and build a business development plan:

Based on the mentioned above, we offer a model for digital maturity assessing, which will be as close as possible to the modern realities of the enterprise in Ukraine. This model involves the determining of digital maturity level in 6 areas of enterprise activity: strategy, personnel, structure, technology, marketing, organizational culture.

3. Definition of directions (arears) of activity which demand digitalization

A review of literature sources has allowed summarizing and describing the follows elements of the enterprise so that to select criteria for the digital maturity assessment, namely:

Strategy - a plan to support and form the competitive advantages of the enterprise and actions aimed at responding or anticipating changes in the external environment, which allows providing efficient operations and sustainable development of the enterprise. To determine a certain level of digital maturity, it is necessary to assess the existence of a digital strategy and the level of its integration with the development strategy of the enterprise, to determine what components the strategy has and how it is implemented.

Personnel are a set of permanent employees who have received the necessary training, have necessary skills and practical experience. Successful implementation of the digitalization strategy involves the readiness of staff to change and their awareness of future changes. Involving, motivating and involving people in the digitalization process are the key to success.
The organizational culture understands a system of material and spiritual values and beliefs that reflect the individuality of the organization, influencing the behavior of staff and the organization as a whole. An important component of achieving a high level of digital maturity is the readiness for change in the field of organizational culture.

Technologies are a set of methods, production processes, software and hardware, united in a technological chain, which ensure the efficient operation of the enterprise. Technology is the main driver of digital transformation. Therefore, their availability and the effectiveness of these technologies determine the level of digital maturity of the enterprise.

In this case, marketing should be understood as the activity of the enterprise, which is aimed at creating demand and achieving the goals of the enterprise through the maximum satisfaction of consumer needs. The company's customers are considered as digital partners, so it is necessary to evaluate the effectiveness of digital channels of interaction.

Structure is the interaction and interrelation of the constituent parts of a whole organisation. In order to assess the digital maturity as accurately as possible, it is necessary to check the structure of the enterprise for flexibility as well as to assess the interaction between its components.

According to the study of enterprises' digitalization process, as well as the analysis of attributes of digital maturity in different models and characteristics of digital transformation, there was identified a list of relevant questions to assess digital maturity in each of the activities of the enterprise. The answers to these questions will help to determine the state of enterprise digital maturity.

The proposed in the article model of enterprise's digital maturity is developed in the form of a questionnaire and consists of 61 questions in 6 components: "Strategy" (13), "Personnel" (15), "Organizational culture" (10), "Technology" (10), "Marketing" (6), "Structure" (7). For each question / statement, 5 answer's options are proposed, from which one must be chosen. A fragment of the questionnaire is presented in table 2.

Table 2: A fragment of the questionnaire of the author's model of digital maturity assessment

Questions to describe the factor	**Answer options**				
	5	**4**	**3**	**2**	**1**
STRATEGY					
Existence of a clearly formulated digital development strategy					
Level of personnel awareness of digital strategy and goals					
PERSONNEL					
The level of measures implementation to develop digital skills and staff skills					
Employees' level of basic computer skills					
ORGANIZATIONAL CULTURE					
The level of coherence and interaction of management levels in the digital transformation					
Existence of measures to overcome (prevent) the resistance of employees that arises in the process of digitalization of the enterprise					
TECHNOLOGIES					
The level of provision of computers and other equipment necessary for the proper functioning of the enterprise					
The level of implementation of effective modern security systems to ensure cybersecurity of the enterprise					
MARKETING					
Availability of a modern interface of the company's website, the use of SEO-optimization technologies					
The level of usage of digital sales channels					
STRUCTURE					

The level of organizational management system flexibility and its ability to adapt to changes in the external environment (including changes associated with the digital revolution)					
The level of usage of modern architectures (API, cloud, etc.) to increase the speed and flexibility of the enterprise					

The assessment of the level of digital maturity firstly is carried out within each component, and then the overall level of digital maturity of the enterprise is determined. For an objective assessment, it is necessary to choose a quantitative scale that allows not only to understand what digital technologies are presented in the enterprise, but also to determine how well they are used. This will allow forming further recommendations for the company, namely the determination of what measures will improve management in the context of digitalization. The evaluation scale consists of 4 levels, which correspond to how well this or that digital technology is used in the enterprise. Table 3 describes the levels of digital maturity.

Table 3: Scale for assessing the level of enterprise's digital maturity

Level of digital maturity	Quantitative evaluation (points)	Description of the digital maturity level
Observers	1-2	The company is skeptical about digital technologies and does not consider their impact on the business seriously enough. The company's management investigates only the practice of digital transformation of competitors or other companies.
Beginners	2-3	The company is very slow to perceive digital technology. The process of digital transformation stretches for a long time, and the digitalization itself is quite superficial and does not cover all areas of the enterprise.
Experienced	3-4	The company supports digital technologies and invests in to innovations and digital marketing. Management focuses on the implementation of technology, but does not measure the effectiveness and analysis of these innovations. Insufficient attention is also paid to the planning, development of digital strategy and the formation of digital competencies of employees.
Innovators	4-5	The company uses all the opportunities provided by the digital technology. The process of digital transformation is systematic and covers all areas of business. Innovation is monitored and evaluated, the company's digital strategy is developed.

4. Determining the state of maturity in various areas of the enterprise.

An expert method of digital maturity evaluation is based on a survey of a group of experts within the questionnaires that were used to assess chossen indicators. The survey was conducted among middle managers (heads of branches and other structural units of the company, heads of departments). The survey was conducted in the form of a traditional written questionnaire.

We apply the developed model to assess the level of digital maturity of the company, which provides a full range of logistics and related services. 'Nova Poshta" is a leader in the logistics market, which provides easy delivery to each customer: from the branch, post office, to the individual customer address. The company provides a range of services, namely: storage of goods in warehouses, picking and sending orders to the recipient; the company's customers can make money transfers and electronic money transactions; Nova Poshta Global is developing an international partner network to provide customers with express delivery services not only in Ukraine but also abroad.

On the basis of questionnaires we form the table of points and calculate average value of estimations of each question (tab. 4). The average level of digital maturity ($\overline{X}$) of each element of the enterprise is determined by the formula [1]:

$$\overline{X} = \frac{\sum_{i=1}^{n} x_i}{n} \quad (1)$$

where x_i – a value of DM_e (digital maturity element) variable; n – the number of variable elements.

Given the goal, it is advisable to conduct a comprehensive assessment of the enterprise's digital maturity in different areas of activity. However, each of the studied elements of the enterprise will have its impact on the overall assessment, so it is necessary to set the weights of each element that have impact on the overall level of digital maturity. For the practical realization of the set goal, the method of ranks was applied. The essence of this method is to assess the experts view on significance of each of digital maturity indicator and to give it some weight. The results of expert evaluation of weights are presented in table 5.

Based on the usage of the method of ranks, we determined the weights for each element in the assessing of digital maturity. It should be noted that the weight coefficients were determined specifically for the case of "Nova Poshta". When assessing the digital maturity of another enterprise, new weights should be determined.

Table 4: The obtained results of the questionnaire

Element	Question number	Respondents										Average value for each variable element, ($\overline{X}$)	Average value for DM_e
		1	2	3	4	5	6	7	8	9	10		
Strsategy	1	4	5	5	5	5	5	4	5	5	4	4,7	3,58

	6	5	5	5	5	4	4	5	5	4	4	4,6	
	7	5	5	4	4	4	4	5	5	5	5	4,6	
	8	1	2	2	3	2	3	3	3	2	2	2,3	
	9	3	3	4	3	2	4	3	4	2	3	3,1	
	10	4	3	3	4	2	3	4	3	3	3	3,2	
Marketing	1	4	4	5	4	5	4	5	4	5	4	4,4	4,37
	2	4	4	4	4	4	5	5	4	4	4	4,2	
	3	4	4	5	4	5	4	5	5	4	4	4,4	
	4	4	5	4	5	4	4	5	5	5	4	4,5	
	5	4	4	3	5	5	4	5	4	4	4	4,2	
	6	5	5	4	5	5	4	5	4	4	4	4,5	
Structura	1	4	3	3	4	4	4	3	4	5	3	3,7	3,79
	2	4	4	3	4	5	4	3	5	4	3	3,9	
	3	2	3	3	4	4	4	3	4	3	4	3,4	
	4	3	3	4	4	5	5	4	4	3	5	4,0	
	5	4	3	5	4	4	4	5	5	3	4	4,1	
	6	4	4	4	5	4	4	4	5	3	4	4,1	
	7	3	3	3	4	3	3	3	5	2	4	3,3	

At the next stage it is necessary to assess the degree of o the respondents' agreement. The consistency of respondents' opinions on the weight of the objects of study is determined by using the coefficien concordance or the coefficients of variation [14] and proposed system of respondents' agreement level [15]. It is established that the analysis of the agreement of experts' opinions by calculating the concordance coefficient is rather incomplete, as this coefficient is focused on checking the unanimity of judgments. If the judgments of experts are concentrated around several points, for instance, the experts are divided into several different groups with the same views within the group; the concordance coefficient does not allow detecting this. The coefficient of variation *Vj* is determined for each element of digital maturity of the enterprise and characterizes the degree of consistency with experts' opinions on the relative importance of the *i*-elements of digital maturity of enterprise. The smaller is the value of *V*j, the higher is the degree of agreement of experts on the relative importance of the *i*-th element of enterprise's digital maturity.

$$V_i = \frac{\sqrt{\frac{\sum_{k=1}^{N}(a_{ik} - a_i)^2}{N-1}}}{a_i}, \qquad (2)$$

where V_i– the coefficient of variation; a_i – weighting coefficien of i-element of enterprise's digital maturity; i – the elements of enterprise's digital maturity; a_{ik} – the numerical value of the weight of the coefficien, which was given by the k-th expert; N – the number of experts who participated in the examination.

Table 5: The results of the respondents' expert assessment of the enterprise's digital maturity elements weight coefficient

Experts	Element of the enterprise *(i)*						The sum of points
	Strategy	Personnel	Organizational culture	Technolog	Marketing	Structure	
1	0,185	0,155	0,143	0,213	0,135	0,169	1,0
2	0,198	0,152	0,132	0,200	0,170	0,148	1,0
3	0,177	0,161	0,154	0,186	0,163	0,159	1,0
4	0,182	0,148	0,137	0,232	0,149	0,152	1,0
5	0,191	0,159	0,144	0,193	0,158	0,155	1,0
6	0,179	0,156	0,151	0,217	0,148	0,149	1,0
7	0,169	0,160	0,150	0,204	0,156	0,161	1,0
8	0,180	0,154	0,141	0,221	0,155	0,149	1,0
9	0,183	0,160	0,129	0,225	0,159	0,144	1,0

10	0,190	0,156	0,150	0,192	0,161	0,151	1,0
$w(DM_e)$	**0,183**	**0,156**	**0,143**	**0,208**	**0,155**	**0,154**	1,0
V_i	0,0445	0,0262	0,0590	0,0748	0,0620	0,0484	

V_i =0,26-0,35 – consistency of experts' opinions on the weight coefficient of the enterprise's digital maturity below average;

V_i =0,16-0,25 – average consistency;

V_i =0,11-0,15 – above-average consistency;

V_i < 0,1 – consistency of experts' opinions is high.

5. Determining the general level of digital maturity of the enterprise

The total value of the digital maturity level of the enterprise is calculated by the formula (3) and presented in Tabl. 6:

$$D_m = w(DM_e) \times DM_e, \quad (3)$$

D_m – the level of digital maturity of enterprise; $w(DM_e)$ – digital maturity elements weight coefficient (Tabl. 5):

$$D_m = 0{,}183 * D_m(strategy) + 0{,}156 * D_m(personnel) + 0{,}143 * D_m(organization\ cultura) + 0{,}208 * D_m(technology) + 0{,}155 * D_m(marketing) + 0{,}154 * D_m(structure);$$

$$D_m = 0{,}183 * 3{,}58 + 0{,}156 * 3{,}05 + 0{,}143 * 3{,}36 + 0{,}208 * 3{,}83 + 0{,}155 * 4{,}37 + 0{,}154 * 3{,}79 = 3{,}6691.$$

Table 6: The results of the assessment of digital maturity the level of "Nova Poshta"

Elements of the enterprise	Values for each subsystem		General significance	
	Estimated value	Characteristics on a criterion scale (Tab.3)	Estimated value	Characteristics on a criterion scale (Tab.3)
Strategy	3,58	Experienced	3,6691	Experienced
Personnel	3,05	Experienced		
Organizational culture	3,36	Experienced		
Technology	3,83	Experienced		
Marketing	4,37	Innovators		
Structure	3,79	Experienced		

6. Identification of areas for improvement in the field, which is far behind the average level of assessment.

The assessment of digital maturity level of organization "Nova Poshta" allows to make conclusions that the company has a general level of digital maturity, named "Experienced", which indicates that "Nova Poshta" invests in digital technologies and tries to automate and robotize warehousing processes. Another novelty of the company is the entering into exploitation the postal drones. So far, the aircraft is being tested, but in the future it will be able to carry about 50 envelopes over a distance of 350 km. The company is also working out the question to minimize human participation in the issuance of parcels, actively developing the project of post offices. The table 6 shows that in this regard, there is a well-developed field of marketing with modern website as well as a convenient application. "Nova Poshta" has pages on social networks and is working to improve the quality of the brand and its recognizability. The visualization of research results, shown in Fig. 2 demonstrates that the most mature area for digitalization is marketing, and the lowest – personnel.

Fig. 2: The Nova Poshta digital maturity chart

With regard to the issue of personnel management in the context of digital transformation, the score is lower (3.05), and therefore it is necessary to pay attention to this area. In order to increase the level of readiness for changes as well as openness to innovation, it's important to satisfy the employees need in digital education and training at all levels. An appropriate level of organizational culture will contribute to this.

Conclusions

Digital transformation of the enterprise is a complex process that must take into account many factors of its internal and external environment. It is impossible to create a strategy or invest in digital technologies without first assessing enterprise's real opportunities and weaknesses. That is why understanding organizational digital maturity is the first logical step towards digitalization.

To simplify the process of digital transformation at the enterprise, it's available to take into account the proposed in article method that allows assessing current enterprise digital state on the base of considered areas, compare these areas with an average level of enterprise's digital maturity. Following these steps will direct to the vital recommendations on the way of improving enterprise digital maturity on the whole.

Moreover, assessment of digital maturity of the enterprise gives the enterprise the opportunity to poit out spesific advantages in the way of digitalization, namely:

- formation the desirable level of digital maturity and the desired state;
- formation of recommendations based on the conditions and features of a particular enterprise, got from provided inveatigation like questionnaire;
- detection of hidden digital potential of the enterprise;
- acquaintance with the opportunities that are provided by digital technologies.

The future investigation will be held on the integration of determining areas of digital maturity improvement into the enterprise management system as well as the formation of digitalization strategy or goals in the general corporate strategy of the enterprise.

Comparative Approach Regarding Good Governance

ZAI Paul Vasile

Babeş Bolyai University, Cluj-Napoca, Romania
zai@fspac.ro

Abstract

This paper tries to analyze good governance using an Eurostat and World Bank approach. In the first part, a brief history of good governance will be presented along with various definitions of the concept and its key characteristics. Then, in the second part, various indicators of good governance at EU 28 level will be shown, together with their corresponding data for the past 10 years and more, according to different sources such as Eurostat and the World Bank. The author also tried to create a model for participatory budgeting.

***JEL Codes**: E6*

Keywords*:* Eurostat, World Bank, Indicators, Good Governance.

Introduction

Governance, as the World Bank defines it, refers to the "the manner in which power is exercised in the management of a country's economic and social resources for development[1]". This simple and clear definition shows both what governance is – exercise of power towards state level resource management, and what its end goal is, namely the socio-economic development of that state. Furthermore, this definition is useful because it also links the age-old concept of governance with the relatively modern concept of "good governance", which emerged during the "government crisis"[2] of the late 1980s of several African countries in which the IMF and the World Bank, at the time, were implementing economic aid programs that were severely hindered by administrative corruption and ineffectiveness.

Nanda (2006) stated that good governance emphasizes the means of achieving development, by fighting corruption, nepotism and bureaucracy, and by instituting principles such as transparency and accountability in government institutions.[3] Moreover, due to these governance issues, the two aforementioned international aids started conditioning financial aids based on good governance principles, so as to ensure the efficiency and effectiveness of those aids.[4] This shift of paradigm meant that the quality of the government now became the main factor of the long-term socio-economic development, and so, sustainability became the key for requesting aid.[5]

According to UNDP (1997), the concept of good-governance has been thoroughly debated, and there are dozens of definitions and views upon it depending on the agent (scholar, institution, organization etc.). Hence, it can be seen

Cite this Article as: ZAI Paul Vasile "Comparative Approach Regarding Good Governance" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

as a series of positive principles which aims to fight administrative dysfunctionalties[6], an instrument that eases financial aids as previously mentioned[7] and also as a fundament for consensus and representation in decision-making[8]. In addition, the World Bank gives the most comprehensive definition of the concept, namely that good governance "is epitomized by predictable, open and enlightened policy making (that is, transparent processes), a bureaucracy imbued with professional ethos; an executive arm of government accountable for its actions; and a strong civil society participating in public affairs, and all behaving under the rule of law."[9]

Thus, linked with the long-term state socio-economical development, good governance is both a means and a goal in itself. It manifests itself on three main levels – political, administrative and social level and, according to some views, incorporates not only public institutions but civil society organizations as well.

The concept of good governance involves and also reinstates that the means of achieving socio-economical development are as important as the goals of doing it. Public administration is no longer an enclosed system which functions independently of its citizens. On the contrary, people's needs are the focus now. Their freedom must be ensured, as well as their dignity, as according to human rights, and they must have a voice in policy making. Therefore, besides efficiency and effectiveness in public institutions, there is also a need for transparency and accountability in the public office, which must now be open to criticism, praise and amendment, since after all, governments must be "off the people, by the people, for the people"[10] as a fundament for both a well functioning democracy and a good state governance that enables long term social and economical development and sustainability. I chose this topic in order to realize a comparative approach between indicators of good governance from E.U. and indicators from World Bank. Another very important motivation was to derermine the situation regarding good governance in the countries from global level.

Methodology

The data used in this paper is exclusively from the European Commission site: Eurostat which is a free provider of a high quality statistic database (it describes itself as follows: "Eurostat is the statistical office of the European Union. Its task is to provide the European Union with statistics at European level that enable comparisons between countries and regions"), and the World Bank site. Taking into consideration the type of data being used, a quantitative research will be conducted with special regards to budget.

Principles of Good Governance

The basis of good governance at the European Union level contains the following five main principles[11]:

Principle	Description
• **Openness**	The European institutions should attach more importance to transparency and communication in their decision-making.
• **Participation**	Citizens must be more systematically involved in the drafting and implementation of policies.
• **Accountability**	The role of each party in the decision-making process needs to be clarified. Each actor involved should then assume responsibility for the role given to him.

[10] See the famous " Gettysburg Address" of US President Abraham Lincoln (1809-1965), available [Online] at http://www.abrahamlincolnonline.org/lincoln/speeches/gettysburg.htm

[11] Source for the principles and their corresponding description is taken from The EU White Paper on Governance Summary, available [Online] at http://europa.eu/legislation_summaries/institutional_affairs/decisionmaking_process/l10109_en.htm

• **Effectiveness**	Decisions need to be taken at the appropriate level and time, and deliver what is needed.
• **Coherence**	The EU conducts extremely diverse policies which need to be pursued coherently.

Of these five principles, participation, accountability and effectiveness are identical to those from the UNESCAP model. Furthermore, the openness principle from the EU level incorporates the transparency component from the previous model. In addition, the coherence principle frames the overall government activity into that of policy integration that aims to ensure the integrity and well functioning of state institutions which can be linked not only with efficiency and effectiveness but also with vision and long-term sustainability that actually depends on the latter. On a final note, it must be mentioned that all these five principles enclose good governance into the activity of public institutions, and somehow remove the external dimension of government, even though they require openness, transparency and participation.

Good Governance Indicators

Table 1: Good Governance Indicators

Source/Agent	Indicators	Information
Eurostat	• Infringement cases • Voter turnout in national and EU parliamentary elections • Shares of environmental and labor taxes in total tax revenues from taxes and social contributions • Transposition deficit • E-government on-line availability • E-government usage by individuals • Level of citizens´ confidence in EU institutions (for sub-theme policy coherence and effectiveness)	At EU level, good governance is strongly linked with the concept of sustainability in the sense of providing a good life quality to everyone from both the present generation and the generations to come.[12]
World Bank	• Voice and Accountability • Political Stability and Absence of Violence • Government Effectiveness • Regulatory Quality • Rule of Law • Control of Corruption	For the World Bank, good governance depends on three major sets of factors: 1. how public authority is exercised in a state, 2. how the government is selected, monitored and replaced, and 3. the government's capacity to formulate and implement "sound" policies that are also representatives for citizens and organizations within that state.[13]
Gross National Happiness (Index)[14]	• Dimension: Political participation -> Indicators: Possibility of voting, Frequency of attendance in decision-making assemblies. • Dimension: Political freedom -> Indicators: Freedom of speech, vote, association, to join a political party, to be a member of an association, equal pay for value, and freedom from discrimination based on sex, religion, age etc. • Dimension: Service Delivery -> Indicators: distance from the nearest health care centre, waste disposal	Good governance is a component of the Gross National Happiness Index which aims to measure the subjective well-being of individuals. Among other components of the index, psycho-logical well-being, health, education, culture, time-use, community vitality, ecological diversity and living standards are very important.[15]

	method, access to electricity and water supply and quality. • Dimension: Government performance -> Indicators: Efficiency in various fields, such as employment, equality, education, health, anti-corruption, environment and culture.	
Source: own processing of data from Eurostat, World Bank		

Having in mind the Eurostat indicators for good governance, one must notice that they are far from being able to encompass even the main components of the concept which were presented in the previous section.

For example, when measuring participation, in terms of voter-turnout in national elections and European Parliament elections, one can notice a slight decrease of 1.5% from 2000 to 2018, which followed a major decrease since the early 1990s.[16]

At EU27 level, there is a slightly big discrepancy between countries regarding national elections. Countries such as Malta, Luxembourg, Belgium, Denmark, Italy, Cyprus, Sweden and Austria have a turn-out rate higher than 80% (even close to 90% for some of those countries), while most of the other countries range from 60 to 80%, and countries from the Eastern Block such as Romania, Bulgaria, Hungary and Poland have less than 40% turn-out rates.

Croatia, the newest entrance into the EU has a slightly increased voter turnout – 59.6% in 2007 and 54.2% in 2018[17]. Its entrance slightly changes the average with only 0.1% decrease for EU28 as opposed to EU27.[18] Among the causes which decrease voter-turnout, young population absenteeism from elections[19] , population size, electoral closeness and electoral expenditures are of great significance.

Analyzing Main Indicators Eurostat

After gathering the required data for the analysis, the author will try to determine, using the indicators, firstly, which countries from the European Union have the highest level of good governance and what policies did they apply in order to reach that level.

The author will also try to find out new correlations and new theories out of this analysis.

1. Firstly, the **"new infringement cases"** indicator will be analyzed. As stated above, this indicator represents new direct actions brought before the Court of Justice, which concern the failure of a Member State to fulfill his obligations. (United Nations, 2007: 25–32; Mayntz, R., 2002: 86–99).

Therefore, the higher the number of new cases of infringement, the worse the level of good governance in that country. The data from Eurostat from year 2012 (the most recent year available) shows the following growth regarding new cases of infringement.

With the exception of Croatia, which has been recently added to the EU, and since there are no recent data to categorize it, the top list of new infringement cases in the member states shows as follows:

The countries with the smallest number of cases are: United Kingdom, Sweden, Finland, Romania, Austria, Malta, Latvia, Estonia, Denmark and Czech Republic. The leading countries with the largest number of cases in 2012 are: Poland, Germany, France, Italy, Spain, Hungary, Bulgaria and Slovenia. The in-between countries which have 1-2 new cases are Belgium, Ireland, Greece, Cyprus, Lithuania, Luxembourg, Netherlands and Slovakia.

[16] European Comission Report, Sustainable Development – Good Governance, available [Online] at: http://ec.europa.eu/eurostat/statistics-explained/index.php/Sustainable_development_-_good_governance#cite_note-6

[17] : Election Guide (CEPPS), Eurostat (tsdgo310).

[18] Idem.

[19] See Delwit, P., 2013, The End of Voters in Europe? Electoral Turnout in Europe since WWII, Open Journal of Political Science, vol.3 (1), pp. 44–52.

In parallel, the *average of the new infringement case numbers growth* (how much did this number grow in these six years) is analyzed, for the same indicator, from year 2007 until 2018. The list rendered the following order: (ascending, from the smallest numbers to the biggest numbers) Czech Republic, Denmark, Estonia, Latvia, Malta, Austria, Romania, Finland, Sweden, United Kingdom, Lithuania, Luxembourg, Netherlands, Slovakia, Belgium, Ireland, Greece, Cyprus, Bulgaria, Slovenia, Spain, Hungary, France, Italy, Germany and Poland.

It can be seen that almost all five leading countries kept their position: Poland, Germany, France, Spain and Hungary, which shows a constant growth in the last six years. The five countries that show the best numbers, which means less new infringement cases, are: Austria, Malta, Romania, Sweden and Czech Republic.

Between 2007 and 2018, the number of new Single Market related infringement cases fell by 38 %. Most of this decline occurred since 2010. Taxation and environmental issues make up the two largest groups of Single Market related infringement cases by policy sector, representing 44 % of all the pending infringement cases in November 2012.[20]

2. Moving on to the next indicator, **the transposition deficit** (which shows the percentage of Single Market directives which have not been notified yet "as national transposition measures" to the Commission in relation to the total number of directives that should have been notified by the deadline) the following can be observed:

After dropping significantly since 2000, the transposition deficit of EU Single Market law reached a new decrease of 0.6 % in November 2018. Promoted by the Internal Market Scoreboard as the 'best result ever', the transposition deficit was 0.4 percentage points below the 1 % target for the transposition of Single Market rules.[21]

Again, for the year 2018, the following 13 countries have big percentages (from 2% to 0.6%) of transposition deficit: Belgium, Poland, Austria, United Kingdom, Slovenia, Cyprus, Italy, Finland, Luxembourg, Lithuania, Spain, Germany and Bulgaria. The countries that have a number of deficits under 0.6% (from 0.5% to 0%) are: Hungary, Greece, Romania, Netherlands, Latvia, Denmark, Slovakia, France, Czech Republic, Sweden, Malta, Estonia and Ireland (with 0%).

Table 2 :Shares of Environmental and Labor Taxes in Total Tax Revenues from Taxes and Social Contributions %

Environmental taxes

	2008	2010	2018
Belgium	4,8	5,07	4,76
Bulgaria	10,69	10,6	10,11
Spain	5,08	5,19	4,82
France	4,13	4,15	4,08
Malta	10,18	9,34	8,86
Netherlands	9,58	9,83	9,12
Romania	6,35	7,52	6,84
Slovenia	8,06	9,64	10,15
Slovakia	7,03	6,65	6,18
Finland	6,27	6,55	6,96
Sweden	5,84	6,02	5,64
U. K.	6,54	7,55	7,42

Source: own processing of data from Eurostat

It can be observed that for the **period 2008-2018, the evolution of this problem regarding deficit** renders the following: The top 5 countries with the biggest percentages of deficit are: Poland, Italy, Belgium, Cyprus, Luxembourg and Greece. The top 5 countries with the smallest percentages of deficit are: Malta, Denmark, Latvia,

[20] http://epp.eurostat.ec.europa.eu/cache/ITY_OFFPUB/237EN/EN/237EN-EN.PDF
[21] Idem

Slovakia, Bulgaria and Romania. (S´everine Menguy, 2008: 1093–1105; Paredesa, J., Pedregalb, D. J. and Pérez, J. J., 2014: 84–97).

3. Taking only about the second and third part of the next indicator (openness and participation), which are e-government on-line availability and E-government usage by individuals, the following can be observed (data from annex 3*):

The 10 peoples that have used the internet mostly for interaction with public authorities, for a 3 year period 2008 - 2010 (most recent data) are: (starting with best score) Denmark, Sweden, Netherlands, Finland, Luxembourg, Estonia, United Kingdom, Slovenia, Austria and Germania. The last 6 countries on the list are: Poland, Italy, Czech Republic, Bulgaria, Greece and Romania. Yes, Romania is the last on the list, which means that Romanians hardly go online to search for public information.

Citizens' online interaction with public authorities in the EU rose by 8 percentage points between 2008 and 2018. After a slight decrease in 2011, internet interactions with public authorities have increased again, reaching 44 % in 2018. This trend partly reflects an overall increase in the internet usage across the EU.

4. Moving on to the **environmental taxes**, which represent tax revenues, they stem from four types of taxes: energy taxes (which contribute with around three-quarters of the total), transport taxes (about one fifth of the total), and pollution and resource taxes (about 4 %). (Mutiganda J. C., 2013: 518–531; Aronson, R. and Schwsrtz, E., 1996: 114–136).

The author of this paper extracted the data from Eurostat for a period of 3 years regarding this indicator, measuring the level of the revenues that comes from this type of environmental taxes. He chose a period no longer than 3 years because after verifying other options, he noticed that the data was constant.

The top ten countries that have the lowest level of environmental taxes (under 7%) are: France, Belgium, Spain, Germany, Sweden, Austria, Lithuania, Luxembourg, Slovakia and Hungary. The countries that have the highest level of taxes (over 8%) are: Slovenia, Bulgaria, Netherlands, Malta, Croatia, Ireland, Latvia, Estonia, Greece and Denmark.

Shares of Environmental and Labour Taxes in Total Tax Revenues from Taxes and Social Contributions %

Taxes on Labour

Chart 1

Source: own processing of data from Eurostat

This indicator "Economic instruments" has two layers. It considers the shares of environmental and labour taxes in total tax revenues from taxes and social contributions. One layer is environmental taxes, which has just been analysed and the second is labour taxes.

Taxes on labour are defined as all personal income taxes, payroll taxes and social contributions of employees and employers that are levied on labour income (both employed and non-employed). On average, about 65 % of labour taxes consist of social contributions.

The next graph will helps see the existent labour taxes level measured in percentage in each country of the EU.
It can also be seen that Bulgaria, Malta, Cyprus, United Kingdom, Romania, Poland, Croatia, Greece and Ireland have a level under 45 %.

The share of labour taxes in total revenues from taxes and social contributions showed a fluctuating but an overall increasing trend between 2000 and 2011, reaching almost 55 % in 2011. This is compared with an overall decline in the share of environmental taxes over the same period, reaching 6.17 % in 2011. This trend counters the Europe 2020 strategy's argument that 'raising taxes on labour, as occurred in the past, at great costs to jobs, should be avoided'.[22] Nevertheless, there are large differences in the share of labour taxation among the Member States, ranging from 33.4 % to 58.1 %.

Level of Citizens' Confidence in EU Institutions %

Chart 2

Source: own processing of data from European Commission, Eurobarometer

With regards to the environmental taxes, only two Member States (Bulgaria and the Netherlands) showed a share above 10 % of the environmental taxes in total revenues from taxes and social contributions in 2011, and two others (Malta, Slovenia) had a share above 9 %. In the remaining Member States, the share of the environmental taxes ranged from 4.15 to 8.94 %.[23]

5. Next on the list is **the level of citizens' confidence in EU institutions.** This indicator is expressed as the share of positive opinions (people who declare that they tend to trust) about the institutions.

On average, in the period 2011-2018, people in Denmark, Luxembourg, Belgium, Hungary, Estonia, Sweden, Slovakia, Bulgaria, Finland and Malta trust the EU institutions the most, while people from countries like UK, Spain, Greece, Cyprus, Italy, Slovenia, France, Latvia, Germany and Ireland have low trust level in the EU institutions.

Less than half of the EU citizens have trust in the three main EU institutions. In 2012, the European Parliament was the most trusted among them (44 % of the citizens say they trust it), followed by the European Commission (40 %) and the Council of the EU (36 %). Citizens' trust in political institutions on all political levels is generally low, especially regarding the political parties and institutions at the national level. [24] In order to create a good governance

[22] http://epp.eurostat.ec.europa.eu/statistics_explained/index.php/Sustainable_development_-_good_governance

[24] http://epp.eurostat.ec.europa.eu/cache/ITY_OFFPUB/237EN/EN/237EN-EN.PDF

level in the EU, several lists of scores obtained by these countries were created for each indicator. The countries that constantly got good scores in every list are: **1. Estonia, 2. Malta, 3. Denmark, 4. Sweden, 5. Bulgaria.** (6. Netherlands, 7. Latvia, 8. Finland, 9. Ireland, and 10. Luxembourg).

Analyzing Main Indicators World bank

Control of Corruption

The first two states with the best results in corruption control are Germany and UK, but both of their values were steadily declined in the 2003-2009 period, and only after the 2008, the crisis started to rise again. Furthermore, this gradual decline in corruption control is present in all the six countries, and the most visible one belongs to Bulgaria, which started from 2005 and continued through 2008 and 2009.

Control of Corruption in Germany, France, UK, Romania, Hungary and Bulgaria in the Period 2003-2018.

Chart 3

Source: own processing of data from World Bank

However, in most of the countries, the emergence of the crisis triggered slight increases in corruption control, when severe state interventions were actually required, and needed as much control as possible over corruption cases, which led to inefficiencies and waste of precious financial resources due to private interest use of the public money. Unfortunately, Romania and Bulgaria present negative values in corruption control. While in Bulgaria, there was that serious downfall, in Romania, there were slight increases over the years that were weakly affected by the financial crisis.

There was also a downfall in government effectiveness related to service provision, proper policy making, state commitment and credibility in the case of Germany, France and UK which reached similar values for all the three Western states in 2018. The other three countries are more dispersed, with Hungary following the Western trend for the decline in government effectiveness, then by Bulgaria which again had a series of increases and decreases during the analysis period, and of course Romania, which although it had less abrupt shifts, still maintained negative values related to government effectiveness up until 2018, and it appears in that it will reach a positive value in the forthcoming years.

Government Effectiveness in Germany, France, UK, Romania, Hungary and Bulgaria in the Period 2003-2018.

Political Stability and Absence of Violence and Terrorism in Germany, France, UK, Romania, Hungary and Bulgaria in the Period 2003-2018.

Chart 5

Source: own processing of data from World Bank

There is a severe downfall and subsequent uprisings in the political stability visible for all the analyzed 6 countries after the 2008 financial crisis, which can be explained by the increased level of social unrest due to diminishing incomes, high unemployment rates and severe austerity measures. One cannot but notice the heavy downfall of stability that happened in the UK in 2009, when it was lower than that of both Romania and Bulgaria, but which then started to increase after 2010, surpassing again the two countries. Hungary was one of the most stable countries at the beginning of the analysis period in 2003, but up until 2018, it drastically shifted a couple of times and fell behind Germany, which has the highest values from all the 6 countries and which experienced a major increase in the political stability from 2004 to 2005.

As for France, the country had two major uprisings and downfalls in the decade, ending up with a slightly lower value in 2013 compared to the UK. When it comes to legislation quality, according to the chart, the United Kingdom leads, followed by Germany, then France, then Hungary, and in the last two places, Romania and Bulgaria. For most of the countries, the shifts are not abrupt, except in the case of Romania where there is rather a significant increase from 2003 to 2006, in the period before entering the EU that continued with slightly lower increase values up until 2018. Last but not least, it is interesting to see that the countries are paired-two by having similar evolutions throughout the years.

As it was with the regulatory quality, the United Kingdom again leads in the Rule of Law dimension. Its course throughout the decade runs very close to and in parallel with Germany. France is again next, with a couple of shifts that somehow translate into a stagnation on this dimension since the values in 2018 are similar to those from 2003 despite those subtle increase-decrease turns. Bulgaria and Romania have an overlapping evolution which ends in 2007, the year in which they both entered the EU, when Romania had a slight increase in values up until 2018 while Bulgaria continued steadily, thus ending up being surpassed by Romania.

For Germany, France and the UK, regarding voice and accountability in the country, a small peak can be noticed for all the three in 2004, followed by a steady evolution in which Germany emerged as the leader, followed closely by the UK, and then by France. In the case of Hungary, a steady decline can be observed on the chart. Whereas Romania and Bulgaria again had an almost parallel course of a slight decline after their 2007 EU integration.

World Bank – Governance Indicators Correlation

One can see that for the most part, there is a direct correlation between corruption control and voice and accountability in Romania for the respective time period.

From 2003 to 2006, in the case of both indicators, a slight increase is visible which can be explained by mentioning that during that respective period, Romania was able to absorb pre-accession funds from the EU. Therefore, the corruption control inside the public institutions was increased, as a condition for administrative capacity, and concurrently public institutions in the country also became more open and representative to ensure better resource management and policy formulation and implementation. Then, after Romania's entry in the EU in 2007, the two indicators had a similar evolution - a slight decrease, followed by a slight increase, as more development funds were available to the country to access, both for public institutions and civil society organizations. Then, after the 2008 crisis, the indicators passed through a downfall, one more severe in the case of corruption control, than in the case of accountability and public voice, perhaps because the economical uncertainty triggered an increase in acts of corruption. After the crisis, the indicators took a different direction, so while the voice & accountability remained constant, at a significant level lower than before the crisis, the control of corruption shifted rather drastically, increasing after the crisis, then decreasing after 2011, followed immediately by another increase. This period was considered as one of many political scandals in the country as multiple cases of broad-scale corruption were uncovered, many political and public charts were caught in corruption scandals and some of them were even sent to prison. Of course, the parliament and the presidential elections in that period also contributed to these shifts as a consequence of the many power shifts caused by them.

Conclusions

Good governance is an absolute must in all countries because without proper resource management at state level, proper openness and participation, control of corruption, accountability, trust in public institutions, and sound legal frameworks, corruption, waste and loss of legitimacy become prevalent. Of course, other principles must be included so as to ensure good governance, such as transparency, efficiency and equity so that state institutions provide the best goods and services to citizens and make the most satisfying decision for all of them. Then, the measurement of good governance, by Eurostat and the World Bank, focuses on internal processes, how institutions should function and what principles to implement, like for example those mentioned above, but the author of this paper suggests a new series of indicators which focuses on the results or outcomes of state institutions, namely the real GDP/capita which measures the economical performance in terms of welfare and population income increase, and also proper resource allocation in social fields so as to diminish the rate of poverty risk for citizens, in environmental policies in order to reduce pollution and ensure long term socio-economical development and sustainability, and also in innovation, research and development in order to access more and more useful technologies which increase goods and service production and provision. As for concrete results, almost in all governance indicators from the World Bank, those mentioned before and also in terms of the economical performance, there is a high discrepancy between the Western States and the Eastern States, with better performances present in the Western States such as UK, Germany, France, Netherlands and Luxembourg, in contrast with the Eastern States such as Romania, Bulgaria and Hungary.

In order to achieve the principles of transparency, collaboration and involvement of citizens, a research instrument was created according to social sciences, by which the opinions of citizens will be collected, centralized and studied. This semi-structured guide interview allows respondents to identify by themselves as many local problems as possible and then evaluate them by the indicators of costs, emergency, period of time and number of people affected. The idea behind this method is that it will help in studying the differences between the evaluation of citizens and that of an expert, differences which consist in a helpful instrument for studying the degree of public awareness on local problems.

The author of this paper hopes that the instrument will be successfully applied through the local authorities' collaboration and citizens' implication. That will be a real achievement for his academic background and a strong sign for participatory democracy in allocating public funds for local problems.

Abstract

Social restrictions and suggestions to stay at home in the era of the Covid-19 pandemic have changed Indonesian people's habits to interact with one another, including donation activity. This study aims to determine the factors contributing to Donation Switching Behavior from the use of cash to Financial Technology during the Covid 19 Pandemic. This study uses the Technology Acceptance Model (TAM) with the addition of the Safety Needs and Trust variables. Data obtained from a questionnaire analyzed by PLS-SEM. The results showed that Perceived of Use and Trust had a significant positive effect on Switching intention to pay for digital donations through financial technology platforms. Other variables, Perceived of Used and Safety Needs, do not affect Switching Intention. On the other hand, Switching Intention supports Switching Behavior to make digital donations during the Covid-19 pandemic.

Keywords: Digital Donations, Financial Technology, Switching Behavior, Covid-19 Pandemic.

Introduction

The uncontrolled spread of COVID-19 has caused more than 800,000 people to die from all over the world (WHO, 2020). To reduce the spread of the coronavirus, Indonesia government has implemented a lockdown and physical distancing. The government also continues to campaign for the slogan to stay at home and advocate work from home and learn from home to limit meetings between people. It directly affects the performance of companies and other institutions. The situation in this pandemic has caused a huge challenge that has never happened before, the company will experience many changes so it is necessary to rethink the strategy of a company to survive (Pantano, 2020).

Finally, the employees of the company also lose their income and even their jobs. The World Bank (2020) claims that this pandemic is hitting workers with daily wages in emerging countries because more than 23 million people will become lower. It means that the coronavirus's impact has not only caused problems for human health and safety but has also penetrated economic and social problems.

On the other hand, a positive effect of efforts to control the coronavirus spread is increasing digital services. The implementation of lockdown and physical distancing has limited the interaction space between people. It causes people to switch from direct interaction to digital services. That way, they can protect themselves from the possibility of contracting the virus. The pandemic forces people to access extraordinary digital leaps that require significant adjustments among the community (Iivari et al., 2020).

Redseer collected data showing the increasing use of digital services in Indonesia during the COVID-19 pandemic. The sector that experienced the most increase was e-commerce by 69%; the use of digital wallets also increased by

65% (Katadata, 2020). The report submitted by The Financial Services Authority (OJK) of Indonesia also shows the growth of lending based on financial technology of 185.54% year-on-year (Detikcom, 2020). The data above shows that the migration of people to use financial technology is very significant for their daily activities. It also means that financial technology has a critical role in supporting public financial transactions during a pandemic in the financial sector.

Moreover, related to the migration to use financial technology for financial transactions, financial technology can be one of the choices for people to collect donations during a pandemic. That is how, in this study, we highlight the factors that contributed to the behavior of shifting donations from using cash to financial technology during the Covid 19 Pandemic. Research on switching to financial technology services is still very limited and still focuses on commercial financing. Afandi (2020) reviews the switching of banking customers to financial technology lending services. Another study analyzed customer switching to internet banks (Cheng and Davis, 2012; Yen and Malarvizhi, 2016; Yu, 2015; Devlin and Yeung, 2003).

Literature Review

Since Keaveney (1995) introduced, studies on customer switching are continuously developed by researchers from various fields. Ross (1999) discusses the service provider switching model, Colgate and Hedge (2001) review the switching process in retail banking, while Marshall et al. (2011) in the financial market. Bansal et al. (2005) use migration as an analogy to explain the concept of consumer's switching behavior. Consumer's switching behavior is a migration of customers from one service provider to another. According to Bansal et al. (2005), migration can occur because of consumers' willingness at any time because consumers feel they have no choice but to migrate, for example, if their service provider closes, or because they adjust their needs.

This research highlights people's migration in donating using financial technology during the COVID-19 pandemic. This research focuses on the migration of people in donations using financial technology during the COVID-19 pandemic by examining the factors that influence it. Use of FinTech in line with the lockdown and physical distancing rules because FinTech focuses on the use of digital services it diminishes the need for physical interaction.

The Financial Stability Board (FSB) defines financial technology (FinTech) as a form of technology-based financial innovation that can produce new business models, applications, processes or products with material effects related to financial markets, institutions, and financial services, providers. FinTech products can be divided into four categories based on the type of innovation; Payment, e-aggregator, risk and investment management, and peer to peer lending and crowd-funding. Rashmi (2018) discovered that implementing non-cash transactions increases GDP by using cards and reduces social costs, increasing financial inclusion as a society can adapt to electronic payments. Ragaventhar (2016) found that the cashless society can be described as an economic condition when financial transaction activities are not carried out with physical money in the form of paper or coins, but through transfer of information between transacting parties.

The Technology Acceptance Model (TAM) is built from two main factors, perceived usefulness and perceived ease of use (Davis, 1989). Perceived usefulness theorized to be influenced by perceived ease of use (Davis, 1989; Pavlov, 2003; Diop et al., 2019; Alsamydai, 2014; Ghani et al., 2017; Ha and Stoel, 2008). According to Lin and Wang (2017), a user is likely to switch if the service can be more useful. It is perceived usefulness that has positive and significant effects on switching intention (Fahmi et al., 2018; Msaed et al., 2017). Moreover, several studies have also concluded that perceived ease of use influences switching intentions (Fahmi et al., 2018; Msaed et al., 2017; Syah et al., 2018; Afandi and Mutaali, 2019; Afandi, 2020). We used an extended Technology Acceptance Model to evaluate switching behavior in donations using FinTech during the COVID-19 pandemic by adding safety needs and trust.

The number of people infected with the coronavirus is increasing every day. Therefore, in these times, security and safety are essential. Refer to Maslow's hierarchy of needs theory, safety needs are protection, security, order, stability, and freedom from fear (McLEod, 2018). In particular, Berry et al. (2020) divided safety needs in a pandemic into four categories; physical, emotional, financial safety, and information safety. The four categories are to serve as

benchmarks for the acceptance of a service product during the pandemic. It means safety needs can also affect technology adoption during the pandemic. The study discusses safety needs as an effect of consumer behavior is still limited. So, this research will enrich the literature on this subject.

Online transactions have characteristics of uncertainty, dependability and risk (Mulia et al., 2020). So, consumer trust has become vital for business success in the electronic-based payment system (Mondego and Gide, 2018). Trust in business service could be measured by three dimensions: competence, benevolence, and integrity (Mayer and Davis, 1999).

Trust has a positive effect on switching intention (Lin and Wang, 2017; Kordnaeij et al., 2015; and Al Ghammari and Ahmed, 2017). In other studies, trust is significantly related to brand switching (Tumbol et al., 2017). Furthermore, customers' intentions to switch positively affect their actual switching or switching behavior (Bansal et al., 2005; Lin and Wang, 2017; Sahi, 2016).

Based on the relationships proposed by the TAM model, we consider the following hypotheses:

H1: Perceived Ease Of Use is positively related to the switching intention in donations using FinTech during the COVID-19 pandemic.
H2: Perceived Usefulness is positively related to the switching intention in donations using FinTech during the COVID-19 pandemic.
H3: Perceived Ease Of Use is positively related to Perceived Usefulness.
H4: Safety Need is positively related to the switching intention in donations using FinTech during the COVID-19 pandemic.
H5: Trust is positively related to the switching intention in donations using FinTech during the COVID-19 pandemic.
H6: Switching Intention is positively related to the switching behavior in donations using FinTech during the COVID-19 pandemic.

Figure 1: Research Model

Research Methodology

This study uses primary data collected using an online survey in June 2020 during the COVID-19 pandemic. The sample and population in this study were Indonesia people who never have, rarely, and only occasionally or not often use FinTech to donate before the COVID-19 pandemic. Then, the data collected analyzed by partial least square structural equation modeling (PLS-SEM) using smart PLS software. PLS-SEM is a statistical modeling technique and is primarily used to develop theories in exploratory research (Hair et al., 2017). The questionnaire's measurement tool uses a five-point Likert scale ranging from "strongly disagree" to "strongly agree."

The measurement items based on theory and previous researches. The measurement items of perceived ease of use and perceived usefulness adapted from Ghani et al., (2017), Mulia et al., (2020), and Niswah et al., 2019. Safety needs items develop from Berry et al. (2020). The measurement items of trust, refer to Mayer and Davis (1999), Lin and Wang (2017), and Mulia et al., (2020). Both measurement items of switching intention and switching behavior were adapted from Bansal (2005), Lin and Wang (2017).

Stage of evaluation	**Parameters**	**Role of thumbs**
Evaluation of measurement model		
Reliability (internal consistency)	Cronbach's alpha Composite reliability	≥ 0.70 – 0.95 ≥ 0.70 – 0.95
Convergent validity	Indicator reliable by outer loading AVE	≥ 0.70 ≥ 0.50
Discriminant validity	Outer loading or Fornell-Larcker criterion	outer loadings > cross-loadings the square root of AVE > its correlation with any other construct
Evaluation of structural model		
Coefficient of determinant	R2	values of 0.75, 0.50, or 0.25 can be described as respectively substantial, moderate, and weak
Predictive relevance	Q2	>0
Size and Significance	Path coefficients T statictics P value	-1 - +1 represent negative to positive relationship t value > 1.96 p value < 0.05
F2 effect sizes		Values of 0.02, 0.15, and 0.35 indicate an exogenous construct's small, medium, or large effect, respectively

Source: Hair et al., 2017; Garson, 2016

Meanwhile, accepted and rejected hypothesis criteria as follows.

a. Assess the significance value and outer weight of each indicator. Weight value which suggested are positive and t-statistic greater 1.960 (p-value < 0.05 for two-tailed. The indicator with a value less than this requirement should be dropped out from the model and then re-analysis.

b. Assess the inner weight from relationship on latent variable. Weight of value should be showed positive with t-statistic greater 1.960 (p-value < 0.05) for two-tailed.

c. Alternative hypothesis (Ha) has accepted if weight value from relationship on each latent variable showing positive value with t-statistic greater 1.960 (p-value < 0.05) for two tailed. Contrarily, H0 failed to rejected if weight value from relationship on each latent variable showing negative value with t-statistic greater 1.960 (p-value < 0.05) for two tailed.

Data Analysis and Results

Table 1 presents demographic information about gender, education, occupation, income, and knowledge of donations through the financial technology of respondents who participated in the study. Table 1 shows that slightly half of the respondents were women (65.45%), while the remaining half were men (34.55%). For the education sector, the results showed that the majority had degrees (59.16%), high school (21.99%), master's (12.04%), and diploma (6.81%). Likewise, the results of the study show that the majority of those who earn less than IDR 3,000,000 (45.03%), earn between IDR 3,000,000 - IDR 5,000,000 (23.56%), earn between IDR 5,100,000 - IDR 10,000,000 (23.04%) and the rest have income between Rp.10,100,000 - 15,000,000 (6.28%), and have income above Rp.15,000,000 (2.09%).

Table 1: Descriptive Analysis of the Demographic

Variable	Content	N	Percentage (%)
Gender	Male	66	34.55%
	Female	125	65.45%
	Total	**191**	**100.00%**
Education	High School	42	21.99%
	Diploma/Certificate	13	6.81%
	Degree	113	59.16%
	Master	23	12.04%
	Total	**191**	**100.00%**
Occupation	Student	48	25.13%
	Civil Servant	18	9.42%
	Private Employee	53	27.75%
	Entrepreneur	15	7.85%
	Professional (Consultant, Doctor)	8	4.19%
	Academics (Lecturer, researchers)	10	5.24%
	Wife house	26	13.61%
	Other	13	6.81%
	Total	**191**	**100.00%**
Income	< Rp. 3.000.000	86	45.03%
	Rp. 3.000.000 - 5.000.000	45	23.56%
	Rp. 5.100.000 - 10.000.000	44	23.04%
	Rp. 10.100.000 - 15.000.000	12	6.28%
	> Rp. 15.000.000	4	2.09%
	Total	**191**	**100.00%**
Know about FinTech for donation	Yes	118	61.78%
	No	73	38.22%
	Total	**191**	**100.00%**

Measurement Model

In the first-stage measurement model, we evaluated the internal consistency reliability with Cronbach's alpha and composite reliability values. Cronbach's alpha value and reliable reliability values are variable values that are higher than 0.7. This testing technique is a questionnaire testing technique that is often used (Bryman and Bell, 2007), and can detect inconsistent indicators (Malhotra, 2012). In table 2, it can be seen that the Cronbach's alpha value PEOU = 0.935, PU = 0.917, SB = 0.896, SI = 0.907, SN = 0.766, TRUST = 0.885. and the composite reliability values were PEOU = 0.951, PU = 0.917, SB = 0.897, SI = 0.907, SN = 0.766, and Trust = 0.886. These values assume that the six variables are consistent and reliable.

Table 2: Items loading, Composite Reliability (CR), internal consistency reliability (ICR)

Construct	Items	Item loading	Composite Reliability	ICR (Cronbach's alpha)
PEOU	PEOU1	0.856995587	0.951247477	0.935698116
	PEOU2	0.92007398		
	PEOU3	0.928222917		
	PEOU4	0.901446172		
	PEOU5	0.852011436		
PU	PU1	0.837287855	0.938100549	0.917481518
	PU2	0.878964897		
	PU3	0.891865613		
	PU4	0.878430493		
	PU5	0.848210191		
SB	SB1	0.857683942	0.935439726	0.896788069
	SB2	0.934103351		
	SB3	0.936976893		
SI	SI1	0.890320668	0.941775647	0.90707534
	SI2	0.930546907		
	SI3	0.933934275		
SN	SN1	0.828630877	0.844903012	0.766144857
	SN2	**0.665813753**		
	SN3	0.847987306		
	SN4	0.767742396		
	SN5	**0.464548187**		
TRUST	T1	0.872404337	0.920947248	0.885571178
	T2	0.855238655		
	T3	0.847457889		
	T4	0.875817207		

Other measurement tests such as item loading criteria are also checked so that all questions are valid and reliable to be used as a variable measure in the survey. Convergent validity values indicate the value of different instruments capable of measuring the same construction (Portney and Watkins, 2000). This value can be measured by loading the factor item in the model construction. Barclay, Higgins, and Thompson (1995) describe the observed principle for convergent validity by maintaining items with a load of 0.7 or more. The table shows that all items except SN2

(0.6658) and SN5 (0.4645) have item loading values above 0.7. Meanwhile, items with a value below 0.7 were excluded from the analysis model.

Discriminatory validity is ensured well when the AVE value is above the threshold value 0.5, and the square root of AVE is more significant than all other cross-correlations (Gefen and Straub, 2005). The table shows that the diagonal (thickness) value is greater than the corresponding correlation value in the adjacent column and row, so the discriminant validity is confirmed.

Table 3: AVE and Discriminant Validity

	Average Variance Extracted (AVE)	PEOU	PU	SB	SI	SN	TRUST
PEOU	0.796	**0.892312**					
PU	0.752	0.774273	**0.867197**				
SB	0.829	0.482656	0.37916	**0.910329**			
SI	0.844	0.496037	0.586211	0.625568	**0.918481**		
SN	0.531	0.577501	0.711601	0.371686	0.565939	**0.728595**	
TRUST	0.744	0.559985	0.582842	0.580582	0.645839	0.58467	**0.86281**

In determining the model's effectiveness in terms of predictability, we evaluate the coefficient of determination (R2), which can indicate that the model is working well for most of the variables. The determination coefficient (R2) describes the proportion of construct variants that can be predicted by the model's antecedent constructs. Although there is no specific limit value for measuring R2, a high value demonstrates a better variable contribution (Gefen et al., 2000). R2 values higher than 0.1 can indicate the usefulness of endogenous variables in the model (Falk and Miller, 1992).

The table below shows the coefficient of determination for all variables in the model. Most of the variables have a value of more than 0.1. In terms of choosing the ultimate criterion variable, most of the variance is. The variable affecting PU = 59.9%, SB = 0.391, and SI = 0.494 so that the model can explain the three variables influenced by the independent variable.

Finally, the overall measurement test is well. It indicates that all statement items are valid and reliable and can use as a measure of variables in the survey.

Table 4: R Square

	R Square	R Square Adjusted
PU	0.5994993	0.59738
SB	0.391335	0.388115
SI	0.49497	0.484109

Structural Model

Figure 2: Structural model

Table 5: Path Coefficient Result

Hypothesis	Path Coefficient	T Statistics (|O/STDEV|)	P Values	Result
H1: PEOU -> SI	0.24338005	0.244	0.807	Rejected
H2: PU -> SI	-0.02012531	2.106	0.036	Accepted
H3: PEOU -> PU	0.77427343	17.526	0.000	Accepted
H4: SN -> SI	0.15667408	1.685	0.093	Rejected
H5: Trust -> SI	0.42365459	5.962	0.000	Accepted
H6: SI -> SB	0.6255677	11.017	0.000	Accepted

The results of the Smart PLS structural model can be illustrated in the table below, which demonstrates the relationship of constructs of this study. The path coefficient results are available in the table whose results are also shown in the modeling figure. Perceived Usefulness has a significant negative relationship with SI, while Trust has a significant positive relationship with SI, and SI also has a positive effect on SB. On the other hand, the Perceived Ease of Use and Safety Needs variables have an insignificant relationship with Switching Intention to make donations through Fintech during the Covid-19 Pandemic.

This study found that most respondents considered financial technology easy to use.? However, the research results do not show the effect of Perceived Ease of Use on Switching Intention. H1 was rejected because the relationship between Perceived Ease of Use and Switching Intention has a t-statistic <1.96 and p = 0.807. The results of this study are different from Fahmi et al. (2018, Syah et al. (2018), and Msaed et al., (2017). In previous studies, they found a positive relationship between Perceived Ease of Use and Switching Intention. This study's difference in research time was held since social restrictions were imposed during the Covid-19 pandemic. In contrast, previous research was conducted when there was no pandemic, and there were no social restrictions. Bansal et al., (2005) found that changes or migration of behavior can only occur because of the user's willingness when they have no other choice but to migrate according to their needs.

This study resulted in the finding that Perceived of Use affects Switching Intention such as research H2. Perceived of Use has a positive and significant effect on Switching Intention with a t-statistic of 2.056 and a p-value of

0.040. This finding is in line with research conducted by Fahmi et al. (2018). The research shows that the Perceived of Use financial technology positively influences switching intention. In particular, the perceived benefits affect the public in making donations using financial technology services. Therefore, most respondents answered firmly that the ease of using and accessing financial technology through their devices could save time, be flexible, and feel comfortable. In Indonesia, large-scale social restrictions (PSBB) have been in place since April 2020, a month after Covid-19 began attacking Indonesians. Thus, this study sees a change in the intention to share assets (donations) to poor people through financial technology.

Perceived Ease of Use in the results of this study positively affects Perceived of Use to support H3. PEOU has a significant effect on PU with a statistical value of 15,831 and a p-value of 0.000. The positive effect of the relationship between these two variables confirms the findings of Davis (1989), Pavlov (2003), Diop et al. (2019), Alsamydai (2014), Ghani et al. (2017), Ha and Stoel (2008). These findings suggest that the easier a financial technology service is to use, he more people will use the service so that the public can change intention to use it at one time or continuously.

Variable Safety Needs does not affect Switching Intention. Thus, H4 is not supported. The question of safety needs relates to the safety needs of making donations with technology financial services when the Indonesian government imposes social restrictions.

The findings show that Trust has a positive effect on switching intention so that H5 is accepted. Trust affects Switching Intention with a statistical value of 6,026 and a p-value of 0,000. The positive influence of the two variables supports the findings of Lin and Wang (2017), Kordnaeij et al. (2015), and Al Ghammari and Ahmed (2017). Trust is an essential element that underlies electronic transactions. Therefore, it is necessary for service providers of products to build user trust. Digital donation requires an added value that donors can accept so that Trust can grow in users' minds so that it does not raise suspicion and does not dampen changes in intention to use digital financial platforms. Indicators of service capability, policy and service provider integrity are used in the Trust variable research question.

The final research hypothesis (H6) is accepted because it has a T-statistical value of 11.017 and a p-value of 0.000. Switching Intention positively and significantly influences switching behavior. The results of this study confirm the previous findings of Bansal et al. (2005), Lin and Wang (2017), Sahi (2016), which show the significant influence of these two variables.

Discussions, Implications and Conclusions

This research focuses on the transition of people to making donations via digital platforms during the Covid-19 pandemic. Social restrictions and orders to stay at home force people not to leave the house so that behavior changes from the normal era. The Indonesian community usually makes donations in various ways, by donating directly to charities, places of worship, foundations, or donating by meeting directly with people in need. Donations positively impact economic growth because this behavior is a distribution of income, especially during the Covid-19 pandemic.

This study concludes that the variable that positively and significantly supports the transfer of one's intention and behavior to donate using a digital platform during the Covid-19 pandemic in Indonesia is Perceived of Use. These results indicate that digital donations users already have a high level of confidence in switching intention of digital donation activities.

Trust variable also has a significant positive effect on Switching Intention. These findings indicate that trust is a factor that needs to be considered in the efforts of digital service providers so that they are able to change the intentions of digital donors.

In addition, Perceived Ease of Use also has a positive influence on Perceived of Use. These results prove that the ease of using technology in conducting donation activities through digital platforms provides more benefits and provides a positive response by potential users to attract them to use digital donation services.

Furthermore, Switching Intention also has a significant effect on Switching Behavior. These results indicate that Switching Intention indicates a change due to a shift in perspective on an object that makes individuals change their behavior, starting with an interest in finding information about digital donation services, considering using it, and making donations through financial technology.

The results of the influencing variable have implications for academics and stakeholders. For researchers, this research can become a foundation that leads to further research on digital donations in the Covid-19 pandemic era. This study explains the factors that can make people shift their intention and behavior to use financial technology services for stakeholders, especially donation service providers. This is because the public considers practical payments, benefits both the giver and recipient, time efficiency, and costs. Public trust can also be built from well-targeted distribution of donations.

Providers of the donation platform at a financial technology provider can continue their experiments so that the public can start accepting so that donation transactions can continue during the global crisis due to the Covid-19 pandemic. Future research should try to develop more variables to contain a more accurate sample representation.

Abstract

The article examines the patterns and specifics of the development of social processes and managerial reality, typical for most European countries at the end of the 20th and the beginning of the 21st century. Based on the methodology of public administration, the main trends in modern society and governance development are identified, analyzed and generalized: changes in public administration priorities under the influence of ambiguous socio-political processes at the turn of the century are substantiated. The controllability of administrative structures is characterized as a basis of sustainability of the society and governance. The problems of social interaction, responsibility and democracy in modern management practices are defined. It is suggesed that the influence of information technology and the revitalization of the civil society have led to such changes in social reality, the assessments of which are ambiguous and controversial, both in countries of democratic transformation and in mature European democracies. They have influenced the formation of certain trends, which sometimes show opposite and not always constructive directions. It is argued that improving the efficiency of public administration by involving public in the development and implementation of policies, improving the timing and quality of qualified management decisions determine an important positive trend in the development of public administration the and society as a whole. At the same time, the change of generations of managerial elites in post-totalitarian countries has led to problems against the background of attempts to simplify the essence and algorithms of management and spontaneous changes in the institutional structure of society and government. Gaining experience, mastering modern communication technologies and professional training, obviously, have a chance to balance these trends in favor of improving the quality of both management and society i life n general.

Keywords: Governance, Information Technology Influence, Social Transformation, Manageability.

Introduction

The existing public administration systems in the vast majority of developed countries in Europe and the world are in a state of permanent reforms against the backdrop of dynamic changes in geopolitical balance, geostrategic imperatives and relevant national strategies. There are changes in the attitudes and priorities of states, attitudes and aspirations of individuals and social groups in different spheres of society's life. The sphere of public administration during the second half of the XX - beginning of the XXI century has been substantially updated, both as regards the interpretation of the role and place of governance in the context of social change, and concerning methods and tools for the implementation of immanent governance functions. There is a need to clarify the conceptual approaches of government bodies to social interaction in crisis situations of different origins.

The methodology of scientific research of the indicated processes and senses is conditioned by the recognition of the principles of human rights as fundamental in the modern paradigm of state administration. The genesis of the conceptual positions of human rights in society and governance are considered on the basis of the dialectical method of cognition. The dialectical method also allowed substantiating the causal relationships between social

Cite this Article as: Larysa NOVAK-KALYAYEVA and Jarosław CZERW "Regularities and Specific of Modern Governance Development Under the Influence of Information Technology and Sociopolitical Transformations" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

processes and phenomena, which resulted in the introduction of human rights methodology in governance theory and practice, including the concept of sustainable development. It is on this basis that the basic imperatives of the development of modern society and governance are formed. At the same time, the interpretation of these processes has never been unambiguous in the historical retrospect and remains debatable in our day. The historical method is used in the retrospect of European state-building and governance in the context of the emergence, establishment and development of humanistic ideas. The axiological method has made it possible to characterize the social values which are accumulated in the concepts of human rights and sustainable development and are transposed to the criteria of the effectiveness of public administration.

The issues of public administration efficiency are being actively discussed in interdisciplinary discourse by such scholars as V.Bakumenko (2003), Z. Bauman (1996), G.Rouet, G.C.Pascariu (2019), J.R. Grote (2018), J. Kooiman, (2003), P. Nadolishniy, P. (2003). V.Schmidt (2019), M.Wood (2019) etc. This perspective has significant practical potential, which determines the relevance and timeliness of its further development against the background of current challenges and threats. The purpose of the article is to identify and analyze the main trends in public administration in the dynamics of information technology and socio-political changes, summarize their impact, in particular on efficiency, social interaction and democratization of society and governance at the end of the 20th and the beginning of the 21st century.

Analysis and Results

Changing priorities of public administration under the influence of ambiguous socio-political processes at the turn of the XX century

Reforming the management system in accordance with the specifics of social development of each country can ensure the alertness and adequacy of public administration in solving current problems and determining strategic prospects, in particular local communities. The main feature of the current stage of the development of both advanced European democracies and countries of democratic transit is the commitment of governments to rationalize the national system of public administration and to raise the level of its efficiency. One of the most effective and efficient ways to achieve this goal is to democratize management practices, particularly by involving the public in governance processes. Such an approach could bring positive effects on the level of public legitimacy of the government and guarantee the support of population in the implementation of public policies. The rule of law as a basic component of public administration stimulates a public debate on freedom of thought within the democratic tendency aimed at developing a dialogue between the society and the government in order to increase the effectiveness of the latter.

Despite the strong skepticism of scholars, in particular executives, political scientists, sociologists, philosophers, economists of the late XX - early XXI centuries, who have expressed some reasoned doubts about the ability of the state and government to influence the development of the society in terms of information and technological changes and deep individualization and political subjectivity of citizens, a modern state, as a guarantor of security, productivity and sustainability of society, has not exhausted its potential.

There is a reassessment of the principles and theoretical concepts typical of the last century. The point is that the concepts of "welfare state", "social state", "new state management", "low-cost state", etc., embodied in the 2nd half of the 20th century, have largely exhausted themselves. This has led to the emergence of more balanced approaches, typical of the theory and practice of "appropriate governance", "activating state", "e-state" and so on. There are also the attempts to form a "generalized model" of public administration capable of meeting national needs and harmonizing basic approaches at the integration level. The search for a universal approach to public administration reforms is becoming a transnational movement which is aimed to optimize these reforms and is based on the theoretical research in the field of public administration in the interdisciplinary discourse.

Interdisciplinarity demonstrates the organic connection of the theory of public administration with philosophy, political, legal, economic and other sciences, the subject of which is society and its functioning. Economic, psychological, legal and sociological aspects of development and functioning of management structures, in which mechanisms and tools that can satisfy the society regarding the management are formed, condition the variety of proposals to achieve the benefits of a "well-organized society" led by authoritative leaders and effective public management based on the conscious support of civil society and entrepreneurship and in close cooperation with them.

At the turn of the century, theoretical and methodological studies of the conceptual foundations of public administration have demonstrated ambiguous approaches in assessing the prospects for their improvement or reform. J. Habermas (1992), in particular, questioned the ability of European nation-states to "manage national economies as their own economic resources" in the context of globalization. In turn, the adherents of the postmodernism minimized the analysis of the issue of the dominant theories of public administration to the need to recognize their random nature. D. Farmer (1995) encouraged theorists of administrative management to abandon their residual scientism and recognize that public administration is "one more language game" among others in order to "overcome the fascism that we all have". According to the scientist, it is necessary to fight for "anti-administration", which is radically open to a variety of "coincidence" and "otherness" (D. Farmer, 1995, p.228), and "in this way, perhaps, we will be lucky to develop an anti-program and form an anti-institutional line of thought, still providing services"(D. Farmer, 1995, p.243). The issue of responsibility for the consequences of such management was left far from the author's spotlight. Z. Bauman (1996) was more optimistic about the process of state transformation in European countries, emphasizing that, "against the background of a conflict-ridden planet, Europe looks like a laboratory where the tools to improve public administration are still being developed". Attempts, according to Wilson's advice, to adapt the modern science of public administration to the "basic practical needs of democratic self-government" were ultimately aimed, according to V. Bakumenko (2003), at achieving public independence and administrative efficiency.

Political and economic elites, personal positions of government officials and politicians, who sought to strengthen the existing system of public administration and restore public confidence in public institutions, led to the nature of administrative reforms which have been in progress in some European countries and the EU since the early80's of the 20th century. Despite the significant interest of scientists in the theoretical issues of public administration in different countries, in the scientific literature, according to J.Czerw (2020), there is still no consensus on the ability of individual, territorially determined theoretical approaches to ensure the effectiveness of public administration in practice.

The common traditions of European management culture,which are approximately the same for the most developed European countries, and socio-economic and political conditions have become important regional factors in the process of modern governance universalization. Specific socio-cultural characteristics such as traditions, customs, psycho-emotional characteristics of the population are individual for each European country and significantly affect the current situation. They are becoming demonstrative under the influence of globalization and imperatives of expediency, efficiency and effectiveness of public administration, both nationally and and at the integration level. The ambiguity in the assessments of social experiments of the implementation of certain concepts, in particular European ones, does not diminish the importance of the practical experience of European countries to implement the theory.

At the turn of the century, a common trend is the desire of modern managers to determine the structural-functional, instrumental and tactical algorithms of public administration, taking into consideration the complexity of multilevel and multifunctional management structures at the integration level and the effectiveness of multilevel governance in decentralization (L.Novak-Kalyaeva et al, 2018). For most of the "old democracies", which developed and implemented efficient social models, offering the population their specific but effective approaches to solving problematic aspects of life of all population categories, the social component remained important but was not longer as acute as in the postwar years. The vast majority of citizens of the developed countries in Europe and America were provided with the ability to satisfy their essential daily needs and receive assistance from the state in case of need. New approaches to the interaction of government and society have led to social activity of the people and accountability and controllability of the government on the basis of decentralization and professionalism of public administration. Instead, the implementation of the policies and management concepts aimed at improving the welfare of the population remains an unconditional priority for Ukraine. That is, the social determinant remains relevant and predominant among others.

Generalization of the latest approaches to governance has been proposed by international structures, which have identified common factors for all countries that determine compliance or inconsistency of public administration with the needs of society at the present stage of its development. The United Nations has stressed the necessity to improve the governance through human development and political reforms of public institutions. According to the UN the guiding principles of proper governance should be as follows: a focus on the rule of law, efficiency, consensus in management, activity, predictability, transparency, responsibility, intelligibility, fairness and ability to respond adequately to public inquiries (UNESCAP, 2009).

The major donors and international financial institutions, including the International Monetary Fund and the World Bank base their efforts on the belief that the recipient will use financial assistance and loans to implement reforms that ensure effective governance by eliminating inefficient management and corruption. In particular, in 1996 the International Monetary Fund (IMF) stated that “the implementation of appropriate governance in all its aspects, including through ensuring the rule of law, improving the efficiency and accountability of the public sector and combating corruption are the key elements of the structure, in which the economy can prosper " (The IMF's Approach, 2005). According to the IMF analysts, corruption in the economy was due to inefficient economic governance and inconsistency of proportions when regulation was either too much or too little. In 1992 the World Bank, which was more closely associated with the reform of economic and social resource management, highlighted three aspects that affect the nature of governance in a country: the type of political regime, the process by which power is exercised for the purpose to develop the management of economic and social resources, the government's ability to form the policy and ensure its effective implementation.

Manageability of management structures as the basis of sustainability of the society and governance

The imperative for implementation of modern approaches to governance was " manageability of management", because one of the most important general consequences of changes in public and private governance is a significant loss of traditional institutions of control, deregulation of checks and balances system of power, mechanisms of its accountability when populists and non-professional politicians and managers come to power, or the use of outdated or less effective practices. Such issues are important for interdisciplinary research, and the science of public administration is an element that unites the components of interdisciplinary discourse, in particular the problems of governance, accountability and legitimacy of power.

Effective governance always requires a certain centralization and concentration of political power in order to ensure human security, that is to solve the problems of rational social order, crime, civil conflicts and wars, including hybrid ones; protection of people from threats of natural and technological origin, problems of physical and economic survival; protection of nature from people, that is the problems of greening the governance and environmental thinking. In the modern world the differences between the public and private enterprise, between politics and economics, between politics and administration, as well as between the commercial and non-profit sectors are exacerbated.

Overcoming or at least reducing contradictions is a challenge for the governing bodies and self-organization of the population. It is about developing an updated system of checks and balances in order to control the exercise of powers, prevent possible abuse and arbitrariness of their use, motivate the authorities to be accountable and protect citizens, consumers and employees. The latter is always a source of tension at all levels of governance and administration. In this context the loss of compliance or balance reduces the power and impedes the ability of authorities to act and ensure the policy implementation (Support to political parties, 2020).

Thus, manageability in the context of public administration means a fairly high level of political and institutional stability and efficiency of a decision-making process at all levels of governance. This applies to the continuity of rules and institutions, as well as the pace of the response to public demands, the consistency and effectiveness of management decisions. In practice, this is a shortcut between a request from the society and the result of government actions in order to respond to that request. In general, it is the potential for further adaptation between the standard and its implementation, between the regulation and its results, between supply and demand for policy and administrative services. Controllability depends on the quality of the management, that is the level of maturity of organized society and its ability to rely on overall responsibility in the implementation of decisions and in the art of appropriate management.

Controllability in the society is determined by certain indicators, in particular the intensity of the existing demand for public policy, that is how satisfied the community is with services and changes in regulations; the intensity of political conflicts and the ability to resolve them proportionately and meet the demands; the nature of obstacles to meeting society's request. In particular, according to J. R.Grote, (2018), it is necessary to identify whether they are the result of chronic problems and outdated structures, the capacity of the institutional system, especially the political one with its normative-legal environment concerning the response to the demand of society and the expediency of the division of competencies for its satisfaction among different branches of governance; measures of autonomy, corporatism and direct influence at all levels of governance; the level of governance in a civil society in

general, and also regarding the possibility to exercise public control over government institutions; the level of the civil society involment in the development of rules and in activities for the benefit of the state interests.

In each country the strength or capacity of state organizations is imposed, firstly, on democratic political institutions that exercise the rule of law, human rights, stability, efficiency and legitimacy of government or administration; secondly, on the quality of public policy, especially their economic and social component, in particular at the operational level, in accordance with the adopted strategic goals; thirdly, it depends on the quality of public administration that implements these laws and policies and is able to be effective in terms of increasing society's demand for social services provided by the state. Ensuring the governability in public administration is imposed on the strategic core of the government, which should be formed of professional senior public officials and provide the highest quality services in conjunction with elected politicians in accordance with the public decisions. On the other hand, each government should rely on the decentralized state infrastructure, each structural element of which, that is an agency, according to J. Kooiman (2003), is responsible for the result, not for the implementation of the procedure in order to ensure the efficiency of social services at a high scientific level, which is the characteristic of modern democracies.

The main areas of adaptation to the modern public administration systems are informatization, debureaucratization, decentralization, privatization and implementation of economic mechanisms for regulating management processes and service administrating. The general tool for the implementation of the identified plans was the intention of governments to improve the quality of budget services through the active cooperation of public administration bodies with non-profit structures, business and population. The implementation of such approaches is characterized by the desire to ensure the high quality of public services provided to population by creating an effective system of consumer protection, introducing special procedures for resolving conflicts and conducting regular surveys of consumers on the quality of services. The standards of work with the citizens developed by British executives include the requirements and define the basic indicators of the successful work of public administrations with the population. At the same time, annual reports on indicators of the best practice code are posted on the official websites of the local administrations. In order to increase the transparency and efficiency of services provided to the population, it is advisable to assess the results of the implementation of state reform programs based on the analysis of public opinion on the quality of public services (C.Berry, 2009).

The trends in the development of public administration show ambiguity and variability in the assessment of the results of administrative reform. On the one hand, the introduction of technology and informatization of communication between citizens and public authorities have improved the quality of budget services. In this context, the modern paradigm of public administration determines the tendency to regard information as a strategic resource. Proper information support of management processes has become a necessary basis for effective management decisions. The implementation of the ”E-Governmet” system has had a significant impact on management practices, as new procedures, approaches, structural and substantive innovations have been introduced, and they have dramatically raised the level of the efficiency of public authorities. At the same time the issue remains controversial, particularly in the context of significant dependence on the infrastructure condition and appropriate qualifications of both the civil officials and the consumers of the services.

The formation and activation of political networks and the practice of multi-level governance as universalized, in particular for the European administrations have become a step forward in the development of the modern management process (L.Novak-Kalyayeva et al., 2019). The European Union as a political entity is characterized by a multilevel structure of power, and its significant number of levels differs considerably in the standarts of competencies and methods of making management decisions. We are talking about the existence of supranational, regional and national structures, which at the integration level lose the general hierarchy and tend to appropriate situational subordination, while at the national, regional and local levels there is a standard scheme of subordination with a tendency to form a new configuration of national "verticals of power". There is a blurring of national characteristics and unification of the processes and structures of public administration. On the other hand, in this context, the modern period is characterized by a significant controversy of arguments against the background of the crisis of legitimacy regarding the division of competencies between supranational and national levels, and between executive and local governments at the national level.

Problems of social interaction, responsibility and democracy in modern management practices

The formation of new forms of interaction of public administration agencies of different levels takes place against the background of cooperation between supranational and national authorities, which is blurring the hierarchical relationship of subordination within the national borders. Problems of duplication and uncertainty of powers and competencies are typical of the national level in European countries, which have been in the state of administrative-territorial reforms since the early 1980s, gradually restructuring their governance systems to meet the demands of the effective and professional government. This situation in some way reduces the effectiveness of local authorities.

Self-organizing network, “governance without government”, has been typical for the Internet, radio and mobile users from the beginning of the 21st century. Subsequently, networking within the framework of neo-institutionalism proposed a variety of network structures, within which certain resources are also produced, in particular information and others, based on personal and informal relationships. It is connections that are treated as a valuable resource in the real world, despite their ambiguous impact on the efficiency of markets and management processes.

Government officials are surrounded by specific people and act under their diverse influence, in particular while taking decisions and making policy . The distribution of subsidies, grants, tenders, even the sequence of services can be motivated not only and not so much by state interests, but by personal preferences, political positions and friendly relations, and not without prejudice. Despite considerable autonomy from the state, networks can be run by different officials or political leaders. Networks can be an alternative to the market mechanism and the state hierarchy, in particular, and personified as elite, diaspora, corporate or professional groups. At the same time these are ambiguous prospects, because in the context of European integration, network management is a reality that involves increasing both centralized regulation and the involvement of an increasing number of national actors. The latter lose some legitimacy in the network management system in favor of the central administration. The network management, in turn, creates new problems of legitimacy. Whether the informal networks can be considered satisfactory substitutes for democratic accountability of representatives whose right to power (mandate) is derived from general elections based on formal equality of all citizens is the issue that, according to J.Czerw (2020), has been debated by the scientific community since the beginning of the 21st century.

The main problem of “governance without government” is the lack of accountability, that is the fact that “most teams in the globalized space are not responsible for their actions” (P. Rosenau, 2000), regardless of whether they are non-governmental organizations, expert groups or international organizations. In international law the "democratic discipline of law" gains more importance, that accepts, for example, going beyond the system of human rights treaties. Against this background, the consequences for the relationship between a democratic government, the responsibility of officials acting at their own discretion in accordance with personal beliefs and understanding of "good and evil" and international law are questionable. In this way, the representativeness of democracy compared to bureaucracy becomes problematic, as both the priority of activities and the requirements of accountability to citizens change. The problem of democratic accountability exists, in particular, because elected officials lose their power over public bureaucracies and individual leaders, and opportunities to maintain public control are considerably narrowed or diminished. Privatization and delegation of “independent” regulatory agencies reduce the ability of citizens to control these institutions through representative democracy. Summarizing the results of this situation, R. Barnes (2000) defined it as "exile of the state", because the transfer of public services to the agencies simultaneously fragments the government and blurs the understanding of responsibility. Transparency of political decision-making makes it possible to determine the location of the source, that is to determine where decisions are made and who is directly responsible for them. Thus, legal certainty, equality before the law and protection of legal interests may be threatened by a loss of credibility or function when, in the light of the information and communication technology revolution, such institutions of representation as parliaments and political parties are engaged.

Involving new combinations of social, economic and political interaction, which may differ from the civil society, the market and the state, causes tensions in the modern society within interactive governance. In particular, advisory or discursive policy analysis based on the new communication policy helps members of the society (individuals, groups, formal and informal structures) to state their problems and participate in their solving (according to the government's response).

At the same time, against the background of populism, which in recent decades has characterized the state of individual political systems at almost all levels of governance, there is a destabilization of public order and democracy, which largely interact and determine the relationship between the state, the market and the civil society. There is an active personalization of politics and a significant shift of power in favor of professional leaders inside political parties, which limits the influence of ordinary members of the party (M. Gotta, 2000); there is a change in the source of policy from the legislature to the executive, and in some cases to the presidential power. As a result, the marginalization of parliamentary institutions and the technocratization of policy-making processes are progressing. In the countries with democratic transit, the manipulation of the judiciary is usually used as a tool for political competition and influence in policy-making. Destabilizing trends associated with the processes that exist in the relationship between the state and the market are characterized by increased sectoral self-regulation, the implementation of commercial (corporate) logic in management processes, as well as personalization and dramatization of policy when public tasks and functions are implemented on the basis of deregulation (liberalization) and outsourcing (privatization), and when the spheres of regulation and market competition are outside the effective democratic control. As a result, the level of trust in the government decreases, the number of citizens who neglect their responsibilities as voters, or determine their positions in the elections emotionally, "from the opposite" or indifferently and "for a reward" increases. There is a decline in collective identities and conscious individualization. Ideological identification of parties is also declining, programs are being replaced by slogans, the distance between politicians is increasing, and the radicalization of arguments minimizes the possibility of a program-based coalition. The intensification of direct consultations with citizens in the form of referendums indicates the unwillingness of the political leadership to take full responsibility for their own actions (R. Barnes, 2000).

The results of the World Values Survey (WVS, 2015) argue that the trust in the government depends mainly on the availability of key assets, among the most important of which are security, health, education, housing, transport, electricity , management of infrastructure and investments that the private sector is not ready to finance, and adequate regulation of socio-economic activities. The joint confrontation of threats and overcoming the consequences of the COVID-19 pandemic have actualized the demand of the population of European countries and most national governments for sectoral centralization in crisis conditions. The need to coordinate joint efforts on the basis of the complete picture and the ability to quickly develop and effectively implement the management decisions for the public benefit have become the real challenges for the European community and its leadership.

Institutional sustainability of the modern governance as a competitive strategy for its modernization

A lot of key aspects of modern management were considered by J. Kooiman (2003), noting the practices of meta-management (management of the management). The latter is the basis for formation and implementation of the projects of the World Bank and the International Monetary Fund, and the interaction management is a tool for implementing meta-management in the context of globalization, glocalization and Europeanization of the management (The IMF's Approach, 2005),. Types and methods of social relations that provide modern management interactions with a clear political aspect belong to competing management models, such as "art of management" (M. Foucault), which deals with the historical and political nature of interaction management. This term has a strong qualitative aspect when it comes to how the government and the administration carry out management actions, how people (officials) manage or behave, and how these two processes are interrelated.

The practices of the "art of management" necessitate the use of the technology of power, the technology of market and the technology of self-realization of the person in managerial actions. They relate to the ability of individuals to control and implement guiding influence on the environment at different scales. The guiding force here is not the rule of law, but the interest of personal and public benefit and personal responsibility, which are realized independently of the government on the basis of normalization. In the broadest sense, this means living in accordance with established norms and self-esteem, realizing and using one's own capabilities on the basis of constant self-esteem, personal discipline and self-improvement.

Each of the technologies presented as the "art of governance" can work simultaneously, separately or together, or even overlap from time to time, helping to set the boundaries of the role of the government in a given society. The emphasis is on pluralism, personality and mutual responsibility, which distinguishes the latest approaches to politics and governance. This understanding of pluralism is considered the norm of the politicy designed to respond to the many interests and identities of the modernity within the social diversity, multiculturalism, complexity of structures

and interactions, accelerated by the dynamics of the society as a whole, when politics becomes the environment and the tool for empowering people and improving the exercise of their freedom of choice (L.Hooghe, G.Marks, 2001).

The processes of multilevel management illustrate the current trend of convergence of theory and practice of the management, according to which theoretical generalizations are made on the basis of both theoretical hypotheses and practical steps (C. Berry, 2009). In this sense, it is interesting to remember the history of the formation and implementation of "sustainable development" as a new focus of management, the ideas of which, developed and announced by L.C. Caldwell (1963), found practical confirmation only in 1990th.

Discussion

Finding ways to preserve economic, social and environmental balance

There is an organic connection between the principles of sustainable development and the principles of public administration, embodied in the concept of institutional sustainability of public administration. In this context, the institutional sustainability of government structures, both state and self-governing, means that they are able to maintain structural integrity, functional integrity, ability to interact, regroup and update in accordance with the new conditions created by the crisis, especially in the situation of destructive or threatening external or internal influences of temporary or long-term nature (L.Novak-Kalyaeva et al., 2018). The increasing intensity of natural, social and economic phenomena in the globalized world has raised the issue of sustainability of the governance structures at the regional level in the context of the system's ability to adapt to changing conditions and scope of responsibility, challenges and threats, risks or opportunities. Adaptation is considered as the process by which any system (a state, a region, a municipality, an institution, etc. adapts to changes. Adaptation can be reactionary, as the consequence of the crisis that has already occurred (for example, economic shock), or expected, as the adaptation to the long-term trends.

In conditions of aggressive external influences or critical states the systems are able to self-regulate, changing their internal structure. The argument is formed around the idea that sustainable socio-economic systems are constantly able to reorganize their institutional and economic structures. Sustainability, in this context, is considered as a constant evolutionary process, rather than just restoring or achieving a new stable state of equilibrium (J.Simmie, and R.Martin, 2010). Management of local economic development can be considered sustainable if it is able to reorganize the structures and / or functions of the economic system so that to maintain the acceptable growth and development in the medium and long term. The adaptive resilience of territorial social systems and the institutional resilience of relevant goverment structures (municipalities) are based on their ability to evolve and is considered as the system's ability to return to pre-crisis conditions, in particular in terms of income and employment.

In times of crisis, it is desirable not only to return to the level of development, but also to adapt to new conditions and attain new views of development. Institutional sustainabilit and adaptability in the long run contributes to the weakening of ties between the participants of the system, which allows flexible restructuring of its internal structures in the new environment. The research on the sustainability of public administration focuses on finding an appropriate paradigm that ensures stable growth and development over the long term. Such development should be aimed at the maintaining economic, social and environmental balance. Institutional sustainability of municipalities with adaptive self-government provides them with a higher adaptive capacity compared to others, even at a lower level of their social and economic adaptability.

The tools for determining the sustainability of municipal structures were offered by G. Masik and O. Sagan (2016), who included the following indicators in the sustainability criteria: strategic planning (quality, including the current state and the role of strategic documents and the adequacy of measures, that is their connection with the local problems) , cooperation (with local companies, residents, NGOs and government agencies), functioning of municipal institutions (quality monitoring, qualification of officials, knowledge management). The researches of Polish regions have allowed scientists to determine the sustainability index, which takes into account the indicators of GDP, the employment, the income, the number of businesses and export earnings of innovative products and others. The international researches usually include not only the regional indicators, but also the national ones and the surveys of population, economy, social and natural conditions. According to the results of the research, the most representative indicators of the regional stability are proposed to be the dynamics of the gross domestic product and the employment (L.Novak-Kalyaeva et al, 2018).

The sustainability has become a key concept in both domestic and foreign policies of the EU and the most democracies around the world. The areas of strategic importance, such as public and economic governance, growth and sustainable development; energy, environmental and social spheres develop their own concepts of sustainability, operational and strategic documents on the basis of its generally recognized principles. In times of the permanent crises of various origin and intensity, the health care, the education system, the labor market and the foreign relations are directly dependent on the ability of management to anticipate and confront the threats and challenges. Political governance and public administration had to be smarter, more inclusive and more resilient in order to respond to internal and external shocks adequately (G.Rouet, G. C.Pascariu, 2019). It is important not to lose long-term and medium-term influence on stability, security and sustainable development in the context of structural economic, social, institutional and political instability. The identification of the areas of economic growth, stagnation zones, the impact of external funds on the development, including social, economic and spatial cohesion do not lose their significance.

Conclusion

Improving the efficiency of public administration by involving the public in the development and implementation of policies, optimizing the timing and quality of professional management decisions determine an important positive trend in the development of public administration and the society as a whole. At the same time the change of generations of managerial elites in the post-totalitarian countries has provoked the tendency to simplify the essence and algorithms of management, which negatively affects the institutional structure of the society and government. Thus, there is no doubt about the need to oppose destructive tendencies against the background of populism, the uncertanity of foundations of democracy and social interaction. The most constructive way to balance the main trends of the society and governance development against the background of globalization, integration, decentralization and information technology impacts will be the development of the critical self-assessment strategy. It is a matter of governments and integration management structures defining their real capabilities and limitations in such a way as to ensure an appropriate balance between the state, the private sector and the civil society. This approach requires as much transparency as possible on the part of the state in order to ensure the support of the society and business in the development and implementation of the policy. The concept of sustainability is another idea of the sustainable development issues, as the emphasis is on the strength of institutional systems and their ability to constantly change. Sustainability is expected to be the most constructive strategy, and gaining the experience, mastering modern communication technologies and training obviously has a chance to balance both trends in favor of improving the quality of both the management and the life of society.

Abstract

The process of transformation of European institutions in the field of security and defense is surveyed in the context of ensuring their institutional sustainability in the view of new geopolitical challenges and threats. The institutional system of governance in the sphere of EU security is scrutinized on the base of a systematic approach. The formation processes of a modern system of collective security and defense in Europe are researched in their dialectical connection as to ensure effective cooperation of institutions. The positions in the capability assessments of the institutions of governance of the European security system and the prospects for improving their effectiveness are generalized, in particular, within NATO in conditions of current conflicts. The deepening of integration in the provision of collective protection is being updated due to the need to expand the powers of the EU's supranational institutions on security and defense and in order to mobilize efforts to counteract global threats. Emphasis is placed on rethinking the European Union's ability to countervail threats related to gaining strategic autonomy. The justification is based on the conclusion that in order to ensure the institutional sustainability of the EU supranational security structures it is expedient to unite the military-strategic plans of all EU defense institutions of different levels and to ensure their compatibility with NATO structures on the basis of centralized management (Joint Command), the decisions of which must be mandatory to perform by all countries included in the system of collective security and defense. The measure of national sovereignty limitation, in this context, must correlate with the scale of threats and be adjusted in conditions of real military-political situation. It is concluded that a joint integrated system for monitoring the identification of threats and the effectiveness of existing management structures in the field of security and defense is able to optimize all defense institutions on the basis of crisis management and counteracting hybrid threats on an ongoing basis.

Keywords: European Security Governance, Institutional Sustainability, Collective Defense, Geopolitical Threats

Introduction

One of the most important areas of cooperation between the EU countries is the formation of a common security environment in order to prevent and eliminate military conflicts and achieve international understanding. In recent decades, military conflicts of varying intensity and scales, both outside the EU and outside the continent, have remained a potential threat to all European countries, also in modern conditions. The system of collective security and defense of the EU countries must be ready to organize a reliable defense of European countries, in particular, countries that are the EU's geopolitical neighbors of the first order like Ukraine. The problems became relevant against the background of a change in the positions of the US military and political leadership on ensuring European security by NATO forces. Reduction in the dynamics of EU spending on the army in the last quarter of the twentieth century and the ambiguous position in assessing the level of European security at the turn of the century had their effect at the beginning of the XXI century. Leaders of individual member states assessed the level of external dangers differently. Thus, European security and defense policy has proved ineffective in the face of

new challenges and threats, which has contributed to the raised awareness of the need to reform the EU's security structures, as well as the system as a whole.

The European Union's global security policy, set out in the relevant Strategy adopted in 2016, embodied a new consolidated view of protecting Europe's common future. The question then arose about the ability of existing institutions to ensure the security of an individual EU member state in the event of external aggression, including hybrid. The creation of separate from NATO European defense institutions was seen as a possible option for their optimization. The tasks of responsibilities allocation, ensuring institutional stability and functional integrity of management structures in developing common approaches to the formation and implementation of appropriate strategies and tactical algorithms have so far been interpreted ambiguously, both in theoretical and practical terms. At the same time, the search for the optimal way to create a new configuration of security institutions at different levels is still continuing, the latter fact confirms the relevance and significance of the chosen topic.

Conceptual principles for solving problems of international security have been studied, in particular, by Howorth J. (2007), Mandragelya V. (2011), Novak-Kalyayeva L. (2016), Nowak A. (2006), Shay D. (2019), Walt S. (2005), Witney N. (2008). At the same time, in the conditions of modern permanent changes in the nature of armed confrontations, constant improvement of means of attack and defense and intensification of terrorist threats, research of tasks and supranational structures of EU security governance becomes particularly important.

The methodology of this study is based on a systematic approach, with the help of which, in particular, the institutional management system in the field of EU security was studied. The processes of formation of the modern system of collective security and defense in Europe are examined on the basis of the dialectical method. The axiological method provided an opportunity to consider the effectiveness of the institutions of the European security system in terms of modern wars and conflicts and to justify the position as for their effectiveness and political perspective.

The aim of the article is to determine the priorities of institutional development of EU security structures against the background of ambiguous results of reforms and geopolitical changes that influence the European and world community as a whole.

Analysis and Results

Institutional sustainability as a Factor of Management Efficiency

Economic crises, local wars and terrorism, financial hardships, hunger and poverty become arguments in the debates over the governance effectiveness in the face of permanent crises of various origins. The ability of management structures to maintain their functionality, productivity and competence to act constructively during crises and in the new post-crisis reality is defined by the term institutional stability. Crisis phenomena of various scales and nature can be a natural consequence of long-term cyclical processes and in this case they are more or less predictable. At the same time, they can be a spontaneous result of certain processes, events, actions, extraordinary situations that are difficult to anticipate. The security and defense sector may face an urgency of a prompt response to the threat. That is, it is important to quickly assess the threat and act in the interests of the society, which the expert structures in this area are designed to protect. In the conditions of hybrid threats of different genesis and orientation, the structural-functional and qualitative characteristics of management structures largely determine whether the society will be protected and will have the prospect of sustainable development.

Transformation processes that take place almost permanently at all levels of governance in the field of security and defense do not narrow or facilitate the responsibilities of management structures. Ensuring their resilience and ability to adapt during periods of change helps to avoid conflicts between old and new institutions, functions, structures, approaches to assessing the current situation and vision of perspective. All the above mentioned leads to increased attention to the institutional approach, which considers the peculiarities of institutional dynamics and claims to explain the most general patterns of development of any society and management.

The genesis of the ideas of institutional theories has been actively studied for the last two centuries. Still, according to O. Ryby (2010), there is no agreement on a universal definition of this concept both among the representatives of the science of public administration and within individual institutional theories. Accordingly, there is no unity in solving the other key issues of the institutional aspects of the economy, politics and governance functioning, the

interpretation of which is quite scattered and unsystematized in the interdisciplinary discourse.The way of explaining the main characteristics, features of functioning and changes of the institution varies, mainly depending on the way the institution is viewed (as a norm, regulator of behavior, formal organization or informal rule…). Institutions (social, legal, governmental) are the basic unit of institutional theory, and their complex is its subject. The concept of "institution" is seen as an established form of organization, regulation and ordering of public life, people's activities and behavior. They also include a set of social norms, patterns of behavior and activities; in law they include a set of law rules that regulate any defined relationship (D.S. North, 1993).

Thus, institutions are considered to be social, political, economic structures, phenomena and processes that interact in society on the basis of rules, with assistance and under control of corresponding structures that legitimize, legalize and regulate such interaction. That is, institutions operate in the legal field in order to meet certain needs of society and at its request.

As Ilchenko (2015) mentioned, the main role of institutions in society is to reduce uncertainty by establishing the stability of interactions. Institutions identify and limit the set of alternatives that each person, structure or process has. They give a certain structure to the relationship between people, between an individual and society, or the state, and between them all. The most important functions performed by social institutions, as a rule, include creating opportunities to meet the needs of members of society and their socialization, ensuring social integration, stability of public life, lives of individuals, etc. According to Kirillov (2004), the institution of public administration, in this context, can be considered as the activity of state administration bodies; or as an opportunity to use state institutions to achieve public goals of individuals or various social groups; or as a technology for harmonizing personal and public interests; or as a way to provide certain guarantees through institutionalized control over the formation and use of public resources and goods, etc. Reforms of public administration as an institutional complex as a whole must be accompanied by changes in the specific systems of its institutions. At the same time, changes in their informal components can be the key to the effectiveness of such reforms, as well as the stability of formalized governance structures. The institutional sustainability of management in the field of security and defense, as part of the institutional one, is of great importance today. The success of policy development and implementation in the research area directly depends on the stability of management structures, their ability to foresee threats, manage risks arising as a result of sudden or gradual changes in the external or internal context.

Transformation of supranational institutions in the field of security against the background of global threats of the late twentieth - early XXI century

For developed democracies, conceptual approaches to providing security are based on the requirements of compliance of public policy with the liberal doctrine, according to which the existence of a developed civil society is the main guarantor of the security of the individual, society and the state. Attention is consistently focused on the political, economic and military-political aspects of security. Political aspects take into account the threats to the foundations of democracy from globalization, the consequences of information and technological influences, changes in traditional ideas of state sovereignty, alternative models of political transformations, and so on. Military-political and military aspects cover the relationship between the civilian and military sectors, which transform into the so-called problem of civil-military relations. An important factor that determines the specifics of modern wars, as I. Ballah (1972) emphasized, is the institutionalization of new political components - supranational and regional entities represented by interstate economic, political and military blocs, as well as transnational economic and financial corporations; states not recognized by the world community; nations and territories fighting for self-determination; various terrorist and criminal groups, etc. The political content of wars in modern conditions has changed significantly due to the fact that they reached a much higher - transnational, global level. Global policy of ensuring international security is a purposeful, coordinated or independent activity of states, international (governmental and non-governmental) organizations and other subjects of international law to eliminate (neutralize, reduce) a set of dangers, threats, risks and challenges on a global scale, and development of effective mechanisms and tools to counter them. (Kalyayev et al, 2019). In order to ensure and strengthen the external security of the world community members, primarily the nation-states, it is necessary to create a system of international security which is based on a set of obligations, guarantees and capabilities of its subjects.

Geopolitical rivalry and the fight of great powers for resources are projected at the regional and local levels in the form of stimulating local conflicts. Although modern conflicts are mostly internal in nature and are based on interethnic, national or interfaith contradictions, external interference from the side of powerful states very often contributes more to the aggravation of conflicts than to the settlement of them. Modern experience shows that it is

impossible to counter international threats by the means of separate states and even individual organizations. To solve this problem we need a concerted effort, and above all, of international organizations that ensure the security not only of individual countries but also of entire regions. In addition, combating such threats requires such a large number of resources that it can only be found in the case of broad cooperation between states and international organizations.

To analyze the security system we will define its main subjects. It is important that the purpose of creating supranational security governance structures of the EU was to ensure coordination of efforts of European countries, members of the EU in the field of security and defense. It envisages involvement of many actors of pan-European, state, regional, public and private levels of administration, which are not in hierarchical subordination, into resolving security and defense issues. The main EU institutions of a supranational nature are the seven main governing bodies of the EU: the European Parliament, the European Council, the Council of the European Union, the European Commission, the EU Court of Justice, the European Central Bank and the European Court of Auditors.

The institutional model of governance in the EU, in the form which is defined by the Single European Act and the Lisbon Treaty, is marked by certain features that significantly distinguish it from national systems:

– by the presence of two types of institutions: interstate and supranational. In this case, the members of the first type of bodies (Council of Ministers) act as official representatives of the member states, and the members of the second types of bodies (European Commission) act as independent individuals who are not affiliated with the states that delegated them;

– by the absence of separation of powers into the legislative and executive branches: legislative powers are alloted between the Council and Parliament, and executive powers - between the Council and the Commission. This is a unique managerial experience, particularly for young democracies;

– by the absence of vertical management structures and a central regulatory body;

– by the existence of a checks and balances system established by the fundamental documents of the EU, under which none of the European institutions can make decisions on its own, and which ensures the balance of supranational-intergovernmental dualism.

At the same time, some institutions are directly engaged in the field of security and defense. They are:

The European Council, which, at the level of Heads of States and Governments with the right of a final decision and political responsibility, clarifies issues related to foreign and security policy, sets out a common strategy to be implemented by the European Union in matters of common interest for member states. The European Council implements it through joint activities and the development of common positions;

The Secretary General of the European Council who has the authority of the High Representative on issues of common foreign and security policy;

The General Affairs and External Relations Committee (GAERC), the Committee of Permanent Representatives (COREPER), which formally employs state ambassadors in EU, and the Political and Security Committee;

High Representative for the Common Foreign and Security Policy - HR-CFSP;

European Commission - EC, influences solving security issues through the Directorate General for External Relations and the Commissioner for External Relations.

The European Parliament is responsible for passing laws, and supervising and monitoring the applying of executive powers by the institutions of the European Union. The views of the European Parliament are taken into account in the development of security and defense policy.

The Council of the European Union, ie the Council of Ministers, considers the proposals submitted by the Commission and is the main governing body of the Union; it is responsible for setting political goals, coordinating national policies and resolving disputes between members or other institutions. The European Defense Agency

(EDA), founded by the Council of the European Union, supports member states in their efforts to improve Europe's defense capabilities in the field of crisis management, European security and defense policy. The Agency still faces the task of developing a military resource base, defense scientific research and development, and pan-European projects of cooperation on armaments issues, and creating a common competitive market for military products.

In addition, two more institutes were established in 1999. The European Union Military Committee (EUMC) is the highest military structure of the Council, which comprises the Chiefs of Defense. Its main function is to provide unanimously approved by all Committee members advice to the European Council through the COPS on issues related to the military domain and recommendations for action. Such unity is essential when using EU forces for military operations. The last institution is the European Union Military Staff (EUMS), which consists of more than 150 senior officers from 15 member countries. It provides military expertise for operations. The headquarters operates under the auspices of the EU (through COPS), and is directly subordinate to the EUMC. After 2004, three more structures were added to the institutions of the European security sector. The Political and Security Committee (COPS) became the most important one. It is responsible for monitoring the international situation in the context of common foreign and security policy and for developing policy implementation plans for the Council.

According to scientists, in particular, S. Andryushin (2015), the EDA did not have a single development strategy for a long time. This situation persisted until 2019 and it negatively influenced the effectiveness of the EDA as a security institution (Security and defense, 2019). The lack of a consolidated view of the GAERC concept in the EU in the context of deeper integration also had its effect. Nevertheless, the Agency managed to demonstrate its effectiveness. Meanwhile, the decisions of the European Council demonstrate the development and continuous improvement of the EU's single EOA development strategy which indicates considering the possibility of granting it supranational powers.

Search for Common Positions and Changing the Paradigm of Military-Political Management

The debate over institutional changes has virtually continued since the beginning of the 21st century. EU Member States, recognizing the need for intensive cooperation and enhancing the Union's security capacity, were not prepared to lose national control mechanisms. There have been contradictions between the supranational functions of the Commission and the intergovernmental functions of the Council. Under such conditions collective decision-making was extremely difficult and time-consuming. As V. Mandragelya (2011) mentioned, institutional problems raised the most questions. For example, interdepartmental competition constituted a problem, as the implementation of certain decisions faced wars of influence, especially between the Commission and the Council Secretariat. This issue has been particularly acute in the field of civil crisis management (Nowak A., 2006). Complex relationship between member states and the EU presented one more problem. It was rather "governance without government", where sometimes a sporadic separation of powers between individual states and Brussels took place (Sbragia A. 2007). The third challenge is institutional density. The European Union has competed with other international institutions in the field of security. These are, first of all, NATO, the OSCE, the UN, which have different approaches and potentially conflicting interests.

On the next issue, it should be noted that NATO is still a key factor and guarantor of national sovereignty and countering external threats to the EU, in accordance with the provision of Article 5 on "collective assistance".

Since the end of World War II, the American military presence, and especially NATO's nuclear component, has ensured the security of Allies based on the principles of collective and territorial defense. Under the de facto military and political guardianship of the United States, the level of economic development, quality of life, civil rights and freedoms in the European Union have reached the highest standards in the world. That is why the countries of Western Europe have not formed a common policy in the field of foreign policy, security and defense. Concentrating integration processes in the socio-economic and socio-political spheres, they did not see an urgent need to become more active in this area, given NATO's guarantees. Meanwhile, at the turn of the century, both the new US position and the EU's desire to become an independent center of power with its own course in world politics, capable of defending its interests, began to take shape, leading to a revision of EU positions. (Walt S., 2005).

In general, there has been a rather tense struggle between the three main approaches to the ESDP. Different interests of EU members, as well as resources and, more importantly, different security cultures, have become the drivers of

institutional reforms in the ESDP. Strengthening the military component, increasing professionalism and capabilities of the military, improving decision-making structures and transforming the EU into an independent and autonomous player in this domain - this was the position of the French management and military elites.

British government shared the position of France and was aware of the paradigm shift and the need to increase the military power of EU member states. At the same time, maintaining the central role of NATO as the main instrument of European defense was not ruled out. The duplication of the alliance's institutional structures at the European level remained a problem.

For the positions of some Scandinavian countries and Germany the priority was to strengthen the civilian component and resources of the ESDP, based on a comprehensive approach to crisis management, starting from crisis prevention and to post-conflict stabilization.

The mechanisms for the implementation of fundamental EU legislation acts rather than their content should be considered the main problem in this dimension.The Political and Security Committee, the Military Committee, the Military Headquarters, the European Satellite Center, the Information Collection and Storage Center became the institutional basis for the implementation of the idea of a pan-European security system in the EU. The ultimate goal of these efforts was the creation of the European Rapid Reaction Force (ERRF) with a strength of 60,000 troops, with its own command, communications, intelligence, naval contingent and aviation to carry out humanitarian, rescue and peacekeeping operations or combat operations on crisis management.

Apart from these functional tasks, the creation by the European Union of the European Rapid Reaction Force (ERRF) was primarily intended to demonstrate the EU's ability to pursue an independent security and defense policy on the European continent and to get rid of dependence on the United States in solving purely European affairs. According to European politicians, this gave the opportunity to institutionally assert the EU as a strong, independent geopolitical actor.

In 2003 the European Security Strategy was adopted to conceptualize this policy. The Strategy represented common to EU member states threats, goals and objectives in the security and defense field. The provisions of the Strategy were set out at the European Union summit on 13 December 2007 in the "Treaty of Lisbon amending the Treaty on European Union and the Treaty establishing the European Community". According to the provisions of the Lisbon Treaty, the transition to a common defense policy is implemented based on a unanimous decision of the European Commission. The Treaty provides for the collective responsibility of EU member states, mandatory assistance by all possible means to the country that becomes the victim of aggression. In fact, the provisions of the Lisbon Treaty for United Europe on "mutual assistance" duplicate Article 5 of the Washington Treaty on establishing NATO. The North Atlantic Alliance is characterized by the Strategy as one of the main elements of the international security system. At the same time, the contractual and legal obligations of the EU member states in the field of security and defense are implemented in view of the unconditional supremacy of the UN Charter provisions, without violating the specific provisions of the national legislation of neutral countries and the obligations of membership in the North Atlantic Alliance. The Lisbon Treaty provides for the creation of the post of EU High Representative for Foreign Affairs and Security Policy, which combines the functions of the High Representative for CFSP and the Commissioner for External Relations.

Due to the aggressive actions of the Russian Federation the creation of the European Defense Alliance, which will help NATO, is on the agenda. The idea of the practical content of the EU's Common Security and Defense Policy CSDP took shape in June 2016 with the presentation of a new Global Strategy on Foreign and Security Policy. The idea is that the creation of a European Defense Alliance in partnership with NATO will allow the EU to act autonomously in operations abroad to stabilize the neighboring area and enhance EU's role as a security guarantor. The European Parliament's resolution called for the establishment of a Directorate-General for Defense, which would be responsible for the internal aspects of defense and security policy at the EU level, and also suggested creating a European Intelligence and Situation Centre (EU INTCEN).

In early December 2017, the EU Council decided to launch the Permanent Structured Cooperation (PESCO) program in the field of defense of EU member states. The program will allow to jointly counter military threats from Russia and strengthen the EU's defense capabilities, unless disputes and disagreements between the participants impede this. The main goal in the field of defense is to increase the EU's potential to act autonomously from NATO if necessary, to strengthen the Union's security capabilities by deepening cooperation between member

states regarding the efficient use of available resources, along with a parallel increase in defense budgets. As part of the institutionalization of security guidelines, it was proposed to create a separate headquarters to manage all EU operations abroad.

At the first stage, the pan-European center should coordinate the issues of medical care, joint use of transport aviation, exchange of intelligence data. The formation of the EU Military Planning Conduct and Capability Facility became the first result of suchlike integration initiatives. Although it has not become a classic full-fledged military headquarters yet, it will be responsible for EU military operations. However, the EU has no plans to distance itself from NATO, but instead it deepens cooperation with the alliance. According to some experts, Europe is powerless without American military-strategic, satellite, intelligence capabilities and air defense technologies. At the same time,the implementation of PESCO projects should improve the defense capacity of EU member states, in particular the ability to withstand challenges and threats from Russia.

Today, in case of a military conflict, the EU countries are unable to guarantee their security individually as their defense spending and security capabilities do not meet modern requirements. The main goal for the development of European military capabilities requires the ability to rapidly deploy (within 60 days) and keep operationally powerful forces at least for a year. The permanent structured cooperation in the field of defense and security currently involves 25 participating countries: Austria, Belgium, Bulgaria, the Czech Republic, Croatia, Cyprus, Estonia, Finland, France, Germany, Greece, Hungary, Italy, Ireland, Latvia, Lithuania, Luxembourg, The Netherlands, Poland, Portugal, Romania, Slovenia, Slovakia, Spain and Sweden.

The goal is also to create smaller rapid response units that will be at a very high level of readiness. The achievement of the stated goal is significantly hampered by the crisis processes in the European Union caused by both internal events and external factors. It has become especially evident recently.

The first event in this context was Britain's decision to leave the European Union. This raised the question of the possibility of further British-French defense cooperation, which was considered to be the engine of European integration in the security sector. In any case, the European Union has closely approached the issue of further integration of member states in the field of CSDP. On September, 11, 2016, the EU introduced their own vision for strengthening defense cooperation within the EU to NATO officials. First of all, it meant to create a separate headquarters to manage all EU operations abroad. At the first stage, the pan-European center should coordinate the issues of medical care, joint use of transport aircrafts and exchange of intelligence data. Franco-German initiatives also provided for full combat readiness of joint combat tactical groups, as well as the introduction of a joint budget for the development and purchase of transport aircrafts, satellites, UAVs and cyber gadgets and equipment.

At the same time, the creation of a certain supranational structure in the form of a pan-European army was denied, it was only a matter of strengthening cooperation between EU member states. The first result of such integration initiatives was the establishment of the EU military headquarters, namely, Military Planning Conduct and Capability Facility. Although it has not become a classic full-fledged military headquarters yet, it will be responsible for EU military operations. The European Commission preparation of proposals to strengthen cooperation in the field of CSDP and their discussion at an informal meeting of defense ministers of EU member states in November 2016 became the logical development of these measures.

Discussion

The European Parliament supported the idea of creating a European Defense Union. The developments of the European Commission, the European Parliament and other governing bodies resulted in the adoption of a number of documents united in the so-called "Winter Package" on the European Security and Defense (2016 EU Security and Defense Winter Package) at the December 2016 meeting of the EU Council at the level of heads of states and governments. It includes: new political goals and intentions in the field of security and defense - the Implementation Plan of the EU Global Strategy on Security and Defense (Implementation Plan on Security and Defense); financial resources, defined in the European Defense Action Plan; a set of proposals for the implementation of the EU-NATO Joint Declaration. Further integration processes in the field of EU CSDP were implemented in the form of bringing to life a plan of "permanent structured cooperation" (PESCO) of the EU countries in the military-political sphere, which was given the "green light" by the EU leaders at the summit in Brussels on June 22, 2019.

It can be stated that this project combined the European Defense Action Plan, previously approved by the European

Commission, and the EU Global Strategy Implementation Plan. On June 17, 2019, the Ministers of Defense of Germany, France and Spain approved the largest defense project in Europe - the air combat system of the future, which should be ready for combat use by 2040. Apart from combat aircrafts, the system will also include escort drone units, flagship and patrol aircrafts, ground stations and satellites. The total cost of the project is estimated at up to 50 billion Euros. () Also on the same day, the Foreign and Defense Ministers of all 28 EU countries approved the EU Global Strategy, which outlines common defense and security capabilities and considers ways to further strengthen the EU's role as a global player.

The United Nations should be considered one of the general security institutions operating in Europe. According its statute (Article 51 of the UN Charter) the inalienable right to individual or collective self-defense is guaranteed to all UN member states. It authorizes actions that they can take to exercise this right until the UN Security Council takes the necessary measures to preserve international peace and security. It should be noted that all European security institutions operate within the requirements of the UN Charter.

Lately, the United Europe has managed to move from individual proposals on how to step up security and defense cooperation to concrete approved plans that look quite ambitious. Rethinking the importance of independent ability to withstand threats has already begun, it has gained strategic autonomy and raised the issue of CSDP to the highest level of attention - to the level of heads of states. In addition to political decision-making, some practical steps were taken in the first year of implementation of the Global Strategy to strengthen this security and defense dimension in the EU.

Firstly, a number of documents were approved, combined in the so-called "Winter Package" on European Security and Defense, which became the framework for the later adopted plan of "permanent structural cooperation"

Secondly, the EU has strengthened its defense governance structures. The creation of the EU military headquarters became a step in the implementation of the EU Global Strategy.

Thirdly, the creation of the EU military headquarters has provoked expert discussions about the creation of a "European army". Today, it is unlikely that the European Union will take such a step. The formation of a "European army" creates risks of splitting transatlantic unity, as not all EU countries support this idea. What is more, it is extremely difficult to draw a demarcation line between the EU and NATO powers in the field of security and defense. However, some elements of the common policy in the field of security and defense are being implemented in the European Union in the form of combat tactical groups, as well as expert discussions on the possibility of creating the so-called "Defense Union" (also proposed by the European Parliament in November 2016).

Fourthly, cooperation between the EU and NATO has intensified, as had been planned by the Global Strategy. For the European Union, the Alliance remains a mainstay in Europe in terms of countering military threats, as no EU member state has sufficient military capabilities. The EU-NATO Joint Declaration, signed in June 2016, set out the areas for this cooperation, which were detailed in a set of EU proposals in December 2016. However, this package of 40 proposals for EU-NATO cooperation is more of an indicator than a planned arrangements for the development of cooperation. One of the successful examples of cooperation between the EU and NATO in modern conditions and with the existence of new challenges was the signing by the EU and NATO member states of the agreement on the establishment of the Center for Countering Hybrid Threats in Helsinki in April 2017.

Fifthly, the EU countries are forced to reconsider national defense spendings. A number of countries have already announced an increase in defense spendings.

In order for the EU to succeed, it is necessary to focus on the following tasks: decisive, urgent action in key areas of the defense sector; persistent pooling of efforts and resources; improving the efficiency of the European Defense Agency (EDA). The practice of specialization of roles (Lithuanian water purification units, Czech experience in protection against nuclear and chemical weapons, etc.) also seems promising. Despite the international consensus on the goals, models and framework for security sector reform, as noted by N. Witney (2008), there was a conceptual-contextual gap between political practice and oriented ideals in different environments. The programming of reforms had a narrow focus on individual security institutions (most often, the police and the armed forces) and demonstrated a return to previous models of training and equipping the structural elements of the security and defense systems in the face of security crises.

In May 2019 cooperation between 23 EU countries in the field of intelligence began. This indicates strengthening of

contacts on a new platform called the European Intelligence Board (Intelligence College of Europe, ICE).

In fact, in the EU governance system in the field of security and defense there was no separate institution, which, as part of the structural and functional scheme, would implement and be responsible for the EU policy in this direction. However, some infrastructure has been created. In particular, the post of High Representative for the Common Foreign and Security Policy (CFSP) to be held by the EU Secretary General of the Council was established under the Amsterdam Treaty (1997, Article 15). The Lisbon Treaty (2007) provided for the creation of the post of EU High Representative for Foreign Affairs and Security Policy, which combined the functions of the High Representative for the CFSP and the Commissioner for External Relations. The PESCO program (2018) provided for the establishment of the headquarters for joint military operations and the establishment of the EU military headquarters.

Some researchers, as I.Surina (2020), in the field of international security suggest that the new EU strategy may launch a European strategic culture that would be seen as an integral part of military alliances and political organizations. At the same time, it is considered one of the "most serious challenges, as all member states have their own history and national traditions, but the fact that the content of these traditions implies contradictions between their own reality and the wider European stratum is extraordinary " (Howorth J, 2007). The general content of the European Security Strategy suggests that the EU actually uses a wide range of instruments in its security and defense policy. However, these tools are part of the "soft power" concept. For the present,the introduction of tighter security regimes in public places and strengthening cooperation between law enforcement agencies of European countries on combating terrorism, illegal migration, organized crime, drug trafficking, etc. seems to be really promising (Shay D, 2019).

This proves that European security and defense policy remains somewhat insensitive for the Member States and that they are not prepared to bring in a military dimension to its implementation. Partnership with Allies makes the role of partners in international security more essential. At the same time, changing NATO's collective defense priorities has put the issue of partnership in the background. Rebuilding partnerships can help convince the public that the Alliance has a political rather than a purely military approach to security. The issue of insufficient funding of defense and security needs by European countries has already become a chronic problem for the EU member states. Therefore, the reassessment of collective views on the dangers and risks of splitting the Alliance should be considered an important component of ensuring collective security in the new geopolitical environment. Only the unity of NATO and the EU in the face of new threats and challenges can be a guarantee of security.

Conclusion

State security policy in the EU member states must be viewed through the prism of two interrelated tendencies : the intensification of the struggle for the expansion of national interests and leadership in the geopolitical space, Russia's efforts to restore lost influence in the international arena, and so on. This, in turn, requires significant reforms and closer consolidation of actions of international organizations, primarily the UN and the UN Security Council, the IMF, the WTO, especially in terms of ensuring that the aggressor is brought to justice for violating international laws.

It is necessary to ensure the unity and compatibility of military-strategic plans of all EU defense institutions of different levels with NATO, with the establishment of a system of centralized management (joint command) whose decisions should be binding on all countries included in the collective defense system. This implies the possibility of limiting national sovereignty to the extent required by the military-political situation. It is advisable to introduce a single monitoring system for the strategic and operational identification of hazards and threats, and for the effectiveness of existing security and defense institutions. It is important to optimize all defense institutions by informatizing management systems, and by providing highly qualified managers with experience in crisis management and organizing the resistance to hybrid threats.

Abstract

This paper presents and analyzes a virtual environment for exposure therapy. The lack of a viable solution to help treating pyrophobia, as well as the abundance of articles demonstrating the success of therapy with virtual media and virtual reality equipment represented the basis for the Pyrophobia-3D project. Developed as a 3D game, the application managed to produce conclusive results after testing with the help of 8 participants, of which 4 men and 4 women. The player is placed in a virtual environment that simulates a fire in an office space, the objectives being to extinguish the flames with the help of the fire extinguisher, but also to save as many documents as possible. The quantitative and qualitative results demonstrated that our approach was effective for reducing pyrophobia-related anxiety and we will continue to address this niche of pyrophobia therapy with other virtual scenarios.

Keywords: Phobia, Pyrophobia, Virtual Reality, Game

Introduction

The context

Fear is one of the first survival instincts that man has. People have tried to defeat their fears through a wide variety of methods that worked more or less, depending on each individual. One method that has proven to be effective in studying the behavior of all individuals on the perception of trauma / fear is Virtual Reality (VR). Over the last decade, virtual reality had a strong impact on exposure therapy. Exposure therapy is a type of behavioral therapy that helps people manage their fears. It is manifested through a gradual exposure to situations that cause fear and anxiety. The purpose of this therapy is to create a safe environment in which the person can reduce his/her anxiety in order to improve their life quality. In exposure therapy, the specialist may recommend several methods of exposure, depending on the needs of each patient:

- Imaginary exposure - in this type of exposure, the patient must imagine a situation that would cause discomfort, facing it with the specialist. For example, a person who is afraid of heights may imagine that he/she is on the top of a very tall building.

Cite this Article as: Dimitrie COADA, Oana MITRUT, Alin MOLDOVEANU, and Florica MOLDOVEANU "Pyrophobia-3D: A Virtual Environment for Fear of Fire Therapy" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

- In vivo exposure - in this type of exposure, the specialist induces the confrontation with the patient's fear gradually, by introducing indirect scenarios. For example, a person who is afraid of snakes may first watch an image of a snake, then watch a video of a snake, and after many therapy sessions, he/she can touch a non-venomous snake.

- Virtual reality exposure - in this type of exposure, the specialist simulates a virtual environment, specific to each phobia, with the help of virtual reality glasses. The patient will wear VR glasses and will be exposed to various scenarios that should help reduce his/her fears. For example, a person who is afraid of dogs can use VR glasses to enter a virtual environment where he/she can play with a dog and feel comfortable around him.

The problem

The fire was discovered by Homo erectus about 400,000 years ago. Our ancestors discovered that if fire is handled carefully, it can become extremely useful. Over the years, the risk of uncontrolled fires has decreased, but has not permanently disappeared. Psychology describes phobias as anxiety disorders, characterized by an irrational fear of specific situations or things. People with phobias have tense mental symptoms (anxiety, loss of control, fear) and vegetative symptoms (more frequent heartbeats, fainting, sweating, breathing problems) (Horváthová et al, 2015).

Pyrophobia is a pathological condition manifested through an exaggerated fear of fire (Pyrophobia definition). In general, the fear of fire occurs as a result of an unpleasant event during lifetime. Most people who suffer from pyrophobia are aware that this fear is superficial, even if the anxiety persists. The smell of burned materials, the smell of smoke, a lighted candle or even a burning match can trigger a panic attack. Exposing a person to a real fire in order to cure pyrophobia would be far too risky and far too expensive. Pyrophobia can become an impediment in an individual's daily life, and the only effective solution to cure this phobia is virtual reality. Exposure through virtual reality, without any risk, to different situations in which fire plays an important role, can train the psyche towards a welcomed balance.

Objectives

The main objective of this project is to create a virtual 3D environment that can help in the pyrophobia therapy. This virtual environment consists of an interactive game that will aim to heal using exposure therapy. The game consists of two scenarios:

- The first scenario is an office building where the player will have to collect boxes containing important documents and to extinguish fires with a fire extinguisher.
- The second scenario is an outdoor scene in which the player can play with fire. It can burn the grass, burn some wood constructions, as fire spreads progressively.

In parallel, data will be collected for each subject. After a subject suffering from pyrophobia navigates through the virtual environment several times, there may be decreases in the level of anxiety caused by fire. The data collected can be interpreted further by a specialist, in order to assess the efficiency of the virtual environment. The environment is safe, as it will not expose the subjects to physical risks, such as the fire itself. It offers the convenience of being used on any computer / laptop, without the assistance of a specialist.

Requirements Specification

The Pyrophobia-3D virtual environment has been designed specifically for people suffering from pyrophobia. It can be used by people of any age. In order to create a satisfactory and functional product, an analysis of the potential users was required. First of all, the percentage of people who suffer from a phobia must be checked. The case study presented in (Sana et al., 2015) involved 200 random persons from various age groups. The study shows that 21% of the people suffer or have suffered from some form of phobia and 79% do not suffer or have never suffered from any phobia.

Secondly, we researched the percentage of people who might have pyrophobia. We designed a questionnaire in order to identify the percentage of people who suffer from fear of fire. The persons who filled in the questionnaire were between 18 and 78 years old. Given the fact that all people react instinctively, with fear, in front of fire, we will consider only the most determined answer (High Fear). From this questionnaire, it appears that 20% of people suffer from pyrophobia. At the same time, 10% answered that pyrophobia is a problem they should deal with, and 15% that their life would be easier without its existence. Lastly, given the fact that Pyrophobia-3D is a computer-run virtual environment, people who use this virtual environment should have a minimal knowledge of how to operate a mouse and a keyboard. According to the International Telecommunication Union (ITU), 53.6% of the world's population uses the Internet (Statistics).

Functional Requirements

Here are the functional requirements:

- Implement an office and a lawn as realistic as possible
- On the home screen: fill in the username and the number of the session
- The " Start Game!" button starts the game
- The viewing point of the game is First Person
- Help menu by pressing the F1 key
- Statements that the player must appreciate, depending on his/her level of anxiety, used to analyze the player's condition. They appear during the game and a file is generated based on the name and session number entered on the home screen.
- The player will move around using the keys W, A, S, D and with the mouse
- Apply gravity to make it possible to go down and up the stairs
- Targeting and activating the level 1 fire extinguisher and the level 2 torch will be done with the mouse.
- Dynamic continuity of fire burning
- Warning if the player is too close to the fire
- Extinguish the fire with the help of the fire extinguisher
- Lift the boxes with the F key
- Counter for the number of fires extinguished and for the number of boxes raised
- Activation of the portal to level 2 after all the fires have been extinguished and all the boxes have been lifted
- Spread of fire on surrounding objects depending on the wind
- End the game by pressing the ESC key

Non-Functional Requirements

- Here are the non-functional requirements:
- Strategic placement of the fires and boxes
- Create an intuitive scene by placing objects correctly
- Choosing the mouse sensitivity and speed of the player
- Choosing the right statements (which appear during the game) to be able to draw the correct conclusions at the end of the game
- The text of the instructions and the text at the beginning of the game must be easy to understand
- The virtual environment by walking around the player must have a realistic structure
- The player needs to have Internet access in order to fill in the online questionnaire

System Requirements

Running the virtual environment requires a computer, a mouse, a keyboard and a monitor. The resolution and level of graphics quality can be set before the game starts, in order to increase compatibility with as many computers as possible, whether they are from older generations or from newer generations. By running the game on many

computers, we noticed that the minimum operating requirements of the virtual environment are the following: 1 GB RAM, 1GHz processor speed, any audio card, video card / integrated video card and 1 GB available disk space.

Motivation

Given the analysis of potential customers above, we came to the conclusion that pyrophobia is a real problem in the lives of some people. It is a phobia with which you can be born or which you can acquire. Therefore, the motivation of this paper is to create a reliable virtual environment, which can have a positive impact on people suffering from pyrophobia. We wanted to develop a functional product, based on a scenario that the users can encounter in everyday life.

Market Research

Over the last thirty years, the virtual reality industry has grown exponentially. Virtual reality has been introduced for the first time in the gaming industry.

3.1. Similar Applications

The paper presented in (North et al, 1995) is one of the first psycho-therapy works in which virtual reality was used. Published by Max M. North in 1995, the paper aimed to study the effects of virtual reality on agoraphobia - the fear of open spaces. Agoraphobia is one of the most serious and prevalent anxiety disorders in the psychiatric field. This represents about 60% of all phobias encountered so far (Michelson et al, 1985). Agoraphobia is defined as the fear of being in places or situations from which escape can be difficult or embarrassing. Agoraphobia leads to the avoidance of situations such as: being alone outside home, being alone at home, being in a crowded world or in public transportation. Sixty students suffering from agoraphobia participated in a study for this project. Two questionnaires were applied, before and after using the virtual environment, after which the results have been compared.

Most people have not been trained to react correctly in the event of a fire. Because of this, many can get stuck or take decisions that lead to unfavorable situations that can endanger their lives. The project presented in (Zhang et al, 2017) is based on the implementation of a program that teaches the users several recommendations in case of fire. It was designed for students in a university campus. The creators claimed that the training methods that already existed were not effective enough due to the lack of practice. The system was implemented using the Unity graphics engine. Campus scenes were created, such as a dormitory room or an amphitheater. In these scenes, there are implemented various scenarios that can occur in real life.

The virtual environment is based on 2 parts:

- Learning the theoretical part - this part presents all types of fire, the sounds of a fire alarm, safety signs, the equipment used in case of fire. This part also contains a test for the learned knowledge.

- Operational practice - contains the part where the users will have to perform certain tasks, such as: find the source of the fire, safe evacuation, extinguish a fire with a fire extinguisher, etc.

Another project that aims to cure a phobia is Arachnophobia (Granado et al, 2007), available on the Steam digital game distribution platform. Fear of spiders is one of the most common phobias. In general, people suffering from arachnophobia develop a behavior that is based on avoiding all spider-related contexts. Many people who suffer from arachnophobia are so afraid of coming into contact with a spider that they eventually refuse any kind of therapy (Davey, 1991).

Comparison between Graphics Engines

In terms of technology, we will compare 3 available graphics engines: CryEngine, Unreal Engine and Unity.

CryEngine is a graphics engine created by Crytek (Cry Engine). This graphics engine is well known for its ability to render extremely realistic environments. At the same time, it is also recognized for the graphic effects it offers, having especially an extraordinary lighting. However, CryEngine is difficult to use and it is not recommended for beginners. Another disadvantage of this engine would be its documentation, which does not contain all the details needed to finish a project, and it is often necessary to use tutorials from external sources.

Unreal Engine is a graphics engine created by Epic Games (Unreal Engine). One of its strengths is that it can process millions of particles in a single scene. There is a special editor for creating materials. However, its documentation has many weaknesses.

Unity is a graphics engine owned by Unity Technologies (Unity Engine). One of the greatest qualities of this graphics engine is its compatibility with many platforms. It can be easily exported to any type of platform. The scripting part is done in C #. Unity also has a large community, so it is the perfect graphics engine for beginners. The documentation is extensive, containing all the details needed to create a game. At the same time, it also has an asset store. This asset store contains a multitude of applications (assets), free or for a fee, which are very useful in many situations (Unity Asset Store).

In conclusion, we chose to use the Unity game engine because it is the most compatible with the functionalities implemented in this project. A decisive factor was the useful documentation and the existence of a community open to any questions.

Pyrophobia-3D

The goal was to create an environment as realistic as possible, in order to help the players understand the scenarios and behave as naturally as possible. We have divided the virtual environment in three main sections which are described below.

Visual Components

The game start screen is the first image that appears in front of the player when the game starts (Fig. 1).

Fig 1. Pyrophobia-3D home screen

A welcome message and an introductory text appear on this screen. The text specifies what must be filled in before pressing the "Start game!" button. Two input boxes are placed. Each box contains the required information for the field to be filled in (name, respectively session number). Under the "Start Game!" button, there is a statement announcing the player which will be the format of the file generated by the game and where it will be saved. The "Start game!" button starts the game when it is pressed.

The next screen is the game screen. This is the screen that appears after a single press of the start button. This screen presents in the upper left corner, the number of fires extinguished from the total number of fires (8) and the number of boxes raised from the total number of boxes (7) (Fig 2). Thus, the user knows his progress in the game at any time.

Fig 2. Level 1 screen

When the F1 button is held down, the instruction popup window appears, presenting the objectives that need to be achieved in order to move to the next level (Fig 3).

Fig 3. Pop-up instructions

When the player gets too close to the fire, a warning message appears. This warning message disappears when the player moves away to a safer distance from the fire (Fig 4).

Fig 4. Fire removal message

At the same time, when the player is in the vicinity of a box, a message appears indicating what needs to be done to collect the box - press the F key (Fig 5).

Fig 5. Box lift message

There are points on the map that trigger the display of 3 status statements that are used to measure the functionality of the game. The user must tick an option for each statement (Fig 6).

Fig 6. Emotional statements

The display from the game's second level contains the operating instructions in the upper left corner and the game mode in the upper right corner (Fig 7).

Fig 7. Level 2 indications

The Game Mechanics

In order to arouse the interest of potential users, the game has implemented certain objectives that the player must achieve in order to reach the end of the game. He/she can move in the virtual environment by using the keys: W, A, S and D. There are small fires inside the office, that lead to the first target. The player must find and extinguish all the 8 fires inside the office building. He/she will put out these fires with the help of the fire extinguisher. The fire extinguisher is already placed in the player's hand at the beginning of the game and can be activated by clicking the left button of the mouse. The aiming of the direction in which the fire extinguisher shoots is done with the help of the mouse (Fig 8). In order for the fire to be extinguished, it must be touched by the fire extinguisher foam for 3 seconds. When a fire is extinguished, the counter will be updated.

Fig 8. Extinguishing a fire with the fire extinguisher

There are 7 boxes more, containing documents that need to be saved from the fire. When a box is collected, the box counter in the upper left corner is updated, and the box disappears, along with the help message stating that the box should be lifted. Once all the boxes have been collected and all the flames have been extinguished, the portal that makes the transition to the next level is activated. This portal is located to the exit of the office building (Fig 9).

Fig 9. Portal to the next level

When the player passes through the portal at the exit of the building, he is teleported to level 2. In this level, he/she holds a torch in his/her hand with which he/she can set fire to objects in the virtual environment. Wooden huts, grass and wooden barrels can be set on fire (Fig 10).

Fig 10. Level 2 fire

In this level, the fire is extinguished by itself and the area on which it burned changes to highlight the damage caused by the burning (Fig 11).

Fig 11. Burning marks

The game ends once the player presses the ESC key.

Data Collection

The application has implemented a mechanism for collecting live feedback from the player. There are 3 sentences for which the player must give a rating, depending on his or her emotional state.
The sentences are as follows:

- "I feel completely safe"
- "I feel anxious"
- "I feel that I can control my emotions"

The ratings that the player can give are the following:

- I totally agree

- I kind of agree
- I somewhat disagree
- I totally disagree

These 3 phrases will appear 5 times during the game. The answers will be saved in a txt file. The file name will have the structure *(PlayerName)(SessionNumber).txt*. The data collected for a number of 20 people who tested the application is analyzed in Chapter 5.

Case study and results evaluation

We created a questionnaire (a form) that collects data related to pyrophobia. The following table lists the questions in the questionnaire, together with the possible answers.

Table 1: Pyrophobia questionnaire

Question	Answers				
How afraid are you, when you think about fire or flames?	Extremely afraid	Very afraid	Afraid	Little afraid	Not at all afraid
On a scale from 1 to 10, how serious do you think your pyrophobia is?	1-2	3-4	5-6	7-8	9-10
How severe your pyrophobia symptoms are?	Very serious, I used drugs to fight them	Serious, but I avoided using drugs	They are noticeable and I used drugs	They are noticeable, but not uncomfortable	I did not have any symptoms
Do you imagine often that you are put into situations involving fire or flames?	Yes, very often and the feelings of fear is very strong	Sometimes, and the feeling of fear arises	Sometimes, but they don't have such a high impact	From time to time	Never
Did this fear have a negative impact on the relationship with the people around you?	Yes, it had a negative impact on the relation with other people	An observable impact	There have been difficult moments of interaction	Very little	Not at all
How much does this fear affect your everyday life?	It destroys my life	It is a problem I have to deal with	Life would have been easier without her	Acceptable	It has no impact
If you could get rid of this problem, how do you think your life would be?	It would change my life in many ways	It would be an improvement to my life	A great relief	It would be much better	It would not make a difference

This questionnaire has been answered by 20 people, 12 men and 8 women, aged 18-78 years. We made a selection based on the answers provided and we kept 8 people who had a higher fear of fire than usual, of which 4 females and 4 males.
In Pyrophobia-3D we used 3 instruments to measure the player's progress in the virtual environment. These three instruments are based on the three sentences that analyze the level of the following feelings: the feeling of safety, the feeling of anxiety and the feeling of control over emotions. As we mentioned in the previous chapter, in the virtual environment there are several points that trigger the display of the panel containing these three sentences. At the end of the game, a file containing all the players' answers is generated. For each feeling, an intensity index will be calculated according to the players' answers. The answers will have the following impact:

- I totally agree – it is worth 4 points
- I kind of agree – it is worth 3 points
- I somewhat disagree – it is worth 2 points
- I totally disagree – it is worth 1 point

The intensity of each feeling will be calculated based on the mean of the values of the answers given by the player. The index is interpreted as follows:

- In the interval [1; 2] - the feeling has low intensity
- In the interval (2; 3] - the feeling has medium intensity
- In the interval (3; 5] - the feeling has strong intensity

In order to assess the impact of the virtual environment, we collected data from three different game sessions. The user we chose to give as an example had a medium-to-high pyrophobia level. In the chart below (Fig 12) it can be seen that during the three game sessions, the feeling of anxiety decreased in intensity from a strong level of 3.4 to an average level of 2.2.

Fig. 12: User1 analysis. Blue – safety, Orange – anxiety, Grey – control over emotions

At the same time, Pyrophobia-3D helped to improve user safety and control. The table below presents the index values of the other participants in the study during the 3 game sessions (Table 2).

Table 2: Results of the case study

User	The evolution of the safety index	The evolution of the anxiety index	The evolution of the control over emotions index
User 2	1.2 - 1.4 - 2.2	2.8 - 2.4 - 1.8	2 - 2.2 - 2.4
User 3	2 - 2.2 - 2.2	2 - 1.8 - 1.6	3 - 3.2 - 3.2
User 4	1.4 - 1.4 - 1.8	2.6 - 2.4 - 2.4	1.6 - 1.6 - 2
User 5	1.4 - 1.6 - 1.6	3.4 - 3.2 - 3.2	1.8 - 2.4 - 2.4
User 6	1.6 - 2 - 2.2	2.8 - 2.6 - 2.2	1.8 - 1.8 - 2
User 7	2.2 - 2.4 - 2.8	2.2 - 2 - 1.6	2 - 2.6 - 3.2
User 8	2.6 - 3 - 3.4	1.8 - 1.8 - 1.4	2.4 - 2.4 - 2.8

The purpose of the second questionnaire (Table 3) was to receive feedback from the game users in order to improve certain aspects in the future. The purpose of the game and the mechanics have been appreciated by most users, with relevant changes in their perception of fire.

Table 3: Feedback questionnaire

Question	**Answers**			
What do you think about the graphics of the Pyrophobia-3D game?	I really like it	It is OK	It is OK, but it can be improved	I do not like it
On a scale from 1 to 10, how intense is your fear of fire?				
Did you feel any anxiety while playing Pyrophobia-3D?	Yes, mostly	Yes, a few times	Yes, only once	Not at all
Did you find that the game objectives are relevant in relation to the pyrophobia therapy?	Yes	No		
On a scale from 1 to 10, what rating would you give to the mechanics of extinguishing the fire with the fire extinguisher?				
Have you found yourself in a scenario that you think you might encounter in your daily life?	Yes	No		
With what percentage do you think your level of pyrophobia has dropped after playing this game?	0-20%	20-40%	40-60%	60-100%
Do you have any other suggestions for improving Pyrophobia-3D?				

62.5% of the users considered that they really liked the application and 37.5% stated that the application is nice. 50% felt anxiety while playing the game. 87.5% considered that the game objectives are relevant in respect to pyrophobia therapy. All the respondents stated that they found in the game a scenario they might encounter in their everyday life. 62.5% of the users said that their pyrophobia anxiety level decreased by 20-40%, 25% of them considered that the anxiety reduced with 40-60% and 12.5% of the users stated that the anxiety decreased with less than 20%.

Conclusions

In conclusion, the systems for phobia therapy have a great importance and can have a positive impact on the people's lives. As we saw in Chapter 2, pyrophobia is one of the few fears for which a virtual environment has not been created yet. Therefore, we designed Pyrophobia-3D, that includes all the features necessary for virtual therapy.

Fear of fire can become an impediment in the daily life of a person suffering from pyrophobia, who can develop an involuntary obsessive-impulsive behavior. In the case study from the previous chapter, we demonstrated the ability of a virtual environment designed to significantly reduce the anxiety resulting from pyrophobia. At the same time, the use of exposure therapy in a virtual environment eliminates the risks.

Regarding further development, by taking into account the suggestions received in the feedback questionnaire, we plan to introduce a new level and a scenario with a fire in the house. Also, we aim to integrate sensors for physiological signal monitoring in order to better evaluate the emotional states, as exemplified in Ferche et al (2015) and Moldoveanu et al (2019).

Abstract

The scope of this publishing item is to reflect the research status around test data generation by Artificial Intelligence methods and what could be the influence factors for the decision of the IT management in banking sector for the professional usage of AI. This article also aims to outline the differences between test data generation by traditional approach versus Machine /Deep Learning algorithms as subset of AI.

Keywords: Artificial Intelligence, Banking, IT Management, Product brand, Testing, Test data.

Introduction

A product alone can influence strongly the threshold for a purchase request in the public (e.g. Apple, Porsche, Netflix). That´s why, products are essential for the financial success of a company - on the other hand, it means it strengthens the brand of a company on global marketplace. A term was created to combine product and brand - the product brand. "Product brands refer to the individual products of a company and are the foundation of its brand world" (Trust, B. (2020, February 26)).

When the banking sector will be considered with its products - there are mostly digital ones. On the other hand, those products will be traded on digital marketplaces and composed by a combination of single data units (BaFin, Studie: Big Data trifft auf Künstliche Intelligenz, 15.06.2018)(Insights, M. (2020, April 02). Those product data will be delivered from various companies, like asset data, trading data and tax data.

All these data are not longer to be considered as technical ones, rather be a multiple combination of many single data in order to be a business logical construct. From a management scope of view those business data are classified and rated as capital and treasure of banking (Insights, M. (2020, April 02)).

These data constructs has been evolved to a "Quasi" currency, which are traded on various marketplaces as such one and those needs an appropriate supporting technology like AI (Schulz, Bastian. (2019, July 11)). Professor Ben King said: " The field of business analytics is the ‘gold rush’ for the millennial generation. Our information age creates a wealth of data and the tools to access it ..." (Davis, B. (2015, May 14)).

Data segments within banking operations can be divided into the main groups of productive data and test data.

Productive data are the summary of data representing an information universe of an organization to handle the daily operations in interaction with its stakeholders.

Test data are data as one of the created or selected basics of IT test management discipline. Next to test cases, the purpose of those ones is to be essential input part during the execution of test runs. This special segment of data supports the quality check of a system, objects and processes.

Method

In the first part of this article we are going to focus in general on the topics of Test Data with its expressions, Test levels depends on the focus, Bank IT management as a special part of Management and AI with its essential parts. After the clarification of those terms, the minimal preconditions for the Test Data creation process in general and for AI specially will be listed.

As a next step for this scientific work product, the process of Test Data creation will be described from worldwide most used IT system, called legacy system, until the handover into Artificial Intelligence technic approach.

Moreover, the advantages of AI created Test Data versus traditional ones will be shown.

Finally, to obtain an overview about the differences between the traditional Test Data creation discipline and the AI oriented, with a script listed in sequence steps based on main indicators those ones will be visible.

Test Data Creation

Some test data will be created manually and others (semi)automatically related to the purpose and objective of usage.

One of its attributes is the ability for re-use. A part of them can be re-used multiple times, others are planned for single use. For example, attributes with multiple test usability within banks can be the ISIN of an asset, but another part of the same object - the maturity date is for single use. Most of multiple use data are recoverable for following test sessions by the current IT system environment with appropriate effort.

But under the current circumstances to recreate a single use data with old core banking applications - called legacy systems - has got many restrictions in order to model the business context of an expired test data after a test run.

Often, the best practice is here, the complete creation of that data by manual work of a bank and / or IT specialist. Another weakness of the legacy system is the requirement to generate new test data based on the combination of findings of historic test data and its results after the runs. It needs a considerable effort to fulfil this demanding request.

One possibility of solution can be the support by Artificial Intelligence by doing via Machine Learning (Matt High. (2020, April 13))(Litzel, Nico and Anja Klauck (2020, February 26)) and Deep Learning algorithms and functions corresponding with Big Data Analytics.

Test levels

The defined test data will be used in combination with test cases during various test runs/sessions.

Common levels for each focus are (Hooda, I., & Chhillar, R. (2015, February)):

Smoke Testing

It is a pre-testing to reveal simple failures severe enough. This tests has to cover the most important functionality of a component or system, used to aid assessment of whether main functions of the software appear to work correctly.

Regression Testing

This kind of testing has to ensure that previously developed and tested software still performs after a change.

Unit Testing

The lowest level of testing mainly performed by developer to test the unit of code encapsulated.

Integration Testing
This is to test the data and message flow between various modules to make sure data is flowing across various components correctly.

System Testing
The overall system is tested to ensure that it is behaving or functioning as intended and as specified in requirement document. Regression testing is performed to ensure that nothing is broken in system after fixing bugs and testing bugs.

End-to-End Testing
The whole workflow chain of a use case will be tested with focus on data and message flow.

Bank IT Management

IT Management is an organizational derivative from the common management of a company with a special focus. It has the task with the steering of the IT in general. Concrete, it is not delimited for the responsibility of Hard- and Software rather to give guidance on orders, objectives and personal-related issues with intersection to the IT topic.

The main objective of the IT Management is to contribute an added-value to the overall earnings performance of the company in which ideally the quality level increases and in the same time the costs will decrease as well as the risks will be mitigated (Raffael Herrmann (2012, September 09))

Artificial Intelligence (AI)

AI as an abbreviation of Artificial Intelligence is the ability of a digital computer or computer-controlled robot to perform tasks commonly associated with humans, such as the ability to reason, discover meaning, generalize or learn. Some other comparable definitions are:

"Artificial Intelligence (AI) is a general-purpose technology that has the potential to improve the welfare and well-being of people, to contribute to positive sustainable global economic activity, to increase innovation and productivity, and to help respond to key global challenges. It is deployed in many sectors ranging from production, finance and transport to healthcare and security." (OECD-LEGAL-0449, 05/2019)

The WTR (World Trade Organization) has the following definition for AI:
"Artificial intelligence (AI) is the ability of a digital computer or computer-controlled robot to perform tasks commonly associated with humans, such as the ability to reason, discover meaning, generalize or learn from past experience." (World Trade Organisation. (2018)).

Machine Learning as a sub-method of AI is the ability to adapt to new information and event circumstances and to detect and extrapolate patterns. It delivers decisions and solution constructs after learning trainings sessions (Eberspächer, Jörg, and Thomas Goetz. (2014)). Deep Learning as the conclusion engine of Machine Learning splits the solution generation process into many hierarchical interim layers analogical an artificial neuronal network. After various execution steps including the analysis of the data universe (Big Data Analysis) the solution will be created. The underlying algorithms, functions and procedures generates dedicated conclusions with an interpolation and extrapolation statistical approach.

Here is to be observed that the AI engine can generate new attributes like creation date, interest rate and others based on past and present information as well as predicted analysis (Jasrotia, A. (2018)) of relevant information impacts and influences.

Basic conditions

To implement this service, what are the necessary minimum conditions or requirements of a successful AI service in general?

a) Data accuracy
In this context the quality of the results depends on the input data quality directly. It means, in case of weak quality of the data repository and pool the AI related conclusion results are wrong often.

b) Huge amount of data / big data lakes
Because of that, the quality of well-trained AI engine with the belonging algorithm and functions increases with the high volume of available well-structured data and numbers of performed trainings sessions. This engine is self-adaptable depends on the findings of each training (re-)run.

c) Performing technical environments
To perform AI training / conclusion sessions with an expected qualified outcome within an acceptable response time it is mandatory to fall back to a high performing IT backbone.
For example: The Quantum technology opens the possibility to have access for necessary performance (Mayer-Crenu, A. (2020, February 19))(Deeg, Janosch (2020, February 20)).

AI for Banks

Reasons for AI usage for Bank task coverage

Why does it provides the occasion of AI usage for test data generation within the banking sector?
The banking industry owns the biggest size of data comparable to other industries.
One of the reason is that Financial institutes has got a lot of interdependencies between information systems and related processes internal and external.
That´s why, as described before, one of the conditions is given that the quality of the AI conclusion results will be high (Matt High. (2020, April 13))(Litzel, Nico and Anja Klauck (2020, February 26))(FSB - Finance Stability Board. (2017, Nov 1))(BaFin. (2019, Jan.)).

To achieve and to keep the data accuracy in banks on an appropriate level are a real problem to solve independent of usage of AI or traditional IT. The experience of data clean-up and enrichment projects in the past shows a disproportion of investment of resources like time, budget and human capital to the revenue outcome.

Despite promising approaches like database refactoring the amendment covered only the redesign of technical structures (DB-Scheme, Relations, Data administration, Access possibilities, etc.) while retaining data behavioral and informational semantics - it was not a change from the data quality itself.

The AI discipline can serve parallel with a fluent data and algorithm modification during the engine trainings.

Data sources

Which can be the data sources for the AI engine in the bank?

As a result of the AI technical discipline, it offers the generation of conclusions from various
data sources - the derived information. This data portfolio consists of bank internal sources as well as of bank external static and dynamic oriented data edges - the Big Data pool with various data lakes.

From a business perspective of a bank the underlying data of the daily business has got a widespread of the scope (Risk Management, Trading, Accounting, Supervision, Front Office, Back Office, Corporate Management, etc.). All these are compositions with several weights of real-life, historical, predictive data (models, simulations) from internal and external feed.

1. Real-life data
They delivers one of the most valuable basic source for generation of similar test data in combination with data masking.
2. Historical data

Often, they stored as time series based pillar data; there are single data itself as well as constructs are essential sources too for the extrapolation of future test data constructs based on empirical values.

3. Data sources bank externally
These are data which the bank not owned, is not able to generate initially; that´s why the organization imports the data as spectrum/cluster/group from external suppliers into the own core banking environment. This could be messages, asset prices, interest rates, lending values, tax data, external security events, etc. from data suppliers, government, public surveys, etc. with an interim step of structuring there are also valuable basics.

Benefits of AI

What is the advantage of AI created test data versus conventual ones?

A general introduction for this question are described in (Maitino, Phil(2020, Jan. 17)).
As follows the concrete advantages for AI created test data:
a) Apparently "senseless" test data were be generated, which perhaps would never be created by cognitive manually intervention. But exact those data supports the explorative test approach without any reference to the test scope. The system reaction will be checked in case of fail-safe, fail-operational, ABEND (Abnormal End), undefined / unclear situation - every status can be simulated by this portfolio of test data.

b) The numbers and effort for single use test data definition by hand with several characteristics will be reduced, whilst the AI will generate those ones repeatable and similar new ones as proposed by the conclusion algorithm.

For example: Exactly for the test object security event of interest rate maturity the same one will be generated and another one will be suggested with the same interest rate but another interest period.

c) The AI is able to extend the test data universe on horizontal level in general, whilst for semantical similar logical units in comparison with the initial object those new ones will be generated likewise. This is possible on conclusion based on existing test objects stored in historical executed test sessions in relation to a strategy paper of the bank management with the hint to publish new products out of the product line.
For example: The semantical business need for securities with fixed terms for testing will be enlarged with securities with variable terms.

d) The test object spectrum will be extended on vertical level (Data enrichment): the existing data construct from pretests will be extracted out of the data lake, enriched with further attributes and restored again. It delivers the opportunity to expand the functional business tests on a repeatable regeneration sequence, but with an mutated object under changed circumstances.

Data Creation Script / Process steps

For the comparison of the Test Data creation process with traditional IT and the AI approach it offers itself the cost factor manual intervention versus automatical workflow.

The process can splits into the steps:

- Preliminary work
The existing data should be analyzed to detect wrong content, bad combinations, senseless semantics, obsolete components, wrong plausibilities as well as incorrect redundancies.

- Initial work
Depends on the planned purpose of the test data new ones has to be conceptual defined or retrieved and combined out of data warehouses, data lakes and stocks in general.

- Generation
In a further step the data has to be generated along the defined drafts.

- Maintenance
The created or used data should be re-analyzed and archived as reference items for later test sessions. In addition, the supporting tools and technical mechanism has to be updated onto the current findings of improvements and issue fixings.

Expandability / Scalability

Those questions will be raised:

On which degree has the approach, tool, process the chance to perform on a higher level? How can be the usage of resources for further development of that process more efficient?

As follows the table shows some relevant actions along the process steps for both approaches - Traditional IT and Artificial Intelligence:

Process steps	Traditional IT			Artificial Intelligence		
Preliminary work	- Data Clean-up	X		- Clean-Up Algorithm preparation - Data Clean-up	X	 X
Initial work	- Creation new date by hand - Selection data out of existing data stores/lakes	X X		- Initial data stock will be generated based on existing data stores/lakes		X
Generation	- By usage of data generation tool based on manual implemented rules	X	X	- Self-Generation of data based on high sophisticated self-learning algorithm / functions		X
Maintenance	- Maintenance effort focussed on data reference models, interpretation rules and generation tool	X		- Autonomous fine adjustment of algorithms and functions, self-paced training of technical components mentioned (unsupervised learning		X
Expandability / Scalability	- Limited on the interpretaion rule set/model - Strong dependency from regular maintenance work	X	X	- Possible high scalability on the basis of self-paced learning algorithms and functions (Machine / Deep Learning)		X

Legend:

- Manual intervention

- Automatical workflow

Figure 1: Data creation process - Comparison Traditional IT - Artificial Intelligence

After finish of the appropriate process step a quality gate has to be checked to satisfy the level beforehand defined.

Conclusion

AI offers the possibility to generate test data close to the production standard splitted into for multiple and single use during regular und unscheduled test sessions on core banking systems. The scope extends over Smoke and Regression tests for daily bank business as well as Integration, System and End-to-End tests for forecasted system changes in form of upgrades, updates, releases and patches.
A concrete bullet point plan (Script Test Data creation) have to underpin the proceeding with a strict satisfying indicator for each milestone of a completion step. It is recommended to start with a small task to gain in short time the appropriate results with a high transparency of the creation workflow. Moreover, the effort for possible amendments and adjustments of code, data, environment, etc. is on moderate level.

An agile project management is a suitable approach to support this short-term planning and to monitor the progress with the possible daily status view.

Abstract

This article examines the comprehensive implementation of the concept of sustainable development, helps to make eco-tourism more important every year. An important goal of this article is the efficient and rational use of resource potential and the optimal solution of regional development problems. The ecotourism industry performs important functions in the development of the economic complex and economy of the country, district, region as it increases local incomes; creates new jobs; promotes the development of industries focused on the production of ecotourism services; develops social and production infrastructure in tourist centers; increases budget revenues. Entrepreneurs' interest in ecotourism can be explained by a number of factors: in order to start an ecotourism business, you do not need large financial investments; in the market of ecotourism services, despite the competition, both large and medium and small companies and firms can successfully interact; ecotourism business allows you to quickly turn capital. The results of environmental activities are assessed by ecological and economic efficiency. The concept of ecological efficiency includes reclaimed land and disturbed landscapes, planted forest areas instead of cut down or killed by acid rain, contaminated groundwater, frost, hurricanes, felling of diseased trees and shrubs, restored meadows and forest litter, conservation and reproduction of rare species of flora and fauna and other restorative measures. The main indicator of ecological efficiency of environmental measures in relation to recreational resources is the possibility of their use for their intended purpose with the subsequent receipt of economic benefits.

Keywords: Tourism, Ecology, Ecological Tourism, Business, Development, Economy.

Introduction

Comprehensive implementation of the concept of sustainable development makes ecotourism more and more important every year. Efficient and rational use of resource potential and optimal solution of regional development problems are the two most important goals of the sustainable development strategy for any territory. These two goals would be realized in the development of ecological tourism, which will preserve the unique beauty of natural areas, reduce anthropogenic pressure on the environment, increase the younger generation's knowledge of nature and experience with it, improve the welfare of local people and more. That is, ecological tourism can be called sustainable ecologically balanced tourism. Due to the prospects for the development of ecotourism in Ukraine, it is interesting to interpret the concept of ecotourism adopted in international documents, its principles and criteria, the study of the relationship between the concepts of ecotourism and sustainable tourism.

The purpose of the article is to theoretically analyze the importance of ecological tourism in the context of hotel and restaurant business management in the conditions of stability of ecosystems of territories

Theoretical and methodological fundamentals of ecotourism

The International Ecotourism Society (TIES) in 1990 gave the following definition: "Ecological tourism is a responsible trip to natural areas that promotes nature protection and improves well-being of local population". In 1996, the International Union for Conservation of Nature (IUCN) officially adopted a partially revised definition proposed in 1983 by Mexican economist, architect, and ecologist Hector Ceballos Lascurain, "ecotourism is ecologically responsible traveling and visiting relatively untouched natural areas in order to study, admire and explore nature and related cultural monuments, which contribute to the preservation of the environment, cause minimal damage to nature and create socio-economic benefits to local population."

Ecotourism is an effective means of economic and social revival. The ecotourism industry performs important functions in the development of the economic complex and economy of the country, district, region as it increases local incomes; creates new jobs; promotes the development of industries focused on the production of ecotourism services; develops social and production infrastructure in tourist centers; increases budget revenues. Today, ecotourism is one of the few fastest growing businesses. Entrepreneurs' interest in ecotourism can be explained by a number of factors: in order to start an ecotourism business, you do not need large financial investments; in the market of ecotourism services, despite the competition, both large and medium and small companies and firms can successfully interact; ecotourism business allows you to quickly turn capital [2].

Ukraine has sufficient ecotourism resources, the use of which, along with growing tourism services, will naturally contribute to the intensification of infrastructure development and territorial organization of ecotourism activities [1]

The results of environmental activities are assessed by ecological and economic efficiency. The concept of ecological efficiency includes reclaimed land and disturbed landscapes, planted forest areas instead of cut down or killed by acid rain, contaminated groundwater, frost, hurricanes, felling of diseased trees and shrubs, restored meadows and forest litter, conservation and reproduction of rare species of flora and fauna and other restorative measures. The main indicator of ecological efficiency of environmental measures in relation to recreational resources is the possibility of their use for their intended purpose with the subsequent receipt of economic benefits.

Different approaches are used to assess methodological approaches to determining the environmental damage caused to recreational areas. Thus, the fee for the use of recreational resources is a mechanism for the extraction of differential rent, which is defined as the difference between the value of the use of natural resources and the regulatory level of the reduced costs to ensure its use for recreational purposes. However, when using natural ecosystems and their individual elements, it is necessary to take into account the rule of the degree of transformation, which is the inadmissibility of exceeding the limits of the ability of self-support and self-restoration. In this case, the unit of renewable resource can be obtained for a certain period of time, which is determined by the speed of functioning of ecosystems, as well as the physical parameters of the environment.

Pollution of air, water and soil has a significant impact on the sustainability of the ecosystem, and the resistance of different components of the biosphere to the same actions is ambiguous. Thus, black wattle and narrow-leaved

linden are resistant to sulfur dioxide (SO_2) and nitrogen oxides (NOX), European larch, birch and beech have intermediate sensitivity to SO_2, and silver fir – to NOX, at the same time it is sensitive to SO_2, and European birch and larch are sensitive to NOX [2].

The concept of sustainability in ecology is interpreted ambiguously, and therefore its assessment is carried out on various grounds, manifestations [3]:

1) the difference of the system of one state relative to another (Z2 – Z1 = ΔZ);
2) the allowable value of the difference from the base state, i.e. its variability (Z0 – Z1 < ΔZ);
3) the time interval within which changes occur or sustainability is assessed (Δt);
4) the influence of external factor (F) or their group, against which stability is assessed. According to the ratio of these manifestations M. D. Hrodzynskyi [5; 4]:

- resistance (elasticity, inertia) – the ability of the ecosystem (E1) under the influence of the factor (F1) during the time (Δ t1) to stay within certain limits (stability) (Z1); F1 /Δt1 ← Z1;
- plasticity (mobility) – the ability of the ecosystem (E2) after the cessation of the factor (F1) during the time (Δ t1) to return to the original stable position (Z2); F2 /Δt2 →Z2.

Thus, sustainability can be considered, on the one hand, as the ability of the ecosystem to counteract the influence of external factors, to preserve its essence and quality characteristics in the state Z1, and on the other – to restore its properties, i.e. to be plastic (Z2) [6]. Therefore, resistant and plastic sustainability are completely different properties of ecosystems. The more the ecosystem resists the influence of external factors, the harder it is to break, but if it is broken, then it is difficult to return it to its original state. That is, the higher the plastic resistance is, the lower the resistance of ecosystems is.

In addition, the features of scattering of pollution over the study area and its functional purpose must be taken into account. In relation to air pollution, environmental effectiveness of measures (E) to reduce emissions is determined by the formula [7]:

$$Э = \sum_{i=1}^{n} \Delta M_i f_i K_0 \quad \text{unit of weight/h}$$

where ΔM_i - change in the weight of emissions of each i-component of pollution, units of weight/hour;

f_i - the coefficient characterizing the scattering conditions of the impurity in the atmosphere, depends on the height of the pipe, vertical and horizontal mobility of the atmosphere, the type of impurity. Approximately for gases it is taken equal to one, for dust and ash, with a degree of purification of less than 75%, f_n =3, and 90% - f_n =24;

K_0 - the value of relative danger of the territory of different purposes, taken according to table 1 [4].

Table 1: The value of the coefficient K_0

Type of territory	Value K_0
Resorts, holiday centers, reserves, natural reserves	10
Suburban recreation areas, garden cooperatives	8
Territories of industrial zones	4
Forests	0,2

In addition to regular man-made emissions that have a negative impact on ecosystems, significant environmental damage is caused by accidental, volley emissions and discharges of harmful and toxic substances. The magnitude of the damage depends on the absolute volume and toxicity class of the components of the emission (discharge), its duration over time and the area of distribution.

When carrying out environmental activities in the normal technological mode of polluting enterprises, full economic effect, for example, from the purification of emissions from dust and gases can be determined by the formula for the accounting time period (quarter, half-year, year) [4]:

$$Э_0 = \sum_{i=1}^{2} \left(\Delta y_i + \Delta D_i \right), \text{ UAH,}$$

where Δy_i - the amount of damage prevention by reducing payments for dust emissions (i = 1) and gas (i = 2) after commissioning of dust and gas cleaning equipment, UAH;

$$\Delta D_i = Ц_i \bullet M_i$$

where $Ц_i$ - unit cost of the extracted i-component, UAH/unit of weight;

M_i - mass of the removed i-component, unit of weight (t/kg).

Annual economic effect for the company from environmental activities is calculated by the formula

$$Э_г = \Delta П_i + \Delta Д_{гi} - \Delta C_i - E_н \bullet \Delta K_i, \text{ UAH/h,}$$

where $\Delta П_i$ - change in the amount of payment for pollution (by components), UAH/h;

$\Delta Д_{гi}$ - additional income over the year from the use or sale of extracted components, UAH/h;

ΔC_i - increase in operating costs after installation of filters for the i-pollution, UAH/h;

E = 0,15 - normative coefficient of economic efficiency of one-time expenses, assigned per year;

ΔK_i - increase in costs for design, purchase and installation of filters, UAH

With unfavorable ecological conditions in industrial and other zones it is impossible to develop ecological tourism at the local level. Therefore, there is a secondary economic damage caused, firstly, by the need to export outside the region or country of money used for recreation, and secondly, the population must bear the cost of travel to other places.

Conclusions

Work on the restoration of existing ecosystems for the sustainable development of ecological tourism should be based on thorough research of air, water and soil pollution. Restoration of the resilience of the ecosystem is the key to increasing its plastic resilience. Therefore, sustainable ecotourism is successfully developing with sufficient resistance of the ecosystem to the influence of external factors, which are often significant flows of tourists in a given area.

It is necessary to conduct environmental activities in the normal technological mode of enterprises that pollute the ecosystem of the territory intended for ecological tourism. To assess ecological damage caused to recreational areas, a number of methods are presented that are necessary for the restoration of ecosystems of areas intended for sustainable development of ecological tourism in Ukraine.

Analysis of Awareness and Attendance Criteria in the Mala Fatra Region

Miriam GARBÁROVÁ

University of Zilina, Žilina, Slovak Republic
Miriam.Garbarova@fpedas.uniza.sk

Abstract

It is known that the tourism sector positively contributes to the process of economic growth of a country through different channels. The paper deals with the issue of tourism in the Mala Fatra region in the Slovak Republic. The main objective was to analyze the awareness of the Mala Fatra region, the attendance of the destinations in the Mala Fatra region and the visitors' preferences in the tourism sector. To meet this goal, a questionnaire survey was conducted to determine awareness of the Mala Fatra region, attendance of the Mala Fatra destinations, satisfaction with services in these destinations and to identify factors that are important for choosing a destination. Based on the analysis of the results of primary research, it is possible to categorize the respondents to three segments. The results of primary research and identified criteria could contribute to the best possible design of the tourism offer of the Mala Fatra region for a specific target group in the future.

Keywords: Tourism, Mala Fatra Region, Destination, Visitors.

Introduction

Tourism is a set of activities aimed at meeting the needs related to travel and residence of persons outside the place of permanent residence, usually in leisure time. Their goal is relaxation, exploring, health, entertainment, cultural and sports activities. Also, business trips and gaining a comprehensive experience, as mentioned in materials of Ministry of Transport and Construction of Slovak Republic.

According to Šefčík et al. (2019), tourism is very often described as a complex socio-economic phenomenon that affects a wide range of economic and non-economic (social, psychological, ecological, geographical) areas of society.

Gúčik (2011) stated that tourism becomes a factor of regional development, usually where there is a suitable primary offer, such as cultural, historical, natural attractions and destinations causing visitation. Where the primary supply of tourism is the most attractive, tourism is the subject of economic appreciation and a tool of regional development. Tourism can be in various positions as an economic activity. The greater supply of tourism in the region and its role will be more critical as a tool of its economic and social development.

Sanjeev & Birdie (2019) mentioned that tourism is among the fastest-growing industries in terms of both income generation and job creation. The World Travel and Tourism Council 2019 report on travel and tourism impact exhibited that the share of tourism represents about 10.4% of global GDP and 319 million jobs (i.e. 10% of the total employment) globally.

The tourism sector is recognised to positively contribute to the economic growth process of a country through different channels, including the fact of course that it is a currency earner sector; that stimulates physical and human capital accumulation, and pushes (and uses) technology and innovation. As stated by Mayer & Vogt (2016), at the same time, tourism promotes, directly and indirectly, other economic industries such as transportation, hospitality or retailing.

According to Brida, Gomez and Segarra (2020), tourism is a significant sector of diffusion of technical knowledge, and potentially it can stimulate research and development.

As mentioned by Gúčik (2010), the set of elements that, in various combinations, form the goods of tourism form the offer of tourism. Their consumption affects the final effect of tourism. The bearer of the offer (object) of tourism is the destination, companies and institutions of tourism. The nature and scope of the offer are determined by the primary offer and the secondary offer derived from it. Primary offering associate with the natural, cultural and historical

Cite this Article as: Miriam GARBÁROVÁ" Analysis of Awareness and Attendance Criteria in the Mala Fatra Region" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

potential of the country for tourism. This potential has a specific functional and time usability in tourism in terms of the motivation of the visitor - customer. The primary offer can be given by natural conditions or created by human activity, which consists of cultural-historical conditions and organized events. On the other hand, Rentková and Vartiak (2017) discovered that the situation is quite different in the countries belonging to emerging markets, where tourism is vital for the economic survival of those countries. If the goal of visitors in tourism is resting, health, sports or cultural activities in a suitable environment, then the secondary offer is a means to achieve this goal, because it creates the conditions for the use of the primary offer and adapts to it, Gúčik (2010) continued. The secondary offer consists of three basic groups of factors, namely tourism institutions in destinations, tourism infrastructure and general infrastructure.

Gretzel, Fesenmaier, Formica, & OLeary (2006); Khalilzadeh & Wang (2018); Line & Wang (2017); McCamley & Gilmore (2018); Pike & Page (2014); Vartiak (2015) mentioned that destination marketing is a naturally complex proposition involving the cooperation of agencies at the national, regional and local level; the collaboration between governmental, commercial, and non-governmental not-for-profit groups is critical. A large mass of literature focuses on this very relationship, reviewing the challenge that nations face in trying to "identify and satisfy consumer needs more effectively than their rivals".

Gúčik (2010) found out that the proportions between the primary and the secondary offer depend on the quality of the primary offer, which limits the optimal functional use of the secondary offer. In terms of time, this is a permanent offer that is associated with year-round service. It is also a seasonal supply, which is conditioned by the occurrence of seasonal events causing demand. In economic terms, the offer represents economic goods, of which consumption satisfies their guests' needs. By consuming them, visitors gain a utility effect (experience), while businesses and tourism institutions gain a value effect (sales, taxes). The characteristic features of the offer include diversity and complexity, commitment to large investments, a high degree of readiness to provide services.

Aguiló, Rossello, & Vila (2017); Brida, Cortes-Jimenez, & Pulina (2016); Brida & Scuderi (2013); Dogru, Sirakaya-Turk, & Crouch (2017), Čorejová, Genzorová & Stalmašeková (2017), Rentková & Vartiak (2017) mentioned, effective promotions of destinations, attractions and services requires careful consideration of the target markets, likely effectiveness and the costs of gathering data thereon.

According to Brida, Gomez and Segarra (2020), many governments are paying greater attention to support and promote tourism as a potential source of growth and employment and as a sector which adds value to cultural, natural and other capital with no market price. On the other hand, in the academic sector, there is a growing interest in the relationship between tourism and economic growth.

The Mala Fatra Region

The Mala Fatra region is located in the north of Slovakia in the Zilina region. The area of Mala Fatra is a trendy summer and winter tourist destination. The Mala Fatra region offers many exciting attractions, or a relatively large number of bike paths.

By https://www.regionmalafatra.sk, Mala Fatra is undoubtedly one of the most beautiful tourist destinations in Slovakia. It offers 17 km of ski trails, 22 km of cross-country trails, 600 km of marked bike paths and 150 km of marked hiking trails.

Table 1 shows the accommodation statistics of the Mala Fatra region in the years 2018 and 2019. Zilina has the highest number of accommodated visitors and overnight stays, as it offers the widest range of accommodation facilities. As we can see in comparison with 2018, the number of visitors increased and with it the number of overnight stays, which shows that tourism in Mala Fatra is growing year on year.

Table 1: Accommodation statistics of Mala Fatra municipalities for the years 2018 and 2019

Village	Number of visitors		Number of overnight stays		Number of accommodation facilities		Number of beds	
	2018	2019	2018	2019	2018	2019	2018	2019
Zilina	87 014	10 2901	205 763	214 077	39	42	2 213	2 175
Bela	18 547	22 393	39 969	44 464	8	8	400	401
Terchova	35 632	43 453	84 766	103 847	39	55	1 183	1 702
Strecno	9 870	11 530	26 774	29 752	3	4	175	185

Source: Custom processing by Accommodation statistics of the region Mala Fatra, sent by email from: riaditel@regionmalafatra.sk

The Mala Fatra region offers many attractions. Nevertheless, its capacity is not fully utilized nowadays. The region is mostly visited by the local population. Visitors stay in it mainly in the summer and for a one-day stay, despite the fact that the region is suitable for year-round and multi-day recreation.

The aim of regional tourism organizations is to increase the number of visitors in the region, which would also increase business activities and employment in the region and thereby improve the living standards of the local population.

Therefore, the aim of the primary research is to find out awareness about the Mala Fatra region, to find out the attendance of the destinations in the Mala Fatra region and to identify the factors that are important for visitors when choosing a destination.

Methodology

The marketing research consists of two parts. Based on the calculation of the sample, the minimum number of required respondents was determined. The implementation part of the marketing research was focused on the collection, evaluation and interpretation of data obtained through an online questionnaire survey.

The primary research was conducted through an online questionnaire survey using Google Forms. The questionnaire consisted of 21 questions, which accounted for 3 identification questions and 18 substantive questions, which were used to collect data such as awareness of Mala Fatra destinations, attendance of Mala Fatra destinations, criteria for choosing a destination, etc.

Data were collected by an online questionnaire survey of the population of the Slovak Republic from 10/05/2020 to 20/05/2020. The analysis of merit questions was performed on a sample of 418 respondents older than 15 years. 51.8% of female respondents and 48.2% of male respondents participated in the online questionnaire survey.

The largest number of respondents, 47.8%, were young people aged 16-25. The second most represented (21.6%) were respondents aged 26-35 years. Respondents aged 36-45 were in third place with 11.1% representation. This was followed by respondents aged 46-55 years with 8.2% representation, followed by respondents aged 56-65 years with 5.6% representation, respondents aged 66 and over accounted for 4%. The lowest proportion of 1.6% were respondents under 15 years of age for whom the research was not primarily intended, and their sample was not included in the analysis of merits questions.

The third identification question categorizes respondents based on their social status. The largest group of respondents, 40.7% were students. They were followed by employees 33.6%, respondents radiating into the self-employed group accounted for 8.9%. The research also participated in 5.6% of mothers on maternity and 7.1% of pensioners. Unemployed respondents were the least numerous group (4%).

Results

Awareness of the destinations of Mala Fatra was investigated by analysis of answers. As can be seen in Figure 1, up to 77.8% of respondents know Strecno Castle. It is followed by Janosik holes in Terchova known by 73% of

respondents. Then Vratna Valley is known by 67.5% of respondents, followed by Statue of Janosik in Terchova, which is known by 59.3% of respondents, rafting in Strecno known by 52.9% of respondents, sightseeing towers – Duben and Strecno known by 51.7% of respondents. Cycling routes around Zilina and Terchova are known by 48.6% of respondents, Château Gbelany is known by 40.2% of respondents, only slightly fewer respondents (39.2%) know Krasnany Castle, and the least known destination of Mala Fatra is Domasin Meander (32.8% of respondents).

Fig. 1: Awareness of the Mala Fatra destinations

The research examined where the respondents learned about the destinations of Mala Fatra. Most respondents (63.4%) know the Mala Fatra destinations from family members or acquaintances, 45.9% of respondents obtained information about those destinations through social networks, 43.5% of respondents found out about the destinations through the official websites, and 30.9% of respondents received information about the destinations through newspapers, television or leaflets.

As many as 92.1% of respondents have already visited one or more of the destinations in Mala Fatra, and only 7.9% of respondents have not visited any of them yet.

Most respondents, 64.9%, visited Strecno Castle and Janosik Holes in Terchova (59.7%). Vratna Valley was visited by 42.6% of respondents, the Janosik Statue in Terchova was visited by 39.5% of respondents, 37.9% of respondents visited Sightseeing Towers – Duben and Strecno, cycling routes around Žilina and Terchová by 36, 6% of respondents and 28.6% of respondents sailed on rafts in Strecno. 17.7% of respondents visited Château Gbelany, and 16.6% of respondents visited Krasnany Castle. The least respondents, 15.1%, visited Domasinsky Meander (Figure 2).

Fig. 2: Attendance of the Mala Fatra destinations

The main reason why most respondents (80.5%) visited the destination of Mala Fatra was nature. Other reasons were sports (34.5%), history (31.7%) and cultural enjoyment (30.9%).

Respondents visit the destinations of Mala Fatra usually in summer (56.6%), in spring it is visited by 19.2% of them, 18.2% in autumn and only 6% in winter.

It was also examined how many times the respondents visited the destinations of Mala Fatra. Most respondents 41% visited Mala Fatra destinations 3-5 times, 21.3% of respondents visited Mala Fatra destinations 6-10 times, 20.3% of respondents visited those destinations only 1-2 times, and 17.4% of respondents visited the destinations of Mala Fatra more than ten times.

There are only 35.3% of respondents who used accommodation services in the destinations of Mala Fatra, and 64.7% of those who did not use accommodation services.

It was found out what is the average time the respondents spent visiting one of the destinations in Mala Fatra. 66.8% spent an average of 1 day there, 26.5% of respondents spent an average of 2-3 days in the destination. The average number of respondents who spent 4-7 days in Mala Fatra was 4.2%, and only 2.6% of respondents spent more than seven days in the Mala Fatra destinations.

Up to 80.3% of respondents used catering services in the destinations of Mala Fatra and only 19.7% of respondents have not yet used catering services.

The question concerning the evaluation of the respondents' satisfaction with various aspects of the destinations of Mala Fatra was optional, as the respondents did not have to experienced all the elements. Thus, they would not be able to evaluate them. In this case, the respondents assessed only the aspects they encountered in the destinations of Mala Fatra. The pros of Mala Fatra's destinations are the natural attractions, with which up to (261) respondents were satisfied, 109 respondents were somewhat satisfied, only 5 respondents were somewhat dissatisfied, and no respondents were very unhappy. Other aspects of Mala Fatra's destinations were rated by the respondents as follows (Figure 3):

- Price – 66 very satisfied, 202 somewhat satisfied, 90 rather dissatisfied, 6 very unhappy respondents.
- Transport accessibility to the destination – 45 very satisfied, 218 somewhat satisfied, 83 rather dissatisfied, 13 very unhappy respondents.
- Possibility of parking - 44 very satisfied, 180 somewhat satisfied, 108 rather dissatisfied, 63 very unhappy respondents.

- Accommodation (was rated only by 136 respondents) - 39 very satisfied, 75 somewhat satisfied, 19 rather dissatisfied, 3 very unhappy respondents.
- Refreshment - 85 very satisfied, 188 somewhat satisfied, 36 rather dissatisfied, 0 very unhappy respondents.
- Cultural and historical attractions - 167 very satisfied, 168 instead satisfied, 16 somewhat dissatisfied, 2 very unhappy respondents.
- Sports activities - 114 very satisfied, 192 somewhat satisfied, 31 rather dissatisfied, 0 very unhappy respondents.

Fig. 3: Satisfaction ratings

Respondents were able to express what they liked the most during their visit of one of the destinations in Mala Fatra. The question was answered by 81 respondents who enjoyed the most: nature, tourism and historical monuments.

Respondents could also describe what they would change or improve in the destinations of Mala Fatra. The question was answered by 76 respondents who would like to change/improve in particular: cleanliness of the environment, more student discounts and more parking places.

The destinations of Mala Fatra has not been visited by 33 of the respondents yet (Figure 4). The reasons were: lack of time (72.7%), poor transport accessibility and lack of information about destinations (36.4%), high prices (12.1%), an uninteresting offer of destination and insufficient accommodation services (3%).

Fig. 4: Reasons for not visiting the Mala Fatra destinations

The aim was also to find out if the respondents who have not visited the destinations of Mala Fatra yet were interested in visiting it in the future. Up to 97% of these respondents are interested in visiting one of the destinations in Mala Fatra in the future, and only 3% of respondents are not interested.

We also examined which of the following destinations the respondents would like to visit in the future. Most respondents (59.4%) would like to visit Janosik holes in Terchova, Strecno Castle would like to visit 56.3% of respondents, the statue of Janosik in Terchova 3

1.3% of respondents. Destinations Vratna Valley and rafting in Strecno would like to visit 18.8% of respondents, sightseeing towers - Duben, Strecno would like to visit 15.6% of respondents, Domasinsky Meander and Château Gbelany 12.5% of respondents and the least respondents (9.4 %) would like to visit the destinations of Krasnany Castle and cycling routes around Žilina and Terchova.

The importance of the criteria in selecting a destination was also examined. Price is significant for 250 respondents and important for 117 respondents, relatively unimportant for 38 respondents and trivial only for 12 respondents. For other criteria of importance, respondents answered as follows (Figure 5):

- Natural attractions are significant for 232, necessary for 172, relatively unimportant for 12, and trivial for only one respondent.
- Transport accessibility to the destination is essential for 110, necessary for 204, relatively unimportant for 90, and trivial for 13 respondents.
- The possibility of parking is significant for 139, necessary for 148, relatively unimportant for 105, and insignificant for 25 respondents.
- Accommodation is essential for 55, necessary for 150, relatively unimportant for 171, and insignificant for 41 respondents.
- Refreshment is vital for 106, essential for 232, relatively unimportant for 69, and insignificant for 10 respondents.
- Cultural-historical attractions are significant for 182, necessary for 182, relatively unimportant for 46, and insignificant for 7 respondents.
- The possibility of sports is significant for 177, necessary for 149, relatively unimportant for 61, and insignificant for 30 respondents.

Fig. 5: Criteria of the importance of choosing a destination

Discussion

This primary research could be used to design the marketing strategy and marketing communication strategy of this region. However, regional participants should focus this strategy on the individual segments that emerged from the primary research. Based on the analysis of the results of primary research, it is possible to segment the respondents as follows:

The segment of young active visitors consists of visitors aged 16 to 35 years. They visit the destination mainly for nature and sports. They usually spend a day in the region. Most of them are students, and therefore they consider price to be an essential criterion.

The mobile visitors' segment consists of men and women in the age category from 36 to 55 years. Comfortable transfer to the destination and also the possibility of parking is an essential criterion for them. They visit the destination mainly because of nature and culture. In the region, they tend to spend one day or 2-3 days.

The passive visitors' segment consists of men and women aged 56 and older. They visit destinations mainly because of nature, culture and historical monuments. They consider price and food to be essential criteria for destination selection. They also tend to spend one day or 2-3 days in the region.

Categorization and segmentation of visitors is an essential factor in the design and creation of a new tourism offer or product. It is crucial to know to whom the new product will be offered and whether the segment is interested in this offer.

Genzorova, Corejova & Stalmasekova (2018) stated that people today are more willing to spend money on travel than ever before. Because of new possibilities, traveling is easier and travelers can choose options quicker for immediate travel. As Stofkova & Repkova Stofkova (2020) mentioned, modern technologies began to offer a huge amount of data, information. Today, people´s decisions are influenced by the use of mobile applications in tourism, which can help not only with finding accommodation the world over, but also with transport to the destination, raising awareness of the destination and making destination more attractive. Currently, there are several mobile applications that can be helpful to visitors of the Mala Fatra region. These mobile applications are mainly related to hiking and cycling routes in the region. They could be extended with other tips for trips in the area, booking accommodation, buying ski passes or tickets to wellness centers.

As can be seen from the research results, the criteria of the importance of choosing a destination include the possibility of parking and transport accessibility to the destination. The use of shared services in the field of transport and travel can therefore be an opportunity, not only for the individual but also for the region. These services are currently used mainly by young people. As Stalmašeková et al. (2017) mentioned, a simple person no longer has to rely on public transport, but can often choose to leave and arrive at the chosen destination himself. The opportunity to ride with someone who has the same path brings many benefits. In a research study by Garbárová & Hollá Bachanová (2018), in Slovakia, there are already quite a lot of platforms, through which the services of the shared economy are implemented. However, compared to other countries, it is still just beginning. Shared economy services are mostly used by young people between the age of 21 and 30, mainly by employees and students. Their feedback on the use of services is positive, and therefore they return to these platforms and spread them among other people. Respondents from the Žilina Region knows mainly platforms "Uber" and "BlaBlaCar". The services of the sharing economy use 58 % of respondents. The reason for their use is primarily to obtain cheaper fare and saving money.

Another option to make the Malá Fatra region more attractive for visitors could be a suitably chosen loyalty program. According to Hollá Bachanová & Garbárová (2019) Loyalty programs of Slovak travel agencies are simple and do not offer a redesigned remuneration system to customers. Conversely, as has emerged from the analysis, foreign travel agencies offer their customers much more benefits and ways of rewarding. Slovak travel agencies should redesign the loyalty reward system to achieve customer satisfaction, which may affect profitability.

Conclusion

Awareness of the Mala Fatra destinations is obtained through a variety of sources. Most respondents found out about the Mala Fatra destinations from family or acquaintances.

The criteria based on which visitors choose which destination to visit can vary. It was found out that for students, the price criterion is fundamental because most of them not having a steady income yet. They would welcome various student discounts that they could apply in the destinations of Mala Fatra. Men, as frequent drivers of motor vehicles, consider an essential and critical criterion when choosing a destination where they can park their car comfortably. Young people aged 16 to 25 think the possibility of sports as an integral and crucial criterion when choosing a destination.

The purpose for which most respondents visited the destinations of Mala Fatra is nature. Most respondents visited Mala Fatra destinations 3-5 times and usually visited this destination in summer. Accommodation services in Mala Fatra were used by only 35.3% of respondents because most respondents spend only one day in the destination. Conversely catering services in the Mala Fatra destinations has been used by 80.3% of respondents.

The reasons for not visiting Mala Fatra differ, and the most common reason is lack of time, but also poor transport accessibility and lack of information about the destinations. Students did not visit Mala Fatra due to high prices in the destination.

Nowadays, social networks represent a great opportunity that the destinations of Mala Fatra should use effectively. Through social networks (Facebook, Instagram, Twitter…), destinations can become better known to the younger people but also, the older generation; so they can quickly and effectively publish all the necessary information or news to their followers.

Also mobile applications can help people not only with finding accommodation, but also with transport to the destination, raising awareness of the destination and making destination more attractive. Thanks to mobile applications tourism today is much simpler.

The Malá Fatra region has great potential in tourism, which it is trying to use more or less today. However, it still has a huge number of opportunities that can be used to further development of tourism.

The region has a huge potential to develop many forms of tourism in the future. From geographical point of view, it can focus not only on national but also on international tourism. According to the number of participants, individual as well as collective tourism can develop. By age, tourism in the Mala Fatra region can be targeted at all age groups of visitors. From a geographical point of view, it is not only national but also international tourism, according to the number of participants it can develop both individual and collective tourism, according to the age of the participants it can focus on all age groups from families with children to seniors. Within domestic tourism, one-day events and trips or weekend stays have great potential. From the point of view of tourists and visitors from abroad, the region has the opportunity to focus on multi-day stays. In domestic tourism, one-day events and trips or weekend stays, have great potential. In terms of foreign tourism, the region has the opportunity to focus on multi-day stays.

Abstract

Nowadays, cities are a source of benefits and problems related to social, economic and environmental aspects. There is no doubt that the benefits of urbanization are drawing more and more people to live in urban centers. However, such a situation favors the creation of many threats to various socio-economic spheres. Smart cities and advanced information and communication technologies are now becoming the research area of many scientists. Attempts to define and characterize the Smart City concept show how many disciplines are interested in addressing this topic. However, research on Smart City and its components lacks a clear definition of the directions of scientific research supported by practical ICT solutions, taking into account the correlation of scientific research in the field of Smart City. To this end, the authors carried out a detailed structured review of scientific articles to provide a synthetic insight into the characteristics of current smart city research. The article presents a bibliometric analysis showing the correlations of the studied phenomena in economic practice. The presentation of the author's visualization of the use of ICT in the Smart City concept based on a review of scientific articles with the use of an advanced analysis of the interdependence of identified research areas in the field of Smart City, will allow to determine the relationship between the variables and their directions and scenarios for future research. The authors also made a schematic classification of the areas of the analyzed systematic units - taxa (keywords and areas of coexistence). The VOS Viewer and CitNet Explorer software used enriched the bibliometric analysis by showing the degree of correlation of the studied areas by means of visualization of network connection maps.

Keywords: Smart City, Bibliometric Analysis, Visualizations, ICT.

Introduction

The ongoing process of globalization and the transformation of cities into the new Smart City concept implies an increase in the efficiency and quality of services provided by governments and enterprises, which results in a measurable rate of growth in the quality of life of residents. This process requires scientists to use a range of activities and tools that include collecting data, processing and using a range of information to disseminate it to citizens.

The growing spread of information and communication technologies (ICT) in many areas has resulted in an increased increase in research results and the interest of various communities in the Smart City concept.

The article presents a bibliometric analysis of the Smart City concept based on information and communication technologies on the grounds of the analysis of research documents indexed by the Scopus and Web of Science

platforms published in 2008-2020. The study analyzes various bibliometric patterns: publication, citation and occurrence of keywords, and visualizes the basic bibliometric aspects of research conducted in this field.

Despite many scientific studies on the Smart City area, most of them focus only on presenting a certain perspective and description of phenomena. General bibliometric analysis enriched with research visualization is still rare. The author's visualization of collected data presented in this article shows areas related to current scientific research in the field of smart city, which may help future researchers and practitioners to define new frameworks and assumptions for the evolution of Smart City concepts.

The aim of the article is to present the author's visualization of the use of ICT in the Smart City concept based on a review of scientific articles using an advanced analysis of the interdependence of identified research areas in the field of Smart City. The analysis will allow to determine the strength of the correlation between the variables and their directions and scenarios for future research.

Problem Description

The basic factor for the development of the Smart City concept is the permanent increase in the importance of the ICT information and communication infrastructure in all urbanization processes of cities (Lombardi et al. 2012, pp. 137-149). Information and communication technologies play a key role in the development of an agglomeration, at the same time determining the increase in the importance of social capital, ecology and progress in the area of education of city dwellers (Komninos 2019; Caragliu 2019; Romanelli 2020).

This constantly developing area of research on modern ICT solutions contributes to the growing interest in it both in literature and in business practice. In the scientific literature, you can find many definitions of the concept of smart city, as well as many characteristics that describe this phenomenon (Komninos 2002; Mayring 2003, Yap et al. 2010; Dawe et al. 2016; Peprah et al. 2019; Dinh et al. 2020). Summarizing the considerations covering most of the approaches, it can be assumed that smart cities mean integrating, through ICT solutions, such areas of city functioning as: economy, environment and infrastructure.

According to Zanella (Zanella et al, 2014) can be said that it is "effective use of public resources, improving the quality of services offered to citizens, while reducing operational costs of administration, achieved through the deployment of the urban Internet of Things, i.e. Communication infrastructure that provides unified, simple and cost-effective access to a large number of public services, thereby triggering potential synergies and increasing transparency for citizens." Yigitcanlar (Yigitcanlar et al, 2019) indicate that smart city: improving economic and administrative decision making through technological innovation; improving social inclusion in the development and adaptation of the emerging technologies; raising the profile of high-tech industries in contributing to the economic growth; effective embedding of technology in wider physical and social systems the smart city model has been promoted as an ample instrument to manage aforementioned urban and environment al challenges.

The evolution of the definition of Smart City over the years has led to the emergence of new areas of this concept. From the four areas described by Komninos (Komninos 2002; Sharifi 2020), another two were created, described by Novotný, Kuchta, Kadlec (Novotný et al, 2014). It can therefore be seen that cities develop extensively. Scaling basic services to meet increasing demand and is a challenge for cities. A smart city that combines its physical infrastructure, social system and economic framework with information systems (ICT) to increase the overall efficiency of operations can be seen as a single approach. Increasing operational efficiency can be achieved by making better operational choices, combining good management analyzes through continuous modeling of phenomena and processes.

The current lack of a scientific approach to the development and transformation of the new Smart City concept (taking into account the current economic condition of cities) contributes to stagnation in the area of development of new innovations improving the quality of life of city residents. The model of the Smart City concept, updated and enriched with a review of new ICT tools, would enable research cooperation between countries (regions), organizations and authors based on a series of collaborative analyzes. Synthetically collected data, such as the number of research centers dealing with a selected topic, the country in which the research is conducted, or the number of publications from given research centers, will contribute to the expansion of groundbreaking information for researchers and practitioners from research communities related to smart cities.

Methodology

In order to achieve new research goals and the presented assumptions, a detailed identification of the main trends in the scientific literature characterizing the use of ICT tools in research on the Smart City concept was made on the basis of bibliometric analysis of articles published on the web using the Scopus and Web of Science databases. The research period is set for the years 2008-2020. The authors used VOSviewer and CitNetExplorer software to perform bibliometric analysis and then to visualize research trends regarding the current level of use of ICT tools in order to further develop the Smart City concept.

The result of extensive analysis of scientific articles is the development of the existing theory and the resulting new view, becoming the beginning of a new, current method of managing innovative cities.

Literature review is a widely used and accepted approach to research as well as a necessary step towards structuring the research area and an integral part of any research conducted (Mentzer & Kahn, 1995; Easterby-Smith et al. 2002), both quantified in terms of management and logistics. Taking into account the considerations of J. Meredith (Meredith 1993), it should be emphasized that there are seven types of conceptual methods that are grouped into three categories: conceptual models (consisting of: conceptual description, taxonomy and typology, philosophical conceptualization); conceptual framework (conceptual induction, conceptual deduction, conceptual system) and theories (meta-frames).

State of the Art

A detailed analysis of the scientific literature allows to observe the multifaceted development of smart cities, the functioning of which is based on sustainable development with the use of ICT. The Smart City concept is defined as: smart cities, cities based on innovative knowledge, Smart City and City Logistics or a digital city or a cognitive city (Peprah et al. 2019). The interest of scientists representing various fields of knowledge and science shows that it is difficult to identify and adopt a clear and universal definition of a smart city. Smart city practitioners and researchers approach the concept differently due to their main orientation and research lines, e.g. technology, economy, society, environment and management (Yigitcanlar 2017; Lom 2020).

The Smart City concept is an innovative idea whose goal is to manage the city as and its resources in an ecological, modern, economical and effective manner. Contemporary urban areas are constantly developing their own innovative technologies, primarily information and communication technologies (Kumar et al. 2020). These changes are aimed at improving the functionality of cities together with the improvement of all intra-structural processes. To exploit their potential, it is necessary to symbiate modern technical solutions with the existing and modernized infrastructure. Thanks to that every city that is "smart" will be a progressive place that cares for improving the comfort of life of its residents without degrading the natural environment.

The authors, taking into account the evolutionary nature of smart city levels in the concept, proposed new stages of advancement, taking into account the current level of urbanization of cities, as shown in Figure 1.

Fig. 1: The development pyramid of the Smart City concept based on the management of ICT technologies

Source: own elaboration.

The evolutionary nature of the Smart City concept proves that cities are constantly evolving and expanding the scope of their operation. Globalization processes and highly developed urbanization require scientists and practitioners in this area to make constant measurements, research and analyzes in order to model the city system in the most accurate way, increasing the quality of life of the inhabitants.

Attempts to define and characterize the concept of Smart City along with the evolutionary nature of this phenomenon show how many disciplines are interested in addressing this topic. However, research on the Smart City concept and its components lacks a synthetic definition of the directions of scientific research supported by practical ICT solutions. To this end, the authors conducted a detailed, structured review of scientific articles to provide synthetic insight into the characteristics of current smart city research.

Data collection and Limitations

One of the most difficult decisions when using content analysis is choosing the right documents (papers). Searching for and analyzing data is quite complicated, and one of the problems is new content and articles appearing almost daily. The authors decided to use the Scopus and Web of Science databases. In the first stage, which concerned only the classification of relevant documents, the analysis was limited to: article titles, keywords and abstracts. For further analysis (including the creation of a taxonomy), the entire content of the articles was analyzed in order to indicate the multiplicity of definitions, including the area scope of the smart city concept as well as the categories and elements included in the concepts described, including the areas of research on innovative ICT technologies.

In the first phase of the research, a comprehensive approach to analysis was adopted, including publications and the latest research results in the field of "smart city" and "ICT management" in the years 2008-2020. In the course of research it turned out that the databases (Web of Science and Scopus) contain very large amounts of publications.

Therefore, the authors decided to conduct several stages of research in order to eliminate documents according to predetermined criteria. The first step and stage of the research was to identify documents from the above-mentioned databases. In the first stage, the concept of "smart city" and the scope of 2008-2020 were taken into account. Over 5,000 documents appeared in both databases. Therefore, the authors decided to go to the second stage and limit the search. The search was limited to an "article" only, so, for example, conference papers or a book chapter were deleted. Nevertheless, the number of items exceeded 1500 documents, so the authors moved to the third stage, in which the categories / topics were limited. The focus was on aspects of economics, business, social sciences, computer science, engineering and urban planning. This means that publications in the field of chemistry, library science and architecture were rejected. However, the number of publications was still very large, therefore further stages of research were carried out, introducing further restrictions. As it was recognized that there was a link between the exact (technical), humanities, arts and social sciences in a given topic, it was decided to deepen the analysis.

This time the focus was exclusively on the field of social sciences and limited to related issues. In this way, it was decided to focus only on the area of social sciences, limiting ourselves to issues related to: economics, business and management, thus rejecting the field of technical sciences (from this point of view, the authors would like to indicate the interest and research on the smart city in the context of business and management). A total of 430 articles were fully scanned on the basis of this selection. The full analysis allowed for the elimination of repeated publications in both databases and those that did not fully reflect the issues related to a smart city in the field of social sciences. As a result, 377 publications were submitted for further analysis, which were reviewed and based on them, analyzes were made that allow to draw conclusions and indicate limitations related to the concept and essence of smart city in the field of social sciences, with particular emphasis on the management of ICT technologies in smart city research.

Table 1: Number of publications in the "management of ICT technologies in a smart city" area of social sciences (economics and management) in 2008-2020.

NUMBER OF PUBLICATIONS BY YEAR		
YEAR	**SCOPUS**	**WEB OF SCIENCE**
2008	0	1
2009	0	0
2010	0	2

2019	61	40
2020	12	9
Total	195	182

Source: own elaboration.

Content analysis may also take into account the country of origin and the affiliation of authors who conduct research in the field of ICT technology management in terms of the Smart City concept. This is an interesting analysis that shows that both Scopus and the Social Science Web of Science are mostly published by Italian authors, followed by UK and US authors. Europe and the USA dominate the top 10 affiliations. Authors from India are 5th in the Web of Science database, and Chinese are 7th in both databases. This may indicate that social, economic, technical and technological aspects dominate in highly developed countries. The concept is also highly advanced due to the extensive infrastructure. The presence and interest of authors from China and India may also

indicate that the subject matter is beginning to gain popularity in these countries as well, which is probably related not only to the theoretical aspect of the concept, but also to practical solutions that need to be scientifically substantiated.

Table 2: Scientific articles in Scopus and Web of Science databases by the author's related entity (country)

THE LARGEST NUMBER OF ARTICLES IN SCOPUS AND WEB OF SCIENCE DATABASES BY AFFILIATE (COUNTRY) OF THE AUTHOR				
No.	**Scopus**	**Number of authors**	**Web of science**	**Number of authors**

Source: own elaboration.

While analyzing the most popular journals, it can be pointed out that the authors most often publish in Cities, Technological Forecasting and Social Change (which can be found in both databases), Advances in 21st Centures Human Settlements, Journal of Cleaner Production, Smart Economy in Smart Cities.

Table 3: Source title (10 most popular) - in the field of economy, business, management

SCOPUS	WEB OF SCIENCE
number of publications >10	
cities(31)	technological forecasting and social change (34)
technological forecasting and social change (30)	advances in 21st century human settlements (29)
journal of cleaner production (13)	smart economy in smart cities (29)
number of publications (from 3 to 9)	
• INTERNATIONAL JOURNAL OF SERVICES TECHNOLOGY AND MANAGEMENT • JOURNAL OF SCIENCE AND TECHNOLOGY POLICY MANAGEMENT • KNOWLEDGE MANAGEMENT AND E- LEARNING • JOURNAL OF THEORETICAL AND APPLIED ELECTRONIC COMMERCE RESEARCH • PRODUCTION PLANNING AND CONTROL • BUSINESS HORIZONS • INNOVATION	• SOCIAL SCIENCE COMPUTER REVIEW • TECHNOLOGY INNOVATION MANAGEMENT REVIEW • CAMBRIDGE JOURNAL OF REGIONS ECONOMY AND SOCIETY • SMART CITIES ATLAS WESTERN AND EASTERN INTELLIGENT COMMUNITIES • SPRINGER TRACTS IN CIVIL ENGINEERING • ENERGY POLICY • JOURNAL OF SCIENCE AND TECHNOLOGY POLICY MANAGEMENT • PROGRESS IN IS • SMART CITY IMPLEMENTATION CREATING ECONOMIC AND PUBLIC VALUE IN INNOVATIVE URBAN SYSTEMS • IEEE SYSTEMS JOURNAL • INTERNATIONAL JOURNAL OF SERVICES TECHNOLOGY AND MANAGEMENT • PRODUCTION PLANNING CONTROL • PUBLIC ADMINISTRATION AND INFORMATION TECHNOLOGY • UNDERSTANDING SMART CITIES A TOOL FOR SMART GOVERNMENT OR AN INDUSTRIAL TRICK

Source: own elaboration.

The publications selected and presented relate to a limited selection only. Other journals (e.g. Sustainable City and Society) are also very popular among scientists, but the analysis of titles and keywords eliminates them from the analysis, because the most frequently analyzed areas are: the use of multi-criteria methods, smart energy grids, smart city, mechanisms of transformation, aspect of financing development smart city, privacy protection through multidimensional data, hybrid approaches using the BWM method, cybersecurity, urban climate justice, smart city forest, ITS, the ZEB principle in creating smart cities, inference and analysis of big data, itinerant healthcare, mobile processing in cloud, COVERS-UP, optimization of solid waste collection using GIS, ECG, ANP and DEMATEL biometrics.

Keywords are interesting to analyze (in the field of economics, business, management). The most popular (in both databases) are: smart city, smart cities, innovations and urban planning. Interesting for analysis (in the field of economy, business, management) are keywords. The most common (in both databases) are: smart city, smart cities, innovation and urban development.

Other keywords are largely related to modern technologies, the concept of sustainability and the research method chosen: case study. Further analysis was performed using VOSViewer software (version 1.6.11). The article contains a taxonomy in the field of smart city that has not been present in the world of science so far.

Fig. 2: Map of connections related to the most common words in publications in the field of smart city and ICT

Source: own elaboration (with the use of VOSViewer software).

On the map shown in Figure 2 (limitations of 7000 events (words), repeated at least 5 times 185, limitation to 60%, 112 records), the most frequently used words in smart city publications are the most frequently mentioned words such as: department, approach, city concept.

Figure 3 shows a map of connections related to geographical areas from which the authors of scientific publications on Smart City come from, including ICT solutions. The map shows the collaboration of authors from different geographic areas. As part of the scientific cooperation, the authors of scientific publications in the field of smart city provide the following links: scientists from Singapore cooperate with scientists from India and Hong Kong. Additionally, Hong Kong is establishing cooperation with South Korea, the United States, Brazil and Europe.

Research centers from Poland, the Netherlands, Finland, Austria, Spain, Belgium, Italy, France and Great Britain cooperate in Europe. A separate research center is Japan, whose representatives cooperate with Great Britain and Brazil.

Fig. 3: A map of links related to geographical areas from which authors of scientific publications on Smart City originate

Source: own elaboration (with the use of VOSViewer software).

Another area of bibliometric analysis using the VOSViewer tool concerns the most common keywords related to a smart city and ICT technology - Figure 4.

Fig. 4: Map of the most common keywords characterizing publications related to smart city

Source: own elaboration (with the use of VOSViewer software).

Figure 4 (limitation of 18374 events (words), repeated at least 10 times 615, limitation to 60%, 982 records), shows that the most frequently repeated keywords are smart city and smart cities, followed (with fewer repetitions) by cities, city, big data, Internet, IoT, networks, systems, model, sustainability, smart grid and innovation.

Next analysis is the map of connections related to the most frequent areas of searching for readers of publications in the field of smart city and ICT.

Fig. 5: Map of connections related to the most frequent areas of searching for readers of publications in the field of smart city and ICT.

Source: own elaboration (with the use of VOSViewer software).

When interpreting Figure 5 (limitation of 1014 events (words), repeated at least 5 times 102, limitation to 60%, 98 records), it should be pointed out that the search areas for readers include smart city as the most common word and words such as development, innovation, technology or city and abstract.

Conclusions

Undoubtedly, the application of new technologies (ICT) is a challenge for cities, but also an opportunity for further development. Modern cities using the smart city concept are becoming increasingly competitive and at the same time more sustainable. The analysis may be the first step towards further research, including the creation of dedicated indicators and measures of functioning and evaluation of smart cities.

The article reviews scientific literature in the area of Smart City with regard to the management of ICT technologies. The publications from the Scopus and Web of Science databases on smart cities from 2008 to 2020 were analyzed in detail.

Over the last 12 years, the subject of the smart city has become an area of intense research by many scientists, the most noticeable of which is the rapid increase in the number of publications since 2010.
A reduced number of publications is seen in 2020. This fact is mainly due to the pandemic situation related to the COVID-19 virus.

The presented analyzes show leading research centers dealing with Smart City and ICT issues, which include, in particular, Italian research centers.

Through the scientific analysis of the cooperation of countries (regions), VOSViewer divided the 25 analyzed countries (regions) into 6 closely related research camps, led respectively by the United States, China, England, Spain, Italy and Australia. They also collaborated on smart cities research - both in author's and national cooperation, the USA and China were in the top two, but the two main countries in smart city research had a different approach to the intellectual environment, and China. he had a more cooperative attitude. In fact, China is one of the new research centers in the world. High-intensity co-authorship countries / regions have a strong co-authoring regime.

Based on the analysis of the network with keywords, the main research areas in the field of smart cities can be distinguished: smart growth; telecommunications and IT; a smart strategy for sustainable development; innovation and technology.

Although research on the concept of Smart City and ICT has been going on for years, bibliometric analysis is still one of the few sources that allows for a broad view of the issues undertaken by scientists, as well as for getting to know the directions of development of a given issue. As the analyzes show, the Smart City area is constantly evolving and requires further research on their development.

Abstract

Micro entrepreneurs contribute significantly to economic growth, and poverty eradication through self-employment, and job creation. However, micro-entrepreneurs are believed to wrestle with effective financial recording and planning. In the absence of proper bookkeeping, business analysis, and hence future growth planning are difficult. This exploratory study draws on the Social Entrepreneurship Book Keeping Program initiated by the Faculty of Accountancy, Universiti Teknologi MARA Cawangan Selangor, in 2018. This study examines whether the micro-entrepreneurs at *Pasar Tani* maintain a proper record of their business transactions, and if not, what are the reasons for not doing so. Using a purposive sampling design involving sixteen micro-entrepreneurs, this study finds a striking result that half of them did not record their business transactions at all. The other half recorded their transactions but to a very limited extent. Furthermore, most of them had no accounting background and were not aware of the importance of bookkeeping for their business growth. Interestingly, 62.5% of the micro-entrepreneurs indicated that they were keen to learn more about accounting even though only 37.5% of them claimed that such a learning opportunity exists. Together, the findings of this study suggest that more accounting short courses and training programs should be organized and promoted to assist the micro-entrepreneurs with their financial recording and planning.

Keywords*:* Bookkeeping, Financial Records, Accounting, Micro-entrepreneurs

Introduction

Bookkeeping is part of the accounting process, which entails recording and reporting the financial transactions or economic events of a business. Extant literature on bookkeeping practices among micro-entrepreneurs documents mixed evidence. However, the definition of a micro-entrepreneur 'depends on the purpose to which it is to be put so that different aspects of smallness may therefore be more appropriate for some purposes than for others' (Haynes, 1992, p. 39). The SME Corporation defines micro-entrepreneurs as firms with annual sales of less than RM300,000 or employees of less than 5 (SME Corporation, 2020).

The main contribution of this study is that it focuses on the micro-entrepreneurs in the smaller annual sales brackets between RM40,000-60,000. To date, empirical evidence on this smaller group of micro-entrepreneurs is scarce. These businesses are interesting to study as they have a simple business model with a single sales source and very few cost items. This simplicity potentially further discourages the entrepreneurs from recording their business transactions

Cite this Article as: Halim Shuhaimi YEOP JOHARI, Cedrena NADINE and Seri Ayu Masuri MD DAUD "An Exploratory Study on the Bookkeeping Practices among Pasar Tani Micro-Entrepreneurs" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

thinking that it is not necessary. Furthermore, most of these businesses are financed by the owner's personal savings. The absence of pressure from fund providers may further disincentivize them from having proper bookkeeping.

Arguably, a proper accounting system is critical for the decision-making process even for small-scale business entrepreneurs (Hatteu, 2012; Umeji & Obi, 2014). For example, business transaction records are required for an accurate break-even or profit margin analysis (Chepkemoi, 2013). According to Germain (2009), one of the causes of business catastrophe and bankruptcy within the few months of operation was the failure to embrace the practice of proper recording of business financial transactions or bookkeeping.

This study draws on the Social Entrepreneurship Book Keeping Program initiated by the Faculty of Accountancy, Universiti Teknologi MARA Cawangan Selangor, in 2018. This program was intended to assist micro-entrepreneurs at *Pasar Tani* to record their business transactions in accordance with the established accounting principles. The program involved 96 first year degree students majoring in Accountancy, 30 supervising lecturers, and 16 micro-entrepreneurs. The students were assigned as Junior Consultants to help the micro-entrepreneurs record their business transactions in a cashbook. While doing so, the students were given the opportunity to conduct a survey and interview the micro-entrepreneurs to find out more about their business and bookkeeping practices. At the end of the project, the students presented their findings to the lecturers verbally and in writing. Their presentations and written works were then graded accordingly.

Using the students' written reports, we attempt to address the following research question: Do the *Pasar Tani* micro-entrepreneurs maintain a proper record of their business transactions, and if not, what are the reasons for not doing so? The remainder of this paper is organized as follows. Section 2 reviews the extant literature on bookkeeping among micro-entrepreneurs. Section 3 presents the research method, followed by results and discussion in Section 4. Finally, Section 5 concludes.

Literature Review

The extant literature has established that failures of micro-enterprises exhibit a homogenous process including lagged response towards issues at hand and hence delayed or even incompetent rectifications (Ropega, 2011). While these factors may lead to business failure over time, a failure to embrace proper bookkeeping is suggested to cause a more immediate catastrophe within as short as several months (Germain, 2009).

Lussier (1995) develops a model to predict the success or failure of small businesses using 16 quantitative and qualitative managerial factors. This model has been tested across industries and nations with its prediction accuracy above 50%. Lussier's model has also been tested for a sample of micro-entrepreneurs with 0-10 employees (Lussier & Corman, 1996). This well-tested model includes bookkeeping and financial control as one of the predictors. As decision making depends heavily on the maintained business records, the absence of proper bookkeeping potentially translate into poor decision making (Duli, 2019).

Despite the established importance of proper bookkeeping, empirical evidence suggests the level of its implementation among micro-entrepreneurs is still low. This is particularly evident in developing countries including Nigeria (Umeji, 2014), and the Philippines (Duli, 2019; Yap, 2019). Even in countries where micro-entrepreneurs practice bookkeeping pervasively such as South Africa, it is mostly done manually and without completing the bookkeeping cycle (Nyathi & Benedict, 2017).

An important deterrence of the bookkeeping practice among micro-entrepreneurs is potentially their lack of bookkeeping skills and awareness of the bookkeeping importance. A survey by Umeji (2014) documents that record-keeping was one of the skills perceived to be very important by the micro-entrepreneurs in Nigeria, but the levels of possession were still below expectations.

Research Method

This cross-sectional study was carried out in a non-contrived setting with little interference from the researcher. That is, the researcher had direct contact with the subject of study (the micro-entrepreneurs), however, the normal flow of work among the subjects was not significantly disrupted.

The data of this study is sourced mainly from the written reports submitted by the Accounting undergraduate students involved in the Social Entrepreneurship Book Keeping Program. The sample of this study is sixteen conveniently

selected micro-entrepreneurs of *Pasar Tani* who were involved in the Social Entrepreneurship Book Keeping Program. This program was organized by the Faculty of Accountancy, Universiti Teknologi MARA Cawangan Selangor, Puncak Alam Campus as one of its entrepreneurship and community engagement activities. This program was carried out at a *Pasar Tani* in Saujana Utama, Puncak Alam in the following four phases: 1) 29 September 2018, 2) 3 October 2020, 3) 5-16 October 2018, and 4) 17 October 2018.

In the first phase, 96 students and accompanying lecturers visited the *Pasar Tani*. They then distributed the survey questionnaire to sixteen randomly selected entrepreneurs who received complimentary consultancy services from the students and lecturers. Working in a group of 6, the students then conducted follow-up interviews with the micro-entrepreneurs to collect richer information needed for their reports in the second phase. Both survey questionnaires and interview protocols were reviewed by lecturers supervising the project. The final survey questionnaire and interview protocols were standardized for all student groups. Next, in the third phase, students transcribed their interviews and analyzed the collected data from both the survey and interview. Then, the final reports were prepared following a standard format outlined by the supervising lecturers. In the final phase, students presented their findings before the micro-entrepreneurs and supervising lecturers. Each group of students also handed in their written reports to their supervisors. Survey responses and interview transcriptions were also attached to the final reports.

Results and Discussion

Current Practice of Recording Business Transactions

Figure 1 presents the results of the survey and a structured interview with the *Pasar Tani* micro-entrepreneurs.

Fig. 1: Number of entrepreneurs that record their business transactions, have the opportunity to learn accounting, and have an interest in obtaining accounting assistance.

As indicated in Figure 1, half of the interviewed entrepreneurs recorded their business transactions, while the remaining half did not record anything at all. It is important to note that those micro-entrepreneurs that recorded their business transactions did it to a very limited extent. For example, one of the micro-entrepreneurs recorded only the cash outflow. That is, none of the interviewed micro-entrepreneurs maintained proper bookkeeping.

In terms of the opportunity to learn accounting, only 6 (38%) of the micro-entrepreneurs reported that they had such an opportunity. Interestingly, 10 (62%) of the surveyed micro-entrepreneurs stated that they were interested to attend accounting training or workshops should such an opportunity exists. These findings suggest that majority of the micro-entrepreneurs did not have bookkeeping knowledge or even the opportunity to learn that knowledge.

Reasons for Not Recording Business Transactions

Several common reasons for not recording their business transactions were reported by the interviewed micro-entrepreneurs. The reasons include time and labor constraint, lack of bookkeeping knowledge, lack of discipline, lack of trust in employees, and the perception that bookkeeping is not important and costly. All of the sample entrepreneurs mentioned a combination of a few of these reasons. Figure 2 depicts the number of entrepreneurs that pointed out each of those reasons.

Fig. 2: Reasons for not recording business transactions among *Pasar Tani* micro-entrepreneurs

Figure 2 reveals that 15 (93.75%) of the interviewees associated the absence of proper business transaction records with their lack of bookkeeping knowledge. 11 (68.75%) of them faced time constraint while 9 (56.25%) believed that bookkeeping is not important leading them to resort in not practicing bookkeeping.

Together, an important implication of the above findings is that more bookkeeping and accounting training opportunities should be made available to *Pasar Tani* entrepreneurs if bookkeeping practice is to be improved among them. Furthermore, the findings of this study bear out the conjecture that 'continued policy support for new business start-up micro-enterprises must be based on a stronger training element' (Smallbone, 1990, p. 44).

Conclusion

The importance of proper bookkeeping has been well established including its bankruptcy-inducing effect. However, a large number of micro-entrepreneurs are still not keen to maintain a proper business recording. The findings of this study extend our understanding of this issue by documenting that a lack of bookkeeping knowledge is another major hindrance to proper bookkeeping among micro-entrepreneurs. This low level of knowledge potentially leads to a lack of awareness of the importance of bookkeeping.

In addition, a simple business model, and the absence of pressure from external fund providers are the disincentives to a proper recording system. Many micro-entrepreneurs believe they could manage just fine without the records. An interesting area for future research would be to analyze the costs and benefits of proper bookkeeping to micro-entrepreneurs particularly to those in the smaller sales threshold. Given a simple business model and the absence of agency problem, it would be interesting to delve into the net benefits of a proper financial recording.

Notes

Pasar Tani is a form of marketplace in Malaysia established in 1985 by the Federal Agricultural Marketing Authority (FAMA). The business concept of *Pasar Tani* is to provide a niche market for the micro entrepreneurs who are mainly farmers or producers to market their products directly to consumers.

Lussier's Model has been tested across industries including retail (Lussier, 1996a), services (Lussier, 1996b), and real estate (Lussier, 2005). This model has also been tested across nations such as Central Eastern Europe (Lussier & Pfeifer, 2001), Chile (Lussier & Halabi, 2010), Israel (Marom & Lussier, 2014), Pakistan (Hyder & Lussier, 2016), and Ghana (Gyimah, Appiah & Lussier, 2020).

Abstract

Marketing is one of the areas most affected by Artificial Intelligence (AI), Building from extant research and recent developments related to the field of Artificial Intelligence, the authors offer specific answers that can lead to a better understanding especially since AI is not as easy to understand as it seems and that a good number of marketers think that AI would be beneficial to them in their work. However, the fear is felt about what it will generate once installed. We demonstrate based on Artificial intelligence replacement theory that in marketing the type of human work and the tasks play an essential role.

Keywords: Artificial Intelligence, Marketing, AI Replacement Theory.

Introduction

We have been witnessing the rise of artificial intelligence (AI) in recent years and all sectors are directly or indirectly affected, in the future artificial intelligence is likely to substantially change at the same time customer behaviors and marketing strategies, including the way that firms market products and services to consumers (Dhruv Grewal et al, 2019). In the future artificial intelligence will affect also sales processes in various industries, and sales people will be assisted by an AI agent that monitors tele-conversations in real time (Davenport at al, 2019), in the same way, we can give the example of companies such as Netflix, Amazon and e-Bay that adopt intelligent agent technologies for recommendations, personalization and price-comparison engines to facilitate exchanges in the market place (Iacobucci et al., 2000). In analysis of more than 400 artificial intelligence use cases, 9 business functions across 19 industries, indicates that the greatest potential value of artificial intelligence pertains to domains related to marketing and sales (Chui et al., 2018), and marketers intend to use artificial intelligence in multiple areas like personalization, segmentation, predictive behaviors related to customer and analytics linked to marketing strategy (Columbs 2019).

The role of the technological advances is becoming profound in our lives especially by influencing who our friends are, what we buy, who we hire also even how elderly and children are cared for (Arun Rai, 20191). In spite of being major source of innovation, artificial intelligence threatens human service jobs also (Ming Hui Huang, 2018). For example, researchers find that a significant percentage of the tasks in high- paying jobs, such as Physicians, senior managers and portfolio managers can be automated by using current technology (Chui et al., 2015).

In light of the above the aim of this paper is to provide a comprehensive understanding of How is artificial intelligence (AI) increasingly reshaping marketing by performing various tasks, constituting a major source of innovation? We focus on the following research questions that deal with conceptual and theoretical understanding, applications and artificial intelligence outcomes: First With the buzz surrounding artificial intelligence (AI), today's marketers can feel as much in a sea of opportunity as in a minefield plagued by productivity traps, the question we

Cite this Article as : Zineb JOUHARI, Younes LAFRAXO and Mohamed Larbi SIDMOU " A Conceptual Study : Marketing and Artificial Intelligence" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN : 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

have to answer is How Artificial Intelligence Is Transforming Marketing? Artificial intelligence (AI) generates many fantasies and fears, in particular because it makes it possible to empower certain tasks in an increased way, thus playing a major role in the mutations of work, the next question that we will have to answer is What is the impact of artificial intelligence on employment? Regarding the relationship between artificial intelligence and human intelligence is it integration or rather a replacement is it a "Human Replacement or Integration?" The objective of answering this question and knowing if artificial intelligence replaces us all, until the last; or, on the contrary, that it will only increase our capacities tenfold, constituting a breeding ground for unsuspected growth and productivity.

Introduction to Artificial Intelligence

Artificial intelligence (AI) is the simulation of human intelligence processes that allows computer systems to automatically learn from experience and perform human-like tasks to improve efficiency of daily tasks (Aghaei, Nematbakhsh, & Farsani, 2012).

Usage context or industry	Description
search engines (e.g., Google)	Google Assistant speech recognition AI uses deep learning to
	Understand spoken commands and environment. Questions
	Thanks to techniques developed by the Google Brain project by the
	Google. Google's translation tools now also comes under the Google
	Brain umbrella, and operates in deep learning.
Social media (e.g., Facebook)	Facebook is building a business with long-term prospects where the
	role of Facebook Artificial Intelligence is unfathomable.
	AI enables machines to learn to clarify data, all by themselves.
	The simplest example of this would be AI image analysis identifying
	dog, without telling that machine what a dog looks like.
Multinational enterprise (e.g., Apple)	Apple's investments in AI won't boost its near-term revenue growth,
	But they'll strengthen its hardware devices and tether more
	Users to its services ecosystem. That improvement should widen
	Apple's moat gives it an edge against Google's fragmented universe of
	Android devices.
Self-driving car Artificial intelligence will learn much faster than people, because	
	When a self driving car makes a mistake, all driving cars learn from
	it because of connectivity.

From the above we can say that the artificial intelligence have revolutionized approximately every aspect of human existence.

Artificial Intelligence and Marketing Transformation

Artificial intelligence is known for its sophisticated personalized recommendation systems, predictive analytic capabilities (Dhruv Grewel et al, 2019), which make it easier to contribute to consumer well-being, generally by making the choices more efficient, easier and more practical (Quentin André et al, 2017). The facilitation of the automation of some consumer needs does not make the Artificial intelligence a one-sided currency, because it could also undermine sense of autonomy which may be detrimental to consumer's well being. For example if you searched a platform video to watch a movie such as Netflix, Artificial Intelligence was no doubt integrated in your decision about what to watch which can be useful in terms of facilitating choices which will undoubtedly be based on previous choices of films or series, but which at the same time forces us to somehow make restricted choices as mentioned in the new documentary-drama from Jeff Orlowski, social media dilemma (2020) that explore the dangers of social networking through interviews with tech experts.

Marketing which is defined as the analysis of consumer needs and the set of means of action used by organizations to influence their behavior is not really valid with the presence of such systems. This is why marketers these days use sophisticated algorithms that sift through vast amounts of consumer data, for example, allow online marketers to deliver the right product or service, relieving consumers of not only research costs, but also unpleasant and difficult compromises, which the consumer often chooses entails (Quentin André et al, 2017).

Chatbots is an innovation that has also revolutionized the way marketers treat their consumers, the example of Jasper can perfectly answer the question of how. Jasper is a new AI application meant to act just like your best friend because it is programmed to ask meaningful multiple questions about your life so that it can offers you emotional support with no judgment (Fowler.G., 2019). This kind of technologies learns about human habits and interests over time, it could also adopt your linguistic sytanx in the way a very close friend might. All the capabilities that serve to better understand consumers can be used by marketing managers to offer them the best offer in an effective and efficient way.

Artificial Intelligence and Employment

according to the previous analyzes we could say that the question is no longer do we now need artificial intelligence for our organizations, contrariwise how our organization can incorporate AI in strategies in effective way(Davenport, 2018). Chui, Manyika, and Miremadi (2015) find that a significant percentage of the tasks performed by those in high-paying jobs, such as portfolio, physicians, senior managers and senior managers, can be automated by using current technology. Which mean that the jobs are replaced by AI and that the number of employees decreases? Based on AI Job replacement theory, The decision between using the AI or not should be taken at the task level, which means that an organization needs of task portfolio of a job is to optimize the division of labor between AI and workers, Firms must take into consideration several factors: Nature of tasks, nature of service, strategic emphasis of firms (Ming-Hui Huang et al, 2018).

Understanding the nature of service work, why and how AI may substitute or replace humans in each type of task is necessary to make the right choice. As the various AI technologies have matured for implementation today, managers need to have a clear understanding of the potential pitfalls, capabilities, and benefits in order to be able to map out a roadmap of artificial intelligence applications.

The observation that I A constitutes a source of innovation is increasingly replacing service jobs, motivates us to explore more rigorously and fully the way AI will reshape service and the following research may give importance to this exploding topic.

Abstract

The present research aims to analyze the national innovation systems in various European Member States in order to establish what could Romania do to develop a competitive Research & Development (R&D) system. The study is based on the European Innovation Scoreboard (EIS) which categorizes Romania as being a modest innovator, revealing the necessity of improving the situation of the Romanian R&D system. The main objective of the paper is to present a short history of the EU research programmes and the national innovation system of different European countries. The comparison will be made amongst countries situated on different positions in the EIS in order to reveal some treats of them enabling some good examples and streams for Romania, which occupies one of the latest positions. The research methodology consists of an exploratory study using secondary data analysis, collected from the European Union (EU), and The Organisation for Economic Co-operation and Development (OECD) official documents. In the first part, document analysis was conducted in order to present the situation regarding the research and innovation system in four European countries. The countries were selected according to the four categories mentioned in the European Innovation Scoreboard. One example for each category of countries (leader, strong, moderate, and modest innovators) was chosen for analysis. In the second part of the study, a comparative analysis among these countries, using statistical indicators was conducted to observe the differences between leaders, strong, moderate, and modest innovators. Finally, the study ends with a series of conclusions and recommendations for Romania. The study revealed the need for Romania to improve various aspects regarding its R&D system, such as: set up incentives to increase technological transfers between the public and private sectors, create business and research clusters according to the American 'Silicon Valley' model, create an attractive special tax status for the innovative start-ups or adopt a favorable tax regime for patents.

Keywords: Innovation, European Innovation Scoreboard, Romanian R&D System

Introduction

A short history of EU research and innovation policies

In 1958, the Community research was limited to only two specific energy fields since the research was not included as a competence area for the Community (European Parliament, 2017). The involvement of the European Union (EU) in research activities (outside the coal and nuclear fields) began in the 1970s with the adoption of the Council of the first Community research programmes. These were adopted one after the other, responding to the need for applied research in a specific area at an emerged European level. At the beginning of the 1980s, the European

Cite this Article as: Constantin M. PROFIROIU, Corina-Cristiana NASTACĂ and Ariana NĂSTĂSEANU "A Comparative Study of The National Innovation Systems in Various EU Countries – Possible Lessons for Romania" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Commission (EC) proposed a strategic tool to manage the technological applications at the Community level through the framework programme (FP) for research and development (European Parliament, 2017).

The first framework programme (FP1) was adopted in 1983 reflecting the principle of the subsidiarity that allowed the EU's intervention for the cases when the Member States could not tackle individually the challenges. The Single European Act (Official Journal of the European Union, 1986) introduced research as a Community competence in the Treaty establishing the European Economic Community and provided a firm legal basis for the adoption of the following FPs. FP2 and FP3 were adopted in 1987 and 1990 respectively with increased budgets. The Treaty of Maastricht (Official Journal of the European Union, 1992), which entered into force in 1993, modified the legal basis for the adoption of FPs, transforming them into financial tools for EU research activities. It also broadened the range of topics for which research programmes could be conducted by the EU. FP4 and FP5 adopted in 1994 and 1998 enlarged the scope of the FP and the focus on pre-competitive research was abandoned in favour of an approach that would see the FP addressing societal challenges and supporting a wider range of activities in the innovation process. The development of the European Research Area concept in 2000 marked a clear shift in the evolution of the FP.

Moreover, FP6 and FP7, adopted in 2002 and 2006 respectively, were designed to implement this EU research policy aiming at addressing the fragmentation of the European research landscape. The adoption of the Europe 2020 strategy and the Innovation Union flagship initiative in 2010 influenced the structure of Horizon 2020, which was adopted in 2013 (European Parliament, 2013).

As the FP evolved, the instruments used for its implementation diversified. The initial grants for transnational cooperative research projects were complemented, inter alia, by the development of agile public-public and public-private partnerships, the establishment of new structures, such as the European Research Council (ERC) and the European Institute for Innovation and Technology (EIT), specific instruments for Small and Medium-sized Enterprises (SMEs) support, and individual mobility grants for researchers. With Horizon 2020, the FP became a complex programme of programmes fostering the science transfer into economic and societal benefits. Therefore, in 2014, the FP of the EU built financial streams to support the innovation process and supported various EU policies. Complexity in the management and implementation of the FP brought about a new level of fragmentation at the EU level regarding the funding of innovation-related activities.

Measuring Research and Innovation Performance

Since the 1960s, OECD has initiated the first comparative analysis of science and technology policies. Since then, many scholars have manifested their interest in international comparisons (Nelson 1993, Freeman, 1995, Edquist, 1997, Laredo & Mustar, 2001, Lundvall, 2010).

Every 10 years, OECD engages the policy community, data users, and providers into an open dialogue to review and develop its long-term agenda on science, technology, and innovation (STI) data and indicators. This event, "OECD Blue Sky Forum" (OECD, 2020), represents an open and unconstrained discussion on evidence gaps in science and innovation and on initiatives the international community can take to address data needs in this area.

To compare innovation performance, the European Commission uses inter alia, the 'Indicator of Innovation Output', produced by the Joint Research Centre (JRC) (Vertesy & Damioli, 2020), which measures the extent to which ideas from innovative sectors are sold on the market, offering better jobs and increasing the competitiveness of Europe. The Research Excellence composite indicator developed by the JRC tries to measure the capacity of the national and European Research and Innovation (R&I) system to diffuse knowledge and technology as well as the role of structural change towards a more knowledge-intensive economy.

The EU's methodology applied for measuring the performance of national innovation systems is using 27 performance indicators, distinguishing between ten innovation dimensions in four main categories introduced the new European Innovation Scoreboard measurement framework. The objective of this regrouping is to better distinguish between framework conditions, investments in innovation, enterprises' innovation activities, and the impact of these activities. The second change brought since 2017 deep revised edition has intended to add one more dimension to better capture the environment in which enterprises operate.

According to the last analysis made by the European Commission (2020), Denmark, Finland, Luxembourg, the Netherlands, and Sweden are Innovation Leaders with innovation performance well above the EU average. Austria, Belgium, Estonia, France, Germany, Ireland, and Portugal are Strong Innovators with performance above or close to the EU average. The performance of Croatia, Cyprus, Czechia, Greece, Hungary, Italy, Latvia, Lithuania, Malta,

Poland, Slovakia, Slovenia, and Spain is below the EU average. These countries are Moderate Innovators. Bulgaria and Romania are Modest Innovators with performance well below the EU average (European Commission, 2020).

The European Innovation Scoreboard (European Commission, 2020) shows an improved overall innovation performance. For the EU as a whole, it increased by 8.9 percentage points between 2012 and 2019. Over the same period, the performance improved for 24 Member States, most notably for Lithuania, Malta, Latvia, Portugal, and Greece, where the innovation performance grew by more than 20 percentage points.

Comparing the EU's average to a selection of global competitors, the EU continues to have a performance lead over the United States, China, Brazil, Russia, South Africa, and India. South Korea is the most innovative country, performing 34% above the EU's performance score in 2019. Since 2012 South Korea, Australia, and Japan have increased their performance lead over the EU, while the gap between the EU and the United States, China, Brazil, Russia, and South Africa has become smaller.

International Cooperation in Research

The international cooperation research programme was commenced in 1983 when the European Commission launched a dedicated programme called the Science and Technology for Development (STD) Programme. It had three editions: STD1, 2, and 3, which ran in parallel with The Community's Research Framework Programmes (European Parliament, 2017).

In 1992, the Programme was integrated into the Fourth Research Framework Programme (1994-1998) as the International Cooperation Programme (INCO) and has, ever since, been an integral part of all Framework Programmes (European Parliament, 2017).

The Seventh Framework Programme (2007-2013) placed a new emphasis on international research cooperation, including mainstreaming international cooperation across the entire spectrum of FP7 activities. The Seventh Framework Programme also included strategic activities underpinning the building of a European Research Area open to the world that require a policy dialogue with major regions of the world and true partnership with those countries with which an S&T (Science & Technology) Cooperation agreement has been signed (European Parliament, 2017).

In Horizon 2020 (H2020), International Cooperation is a cross-cutting priority and not a separate activity; also, part of Societal Challenge 6 focuses on specific international cooperation policy support activities. Horizon 2020 is fully open to the world, allowing researchers from all over the globe to take part in projects. Furthermore, many calls particularly encourage the participation of organizations from specific partner countries that are not EU Member States or associated with the framework programme (European Parliament, 2017).

Countries such as China, Brazil, Russia, India, and other economies that have grown strongly over the past years will continue to be important partners for the EU. This is reflected in the fact that all these countries will still be able to participate in all parts of Horizon 2020, allowing their researchers to cooperate with their counterparts in the EU on topics of their choice.

Some of these countries, and in particular those where the Gross Domestic Product (GDP) is exceptionally large, will, however, no longer enjoy automatic access to EU funding, even if the country in question is classified as middle-income by the World Bank. This reflects the fact that over the past years, these countries made considerable efforts to invest in their research and innovation systems and strengthen their qualities. These countries are therefore now capable to cooperate with the EU based on a partnership among equals. The new strategy foresees to complement this change in the approach to automatic funding by increased efforts to facilitate the funding of participants from these countries through their national channels.

Research Methodology

The present research aims to analyse the national innovation systems in various European Member States in order to establish what could Romania do to develop a competitive Research and Development system.

The basis of the study is the European Innovation Scoreboard which categorizes Romania as being a modest innovator.

The main objective of the paper is to present a short history of the EU research programmes and of the national innovation systems in different European countries. The comparison will be made amongst countries situated on different positions in the European Innovation Scoreboard with the purpose of revealing some treats of them enabling some good examples and streams for Romania which occupies one of the last positions.

The study proposes three research questions:

1. Which is the situation regarding research and innovation among the Member States?
2. What have the other Member States done in order to become innovative leaders and strong innovators?
3. Which are the lessons for Romania to improve its position in the European Innovation Scoreboard?

The research methodology consists of an exploratory study using secondary data analysis, collected from the EU and OECD's official documents. The study is based on qualitative research methods. In the first part, a document analysis was conducted to present the situation regarding the research and innovation systems from four European countries. The countries were selected according to the four categories mentioned in the European Innovation Scoreboard. One example for each category of countries (leader, strong, moderate, and modest innovators) was chosen for the analysis.

In the second part of the study, a comparative analysis between these countries, using statistical indicators was conducted to observe the differences among leaders, strong, moderate, and modest innovators. Finally, the study ends with a series of conclusions and recommendations for Romania.

One Example for Each Category: Leader, Strong, Moderate, and Modest Innovators.

In the next part of the study, the situation concerning the research and innovation systems in various European countries will be presented. According to the four categories mentioned in the European Innovation Scoreboard, namely leader, strong, moderate, and modest innovators, one example for each category of countries was chosen for analysis.

Sweden

Sweden represents a success story for a seamless determination to shift the historical paradigm. A century ago, Sweden was among the poorest countries of Europe but in a couple of years, it has consolidated its position as an European leader in innovation. The latest innovation scoreboard supports this statement. Sweden is one of Europe's top three spenders in the research and innovation area, investing 3.6% of its GDP in R&D in 2003. Analysing data since 2003 and comparing it with the EU-wide target of 3% GDP allocation to R&D by 2020, there is a first success factor for the top position occupied by this country (World Bank, 2019).

Each year, Harvard Business School compiles the National Innovation Capacity Index, a study of different countries' innovation potential. In 2010, Sweden was ranked eighth among 173 countries. In terms of trained engineers per capita, Sweden ranked second, close behind Japan. The study also notes that in the past 15 years, Sweden has had the second-fastest growth rate in the number of patents per capita (Porter & Stern, 2010).

A new system for the allocation and redistribution of the appropriations for research and postgraduate education to the higher education area was introduced in Sweden in 2009. The model aims to reward quality in research and give higher education institutions to manage the incentives to take measures and increase the quality and relevance of the research undertaken at their institutions. This is done by allocating parts of the research appropriations based on two indicators: publications/citations, and external funding of research (Joint Research Center, 2017).

This new system also gives incentives to the universities to cooperate with the private sector as the more external R&D funds they receive from i.e. the Swedish firms, the more they receive from the state through the redistribution of appropriations. The impacts are visible: as a result of the new system introduction, external funding from foreign firms to Swedish universities, which has been more or less constant up to 2008, has started to grow steadily. The proportion of public funding, that was annually redistributed along with the new model, was initially 10% and has increased to 20% from 2014 onwards (Jonkers & Zacharewicz, 2017).

The competitive funding model spurs competition between universities since better performers will receive more basic funding than others, which promotes a more strategic approach to the specified quality and efficiency criteria. The model can be implemented without necessarily increasing the total funding, and does not need to result in major shifts in the basic funding, since all universities tend to increase their performance and efficiency.

At present Sweden investigates possible future developments of the resource allocation system, which may include peer/expert review, as well as performance/output with the surrounding society.

In 2019, Sweden had the second-highest share in the EU of Human Resources in Science and Technology (HRST) of the total active population (60.7%). The distribution of total HRST full time employed by sector of performance was 29% in business, 35% in government, and 36% in Higher Education Institutions (HEI) in 2014. The share of female researchers was also above the EU average (45.7 vs. 41% in 2014) (Eurostat, 2020).

According to Doing Business 2020 (World Bank, 2019), Sweden is situated in the 10th position and second among EU Member State, reflecting the competitiveness of its economy.

In terms of participation in H2020, Sweden's success rate is higher than the EU average, 14.77% compared to 12.02%. The net EU contribution to the Swedish organizations amounts to 1.94 billion Euro (8th position of 28 EU states) out of which 291 MEUR (Million Euros) represents the contribution to the innovative SMEs.

In Sweden, two of the most worldwide well-known innovations were created: Spotify, an online music service that lets users stream millions of tracks on demand to their computer or mobile device. It offers a monthly subscription service or a free version supported by advertising. Founded in 2006 by two Swedish entrepreneurs Daniel Ek and Martin Lorentzon, the company is now multinational. The second one, Skype (the online phone system free of charge) was founded in 2003 by two entrepreneurs, Niklas Zennström from Sweden and Janus Friis from Denmark. Skype was acquired by eBay in 2005 and sold to Microsoft in 2011.

France

France has put efforts into boosting its innovation capacity since early 2000. In 2005, it created clusters ('pole de competitivite') to foster collaboration between the universities, start-ups, SMEs, and research organizations. The R&D subsidies were designed as an appropriate policy tool for stimulating private investment in R&D (Fu et al. 2012; Meuleman & De Maeseneire, 2012).

French R&D investment as a share of GDP is below the 3% target for 2020. Total R&D intensity remained stable in 2018 at 2.20% GDP, above the EU average of 2.12%. However, it decreased from 2015, when it stood at 2.25%. Public R&D spending for 2017 and 2018 (0.73% of GDP) was almost the same as in 2007. The business sector's R&D spending for 2017 and 2018 (1.44% GDP) was the same as in 2012 (European Commission, 2020).

An important characteristic of research in France that differs from almost all the other OECD member states is the central role played by the State in its financing- around 50% of all research and development expenses.

As mentioned by the same report, France remains the 16th most innovative country in the world according to the World Intellectual Property Organisation's Global Innovation Index. Also, it ranks 11th in the 2019 European Innovation Scoreboard and is positioned as a strong innovator behind the group of innovation leaders (European Commission, 2019).

In regards to the total patent cooperation treaty applications, France occupies the seventh position of the ranking led by Sweden (JRC, 2020).

According to Doing Business 2020 (World Bank, 2019), France is situated in the 32nd position, the second EU Member State, which reflects the competitiveness of its economy. Concerning the private funding of innovation, the French system includes most of the other mechanisms found in other advanced economies but their level of development and availability, especially regarding the availability of cheap capital for start-up's, often lacks behind what can be found in the national strategies of innovation of world leaders of innovation like the United States.

In order to incentivize the companies to stimulate more spending on research and development, France introduced in 2008 the R&D tax credit. Tax incentives give firms the freedom to choose their R&D projects without targeting a particular sector or technology and are, therefore well-suited to the complexity and multidisciplinary nature of innovation processes (Quemener, 2017).

As regards funding mechanisms for research and innovation in the economy, the role played by the "business angels" and venture capital is still insufficient. France is even below the average of the European Union for the availability of venture capital expressed as a percentage of GDP and that situation persists despite the creation of

the Fond National d'Amorçage (FNA/ National Fund for Start-up Companies), which represents only around 100 million euros of investment per year (Kornprobst & Douady, 2015).

In 2019, France modified a set of rules to make interactions between research labs and the private sector much more fluid (e.g. allowing a public researcher to spend 50% of his or her working time in a private company or to keep shares of a company he or she created) and launched an Innovation Council to foster breakthrough innovation.

In 2019, France had a higher share in the EU of Human Resources in Science and Technology of the total active population (53.4%) than the EU 28 states' average (48.5%). The distribution of total HRST full time employed by sector of performance was 29% in business, 35% in government and 36% in HEIs in 2014. The share of female researchers was above the EU average (45.7% vs. 41% in 2014) (Eurostat, 2020).

In terms of participation in H2020, France's success rate is higher than the EU average, 15.55% compared to 12.02%. The net EU contribution to the French organizations amounts to 6.37 billon Euro (3rd position of 28 EU) out of which 920 MEUR represents the contribution to the innovative SMEs.

Spain

Spain belongs to the Moderate Innovator Group. Low investment in R&D is holding back Spain's innovation performance. Total R&D expenditures declined from 1.35% of GDP in 2009 to 1.24% in 2018. Public R&D expenditure was cut during the crisis and the cuts have not been reversed. Public investment in R&D declined from 0.65% to 0.54% of GDP between 2009 and 2018, well below the EU average of 0.69%. Private investment in R&D fell from 0.73% of GDP in 2007 to 0.64% in 2016. It has since recovered to 0.7% in 2018, but it is still low compared with the EU average of 1.41% (2018).

The relative strengths of its innovation system are in human resources, innovation-friendly environment, and attractive research systems. Its relative weaknesses are in innovators, linkages, and finance and support.

The Spanish authorities have reacted to the 2008 crisis by implementing a programme of structural reforms with the view of alleviating barriers and finding new sources for growth and jobs. Along with fiscal consolidation, restructuring of the banking sector, and modernization of public administration, structural reforms are being implemented in the labour market and new strategies have been adopted to promote R&D, innovation, digital economy, and entrepreneurship.

In 2013, after a wide consultation of stakeholders, the Spanish government in agreement with the Autonomous Communities approved a new Spanish Strategy for Science, Technology, and Innovation for the 2013-2020 period (henceforth, the Strategy) (Spanish Government & The Ministry for Economy and Competitivity, 2020). The Strategy briefly pursues four main goals:

1. Promoting talent generation and employability of human resources in R&D, including mobility within the public sector and between this and the private sector.
2. Raising excellence in research.
3. Boosting business leadership in R&D.
4. Responding to societal challenges.

A National Plan for Scientific and Technical Research and Innovation (PECTI) (2013-2016) has been established to implement the Strategy (The Ministry for Economy and Competitivity, 2013). The main changes brought by the current strategy, compared to the previous ones are:

- The integration of science, technology, and innovation into a single strategy (before being two separate strategies).
- A wider consultation process and active involvement of regional policy-makers.
- An increased focus on coordination of the action of public administrations.
- A stronger emphasis on societal challenges.

In addition, Spain has adopted a law to support entrepreneurs and their internationalization, which includes specific references to RDTI activities. The law adopted in 2013 is supposed to, inter alia, provide the creation of a regime of limited liability for entrepreneurs, the establishment of out-of-court settlement mechanisms to allow formerly bankrupt entrepreneurs a fresh start, and also fiscal, financial, and other measures to support company growth. To

promote business growth, it extends the list of activities that are not subject to municipal licenses and reduces obstacles for entrepreneurs to gain access to public contracts.

The International Peer Review Panel commissioned by the Spanish Ministry of Economy and Competitiveness and the State Secretary for Research, Development and Innovation that reviewed the Spanish research and innovation system believed that finding new sources for sustainable growth and employment in the Spanish economy requires deep changes on three fronts:

1. A reform of the public research system so that it can increase its productivity, quality level, and relevance to the needs of the Spanish economy and society;
2. The upgrade and expansion of innovation capacities in the private sector in view of changing the economic specialization towards more added-value and knowledge-intensive activities;
3. A better exploitation of the R&I potential presented all around the country through the creation of national-regional synergies in resources and policies.

The Spanish economy's low innovation performance is also related to shortages of technical skills. High early school leaving rates undermine equal opportunities and contribute to the high share of low-skilled training in the population. The low attractiveness of vocational education and training amplifies shortages of medium to high technical skills. School-to-work transitions remain difficult, as job opportunities are limited and often of low quality. At the same time, the economy does not create enough high-skilled occupations, reflecting its low innovation dynamics.

In 2019, Spain had a smaller share of HRST of the total active population (46.5%) than the EU 28 average (48.5%) (Eurostat, 2020).

In terms of participation in H2020, Spain's success rate is higher than the EU's average (12.02%). The net EU contribution to the Spanish organizations amounts to 5.22 billion Euro (4th position of 28 EU) out of which 1.11 billion EUR represents the contribution to the innovative SMEs.

Romania

Romania is a Modest Innovator. The country's innovation performance is poor, ranking last in the EU according to the 2019 European Innovation Scoreboard (European Commission, 2020). Investment in employee training and ICT solutions is lower than the EU average (European Innovation Scoreboard, 2020). R&D investment is very low, with an R&D intensity of 0.51% of its GDP in 2018, well below the 2020 national target of 2% and the EU average of 2.12%. Public R&D investment was 0.2% of its GDP in 2018. Private expenditure on R&D was only 0.30% of GDP, below the EU average of 1.41% (European Commission, 2020).

Four smart specializations defined at the national level were aggregated through the foresight-based elaboration process in the National Strategy for Research, Development, and Innovation (NSRDI) 2014-2020 (Romanian Government, 2014):

- Bioeconomy (based on the agricultural potential of the country),
- ICT (currently the most dynamic RDI sector in Romania),
- Energy and environment (related to the challenges of energy efficiency, and water resources),
- Eco-technologies (focused on new-generation vehicles and equipment, the generation of bio-resources, depolluting and waste reuse). The set of specializations was then expanded by political decisions in the adopted form of the National Strategy to include: space and security, energy production, climate change, and new materials (substitution of critical materials, new polymer materials, and nanomaterials).

Romania is a market with potential, a strategic location for exports to Turkey, the Middle East, and the Balkans, as well as a business environment that offers opportunities, but also vulnerabilities. According to Doing Business 2016, Romania ranked 37 out of 189 countries in the ease of doing business, lower than Poland, Slovak Republic, and the Czech Republic, but higher than Bulgaria and Hungary. Romania ranks 45 on the ease of starting a business, while the lowest rankings are on the ease of getting electricity and construction permits, for which the procedures remain complex.

In 2019, Romania had the lowest share in the EU's HRST of the total active population (28.2%) (Eurostat, 2020).

In terms of participation in H2020, Romania's success rate is very close to the EU average, 12.47% compared to 12.02%. The net EU contribution to the Romanian organizations amounts to 234.2 MEUR for SMEs (20th position out of the 28 EU states) out of which only 27.84 MEUR represents the contribution to the innovative projects.

The number of new doctorate graduates is relatively high (1.14 new doctorate graduates per 1000 population aged 25-34 compared to 1.07 (EU 28 average), while the number of researchers per thousand of the population is only 1.38 compared to 5.36 (EU 28 average), Romania having the lowest share of researchers per total population (Eurostat, 2015). The new doctoral schools – initially funded through Structural Funds – provided financial support to about 7800 Ph.D. students in 2015. Nevertheless, the figure is not reflected in the number of researchers increase, which tends to remain constant, with small fluctuations around 27.000 (and, respectively, total R&D personnel of around 43.000). For the 2014-2020 period, the new objective in terms of researchers was to double their number and simultaneously reach a share of 45% in the business sector (NSRDI 2014-2020) (Romanian Government, 2014).

Romania with its free education system, coupled with a rewarding system for students, but the underpaid and unsatisfied staff, and with a relatively high supply of Ph.D. holders, continues to face substantial challenges, both for increasing the number of researchers and for reducing the serious brain-drain phenomenon. The country has a significant number of researchers (World Bank, 2014) and more than 20.000 doctors working abroad, its best graduates are recruited by top world universities, who do not return, while many good graduates from soft fields work in sectors, which do not correspond to their level of expertise and specialization.

Comparative Analysis of the main Research and Development Indicators for the four cases presented

In order to have a common ground for analyzing the performance in the innovation sector, the main R&D indicators for the four countries are presented below.

Table 1: Main R&D indicators – Sweden

	2010	2011	2012	2013	2014	2015	2016	2017	2018
GERD (as % of GDP) See the key-indicator	3.17	3.19	3.24	3.27	3.11	3.23	3.25	3.37	3.32
GERD in national currency (Million units) See the key-indicator	113207	118809	120911	124635	123848	137146	143372	155532	160351
R&D funded by abroad (as % of GDP) See the key-indicator		0.35		0.22				0.34	
R&D funded by EC (% of GDP)		0.05		0.06		0.05			

Source: Data extract from European Commission, (2020) Research and Innovation Observatory – Horizon 2020 Policy Support Facility, (2020)

It can be noticed that in Sweden's case, a steady increase of the General Expenditure for Research and Development (GERD) has occurred since 2010, exceeding the seal of 3% setup as aimed by the European Union. Overall, the percentage of the R&D activities funded by the EU remained unchanged, representing 0.05% of the GDP. The correlation between the high investment through public funds, doubled by enablers of the innovation ecosystem might represent a key success feature of Sweden's top position in the European Innovation arena.

Table 2: Main R&D indicators – France

	2010	2011	2012	2013	2014	2015	2016	2017	2018
GERD (as % of GDP) See the key-indicator	2.18	2.19	2.23	2.24	2.23	2.27	2.22	2.21	2.2
GERD in national currency (Million units) See the key-indicator	43468.832	45111.514	46519.037	47362.045	47918.737	49839.13	49650.923	50619.332	51768.559
R&D funded by abroad (as % of GDP) See the key-indicator	0.16	0.17	0.17	0.18	0.17		0.17	0.17	
R&D funded by EC (% of GDP)	0.03	0.03	0.03	0.03	0.04		0.03	0.03	

Source: Data extract from European Commission, (2020) Research and Innovation Observatory – Horizon 2020 Policy Support Facility, (2020)

In the case of France, it can be observed that gross domestic expenditure on R&D (GERD) as % of GDP was maintained at almost the same level in all the analysed years (between 2.18% and 2.2%) with the highest allocation in 2015 (2.27%). As far as GERD in the national currency (million units) is concerned, it can be noticed that the amount increased in each analysed year. The R&D activities funded by the European Commission (as % of the GDP) kept the same pace over the eight-year span analysed and reported to the European Commission. However, the percentage of R&D activities funded abroad is constant, compared to the EC contribution which is higher. This can be explained by the strong international collaboration of the French main actors involved in the innovation ecosystem.

Table 3: Main R&D indicators –Spain

	2010	2011	2012	2013	2014	2015	2016	2017	2018
GERD (as % of GDP) See the key-indicator	1.36	1.33	1.3	1.28	1.24	1.22	1.19	1.21	1.24
GERD in national currency (Million units) See the key-indicator	14588.455	14184.295	13391.607	13011.798	12820.756	13172	13260	14063	14946
R&D funded by abroad (as % of GDP) See the key-indicator	0.08	0.09	0.09	0.09	0.09	0.1	0.1	0.1	
R&D funded by EC (% of GDP)	0.04	0.05	0.06	0.06	0.05	0.06	0.06	0.06	

Source: Data extract from European Commission, (2020) Research and Innovation Observatory – Horizon 2020 Policy Support Facility, (2020)

As regards Spain, it can be observed that gross domestic expenditure on R&D (GERD) as % of GDP decreased from 2010 in all the analysed years (between 1.36% and 1.24%). As far as GERD in the national currency (million units) is concerned, it can be noticed that the amount is rather flat. The R&D activities funded by the European Commission (as % of the GDP) increased from 0.04 to 0.06, as a result of Spain's very active presence in EU FP, especially in H2020. The % of R&D activities funded abroad increased from 0.08% to 0.1%. This can be explained by a strong international collaboration of the Spanish organizations.

Table 4: Main R&D indicators – Romania

	2010	2011	2012	2013	2014	2015	2016	2017	2018
GERD (as % of GDP) See the key-indicator	0.46	0.5	0.48	0.39	0.38	0.49	0.48	0.5	0.5
GERD in national currency (Million units) See the key-indicator	2413.467	2786.83	2872.728	2464.779	2555.662	3476.933	3675.142	4317.087	4769.28
R&D funded by abroad (as % of GDP) See the key-indicator	0.05	0.06	0.07	0.06	0.07	0.09	0.05	0.04	
R&D funded by EC (% of GDP)	0.04	0.05	0.05	0.05	0.04	0.06	0.04	0.03	

Source: Data extract from Research and Innovation Observatory – Horizon 2020 Policy Support Facility, 2020

The last analyzed case, Romania, kept the level of the gross domestic expenditure on R&D (GERD) as % of GDP from 2010 in all the analysed years on a flat curve (between 0.46% and 0.5%). As far as GERD in the national currency (million units) is concerned, it can be noticed that the amount has increased, reflecting the increased level of the GDP in absolute figures. The R&D activities funded by the European Commission (as % of the GDP) surprisingly decreased from 0.04 to 0.03. The % of R&D activities funded abroad remains flat and modest.

Conclusions and Lessons for Romania

Analysing various policies applied either in Europe or overseas, some commonalities can be depicted:

- Steady public and private financial support for research and innovation, long-term commitment and predictability.
- Analysis and identification of national capabilities.

History shows that focusing on a limited number of areas is a good recipe for success. The Swedish government for instance has chosen to focus strategic investments on three key areas: medicine and bioscience, technology, and climate.

- Long term development and access to big research infrastructure.

The EU Member States and the Associated Countries to Horizon 2020 operate a diverse system of RIs ranging from well-established sectors like *physics, astronomy, energy and materials science*, mostly based on large single-sited laboratories, to the fast-developing *health, food, environment and cultural* innovation sectors where novel architectures of RIs are being developed that build on distributed capacity and specialty. The scientific and economic advantage in operating as research infrastructures in merit-based open-access mode has prompted an evolution of national and macro-regional based initiatives towards fully pan-European and international organizations, as broad consortia allow the optimization of the investment of both human and financial capital resources and the maximum impact and return to society. The RI system is also intrinsically more dynamic and responsive to the needs of a multidisciplinary approach increasingly required when addressing the so-called "grand challenges" that can be difficult to tackle in a sectorial way (economy vs. society vs. knowledge) or within the framework of academic disciplines.

The story of CERN (the European Organization for Nuclear Research) from post-war Europe to the present time has been thoroughly analysed as an example of how a science-driven facility can become a reference institution for shaping science policy worldwide. This transition has been fed by a strong focus on scientific excellence and by the open collaboration model developed at a global level by CERN.

An advanced system of RIs operating through merit-based open access to science and the data is a key attractor for young people to engage in science and innovation in Europe, or to come to Europe to perform their research projects. RIs are the most effective solution to provide state-of-the-art instruments and methods for performing research on a large scale. Most of the resources that can be accessed by users of the RIs would not otherwise be available to the vast majority of researchers or simply not available at all. By strategically linking advanced education and training at RIs with the academic curricula in all disciplines as well as with the "continuous advanced training" of technical staff employed in industry or government one can have a greater number of highly skilled user-scientists and a greater number of more effective innovation experts. In order to address the great challenges, Europe needs a new generation of highly trained people capable of generating new data through research, effectively exploiting data for innovation and of integrating cross-disciplinary knowledge.

An interim report (2016) on the role of RIs in innovation was produced by the Working Group on Innovation stressing the concept of "industry as a full partner of RIs" (supplier and user) as a way forward to promote extensive partnerships on joint R&D projects and cooperative programs, development of advanced technologies, innovation, and training. RIs and industry can generate active ecosystems of innovation exploiting their complementary enabling technologies and support services. The RIs are also unique places to train new generations of scientists and engineers in these very new interdisciplinary areas related to the Grand Challenges.

New scenarios arise where new proposals of high quality and scientific profile have significant overlaps in mission and use with existing European Strategy Forum on Research Infrastructures (ESFRI) RIs (Project or Landmark). ESFRI does not consider it to be healthy to have projects competing in the same area of the roadmap as the decisions for support may become complex and difficult.

Nevertheless, the merit of the projects presses one to consider how to proceed optimally by involving the concerned ESFRI infrastructures, in an evaluation of the synergies with such new proposal by means of agreements or common science programmes to the benefit of the European and international users' community.

As regards spurring innovation, Romania would benefit from exploring some models already tested and proved in all the three countries analyzed in the article:

- Set up incentives to increase technological transfers between the public and private sectors
- Creation of business and research clusters on the American 'Silicon Valley' model
- Creation of attractive special tax status for the innovative start-ups
- Adopt a favorable tax regime for patents. In France, for the patents that have been filled or acquired, it is allowed to deduct from the taxable profit (corporate tax or personal income tax depending on the legal structure of the company) an amortization equal to one-fifth of the value of the patent each year during five years, even though patents are protected by the Institute National de la Propriété Industrielle (INPI / French Patent Office) for 20 years.

- Better payment and attraction of young researchers in the research field.

The present study approached a matter of great interest, especially for Romania, in the context of Horizon 2020 when the European Union allocated the most significant amount of funds in its whole history. Romania should focus on developing the R&D system which has a significant impact on the economic and social development of the country. The research limitations consist of the fact that analyses only four countries from the European Innovation Scoreboard and also did not compare the situation from European countries with states such as United States or China. Further research will be conducted in order to create a comprehensive picture regarding the R&D systems from several Member States compared with states from other continents.

Abstract

The management and control of renewable resources through smart networks represent the future of technology and sustainable development. This paper conducts a study on monitoring the structural health of Smart Grids, more exactly of its nodes - Micro Grids. The main purpose of the research is the estimation of energy demand by modeling the wind speed distribution, determining the power and energy production of the wind turbine. Thus, the Weibull distribution with two parameters, scale parameter and shape parameter, was used in the sense of nonlinear control of the probabilistic wind speed distribution. Using the Maximum Likelihood Method and an algorithm coded in Python, each value in the reference range of the shape parameter was assigned corresponding values of the scale parameter for the two human settlements. Subsequently, by applying the Grammatical Evolution algorithm, which implies a context-free grammar, the best relation which depends on the environmental variables for the scale parameter was obtained. In the future, we intend to improve the nonlinear control of the statistical distribution by completing the Grammatical Evolution algorithm and adding the location parameter in the Weibull distribution.

Keywords: Micro Grid, Wind energy, Weibull distribution, Grammatical Evolution.

Introduction

Smart networks "Micro Grid", which were presented in fig. 1 by Kuo and Lu, in their research study from 2013, are in fact nodes of a one bigger network named "Smart Grid". "Micro Grid" is a project proposed within the concept of "Smart City", which suggests changes in the organization of the infrastructure of a human settlement. "Micro Grid" is based on intelligent principles of energy production, storage and redistribution. The main idea is that the energy in these networks is never lost but is redirected to the nodes where energy demand is higher. In addition, the “Micro Grid” has the advantage of being completely autonomous, both in the city and in rural areas, in case of damage to the National Power System (NPS).

Wind energy requires anticipating the distribution of wind speed to estimate the value of its production. The estimated value will be reported to the energy dispatcher, in order to regulate the energy flow coming from hydropower plants, respectively thermal power plants. In the case of a “Micro Grid”, based on these predictions, the energy demand can be estimated depending on the area in which it is located, and the climatic factors of this area.

Cite this Article as: Semion PELESKOV, Ana-Maria-Ruxandra RESCANU and Mihai REBENCIUC“ The Role of Wind Farms in Estimating Energy Demand in A Microgrid” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Thus, two problems are identified: modeling the wind speed distribution (WSD) and simulating the estimation of the amount of energy produced. In this paper, the wind speed distribution is modeled using two methods: the Maximum Likelihood Method associated with Weibull's Distribution, and by applying Grammatical Evolution. The amount of energy produced is estimated by the Analytical Equation of Wind Energy Production.

Fig 1. General scheme of Micro Grid

Biomimicry in Programming

Many areas of human life depend on technologies, which are based on principles that have been borrowed from nature. BIA (Biologically Inspired Algorithms) are the technologies underlying Genetic Programming (GP) and Grammatical Evolution (GE). Conventionally, these algorithms use the terminology, principles and processes enunciated by Charles-Robert Darwin in 1859 in his work "On The Origin Of Species".

The Genetic Algorithm (GA) is a technique for obtaining the minimum point of a multidimensional function. In the language of evolutionary theory, the result of the Genetic Algorithm produces a population that best fits an environment presented in the problem. In the book written by O'Neil and Brabazon in 2006, they have structured all BIA's as in the fig. 2. In addition, there are marked programming formalities applied in this research.

Fig. 2: Tree type scheme of the main BIA's highlighting those applied in the paper

Genetic Programming

GP has two fundamental differences from GA. Instead of evolving binary strings, which represent an indirect coding of a potential solution, in GP the search is applied directly to the solution, in this case, the solutions being programs. In the GP formalism pronounced by John Koza in his study from 1998, these programs have the form of an "S-expression", which represents a syntax scheme. Fig. 3 represents his vision of coding a row:

$$\sin(x) + (3.14x) + \left(\frac{y}{x}\right), \text{ x, y are predefined constants}$$

(+ (sin x) (* x 3.14) (/ y x))

Fig. 3: "S-expression" example (left), and associated syntax tree (right)

In GP, it is recognized that the length of the solution cannot be known from the beginning, so the number of genes (codons) must also have evolved itself.

Each individual in a population in GP goes through a certain "life" which consists of processes similar to those in nature: birth, crossover, mutation, reproduction. After the initialization of the first population, each participating individual goes through the following procedures cyclically as presented in fig. 4.:

1. **Selection.** It is a process of choosing the most suitable individuals (according to the "fitness" function) to produce the next generation of the population. There are several selection modes, which are chosen according to the requirements of the problem;
2. **Crossover**. The procedure consists of recombining the parents' genes. There are several possible ways to perform a crossover (crossing over): at one point, at two points, etc.;
3. **Mutation.** This process is made to avoid cases when the population "falls" in a local minimum of the function, not reaching the optimal solution (global minimum). It represents a small random change in the values of several parental genes;
4. **Reproduction.** It is a process, which creates a new generation based on all the steps taken before. Once a new generation has been created, the cycle repeats.

Exit conditions will be discussed in the subchapter 2.

Fig. 4: An individual's life cycle in GP

Grammatical Evolution

GE is a completion form for GP based on the formalism of a grammar. A set of rules called Backus-Naur Forms (BNF) is used to represent a context-free grammar. This is a language, proposed by John Backus and Peter Naur as a formal notation to describe the grammar of any other language. Among the advantages of applying Grammatical Evolution we can mention:

1. Application of a “mapping” algorithm for transforming a “genotypic” binary or integer string produced by the GP into a “phenotypic” output program. In other words, the transition from tree-type syntax (GP) to linear-type syntax is performed;
2. GE has a modular architecture as presented in fig. 5. In an algorithm, the search engine, the objective function and the grammar are distinct objects, which provide more space for optimizations;
3. “Output” of a GE is data written in arbitrary languages programmed in the BNF.

Fig. 5: Representation of the modularity of the GE design (Brabazon, O’Neil and Dempsey, 2009)

A BNF grammar represents a tuple containing 4 components fig. 6:

1. N – are non-terminal symbols. They are expressions that after the mapping process will turn into T;
2. T – are terminal symbols. The "output" of a program will always contain only these types of symbols;

3. P - are production rules that fully describe what will happen to N following the mapping process. A remarkable example is shown in fig. 7;
4. S - is the start expression. Obligatory a member of N.

```
G = {N, T, P, S}
N = {<expr>, <biop>, <uop>, <bool>}
T = {and, or, xor, nand, not, true, false, (, )}
S = {<expr>}
```

Fig. 6:Representation of the grammar in the example "Boolean Expression" (P is omitted)

```
# "::=" - becomes, "|" - logic "or"
# (n) - choice count
<syntax> ::= { <rule> }
<rule> ::= <identifier> "::=" <expression>
<expression> ::= <term> { "|" <term> }
<term> ::= <factor> { <factor> }
<factor> ::= <identifier>          (0)
           | <quoted_symbol>       (1)
           | "(" <expression> ")" (2)
           | "[" <expression> "]" (3)
           | "{" <expression> "}" (4)
<identifier> ::= <letter> { <letter> | <digit> }
<quoted_symbol> ::= """{ any_character }"""
```

Fig. 7: BNF grammar describing BNF rules

The mapping process begins when the GP returns a new generation. Starting with the first individual of the population, a rule for calculating the remainder applies to each of its codons.

RULE = c mod r,

where "c" - codon value, and "r" - the number of possible choices of a non-terminal symbol.

For example, in the case shown in fig. 7, let the next term N be <factor>, then c = 10, then calculating 10 mod 5 = 0, we get that <factor> becomes <identifier>. The cycle repeats, moving to the next codon value. Process runs cyclically until one or more of the following conditions are satisfied:

1. The program is completely generated. All members of N went through the mapping process and turned into T;
2. The mapping process has reached the end of an individual's genome. Then the wrapping operator is applied which starts the process of reusing the genome;
3. The number of iterations of the wrapping operator is reached. In this case the individual is associated with the lowest value of the "fitness" function, which leads to its elimination from the population. The second option is for the individual to associate with a default value.

In the end, when GP reaches the limit of generations, he returns an answer written in arbitrary language, according to predefined grammar.

Weibull Distribution. Wind Speed Modeling

Weibull Formalism

The Weibull distribution is very often used for modeling wind speed data. This paper uses the 2-parameter Weibull Distribution and the Maximum Likelihood Method (MLM) for a more accurate approximation of the shape parameter and the scale parameter.

The probability density (PDF) of the Weibull distribution is given by the relation (1) which is demonstrated in the research by Ciucu, Rebenciuc and Petre, 2013:

$$X(\beta, c) = f(x) = \frac{\beta}{c^{\beta}} x^{\beta-1} exp\left(-\left(\frac{x}{c}\right)^{\beta}\right), \quad for\ x > 0, \tag{1}$$

where x is the wind speed and $X(\beta, c)$ is a random variable with parameters β, respectively, c of Weibull distribution.

The cumulative distribution (CDF) of the Weibull distribution is given by the relation (2):

$$F(x) = 1 - exp\left(-\left(\frac{x}{c}\right)^{\beta}\right), \tag{2}$$

where β is the shape parameter (dimensionless), c is the scale parameter that is measured in $(m \cdot s^{-1})$.

Usually, the shape parameter β takes values between 1.5 and 3, each number being assigned to a certain climate. Scale parameter c depends on β and is directly proportional to the average wind speed.

Further in the paper, the Maximum Likelihood Method is used to estimate the shape parameter and the scale parameter, respectively. The estimated values are obtained by solving the nonlinear equation:

$$\frac{1}{\beta} - \left(\sum_{i=1}^{n} x_i^{\beta}\, ln\, x_i\right)\left(\sum_{i=1}^{n} x_i^{\beta}\right)^{-1} + \frac{1}{n}\sum_{i=1}^{n} ln\, x_i = 0 \tag{3}$$

$$c = \left(\frac{1}{n}\sum_{i=1}^{n} x_i^{\beta}\right)^{\frac{1}{\beta}} \tag{4}$$

The solutions of equation (3) are determined with the Newton Method, applied iteratively, and the results will be the approximate values of the parameters of the Weibull distribution, respectively $\hat{\beta}$ and $\hat{c}$.

Case Study

In the present case study, two geographical areas in Romania are considered, in which the wind speed and the behavior of the Weibull Distribution parameters during a day will be analyzed. The purpose of this study is to estimate energy production, respectively the role of wind farms in estimating energy demand, for two different types of human settlements, respectively two different climates.

The Gorbănești Commune from Botoșani County and the city of Timișoara are taken as references for study. Gorbănești commune is located in the northeastern extremity of Romania, in the center of Botoșani county, the area being characterized by a hilly relief. The climate is temperate-continental, being strongly influenced by the air masses in the east of the continent (extreme-continental influences). The city of Timișoara is located in the south-east of the Pannonian Plain, in the western part of Romania. The climate is moderate continental temperate, with sub-Mediterranean influences. The registered values of wind speed are presented in table 1 for Gorbănești commune, respectively in table 2 for the city of Timișoara. All recordings was taken on 05.05.2020 from open weather data source www.windfinder.com. Fig 8. represents the variation in time of the wind speed for Botoșani, respectively, Timișoara.

Table 1:The wind speed in Gorbănești commune

Wind Speed	Time
5.14	00:00
3.09	06:00
3.09	12:00
2.06	18:00

Table 2: The wind speed in Timișoara

Wind Speed	Time
0	00:00
1.03	06:00
2.06	12:00
2.06	18:00

Fig. 8: Variation of wind speed in time

The values in tables 1 and 2 are entered in formula (4), for each value of the shape parameter $\beta \in [1.5, 3]$, obtaining this way the scale parameter c. The calculations are performed using a Python program illustrated in fig. 9

```
import numpy as np

def scale_param(ws, time_arr, beta_arr):
    for s in range(len(ws)):
        print(f"Wind speed: {ws[s]} m/s, Recorded: {time_arr[s]}")
    for i in range(len(beta_arr)):
        summ = 0
        shape_param = beta_arr[i]
        print(f"\nShape parameter (beta) = {round(shape_param, 2)}")
        for j in range(len(ws)):
            xjpowk = ws[j] ** shape_param
            summ += xjpowk
        c = (1/len(ws) * summ) ** (1/shape_param)
        c = str(c)[:6]
        print(f"Scale parameter (c) = {c}")

ws = [5.14, 3.09, 3.09, 2.06]
time = ["00:00", "06.00", "12:00", "18.00"]
beta_arr = np.arange(1.5, 3.01, 0.01)
print("Data for 5 may, 2020:")
scale_param(ws, time, beta_arr)
```

```
C:\Python37\python.exe "D:/OneDrive/Poli
 GE/Assets/scale_param.py"
Data for 5 may, 2020:
Wind speed: 5.14 m/s, Recorded: 00:00
Wind speed: 3.09 m/s, Recorded: 06.00
Wind speed: 3.09 m/s, Recorded: 12:00
Wind speed: 2.06 m/s, Recorded: 18.00

Shape parameter (beta) = 1.5
Scale parameter (c) = 3.4357

Shape parameter (beta) = 1.51
Scale parameter (c) = 3.4375

Shape parameter (beta) = 1.52
Scale parameter (c) = 3.4393

Shape parameter (beta) = 1.53
Scale parameter (c) = 3.4411

Shape parameter (beta) = 1.54
Scale parameter (c) = 3.4430
```

Fig. 9: The code sequence for determining the scale parameter

In the code sequence, the vector $\beta \in [1.5, 3]$ is recalculated with step 0.01 for accuracy, for the identification of the most appropriate value for the proposed climate. The values for the shape parameter β, respectively for the scale parameter are presented în table 3 for Gorbănești Commune, respectively table 4 for the city of Timișoara.

Table 3. Values of β and c, for Gorbănești

	Shape parameter β	Scale parameter c	
β_1	1.50	3.4357	c_1
β_2	1.51	3.4375	c_2
...	...	...	...
β_{152}	3.00	3.7056	c_{152}

Table 4. Values of β and c, for Timișoara

	Shape parameter β	Scale parameter c	
β_1	1.50	1.1598	c_1
β_2	1.51	1.1592	c_2
...	...	...	...
β_{152}	3.00	1.5480	c_{152}

Thus, when values of β are high, the wind is more stable than for small values.

The values obtained can be processed using Grammatical Evolution (GE) to determine the scale parameter c, depending on time and variables introduced by the environment. To exemplify the process, we considered the logic diagram represented in fig. 10, and we introduced the variables I, solar radiation, T, ambient temperature, and P, atmospheric pressure. The estimation of the scale parameter is performed as a function of time, t, and variables $I(t-1)$, $T(t-1)$, and $P(t-1)$.

Fig. 10: Logic scheme of the GP algorithm, Borunda et al. (2020)

The BNF grammar-based code sequence that will output the expression of the c-scale parameter is presented in fig. 11.

```
<c> ::= "c = c(t) = " <c_polynomial>
<operator> ::= "+" | "-" | "*" | "/" | "^"
<char> ::= "I" | "T" | "P"
<int> ::= [0-9]
            | <int> <int>
<float> ::= <int> "." <int>
<ct> ::= <int> | <float>
<function> ::= <ct> "*" <function>
             | <char> "(t-1)"
             | <char> "^" <ct> "(t-1)"
<monomial> ::= "(" <monomial> <operator> <monomial> ")"
             | <function>
<c_polynomial> ::= <monomial> <operator> <monomial>
```

Fig. 11: BNF grammar code sequence

Output examples generated by algorithm from fig. 11.:

1) c = c(t) = 3*I(t-1)*((I^0.6(t-1)-T(t-1))-I^5(t-1))

2) c = c(t) = (I(t-1)^T(t-1))^P(t-1)

Starting from the code sequence of fig. 11, a new program can be made using Genetic Programming (GP) to automatically select the most suitable expression for the scale parameter.

To model wind energy production, according to the Wind Association, the power of a wind turbine can be approximated by the relation (5) illustrated in the research of Yu and Tuzuner from 2008:

$$P = 0.5A\rho CpNbNg(ws)^3, \quad (5)$$

where P is the motor power (Watt), A is the rotor surface exposed to wind (m^2), ρ is the air density, ws is the wind speed, Cp is the performance coefficient, Ng is the generator efficiency, Nb is the bearing efficiency.

Based on the characteristics of the turbine rotor, it is possible to simulate energy production, useful for estimating energy demand.

Conclusions

In conclusion, wind farms have an important role not only in estimating energy demand, but also in monitoring of the structural health of Smart Grids. Based on the implementation of a GE algorithm in the code sequence exposed in the case study, the exact value of the shape and scale parameter can be estimated, respectively. Each climate can be associated with a specific value of the shape parameter, which means that the Grammatical Evolution will progress in a unique way for each climate and human settlement. With the help of the Weibull Distribution, the wind speed distribution can be modeled, and the value of energy production could be simulated. In this paper Maximum Likelihood Method was applied to assign corresponding values of the scale parameter for the two human settlements using an algorithm coded in Python.

In the future, we intend to improve the nonlinear control of the statistical distribution by completing the Grammatical Evolution algorithm and adding the location parameter in the Weibull distribution. Regarding to the MicroGrid, we intend to study a network structural health and verifying if there are any quantum phenomena in case the network is damaged.

Abstract

The poor performance of tertiary graduates in Nigeria has been the subject of speculation for stakeholders in the education sector. In pursuance of Academic excellence, Nigeria's target is to become one of the top 20 economies. Performance is the ability of a student to complete a task. The task completion results could be positive or negative. Academic performance in private universities is undulating between first and third classes. These results are in public universities. If the result is positive, it indicates that the student performs brilliantly or excellently, but on the other hand, if it is negative, it indicates woeful performance. Student performance is an outcome of a rigorous evaluation through examination or other assessment methods. Performance criteria start from day one on campus, and it extends and accumulates to the end of the student's study. The study uses 1841 students' academic records from seven Engineering departments from the School of Engineering, Covenant University, Nigeria. This study examines the relationship between the first year and final year results and the reliability between first year results and final year results. The methodology adopted in this study is a quantitative technique. The analysis for the study carried out with IBM SPSS version 27 using Pearson correlation and Tau statistic. The Pearson correlation coefficient shows a strong positive correlation between the students of the first year and final year results, and it shows a significant linear relationship between students' first and final year results from the seven departments. This work will serve as a valuable source of advice to stakeholders in the education sector, inside and outside the university system, to enhance students' academic performance in the University system.

Keywords: Tau Statistic, Agreement Index, Significant, Academic Performance, Cumulative Grade Point Average

Introduction

Performance is the ability of a student to complete a task. The task completion results could be positive or negative. Academic performance in private universities is undulating between first and third classes, rare in public universities. If the result is positive, it indicates that the student performs brilliantly or excellently, but on the other hand, if it is negative, it indicates woeful performance. Student performance is an outcome of a rigorous evaluation through examination or other assessment methods.

Performance criteria start from day one on campus, and it extends and accumulates to the end of the student's study. Student performance literature is growing globally, and recent studies touched on the effect of flipped classroom versus traditional teaching on student performance using meta-analysis.

The authors discovered the flipped classroom's moderative positive effect on student performance regardless of discipline and education level (Strelan, Osborn, and Palmer, 2020). Different factors are responsible for student performance; Schwartz and Rothbart, (2020) study shows the impact of universal free meals on student performance and concludes that increases in school free lunch improve poor and non-poor student academic performance.

Tomasevic, Gvozdenovic, and Vranes (2020) also contributed to the literature on student performance and gave an overview and predict student examination performance with supervised data mining techniques. The authors conclude that adequate data acquisition functionalities and the student's interaction with the learning environment require a robust student examination performance.

Sunday et al. (2020) focused on student performance in the context of programming education by using classification data analysis techniques and discovers class attendance as the determinant of success or failure of student academic performance.

The poor performance of tertiary graduates in Nigeria has been the subject of speculation for stakeholders in the education sector every year, mainly because of its target of becoming one of the world's top 20 economies this year (https://digitalcommons.unl.edu/libphilprac).

Recent statistics published by the review bodies have shown that good performance is scarce as average performance rises. This research analyzed the relationship between the first year and final year results and the reliability between the first year and the final year students of seven Engineering department at Covenant University.

The first-year performance represented the class of degree that the students start engineering courses from 200 level and the final year result was the class of degree at graduation. Reliability approaches determine the consistency between the first year and the final year to know the coefficient of reliability between them.

The agreement is a particular case of association and not the other way around. It represents the degree to which the observer classifies a given subject identically into the same group. In contrast, the association's measure represents the strength of the predictable relationship between the two observers or raters' ratings. Notwithstanding estimating the psychometric nature of different ratings, it is possible to ascertain the interrater reliability or interrater agreement. The interrater reliability coefficient indicates the accuracy of the response pattern or the ranking of responses between two or more raters, regardless of those ratings.

Jolayemi (1990) suggested a statistic for the calculation of agreement that uses the Chi-square distribution. The statistic evolves from the coefficient of determination R^2, an index for the regression model's stated variability, which applies to the square contingency table. Despite the impact of the recent studies examined, there is still a gap in tau statistics as a reliability measure for students' academic performance.

This study intervenes to fill this gap and to contribute to the student performance literature. The outstanding research question that this study intends to answer is: Why is it essential to examine the reliability measure of academic performance in a tertiary institution, and what is the impact of the student performance reliability to students and the University decision-makers? The study intends to check whether there is a strong correlation between the first year and final year result and examine if there is a significant linear relationship between the first year and final year result of students across the School of Engineering School.

This study divides into five parts, and for clarity, the first part is an introduction, second, literature review, third, methodology, fourth, discussion, and finally a conclusion. The study also discusses the study limitation and future study.

Theory of Academic Performance

Students have the capability for extraordinary academic achievement in a University environment. This proposition diver among different students. Down-to-the-earth accomplishments happen in day-to-day practice in University settings. At the beginning of the semester, the teachers and administrators take a turn to inspire the students to pursue their dreams to come out with flying colors at the end of their study. Since accomplishments are a shared vision of the entire academic community, a theory of performance is applicable in many learning contexts.

The theory of academic performance (ToP) emanates from Elger (2007), and the author described ‘perform’ as an ability to produce a valued result and ‘performer’ as an individual or a group that engages in collaboration while the level of performance as the location in an academic journey. According to Elger (2007), there are six components of performance levels, and they are: level of knowledge, levels of skills, level of identity, personal factors, and fixed factors and proposed three axioms for effective performance as performer’s mindset, immersion in an enriching environment, and engagement in reflective practice.

The theory of performance challenges educators to improve their performance through empowerment to help others learn effectively and grow. This type of learning will foster quick success and produce knowledge that will influence society. Inferring from the study of Wiske (1998), performance indicates learning-for-understanding.

Higher academic performance produces results that lead to an increase in academic quality. This process creates an environment where performance exceeds the expectations of the academic community stakeholders. There will also be a decrease in cost; that is, the financial resources involved in producing the desired result will be reduced. Higher academic performance will also increase capability, capacity, knowledge, skills, and motivations. This development is a good signal for the university publicity and acceptance.

Applying the academic performance theory to the Private University results, the performer will need to stabilize the students at the forefront and encourage the backing students to improve drastically. The performer can set a challenging goal for the student from the beginning of the semester and allows failure as part of the rubrics to motivate high performance. This intervention should be a gradual process.

Related Literature

The literature on academic performance across different levels of education globally is advancing, and this development established the visibility of academic performance research domain. Earlier, Brown et al. (2008) examined social cognitive as predictors of academic performance in College setting using meta-analytic. Turner, Chandler and Heffer, (2009) digressed from social cognitive and researched on the influence of parenting styles, achievement motivation and self-efficacy of College students. Since academic importance is all-encompassing, Akiri and Ugborugbo, (2009) focused on how teacher's effectiveness impacts the academic performance of the secondary school students. Similarly, Akinsolu, (2010) combined teachers and students' academic performance as an implication for planning in Nigerian Secondary Schools. Also, Koles, et al. (2010) studied the impact of team-based learning on medical students' academic performance while Li, Chen and Duanmu,

(2010) embarked on a comparative study of Chinese students and their colleagues in other international schools and gives insight into the determinants of international students' academic performance. Gaultney, (2010) studied the effects of sleep disorders of college students on their academic performance while Farooq, Chaudhry, Shafiq and Berhanu, (2011) researched on the factors that affect students' academic performance quality. It means the students perform, but not all the students did not attain academic performance quality level.

Investigating student performance is very in institutions to help students work hard and assist administrators in their plans to get the best performance from their students. Several researchers have worked on different areas of academic performance. Samaha and Hawi (2016) used Pearson correlation and Multivariate analysis of variance to examine if satisfaction with life mediates stress and academic performance facilities Smartphone addition.
Also, Balogun, Oyelere and Atsa'am (2019) examined the relationship between student's first year and final year academic performance using Regression and Correlation analysis.

Kusurkar et al. (2013) applied a structural equation modelling technique to assess how Relative Autonomous Motivation (RAM) influences academic performance through a sound research strategy and higher study effort.

Giunchiglia et al. (2018) examined the impact of social media on students' performance, and the result showed that social media usage negatively impacts students' academic performance. Similarly, the study carried out by Paul, Baker and Cochran, 2012; Junco, 2012; Meier, Reinecke and Meltzer, 2016 showed a similar result.

Balogun, Moshin and Olaleye (2020) used Cohen's kappa, Intra kappa statistic and Pearson correlation coefficient to determine the agreement and relationship between students' first year Grade Point Average (GPA) and final year Cumulative Grade Point Average (CGPA).

In the same vein, Elepo and Balogun (2016) applied Kappa statistics to investigate student's academic performance using the students' first-year GPA and graduating CGPA.

Literature on Predicting Academic Performance

Fernandes et al. (2019) applied Gradient Boosting Machine (GBM) to predict student's academic performance at the end of the school year. The result shows that the neighbourhood, school, and age indicate students' academic success or failure.

In a study carried out by Miguéis et al. (2018), the authors proposed a two-stage model that uses students' first year to predict their overall academic performance. The result shows Random Forest to be superior to other methods used in terms of accuracy.

Iyanda et al. (2018) conducted a comparison of neural network models to predict student academic performance based on a single performance factor. The result shows that the Generalized Regression Neural Network performs better than the Multilayer Perceptron model in terms of accuracy to predict students' academic performance.

Zaffar, Savita and Hashmani (2018) applied the Feature selection algorithm, a form of Educational Data Mining (EDM), to predict students' academic performance. The result shows a 10% difference in the prediction accuracy between the dataset with different features.

Material and Methods

This study collects data from the School of Engineering which comprises of Chemical, Civil, Computer, Electrical and Electronics, Information and Communication, Mechanical and Petroleum Engineering of Covenant University, Nigeria, during the 2005/2006 academic session were followed-up to their year of graduation in 2010.

The study further checked the spreadsheet of each student to know the category or class of degree they started with 100 level for students who admitted with University Matriculation Examination and 200 level for direct entry.

The appropriate class of degree for each student recorded and equally checked to know the class of degree that he or she later graduated. The study is limited to the first year and final year students' academic performance from seven departments in the School of Engineering from 2005/2006 to 2009/2010 sessions.

The analysis for this study carried out using IBM SPSS version 27 using Pearson correlation and Tau statistic.

Pearson Correlation

Accord to Wang (2012) a nonparametric measure of association for two random variables is known as Pearson correlation coefficient r. It has the value between +1 and -1.

The Pearson correlation coefficient defined as:

$$r = \frac{n(\sum XY) - \sum X \sum Y}{\sqrt{[n\sum X^2 - (\sum X)^2][n\sum Y^2 - (\sum Y)^2]}}$$

Tau Statistic

Jolayemi (1990) suggested a statistic for an agreement calculation that uses the Chi-square distribution. The statistic was introduced from the perspective of R^2, the coefficient of determination, an index for the stated variability of the regression model applied to the square contingency table. The author proposed a theorem that was also shown to consider the I x I (square) contingency table obtained by classifying the same N subjects in one of the possible I outcomes by two raters.

The Pearson Chi-square (χ^2) statistic for independence is said to be at most $(I-1)N$. The author also proposed a statistic which measures agreement, the statistic is denoted by $\tau = \sqrt{\lambda}, -1 < \tau < 1$.
Where the λ which is R^2 type statistic is defined by $\lambda = \frac{\chi^2}{max(\chi^2)}$ and
max(χ^2) is proved to be $(I-1)N$. Hence, $\lambda = \frac{\chi^2}{(I-1)N}$.

The benefit of this statistic over kappa is that $(\lambda = \tau^2)$ is possible to make an inference to τ even by means of λ , which estimates the stated variability shown by the configuration of the table. The author also proposed some arbitrary division based on $|\tau|$ with the respective strength of the agreement, as Landis and Koch also proposed for the Cohen Kappa statistic (Landis & Koch, 1977).

Range of Tau Statistic with the Respective Strength of Agreement

$\lvert \tau \rvert$ statistic	Strength of agreement
0.00 — 0.20	Poor
0.21 — 0.40	slight
0.41 — 0.60	moderate
0.61 — 0.80	substantial
0.81 — 1.00	almost perfect

When $\tau < 0$, the agreement is negative.

Result

This section comprises of the results from Pearson correlation and Tau statistic. A sample of the R code used for the Tau statistic is attached at the appendix section.

School of Engineering	0.5230	Moderate	2014.50	<0.001	Significant

Confidence Bound for the tau statistic for School of Engineering

The 95% confidence interval is defined as follows:

$$C.I. = \tau \pm Z_{\alpha/2}\sqrt{\frac{\tau(1-\tau)}{n}}$$

$$= \tau \pm Z_{1-\alpha/2}\sqrt{\frac{\tau(1-\tau)}{n}}$$

$$= 0.5230 \pm 1.96\sqrt{\frac{0.5230(1-0.5230)}{1841}}$$

$$= 0.5230 \pm 1.96(0.011640808)$$

$$= 0.5230 \pm 0.02282$$

$$= (0.50018, 0.54582)$$

Interpretation: the 95% confidence interval shows that the reliability coefficient for the School of Engineering is between 50% and 55%.

Discussion

This study aims at examining the relationship between the first year and final year results and the reliability between first year results and final year results from seven Engineering departments and the School of Engineering. From the result of the Pearson correlation coefficient, it shows there is a strong positive correlation between the students the first year and final year result, and it also shows there is a significant linear relationship between students first and final year result from the seven departments.

For Chemical Engineering, about 58% of the variation was accounted for, the remaining 42% was due to the variance of the first year even when the final year was taken into account, about 58% of the students would end up with the class of degree they started with.

For Civil Engineering, about 53% of the variation was accounted for the remaining 47% was due to the variance of the first year even when the final year was taken into account, about 53% of the students would end up with the class of degree they started with.

For Computer Engineering, about 56% of the variation was accounted for the remaining 44% was due to the variance of the first year even when the final year was taken into account, about 56% of the students would end up with the class of degree they started with.

For Electrical and Electronics Engineering, about 54% of the variation was accounted for the remaining 46% was due to the variance of the first year even when the final year was taken into account, about 54% of the students would end up with the class of degree they started with.

For Information and Communication Engineering, about 52% of the variation was accounted for, the remaining 48% was due to the variance of the first year even when the final year was taken into account, about 52% of the students would end up with the class of degree they started with.
For Mechanical Engineering, about 59% of the variation was accounted for, the remaining 41% was due to the variance of the first year even when the final year was taken into account, about 59% of the students would end up with the class of degree they started with.

Furthermore, For Petroleum Engineering, about 50% of the variation was accounted for, the remaining 50% was due to the variance of the first year even when the final year was taken into account, about 50% of the students would end up with the class of degree they started with. Lastly, For School of Engineering which comprises all the departments, about 52% of the variation was accounted for, the remaining 48% was due to the variance of the first year even when the final year was taken into account, about 52% of the students would end up with the class of degree they started with.
The chi-square shows there is significant association between the first year and final year results from the seven Engineering department and the School of Engineering ($p - value < 0.001$).

The results of this research shared similar findings with other existing studies. For example, the study carried out by Balogun, Moshin and Olaleye (2020) which adopted kappa statistic as their method of analysis using data collected from a private University while in our study tau statistic was adopted to examine the academic performance of students from private University. From both studies, we noticed that a reasonable proportion of the students will end up with the class of degree they started with in their first year. Besides, Banjoko et al. (2015) applied kappa statistic using data collected from public University while we implemented tau statistic using the academic performance of students from private University. Both studies revealed that more than half of the students' considered will end up with the class of degree they started with in the first year. Also, the study conducted by Elepo and Balogun (2016) examined students' performance from a public university using Kappa statistic on the data from public University while our study considered the academic performance of students from private University. The summary of the findings of both studies showed that majority of the students will end up with the class of degree they started with in the first year. Lastly, Ibidoja, Ajare and Jolayemi (2016) and our study adopted tau statistic, but the data considered differs. The findings also showed that majority of students will end up with class of degree they started with in the first year.

Conclusion

The study shows that there is a strong correlation between the first year and final year result and also it shows that there is a significant linear relationship between the first year and final year result of students across the seven departments in the School of Engineering.

The analysis showed that the relationship between the first year and final year in the Department of Chemical, Civil, Computer, Electrical, Information and Communication, Petroleum Engineering and the School of Engineering which comprises of all the departments were moderate.

From the tau statistic, it shows that about 58% of the students from Chemical Engineering department would end up with the class of degree they started with while about 58% of the students from Chemical Engineering department would end up with the class of degree they started.

The result from tau statistic reveals that about 53% of the students from the Civil Engineering department would end up with the class of degree they started.

It also shows about 56% of the students from the Computer Engineering department would end up with the class of degree they started and about 54% of the students from the Electrical and Electronics Engineering department would end up with the class of degree they started.

Similarly, the result shows about 52% of the students from the Information and Communication Engineering department would end up with the class of degree they started.

The tau statistic shows that about 59% of the students from the Mechanical Engineering department would end up with the class of degree they started with,

Furthermore, the result from tau statistic shows that about 50% of the students from Petroleum Engineering department would end up with the class of degree they started with, and about 52% of the students from the School of Engineering which comprises of all the departments would end up with the class of degree they started.

The study also shows there is a significant association between the first year and final year results of students from the seven departments and in the School of Engineering of the University. The 95% confidence interval shows the School of Engineering's reliability coefficient to be between 50% and 55%. This study is limited to secondary data extracted from the academic records of students of seven departments from the School of Engineering from the 2005/2006 session to the 2009/2010 session of Covenant University, Nigeria. Future research will make a comparison between tau and kappa statistic. Also, the various outcomes of this work will serve as valuable therapy tools for stakeholders in the education sector inside and outside the university system to enhance students' academic performance in the system. This research would also support parents and guardians from introducing the requisite steps to help enhance their children's academic performance at the university.

Lastly, this study recommends that students spend a lot of their time reading than using it on social networks and watching soccer. Students should develop the practice of reading books in the library and using books in the library. Students should use internet facilities to research their courses.

Abstract

An event can exist at a particular time and place, specifically prepared and developed with a certain purpose and for a target audience. According to the purpose and other factors, one can categorize events in a multitude of classifications. In this sense, this paper will focus on food and wine touristic events.
A touristic event has the potentiality to attract new people to a region and, as such, attract new money, enhancing not only the economic activity of the region, but also its visibility, its image, and the diffusion of local culture.
An event moves people, creating jobs and increasing the revenues for a country or a region, and can also develop the destinies' notoriety and increase the demand in low seasons.
This potential economic enhancement and cultural visibility is increasingly appealing for local and regional public and private entities as part of the economic and promotional development strategy of the region. As such, it is relevant to understand the annual Vinho & Sabor Douro, a wine and taste festival, that happens in Torre de Moncorvo, regarding its economic impact and how it promotes local culture and products.
A survey was conducted in order to estimate the behaviour of exhibitors and visitors of the event. With the data collected it was possible to understand the importance of this event regarding exhibitors' revenues, visitors' preferred products, and how much the visitors spent, which allowed to estimate the economic impact of the event for the region.

Keywords: Wine and Food Festival, Cultural Tourism, Economic Impact, Torre de Moncorvo**.**

Introduction

For a long time now it is accepted that tourism is a tool for regional development (Moscardo, 2007). Among different types of tourism, event tourism has gained a considerable importance. An event can exist at a particular time and place, prepared and developed specifically with a certain purpose and for a target audience (Getz, 2009).

When a touristic event occurs there is the potentiality to attract new people to a region and, as such, attract new money, enhancing not only the economic activity of the region, but also its visibility, its image, and the diffusion of local culture (Almeida & Araújo, 2017). An event moves people, creating jobs and increasing the revenues for a country or a region, and can also develop the destinies' notoriety and increase the demand in low seasons (Getz & Page, 2016).

This potential economic enhancement and cultural visibility is increasingly appealing for local and regional public and private entities as part of the economic and promotional development strategy of the region (Allen, O'Toole, Harris, & McDonnell, 2010).

Although, literature presents some studies regarding economic impact analysis that certain events have in regions, it still lacks examples of deprived and isolated regions, that struggled harder to attract visitor, such is the case of Torre de Moncorvo. In this sense, this work intends to present the case of the wine and food festival to shed more light on the subject.

Literature Review

In the broader area of tourism one can find different types of tourism among which there is event tourism. This type of tourism regards the movement of people with a particular interest in participating in events. Events have been, for a long time, part of local, regional and national strategies regarding destination's development, since they are important promoters of tourism (Getz & Page, 2016).

Food tourism can be define, in the words of Hall and Mitchell (2001, p.308) as "as visitation to primary and secondary food producers, food festivals, restaurants and specific locations for which food tasting and/or experiencing the attributes of specialist food production regions are the primary motivating factors for travel". Food tourism can be define in a simpler way as the search for an unique experience regarding eating and drinking. According to World Food Travel Association, "is the act of traveling for a taste of place in order to get a sense of place". Usually, this search for food experiences is related with an interest about the origin of the products, the authenticity of the food, the culture and traditions of the places (Cunha, Barroco, & Antunes, 2019; Hall & Sharples, 2008).

In literature, tourism has infinite references and only a small part refers to food and wine events. However, the focus in this niche is increasingly growing, not only for the economic interest of the producers but also because they have the potential to attract visitors to the regions and lead them to contact to local producers that wouldn't happen otherwise (Montella, 2017).

Currently, food is seen as a key element to increase the value of a destination and to attract loyal tourists. This connection is stronger when food is related with wine, since both elements can add value to the destination and enable the differentiation and promotion of the regions (Marques, Lopes, & Varela, 2020). Wine events are considered a subcategory of food events. In reality, food and wine events are so attractive due to the gathering of two general interests: people like to eat and to drink. Getz (2019) enhances that the consumption is probably the "core experience", and the visitors that attend the event are focusing on tasting and buying.

Food and wine tourism is when a tourist visits a region with the main purpose of experimenting a specific type of food or wine (Hall & Gössling, 2016). Food and wine tourism complement each other and are also regarded as promoters of local tradition, authenticity and local identity and also contributing to preserve cultural and historical heritage (Getz, 2019).

However, it is necessary to refer that sometimes regions decide do avoid this path and don't promote these events, since the events must be close connected with local development strategies. It can be determined that such an event would do more harm than good to local residents and cultural authenticity (Getz, 2019).

Local economic development strategies that intend to enhance food and wine tourism tend to concentrate in using local suppliers and so reduce the economic leak to outside the region; enhance the product image; enhance branding and marketing strategies and promote local identity; among others (Hall & Gössling, 2016). One way to do so, and a current trend, is the organization of events related to food and wine, specifically, festivals (Van Niekerk, 2017). In recent years, events and festivals have been extensively promoted as a form of tourism particularly useful for regional development since they attract visitors and their spending to the local economy (Star, Rolfe & Brown, 2020). However, this trend also brought to light that some destination had these events merely to respond to the fact that other destinations were following this path and not because they considered it a strategic action for the region. As such, many events were one time only. When there is a planned and strategic approach to festivals, with a correct adjustment to local infrastructures, manufacturers and products, the region can select the event that best responds to the objectives and can truly differentiate from other regions (Van Niekerk, 2017).

The pursuit of the regions to develop food and wine festivals is easily understood since they are crucial to the promotion and dissemination of local products. Alongside, they can also communicate local cultural heritage and enhance local identity. However, the final pursued result, is always to boost local economy (Dixit, 2019).

There is a perspective extensively studied that emphasize economic benefits, although currently there are some different approaches that consider the possible existence of other benefits not economically related. However, even with this recognition of a different range of benefits that arise from festivals for the hosting regions, one can see in literature that studies focus mainly on four benefits: economic impact of the festival; marketing and service quality related to visitors profile; marketing and service quality related with the festival management; and positive and negative impacts of the festivals in local residents (Getz, 2019; Moscardo, 2007).

This type of events are important cultural and touristic attractions at national, regional and local level.
Portugal is one of the best food and wine destinations in Europe and the Touristic Strategy 2027 (TE 2027) aims to place Portugal as one of the most competitive, innovator, and sustainable destinations in the world. The TE2027 identifies the wine and food product as an strategic asset for the qualification of the destination, since it enhances the touristic experience and adds value to the touristic offer of the regions (Turismo de Portugal, 2017).

According to Getz (2019), destinations have to determine what benefits they expect from events and how can the results be measured. Even the "perceived impacts, whether they are believed to be good or bad, and from whose perspective, is a necessary complement to market research" (Getz, 2019, p.152),. Therefore, it is necessary to understand what benefits and to what range the hosting regions have accomplished them. The economic perspective is always one of the chosen perspectives and when the expectations are not met, usually the events tend to end (Getz & Page, 2016).

Even recognizing the existence of other benefits, due to time and resources constrains, the economic perspective is the focus of this paper. The particular case in study, Vinho & Sabor Douro, is a festival that belongs to the thematic events of food and wine. In the following sections the methodology and results obtained are described.

Methodology

This work was developed based on a literature review regarding specific information about touristic events and the economic impact they can bring to a region. Afterwards, a survey was conducted to understand the behaviour of exhibitors and visitors do a specific wine and food event, the Vinho & Sabor Douro (Wine & Taste Douro). The survey was supported in two structured questionnaires, one directed to the exhibitors of the festival and one directed to the visitors. A pre-test was conducted to 10 individuals. The questionnaires were applied during the event (September 7-8, 2019).

The exhibitors' questionnaire had two sections, the first directed to characterize the exhibitors in terms of professional profile and the second regarded the result of their activity in the festival (sales, revenues, complains, and so on). The visitors' questionnaire had three sections, the first intended to describe their socio-economic characteristics, the second intended to understand their behaviour regarding habits of visiting other events, and on the third section it was intended to understand their behaviour as consumer of the goods and activities available in the festival.

With the collected data it was possible to characterize the exhibitors and their economic results and also the visitors regarding who they are, what they bought and how much they spent.

Results

The municipality of Torre de Moncorvo is located on the south of the Bragança district, integrated in NUT III-Douro. This region is located in the northeast of Portugal and is characterized to be a deprived and isolated region (Figure 1).

Figure1: Location of Torre de Moncorvo

Source: Statistics Portugal (2020; 2018).

Torre de Moncorvo has 532 km^2 and spreads over a geographical area of 532 km^2, has a population density of 16.1 per km^2 (Portuguese mainland is 112.8 per km^2) and an aging index, that is the ratio between individuals with 65 or more years and individuals with 15 or less years) of 394.8 (for Portuguese mainland is 130.6) (Portugal Statistics, 2020). The municipality is divided in 13 parishes and is decreasing the number of inhabitants, easily perceived in the population density, due to different aspects namely decreasing of the birth rate, migration of the young ones either to go to study in other regions or to look for a job.

Although it is a region with severe restriction in terms of population and development indexes it includes the region "Douro Vinhateiro" that is a world heritage protected region by the UNESCO since 2001 and is one of the main touristic attractions to the region. Alongside, the municipality has invested in attracting tourist to the city, not only to appreciate the historic buildings but also to enjoy the cultural agenda, very rich in cultural events, were the Medieval Fair and the Vinho & Sabor Douro are examples.

Torre de Moncorvo's Vinho & Sabor Douro

Due to its location, in the Douro Superior, Torre de Moncorvo is a distinguished wine region with 1,530 acres of vineyard, representing 16% of the Douro Superior and 3.5% of the Douro region. In this context, during September and October, when the harvest occurs, it was developed a wine and food event in order to potentiate tourism and attract those specific tourists that want to taste wine and experiment the surrounding activities concerning its harvest. This event started in 2014 with the designation Sabor Douro Wine Summer Fest and since 2019 is designated Vinho & Sabor Douro (VSD) and it happens every year in a fluvial beach of the Sabor river.

The festival is restricted to wine producers from Torre de Moncorvo, since one of the objectives of the festival is to show and promote local wines. This festival can be a front row for excellent local wines, and at the same time can enhance local economy, since all the products presented and sold in the festival are from local manufacturers.

In 2019 there were 12 exhibitors in the festival, nine wine manufacturers and three enterprises of the food area. The municipality estimates 6,000 visitors to the festival during the two days. These were the individuals that were considered to answer the questionnaire. On the exhibitors side, the entire population answer the questionnaire, and on the visitors side 193 answers were gathered through a convenience sampling.The following sections present the results from the collected data.

Exhibitors results

In this section the results from the exhibitors' questionnaire are presented. A total of 12 exhibitors were questioned.

Exhibitors Sample Profile

Since the festival is restricted to wine producers of Torre the Moncorvo, it was understandable that the exhibitors' place of origin was 50% from the village of Torre the Moncorvo and 50% was from the county. Regarding their economic and legal activity, the main one is "Agriculture, livestock production, hunting, forestry and fishing" and for the remaining three was "restoration".

Participation in this and others Medieval Fair´s

Table 1 shows the participation in this and other similar events. One can see that the majority (%8.3%) has participated in previous editions of the festival, however also the majority usually does not participate in this type of events.

Table 1: Participation in this and other events

Variables	Frequency	Valid%
Previous participation in VSD		
Yes	7	58.3
No	5	41.7
Usual participation in other similar events		
Yes	5	41.7
No	7	58.3

Source: Own elaboration.

Exhibitors' Revenues

Another aspect was regarding the total revenues of the exhibitors, to understand if the event did perform according to the objectives of promoting local wine and draining stocks. Table 2 describes the amounts the exhibitors stated for the two days festival. According to them, almost all (91.7%) estimated revenues under 2499 euros, in average the estimated revenue per exhibitor reached 1,458 euros.

Table 2: Exhibitors' revenues

Variables	Frequency	Valid%
Sales amount (euros)		
Up to 2499	11	91.7
Between 2500 and 4999	1	8.3
Between 5000 and 7499	0	0.0
Between 7500 and 9999	0	0.0
Mean Sales amount (euros)	1458.3	

Source: Own elaboration.

National and foreign visitors' spending

It was possible to distinguish national and international visitors and their spending. Table 3 presents the amount spent by Portuguese visitors and by foreign visitor.

From Table 3 it is possible to see that foreign visitors spend more, in average 47.2 euros, than national visitor that reach in average 38.6 euros.

Table 3: National and foreign visitors' spending

Variables	Frequency	Valid%
Amount spent by national visitors (euros)		
Up to 49	9	81.8
Between 50 and 99	1	9.1
Between 100 and 149	1	9.1
Between 150 and 199	0	0.0
Between 200 and 249	0	0.0
Average spending	**38.6**	
Amount spent by foreign visitors (euros)		
Up to 49	6	66,7
Between 50 and 99	2	22,2
Between 100 and 149	1	11,1
Between 150 and 199	0	0,0
Between 200 and 249	0	0,0
Average spending	**47.2**	

Source: Own elaboration.

Need for Extra Workforce

It was also relevant to find out if the exhibitors required extra labour force to participate in the event. A vast majority (75%) stated that they needed to employ more collaborators. According to Table 4 it is visible that they employed individuals from the region and for the two days vent 13 people were recruited.

Table 4: Extra workforce

Variables	Frequency	Valid%
Need to recruit more employers		
Yes, in the village	6	50.0
Yes, from other places	3	25.0
No	3	25.0
Number employees recruited: 13		

Source: Own elaboration.

Future participation in this event

Lastly, one important indicator that the event had successfully achieve the exhibitors objectives was about the intention to participate in future events. In this question it was a consensual answer with 100% stating that they will participate in future editions of the festival.

Visitors Results

In this section, the results obtained from the gathered data are presented. The estimated number of visitors to the festival reached 6,000 individuals and the total sample registered 193 answers.

Visitors Description

The data collected referred to the main demographic characteristics of the visitors. The majority of the visitors (88.6%) were Portuguese and of the foreign visitors 59.1% were from Spain and 27.3% were from France. This was already expected since the majority of the visitors tend to be Portuguese and the foreign are typically from Spain due to the proximity and from France due to the migrant tradition.

The educational level was mostly with secondary education, having 11.9% only basic educational level and 43.5% a higher education level. Regarding their professional activity the majority is employed (58.3%), self-employed (17.5%), 8.4% are unemployed, 7.6% are students and 7.4% are retired. Their monthly incomes are distributed

along different intervals registering the class “up to 635 euros” 14.7%; “from 636 to 1135 euros” 27.2%; “from 1136 to 1635” 22.1%; “from 1636 to 2135” 18.9%; and “over 2135 euros” 17.1%.

It was also studied with whom did the visitors attend the event as is resumed in Table 5.

Table 5: National and foreign visitors’ spending

Variables	Frequency	Valid%
Visits alone or accompanied?		
Alone	51	26.4
With company	142	73.6
With Whom?		
Life Partner	73	--
Descendants	26	--
Other family members	27	--
Friends	56	--
Other person	1	--
Number of companions		
1 Person	30	25,4
2 Persons	25	21,2
3 Persons	41	34,7
4-5 Persons	15	12,7
6 or more persons	7	5,9

Source: Own elaboration.

The majority of the visitors (73.6%) attended the festival with company and only 26.4% attended alone. From the company identified it was possible to determine that the majority visited the event with their life partner and the second most referred company was with friends. It is visible that , this event attracts small groups with one, two or three people reaching 81.3%.

Length of stay and accommodation

It is relevant to understand if the visitor remain in the region for only one day, for the duration of the festival or if they stay for longer periods. Table 6 presents the length of stay of the visitor not only in the event but also in the region.

Table 6: Visitors’ length of stay

Variables	Frequency	Valid%
Length of stay exceeding one day		
Yes	116	60.1
No	77	39.9
Length of stay in the event		
½ day	85	44.0
1 day	39	20.2
2 days	69	35.8
Average	1.1 days	
Length of stay in the region		
1 day	94	48.7
2 days	49	25.4
3 days	27	14.0
4 or more days	23	11.9
Average	2.1 days	

Source: Own elaboration.

It is noticeable that visitor mostly come one day to the event, reaching 64.2% the visitors that stay half a day or a hole day. However it is also possible to see that although the majority remains one day to visit the festival they remain for longer in the region (51.3% stay for more than one day) and in average they stay for 2 days. As such, it was interesting to see where the visitors stay for the night. Table 7 resumes the different accommodation options.

As can be seen in Table 7 the majority opts for lower price range accommodations, with "camping", "family and friends", "own accommodation" being the three top choices (with 66.1%).

Table 7: Visitors' accommodation typology

Accommodation typology	Frequency	Valid%
Local accommodation	21	18.1
Hotel	0	0.0
Rural Tourism	10	8.6
Camping	26	22.4
Family & Friends	26	22.4
Own Accommodation	25	21.6
Other	8	6.9

Source: Own elaboration.

Usual visitor to this type of event

The visitors were also questioned if they usually attend this type of events, since food and wine events tend to have a more hedonistic visitor with more specific characteristics. 58% of the visitors referred that they came to the festival specifically for the thematic involved.

They also described the number of times they attended these events, as is seen in Table 8. The majority of the 81 individuals that visited the VSD more than once, was repeating the visit between two and three times (69.1%) and 30.9% was visiting for the 4th and 5th time.

Table 8: Visitors' accommodation typology

Variables	Frequency	Valid%
Visits to the VSD		
1st time?	112	58.0
More than once	81	42.0
Number of visits (for repeated visitors)		
2 - 3 editions	56	69.1
4 - 5 editions	25	30.9
6 – 8 editions	0	0.0

Source: Own elaboration.

Visitors' Spending

The last part of the questionnaire to the visitors regarded their spending. What did they buy and how much did they spent. The majority of the visitors bought food in the festival (64.8%). On average the visitors had one meals in the event and spent an average amount of 14.1 euros on food. Overall, the visitors, during their length of stay had 2.3 meals locally (inside and outside the event) and spent an average amount of 34 euros in food.

During their visit 52.1% also bought souvenirs in the festival from local craftsman; 47.6% bought covered almond or almond related products; 19.7% bought wine; 18.7% bought olive oil; 15.5% bought cheese; and with lower percentages there can be identified honey, smoked sausages, and others.

Table 9 resumes the products bought and the amounts spent. It is noteworthy that only the souvenirs were bought in the festival precinct all the other products were bought locally outside of the event.

Table 9: Visitors' spending, per type of product and per value

Products acquired	Valid%	Average amount (euros)
Souvenirs	52.1	15.6
Almond	47.6	4.0
Wine	19.7	2.0
Olive Oil	18.7	4.5
Cheese	15.5	2.2
Honey	9.3	0.8
Smoked Sausages	7.8	1.0

Source: Own elaboration.

Estimated economic impact of the visitors

With the amounts determined for the visitors' spending it was possible to create a new variable that aggregates the different variables related to spending. As such, an average amount of 64 euros per visitor. Since all the products and food were bought locally or in the county, it is possible to assume that all the spending will remain in the region. For a simple purpose of magnitude determination one can estimate that the 6.000 visitors spent in the region almost 400,000 euros. This is clearly underestimated since it was not possible to determine how much the visitors spent for accommodation.

Conclusions

The development and hosting of an event, and as in this case a specific and thematic event, is intended to attract people to the region where it happens boosting the economy and enhancing the image of the region and of its cultural aspects.

With this paper it was intended to describe the wine and food festival that occurs in Torre de Moncorvo every year since 2014. From the results it is possible to see that there are 6,000 visitors in two days in the village and that they spend around 400,000 euros.

With this event, not only there is a boost in the economy, with a great protection of local manufacturers, granting that the money will remain in the region, but also it is an opportunity to promote local wine and other products, such as covered almond that is a premium product and exclusive of the region.

Although there should be other factors considered, in order to more accurately estimate the impact, the intention was to have a magnitude of the impact and to understand in what amplitude can an event stimulate an isolated rural region.

Abstract

The following paper's purpose is to reveal a mathematical study regarding wind turbines and two different distributions of them so the efficiency increases, but also how could Romania as a European country use the green-energy instead of fossil fuels to sustain the requires. Besides, there is a comparison between the standards that were set up in 2011 and what Romania has achieved in 2020 in terms of wind power.

Keywords: Wind, Turbine, Applied Mathematics, Distribution.

Introduction

It is well known that pollution has become a heated issue nowadays and its effects on nature determined people to look for other ways of producing energy, thus wind energy has stepped out. But the problem is how to increase the performance of the wind turbines. This is the aim of our study, to optimize the distribution of the wind power plants that may replace fossil fuel energy in Romania.

What is a Wind Turbine?

To begin with, everyone needs to know how a wind turbine looks like and its principle of functioning. A wind turbine is an ensemble used for over 3000 years with a precise configuration (presented in Fig. 1) that includes the blades (1) meant to capture gusts of wind and to set in motion the rotor (2). This last one gives an impulse to a low-speed shaft (5), then to a gearbox connected to a generator (7). The generator, based on electromagnetic induction, produces wind energy which is then forwarded to an electrical station.

Cite this Article as: Valeria-Alina ANDRONESCU and Elena-Corina CIPU "A Mathematical Study Regarding Wind Turbines" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Fig. 1: Components of a wind turbine

When the weather is unfavorable to producing wind energy, the power plant has an anemometer (9) attached to measure the direction and speed of the wind. If the wind exceeds a certain value, it activates a brake to stop the blades' rotation and any damage to be done.

What needs to be pointed out is the fact that there are various types of wind turbines, but each of them has uses the same principle and the best known is the one with one rotor and three blades, presented above.

There are also turbines with a smaller number of blades, mounted either upstream or downstream, with a shaft either horizontally or vertically (Figure 2. b), with multiple or simple rotors (Figure 2. a). They can also be mounted either on-shore or off-shore. Some examples are shown in the images below.

Fig. 2: Turbines with a smaller number of blades

A wind system is designed to give efficiency to certain parameters set by the manufacturer. Normally, a turbine with a rotor and three blades has:

- A power of 2,5 MW;

- Wind speed: between 3 and 25 m/s (over 25 m/s the turbine stops automatically so as not to endanger the devices inside);
- Tower Height: 90 – 140 m;
- Propeller speed: 6 – 15 rot/min;
- Propeller diameter: 100 – 110 m;
- Weight: 20 – 200 tons.

We present some formulas used to optimize energy production below:

a. $\frac{V}{V0} = (\frac{h}{h0})^{\alpha}$ (1);

Equation (1) represents **the relation of the wind speed *v* as a function of the height *h***, where v_0 and h_0 are the speed, respectively the ground height, and α is the exponent of Hellman, specific to the area, the time of the day, the season, etc.

Table 1: Examples of values for Hellman's exponent

Location and state of the atmosphere	Hellman's exponent - α
The unstable atmosphere above the water surface	0,06
The neutral atmosphere above the flat coastal area	0,16
The unstable atmosphere above human habitats	0,27
The neutral atmosphere above human habitats	0,34
Constant atmospheric conditions above human habitats	0,60

b. $P = \frac{1}{2} C_p \cdot \rho \cdot S \cdot v^3$ (2);

Equation (2) reveals **the power of the turbine** where C_p is the power (performance) coefficient of the turbine, ρ is the air density (approx. 1,25 kg/m^3 under normal conditions of temperature and pressure), S represents the area covered by the turbine blades and v – the wind power. We should point out that for a wind speed of 10 m/s, the power developed by the turbine is 8 times higher than for a speed of 5 m/s.

The graphic below was made using a Mat Lab program and reveals the dependence of the wind speed on the height of the propeller.

Fig. 3.a.Power dependence on the speed of wind b. Ideal efficiency curve

c. **Betz's Limit**: $C_{pmax} = 59{,}3\%$

This limit shows that, in the absence of any friction with air and the friction of the internal components between them, the maximum efficiency of a turbine does not exceed the threshold of 59,3%. However, modern ones reach up to 40-45% efficiency. The picture on the right side illustrates the variation of the coefficient of performance C_{pmax} with the ratio between the peripheral speed of the blades and wind speed for different turbines.

d. **The average distance between two turbines** is **8 rotor diameters** (meaning 8 complete circles of blade rotations). For instance, for a turbine with a diameter of 100 m, the optimal distance would be 800.
e. For **multi-rotor turbines**, the diameter of one rotor shall be calculated according to the following formula: $d = \frac{D}{\sqrt{n}}$ (3), where D is the diameter of a rotor that would replace all smaller rotors in terms of power and n is the number of rotors.

Rightsizing Wind Turbine's Distribution

In the following lines, we will calculate to find out the number of wind turbines Romania needs to completely replace the energy produced with fossil fuels. Foremost, fossil fuels cover about 15 327,9 million kWh in the first 8 months of 2019 and the production in wind farms was about 4406,9 million kWh (218,6 million kWh more than the same period of 2018), according to Transelectrica.

Based on this data, the wind farm that is needed should generate about another 16 billion kWh, besides what it already produces. So 2.2 billion kWh will be required to replace energy from fossil fuels. Given this number, we will be capable of estimating the number of wind turbines, but also their configuration.

For the calculation of the number of turbines needed to get the respective energy in a year, we write: $365 \cdot 2.5 = 912.5 \frac{MW}{year}$ would 1-rotor-and-3-blades turbine produce, and also we get $\frac{2\,100\,000}{912.5} \cong \mathbf{2\,300}$ **turbines.**

Now that the number of turbines is known, the next issue would be adequate space to build. Taking into account the last point's information, namely that there must be 8 times the rotor diameter between two turbines, then it is 800 m. To distribute the 2300 turbines, it will be used the knowledge related to fractals, respectively Peano's curve, which should ensure the optimal distance and efficiency in field distribution.

Peano's curve is an example of a fractal, defined by Benedoit Mandelbrot, as an object whose Hausdorff and topological dimensions are different. A fractal is a fragmented geometric figure that can be divided into parts, so each of them is a copy of the original. The fractal, as a geometric object has the following characteristics:

- it is **self-similar** at least approximately or stochastic;
- it has a **simple and recursive definition**;
- it has **infinite detail and complexity**: any level of magnifications seems identical and has a fine structure at infinitely small scales;
- it has a **fractal dimension** or a self-similarity dimension.

In the book by Salvado (2011), the author notes that Peano's curve is a fractal which, on one hand, is a curve – a continuous geometric shape on the interval [0, 1], and the other hand, it passes through all the points in the 2-dimensional space [0, 1] x [0, 1]. Owing to these properties, it is also called *the space-filling curve*.

We say that a space-filling curve is a curve whose range contains the entire 2-dimensional unit square. These curves are special cases of fractal constructions, in which the fractal dimension is 2. Space-filling curves in the 2-dimensional plane are called Peano curves, as Giuseppe Peano was the first to discover one. Peano discovered a dense curve that passes through every point of the unit square interval onto the unit square.

To construct an example of a Peano curve, we start with a square of vertices (0, 0), (0, 1), (1, 0), and (1, 1). Step 0 is the function $y = x$ (Figure 5 a).

Fig. 5 a. Function $y = x$

Fig. 5 b. Functions used to construct step 1

For step 1, we draw the following functions: $y = x, y = x - \frac{2}{3}, y = x + \frac{2}{3}, y = -x + \frac{2}{3}, y = -x + \frac{4}{3}$ (figure 5 b). The last two figures were made using Geogebra Calculator.

The functions that describe step n are: $y_k = x + p_k$, where $p_k = \frac{-3^n+1+2k}{3^n}$, with $k = 0,\ldots,3^n - 1$ and $y_j = -x + p_j$, where $p_j = \frac{2j}{3^n}$, with $j = 1,\ldots, 3^n - 1$.

The following figures made with the help of the AutoCAD 2017 program have the role of exposing the placement of all wind turbines on the surface that was distributed based on Peano's curve.

Fig. 6: Placement of all wind turbines

Each red dot represents a wind turbine, the distance at which they were drawn is 800 mm, which is equivalent to 800m in the field. As seen from the picture, the advantage of this settlement is the ease with which wind turbines can be built, saving land. Even if they were placed on-shore or off-shore, they would not disturb either agricultural work or marine animals' lives or even prevent off-season fishing, as cameras are monitoring the area.

Fig. 7: New displacement

The total area covered is 1474,5 km^2 and the total amount of electrical power is 5750 MW.

From another point of view, we will now consider another type of turbine, namely turbines with several rotors. As a prototype, we will process the design of Vestas's **4-rotor turbine**, still in prototype condition, but which has ended its testing period.

We will then calculate its power relative to our common turbine (power of 2,5 MW and rotor's diameter of 100m). Using eq. (3), we have that the diameter of a small rotor is 50m, and the power developed by such a turbine is about 5 MW. This means that the number previously calculated will be halved, so it will require there only 1150 multi-rotor turbines that can electrically support the demand. Peano's curve model shall settle these. This time, we will use the same distance between 2 turbines, 800 m. The total area is 739,84 km^2 and the total power: 5750 MW. The photos below were created using AutoCAD 2017 and the green dots are the multi-rotor wind power plants.

Fig. 8: Four-rotor wind turbine (Vestas prototype)

Table 2: Comparison of the 2 types of placement

	Multi-rotor turbine	Single-rotor turbine
Number	1150	2300
Area covered (km^2)	739,84	1474,5
Power (MW)	5750	5750

European standards

According to European Commission, 2011 brought hope in the wind energy field by proposing that 34% of total electricity consumption be provided renewable energy sources, of which 12% represent wind energy, all at the European level. In other words, the target was to triple the percentage in recent years, i.e. about 4,8%. In 2011, the European Commission estimated that wind energy will exceed the 161 GW thresholds by 2020.

It should also be noted that the prices of the construction of a wind power plant have decreased considerably since the first appearances of this invention, reaching about 1,23 million/MW on land and 2-2,2 million/MW offshore. The most common types of turbines are those with a horizontal shaft, mounted upstream and with 3 blades on the rotor which start the movement of the blades at speeds above 3 m/s and to stop automatically when reaching a speed of 25 m/s, to not endanger the electrical installation of the materials.

As for development in the member states, it is different because of the particular levels of economy and investment in this area. Denmark (for instance) is currently the market leader, with the largest offshore wind farm having a capacity of 1200 MW and 174 turbines. Romania is not bad in this regard either, having a great development opportunity, especially in the Dobrogea area (already exploited in this sense) and the Bărăgan area. The figure below unveils the share of energy from renewable sources in the gross final consumption of energy, from 2004 to 2017 and the information was taken from the official Eurostat website.

Fig. 9: Share of energy from renewable sources between 2004 and 2017

Although hardly any investment was made in the area (no other wind turbine was built in 2018), this did not affect production, and it even multiplied it. For the future, Romania aims to reach a percentage of 27,9% of total electricity from renewable sources by 2030, which some specialists have described as “little”, given the percentage that has already been reached (23,9%).

Conclusions

Romania has a very high wind energy potential, which brings many advantages to both the community and the natural environment. Wind energy means reducing gas emissions, helping to reduce dependence on energy savings, and high costs to obtain raw materials, however harmful to humans.

Even if it might seem easier to build a single rotor turbine, that it covers a greater area might become a drawback at some point, thus a wind farm made of 1150 multi-rotor wind power plants with a power of 5 MW each could sustain the demand of electricity in Romania, practically to erase the need of fossil fuels.

Given that our country is so close to reaching its 2020 target in terms of renewable energy production, it can be concluded that the project of 1150 multi-rotor wind power plants meant to save us from pollution is not just a dream, but it can be made true with perseverance and well-trained people.

Abstract

Since the 2020 Covid19 Pandemic people have tried to find various ways to prevent humanity from catching this virus and one of the best examples is China's Corona-Virus application. In this regard, we are creating Covid19 Sentinels which are robots with thermal vision that will especially be placed in areas with a high infection rate and have the role to detect if pedestrians have the Corona-Virus temperature which was agreed through convention that is roughly 37.3 degrees Celsius. Let's say there is a Covid19 static Sentinel in a shop and 4 men enter the shop. The robot will analyze each individual then it will decide if any of them is infected and if one of the individuals is infected then the alarm will trigger. The robot gather some important data from each pedestrian and the most important ones are distance and the temperature as the robot needs to be at a certain range to be very precise so there are not any false alarms; the machine has a set of rules according to Grammatical Evolution based on context free grammar. An future improvement for Covid19 Sentinels are a laser that can pinpoint the infected individual.

Keywords: Covid-19, Security, Grammatical Evolution.

Introduction

This study aims to present a group of robots called sentinels that can analyze the temperature of a man infected with Covid-19. These robots have the ability to analyze through Grammatical Evolution (GE) the color generated by the thermal view in the robot's room.

Grammatical Evolution has the role of forming a grammar for analyzing the colors seen through the thermal chamber. Each color shade has its own HTML code (example: red not combined with another color has the code FF0000).

Grammatical Evolution

Grammatical Evolution (GE) is an evolutionary search algorithm that is similar to Genetic Programming (GP). It is usually used to generate programs with syntax defined by a particular grammar.

It has tangents with principles from molecular biology to the representative power of formal grammars. Because a grammar is used to describe the structures generated by GE, it is commonplace to change the output structures by simply changing the grammar of the plain text. Explicit grammar allows GE to easily generate resolutions in any language. For example, GE has been used to generate solutions in multiple languages, including Schemes, C / C ++, Java, and English.

A grammar is a set of rules that describe the syntax of sentences and phrases in a language. While grammars were originally invented for the study of natural languages, they are widely used in computer science to describe programming languages. This concept can be written as a tuple (N, T, S, P) where:

Cite this Article as: George-Alexandru NEAGU, Stefan-Alexandru MITACHE and Mihai REBENCIUC" Covid-19 Sentinels" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

- N is the set of non-terminal variables or symbols;
- T is the set of terminal symbols;
- S is a special variable called the start symbol;
- P is the production rule for terminals.

The notation for expressing the language of a grammar as a product rule is called Backus Naur Form (BNF). This notation consists of a tuple <T, N, P, S>. An example of a BNF is:

T = {sin, cos, tan, log, +, -, *, /, X, (,)},
S = <expr>,
N = {expr, op pre_op},
P is represented as follows: <expr> :: = <expr> <op> <expr>
| (<Expr> <option> <expr>)
| <Pre-op (<expr>)
| <Var> ,
<op> :: = + | - | * | / .

Thus we can conclude that evolutionary grammars have the following scheme of action:

Fig.1: How Grammatical Evolution works

Application

The chosen formalism that aims to analyze the color seen through the robot's camera and to indicate the individual who has Covid-19 temperature.

The average temperature of the Coronavirus carrier is 37.3 ° C. Using the Heat Index we find that orange is the color that represents the temperature of 38 ° C that has the HTML code of FF6C00.

The thermal view camera registers the human body as a body colored in red, orange or yellow depending on the temperature it has on the camera. Thus, the information is transformed from HTML code into temperature value.

To meet the condition that the robot checks whether the equation

[Temperature om] ^ 2 = [Temperature Covid-19] X 〖[Distant]〗 ^ 3

is found by the program once the 2 variables are introduced, ie [Human temperature] and [Distance] from which the recording is made plus [Covid-19 temperature] which is constant 37.3. Temperatures will be measured in degrees Celsius, and distance in meters.

If the sentinel finds the formula presented in the previous chapter then the person analyzed has the temperature Covid-19 and the program will activate an alarming sound that will alert the people around.

A potential upgrade of this machine is the attachment of a device that helps us always know the location of the sentry in case of theft or in case of finding an individual carrying Coronavirus.

Street Sentinels

Aiming to detect people with Coronavirus, the sentinels will have a static position in relation to pedestrian traffic and will partially scan passers-by from a pole. The distance between the camera and the passers-by is carefully chosen to maximize the success rate of the analysis. At the same time, these sentinels can be placed wherever needed, such as in a grocery store or in an industrial area.

It is supposed to be a grocery store where 4 people enter without respecting social distance. These individuals enter the store one by one and are analyzed by the sentry through the following code sequence using the evolutionary grammars that are in the attached section of this presentation.

The following table shows the data on the individuals entering the store:

Name	Distance	Temperature
Alexander	3.40m	36.1
George	3.50m	37.0
Arthur	3.29m	38.0
Daniel	3.34m	37.4

The program uses the following equation to normalize the error by adjusting the impact on low values (people with low temperature) and high values (people with high temperature:

$$e = \frac{1}{N}\sum \log\left(1 + |p - \hat{p}|\right)$$

where e is the normalized error, N is the number of samples, p is the person's temperature and $\hat{p}$ is the result of the symbolic regression.

This will display the following table:

distanta	temperatura	temperaturaCovid19	GE
1	3.40	36.1	39.3	39.4
2	3.50	37.0	42.8	42.8
3	3.29	38.0	35.6	35.6
4	3.34	37.3	37.3	37.3

After performing the program, it is found that Daniel is infected with Coronavirus with a temperature of 37.3-37.4 showing a mostly orange color on the room with thermal view.

This sentinel requires a very precise point of application to detect the infected individual as quickly as possible.

Conclusion

Thus, through the ideas presented above, the algorithms and lines of code used, we were able to find out with the help of "Sentinels" if there is a so-called infected person in a group of people. The sentinel created by us using Evolutionary Grammys helps the authorities in discovering new cases. We want to expand this in the future to help society and to be able to easily identify an infected person.

Nonetheless, the robot can be raised to the next level by adding a device that can be tracked on the map in case of a robery or if the machine caught a suspect of Coronavirus.

Abstract

In this work, we describe Quantum Fourier Transform (QFT) which basically is a Discrete Fourier Transform (DFT). It's main application is phase estimation, an essential part in Shor's algorithm used in Quantum Computation. We gave a brief introduction about the mathematical language of Quantum Information Science for implementation circuits on QFT and inverse QFT using IBM Quantum Experience and we did an approximation of QFT.

Keywords: discrete Fourier transform, Quantum Fourier transform, Quantum Computing, Shor's algorithm.

Introduction

During the past few decades great effort has gone into realizing a new form of computation – quantum computing. In classical case a single bit can be in two distinct states at any moment of time. A quantum bit, a qubit, has the ability to be in a superposition of both zeros and ones. The deep ways that quantum information differs from classical information involve the proprieties, implications, and uses of quantum entanglement. Entanglement is a quintessential quantum property. Entangled states have quantum correlations stronger than any classical correlations. Consequently, entanglement is an important resource for quantum technologies (teleportation, sensing, communication etc).

Quantum computers provide a new way of solving problems not otherwise realistically solvable by classical computers. One of these problems is integer factorization, which is used as a one-way function in protocols for key distribution and can be efficiently solved by Shor's algorithm as we can see in the bible of Quantum Information by Nielsen and Chuang (2010). In Gramstorm's paper (2018) we discover that finding the prime factorization of an n-bit integer is thought to require $\exp(O(n^{1/3}\log^{2/3}n))$ operations using the best classical algorithm. This is exponential in the size of the number being factored, so this is a great problem for classical computers: it quickly becomes impossible to factor even modest numbers.

Shor's algorithm is used in quantum computation. It consists of a classical part and a quantum mechanical part. Quantum mechanical part uses *Quantum Fourier Transform (QFT)* to find the period of a certain function. One of the most useful ways of solving a problem in physics, mathematics or computer science is to transform it into some other problem for which solution is known. Fourier transform appear so often and in so many different contexts that the transformation is studied for it own sake.

Quantum Fourier Transform is a linear transformation on qubits and is the quantum analogue of the inverse Discrete Fourier Transform (DFT). We define DFT of a signal x, the vector y with the following components:

$$y_k = \sum_{n=0}^{N-1} x_n e^{-\frac{2\pi}{N}ikn}, \mathrm{k} = 0, \dots, \mathrm{N}-1$$

Cite this Article as: Vasile – Laurentiu DOSAN and Elena-Corina CIPU "Quantum Algorithms for Quantum Fourier Transform Used in Quantum Information Theory" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Using notation $\omega = e^{-\frac{2\pi}{N}i}$, equation becomes:

$$y_k = \sum_{n=0}^{N-1} x_n \omega^{kn}, \mathrm{k} = 0, \dots, \mathrm{N}-1$$

with $|\omega|= 1$. We introduce the matrix W,

$$W = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \omega & \omega^2 & \dots & \omega^{N-1} \\ 1 & \omega^2 & \omega^4 & \dots & \omega^{2(N-1)} \\ \dots & \dots & \dots & \dots & \dots \\ 1 & \omega^{N-1} & \omega^{2(N-1)} & \dots & \omega^{(N-1)(N-1)} \end{bmatrix}.$$

W is a symmetric matrix and we can compute the product

$$W \cdot \overline{W} = \overline{W} \cdot W = N \cdot I_N$$

Then, the inverse of W will be

$$W^{-1} = \frac{1}{N} \overline{W}$$

For

$$Y = \begin{bmatrix} y_0 \\ y_1 \\ \vdots \\ y_{N-1} \end{bmatrix}, X = \begin{bmatrix} x_0 \\ x_1 \\ \vdots \\ x_{N-1} \end{bmatrix}$$

The discrete Fourier transform can be written as follows:

$$Y = WX.$$

As we can see in the book by Nielsen and Chuang (2010) and in the book by Nakahara and Ohmi (2008), the quantum Fourier transform is based on essentially the same idea with the difference that the vectors x and y are state vectors, i.e.

$$|x\rangle = \sum_{j=0}^{N-1} x_j |j\rangle$$

$$|y\rangle = \sum_{j=0}^{N-1} y_j |j\rangle$$

where $|j\rangle$ is a basis vector. In other words, QFT is a linear operator whose action on any of the computational basis vectors $|0\rangle, |1\rangle, \dots, |2^n - 1\rangle$ associated with an n-qubit register is described by the transformation:

$$|j\rangle \longrightarrow W|j\rangle = \frac{1}{\sqrt{2^n}} \sum_{k=0}^{2^n-1} e^{\frac{2\pi i j}{2^n}} |k\rangle, 0 \le j \le 2^n - 1$$

Bra-ket notation is a notation for quantum states (vectors in a complex Hilbert space on which an algebra of observables acts). The bras and kets are defined as

$$\langle\phi| = [\phi_1, \phi_2, \dots, \phi_n], |\psi\rangle = \begin{bmatrix} \psi_1 \\ \psi_2 \\ \vdots \\ \psi_n \end{bmatrix}, \langle\psi| = |\psi\rangle^\dagger$$

Using bra-ket notation, we can define the inner product and we can construct matrix as it follows:

$$\langle\phi|\psi\rangle = [\phi_1, \phi_2, \dots, \phi_n]\begin{bmatrix}\psi_1\\ \psi_2\\ \vdots\\ \psi_n\end{bmatrix} = \sum_{k=1}^{n}\phi_k\psi_k$$

$$|\psi\rangle\langle\phi| = \begin{bmatrix}\psi_1\\ \psi_2\\ \vdots\\ \psi_n\end{bmatrix}[\phi_1, \phi_2, \dots, \phi_n] = \begin{bmatrix}\psi_1\phi_1 & \psi_1\phi_2 & \dots & \psi_1\phi_n\\ \psi_2\phi_1 & \psi_2\,\phi_2 & \dots & \psi_2\phi_n\\ \vdots & \vdots & \vdots & \vdots\\ \psi_n\phi_1 & \psi_n\phi_2 & \dots & \psi_n\phi_n\end{bmatrix}$$

In Quantum Mechanics, a state can be represented as a vector in Hilbert space. The simplest quantum state, qubit (in pure state), can be written

$$|\psi\rangle = \cos\frac{\theta}{2}|0\rangle + e^{i\varphi}\sin\frac{\theta}{2}|1\rangle$$

It can be represented on the *Bloch sphere* as a vector with spherical polar coordinates φ and θ.

Fig.1: Bloch Sphere – representation of a qubit using spherical polar coordinates.

If we want to describe a system of qubits, we use the second postulate of quantum mechanics which says that the state of the system is given by the tensor product of the individual states. In other words, if we have 2 states $|\phi_1\rangle$ and $|\phi_2\rangle$, the system will be

$$|\psi\rangle = |\phi_1\rangle \otimes |\phi_2\rangle$$

If $\dim(|\phi_1\rangle) = \mathrm{d}_1$ and $\dim(|\phi_2\rangle) = \mathrm{d}_2$, then $\dim(|\psi\rangle) = \mathrm{d}_1 d_2$. The tensor product between $|\phi_1\rangle$ and $|\phi_2\rangle$ is defined as

$$|\phi_1\rangle = \begin{bmatrix}a\\ b\end{bmatrix}, |\phi_1\rangle = \begin{bmatrix}c\\ d\end{bmatrix} \rightarrow \ |\psi\rangle = |\phi_1\rangle \otimes |\phi_2\rangle = \begin{bmatrix}ac\\ ad\\ bc\\ bd\end{bmatrix}$$

For $|0\rangle = \begin{bmatrix}1\\ 0\end{bmatrix}$ *and* $|1\rangle = \begin{bmatrix}0\\ 1\end{bmatrix}$, we have

$$|00\rangle = |0\rangle \otimes |0\rangle = \begin{bmatrix}1\\ 0\\ 0\\ 0\end{bmatrix}, |01\rangle = |0\rangle \otimes |1\rangle = \begin{bmatrix}0\\ 1\\ 0\\ 0\end{bmatrix}, \ |10\rangle = \cdots = \begin{bmatrix}0\\ 0\\ 1\\ 0\end{bmatrix} \ and \ |11\rangle = \begin{bmatrix}0\\ 0\\ 0\\ 1\end{bmatrix}$$

Quantum Fourier Transform circuits

From the works of Marquenzio et al (2010), Nam et al (2020) and Gyongyosi (2012) we can discover that QFT is the transform which takes the amplitudes of a N dimensional states and computes the Fourier transform on these amplitudes. In other words,

$$\sum_{x=0}^{N-1} a_x|x\rangle \rightarrow \sum_{x=0}^{N-1} \bar{a}_x|x\rangle = \sum_{x=0}^{N-1} \frac{1}{\sqrt{N}} \sum_{y=0}^{N-1} \omega^{-xy} a_y|x\rangle$$

QFT is given by the matrix

$$U_{QFT} = \frac{1}{\sqrt{N}} \sum_{x=0}^{N-1} \sum_{y=0}^{N-1} \omega^{-xy} a_y|y\rangle\langle x|$$

U_{QFT} is a unitary matrix:

$$U_{QFT}^{\dagger} U_{QFT} = \frac{1}{N} \sum_{x=0}^{N-1} \sum_{y=0}^{N-1} \omega_N^{xy} |y\rangle\langle x| \sum_{x'=0}^{N-1} \sum_{y'=0}^{N-1} \omega_N^{-x'y'} |y'\rangle\langle x'| =$$

$$= \frac{1}{N} \sum_{x,y,x',y\prime=0}^{N-1} \omega_N^{xy-x\prime y\prime} \delta_{yy\prime} |x\rangle\langle x'| = \frac{1}{N} \sum_{x,y,x'=0}^{N-1} \omega_N^{y(x-x\prime)} |x\rangle\langle x'| =$$

$$\sum_{x,x'=0}^{N-1} \delta_{xx\prime} |x\rangle\langle x'| = I$$

The QFT is the function that transforms a state in computational basis into a state in Fourier basis :

$$|state\ in\ computational\ basis\rangle \xrightarrow{QFT} |state\ in\ Fourier\ basis\rangle$$

Let's compute U_{QFT} for N = 2:

$$U_{QFT} = \frac{1}{\sqrt{2}}(|0\rangle\langle 0| + |0\rangle\langle 1| + |1\rangle\langle 0| + |1\rangle\langle 1|) = \frac{1}{\sqrt{2}}\begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} = \mathrm{H}$$

where $|0\rangle = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$ and $|1\rangle = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$.

We observe that U_{QFT} for N = 2 is the Hadamard gate (H). If we apply the H operator on the state $|\psi\rangle = \alpha|0\rangle + \beta|1\rangle$, we will obtain the state:

$$\frac{1}{\sqrt{2}}(\alpha + \beta)|0\rangle + \frac{1}{\sqrt{2}}(\alpha - \beta)|1\rangle = \tilde{\alpha}\,|0\rangle + \tilde{\beta}\,|1\rangle$$

Hadamard gates are used for preparing states. It creates an input state with constant amplitudes. Other gates we use for describing QFT algorithm are R_k phase gate and SWAP gate. Phase gate leaves the basis state $|0\rangle$ unchanged and map $|1\rangle$ to $e^{2\pi i/2^k}|1\rangle$. The SWAP gate swaps two qubits:

$$R_k = \begin{bmatrix} 1 & 0 \\ 0 & e^{2\pi i/2^k} \end{bmatrix}$$

$$SWAP = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

The inverse QFT is defined as U_{QFT}^{-1}.

$$U_{QFT}^{-1} U_{QFT} = U_{QFT} U_{QFT}^{-1} = I$$

Examples of QFT circuit implementations on IBM Quantum Experience

Performing QFT and QFT^{-1} in IBM Quantum Experience implies next steps:

1. Prepare each qubit q_n;
2. Perform QFT;
3. Measure all q_n;
4. Reverse the bit order (using a series of SWAP gates);
5. Convert binary to decimal.

Fig.2: QFT on 1 qubit – Hadamard is equivalent for QFT on 1 qubit (0 -> 0 -> 0)

Fig.3: QFT on 2 qubits: 10 -> 01 -> 1

Fig.4: Inverse QFT on 2 qubits: QFT$|01\rangle = |10\rangle$; $QFT^{-1}|10\rangle = |01\rangle$

QFT is linear, it should map:

$$|k\rangle \to F_N|k\rangle = \frac{1}{\sqrt{N}} \sum_{j=0}^{N-1} \omega_N^{jk} |j\rangle = \frac{1}{\sqrt{N}} \sum_{j=0}^{N-1} e^{2\pi i (\sum_{l=0}^{n} j_l 2^{-l})k} |j_1 \dots j_n\rangle =$$

$$= \frac{1}{\sqrt{N}} \sum_{j=0}^{N-1} \prod_{l=1}^{n} e^{2\pi i j_l k/2^l} |j_1 \dots j_n\rangle = \otimes_{l=1}^{n} \frac{1}{\sqrt{2}} (|0\rangle + e^{2\pi i k/2^l} |1\rangle)$$

where $|k\rangle = |k_1 \dots k_n\rangle$ and j = $j_1 \dots j_n$. Note that $e^{2\pi i k/2^l} = e^{2\pi i 0.k_l \dots k_n}$

As example, for n = 2 we have the 2-qubit product state

$$F_4|k_1 k_2\rangle = \frac{1}{\sqrt{2}} (|0\rangle + e^{2\pi i 0.k_2} |1\rangle) \otimes \frac{1}{\sqrt{2}} (|0\rangle + e^{2\pi i 0.k_1 k_2} |1\rangle)$$

A quick example can show the relationship between DFT and QFT as we can find in paper by Hales and Hallgren (2000). We consider the two qubit state

$$|\psi\rangle = a|00\rangle + b|01\rangle + c|10\rangle + d|11\rangle$$

If $a = b = c = d = \frac{1}{2}$, then $|\psi\rangle = 0.5(|00\rangle + |01\rangle + |10\rangle + |11\rangle) = \begin{bmatrix} 0.5 \\ 0.5 \\ 0.5 \\ 0.5 \end{bmatrix}$.

Now,

$$DFT|\psi\rangle = \frac{1}{2}\begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & i & -1 & -i \\ 1 & 1 & 1 & -1 \\ 1 & -i & -1 & i \end{bmatrix}\begin{bmatrix} 0.5 \\ 0.5 \\ 0.5 \\ 0.5 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix} = |00\rangle$$

This example also agrees with the theoretical result of QFT. We have tested the previous calculation using Python (see *APPENDIX B*).

Conclusions

The time for Quantum Information Processing has arrived, its applications are multiple and we can find faster solutions for different problems by using Quantum Computing. In this paper, the building process of the QFT was exposed in detail. We started from the description of DFT, after we gave a brief introduction in bra-ket notation, inener and tensor product in Hilbert spaces. We studied the relationship between DFT and QFT by using algorithms and different examples. The practical examples presented in this paper underlined that QFT is a DFT on quantum states and QFT on one qubit is equivalent with a Hadamard gate.

As future works, we propose a study on the entropy of QFT algorithm. In this novel approach, our direction is computing two different types of entropies: Shannon entropy and von Neumann entropy. For the state vector $|x\rangle = \sum_{j=0}^{N-1} x_j|j\rangle$ the Shannon entropy could be defined by:

$$H(|x\rangle) = -\sum_{n=0}^{N-1} x_n \log(x_n), \mathrm{k} = 0, \dots, \mathrm{N}-1$$

with the convention that for $x_n = 0, x_n \log(x_n) \equiv 0$ with logarithm taken in base 2. More appropriate for quantum states [11]Von Neumann entropy of a quantum state $|x\rangle$ is described by the formula:

$$S(|x\rangle) = -\sum_{n=0}^{N-1} \lambda_n \log(\lambda_n), \mathrm{k} = 0, \dots, \mathrm{N}-1$$

where λ_n are the eigenvalues of the state. On these cases strong subadditivity for different type of staes wil be studied. We also propose to link the QFT algorithm with the Markov chain.

Abstract

This paper proposes a method of analyzing another significant aspect of a database system performance – the stability of the system performances. In this study, the proposed procedure, named C-SGBD is intended to analyze the stability of a relational database system, during a normal runtime execution of the database server. The procedure consists in posing different workloads on the database server and analyze the execution time, in a different manner then the regular benchmarks (e.g TPC systems), comparing the responses of the same system at different workloads of a comparable level.

Keywords: Database systems, database performance evaluation, relational databases

Introduction

The database systems evolved in multiple directions in the last decade, including the No-SQL developments (Abdullah, Resul, 2017), the cloud database systems, the data encryption technologies (Boicea et al. 2017) and the significant improvements and developments of the relational databases. Nowadays, we can affirm, the database domain represents one of the central key points in almost any industry.

The database performance evaluation represents an important detail in the analyzing process for choosing the most suitable database system for every application and most of the studies in this domain focused on performance evaluation basing on some key predefined indicators, significant for the specific industry, such as cost per transaction, transaction time and scalability, fault tolerance.

A significant effort to compare different database systems performances and attributes was achieved, including comparison between No-SQL and SQL (Boicea et al. 2012).

This paper proposes a method of analyzing another significant aspect of a database system performance – the stability of the system performances. In this study, the proposed procedure, named C-SGBD is intended to analyze the stability of a relational database system, during a normal runtime execution of the database server. The procedure consists in

posing different workloads on the database server and analyze the execution time, in a different manner then the regular benchmarks (e.g. TPC systems) (Raab et al. 2020), comparing the responses of the same system at different workloads of a comparable level.

The final indicator that will be obtained at the final of the procedure execution will define a system stability level.

Related work

Most database management system (DBMS) performance evaluation procedures and algorithms are focused on certain key points, such as execution time for a database transaction and a cost per database transaction (Osman, Knottenbelt, 2012). The main goal is to optimize the database response time in order to increase the performance and obtain a lower cost per transaction.

Another direction for increase database system performance is to use a modern storage technology, namely Flash memory, integrated into different subsystems in the DBMS (storage, transaction or buffer managers) (Petrov et al.. 2015).

Improving of queries on distributed database through the query caching method involves transferring of the most frequently accessed data from the remote databases to the local database (Boicea et al., 2016).

In our previous work (Petrescu, Popeangă, ***2003),*** (Petrescu, Popeangă, ***2000)***, we studied the relationship between query optimization and execution plan, reflected in a better performance for a DBMS system. We also analyzed some Cryptographic algorithms for benchmarking systems (Boicea et al., 2019).

Different approaches were implemented, some of them becoming widely implemented and considered as database performance benchmarking standards, such as TPC benchmarks (Raab et al. 2020).

Another significant database performance evaluation domain was directly linked with the database design (Osman, Awan, 2010).

The main approaches are trying to find the optimal database and query configuration, to make the proper transformations, in order to reach the best performance.

The optimization process may be composed by several transformations that preserve equivalence between the initial SQL query and the optimized one. These transformations do not reduce cost every time, and, therefore, must be applied in a cost-based manner by the enumeration algorithm to ensure a positive benefit.

The subsequent database developments involve multiple optimization possibilities for SQL or No-SQL database systems, starting from the known basic principles of optimizing the response time for different queries. Significant progress had been made in the last years, with more complex database systems, involving more powerful technology and cloud working. More indicators are involved now and a modern comprehensive approach of the database performance evaluation domain should take into consideration many other aspects, like security, scalability.

Database performance stability evaluation

Stability in DBMS Performances

Among the most studied performance indicators in DBMS systems, including the execution time and cost per transaction, some significant aspects should be considered in order to assure a stable system and application. It is very important to obtain the optimal execution time and the best cost per transaction, but it is equally important to have a stable DBMS behavior, with constant performances.

Many areas of industry are focused on a general stability and predictability, more than the best performance in a specific domain.

A system stability analysis should start from the variation in performances within the same level of transaction workload and a comparison between two different DBMS can be made starting from this point. This analysis can

complete the previous benchmark directions for DBMS and offer an decision support answer for choosing the most suitable system.

C-SGBD Methodology

This paper presents a basic methodology for defining a complexity indicator for DBMS transactions and analyzing the system behavior during the execution of multiple different transactions of same complexity level. One significant goal is to run the tests on a real database, during the runtime of different online accessed DBMS's.

C-SGBD is a stability performance evaluation for a real runtime DBMS, basing on a database populated with real records, generated in over 15 years by usual runtime of a legal portal website.

We define the *selection term weight* as an indicator for the workload posed to the database query by that selection term.

The methodology consists in a performance analyze of the same DBMS during an usual runtime, between multiple interrogations (distributed equally between the hours of the day) with similar select term weight.

C-SGBD Database Structure

The tested database is composed by six tables: the first five tables are populated with real records, generated in a normal runtime of a website by regular users, the last table being dedicated to the selection term weight, calculated for all the above tables extracted words.

The C-SGBD benchmarking database is composed by five content tables, NEWS (2,381,679 individual selection terms), QUESTIONS (51,803 individual selection terms), BOOKS (113,178 individual selection terms), JOURNAL (3,837,220 individual selection terms), ANSWERS (8,128,808 individual selection terms) and the generated terms weigth table, called WEIGHTS. The first five tables contain real records, with a real content distribution.

The total number of the extracted words, in a non-processed phase is calculated basing on simple SQL commands:

```
SELECT SUM(LENGTH(input) -
LENGTH(REPLACE(input, ' ', '')) + 1) AS
"Word Count" FROM
(SELECT
TRIM(REPLACE(REPLACE(REPLACE(inp
ut,' ','<>'),'><',''),'<>',' ')) AS input
FROM (SELECT text_news  AS input
FROM NEWS) i) r;
```

The weight table content is generated basing on the words distribution in the content tables in the second phase of the methodology.

C-SGBD is designed according to three main objectives:

1. A representative data set for a real environment;
2. Similar experimental environment with the real runtime environment;
3. Similar experimental testing queries with the real runtime queries.

C-SGBD Procedure Structure

The presented procedure is composed by five main phases, combining both database benchmarking procedure and results interpretation. Moreover, in every phase, content based decisions are implemented, to assure a data and query representative behavior.

The main phases are:

1. Database creation and selection terms weight calculation. The database creation scripts are independent on the database platform and content of the tables and the benchmarking set is extracted at runtime from the real environment

2. The selection terms are extracted basing on the text words presented in the real records and the selection terms weight is generated into the sixth table, WEIGHT.

3. A fixed number of benchmarking experiments are run, every experimental set of queries consisting of 1000 different set of queries posing a specific complexity established the by the experimental weight set. The queries must be representative for the real runtime environment and the queries must have a real meaning. The sum of the selection term weight within the same experiment has to respect a minimal value and the queries must contain selections, projections, dataset unions from heterogeneous tables.

4. Response times of the queries, obtained from each experiment, are analyzed, taking into consideration different selection terms weights.

5. The system stability is analyzed, basing on the results variation obtained in the experiments.

The methodology is comparing, within every studied DMBS system, the behavior during the real runtime execution basing on the system stability.

C-SGBD Experimental Conditions and Environment

The main purpose of the experimental methodology is to obtain significant indicators of the system stability for a certain runtime system during a normal operation.

Although the methodology can be addressed to standard application systems running with DBMS, it can be extended to distributed DBMS's or cloud systems.

The present paper is analyzing the response times from different MYSQL DBMS implementations in order to be able to make a comparison between different application servers.

Two different servers will be analyzed: **Server1** and **Server2**, having the following configurations:

Server1:

Architecture	x86_64
Operating System	Linux
Apache Version	2.4.46
MySQL Version	5.6.29-76.2
Kernel Version	2.6.32-954.3.5.lve1.4.71.el6.x86_64

Server2:

Architecture	x86_64
Operating System	Linux
Apache Version	2.4.41
MySQL Version	10.0.38-MariaDB
Kernel Version	2.6.32-531.29.2.lve1.3.11.1.el6.x86_64

The response times are measured during a real runtime of the mentioned systems, in different running moments of the day, in order to obtain values according to a normal functionality of the analyzed system.

C-SGBD experimental framework and procedure

C-SGBD First and Second Phase – Selection Terms Extraction and Selection Weight Calculation

The database tables, used in experiment are populated with real runtime records. The tables contain real text values, describing a legal website, such as:

- Legal news
- Official Law Journal proceedings
- Legal Books descriptions
- Real questions for legal domain
- Real legal answers from website community

The words extraction procedure starts with simple SQL commands, eliminating the special characters.

Every selected table contains a main text value column that will be used in the database queries.

The texts from the records in the mentioned tables are processed and the main items / word are extracted, in the second phase of the methodology.

For every word having a minimum length (significant word), a record in the weight table is updated and the process continues for all the texts in the five source tables: NEWS, QUESTIONS, BOOKS, JOURNAL, ANSWERS.

The general weight for every word is calculated at the end of the procedure, the second phase of the methodology resulting in a table containing, for 31.018 significant words, the general weight.

C-SGBD Third Phase – Database Queries Experiments

The third C_SGBD phase consists in a sequence of three experiments composed by various sets of multiple SQL queries run on the database.

The experiments simulate different situations on database structure:

- Search tables with primary keys but without indexes searched columns;
- Search tables with primary keys but with indexes searched columns.

The queries tend to respect the real runtime queries that a regular user of the website would run on the system, searching for some specific information, taking into consideration the selection term calculated weight.

C-SGBD uses a set of the first thousand weights selection terms, which are used sequentially in different queries run on the five source tables.

Every experiment consists in a set of queries included in a PHP application, having the following structure:

- Database connection
- Selection of the 1000 selection terms, basing on a weight criteria
- For every selection term:
    - Start timer
    - Run queries on the five source tables with the specific weight selection term
    - Fetching the results
    - End timer
    - Result insertion into the RESULTS table

The first experiment uses source tables without ‘fulltext’ indexes on the queried text columns. Every subset of queries is posing the first thousand set of weights on each source table within queries and, at the end of a subset, the execution time is recorded.

The second experiment uses source tables with indexes on the queried text columns. The number of the queries is doubled as the queries are optimized and the response times are lower.

C-SGBD Fourth Phase – Results processing procedure

After the first experiment, the results are processed in order to obtain a level of standard deviation for the response times. Figure 1 shown the minim and maxim response time for every set of queries run on Server1 and Server2.

a) Server1 **b) Server2**

Fig 1. Minim and maxim response times for every set of queries

Figure 2 shown the standard deviation for every set of queries run on Server1 and Server2.

a) **Server1** **b) Server2**

Fig 2. Standard deviation for every set of queries

The second experiment reflects the index presence on the search columns.

Figure 3 shown the minim and maxim response time for every set of queries run on Server1 and Server2 with column index.

a) Server1 b) Server2

Fig 3. Minim and maxim response times for every set of queries with column index

Figure 4 shown the standard deviation for every set of queries run on Server1 and Server2 with column index.

a) Server1 b) Server2

Fig 4. Standard deviation for every set of queries with column index

The recorded response times are reflecting the execution time for the subset queries but, also, include table source changing and the communication time between the application server and the database server, as long the set of queries are included in PHP applications run on the server.

The presence of indexes on the search columns is reflected in an improvement of the results:

a. **Server 1**: 2.6% - first set of queries, 5.35% - for the second set of queries and 1.44% for the third set of queries
b. **Server 2**: 1.53%- first set of queries, 0.76% - for the second set of queries and 3.43% for the third set of queries

C-SGBD Final Phase – Stability Evaluation of the System

C-SGBD fourth phase resulted in some processed results, reflecting the system stability. A level of stability is described by the results standard deviation between the same subset of queries and to have a minimum standard deviation for the result data can be interpreted as a first sign of a good stability for the system.

C-SGBD also takes into consideration other significant information in calculating the final stability indicator:

- The number of the records in a subset *N*
- The period of time when the queries are run, reflected in an indicator *pw*. This indicator is calculated basing on the daily workload of the DBMS server. The workload is underlined by the hosting provided statistics.

As long as most of the queries are run from different clients in a concurrent environment, the raw results also contain the exact time of the recordings. The period of time of every result subset is obtained in a specific level of system workload and pw indicator is taken into consideration when the response time enters in the standard deviation calculation.

The average deviation values calculated basing on all subsets medium deviations, previously obtained, are show in Figure 5:

a) Server 1 b) Server 2

Fig. 5: Average deviation values for every set of queries

Basing on the Gdev obtained and a percentage of the server workload within the running day, for the data generation moment, pw, the final Stability Indicator (SI) reflects the way the system responds during a normal operational runtime, with multiple concurrent users, at different workloads.

SI is obtained by a formula containing both the subset queries deviation obtained at fourth Phase, but also a significance value for the system workload.

The lower SI is indicating the most stable system in the evaluation procedure:

SI $_{Server1}$= 0.068034213

SI$_{Server2}$ = 0.107156

The final phase of C-SGBD can provide an indicator for any DBMS system for its stability during normal operation. As we can easily observe, Server1 proved to be more stable, with lower standard deviations in the response times, although the response times were not the best, comparing with Server2.

Conclusions

C-SGBD can offer a methodology to analyze a software system with database performance stability. The procedure is easy to implement on any system and the data have a high representativeness for a usual system at runtime.

The final indicator, SI, can provide a useful tool to compare two different systems, from the stability in performances point of view.

In the studied systems, Server2 provided lower response times, having better performances in terms of the classic response time criteria.

C-SGBD provides a different point of view to analyze a DBMS, starting from the stability point of view. Using the proposed procedure, C-SGBD results were better for Server 1, which proved to be more stable.

Our efforts in the presented procedure were centered in the system stability of a system at runtime. Its purpose is to evaluate a working, implemented system, to compare two different runtime systems in order to provide useful information in terms of performance stability.

Abstract

Density-based clustering algorithms can accurately identify arbitrary shaped clusters, characteristic which makes them advantageous for many real-life datasets. However, most density-based clustering algorithms are affected by the curse of dimensionality, since they rely on distance metrics and range queries. In this paper, we demonstrate how density-based clustering algorithms can exactly cluster short text documents using a modern document embedding model, specifically Doc2Vec. We evaluate the accuracy of a classic density-based clustering algorithm, DBSCAN, and one of its recent variants, HDBSCAN, using two distinct quality functions, the Adjusted Rand Index and the Adjusted Mutual Information.

Keywords: Text Clustering, Density Clustering, Document Embeddings

Introduction

Clustering is a Data Mining operation that aims to assign similar objects to the same group (cluster) while maintaining dissimilar objects separately. Density-based clustering methods are algorithms (Campello et al., (2013, April)) that define clusters as regions of high density surrounded by sparse regions (Sander et al. (1998)). However, most density-based clustering algorithms are affected by the "curse of dimensionality" and therefore perform well especially for low-dimensional data (Assent, I. (2012)).

Cite this Article as: Iulia-Maria RADULESCU, Ciprian-Octavian TRUICA, Elena Simona APOSTOL, Alexandru BOICEA, Mariana MOCANU, Daniel Calin POPEANGA and Florin RADULESCU "Density-based Text Clustering using Document Embeddings" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In this paper, we evaluate two density-based algorithms for text clustering of a large dataset, i.e., DBSCAN and HDBSCAN which adds hierarchical clustering on top of DBSCAN. To overcome the limitations imposed by the curse of dimensionality, we use two variants of the Doc2Vec document embedding model, i.e., distributed memory (PV-DM) and distributed bag of words (PV-DBOW). Using this approach, the experimental results show that density-based clustering performance is improved.
The rest of the paper is organized as follows. Section 2 presents the outcomes of other papers regarding density-based text clustering. Section 3 details the theoretical concepts which build up the proposed pipeline, describing the chosen preprocessing methods, the architectures comprising the Doc2Vec document embedding models, the analyzed clustering algorithms, and the employed evaluation measures. Section 4 presents the experimental setup and discusses the experimental results. Finally, Section 5 summaries our findings and hints at future research.

Related Work

Several authors have assessed the accuracy of the density-based text clustering process.

Ikonomakis et al. (2019) apply the DBSCAN algorithm on a set of 1201 documents, extracted from the Reuters Corpus. Since the authors are aware that DBSCAN does not cluster high-dimensional datasets accurately, they reduce the dimensionality of the data to 100, using a simple combination of Document Frequency and Inverted Document Frequency (Ikonomakis et al., (2019)). However, their results show that a considerable part of the distinctive information is lost in the process since the DBSCAN algorithm assigns most of the documents (over 900) to the same cluster.

Mendonça et al. (2019) analyze the effectiveness of the following acknowledged clustering algorithms: i) Spectral Clustering, ii) Mean Shift, and iii) DBSCAN, applied to free text documents. The authors assess the aforementioned algorithms on two real-world datasets: i) a collection of BBC sports articles from 2004 to 2005 and ii) a corpus comprised of medical abstracts. Although Mendonça et al. (2019) uses Word2Vec to generate the embeddings, DBSCAN obtains extremely low accuracy (-8.3 Normalized Mutual Information score on the first dataset and -3.2 Normalized Mutual Information score on the second one). Similar to (Ikonomakis et al., (2019)), DBSCAN assigned all documents to the same cluster.

Ingaramo et al. (2008) assess the accuracy of several density-based algorithms, namely MajorClust, DBSCAN, and Chameleon, on short-text and narrow domain text-corpora. The dataset consists of i) a low complexity collection of medium-length documents about well-differentiated topics, ii) a medium complexity corpus comprised of scientific abstracts; the following four categories were targeted: 1) Machine Learning, 2) Heuristics in Optimization, 3) Automated Reasoning and 4) Autonomous Intelligent Systems., and iii) the CiCLing2002 corpus with high complexity, containing narrow domain abstracts. The authors conclude that for medium-length documents belonging to well defined categories, the algorithms are exact. However, terms with low frequencies negatively impact the results, especially when narrow domains are involved.

Methodology

Text Preprocessing

In order to lower the input dataset's dimensionality and to partially eliminate noise, we reduce the word inflections to their base form, employing two distinct methods: stemming and lemmatization.

Stemming. The Porter Stemmer is one of the most popular stemming algorithms and relies on the observation that suffixes of English words consist of smaller and simpler suffixes (Jivani, A. G. (2011)). The algorithm iterates through five steps, trying to apply a set of rules for suffix removal according to a number of conditions. Whenever a rule complies, it is applied to the suffix and the algorithm performs the next step.

Lemmatization. Similar to stemming, lemmatization removes inflectional endings, but instead of trimming words, it transforms them into their dictionary root. Thus, the lemmatization process requires the use of dictionaries. WordNet (Miller, G. A. (1995)) is an open-source English language database that also establishes semantic relationships between words, frequently used in the lemmatization process.

Document Embeddings

In order to be processed by the clustering algorithms, the textual information must be transformed into a numeric format. Although the TF-IDF embedding model (Kim et al. (2019), Truica et al., (2016, September)) is frequently employed for this task, it holds a number of disadvantages: it does not account for the word similarities or the order of the words and it produces high dimensional results. The Doc2Vec embedding framework overcomes these shortcomings and helps improve the clustering algorithms accuracy (Radu et al., (2020, May)). Therefore, we use Doc2Vec word embeddings in our pipeline.

Doc2Vec (also called Paragraph Vector) (Le et al. (2014 January)) is a document embedding method that learns continuous distributed vector representations for text documents of various sizes.
Similar to Word2Vec (Mikolov et al. (2013)), Doc2Vec uses a shallow neural network, with a single hidden layer, in order to compute the n-dimensional vectors. The word embeddings are captured by the hidden layer as a result of the prediction process. Two learning processes are proposed for Word2Vec:
i) Continuous Bag of Words (CBOW), which predicts a word given its context, and
ii) Skip-Gram Model (SkipGram), which predicts a target word's context given that target word, where the context of a target word represents the target word's neighbors.

Doc2Vec extends the aforementioned methods by adding paragraph (document) information into the models and utilizing it in the prediction process (Le et al. (2014 January)). Doc2Vec uses two approaches:
i) Distributed Memory Model (PV-DM), and
ii) Distributed Bag of Words Model (PV-DBOW).

The PV-DM model relies on concatenating or averaging a paragraph feature vector, representing the document, to the word vectors, in order to predict the next word in a context. The paragraph vectors associated with each document are shared only across contexts sampled from the same document, while the word vectors are shared across documents.

The PV-DBOW model adapts the Skip-Gram model to train paragraph vectors for predicting the context, instead of words. The prediction task implies classifying randomly sampled words with respect to the paragraph vector.

The word and paragraph vectors are trained through stochastic gradient descent and backpropagation.

Clustering

In this section we detail the theoretical concepts which underlie the two density-based clustering algorithms which we analyze: DBSCAN and its recent variant, HDBSCAN.

The DBSCAN Algorithm

DBSCAN (Density Based Spatial Clustering of Applications with Noise) (Ester et al. (1996, August)) is a density-based clustering algorithm that accurately discovers clusters with arbitrary shapes.

Ester et al. introduce a formal model for defining density-based clusters as base for the DBSCAN algorithm (Schubert et al., (2017)). DBSCAN relies on the intuition that each cluster extends above a certain density threshold, therefore characterizing density-based clusters using the distance range ε and the minimum number of neighbors $m_{pts}$of each object in the input dataset, using the following concepts: *core points*, *directly density reachability* and *density reachability* [3].

The core points and the objects which are directly density reachable or density reachable from the core points assemble dense regions, separated by regions with low density. Intuitively, a core point's neighbors (the objects situated at a distance less or equal to ε to a core point) belong to the core point's cluster. If any of the core point's neighbors is also a core point, all of its neighbours will be included in the same cluster (Schubert et al., (2017)).

The HDBSCAN Algorithm

HDBSCAN (Campello et al., (2013, April)) is a density-based clustering algorithm that produces a complete density-based clustering hierarchy, which can be further condensed into a simpler form yielding the final clusters.

The algorithm iterates through the following steps: i) the space is transformed such that the outliers are shifted from both the density islands and each other, ii) the input dataset is represented as a weighted graph, iii) the minimum spanning tree of the graph at step ii) is used to build a hierarchy of connected components iv) the cluster hierarchy is condensed according to the minimum cluster size, outputting the resulting clusters.

Space transformation: In order to delimit the outliers from the high-density regions, a custom metric (mutual reachability distance) is used for transforming the distances between the input dataset's objects. The mutual reachability distance relates to each of the input dataset's object $x \in X$ core distance, defined as the distance between an input object and its *k*-nearest neighbor, noted $d_{core}(x_p)$ where $x_p \in X$. The transformation of the original metric in terms of the mutual reachability distance is based on the intuition that objects in sparse regions tend to have larger core distances, as opposed to objects belonging to regions with high density, the outliers being moved away from both the density islands and each other as a result. The mutual reachability distance is presented in Definition 1 (Campello et al., (2013, April)).

Definition 1 (Mutual Reachability Distance) (Campello et al., (2013, April)): The mutual reachability distance between two objects $x_p$and $x_q$in the dataset X w.r.t m_{pts}, is defined as (Campello et al., (2013, April)):

$$d_{mreach}(x_p, x_q) = max\{d_{core}(x_p), d_{core}(x_q), d(x_p, x_q)\}.$$

Building the Mutual Reachability Graph and computing its Minimum Spanning Tree: Using the previously transformed distances, the Mutual Reachability Graph is built. This graph holds the input dataset's objects in its nodes. Any two nodes are interconnected by a weighted edge, representing the transformed distance between them. In order to identify the dense regions (the clusters) at each density level, the Mutual Reachability Graph is computed using a Minimum Spanning Tree. The tree is afterwards separated into a hierarchy of connected components. This is an equivalent optimal version of computing a Single-Linkage hierarchy of the space of transformed distances at each density level.

Condensing the cluster hierarchy: Since the dendrogram computed at the previous step is hard to understand, especially for large and noisy datasets, Campello et al. rely on the following idea in order to condense it: given a probability density function, its connected components can evolve only in three distinct directions as the density level increases: i) they shrink, but remain connected, ii) they are disconnected into smaller components, iii) they disappear completely (Hartigan, J. A. (1975), Gupta et al., (2008)). Therefore, the authors introduce another parameter, m_{clSize}, defined as the minimum number of objects incorporated by a cluster. Therefore, when splitting a connected component (a cluster), if any of its children contains less than m_{clSize}objects, the parent connected component will preserve its identity while the child whose size is less than m_{clSize} will be labeled as noise. Applying the aforementioned method results in a significantly more straightforward hierarchy.

Evaluation Methods

We evaluate the previously described pipeline using two evaluation measures, each from a distinct category: i) the Adjusted Rand Index (ARI), which is based on counting pairs of objects in the resulting clustering versus a ground truth clustering and ii) the Adjusted Mutual Information (AMI), based on the information-theoretical mutual information (Wagner et al., (2007)).

Adjusted Rand Index

The Adjusted Rand Index (ARI) computes the level of agreement between the algorithm's results and a reference clustering (Truica et al., (2018, September)). ARI's formal definition (Equation (1)) relies on the contingency table (Definition 2 (Truica et al., (2018, September))).

Definition 2 (Adjusted Rand Index) (Truica et al., (2018, September)): Given a set $S = \{s_1, s_2, \ldots, s_n\}$ of n elements and two groupings $X = \{X_1, X_2, \ldots, X_r\}$and $Y = \{Y_1, Y_2, \ldots, Y_t\}$ the overlap between X and Y is summarized in a contingency table $[n_{i,j}]$ where $n_{i,j} = |X_i \cap Y_i|$, $a_i = \sum_{j=1}^{s} n_{ij}$, and $b_j = \sum_{i=1}^{r} n_{ij}$.

$$ARI = \frac{\sum_{i,j}\binom{n_{ij}}{2} - \frac{\left(\frac{\sum_i a_i}{2}\right)\left(\frac{b_j}{2}\right)}{\binom{n}{2}}}{\frac{1}{2}\left(\sum_i\binom{a_i}{2} + \sum_b\binom{b_j}{2}\right) - \frac{\left(\frac{\sum_i a_i}{2}\right)\left(\frac{b_j}{2}\right)}{\binom{n}{2}}} \quad (1)$$

Adjusted Mutual Information

The Adjusted Mutual Information (Vinh et al. (2010)) assesses the similarity between a given output (U) and a ground truth (V) and is defined in Equation (2), where MI is the mutual information between clusterings, E represents the expected mutual information, and H is the entropy.

$$AMI = \frac{MI(U,V) - E(C,K)}{avg(H(C),H(K)) - E\ (MI(U,V)} \quad (2)$$

Experimental Results

Dataset

We assess the accuracy of the density-based DBSCAN and HDBSCAN algorithms on a set of 12263 article summaries extracted from the Arxiv database (https://arxiv.org/). We target the following five distinct categories: Databases (3000 documents), Geophysics (3000 documents), Metric Geometry (3000 documents), Genomics (2171 documents), and Economics (1092 documents).

Since both DBSCAN and HDBSCAN are affected by the "curse of dimensionality" (Assent, I. (2012)) we generate low dimensional embeddings using Doc2Vec by setting the model's hidden layer size to six neurons. We train the model for 300 epochs.

We determine DBSCAN's ε parameter following Gaonkar et al. (2013) and Liu et al.'s (2007, June) approach, namely by computing a *k*-distance plot with respect to the 11th nearest neighbor ($k = 11$). We choose the kth nearest neighbor as specified in Liu et al. (2007, June): $2 \cdot dim - 1$, where $dim = 6$ represents the dimensionality of the input dataset.

When combining the Porter Stemmer and WordNet Lemmatizer preprocessing algorithms with the PV-DM embedding model we find that the inflection points of the *k*-distance plot are situated near 0.012, respectively 0.015 values on the OX axis. Thus we set $\varepsilon = 0.0125$, respectively $\varepsilon = 0.015$. We empirically set $m_{pts} = 6$. We establish the *PV-DBOW - Porter Stemmer* and *PV-DBOW - WordNet Lemmatizer* associations' corresponding parameter values in a similar manner, obtaining: $\varepsilon = 0.01$ and $m_{pts} = 5$, respectively $\varepsilon = 0.011$ and $m_{pts} = 6$.

We mention that for the DBSCAN algorithm we use cosine similarity instead of the Euclidean metric since it is frequently used in text clustering tasks.

For the HDSBCAN algorithm, we set $m_{clSize} = 1000$ since the smallest cluster contains approximately 1000 summaries. Then, we vary the m_{pts} parameter, empirically choosing $m_{pts} = 7$, respectively $m_{pts} = 3$ for the PV-DM and PV-DBOW word embeddings model architectures.

Experimental Setup

We run our experiments on an Oracle Linux Server 7.6 machine with 64 GB RAM and 40 CPUs. We choose Python 3.7 as the programming language, making use of its libraries: sklearn (https://scikit-learn.org/stable/), nltk

(https://www.nltk.org/), gensim (https://radimrehurek.com/gensim/index.html) and hdbscan (https://pypi.org/project/hdbscan/).

Results

We display the evaluation results in Tables 1 and 2. The *WordNet Lemmatizer - Doc2Vec with PV-DM architecture* combination yields the best results for both clustering algorithms: 0.56 and 0.46 ARI for DBSCAN, respectively for HDBSCAN and 0.59 and 0.54 AMI for DBSCAN, respectively for HDBSCAN.

As expected, the PV-DM Doc2Vec architecture produces more accurate results for both DBSCAN and HDBSCAN algorithms, since PV-DM is known to achieve significantly more precise results (Le et al. (2014 January)).

Both clustering algorithms obtain lower accuracies when we use the Porter Stemmer for text processing instead of the WordNet Lemmatizer, as a result of stemming being less precise than lemmatization.

Table 1: Adjusted Rand Index values

Algorithm	Embedding	Porter Stemmer	WordNet Lemmatizer
DBSCAN	PV-DM	0.43	**0.56**
	PV-DBOW	0.37	0.53
HDBSCAN	PV-DM	0.41	**0.46**
	PV-DBOW	0.30	0.43

Table 2: Adjusted Mutual Information values

Algorithm	Embedding	Porter Stemmer	WordNet Lemmatizer
DBSCAN	PV-DM	0.51	**0.59**
	PV-DBOW	0.46	0.57
HDBSCAN	PV-DM	0.52	**0.54**
	PV-DBOW	0.5	0.53

We graphically display the Minimum Spanning Trees and the Condensed Trees outputted by the HDSBCAN algorithm, when applying the WordNet Lemmatizer text preprocessing method in combination with Doc2Vec word embeddings, using the PV-DM, respectively the PV-DBOW architecture in Figure 1.

The Minimum Spanning trees (Figure 1 (a) and Figure 1 (c)) offer a number of insights on how the HDBSCAN algorithm represents the input dataset in order to obtain the clusters: both trees are visually partitioned into three main regions, consisting of a large number of nodes, densely interconnected by edges with high weights (marked with dark shades of blue). The principal sub-trees are interconnected by several edges with low weights (marked with light shades of green and yellow). Therefore, each minimum spanning tree is condensed into a representation which contains three clusters of approximately the same size (Figure 1 (b) and Figure 1 (c)).

(a) Minimum Spanning Tree, PV-DM, WordNet

(b) Condensed Tree, PV-DM, WordNet

(c) Minimum Spanning Tree, PV-DBOW, WordNet

(d) Condensed Tree, PV-DBOW, WordNet

Figure 1: The Minimum Spanning Trees and the Condensed Trees for the WordNetLemmatizer used alongside the Doc2Vec PV-DM and PV-DBOW architectures

Conclusions

In this paper we evaluated the accuracy of two related density-based algorithms, namely DBSCAN and HDBSCAN, in combination with two distinct text preprocessing methods (the Porter Stemmer and the Louvain Lemmatizer) and the Doc2Vec document embedding model, for the text clustering task. We evaluated our outcomes using two different quality functions: the Adjusted Rand Index and the Adjusted Mutual Information.

We obtained generally good results, significantly higher than the ones presented in the majority of the other papers on this subject, referenced in the *Related Work* section. The WordNet Lemmatizer in combination with Doc2Vec's PV-DM

network architecture outputs the best AMI and ARI values: 0.59 and 0.54 for AMI DBSCAN, respectively HDBSCAN and 0.56 and 0.46 for ARI for DBSCAN, respectively HDBSCAN.

We consider extending our framework by employing more flexible density-based clustering algorithms such as DENCLUE (Hinneburg et al. (2007, September)). We also intend to use a combination between Doc2Vec's main architectures, PV-DM and PV-DBOW for generating the document embeddings.

Abstract

In this paper, we discuss an purpose, construction mechanism and practical application of classical-quantum decision trees in the process of constructing hybrid classical-quantum decision forests. Traditional computational mechanisms are good at processing data about currently used data storage capacity units. Looking at the speed of growth and the amount of new data owing in, as well as the need to archive historical data, it will soon be necessary to resort to quantum representations of classical methods implemented on quantum computers. The article discusses the practical implementation of quantum recommendation circuits for profiling users of the system.

Keywords: quantum computing, recommendation mechanism, implementation algorithm, quantum circuit, decision trees, machine learning

Introduction

In this article, the authors focus on presenting the concept and physical implementation of the hybrid decision tree model in combination with quantum programming methods for quantum computers. The proposed solution applies to the IBM Quantum Experience hardware platform based on the IBM Q cloud architecture [1,15]. It is one of the mechanisms of the classic-quantum hybrid recommendation system. The test data set is real data containing information about film positions taken from the OMDB database [17].

The amount of new information collected is exponential [18]. Every day, vast amounts of new data are collected that require fast processing and decisions based on them. The presented solution is used to build the classifier being the mechanism of the recommendation system. It is responsible for the proper and effective classification of users according to specific criteria [2,3]. He is responsible for the correct process of profiling system users, which will allow to precisely and precisely define the interests and preferences of each new or existing system user. The expected result is accurate and precise release of predictions, which are apt to coincide with the system users preferences profiles.

The article [19] deals with the issue of quantum version of classifcation decision trees, which were described in the application of the C5.0 algorithm for constructing decision tree classifier in machine learning techniques [6]. A comparative analysis of the complexity of classical algorithms and their quantum counterparts while maintaining a high degree of similarity is presented in the paper [20]. Limitations of such a solution as quantum technology are also indicated. Implementations of the circuit on the IBM QX4 quantum computer are presented in the publication [21], which also presents an example of a circuit that gives probability results without a high degree of interference from technological conditions.
The application of quantum mechanisms in the discussed case consists in increasing the computational efficiency and time optimization for determining consistent features in the profiling stage by determining the

user feature vector. This article introduces the concept of hybrid classical-quantum decision tree due to the use of two separate techniques, classical computer science and quantum computer science. Where for which it is necessary to perform calculations according to the quantum model implemented using Python on the IBM Q quantum hardware platform.

In addition, a complex structure is proposed made of many classical-quantum decision trees, calling it a hybrid classical-quantum decision forest. The structure of such a forest consists of a set of user feature vectors obtained based on the profiling process using classical-quantum decision trees. The practical application of the presented mechanisms and structures is the hybrid classical-quantum mechanism of the recommendation system for film platform users. This paper is a continuation part describing the hybrid classical-quantum methods of recommendation mechanisms and refers to the previously created [22] article.

The organization of the article is as follows: in the part of 2 discusses the application of hybrid classification mechanisms and presents the method of using and combining classical and quantum computing computational methods. Point 3 presents the classic representation of the decision tree. Point 4 presents the proposed hybrid solution based on classic decision trees and the quantum representation of the Grover algorithm. Point 4.1 is a numerical analysis of the amplifing of the determined feature using the Grover algorithm for two and three qubits. Point 4.2 shows the details of making a hybrid decision tree along with examples and how to build hybrid decision forests. The summary of the article is given in the section 5, where the final conclusions and some comments about possible further work on the method described in this article were given. The article end with a list of the cited bibliography.

Application of hybrid classification mechanisms

Hybrid classification mechanisms with high efficiency can be used as independent methods for determining in the shortest possible time the final results being elements of further prediction. Hybridity results from the use in synergic combination of two methods. Classical and quantum. In the proposed solution, quantum computational methods are used as the last element of the entire structure of the classification mechanism responsible for the correct profiling of system users [7]. It allows to determine the appropriate matching characteristic from the whole set and to amplify the amplitude of the probability of occurrence indicated by the mechanism of profiling the final characteristic. The process of creating a user profile with a specific vector corresponding to a given user takes place using classical computer science mechanisms - decision trees and quantum computer science mechanisms - the Grover algorithm. The latter finds its application in the last stage of selection and amplification of the indicated probability value for a given amplitude.

The use of quantum methods is intended to reduce the time needed to perform the profiling process. As mentioned before, recommendation systems, decision support systems and expert systems are one of the key applications. The properties and benefits of the model and quantum environment are designed to reduce the time it takes to create a user profile.

Such a transition through one hybrid decision tree and the creation of a user profile vector can be used as a component in the construction of the entire decision forest. Such a hybrid classic-quantum decision forest consists of vectors containing a user profile [8]. In this way, you can segment user profiles into individual layers based on your vector. The forest built in this way can be divided into smaller ones or combined into larger groups depending on the segmentation rules in force in a given system. The forest of decision trees can be used as an illustration of the users environment.

Another application is the definition of a forest segment as a group of elements used to teach and recommend in complex predictive systems responsible for indicating the positions most popular to new system users who do not have a user profile and history of system activity.

Classical Representation

In the proposed solution, the decision tree will be used in the process of profiling system users. It is an example of a multi-level decision-making process where the description of a specific phenomenon - the user's profile is the use of a full set of conditioning, describing and decision-making features.

Should be a specify set of decision rules for each node. Specify the rules for selecting terminating nodes for which the final classification of the specified profile will be determined. One of the possibilities is the use of

auxiliary algorithms for optimization, e.g. by pruning a tree. It is necessary to determine whether the divisions taking place on the indicated tree nodes are informative, for this purpose the concept of entropy change is used, which in itself for the problem of information theory is presented as the average amount of information on features from an unspecified proabilistic source. Each of these features occurs with the indicated probability . defines the concept of entropy expressed as follows:

$$E_n = -\sum_{n=1}^{i} P(c_i)\log_2(P(c_i)) \tag{1}$$

where $P(c_i)$ specifies the probability of choosing the c_i feature.

The decision tree in the profiling process is created on the basis of entropy changes in subsequent nodes. A large entropy change in the nodes means a high value of the feature, there is the most valuable information coming from this node. The value of zero means that we are dealing with the end of the tree and the same profiling stage, however, this is not a valuable result in the sense of obtaining information.

Hybrid Proposition

The hybridity of the approach is based on the use of the Grover algorithm to strengthen the probability amplitudes of the features indicated in the user profiling process using decision trees. Thus, in the node responsible for the selection of features was used the previously mentioned algorithm. The calculations and the entire implementation of the hybrid tree was written in Python and performed in the Qiskit quantum computing environment. In addition, actual implementation was performed on the IBM Q quantum computer [12].

Numerical Analysis

This part of the article presents the numerical analysis of the process of strengthening alg. Grover for a two-qubit circuit case where N=4, because $N = 2^n$ where *n* is the number of qubits [10,11,14]. In the present case, n=2. We will prove the amplification for the indicated value, e.g. 2, but remember that in a two-qubit system: $00 \to 0, 01 \to 1, 10 \to 2, 11 \to 3.$

$$|\psi_0\rangle = |00\rangle \tag{2}$$

We indicate the following initial state:

We use Hadamard's gate to get the state:

$$|\psi\rangle = H^{\otimes 2}|00\rangle = \frac{1}{\sqrt{4}}\sum_{i=0}^{3}|i\rangle = \frac{1}{2}(|00\rangle + |01\rangle + |10\rangle + |11\rangle) \tag{3}$$

Specify the searched element $|i\rangle$, let it be 2 or $|10\rangle$ The function definition for the searched element takes the form:

$$U_f(|10\rangle|-\rangle) = -|10\rangle|-\rangle \tag{4}$$

otherwise:

$$U_f(|i\rangle|-\rangle) = -|i\rangle|-\rangle \tag{5}$$

For ease of use, enter the additional $|\phi\rangle$status, which is a registry description without the state you specified (without the state indicated in this case, $|10\rangle$):

$$|\phi\rangle = \frac{1}{\sqrt{3}} \sum_{i=0, i\neq 2}^{3} |i\rangle = \frac{|00\rangle + |01\rangle + |11\rangle}{\sqrt{3}} \tag{6}$$

we get the state of $|\psi\rangle$, whose form is as follows:

$$\begin{aligned} |\psi\rangle &= \tfrac{1}{\sqrt{4}}(|00\rangle + |01\rangle + |10\rangle + |11\rangle) = \tfrac{1}{\sqrt{4}}(|00\rangle + |01\rangle + |11\rangle) + \tfrac{1}{\sqrt{4}}|10\rangle \\ &= \tfrac{\sqrt{3}}{\sqrt{4}} \tfrac{(|00\rangle + |01\rangle + |11\rangle)}{\sqrt{3}} + \tfrac{1}{\sqrt{4}}|10\rangle = \tfrac{\sqrt{3}}{\sqrt{4}}|\phi\rangle + \tfrac{1}{\sqrt{4}}|10\rangle \end{aligned} \tag{7}$$

hence we know that the necessary angle for turning for non-amplification elements will be:

$$\theta = 2 \arccos \frac{\sqrt{3}}{\sqrt{4}} = 2 \arccos \frac{\sqrt{3}}{2} \tag{8}$$

$$\frac{\theta}{2} = \arccos \frac{\sqrt{3}}{4} = \frac{\pi}{6} \tag{9}$$

$$\theta = \frac{\pi}{3} \tag{10}$$

which corresponds to the angle $\theta = 60°$and this angle should be turned. Proceed to determining the probability value of for the e$U_f$re registry, determine : $|\psi_1\rangle$

$$|\psi_1\rangle|-\rangle = U_f(|\psi\rangle|-\rangle) = (\frac{|00\rangle + |01\rangle - |10\rangle + |11\rangle}{\sqrt{4}})|-\rangle \tag{11}$$

$$|\psi_1\rangle|\psi\rangle - \frac{2}{\sqrt{2^n}}|i_{uf}\rangle = |\psi\rangle - \frac{2}{2}|10\rangle = |\psi\rangle - |10\rangle \tag{12}$$

therefore:

$$|\psi\rangle = \frac{1}{\sqrt{4}}(|00\rangle + |01\rangle + |10\rangle + |11\rangle) = \frac{1}{2}(|00\rangle + |01\rangle + |10\rangle + |11\rangle) \tag{13}$$

$$|\psi\rangle = \frac{1}{2}|00\rangle + \frac{1}{2}|01\rangle + \frac{1}{2}|10\rangle + \frac{1}{2}|11\rangle \quad |-|10\rangle \tag{14}$$

$$\begin{aligned} |\psi\rangle - |10\rangle &= \tfrac{1}{2}|00\rangle + \tfrac{1}{2}|01\rangle + \tfrac{1}{2}|10\rangle + \tfrac{1}{2}|11\rangle - |10\rangle \\ &= \tfrac{1}{2}|00\rangle + \tfrac{1}{2}|01\rangle - \tfrac{1}{2}|10\rangle + \tfrac{1}{2}|11\rangle \\ &= \tfrac{1}{2}(|00\rangle + |01\rangle - |10\rangle + |11\rangle) \end{aligned} \tag{15}$$

what we get:

$$|\psi_1\rangle = \frac{1}{2}(|00\rangle + |01\rangle - |10\rangle + |11\rangle) \tag{16}$$

Use the operator of rotation around the average to indicate the amplitude of the indicated element:

$$|i_{uf}\rangle = |10\rangle \tag{17}$$

$$|\psi_2\rangle = 0|\phi\rangle + |10\rangle \tag{18}$$

$$\frac{2^{n-2}-1}{2^{n-2}}|\psi\rangle = \frac{2^{2-2}-1}{2^{2-2}}|\psi\rangle = \frac{2^0-1}{2^0}|\psi\rangle = \frac{1-1}{1}|\psi\rangle = 0|\psi\rangle \tag{19}$$

$$0|\psi\rangle = 0(\frac{\sqrt{3}}{\sqrt{4}})|\phi\rangle + \frac{1}{4})|10\rangle = 0|\phi\rangle + 0|10\rangle \tag{20}$$

$$\frac{2}{\sqrt{2^n}}|i_{uf}\rangle = \frac{2}{\sqrt{2^2}}|i_{uf}\rangle = \frac{2}{\sqrt{4}}|i_{uf}\rangle = \frac{2}{2}|i_{uf}\rangle = 1|i_{uf}\rangle \tag{21}$$

$$|\psi_2\rangle = (2|\psi\rangle\langle\psi| - \mathbb{I})|\psi_1\rangle = \frac{2^{n-2}-1}{2^{n-2}}|\psi\rangle + \frac{2}{\sqrt{2^n}}|i_{uf}\rangle \tag{22}$$

where $|i_{uf}\rangle$s the amplitude of the indicated element after the use operator of rotation around the average.

$$|\psi_2\rangle = 0|\psi\rangle + 0|10\rangle + 1|10\rangle = 0|\psi\rangle + 1|10\rangle \tag{23}$$

thus we get:

$$|\psi_2\rangle = 0|\psi\rangle + 1|10\rangle \tag{24}$$

The performed measurement operation results in the form of 100 % gain of the indicated ele$|10\rangle$t , it means that the indicated element is in your database with 100 % confidence. In a two-qubit system, the probability of choosing from a 4-element set of any indicated element is 100%.

Another is the case of strengthening the three-qubits circuit of Grover's algae. The steps of the algorithm are the same as in the case of a two-qubit, so in the case of an eight-element database with the indicated index constituting the initial state, the initial state vector will take the form $|\psi_0\rangle = |000\rangle$. It should be noted that *N=8* becau $N = 2^n$, where n is the number of qubits. In the present case, *n=3*. We will prove the amplification for the indicated value, e.g.: 4, but please note that in a three – qubit system: $000 \rightarrow 0, 001 \rightarrow 1, 010 \rightarrow 2, 011 \rightarrow 3, 100 \rightarrow 4, 101 \rightarrow 5,$ $110 \rightarrow 6, 111 \rightarrow 7$, as indicated above, we have the initial state: $|\psi_0\rangle = |000\rangle$g the Hadamard gate we get:

$$|\psi\rangle = H^{\otimes 3}|000\rangle = \frac{1}{\sqrt{8}}\sum_{i=0}^{7}|i\rangle = \frac{1}{\sqrt{8}}(|000\rangle+|001\rangle+|010\rangle+|011\rangle+|100\rangle+|101\rangle+|110\rangle+|111\rangle) \tag{25}$$

We indicate in the notation amplified and in the context of the database the element 4 or 100 sought, and then the necessary operator with t$U_f$form:

$$U_f(|i\rangle|j\rangle) = |i\rangle j \otimes |f(i)\rangle \tag{26}$$

so for the searched item we get the form:

$$U_f(|100\rangle|-\rangle) = -|100\rangle|-\rangle \tag{27}$$

but otherwise the form will take the following form:

$$U_f(|i\rangle|-\rangle) = |i\rangle|-\rangle \tag{28}$$

Enter the additional $|\phi\rangle$ state, as:

$$|\phi\rangle = \frac{1}{\sqrt{N-1}} \sum_{i=0, i\neq 4}^{N-1} |i\rangle \tag{29}$$

not having the indicated condition:

$$|\phi\rangle = \frac{1}{\sqrt{7}} \sum_{i=0, i\neq 4}^{7} |i\rangle = \frac{|000\rangle + |001\rangle + |010\rangle + |011\rangle + |101\rangle + |110\rangle + |111\rangle}{\sqrt{7}} / \cdot \sqrt{7} \tag{30}$$

therefore:

$$\sqrt{7}|\phi\rangle = |000\rangle + |001\rangle + |010\rangle + |011\rangle + |101\rangle + |110\rangle + |111\rangle \tag{31}$$

where:

$$|\psi\rangle = \frac{1}{\sqrt{8}}(|000\rangle + |001\rangle + |010\rangle + |011\rangle + |100\rangle + |101\rangle + |110\rangle + |111\rangle) \tag{32}$$

$$|\psi\rangle = \frac{1}{\sqrt{8}}(|000\rangle + |001\rangle + |010\rangle + |011\rangle + |101\rangle + |110\rangle + |111\rangle) + \frac{1}{\sqrt{8}}|100\rangle \tag{33}$$

$$|\psi\rangle = \frac{\sqrt{7}}{\sqrt{8}}|\psi\rangle + \frac{1}{\sqrt{8}}|100\rangle \tag{34}$$

hence we know that the angle required for rotation will be:

$$\theta = 2\arccos(\frac{\sqrt{7}}{\sqrt{8}}) = 41.4096^\circ \tag{35}$$

Moving on to calculating the probability value, one should perform the operation U_f obtain the form $|\psi_1\rangle$, so:

$$|\psi_1\rangle = |\psi\rangle - \frac{2}{\sqrt{2^n}}|i_{uf}\rangle = |\psi\rangle - \frac{2}{\sqrt{8}}|100\rangle \tag{36}$$

where:

$$|\psi\rangle = \frac{|000\rangle + |001\rangle + |010\rangle + |011\rangle + |100\rangle + |101\rangle + |110\rangle + |111\rangle}{\sqrt{8}} \tag{37}$$

further:

$$|\psi_1\rangle = \frac{1}{\sqrt{8}}(|000\rangle + |001\rangle + |010\rangle + |011\rangle + |100\rangle + |101\rangle + |110\rangle + |111\rangle) - \frac{2}{\sqrt{8}}|100\rangle \tag{38}$$

$$|\psi_1\rangle = \frac{1}{\sqrt{8}}(|000\rangle+|001\rangle+|010\rangle+|011\rangle+|101\rangle+|110\rangle+|111\rangle)+\frac{1}{\sqrt{8}}|100\rangle-\frac{2}{\sqrt{8}}|100\rangle \tag{39}$$

$$|\psi_1\rangle = \frac{\sqrt{7}}{\sqrt{8}}|\phi\rangle - \frac{1}{\sqrt{8}}|100\rangle \tag{40}$$

Perform rotation operator around the average:

$$|\psi_2\rangle = (2|\psi\rangle\langle\psi| - \mathbb{I})|\psi_1\rangle = \frac{2^{n-2}-1}{2^{n-2}}|\psi\rangle + \frac{2}{\sqrt{2^n}}|i_{uf}\rangle \tag{41}$$

which gives:

$$|\psi_2\rangle = \frac{2^{3-2}-1}{2^{3-2}}|\psi\rangle + \frac{2}{\sqrt{2^n}}|100\rangle \tag{42}$$

$$|\psi_2\rangle = \frac{1}{2}(\frac{\sqrt{7}}{\sqrt{8}}|\phi\rangle + \frac{1}{\sqrt{8}}|100\rangle + \frac{2}{\sqrt{8}}|100\rangle) \tag{43}$$

$$|\psi_2\rangle = \frac{\sqrt{7}}{2\sqrt{8}}|\phi\rangle + \frac{1}{2\sqrt{8}}|100\rangle + \frac{2}{\sqrt{8}}|100\rangle) \tag{44}$$

$$|\psi_2\rangle = \frac{\sqrt{7}}{4\sqrt{2}}|\phi\rangle + \frac{1}{4\sqrt{2}}|100\rangle + \frac{4}{4\sqrt{2}}|100\rangle) \tag{45}$$

For the second iteration, re-apply U_f to get:

$$|\psi_2\rangle = \frac{\sqrt{7}}{4\sqrt{2}}|\phi\rangle + \frac{5}{4\sqrt{2}}|100\rangle \tag{46}$$

Then turn around the average about the form:

$$|\psi_2\rangle = -\frac{\sqrt{7}}{8\sqrt{2}}|\phi\rangle + \frac{11}{8\sqrt{2}}|100\rangle \tag{47}$$

Finally performing the measurement operation for the indicated val$|100\rangle$ will be obtained with the probability expressed in the following way:

$$|100\rangle = (\frac{11}{8\sqrt{2}})^2 = \frac{121}{128} = 0,945313. \tag{48}$$

$$\begin{aligned} f(x) &= |123\rangle \\ &= |123\rangle \\ &= |123\rangle \\ &= |123\rangle \end{aligned} \tag{49}$$

Detail of Performance

The classic-quantum hybrid profiling tree was made in IBM Q cloud technology. With the help of the Python language and the Qiskit programming environment integrated into the IBM cloud.
The completed tree is one of the mechanisms of the proposed hybrid classical-quantum recommendation system. It is used to profile system users.

Algorithm 1 Hybrid profiling tree

Steps of conduct in the hybrid profiling tree:

(I) definition of the user type (new or registered),
(II) implementation of the transition through the levels of the profiling tree,
(III) depending on the selected path, start of the process of amplifying the probability amplitude for the feature of the object indicated in the process,
(IV) measurement of sub-register value,
(V) presentation of the probability result,
(VI) creating a profiling vector for the selected user,
(VII) placing the vector in a database constituting a set of unit elements of the hybrid profiling forest.

The method of operation consists in the fact that on the basis of collected information about the user's activity on his behavior, answers are given to the questions asked in the subsequent roots of the tree. Based on the answers given, one goes to the next stages of queries and so to the last root, which is the last ending list of the tree's execution. For specific cases, it is necessary to perform quantum computation mechanisms in order to quickly find the elements identified based on observation of user behavior.

Fig. 1. The control flow of proposed the hybrid profiling tree

The end result is the resulting vector describing together with the specified degree of final weight. The set values of intermediate and final weights depend on the method of determining the priority of the branch and the requirements specified on the basis of the specifications of the assumed system.

Fig. 2. Diagram of a hybrid classical-quantum profiling tree. The values on the branches indicate the weights for the selected decisions. GA stands for the quantum mechanism of searching for an element in the base and amplifying the probability amplitude using alg. Grover. The parametric value + X means weight gain for the selected decision. It results from the design assumptions of the recommendation system.

Index	Code	Genre	Actor	Title	Director
1	000	Western	Jack Nicholson	The Shawshank Redemption	Stanley Kubrick
2	001	Anime	Leonardo DiCaprio	Untouchables	Quentin Tarantino

(M)

(N)

(O)

Fig. 5. Presentation of two successive test scenarios, where Figures (I) and (L) show the test scenario for the indicated examples. Quantum circuits implemented for scenarios (I) and (L) are presented in diagrams (J) and (M). The corresponding hybrid profiling trees are presented in points (K) and (N), while the graphs (L) and (O) present the results of the obtained gain values for probabilities in the implementation of the quantum circuit using the Grover algorithm for the two indicated test scenarios.

Using the data obtained in this way, we can build a hybrid decision forest. It describes the preferences of users using the system including the values of user profiles. By expanding the implementation of the hybrid profiling tree, the number of paths available will increase and, as a result, the number of possible profiling final results will increase. This affects the size of the decision forest and its height as well as the number of trees.

The shape of the imaged forest structure and density depend on the number and value of samples. The height of the tree determines the value of a single sample, the result obtained in the process of passing through the profiling tree. The density determined by the number of trees in the forest will depend on the number of single passes made through the profiling tree, i.e. the number of user profiles prepared.

The forest can be a structure and a set of learning data for the next stage related to machine learning [9]. With the help of a harvested forest with a properly designed tree, you can make a qualitative assessment of the specific object to which the forest and the associated tree refe [4]r. It is worth mentioning that the forest can be built from one tree or from many trees, however, describing a specific object then such a forest will correspond to a specific issue [5]. If the forest is built of profiling trees directed to different objects, it will not be possible to read the content and evaluate the results contained in the forest in a clear and transparent way. Therefore, for a forest to define and describe an object, it must be built of trees that refer strictly to that object.

Below is a graphic interpretation of the hybrid profiling forest based on data obtained in the profiling process using hybrid trees.

Execution number	Final score
Result 1	2.333
Result 2	1.833
Result 3	1.583
Result 4	1
Result 5	2.5
Result 6	1.5
Result 7	6.833
Result 8	5.833
Result 9	4.833
Result 10	4
Result 11	3

Fig. 6. The table contains the values obtained in the profiling process for each of the possible variants allowed by the tree.

Summary

The proposed implementation of hybrid classical-quantum profiling trees helps in carrying out the profiling process quickly and efficiently, which with a large amount of data contained in the data set is of great importance. The proposed implementation uses a simulator and a real machine available to users of the quantum computing cloud to implement the computational quantum model. The combination of classical computer science and quantum calculations allows you to quickly select a selected element from the database and, in combination with classic calculations, gives you the opportunity to assign other data describing the selected object that is the target of the recommendation. One of the main advantages and an advantage over classic calculations is determining the matching object based on the width of the pattern rather than the number of objects in the database. The number of objects to compare and the width of the wanted vector are not important, but the width of the vector itself. The advantages of combining these two different calculation methods include reducing the time it takes to search for and indicate a matching pattern. The number of objects is not important, but only the width of the object. The disadvantages that should be mentioned are imperfections related to the quantum systems technology itself, namely the quality of calculations and post-calibration time. The decohorency of the system significantly affects the quality of calculations and the final result of the amplitudes of the indicated probability.

Challenges for the Banking Sector in Poland – Towards Fundamental Changes in the Banking Business

Michal BUSZKO

Nicolaus Copernicus University, Torun, Poland
mibus@umk.pl

Abstract

The banking sector in Poland belongs to one of the most stable and modern sectors in Europe. Its strong foundations so far have been manifested in a practically negligible number of bankruptcies and a relatively good handling of the effects of the subprime crisis in 2008-2010. Due to the increase in deposit guarantee costs, the introduction of the tax on bank assets, the foreign currency housing loan portfolios, the strong reduction of interest rates as well as multidimensional stress due to COVID-19 pandemic, this sector faced the greatest challenges in its modern history.
The purpose of this article is to identify the main challenges facing the banking sector in Poland in connection with the COVID-19 pandemic and to indicate the directions of potential changes in the banking business model as a response to such challenges. Literature studies and the multidimensional scaling of proximity (PROXSCAL) model were used to evaluate the impact of the major factors onto banking development in Poland. The study indicated that large and medium-sized banks react similarly to conditions affecting their financial results, a slightly greater differentiation is visible in the group of key largest banks, and the greatest disproportion concerns some medium and small banks with an aggressive sales model. The paper also indicates that banks start to implement the investment banking model (based on commissions and fees) and compensate decline in interest rates by strong reduction of interest on deposits.

Keywords: Bank, Taxation, Covid-19, Profitability.

Introduction

The banking sector in Poland is one of the structures built essentially after the systemic changes introduced in Poland in the late 1980s. Its characteristic feature is that it was created on the basis of state-owned banks, operating yet in the period of the centrally planned economy, as well as with active support of foreign investors. As a result, the sector shows a large share of the state as well as of foreign banks. Until 2015 the share of foreign investors was dominating and exposing the banking sector in Poland to external risks. Despite high involvement of foreign investors in banking assets in Poland, by 2020 no major problems with liquidity or bankruptcy occurred. The relatively high resilience of the banking sector to international turmoil appeared in the period 2008-2010 and aftermath, when none of the banks had to be supplied with public funds. The major problems that emerged during the subprime crisis turned out to be lower capitalization compared to other EU countries and the subordination to of Polish subsidiaries to policies of foreign headquarters. In 2011, the banking sector came under pressure due to the portfolio of mortgage loans denominated in Swiss francs, which until 2009 were the main type of mortgage lending in Poland. In the next years, the sector began to be burdened with costs of contribution to Bank Guarantee Fund (BFG) due to bankruptcies of non-banking institutions (credit unions), problems of over-employment and the digital revolution in banking, the implementation of EU law in the sector, including the CRD4 directive and the CRR regulation as well as the PSD2 directive. The sector had also to face the challenges of the tax on bank assets, as well as the negative impact of the judgement of Court of Justice of the EU in scope of housing foreign currency loans. The challenge turned out to be also the environment of very low interest rates of National Bank of Poland (NBP) reduced almost to zero during COVID-19 pandemic.

The purpose of this article is to describe the main risk factors and challenges for the banking sector in Poland, reinforced by the COVID-19 pandemic, which may threaten its stable operation as well as its long-term development. The author has focused on five of factors, i.e. additional contribution to the Bank Guarantee Fund (BFG), taxation of assets, unsolved problem of foreign currency mortgage loans, reduction of interest rates, and effects of COVID-19 pandemic which have been combined together and materialized in 2020. The initial three factors are considered as most important obstacles in development of the banking sector in Poland (Związek Banków Polskich, 2020). The article will also present the likely directions of changes in the banking business model in Poland in connection with the emerging unfavorable trends, which will most likely have a permanent impact on the activities of banks in Poland.

Contemporary banking sector in Poland and its development

Despite the banking sector in Poland is the biggest in CEE with total assets value of approx. 450 bn EUR it is also one of the smallest in relation to GDP among all the EU countries (Deloitte, 2019). Its total assets represent approx. 88% of GDP, which in 2019 was the fourth smallest value in EU countries (ZBP, 2020). In terms of banking penetration, Poland can be categorized as lower-penetrated in EU and medium- penetrated in CEE. The sector essentially consists of 3 types of units: commercial banks, cooperative banks and branches of credit institutions. The size and features of the banking sector in Poland are presented in Table 1.

Table 1: structure of the banking sector in Poland

YEAR	2 014	2 015	2 016	2 017	2 018	2 019	2020*
TOTAL ASSETS (tn. PLN)	1.527	1.595	1.707	1.777	1.893	2.000	2.279

A characteristic feature of the banking sector in Poland is the high involvement of the state and foreign investors and the declining role of domestic private investors (13.7% share in assets in 2019). A significant share of foreign investors is mainly the result of the privatization of banks and the transformation of the banking sector in the 1990s and the first decade of 2000, although their importance has been declining since 2009, i.e. since the subprime crisis. The risk of a large share of strategic foreign investors is compensated for by a large diversity of countries of their origin (6), including mostly Western EU and the USA.

Relatively low banking penetration in Poland combined with high domestic and sovereign exposure (Kakes, Nijskens 2018), relatively high interest rates, and focus on basic banking products and services were factors preventing banks in Poland from engaging in subprime loans and toxic assets. Their situation, as in case of several other small open economies, was rather dependent on external than internal conditions (Brzoza-Brzezina, Makarski 2010). Despite the economic slowdown during the subprime crisis in Poland, but not recession, commercial banks managed relatively well and did not require support from the state or international institutions, what was often practiced in most EU countries. Nonetheless, they suffered deterioration of financial efficiency as in most of CEE banking sectors (Popovici, 2014). The main problem that emerged in Poland during and in the aftermath of the subprime crisis was relatively low capital

adequacy. To keep the stability of the sector low level of Tier1 capital was supplemented by the capital Tier2 (Konovalova, Caplinska 2020). In the next years both capital adequacy as well as profitability was increasing in Polish banking sector similarly to other countries of CEE (Radulescu, Banica 2018). The other vital problem of the sector that emerged after subprime crisis was indebtedness of individual clients due to mortgage loans in foreign currencies, especially in the Swiss franc. Due to the currency risk, they began significantly charge many large and medium-sized banks in Poland. There were proposed several programs of forced exchange of currency of the credits into PLN however, their costs would charge banking sector with substantial loses and led to bankruptcies of several large and mid-size banks (Buszko, 2018). Due to this reason, just limited facilities were implemented (e.g. lower currency spreads, special supporting funds for borrowers, possibility to change the loan currency at NBP currency rate).

Particular challenges for the operations of banks in Poland

Relatively favorable conditions for banks operations in Poland lasted between 2011 and 2014. The first factors, that significantly influenced the banking sector profitability and its ability to develop started to emerge in 2015 and have been continuing until 2020. The main factors that have been fundamentally determining its financial condition include: a) increased contributions to the BFG, b) tax on banking assets, c) significant reduction of interest rates by the NBP and interchange fee rates, d) provisions due to foreign currency loans, e) deterioration of income and cost parameters in connection with the COVID-19 pandemic.

The first factor that had a significant impact on the profitability of the entire banking sector was the change in the value of contributions to BFG. Due to the bankruptcy of the largest cooperative bank and credit cooperatives participating in the deposit guarantee scheme, commercial banks in 2015 were forced to cover the amount of guaranteed deposits. The change from 1.16 to 4.24 bn PLN, was an increase by approx. 264% and reached level of 28% of employment costs in the whole sector. In the next years the contribution fell to the range from 2 to 3 bn PLN substantially charging the net results of the sector (Komisja Nadzoru Finansowego 2020).

The second key factor affecting bank profitability was the introduction in February 2016 additional tax imposed on bank assets. Since 2009 tax on banks have appeared in most EU countries, however, unlike Hungary and Poland, in most countries the tax covers liabilities and risky instruments (Martysz & Bartlewski, 2018). Only in the year of its introduction, the tax constituted a charge of PLN 3.2 billion, which accounted for 5.2% of the operating result and 23% of the sector's net profit. This tax is paid on assets in the annual amount of 0.44% of the value of assets and is imposed on entities with a surplus in assets over PLN 4 billion. In practice, it is paid primarily by commercial banks, including all listed on the Warsaw Stock Exchange. From 2016, the tax value is one of the main elements of the bank's general management costs (at the level of approx. 20%) and is higher than the payments made to the BFG. According to Polish Financial Supervision Authority (Komisja Nadzoru Finansowego) estimates, the impact of this tax is -1 pp. ROE indicator. Since this tax is imposed on financial institutions regardless of their financial condition and risk, it increases effective tax rate on banks from 19% to approx. 40% (Związek Banków Polskich, 2020). At the same time, this tax increases the ratio of general and administrative expenses to the highest level in developing EU countries in relation to the net operating result (except for Hungary) (Komisja Nadzoru Finansowego, 2020). The tax percentage is the highest in the EU and the purpose of the tax is solely fiscal.

Banks' results have been also under strong pressure due to the third factor, i.e. reduction of interest rates by the NBP and the decrease in the interchange fee resulting from top-down legal regulations in Poland. The reduction in interchange fee affected the decrease of non- interest profit by PLN 457 million in 2015 (Urząd Komisji Nadzoru Finansowego, 2016). Moreover, the results of the banking sector were also deteriorated by the impact of the reduction of interest rates, which could not be offset by the increase in the number and value of transactions. Therefore, in 2015 banks started to achieve lower income, both in terms of interest as well as fees and commissions. In the following years, the net interest income started to improve, but it was the result of the scale of operations and the reduction in interest on deposits. The relative stability of interest rates was significantly disturbed in 2020 by a threefold reduction in interest rates to 0.1% due to the COVID-19 pandemic, which significantly changed the possibility of generating interest income. As a result, in June 2020, interest income from loans granted was significantly lower than 12 months earlier. Counteractions taken by banks, including a significant reduction in interest paid on deposits and an increase in fees and commissions, resulted

in the total interest result in June 2020 being approx. 1.6% higher than in June 2019, and the result on fees and commissions by almost 7.4%. At the same time, the share of fees and commissions in net operating income increased from 18.1% to 20.4%. The sector's profit for the entire year, due to the COVID-19 and interest rate cut is expected to be lower by approx. 25-30% (Szymański, 2020). The financial data of the banks are presented in Table 2.

Table 2: financial results of the bank sector in Poland (bn. PLN)

YEAR	2014	2015	2016	2017	2018	2019*	2019	2020*
TOTAL NET OPERATING INCOME	58 744	57 115	61 772	64 014	64 565	36 143	70 564	34 557

The fourth key factor weighing down the financial results of banks in Poland are foreign currency housing loans granted until 2009, in particular in Swiss francs. The problem of foreign exchange lending was noted in many countries of CEE but in particular in Hungary and Poland (Buszko & Krupa, 2015). In Poland at the end of 2019, such loans represented PLN 98 billion, which accounted for 23% of the value of all housing loans in Poland. Their number amounted to 438 thousand, which accounted for 19% of the total number of housing loans. The problem of foreign currency loans in Poland came from the very low CHF/PLN exchange rate at the time of their originating (mostly in 2008), and then the significant increase of CHF valuation in the following years, (by approx. 122% between 2008 and 2020). This increase generated additional credit risk for banks, which was partially offset by a decline in CHF LIBOR. The problem of loans in Swiss currency applies to the largest banks in Poland, including majority of those listed at the Warsaw Stock Exchange. Due to the change in banking regulations at the EU level, including the CRDIV directive and the CRR regulation, as well as the pressure of government and PFSA, the loans were charged with additional capital requirements of an add-on buffer and a risk weight of 150%. Moreover, after the rapid increase in the CHF exchange rate in January 2015, banks launched an aid program for foreign currency borrowers, defined as a “six-pack”, with the average cost of PLN 1 billion per year. The problem of foreign currency loans materialized in banks as a result of the judgments of the Court of Justice of the European Union, which became the pattern for Polish courts in cases against banks for the use of abusive clauses in loan agreements, especially with regard to determining the indexation of loans with the exchange rate. As a result of EU jurisprudence and the order to return part of the commission on loans repaid before maturity, banks had to account significant provisions, which only in Q4 2019 amounted to over 2% of the carrying amount of foreign currency loans. Just for the largest bank in Poland it accounted for approx. PLN 450 million (Rudke, 2020). It should be added that foreign currency loans are of good quality and their NPL ratio is approximately 3.3%.

In addition to the above-mentioned main factors that burden banks' financial results, one should mention the deterioration of the income and cost stress resulting directly from the COVID-19 pandemic. For this factor, its overall impact cannot be determined yet as the final duration of the pandemic is not known. In addition, it should be kept in mind that banks will feel the negative effects with a few months delay. The observation of the Polish banking sector operation during pandemic points out strong increase in deposits and a decrease in the value of loans granted. Moreover, one could observe replacing of bank lending for companies by the state aid programs, as well as postponement of the repayment of loan installments in form of “credit holidays”. The problem is also a deteriorating quality of loans

portfolio, which is reflected in the provisioning for loans yet from Q1 2020. Just in case of the largest bank in Poland, PKO BP, the cost of risk already increased due to COVID by approx. 0.8 pp. (PKO, 2020).

Positioning banks in Poland

The analysis of the factors influencing profitability of banks in Poland have been supplemented with a multidimensional scaling of proximity (PROXSCAL) model using Euclidean distance and standardized 10 financial variables related to market valuation, profitability, operational efficiency, cost efficiency, interest and commission efficiency. The scaling was made in IBM SPSS Statistics 26 and its purpose was to identify the impact of the cumulated factors affecting banks (including additional contributions, tax on banks, new provisions and low interest rates on the key banks in Poland listed at the Stock Exchange. At December 2018, these banks concentrated almost 71% of the sector's assets on a unit basis, constituting the main component of the value of the Warsaw Stock Exchange (33%) as well as its turnover (28.3%) (Komisja Nadzoru Finansowego, 2019). Taking into account 10 standardized variables, a positional map was prepared, showing the distribution of banks under the influence of five key factors analyzed in the paper. The results are presented in the Fig. 1.

Banks with substantial share of CHF loans: GNB, SPL, PKO, BNP, MIL, BOS, MBK
Red dots – state banks, Blue dots – domestic owned banks, grey dots - foreign owned banks
Normalized Raw Stress = 0.0176, DAF = 0.9824, Tucker's Coef. = 0.9912

Fig. 1: Positional mapping of banks listed at the WSE

Source: own work based on EquityRT data as on 10.09.2020

The chart shows the relative similarity of banks by the size group. In particular, one can find the similarity of the group of large banks with assets of PLN 100-200 billion (ING, BNP, MBK, MIL) and the small BOS bank with assets of PLN 19 billion. The first four banks are foreign owned and the last is belonging to the state but is specialized in financing and servicing projects related to ecology and environmental protection. Its activities in the area of green banking were analyzed by Dziawgo (2014). The largest bank in Poland (PKO) PLN 348 billion with assets value in 2019 is between the group of sector leaders in terms of size and financial results, i.e. SPL and PEO with assets of respectively PLN 210 and PLN 203 bn with large banks (ING, BNP, MBK, MIL) representing assets exceeding PLN 100 bn. The ranking highlights the BHW bank which is the mid-sized unit (with assets from 50 to 100 bn and most closely resembles the parameters of the leaders (SPL and PEO). This bank is representing corporate banking, similarly to PEO, and is the only med-sized unit relatively profitable, financially secure and value creating.

One can also find close proximity of banks with substantial shares of CHF mortgage loans in their mortgage loans portfolio (above 20%). In fact, there are two distinctive subsets, i.e. BOS, MBK and MIL, BNP. The two subsets are between sector leaders and the outliers.

Finally, the chart shows a large deviation of 2 mid-sized banks (GNB and ALR) and 2 small ones (of assets below 50 billion - GTN and IDA). They are characterized by aggressive pricing and selling strategies, but also by poor financial results, low market valuation and structural ineffectiveness. Such results confirm the research of (Beltratti & Stulz, 2012) which points that less aggressive and less risky banks turned out to be better performing during the crisis. Three of the entities mentioned (GNB, IDA and GTN) are owned by a Polish private investor, and the fourth is indirectly owned by the state. None of the foreign owned banks listed at WSE in Poland is in difficult financial condition and there is no direct stress in Polish financial system because of their eurozone origins. The risk and stress due to COVID-19 are already observed in the financial system of eurozone countries (Ito, 2020).

Discussion on the potential directions of changes in the banking sector

The subprime crisis consequences in Polish banking sector helped to get necessary knowledge and experience how to manage banks during the turbulent environment. Thus, in general banks in 2020 were better prepared for the shock than in 2008-2009. The problem of the persistence of bank performance across the crises is vital and Garel et al (2020) developed it with regard to private and public banks. When analyzing the persistence of bank performance across crises, several potential directions of changes in Polish banking can be pointed, including changes in banking business models.

When evaluating the financial proximity of banks in Poland one can find that large banks react similarly to the described negative phenomena, greater diversification is visible among the three biggest banks in the sector, however their results are still positive. The highest diversity can be found in the group of medium and small banks, primarily those pursuing an expansionary and aggressive lending policy. Due to poor results their future existence can be questioned, creating potential for voluntary or compulsory consolidations. This is in line with the research of de Haan and Kakes (2020) who find that after global financial crisis retail-oriented and medium-sized banks suffered most losses. Taking into account the ownership structure of endangered entities in Poland, a reduction of presence of domestic private investors and a duopoly of ownership (the state and foreign investors) should be expected. It will determine valuation of banks as ownership structure strongly influences governance of banks (Caprio et al. 2007).

As the state is at present playing an important role in the banking sector in Poland and the depositors did not experience critical bankruptcies of banks, the trust towards banks is relatively high and rising in time in Poland (Piotrowski, 2020). As depositors are not familiar with such phenomena, one or more mid-size or large bank failures may cause shock on the whole market, putting abrupt and strong pressure on deposit stability.

Low return on equity and assets (ROE and ROA) of the banking sector in Poland and lower than in other sectors in developing countries by approx. 3 and 0.3 pp, will result in a decline in the interest in investing in banks in Poland form the part of foreign investors despite still existing significant development potential in the field of retail customer banking and relatively low concentration of the sector. Thus, one may expect increasing role of the state which will grow due to the lack of private capital from domestic investors.

Deteriorating results caused by simultaneously rising operating costs (salaries and general administration costs) and falling interest income will deteriorate the ability of banks to generate value in a sustainable manner as well as to generate returns on bank shares, leading to a decline in interest in new equity issues

In terms of the banking business model the one can expect putting higher pressure for the search for greater income from fees and commissions, resulting in an increased potential in banks' transition into investment activities with greater risk.

Considering a customer service, one should expect that the Polish model of banking “almost free of charge” will change into paid service for each banking activity. Based on some Western European countries the introduction of the

subscription-based products can be an effective solution for banks. In such business model banks will provide the customer with an all-inclusive package for a fixed monthly fee.

Another effect of limiting interest income may be looking for sources other than strictly financing or banking business activities. A good example is the largest Polish bank - PKO BP that has launched a start-up related to the sale of new or used cars for business purposes.

Due to the permanent decrease in the number of customers visiting bank branches, a manifestation of changes in the business model will be a further reduction in the number of bank branches and a greater emphasis on the use of digital banking. This action will be additionally strengthened by the increase in operating costs in Poland, including in particular an increase of minimum wages. Banks will be then forced to become technological and IT innovators while maintaining some reduced number of stationary branches. Other possibility is the development of pure play internet banks which allows to reduce costs and get economies of scale. Such units may quickly get market share, but they may also generate overexposure in risky markets (Arnold & van Ewijk, 2011). Solutions such as digital cloud, regulatory sandboxes or products offered as part of cooperation with fintech entities should be expected as well.

Due to the high excess liquidity and the conservative approach to selling money in the form of loans in a pandemic, banks may limit or withdraw from accepting deposits, what could be observed in Poland already in 2020 with regard to term deposits for enterprises. The solution may be also to introduce a negative interest rate on savings.

Due to the taxation of bank assets (loans), with the simultaneous exemption from taxation instruments issued by the state treasury, an intensification of the phenomenon of credit crunch, stimulated by preferring bonds issued or guaranteed by the Treasury can be expected.

Summary and Conclusions

The modern banking sector in Poland is facing the greatest challenge in its over 30-year history. The cumulation of threats inherent in both the legislative (restrictions on banks' operations), tax (application of the tax on assets), costs (the need to establish provisions due to court proceedings brought by foreign currency borrowers), financial (extremally low level of interest rates), economic (low customer activity) combined with lower creditworthiness makes banking development less and less profitable on the one hand, and on the other hand reduces flexibility of the whole sector to respond to changes in the environment. As a result, the banking sector may cease to fulfill its functions effectively and lead to the phenomenon of credit crunch. Falling into the trap of limiting access to credit will have very serious consequences, especially in the period of economic recovery from the recession caused by the COVID-19 pandemic. Access to the necessary capital in the economy may then difficult. Moreover, the deterioration of the banking activity in Poland will result in a decline of the sector's competitiveness against other CEE countries and the outflow of private capital, leading to a further weakening of its potential. The central bank's focus on helping borrowers in the pandemic period in the form of a significant and long-term reduction of interest rates will result in the necessity to significantly increase the prices of banking services, strongly and permanently limiting the free of charge banking model in Poland.

Project Management "Wytyczno": As an Example of Disseminating History in Public Space

Justyna MAŁYSIAK

General Tadeusz Kosciuszko Military University of Land Forces Faculty of Management,
Wroclaw, Poland
justyna.malysiak@awl.edu.pl

Abstract

In the area of public history, the implementation of scientific projects is becoming not so much a common practice in the modern world as it is necessary for the implementation of multi-track projects tailored to the expectations of increasingly demanding consumers. The preliminary research was to help to determine what kind of forms of history dissemination would be most appropriate in the course of a scientific-research project, as well as help to determine the level of knowledge about the Border Guard Corps and the battle of the Wytyczno in society, and thus help to take actions aimed at its intensification. Further research dedicated to the issue of history management in public space will certainly help to determine the most appropriate tools and processes that will influence the development of methodology for the professionalization of history education. Currently, this direction is in a constant phase of development, gaining more and more popularity especially in interdisciplinary areas.

Keywords: Management, Public History, Education, Project, Science.

Introduction

Public history, apart from the task of popularizing historical knowledge among recipients, undertakes research on the functioning of knowledge and memory of the past, as well as historical awareness J. Wojdon (2015), J. Wojdon (2018), R. Traba (2014), D. Dean (2018). Microhistory appears more and more often in historical narration. The recipient is no longer only interested in juxtaposing the most important political facts or military events, but is mainly looking for stories close to local stories and stories about the fate of the individual. In all of this, a desire to know and understand one's own identity resounds. Public history historians face an extremely difficult and responsible task T. Cauvin (2016). This is especially true for those past events that tell a difficult story related to the circumstances of World War II.

The report from the research carried out for the "Niepodległa" program on September 16, 2016 proves that over the last three decades the knowledge of Poles about their own microhistory has increased by as much as 37%, and that history itself began to be perceived as a cultural element and a factor shaping social identity. It has been proven that "living history" in the field of public history is the most popular form of conveying knowledge about the past. Poles are also becoming more and more proud of the history of their own country, and they are increasingly respectful of historical heroes P. Kwiatkowski (2016).

The report of "Niepodległa" became an inspiration to conduct research on the issues of dissemination of local history among academic youth and communities of the region. The aim was to serve as a point of reference for the public history initiative, which was to involve students and school pupils in scientific research in the "Wytyczno" project, co-financed by the Ministry of Culture and National Heritage in the program "War Graves and Cemeteries in the Country" for 2019. Within the framework of these undertakings, groups of young people took part in scientific field trips, during which they carried out research and optional activities. The choice of the form of dissemination of knowledge, which is the realization of the scientific project, resulted from the fact that projects in public space concern all social areas. They have a huge impact on our environment, but also on ourselves. Thanks to them, the society is able to associate into civic groups and act for the benefit of the whole local community A. Sobol (2017), W. Kębłowski (2014). It is generally believed that for Western societies, projects, especially civic

ones, are supposed to be a cure for the crisis of civil society and to improve services provided through them D. Kociuba, K. Rabczewska (2019). Many public institutions and

private entities develop competence in the area of efficient project management W. Kucharski (2018). An example is the Aconss Foundation, whose activities are aimed at promoting culture, knowledge and history. The Foundation pilot projects and grants, and is actively involved in the organization of cultural events (http://www.aconss.com).

Main Part

The "Wytyczno" project was supposed to activate both the local community and involve a committed student organism, whose aim was to deepen interest in the discipline of history. Within the framework of the "Riese" project, members of the Scientific Circle participated in preliminary field studies covering the complex of the Owl Mountains undergrounds. According to the assumption of the Scientific Club supervisors, the trips were to contribute to deeper involvement of students in scientific activities, but also to allow them to experience history in an interesting and tangible way. The activities were to engage first of all cadets to get acquainted with the topics devoted to the martyrdom of the Polish soldiers and the memory of those killed during the Second World War. Both projects became a tangible proof that by recognizing the potential of history and skillfully using it for educational purposes, it is possible to contribute in an interesting way to building the awareness of young people. The solid foundations of values such as respect for the homeland, for the heroes, and respect for the history of the country were the substantive basis for these scientific undertakings. Nevertheless, there was still a lack of one important substitute that would allow to go beyond the group of participants and involve the society - first academic, and then local (both in Wrocław and in the towns covered by the research) and national (mission to disseminate research results and information related to the project throughout Poland).

The first step taken to realize these assumptions was to organize a scientific conference on 23.05.2019 entitled "Conference of Polish Soldiers Fighting in Defense of the borders in 1939". It was then that for the first time experts dealing with a given issue were able to gather in one place and present the results of their research from 2017 to a wide academic audience. This event gave the opportunity to conduct further activities in this field. The survey carried out at the beginning of February 2019 had an additional impact, which, among other things, checked the state of knowledge about the KOP formation, as well as about the battle of Wytyczno. The results were exactly as expected. Out of 225 respondents asked about their knowledge of the Border Guard Corps formation, as many as (30.7%) 69 responded that they had no knowledge and (36%) 81got a small extent. (20.9%) 47 people answered that their knowledge was sufficient, (10.7%) 24 people that it was good. However, only (1.8%) 4 people considered it very good.

Title of the graph: Respondents knowledge of the Border Protection Corps formation
Graph no. 15. Source - own work

In the question about the Battle of the Wytyczno, the percentage of people familiar with the subject was even smaller. Only (0.9%) 2 people described their knowledge of the battle as very good, (6.7%) 15 people as good and (8.9%) 20 people as sufficient. As many as (37.3%) 84 respondents admitted that their knowledge of the battle was insignificant, and (46.2%) 104 people considered that they had no knowledge at all.

Title of the graph: State of the respondent's knowledge of the 1939 Battle of the Wytyczno.
Graph no 16. Source - own work

For comparison, the respondents were asked about their knowledge of the Katyn Massacre. It turned out that the trend is completely the opposite, and most people declare at least sufficient knowledge of the subject. (10.2%) 23 people considered their knowledge to be very good, (43.6%) 98 people admitted that it was good and (30.2%) 68 people, sufficient. (13.8%) 31 respondents said that their knowledge is small and only (2.2%) admitted that they do not have such knowledge at all

Title of the graph: Respondents knowledge of the Katyń Massacre

Graph no 17. Source - own work

The problem seemed to be noteworthy in terms of the need to carry out research to promote the Battle of Wytyczno as well as to find the best tool to promote it effectively in the Academy. The aim of the research was, first of all, to indicate the role of history in public space and thought, secondly, to help determine the educational paths and channels of knowledge dissemination approved by society, and thirdly, to examine the role of projects and their presence in this process. The study involved (52.4%) 133 men and (40.9%) 92 women. A random group was taken as a target. There was no focus on people who study history or define history as their basic hobby: actively participating in initiatives related to it, e.g.: belonging to historical reconstruction groups, or working in institutions dealing with heritage and culture promotion. This makes the results of the survey more reliable especially with regard to historical knowledge about the Borderland Protection Corps. Additionally, the opinions concerning the forms of history dissemination are not falsified, but indicate the real expectations of the recipients. Addressing them to groups of scientists or only students would not translate into an evaluation of the phenomenon in a broader perspective, the aim of which was to evaluate the place of public history in social life in general. It was the opinion of an "ordinary" citizen that was to serve as an answer to the question how science (here mainly in the form of a scientific-research project) can affect the public sphere.

Title of the graph: Gender distribution of survey respondents
Graph no 1. Source - own work

The majority of the respondents consisted of young people up to 35 years old including those between 18-26 years old. (12.9%), and between 27-35. – (48,4%). 21.3% of the respondents were aged 36-42, (9.3%) 43-51, (4.4%) - 61 and more, and (3.6%) 52-60. A larger percentage of young people explain the form of making the survey available through social media and the Internet.

Title of the graph: Age distribution of survey respondents
Graph no 2. Source - own work

The majority, as many as (61.8%) 139 respondents declared higher education, (32.4%) - 73 people, secondary education, (4.9%) 11 people vocational education, and only (0.9%) - 2 people basic education.

Title of the graph: Distribution of the survey respondents by education
Graph no 3. Source - own work

Most of the respondents (42.7%) 96 people declared the city of over 250 thousand people as their place of residence; (19.1%) 43 people, city to 50 thousand people, (18.7%) 42 people, city to 250 thousand people; (12%) 27 people, village; while (7.6%) 17 people, city to 100 thousand people.

Title of the graph: Division of survey respondents by place of residence
Graph no 4. Source - own work

With respect to the professional situation, the overwhelming percentage of the respondents declared themselves to be employed (80%) 180 people; (11.6%) 26 people, as learners; (4.9%) 11 people, as unemployed and (3.6%) 8 people as retired.

Title of the graph: Division of the respondents to the survey according to their professional situation
Graph no 5. Source - own work

The research of the introductory part opened the question concerning the knowledge of the concept of public history. The aim was to examine the very reception of the concept in the society, to check if it is aware of participation in the historical space - a wide range of different activities undertaken to promote it, but also the very functioning of knowledge about the past in this space. (40,9%) 92 people replied that yes - the concept is known to them. The vast majority (59.1%) 133 persons replied that they do not know the concept of public history. This means that, as rightly suggested by the researchers who take up the subject of history in public space, in Poland the concept is only just beginning to be popularized, which has a decisive influence on the increase of social awareness of the role of history and its presence in the life of an individual at different levels of absorption.

Title of the graph: Knowledge of the term public history among the respondents
Graph no 6. Source - own work

The next question asked to the respondents concerned the degree of interest in history. A significant percentage of respondents described them as large, as many as 105 people (46.9%) and 40 people (17.9%) as very large. Next (25.9%) 58 people 58 people answered "I'm not interested in much, but there are historical topics that interest me". The respondents admitted that there is little interest, but there is a historical topic that they are willing to explore; (5.4%) 12 people replied that there is little interest, and only (4%) 9 people replied that none. Thus, it should be strongly recognised that history remains in the circles of interest to many people, even if they do not pay much attention to it, there are areas that are attractive to them.

Title of the graph: Interest in history among respondents
Graph no 7. Source - own work

The third question, which asks about the main motivators for learning about history, is helpful in identifying those areas that focus most of the respondents attention. It turned out that what is most attractive to people in dealing with history is the desire to know the secrets of the past. That is, the search for stories that are attractive from the point of view of the recipient, stimulating the imagination and providing answers to existential as well as philosophical, ethical, or mundane or emotional questions - answers to questions about past events of various importance from complicated scientific questions to conspiracy theories popular today. This way the answer was (39,1%) 88 people; for (25,8%) 58 people the most attractive in history is to get to know the region and the country, both in relation to foreign and domestic tourism, but also individual tourism focused on the micro-region. For (13.8%) 31 respondents learning about history is connected with strengthening their sense of identity. It concerns both the role of tradition, the value of patriotism and national pride; for (11.6%) 26 people the motivation is the willingness to educate, and for (9.8%) 22 people the impulse to explore historical knowledge are computer games, films and popular science literature they read.

Title of the graph: Motivation of respondents to learn about history
Graph no 8. Source - own work

The last question, which dealt with the areas of historical interest of the respondents, was about the types of participation in the space that history has. This question listed the most common activities in the area of public history. The highest percentage of respondents (33.8%) 76 people admitted that participation in historical culture is mainly historical tourism; (23.1%) 52 people indicated programs on historical subjects; (17.8%) 40 people thematic literature; (12%) 27 people, participation in historical festivals; (4.4%) 10 people, exhibitions dedicated to historical subjects; the same percentage, (4.4%) 10 people collecting and interest in genealogy also (4.4%) 10 people. Tourism is the most attractive form of learning about history because apart from the knowledge itself, it also provides other advantages such as emotional experiences, the possibility of adventure also in an interactive form, acquiring knowledge while maintaining the function of relaxation, learning only those areas that are most attractive for a person - most often a client for whom the prepared form of knowledge must also serve as entertainment. The same is true of literature and TV programs, which must also combine both knowledge and entertainment. A program or a book must be fascinating and arousing curiosity, then the story becomes accessible to the recipient and more willingly reaches for it. Especially the various historical channels posted on YouTube are proof of this. For some time now there has been a growing interest in this form of education among teachers, who more and more often include it in the scenario of their lessons or museum educators using history in their programs K. Olechnicki, T. Szlendak, A. Karwacki (2016), A. Mikos von Rohrscheidt (2011), M. Machałek (2016). Historical reconstruction attracts people with its interactive form. Battle shows and military themes in particular are popular with the audience through their show and spectacular character. Exhibitions depend on many factors that can influence their attractiveness for the audience. The main factors include attractiveness of the form of the exhibition, subject matter, accessibility for different age groups, price, computerization, workshop support, presence of a guide, power of communication, multimedia etc. Collecting is based mainly on the private interests of the recipient. In turn, genealogy most often arouses the curiosity of people from families where the tradition of collecting information about ancestors has been cultivated for generations. These people often have extensive family trees, which they complement through individual research, worship the memory of their ancestors - during special family reunions, continue their genealogical research on their own, disseminate knowledge about them by distributing souvenirs, photos, objects of historical value, co-creating exhibitions dedicated to family members.

Title of the graph: Declaration of respondents regarding their participation in historical culture
Graph no 9. Source - own work

The last of the survey modules was supposed to help to examine the attractiveness of public history projects for the audience. Particularly focused on the problem of promoting knowledge with the scientific project. The answers were aimed at supporting decisions concerning the application of appropriate methods of promoting research results in the "Wytyczno" project. They were also supposed to show what expectations the society has towards scientific projects, with all dissemination activities in mind. The first question concerned the ways of promoting history. The respondents were asked which of them are the most interesting and attracting their attention. The question could indicate maximum two answers. A total of 425 were indicated, which means that 25 people chose only one answer. The vast majority (56.4%) indicated promotion events in the form of festivals, such as the "Night of Museums";(48.4%) chose historical reconstructions; (25.3%) museum exhibitions; (20.4%) digital applications, in the form of various technical solutions, guides, multimedia presentations; (19.1%) conferences, seminars and thematic lectures, as well as city games, also (19.1%). The vast majority of the respondents were in favor of those forms, whose attractiveness is determined by the showcase. Both festivals with specially composed themes and interesting design as well as delightful historical reconstructions - especially those of military character - are considered the most attractive by the audience.

The curiosity about the form of popularizing the history of World War II among young people was to direct them not to the tragedy of the event, but first of all to the possibility of restoring the memory of the fallen and their direct participation in this process.

Title of the graph: Declaration of respondents regarding their preferences for attractive promotion of history in public space Graph no 10. Source - own work

Many research issues are currently being addressed by the need to disseminate results to the public. This is not surprising given that a project should not only have scientific value, but above all its contribution to science should be useful to people. This is precisely the biggest "pain" of today's humanities, which is difficult to conduct research that results in a product of public benefit. Humanities does not have such tangible products of its activity like scientific and research equipment. Therefore, it faces many problems, the most important of which is the lack of possibility to finance research. For this reason, public history aims to be useful mainly in the field of education. In the question asked to the respondents about the role of the project in the process of education and dissemination of knowledge, almost 90% of people were of the opinion that its contribution in this area is important. Of these (48%) 108 people indicated that it is extremely important and (40.4%) 91 people considered it a very good idea; (10.2%) 23 people considered it not necessarily, and only (1.3%) 3 people said it was not important at all.

Title of the graph: Respondents opinion on the usefulness of a scientific project in the process of education and dissemination of knowledge
Graph no 11. Source - own work

Then the respondents were asked about the most attractive form of dissemination of research results. (32.4%) 73 respondents indicated reports published in social media; (23.6%) 53 people chose a scientific publication; (23.1%) 52 people found it most interesting to involve students in the research; (14.2%) 32 people, lectures and lessons for young people; (6.7%) 15 people conference. The research served to plan activities aimed at disseminating the results of the "Wytyczno" project in 2019.

Title of the graph: Respondents preferences in relation to the attractiveness of forms of dissemination of research results Graph no 12. Source - own work

An additional question in this area concerned the dissemination of information about the scientific project itself. According to the respondents, the most accessible form is short films made available through channels such as YouTube, this way the answer was given by (37.8%) 85 people; less respondents indicated a website (33.3%) 75 people; for (18.7%) 42 people the best form is social media, and for (10.2%) 23 people best form were dedicated city exhibitions. In the "Wytyczno" project it was decided to use mainly social media and public television. It was a excellent solution in communication with recipients interested in the subject of the project.

Title of the graph: Respondents preferences in relation to the forms of dissemination of information on conducted scientific projects Graph no 13. Source - own work

The last question concerned the very place of scientific projects in the public space and was intended to indicate the direction in which today's research tasks should go. It seems that from the perspective of the search for and value of information, the most important for the conducted projects is the efficient transfer of information about undertaken activities, effects and possibilities. The information about the conducted projects would be useful for the whole scientific community and would allow to organize the existing knowledge about the undertaken issues. It would prevent the duplication of ideas and indicate the areas that require further knowledge. Short descriptions of the effects of the projects would be good material for investors, scientists, but also for the society with different interests. This idea was interesting (79.1%) 178 respondents, who believe that the Internet base of this type should be created. (14.2%) 32 respondents considered that there is no opinion on this issue, and only (6.7%) 15 people said that such a solution is not needed. From the perspective of increasing digitalization, scientific publications are slowly ceasing to be a sufficient source of information about the conducted research. Therefore, the base organizing the initiatives of the scientific community in the scope of conducted projects would be an additional, unique source of knowledge and would allow for contact with researchers from various circles and would deepen the professionalization of conducted projects.

Title of the graph: Respondents opinion on the usefulness of the internet database used to disseminate information on conducted research projects
Graph no 14. Source - own work

In the course of the project implementation it was decided to implement the program of the Ministry of Culture and National Heritage 'War Graves and Cemeteries in Poland', which provided support for the care of war graves and cemeteries in Poland, which are an important testimony of important historical events in the country related to fighting and martyrdom. In the "Wytyczno" project sets four main goals for the realization of the research goals. Among them there were: field research, cleanup works covering the area of the cemetery in Wytyczno, archaeological research and archival search in Lublin and Warszawa. There were also actions taken to disseminate the results of the research among the inhabitants of the locations where the research was carried out, as well as among school students from the region and academic students from the AWL.

Dissemination of history among the local and academic community, as well as involvement of young people in its realization, contributed significantly to restoring the memory of the Borderland Protection Corps, as well as the events related to World War II. It should be remembered that the subjects discussed concern a very difficult history, for which the message dedicated to young people must be properly composed. According to the survey conducted for the project, it was decided that the role of education and the mission of history dissemination are very important. The projects promotion actions, carried out since November, had an impact not only on the school youth, but also on the whole cultural life of the region. By engaging children and teenagers in the historical competition, which was mainly based on interviews with their close ones, the project tried to attract the attention of adults. In this way the project became an opportunity for the region to stimulate local initiatives, an object of regional pride in its microhistory, as well as promoting attitudes and values of patriotism. The total group of people who actively participated in the project was over 200. Material concerning the search was published in media. Moreover, an additional activity in the field of public history was the very idea of involving cadets and students of the academy in the work. The contact with history in a direct way was supposed to help young people learn about difficult history not through a museum - dedicated exhibition or literature, but in a more emotional way. Joint research supporting the work of scientists helped to involve young people in the world of science, which at the level of bachelor's and even master's studies they usually get to know in a very modest way. Participation in the project was to help educate young people in history and management, but also to provide them with practical knowledge - including teaching them the logistics of running projects. Looking at the constantly growing number of interested students, membership in the Scientific Club of War History, as well as their great willingness to participate in initiatives such as scientific trips, lectures on history, activity in projects such as the project "Wytyczno" one should conclude that the place of history in the education of young non-commissioned officers is extremely important; that this form of disseminating historical knowledge is very attractive to young people; that historical narration has a significant impact on young people's patriotic and identity thinking; that young people often only need an impulse in the form of an interesting arrangement of the educational message in order to pursue their own knowledge; and that properly managed public history still has a lot to offer, and the AWL initiative is excellent proof of this.

Summary

The broad spectrum of public history activity does not allow to close this notion in a tight framework. The multitude of initiatives undertaken by cultural institutions, science, social organizations or private individuals shows an inexhaustible resource of possibilities to promote history and education within this discipline. It turns out that the scientific project can be successfully used as one of the elements of popularization of history in public space. The "Wytyczno " project meets all the demands made in the mission statement of the American National Council of Public History, which believes that "the promotion of the usefulness of history in society must be done through professional practice" B.J. Howe (1989).

In accordance with the intention of the mission of public history, the "Wytyczno" project referred to the methods of historical discipline through the use of many elements characteristic of the historian workshop, emphasized the dissemination of historical knowledge by engaging pupils and students in practical activities, and strongly influenced public space - both local (internal activities) and national (media promotion, promotion among students of AWL). At the same time, he used all the tools of management sciences in the course of promoting national heritage as well as knowledge and education. It seems that involving young people in such activities as management in practice, especially in the interdisciplinary field, is a new way to stimulate their interests and scientific activity.

General Tadeusz Kosciuszko Military University of Land Forces Faculty of Management, Wroclaw, Poland, jozef.ledzianowski@awl.edu.pl

Abstract

The article presents key aspects of the conditions that are crucial for commanders who also want to be leaders. The authors draw attention to three key determinants, without which it is difficult to say that a commander is also a leader. The article also points out that not every commander will be a leader at the same time, because it requires a great effort and work on themselves from those who want to feel like they are leaders and self-control of their actions. Therefore, the three most important determinants that have a key impact on the formation of a leader's personality and his or her competence in this area should be understood both by the projectors of educational processes in the army and by future and current commanding officers themselves.

Keywords: personality, competences, leadership, emotional intelligence, effective officers' personality, self-management, motivations, emotions, personal and professional profile of the graduate.

Introduction

For many years, there has been a reflection on the leadership competence of a man who stands in a leader position - in the army in a command post - about the extent to which he should display in his personality, the qualities that are ascribed to people generally considered to be typical leaders. There are many approaches to this issue, from which several conclusions can also be drawn, which also give rise to the theses, namely:

- There is a fundamental difference between the personality of a commander and a leader, which can be demonstrated;

- Not every commander will be a leader, but usually every leader is a good commander;

- the key determinants for a commander to be also a good leader are:

- emotional intelligence;

- the so-called effective officer's personality;

- ability to manage oneself and others.

From the professional pragmatics and several dozen years of personal experience of the authors of this article, on the basis of direct work with people and directing human teams, it is clear that being a leader requires not only appropriate professional competences, but above all continuous work on the shape of the and improving own personality. This can be illustrated as shown in Figure 1.

Figure 1: Leader formation model

Source: Own study

First of all, it is important to point out the fundamental differences between commander and command and leader and leadership.

The Lexicon of military knowledge defines **command** as "the entirety of the deliberate activity of a commander and a staff, carried out under a defined leadership system, ensuring high combat readiness and proper preparation of troops for the best possible achievement of the objectives of combat, battle or operation *Lexicon* ... (1979). According to J. Michniak (2003), **command** "is the basic form of directing troops, based on the power to comprehensively shape all elements of readiness and combat capability in relation to directly and indirectly subordinate soldiers, and thus to comprehensively prepare them in peacetime for all kinds of actions and to direct them in peacetime, crisis and war. It is a process through which a commander imposes his will and intent on his subordinates and in which, assisted by his staff, he plans, organizes, motivates and controls the actions of his subordinate troops by using standard operating procedures. and any means of communication. Moreover, **command** is not just about leading human teams in times of peace. The main task of the army is to prepare for combat operations under various conditions. This means that command is also about activating combat capabilities in order to create the combat force necessary for the success of the mission J. Brinkerhoff (1995). Many authors rightly point out that **command is the formal management of people, without emotional involvement**.

On the basis of the above definitions, it can be assumed that a **COMMANDER** is a person who is /designated/ in a full-time position in the **army**, that is to say, a soldier at the head of a type of armed force, tactical union, unit or subdivision. The soldier has certain rights (e.g. to give orders and supervise their execution), but also duties. He is the organizer of combat operations of subordinate troops (soldiers) and commands them during the operations. In peacetime, however, he performs various tasks related to the functions of planning, organizing e.g. training, motivating subordinate soldiers to perform the tasks assigned to them, as well as having competence in the control and self-assessment of the performed tasks, both those assigned to subordinate soldiers and his own.

For example, to characterize the **personality of a commanding officer** in a comprehensive way, this can be presented as follows:

COMMANDING OFFICER'S PERSONALITY: *"is an associated system of relatively stable qualities (qualities, values), dispositions and skills (abilities) that allow an officer to behave appropriately in specific situations, both in peacetime (including participation in humanitarian and peacekeeping operations), in times of various threats (e.g. terrorism or cataclysm) and in times of war. These behaviors are supported by appropriate knowledge and skills and are constantly enriched by new experience and relevant competences, which allow an officer to fulfill the role not only of commander (leader), but also of teacher (trainer) in relation to subordinate soldiers. An officer's personality is determined by: motives, needs, attitudes, worldview, aspirations, self-knowledge, interests, abilities, intelligence, temperament, character and worldview. This personality must be self-reflective, taking into account the constant development of civilization and culture of the modern world".*

So what are the characteristics of **leader** and **leadership**?

Jerzy Kunikowski considers LEADERSHIP as a skill that occurs in the process of commanding and directing people; in target (task) groups, leadership is distinguished by the ability to effectively carry out tasks and to win people over. At the same time, the above mentioned author stated that it is one of the most important skills, predispositions or a group of qualities perceived and desired in contemporary leadership and command, which include: self-confidence, ambition, assertiveness, emotional staunchness, stubbornness and firmness, intelligence and courage J. Kunikowski (2000).

On the other hand, Leszek Kanarski, distinguishing between **command** and **leadership**, describes the former as *influence based on formal powers and procedures and the latter as influence based on personality traits, skills and behaviours* L. Kanarski (2003).

Leadership is both a process and a property. The process of leadership is the unforced direction and coordination of the members of an organised group to achieve a group goal. Leadership as a property, on the other hand, is a set of personality traits attributed to those who are perceived to be using such a faculty-management successfully R. M. Stogdill (1974).

Leadership is an influence on the behavior of others. It is a type of social influence that occurs when one person - **the leader** - is able to cause the desired behavior of someone else, who succumbs to it because of the bond that binds them together, because of the social relationship that occurs between them K. Piotrkowski, M. Świątkowski (2000).

On the basis of the above definitions, it should be assumed that **Leadership** *is based on an emotional connection between a commander (in this case a leader) and his subordinates*, which creates a kind of bond between them. However, a leader is also identified with a **superior**. The superior tells people /subordinates what to do and holds them accountable, also takes responsibility for them, praises them for their successes and defends them in case of failure. The **LEADER** is more than a superior and much more than a commander. According to I. Majewska-Opiełka, the **LEADER** */simultaneously a commander and superior/* is a person who, in a certain group of people /subordinates/ stimulates the process of setting and achieving goals, it is a person who is focused on creating, for themselves and others, enthusiasm and the ability to expose the best qualities of his character. It is a person who does not impose his will by force, but skillfully motivates the members of the group /soldiers/ to carry out tasks etc. I. Majewska-Opiełka (1998).

Main Part

Moving on to considerations about the commander and the leader, the first thing to do is to indicate what professional training each officer graduating from the Military University of Land Forces should receive. This is shown in Fig. 2 below. A graduate of the Academy has a broadly formed personality and such social-professional qualifications which, supported by more and more recent experience in professional work and social life, allow him to become high-class professionals with the highest competencies over time. Such an assumption allows us to state that obtaining a university diploma and becoming an officer of the Polish Armed Forces after passing the appropriate exam for an officer and obtaining officer's position is only the beginning of every officer's journey,

An officer - commander, when starting his professional career in a military unit at his first post, is professionally prepared to carry out all the tasks that arise from his assigned duties. However, in the workplace and at the same time in the military service, he is confronted with many situational, organizational and structural conditions which he has to take into account in his professional pragmatics. Each military unit differs in its own specificity, depending, for example, on the type of army and the structural level in the military hierarchy. In addition, every officer who starts his service in a given organizational structure encounters many new relationships with people who have a personality-specific way of commanding /managing/ and directing people. This difference often results from the individual personalities of superiors, subordinates, people with whom one should work directly, etc.

Given the above, it is easy to guess that a military college graduate must be prepared primarily to adapt quickly to new working conditions. and service and acceptance of the broadly understood organizational culture, prevailing in a given military structure. The whole spectrum of personal and professional qualities an officer acquires during his

or her training at a military university should enable each graduate to adapt as quickly as possible to new conditions of work and service and to fulfil every roles while taking up subsequent official positions and performing various professional functions etc.

Fig.2: Determinants of personal and professional competence of officers graduating from the Military University of Land Forces

Source: Own study

The period of adaptation of a military college graduate to the new conditions of work and service is only a part of the criteria he must meet. During this period, superiors and responsible persons in a given organizational structure play a very important role in order to facilitate quick adaptation to work and service for newly-hired commanding officers in the Military Unit. Other aspects of the professionalism and improvement of social-professional competence of a commander-officer to make him effective in his job, depends only directly on him.

Military pragmatics show that not every commander has the personality traits that a leader should have. It is also not difficult to notice that the competencies of a leader, even at the highest level, are not able to balance the not fully formed personality of a leader. Therefore, it can be assumed that a leader must have both a properly formed leader's personality and competencies characteristic for a leader. This fact is illustrated in Fig. 2.

Fig.3 : Leader determinants

Source: Own study

It is necessary to assume that the main determinant which proves that an officer is not only a commander but also a leader is his **EMOCIONAL INTELLIGENCE**.

"Emotional intelligence" is the term used to describe the understanding of the motivational forces that drive our behavior and that of others. Taking into account the importance of cognition, affect and behavior on the stage of every person's inner theater, emotional intelligence plays an important role in leadership. It can be put in this way: *People who are emotionally intelligent are more likely to be effective leaders. Unfortunately, emotional intelligence cannot be learned from a textbook. Emotional intelligence develops through a process that takes place through experience. Moreover, development in this area is more efficient if it is accompanied by a spouse, friend, colleague, leader, therapist or other qualified person. It will help us to become aware of certain things that we do not see in ourselves, and to become aware of how to react with different people* M. Kets de Vries (2006).

According to Daniel Goleman, **EMOTIONAL INTELLIGENCE** is ***"The ability of us to recognize our own feelings and those of others, the ability to motivate ourselves and direct our emotions, both our own and those with whom we have some connection".*** In other words, *emotional intelligence is the ability to control our emotions and use them to achieve success*. These are skills that are different from academic intelligence, that is, purely intellectual skills, measured by the intelligence quotient, but complement them. Many people who have book knowledge but who suffer from a lack of emotional intelligence work for people with lower intelligence quotients, who have superior emotional intelligence skills. Daniel Goleman believes that emotional intelligence consists of the following emotional and social competences D. Goleman (1999):

- **self-awareness** - that is, knowledge of one's internal states, preferences, abilities and intuitive judgments, that is, emotional awareness, correct sa-moicing, self-confidence, that is, strong self-esteem and awareness of one's abilities and skills;
- **self-regulation** - i.e. control over one's internal states, impulses and abilities,that is self-control, maintaining standards of honesty and integrity, conscientiousness, flexibility in adapting to changes, innovation;

- **motivation** - i.e., emotional inclinations that lead to new goals or facilitate their achievement, that is pursuit of achievements, commitment, initiative, optimism;

- **empathy** - i.e., awareness of other people's feelings, needs and anxieties, i.e., understanding others, improving others, service attitude, political awareness, that means recognition of emotional group currents and relations among power representatives;

- **social skills** - i.e. the ability to arouse desired reactions in others, i.e. influencing others, understanding, conflict mitigation, leadership, creating bonds, cooperation and collaboration, team skills.

The above components of emotional intelligence perfectly describe a commander who claims to be a leader. A person who perfectly copes with his or her emotions, is able to regulate his or her relations with the environment, is aware of his or her mistakes and strives to eliminate them, as well as is perfectly capable of maintaining desired interpersonal relations with everyone and building theamas, as well as taking care of their proper functioning by solving, among others, difficult and conflicting situations, when necessary.

Today it is known that the intelligence quotient is not the main determinant that determines success in social and professional life. It was Daniel Goleman, a long-time Harvard scholar, who first drew attention to this fact. He has been conducting research over many years that has questioned for the first time the validity of the highly worshiped intelligence quotient - a widely held opinion that the intellect itself is needed for success. According to him, tests for the IQ were not unreliable, because people with high IQs often did poorly at work and those with low IQs worked very well. Often people with outstanding intelligence act irrationally, even hopelessly stupid. The intelligence that we show in science has little to do with emotional life. Even people with high intelligence quotients may be inept at managing their private lives, let themselves be carried away by unbridled emotions and act under the influence of uncontrolled impulses D. Goleman (1999).

It is also worth noting at this point, as H. Hamer wrote, that people who are leaders often use their characteristic social style in the process of interpersonal communication - the so-called leadership style. It is characterized by high assertiveness and low spontaneity. It is a style characteristic for typical leaders who are very strict, cold, inaccessible, although effective in their actions. However, it is difficult to imagine an officer-commander who, for example, would use only this social style in the process of training H. Hamer (1994). Therefore, some scientists prefer, apart from the style of communication: *expressive, analytical, leadership and polite* - the so-called **flexible style** - which is a mixture of the above mentioned social styles to varying degrees. This means that depending on the situation, on the experience gained, the social style will be different when *teaching students, training soldiers*, and different when *commanding soldiers on the battlefield*. Just as there are no uniform - *"pure varieties"* - types of mind in every person, so there are no *"pure social styles"* in every person C. G. Jung (1989); E. Pascal (1998).

Another determinant, as we must think, necessary for the personality of any leader, not just a commander, is the so-called **EFFECTIVE PERSONALITY of an OFFICER**.

A. Wielgus - on the basis of the research on officers personalities - believes that in order for an officer to be effective, he must, in his actions, achieve this effectiveness in four inseparable planes, i.e:

- In the area of his own subjectivity (personal psycho-intellectual competence and physical);
- towards other people connected with a given activity (social competences);
- towards the profession (professional competence);
- towards the task (task competence).

At the same time, A. Wielgus points out that an officer must enrich and improve his personality, because professionalism (having specific knowledge and skills) and social and organizational competence may prove insufficient A. Wielgus, after: S. Jarmoszko (2002).

The groups of personal and professional characteristics, resulting from the model of an officer's effective personality, are presented below S. Jarmoszko (2002):

attitude towards each other:

- strong will;
- maturity to himself;
- - self-confidence (in one's knowledge and skills as well as in one's professional and life experience);
- self-criticism;
- ability to manage one's emotions;
- caution

attitude towards professional duties:

- diligence, perseverance, accuracy, punctuality, regularity;
- ability to take risks;
- responsibility, generosity;
- passion for the profession;
- social-professional ambitions;
- creating a vision of action;
- showing initiative, imagination and inventiveness in thinking and acting;

attitude towards people:

- subjective approach to people;
- caring for oneself and others;
- camaraderie;
- ability to work individually and cooperate with others;
- assertiveness, empathy and self-reflection;

external image:

- taking care of proper external appearance;
- the way of verbal and non-verbal communication;
- following all conventions;

professionalism:

- general, directional and specialist knowledge related to the work performed;
- necessary knowledge of psychology, pedagogy and sociology, but also from management, IT or praxeology;
- knowledge of foreign languages;
- intellectual proficiency;
- creative and creative skills;

ethical and moral values:

- patriotism, honor;
- sense of self-esteem;
- respect for the dignity of others;
- moral sensitivity;
- justice, honesty;
- sincerity, principlicity;

the qualities of creative work:

- regime of creative work;
- ability to plan tasks;
- ability to organize the work workshop and carry out tasks;
- competencies characteristic for a person with transgressive orientation;
- discipline and consistency in action, patience, prudence, mental resistance;
- need for achievement, decisiveness;
- self-reflection and the ability to draw conclusions and correct one's behavior (if necessary).
- instrumental and cognitive skills of acting independently and in a team, as well as the ability to make demands on oneself and others, if there is a superiority in relation to other people;
- ability to solve problems and difficult situations and the skill to make decisions in various situations, even those with a high degree of uncertainty and risk.

The so-called effective officer's personality confirms the above assumptions that an officer commander must be prepared for various changing situation-organizational and structural conditions, and each situation, whether it is related to social (private) life or work and professional service, requires a different approach, decision or action, etc.

The last necessary determinant of an officer-commander to be not only a commander, but to have the personality and competence of a leader is the **SKILL OF MANAGEMENT (DIRECTING) OF HIMSELF AND OTHERS**.

Self-management should be seen today as the competence of every person to create both these far-reaching and short-term life plans for personal and professional development. Every officer-in-command should also have this competence. Unless there is a major problem with understanding how a commander is supposed to manage and direct subordinate people (human teams), as every military college graduate must have these competencies in order to fulfill his role in his official position. It is difficult to define and understand the term self-management.

For the purpose of these considerations, "**SELF-MANAGEMENT**" can be defined as follows: "*planning, organizing and controlling the implementation of its own projects, in accordance with its decisions, priorities and motives for action, taking into account its ability to achieve them in a targeted, effective and timely manner". This desired competence is also related to the previously mentioned, i.e. the emotional intelligence and effective personality of the officer*. However, it clearly treats and emphasizes the fact that a person who possesses these competences is not only able to be an empathic, assertive person and have the whole spectrum of desired character and personal characteristics and socio-occupational competences - he is able, first of all, to control his thoughts (often intrusive), he is prudent in assessing his or her skills; he knows his advantages, but also disadvantages and trying to level them out; he does not require from his subordinates more than from himself , he is able to maintain an ideal emotional balance in spheres: physical, intellectual, but also spiritual; can manage time wisely; has a sense of self-esteem; uses the resources of his imagination to create sensible solutions; is a model of qualities and virtues of a Polish Army officer.

Summary

This article points out how important it is for an officer-commander to be a leader too. A military college graduation does not guarantee that personality and leadership skills are acquired immediately. On the contrary, it is a long-term process, based on a multi-faceted and multidimensional approach to this problem. Being a leader requires a great deal of self-effort and a proper understanding of many aspects and problems. Both related to the functioning of one's personality and working with people in various socio-occupational correlations.

To sum up, one can unequivocally answer the rhetorical question, namely: Should every officer-commander be a leader? The answer is yes. However, it depends to a large extent on the personality of the commander himself and whether he properly understands the problems signaled in this article and is able to meet all the expectations that being a commander-leader entails.

Managing of Emotions of Military Students in The Educational Process of The University

Józef LEDZIANOWSKI

General Tadeusz Kosciuszko Military University of Land Forces Faculty of Management, Wroclaw, Poland, jozef.ledzianowski@awl.edu.pl

Lesław WEŁYCZKO

General Tadeusz Kosciuszko Military University of Land Forces Faculty of Management, Wroclaw, Poland, leslaw.welyczko@awl.edu.pl

Abstract

The article presents the most important aspects related to the deliberate and rational management of student's emotions in the didactic process of a military university. The in-depth knowledge of these problems and the well-established competences of academic teachers and commanders of military students subdepartments largely determine how the didactic process will proceed at the university. Whether it will be based on fear and constant emotions, sometimes unjustified, or on mutual cooperation between the teachers and the taught, where emotional intelligence and many of the determinants described in this article will make this didactic process effective and efficient, as a result of which the graduates will have a properly formed personality and acquire the necessary knowledge and skills to be professional commanders (educators and trainers) in military units.

Keywords: Personality, Competence, Leadership, Emotional Intelligence, Management, Emotions, Feelings, Sense of Value, Motivation, Mood.

Introduction

Among many determinants having a direct impact on shaping human life, the most important are the so-called *intellectual and non-intellectual factors*. They describe our image, decide who we are today and who we will be tomorrow. The most important of them are: **personality, emotions and motivations** - as extra-intellectual factors and **thinking, memory and perception** - as intellectual factors J. Kozielecki (1969).

It is impossible to describe all the intellectual and non-intellectual factors mentioned above in the context of the problem addressed. That is why the authors have given a special role to **emotions**, which are of key importance for the course of human thought processes, and thus require high efficiency in dealing with them. Military students are particularly susceptible to various types of emotions, which they practically deal with on a daily basis, both in the course of military life and in the process of education.

Emotions are the simplest experiences of satisfying or not satisfying the organic needs of food, drink, fresh air, protection from the cold, sexual needs, self-preservation instinct (in life-threatening situations) etc. *Psychology* (1966). In encyclopaedic terms, **emotion** is "(...) a mental process. It reflects an individual's attitude towards the stimuli acting on him, it is expressed by a change in the level of general mobilization (stimulation) of the organism, it has a specific sign (positive-feeling of pleasure, negative-feeling of sorrow) and a specific content and form of expression; (...) emotions influence the efficiency of action (...), they also cause changes in the course of thinking, perception and memory processes" *Encyclopedia* (1991). The so-called "emotional coloration of impressions caused by the specificity of individual objects" also belongs to emotions." Some colors, sounds, smells are pleasant, others - on the contrary - cause discontent *Encyclopedia* (1991).

Table 1: Emotions and feelings and their types

EMOTIONS - FEELINGS			
Affects	Moods	Passionate feelings	Higher feelings
Terror	Satisfaction or discontent	Love	Intellectual
Fury	Merriment or Sadness	Hatred	Aesthetic
Desperation	Sorrow	Greed	Social
Wrath	Anxiety	Lust of Power	Moral
Joy	Longing	Ambition	Religious
Aggressive behaviour	Depression	Greed	Stinginess

Source: L. Wełyczko, Zarządzanie procesem umysłowym w pracy twórczej, WSOWL, Wrocław 2012, p. 65.

Man is also subject to various types of stressful situations that interfere with his functioning in a certain way, often even preventing him from taking or abandoning any action, etc.

Stress: a set of processes involving negative emotions and a number of physiological changes (e.g. increased blood pressure, blood supply and skeletal muscle tension), appearing in response to all types of adverse factors, mental trauma, failure, danger or injury or thermal shock, Long-term, chronic stress causes negative health consequences, disrupting the immune system and having a destructive effect on a number of tissues *Słownik* (2005). The main causes of stress are illustrated in Fig.1.

Figure 1: Causes of stress

Source: L. Wełyczko, Zarządzanie procesem umysłowym w pracy twórczej, wyd. cyt., p. 65.

The classification of feelings and emotions is determined by their strength L. Wełyczko (2012):

- strong, powerful;

- weak.

Division of emotions by their nature:

- *unpleasant;*

- *pleasant.*

Division of emotions by content:

- *intellectual;*

- *social;*

- *moral;*

- *aesthetic.*

Division of emotions according to the degree of complication:

- *simple - satiety;*

- *complex - friendship, love;*

- *deep.*

Division of emotions for durability:

- *moods* - a longer lasting emotional state is relatively weak (e.g., well-being or depression, etc.);

- *affections* - strong violent and short term emotional experiences, caused by rage, horror, despair; they endure the possibility of self-control; they depend on personality traits; they do not depend on will; they are based on unsatisfied ambitions and external conflicts;

- *feelings* - they are manifested with distinct vegetative symptoms.

Emotions arise in situations:

- threats;

- limitations;

- deprivation;

- satisfaction.

Emotions can be shaped. An attempt to illustrate the ways of shaping emotions is presented in Fig. 2. (Shaping emotions -> Prevention of depression/stress and apathy etc.-> Motivation through optimism; Mood boosting; Teaching the expression of feelings; Teaching conflict/problem solving etc.; Suppression of aggression, anxiety, fear etc.

Figure 2: Shaping emotions

Source: L. Wełyczko, Zarządzanie procesem umysłowym w pracy twórczej, wyd. cyt., p. 66.

Main Part

How to manage the emotions of military students in the educational process of the University?

The answer to the above question is not so simple at all. It is mainly due to the specific nature of military education and training in which military students participate. Moreover, the dualism of the said education and training consists in the fact that graduates of a military university must obtain appropriate preparation and qualifications, which every graduate of the university (confirmed by a diploma of graduation) and must obtain appropriate qualifications predisposing them to perform the profession of a professional soldier - an officer (after completing military training at the university level and passing an examination in this field - confirmed by obtaining an officer's patent).

The following conclusions can be drawn from the above:

- A military student is particularly vulnerable to various stress and emotional states, due to the specifics of simultaneous education and training;

- the military student is constantly - for the duration of his studies - connected with his environment, in which, with small exceptions (internships, vacations, passes), he is subject to the course of military service;

- to become a graduate of a military school, a much greater effort, both intellectual and physical, is required during the period of study as a civilian student of any other university;

- Being a military student requires self-discipline, perseverance, and a lot of effort and sacrifice that civil students do not normally face.

In order to manage the emotions of military students in the didactic process it is essential to have the ability to manage their emotions and the necessary knowledge and skills in this area. Moreover, it is highly desirable to have so-called **emotional intelligence**, which is a key determinant of being not only an officer-commander /teacher, educator or trainer/, who uses only the established patterns and learned rules in the educational process with soldiers and is inaccessible in mutual contacts with students - on the contrary, having emotional intelligence guarantees reciprocal interpersonal correlations, which are based on widely understood **leadership**. In a word, an officer-commander then becomes an **officer-leader**.

A **leader** is a person who is accepted by others and who can influence the behavior of others without the need for force C. Griffin (2004).

D. Goleman believes that **emotional intelligence** is the ability to recognize one's own feelings and those of others, the ability to motivate oneself and direct one's emotions, both one's own as well as those of people with whom we have some kind of connection. At the same time it gives the 5 most important social competences, which determine emotional intelligence in people who have it, are:

- **Self-regulation** - i.e. control over one's internal states, impulses and possibilities, that is self-control, maintaining standards of honesty and integrity, conscientiousness, flexibility to adapt to changes, innovation;

- **Motivation** - i.e. emotional inclinations that lead to new goals or facilitate their achievement, that is pursuit of achievements, commitment, initiative, optimism;

- **Empathy** - i.e., awareness of other people's feelings, needs and anxieties, that is understanding others, improving others, service attitude, political awareness, i.e., recognition of emotional group currents and relations among power representatives;

- **Social skills** - i.e. the ability to arouse desired reactions in others, that is influencing others, understanding, conflict mitigation, leadership, creating bonds, cooperation and collaboration, team skills D. Goleman (1999).

Usually, leaders are also leaders, such as the lowest-level commanders (team, platoon or company). In this case, the leaders fulfill the role of leaders.

Leaders- commanders usually have two main roles

- They must complete the task because that is what a team is for; the leader takes care of the group's goal; if the goal is not achieved, there is frustration, dissonance, criticism, and ultimately even disintegration of the group;

- Maintain effective relationships, both with team members and among group members; relationships are effective when they contribute to the task and can be broken down into those that affect the whole team, its morale and sense of purpose, as well as relationships with individuals and ways of monitoring them M. Armstrong (2007).

Table 2: Leadership styles and their opposites that leaders can adopt

LP.	LEADERSHIP STYLE GROUPS	
	Leader	
1.	Charismatic: It interacts through its personality, inspires qualities and "aura"; such leaders are often visionaries, goal-oriented; risk-aware and well communicated with their environment.	Deprived of charisma: They rely on self-confidence, a cool, analytical approach to problems and their knowledge (the authorities are held by who knows - know-how).
2.	Democratic: Encourages people to cooperate and makes decisions with them.	Autocratic: Imposes its own decisions, using its position, forces people to follow orders.
3.	Inspirational: Passionates others with its own vision of the future and gives strength to team goals.	Controlling: Manipulates people to force obedience.
4.	Transformative: Motivates people to set themselves increasingly ambitious goals.	Transactional: Exchanges money, work and security for submission to his power.

Source: Own study based on M. Armstrong, Zarządzanie ludźmi, wyd. cyt., p. 50.

P. Tyrała, comparing the desired characteristics determining leadership skills and the resulting benefits in this process, presented it in the following way, as shown in Figure 3 below:

Figure 3: Characteristics that determine leadership skills

Source: P. Tyrała, Kierowanie, Organizowanie, zarządzanie, Zarys prakseologii, Wyd. Adam Marszałek, Toruń 2003, p.166.

Taking into account the predicted characteristics and praxeological skills of an excellent leader and the opinions of many authors in this respect, it is possible to compare the following with regard to an officer, signalling at the same time as those that he should possess in order to be perceived not only as a commander, but as a leader. They include I Majewska-Opiełka (1998); D. M. Stewart; B. Feder (2002); L. Kanarski, B. Rokicki, J. Świniarski - ed. (2000):

- self-esteem;

- proactivity;

- autonomy;

- positive thinking;

- interdependence;

- internal cohesion;

- sense of abundance;

- ability to create visions;

- ability and willingness to learn continuously;

- Decision making ability;
- righteousness;
- enthusiasm;
- imagination;
- willingness to work hard;
- analytical skills;
- understanding for others;
- ability to see opportunities;
- ability to cope with unpleasant situations (difficult and conflicting);
- ability to adapt quickly to change (ability to adapt);
- Ability to take risks;
- entrepreneurship;
- ability to express thoughts clearly;
- clarity of mind;
- ability to administer efficiently;
- open-mindedness;
- perseverance;
- ability to work for hours.
- Creativity, creativity;
- taking care of employees;
- knowledge;
- vision;
- flexibility;
- good organization;
- communication skills;
- self-confidence;
- ability to anticipate and analyse the situation;
- charisma;
- ability to motivate;
- active listening;

- intelligence;

- courage;

- being demanding;

- leadership skills;

- positive thinking;

- conflict resolution skills;

- resourcefulness;

- willingness to change, looking for new solutions.

- decisiveness;

- determination;

- Ability to trust others;

- self-confidence and influence on the environment;

- objectivity in the courts;

- The ability to plan and organize activities;

- optimism;

- readiness to take initiative;

- ability to consolidate leaders;

- professional proficiency;

- resistance to stress;

- ability to use their own strengths and available resources effectively.

In the didactic process at the military university, apart from shaping (forming) students with leadership qualities and skills, where emotional intelligence is the key determinant, should be taught how to manage stress. No one else, like military students, is exposed to all sorts of negative effects of stressful situations, which they are very often faced with during military training and beyond Zimbardo P. G., Johnson R. L., McCann V. (2010) present different views on stress, while pointing out specific sources of this phenomenon - signaling its nature of complexity. According to these authors, external events or situations that cause stress are referred to as **stressors**. **Stress, on the other hand, means physical and mental changes that occur as a reaction to a stressor**. What constitutes a threat to one person, to another can be a pleasant variety. When stress begins, for example, something should be done immediately, which for various reasons is difficult - the body produces more adrenaline. Then it feels like blood hits your head, your pulse is pounding like crazy, your breathing is accelerated, your throat is dry, your hands are wet, but a lot of energy. Then we are dealing with the first stage of stress. The second stage of stress - it's the persistent stress that exhausts vital forces, and the third stage - threatens with nervous breakdown.

Stress can cause *Zarządzanie stresem* ... (2008):

- Decreasing work efficiency (unhealthy stress reduces work efficiency, increases absenteeism and employee turnover; it sometimes forces employees to look for a new job, which affects the efficiency of the whole team, etc.);

- harmful effects on health (prolonged stress can lead to extreme exhaustion and even death);

- energy deprivation (stress, anxiety and anxiety, occurring in excess, may give rise to energy deprivation, from which the work done, as well as the private life of the employee will suffer, etc.);

- Destruction of relationships between people (stress can seriously disrupt various relationships, both at work and at home; it can cause interpersonal conflicts which affect ne-gative feelings or worsen the current situation, including severely disrupting the rhythm of the team, etc.).

Stress is a natural phenomenon and accompanies everyone throughout their lives. There are a number of possibilities to control stress so that it becomes helpful in everyday life and has a mobilizing dimension for effective and efficient action. Lifestyle plays a key role in stress management. It is worth remembering that wellbeing promotes health and increases resistance to stress. On the other hand, mortification, e.g. a strict diet, encourages bad wellbeing, causes stress etc.

In the didactic process, as well as outside it (in the course of military life in a subdivision and military university) students should be taught how to cope with stress. According to J. Strelau, an individual's ability to cope with stress depends on such features as J. Strelau (1999):

- intelligence;
- abilities;
- special skills;
- knowledge;
- personality and temperament characteristics;
- physical characteristics;
- number of experiences related to a given stress situation;
- current state (physical and mental) of the individual.

The simplest and at the same time the most prophylactic prevention of stressful situations are *Zarządzanie stresem* ... (2008):

- Avoiding stressors;
- physical exercise (physical activity);
- healthy eating;
- healthy sleep;
- relaxing reaction.

Students should also be able to maintain the so-called life balance. In order for a person to achieve his or her life goals and aspirations, to enter into adult life after completing primary education and vocational training, working, starting a family, and to live with dignity he or she should achieve a "relative" life balance. P. Wilson points to the eight determinants that determine a person's balance when they interact harmoniously and comfortably P. Wilson (2012):

- personal needs and ambitions;
- responsibilities and family responsibilities;
- tasks at work;
- professional commitments;

- social commitments;

- social responsibility;

- moral and spiritual responsibilities;

- Imaginary responsibilities.

According to the author mentioned above, a harmonious, balanced human personality is created by P. Wilson (2012):

- **physicality** (i.e. all the temporal needs of man, that is health, food, recreation, sleep, sex);

- **spirituality** (these are not only matters related to God, but also life values, the search for the meaning of life, the need to have meaning for the world and the need to help others and even the whole planet);

- **work** (it is primarily a profession, but also a number of mental needs, such as the desire for achievement and creation, the desire for personal development, recognition, respect and self-esteem);

- **social situation** (this is all integration with people; involvement with family, home, friends and society).

The last aspects that need to be taken into account when shaping the personality of military students to deal professionally with their emotions and stressful situations are: **students' self-management**, **self-esteem** and **proper time management**.

Self-management is considered to be personal skill. It means managing one's own life and career, establishing and implementing one's personal plans and goals. It also means having control over one's own life, behavior, resources and creative adaptation to a constantly changing world. The functions of management are: planning, organizing, motivating (stimulating) and controlling (evaluating). Therefore, it is not difficult in this case to talk about the student's planning of his or her closer or further life and socio-occupational life, organizing such activities that allow to achieve the intended closer and further goals and self-motivation for all activities in this area and control (evaluation) of those goals, etc.

It should be assumed that rational self-management shows great maturity and socio-occupational stability, it is good to know what you want to achieve in life and how you are not surprised by the variability of situations, often burdened with stressful states. Everyone should be able to plan his or her life, career and all the actions which - according to his or her needs and beliefs - allow him to consciously manage his resources, i.e: energy, mental and physical resources, and consequently emotions, stress and time.

N. Brandon's sense of self-esteem considers *"...high self-esteem, which is a disposition to experience yourself as a person competent to deal with the basic demands of life and deserving of happiness*". N. Branden (2008). This author points to six pillars of self-esteem, these are:

- **The practice of conscious living**: the more conscious a person is of what they do, the more control they feel and are more effective and the more successful their efforts are;

- **The practice of self-acceptance**: high self-esteem requires acceptance, not self-rejection;

- **The practice of self-responsibility**: responsibility for oneself allows one to feel inner strength. This does not mean that everything has to be done on its own, but it does mean that, even as a team, we don't pass the burden on to others.

- **Assertiveness practice**: it is about respecting one's own needs, desires, values and judgements and looking for appropriate forms to express them;

- **The practice of purposeful life**: in passivity, neither our reason, nor our passions, nor our creative abilities, nor our imagination are fulfilled. Man's life should be a search for the fullest expression of his characteristic abilities, then the answer is obvious;

- **The practice of righteousness**: it means keeping one's word, respecting one's own commitments, fulfilling one's promises.

Time management is the effective self-organization of every work, venture, activity, etc. - It is connected with skilful time management. It is not a simple matter at all. It requires perseverance, determination and appropriate personality traits. Controlling one's own activity is about setting and prioritizing the objectives, planning the means and actions to realize them and controlling the final results. In order to manage time effectively you need to:

- have knowledge about yourself, your temperament, your physiological performance curve, your strengths and weaknesses, your perception of time;

- have attitudes: self-discipline, consistency, concentration, etc;

- be able to plan, set priorities, assignments;

- distinguish between important and urgent things.

Most experts in effective learning are of the opinion that the most important and best way of not wasting time is to draw up a learning plan. It should be filled in with specific tasks or subjects that we want to learn. Remember that a full cycle of learning takes about 1-1.5 hours, and the warm-up time is about 5-10 minutes. After that time comes the moment of proper action with high concentration and high efficiency - it usually takes 45-60 minutes. At the end of the hour you notice a drop in concentration and a feeling of being stuck in a deadlock, then it is best to take a break and relax.

Summary

To sum up the aspects related to the management of emotions of military students in the teaching process of the university, presented in this article, it should be clearly indicated that all lecturers must be professionally prepared for educational work in this area. This preparation must not only include substantive and professional knowledge of the subject being taught, but also broadly understood knowledge of pedagogy (including didactics and teaching methodology), but also the basis of knowledge of psychology. Only a high-class professional with the necessary competences indicated above is able to participate in the "process" of forming emotional intelligence in students and teach them how to cope with various stressful and emotional situations. It is also necessary for academic teachers as well as sub-departmental commanders (direct superiors of military students) to have such a personality, which in each case will be a personal-professional and ethical-moral model for students.

Józef LEDZIANOWSKI

General Tadeusz Kosciuszko Military University of Land Forces Faculty of Management, Wroclaw, Poland, jozef.ledzianowski@awl.edu.pl

Abstract

Planet Earth is our common home in which we live, farm, and in which in 1987 we decided, at the initiative of the UN, to organize our common future. Human needs for natural resources are measured by the size of their ecological footprint. The size of the ecological footprint is influenced by partial footprints, the largest of which is the carbon footprint. The size of this footprint is significantly influenced by waste produced by society. Plastic waste is the most dangerous. The paper presents an analysis of the volume of plastic municipal waste in the years 2006-2018 in Poland and Europe, as well as the situation in the processing of this waste.

Keywords: Earth bio-capacity, ecological footprint, sustainable development, primary production, ecological debtor, life-giving areas, recycling, landfill, energy recovery, post-consumer waste, municipal waste.

Introduction

Recently, the problem of environmental protection worldwide, is becoming more and more popular. What is this interest caused? Well, it is impossible not to notice that violent atmospheric phenomena, hurricanes, floods, catastrophic droughts are something abnormal in our latitude. There was also an increase in air temperature to a level previously not observed. This abnormal situation caused great concern for both meteorologists and the whole society.

The aim of the presented paper is to present the most important problems faced by contemporary societies and international organizations whose activities are aimed at eliminating (or at least reducing the effects) of irresponsible human activity in the field of environmental destruction. In order to explain the problem better, human was also presented as how his destructive activity not only reduced the comfort of life of the inhabitants of the Earth, but it led to the fact that not only the existence of the human race is threatened, but also the life of the entire planet. This is because the planet is being overused by appropriating its primary production. Humanity has left the mark of its existence on planet Earth and must suffer the consequences. Everyone should wonder what I can do to reduce the “cost of my existence on Earth”. Isn’t it too late?

We do not know an answer to the question. May it turn out that this situation still can be improved. The presented work is an attempt to "improve the situation" by increasing the environmental awareness of the society and this is its main goal.

The above presented problems show that the activity of international organizations is very important, but the role of rank and file members of society cannot be overestimated either. Each person has a specific lifestyle and habits, and thus can determine the cost of his existence on Earth.

The basic concept that the authors will use in their further research and analysis is the concept of "ecological footprint". It is an indicator designed to estimate the use of natural resources in relation to their restoration by our planet. The ecological footprint can be calculated for the whole world, for a selected country, but also for an

individual. It is also possible to analyse the factors influencing this value and determine their responsibility for undesirable natural phenomena.

Society as an organism uses raw materials, transforms them into products useful for man, and the useless (harmful) effects of such a transformation are removed from its organism by polluting the environment. It is known that the problem of waste cannot be avoided in the production process, but a lot of this waste can be reused and therefore should be done whenever possible. Thanks to this, waste and unused items will not be wasted, and will be processed and still used by people. In an increasing number of countries, the role of recycling is increasing, and the use of recycling is becoming more and more popular. In Europe, Germany is the leader in this respect, where 67.3% (2018) of the total waste was collected selectively in Poland, this share was only 34.3% (2018). The authors intend to actively engage in the research on environmental hazards posed by waste. The presented work deals with the problem of municipal waste, i.e. waste generated by the society. The amount of this waste depends to a large extent on the ecological awareness of the society. Of course, waste is an integral part of social metabolism and it always appears. The problem is to properly manage this waste. Due to its harmfulness, plastic waste, including packaging with a short life span, is particularly important. The paper presents measures taken by governments and international organizations to reduce the amount of waste produced, as well as measures to reduce the amount of waste going to landfills.

In their research, the authors use the figures available in the Central Statistical Office database (GUS) as well as in EUROSTAT. Standard descriptive statistics methods were used to compile the data.

Main part

The energy of sunlight is transformed by plants and phytoplankton (photosynthesis) into the chemical energy of their bodies. The energy obtained in this way is called gross production of nature. Part of this energy is used to produce a variety of goods, and some for breathing. The rest of the energy is called net primary production.

The volume of this production is measured not in the form of biomass (residues remaining from plant and animal production), but in the form of carbon contained in it. The amount of primary production depends on the ecosystem where it is carried out. For example, the annual production of deciduous forest is about 1300 g/m^2, while the ocean only 120 g/m^2.

According to the researchers, the annual primary production available to all organisms on Earth (in terms of pure carbon) is 224.5 Gt.

Thanks to primary production, life on Earth is maintained. Part of this production is consumed by human. The remaining part is used by other creatures living on the Earth.

Since the mid-seventies, Earth has been terribly exploited by humanity. If we compare the life-giving capabilities of the planet and its exploitation by humans, then we will see that exploitation is enormous.

The area of the globe is 51 billion ha, of which 36.6 billion are oceans and other water areas, while 14.4 billion ha are land. Only a part of those areas is life-giving and biologically productive areas. From 2.3 billion water areas they are productive, and from land 9.1 billion ha. In total, it is 11.4 billion life-giving areas.

These areas are divided into five categories: areas for cereal cultivation, pastures for grazing and hay production, forest areas for wood production, fishing areas and built-up areas.

Around 2000, there were a total of about 6 billion people on earth, or about 1.91 ha of life-giving area. However, people in the world lived as if everyone had 1.91 ha but 2.33 ha at their disposal. In the latest sources we find information B. Ewing, S. Moore, A. Goldfinger, A. Oursler, M. Reed, M. Wackernagel (2015) that as a result of the increase in population and "shrinking" of life-giving areas, on average there is only 1.7 ha per person. This means that humanity lives beyond the life-giving capabilities of the planet. The effects of this condition are unpredictable.

The degree of exploitation of the planet is measured by a unit called the global hectare. The essence of this measure is that consumption is measured not in monetary units, but in hectares needed to produce the goods consumed. These units are called gha (global hectars). The unit of measurement is the average yield per hectare regardless of

the category of area. Productivity is calculated as the amount of good (amount of matter, amount of carbon dioxide absorbed) divided by the size of the area. If the average global efficiency is known, by dividing the quantity of good consumed by this efficiency, one obtains the "demand" for the area measured in these units. Productivity from individual life-giving areas is not the same. For example, if the yield from arable land is 2.1 times higher than the standard yield of the global hectare, the number 2.1 is treated as a scaling factor (equivalence factor). Scaling factors for areas of production nature (producing primary production) are calculated every year B. Ewing, S. Moore, A. Galli, J. Kotzens, M. Wackernagel (2010).

In Fig. 1, graphically also the size of life-giving areas were expressed in real values (hectares) and global hectares.

Fig. 1: Biocapacity areas in ha and gha

Source: [Ewing et al. 2010]

Having scaling factors, you can count the life-giving possibilities of the planet as well as its exploitation. Tab. 1 presents data on the life-giving potential of the planet and its exploitation in 1999.

Tab. 1: Biocapacity of the planet and its exploitation in 1999

Areas	Total Area [bln ha]	Area [ha/cap]	Scaling factor	Total Area [bln gha]	Supply [gha/cap]	Exploitation [gha/cap]
Farmlands	1,5	0,25	2,1	3,2	0,53	0,53
Pastures	3,5	0,58	0,5	1,6	0,27	0,1
Forests for felling	3,8	0,65	1,3	5,2	0,87	0,29
Building	0,3	0,05	2,2	0,6	0,10	0,10
Fishery	2,3	0,39	0,4	0,8	0,14	0,14
CO_2						1,16
Total	11,4	1,91	1,0	11,4	1,91	2,33

Source: M. Wackernagel, C. Monfreda (2004)

In the last row of Tab. 3, the abbreviation CO_2 means areas needed for the absorption of carbon dioxide from the burning of fossil fuels and originating from nuclear power plants.

This is the most important ingredient in the overall exploitation of the planet. The contribution of individual components to the overall exploitation of the planet is shown in Fig. 2.

Fig. 2: Degree of exploitation of the planet by type of area used

Source: W. Ostasiewicz (2016]

The planet's exploitation (in the form of the exploitation factor) can be calculated not only for the entire planet, but also for individual countries, cities and even smaller regional units. In such cases, additional scaling factors are needed because the yield per hectare may be different for different countries or regions B. Ewing, S. Moore, A. Galli, J. Kotzens, M. Wackernagel (2010).

Fig. 3: Participation of selected ten countries in planet exploitation

Source: B. Ewing, S. Moore, A. Galli, J. Kotzens, M. Wackernagel (2010).

As it results from the presented figure, half of the global ecological footprint in 2007 was accounted for by ten countries of the World B. Ewing, S. Moore, A. Galli, J. Kotzens, M. Wackernagel (2010). Of those countries, only the United States alone accounted for 21% of the planet's global exploitation and China for 24%. The rest, around 5 percent, was generated by the other 8 countries listed in the figure above.

Examples of performance factors for different countries can be found in the literature B. Ewing, S. Moore, A. Galli, J. Kotzens, M. Wackernagel (2010).

In the early 1960s, half a planet was enough to provide people with life, in present times 1.7 is needed to meet the current standard of living. The planet earth is over-exploited, and this is called exploitation. Of course, this is average exploitation. Some countries use it less others more. If the life-giving potential of a state is greater than the degree of exploitation, such a state is called an economic creditor, because at its expense other exploiting states live. And vice versa, if the life-giving possibilities in a country are smaller than its exploitation, then that country is called an ecological debtor. For example, in 2010, the life-giving potential of Poland was 2.0 gha per capita, while

the average utilization of these opportunities was 3.8 gha per capita. Thus, Poland's ecological debt this year was 1.8 gha per person. In 2010, Poland had 38042794 inhabitants, so Poland had an ecological debt of 68477029 gha.

In the last forty years, both bio-production possibilities and their use have changed, thus the ecological debt has changed. This situation is presented in Fig. 4.

Fig. 4: Poland's ecological debt in the years 1960-2010

Source: B. Ewing, S. Moore, A. Galli, J. Kotzens, M. Wackernagel (2010).

The contribution of individual countries to the current ecological debt is very uneven. The ecological footprint calculated per capita ranges from below 1gha (for poor countries such as Eritrea or Mozambique), through about 5gha (for countries such as Norway or the United Kingdom) to above 8 gha for the United States and Australia. Israel is the world's largest ecological debtor using ecological opportunities 18 times greater than the country's real ecological opportunities. Poland uses ecological opportunities 2.1 times greater than the country's real opportunities [cf. Global Footprint Network ..., (2014)].

The global situation in the field of Earth exploitation is presented in Fig. 5.

Fig. 5: Environmental debtors and ecological creditors on a global scale

Source: [Ewing et al. 2010]

Ecological awareness is very high in Europe, which translates into the official policy of the European Union and earlier of other European bodies. At European level, the issue of environmental protection is very vital. EU agendas monitor the state of the environment, emission levels in individual Member States and make commitments to limit negative environmental changes.

In Poland, little more than 10% of energy still comes from renewable sources. In order to develop this sector and adapt Polish realities to EU guidelines, a number of legal regulations have been adopted. It is forecast that the share of energy from renewable sources will increase in Poland by 2030 to over 15%. At the same time, the government is protesting against the limit (550 g CO_2 per 1 kWh) imposed by the European Union for power plants supported by the state. These limits harm the Polish coal energy sector, which is considered the guarantor of the country's energy security.

The ecological footprint is a measure of human demand for natural resources. It determines how much biologically productive land and sea areas are necessary to provide people with resources needed for consumption and to assimilate waste related to this consumption E. Nieckula (2011). Waste is a by-product of social metabolism that always appears.

The ecological footprint can be counted separately for each individual, social group, organization or society. Using this indicator, it is possible to assess the pro-ecological behaviour of individual social groups, but also of individual countries. The shaping of the ecological footprint of the entire planet is influenced by partial footprints (see Fig. 2), of which the carbon footprint has the greatest share.

The carbon footprint includes greenhouse gas emissions expressed in CO_2 equivalent. Greenhouse gas emissions are warming the climate and all the negative weather phenomena we are currently experiencing. International conferences and talks are held on the subject of limiting carbon dioxide emissions to the atmosphere [Global Climate, (2016)].

Virtually every human activity increases the carbon footprint, but everyone also influences its size. Both large industrial plants can reduce the release of greenhouse gases into the atmosphere by installing appropriate filters, and each member of the society can reduce CO_2 production through appropriate consumer behaviour. Of course, the impact of individual social units on the size of the carbon footprint is small, for example, it may consist in changing the means of transport to work (changing the car to a bicycle), reducing the waste of electricity, or even changing the diet (switching to a vegetarian diet). However, due to the massive scale of the phenomenon, the combined impact on the size of the Ecological Footprint can be significant.

The share of the Polish society in the global production of CO_2 is quite large. Poland's rank in the world in terms of CO_2 emissions to the atmosphere is 21. This accounts for 0.9% of the world's production of this pollutant [Infamous Ranking…, (2019)].

Waste is a factor that has a strong influence on the emission of carbon dioxide to the atmosphere. Waste is a threat to humans and the environment due to its toxicity, which can cause air and soil contamination and pose a threat to living organisms.

Our considerations will concern municipal waste, i.e. waste related to non-industrial human activity, but produced by society. It is the size of this waste that depends only on the environmental awareness of the society.

Currently, the world produces about 2 billion tons of municipal waste annually. In the latest report of the World Bank we find the conclusion that if urgent measures are not taken, the amount of waste in the world will increase by 70% by 2050 [Śmieci…, (2018)].

The USA produces the most municipal waste in the world. The annual per capita production of waste in this country is 773 kg, which is 12% of the total amount of waste in the world. For comparison, the populations of China and India, which together account for over 36% of the world's population, and collectively generate 27% of the world's waste. The basic way to reduce the size of waste is to reuse it with the lowest possible input of raw materials and energy needed for their processing (recycling).

Pursuant to the ordinance of the Minister of the Environment of September 27, 2001 (Journal of Laws 2001, No. 112, item 1206), the type of waste depends on the source of its generation. According to this criterion, waste is divided into 20 groups. Group 19 in this classification is municipal waste – that is waste generated by the society [Kody…, (2020)].

A necessary condition for recycling waste is its prior segregation. In Poland, since 2017, there is an obligation to segregate waste.

On July 1, 2017, the Unified Waste Segregation System (JSSO) was implemented in Poland and it is valid throughout the country. Municipal waste is collected in four fractions: plastic, glass, paper and mixed waste.

Detailed instructions on waste segregation are contained in the Regulation of the Minister of the Environment of December 29, 2017 [Journal of Law 2017, item 19].

In 2017, Polish households produced 12 million tonnes of waste, which means that the average Pole produced an incredible amount of waste equal to 312 kg. Moreover, despite the fact that the act on waste selection was in force, only about 40% of this waste was segregated.

Fig. 6: Ratio of the amount of waste collected selectively to the total amount of waste.
Source: Own elaboration based on GUS data

The presented figure shows that the situation is slowly improving in this respect. Although in 2018 less than half of the waste was segregated, it was a fourfold increase compared to 2010.

If we consider the volume of municipal waste per inhabitant of Poland in 2010-2018, it can also be noticed that despite the growing wealth of the society, there is no drastic increase in waste (taking into account that a large part of municipal waste is food).

The level of waste remains approximately constant at around 300 kg / person.

The time series describing the amount of waste per person in 2009-2018 in Poland was shown in Fig. 8.

Fig. 7: Amount of municipal waste in Poland per capita in 2009-2018
Source: Own elaboration based on EUROSTAT data

Municipal waste in Poland is sorted into four types: paper, glass, plastic and mixed waste. The mixed waste can only be disposed of. The remaining types of waste are recyclable.

The structure of municipal waste according to segregated types is presented in Fig. 9.

Fig. 8: The structure of waste by selected types in Poland in 2010-2018
Source: Own elaboration based on EUROSTAT data

Glass waste is an excellent recyclable material. Some used glass packaging can be recycled into identical new packaging. Processing glass reduces the amount of this waste in landfills, although they do not pose a threat to the environment, but only spoil the landscape. Moreover, making glass products from waste is more environmentally friendly than producing from raw materials, as the level of carbon dioxide emissions in production is much lower. Waste paper is a similarly easily recyclable material. This raw material has been used for years in the production of inferior quality paper and other products.

The presented structure shows that plastics account for quite a large share in the total amount of waste. Plastics obtained from crude oil are particularly dangerous to the environment because the process of their decomposition takes up to several thousand years. When abandoned in landfills, they emit poisonous substances that contaminate water and soil. If you burn them yourself, poisonous substances are released into the atmosphere.

Although there are generally known disadvantages of plastic, the fact that the use of this material in everyday life is sometimes inadvisable, the share of this material (as shown in the drawing) in the lives of Poles is very large. In this respect, Poland is not alone. The use of products with a short life cycle is particularly harmful, as they produce a lot of waste. Recently, the issue of water pollution with plastic waste that threatens the life of marine flora and fauna has aroused a lot of emotions. If the trend continues, it is predicted that by 2050 there will be more plastic in the seas than fish.

Despite the fact that plastic waste is very harmful to the environment, the demand of EU countries for this product in 2018 was 51.2 Mt, with 25 percent of plastics in 2018 consumed by Germany, the largest economic power, and also a country with the opinion of the greenest in Europe. Poland was the sixth country in terms of demand for this product. The six largest countries in the European Union consume 80 percent of European plastics production. Of course, among plastic products there are products with different life cycles as well as products with different decomposition periods. From the point of view of the ecological footprint, the most harmful is waste produced by society, i.e. municipal waste directly affected by members of society. It is both the amount of generated waste and the management of this waste.

In January 2018, the European Strategy for the Management of Plastics in a Circular Economy was developed [Communication… (2018)]. This strategy defines the contribution of the European Community to achieving sustainable development goals. This strategy will help protect the environment, reduce marine pollution, reduce greenhouse gas emissions and reduce dependence on fossil fuels.

In May 2018, the European Commission developed new EU-wide rules [Proposal…(2018), ANNEX... (2018)] for the use of ten single-use (plastic) products, the most common pollutant for beaches and marine waters by the people who use them. If we add to this items abandoned by fishermen while fishing at sea, we get a huge amount of waste, accounting for about 70% of the total pollution of the seas and oceans.

Ultimately, the problem of single-use items is to be solved by Directive 219/905 of the European Commission of 5 June 2019. Article 5 of this directive prohibits the marketing of ten different plastic products that have environmentally safe alternatives. Thus, from July 2021, plastic spoons, plates, knives, etc. will disappear from stores (also in Poland). In the following years, trade in plastic products will be further reduced.

The amount of plastic waste generated in the EU in 2018 is estimated at 29.1 Mt, while in 2006 it was 24.5 Mt. This is a 19% increase compared to 2006. It is encouraging, however, that in the period 2006-2018 the amount of waste recycled doubled. Nevertheless, 25 percent of plastic waste still ends up in landfills [Plastic…, (2019)].

However, if we compare the situation in 2006 and 2018 in terms of the basic methods of processing plastic waste (recycling, energy recovery and landfilling), it will also turn out that there has been a clear improvement.

Tab. 2: Processing of plastics by type of processing in 2006 and 2018

Processing method	Year 2006	Year 2018	Increase in 2018 compared to 2006	Average annual rate of change
Storage at Mt	12,9	7,2	-44 %	-1,1
Energy recovery in Mt	7,0	12,4	77 %	4,8 %
Recycling in Mt	4,7	9,4	100 %	5,7%

Source: Own elaboration based on: [Plastic.., (2019)]

Despite a significant improvement in waste treatment, still 25% of waste generated in 2018 is sent to landfills.

This is a very significant improvement compared to 2006, when 50% of the waste was landfilled.

The figures below characterize the situation with regard to the use of plastic packaging (packaging becomes waste at the end of its life). It seems to be the most carelessly used plastic product due to the short life span of this product. In extreme cases, plastic bags for shopping are used only once (despite the appeal printed on these bags encouraging the repeated use of the product), the same is the case with disposable cups, plates, etc.

In 2018, the amount of plastic packaging waste was 17.8 Mt, while in 2006 it was 14.9 Mt. Thus, there was a large 19% increase in the period 2006-2018.

The situation with the management of this large amount of waste is slightly better. This situation is presented in Tab. 3.

Tab. 3: Processing of plastic packaging by type of processing in 2006 and 2018

Processing method	Year 2006	Year 2018	Increase in 2018 compared to 2006	Average annual rate of change
Storage at Mt	7,2	3,3	-54	-1,2
Energy recovery in Mt	3,8	7,0	84	4,1
Recycling in Mt	3,9	7,5	92	4,6

Source: Own elaboration based on: [Plastic…, (2019)]

The presented data show that the situation with regard to the management of plastic packaging is also improving.

In 2006, the share of packaging in landfills was almost 50%, while in 2018 this percentage was only 18%. The situation in terms of reducing the poisonous effect of waste is improving.

It can be hoped that the actions of international environmental organizations, as well as the behaviour of a society whose ecological culture is growing, will cause the present generation to want to leave the Earth in the best possible condition for the next generations. It certainly will not implement the idea of sustainable development, because through its hundred years of destructive activity it has caused damage that will have to be repaired for many hundreds of years.

Summary

Half of the planet was enough to provide people with a standard of living in the 1960s. The exploitation of the earth's life-giving possibilities has been recorded since the mid-seventies and is increasing. It takes 1.7 planets to provide the current standard of living for the entire population. The terrestrial planet is overused. The answer to this exploitation is unfavourable changes in the natural environment, which are currently observed in the form of unfavourable atmospheric phenomena resulting from climate warming. You can guess what the effects of this will be.

We are already witnessing the cracking and melting of glaciers, rising water levels and thus shrinking living areas for some animals and birds. The carbon footprint is responsible for these changes. Fortunately, its size is influenced by the governments of individual countries, but also by individual members of society, for example by rationalizing the use of electricity, water, changing the means of transport, and changing the way of eating (reducing the consumption of animal products in favour of plant products).

Waste is an inherent factor related to the functioning of society. Waste has an increasing impact on the size of the carbon footprint, and their landfills take up more and more land. People are able to go to shopping malls without any clear purpose or need, buy unnecessary products and then throw them into the garbage. The most glaring example is plastic waste. Plastic is a very popular material and the demand for plastic products is very high. The variety of plastic products is also very large, both due to the chemical composition of the material used and the life time of the manufactured products. The most harmful in terms of their quantity are products with a short life span, i.e. everyday items, plates, forks, etc., and above all, disposable packaging, i.e. all kinds of bags, handbags and containers. Plastic is a material whose decomposition time often reaches several hundred years, i.e. the life span of several generations.

It is known that plastic is a relatively new product. The era of plastics began in 1907, when the combination of phenol and formaldehyde gave rise to what we know today as *bakelite*. Later, various versions of this product were created.

Nowadays, plastic is everywhere, even in the most unexpected places. Disposable packaging, such as a plastic shopping bag, has become a plague, although such a bag can be replaced with a reusable cloth bag.

Until recently, mineral water and other drinks were sold in interchangeable glass bottles. Currently, we use plastic packaging, which, when empty, is scattered everywhere in parks, streets, beaches and in the water. The composition of the material used in their production is not always indifferent to health. One might wonder if it is not possible to return to glass packaging that can be used repeatedly, and furthermore, the processing of glass waste is much easier than that of plastic.

The real tragedy is water pollution with plastic waste. This waste is eaten by animals, which is a deadly threat to their lives as they cannot digest it and they starve to death. Appeals to society regarding ecological and even cultural behaviour do not work.

It seems that the most effective solution would be to ban the production of plastic articles at least the most harmful to the environment. The solution proposed by the European Union is heading in this direction.

Another solution is to develop a technology for the production of plastics whose decomposition time would be shorter as well as plastics that would be easier to recycle.

Abstract

The article presents an example of data classification in a risk assessment of credit sales. Firstly, the classical data is converted to the form of quantum states, and then the classification is performed with the use of two different quantum circuits: the variational circuit and the SWAP-test. The variational circuit works with qubits, and the SWAP-test is generalized for qudits. This generalization allows simplifying the circuit's structure while the correct classification is preserved. Both approaches need relatively small number of qudits to solve the tasks, so they are very prospective for the physical quantum realization (especially for qubits) in the nearest future.

Keywords: Quantum Classification, Variational Quantum Circuit, SWAP-Test, Qudits

Introduction

The works on a development of quantum computing last constantly for several decades. Regularly, we can find information that new, more efficient and stable, quantum devices were built. Thanks to the exponential capacity of data processing, quantum machines are seen as a potential solution to the problems which classical computers cannot cope. Researchers also prepare quantum versions of known solutions like quantum optimization (see: Hogg et al (2000) and Farhi et al (2014)) or quantum machine learning (what is shown in Aïmeur et al (2006), Biamonte et al (2017), Casares et al (2020), Schuld et al (2014)), hoping to find more efficient approaches to many tasks.

In this work, we would like to consider using some tools of quantum machine learning to solve a classification problem. For problems of binary classification such approaches like artificial neural networks or decision trees may be used, but we have found two very simple quantum circuits which will be able classify data rapidly. The novelty of our solution is based on data preparation as quantum states and decreased number of needed quantum gates kinds – previous approaches are presented in journal articles: Mitarai et al (2018) and Pérez-Salinas et al (2020).

Decision Task

In this work, we solve a decision task concerning a risk assessment of credit sales. Usually, wholesalers resale commodities but their customers do not pay just after the process of ordering. The customers obtain goods and an invoice with a payment date. It happens that the payment time is passing, invoices are unpaid, and customers place a new order. Some employees of the debt collection, or sales, department have to make a decision if the commodities may be released or the sale should be stopped (maybe the customer went bankrupt and is insolvent, or the client simply is a fraud). Let us present an exemplary vector of input data in this situation:

$$X = (x_1, x_2, x_3, x_4, x_5, x_6, x_7), \tag{1}$$

Cite this Article as: Joanna WIŚNIEWSKA and Marek SAWERWAIN "Quantum Classification in the Risk Assessment of the Credit Sales" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

x_1 - the sum of all customer's dues [real number], x_2 - the sum of customer's dues which should be already paid [real number], x_3 - number of days past due for the oldest claim [integer], x_4 - the payment amount declared by the client as paid, but still not posted on the account [real number], x_5 - past customer reliability [Boolean value], x_6 - cooperation with reliable recipients [Boolean value], x_7 - a promissory note from the customer [Boolean value].

In the presented example, the decision to continue or to stop issuing goods is made after analyzing seven factors. Let us say that the customers which are candidates to stop the sale are characterized by more than 20% value of amount due which should be already paid to whole client's dues, and more than 6 days delay in paying of the oldest due. However, there are some attenuating circumstances. Customer may have paid his debt, but the amount of money is not yet posted on the account – if the client declares transfer decreasing value of his overdue payments to at least 20% of his total account, the trade lock shouldn't be placed. There are also other factors which may have a positive influence on making decision: the client buys goods from wholesalers for a long time and has always been reliable, client's recipients are known as a reliable companies and probably pay their dues to our customer, customers sign promissory notes (or utilize other debt instruments) to assure the ease of the debt recovery.

As it may be observed, the decision about continuing trading cooperation is met on a basis of vector X entries which are numbers of different types (Boolean values are mapped into zero and one). Generally, the vector X may have n numerical entries:

$$X = (x_1, x_2, x_3, \dots, x_n), \tag{2}$$

and the decision may be written as a vector Y:

$$Y = (y_1), \tag{3}$$

where y_1 takes value 0 if the customer is blocked and 1 if the sale is continued (so-called two-valued decision).

Quantum Preliminaries

This paper refers to supporting decision making with circuits of quantum gates, so in this section some definitions of basic concepts, used in the field of quantum computing, are presented. We focus only on qudits, which are less widely used than qubits. A broad introduction to quantum computation can be found in the textbook by Nielsen and Chuang (2000).

Apart from the notion of qubit, it is possible to introduce more generalized unit of the quantum information called qudit. Qudits are characterized by the freedom level $d \geq 2$. The most popular qudit is a qubit because its freedom level $d = 2$, so it refers to the classical bit. A state of the d-level qudit may be presented as a d-element normalized column vector (in this work, we refer only to so-called pure quantum states):

$$|\psi\rangle = \begin{pmatrix} \alpha_1 \\ \alpha_2 \\ \dots \\ \alpha_d \end{pmatrix}. \tag{4}$$

The marking $|\cdot\rangle$ denotes a column vector, called ket in the Dirac notation, and normalization means that $\sum_{i=1}^{d} |\alpha_i|^2 = 1$ where α_i are complex numbers.

Several qudits can be connected by tensor product into a quantum register:

$$|\Psi\rangle = |\psi\rangle \otimes |\phi\rangle = |\psi\phi\rangle \tag{5}$$

where two-qudit state $|\Psi\rangle$ is a column vector, too. Let us assume that $|\psi\rangle$ is an a-level qudit state and $|\phi\rangle$ is a b-level qudit state (a and b may be different or the same integer numbers) – in this case the vector expressing $|\Psi\rangle$ has $(a \cdot b)$

elements. As we may see in the above equation, the sign $\otimes$ may be omitted when the Dirac notation is used. We would like to note that there are states called entangled (see: Erhard et al (2020)) which cannot be expressed with a tensor product.

Another way to present quantum states is the superposition equation. It strongly refers to the concept of a computational basis.

Before the definition of a computational basis, we have to mention about conjugate vectors which in the Dirac notation are symbolized as $\langle \cdot |$, and called bras. The adjoint $\langle \phi |$ is calculated as a conjugate transpose of $|\phi\rangle$ (bras are always row vectors). We can perform an operation of the outer product on kets and bras: $| \cdot \rangle \langle \cdot |$ which always results with a matrix. The inner product $\langle \cdot | \cdot \rangle$ returns a scalar value. If the vectors $|\psi\rangle$ and $|\phi\rangle$ are orthogonal, their inner product equals zero (the orthogonality in two- and three-dimensional spaces results with perpendicularity).

A computational basis for x-qudit system, assuming that all qudit have the same freedom level d, is a set of d^x d^x-element orthonormal vectors. The orthonormality means vectors are normalized and orthogonal one another. The most popular basis is the standard basis. It consists of vectors which have $(d^x - 1)$ elements equal 0 and only one element which is 1. Of course, in each vector the 1 occupies different position in a vector, e.g. for the 1-qubit system $(d = 2, x = 1)$ the standard basis is

$$|0\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \ |1\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix}. \tag{6}$$

Now, we can come back to the superposition. The superposition equation defines a quantum state with the use of basis states (vectors from a particular basis). For example, one-qudit state (freedom level d) may be expressed with the vectors from the standard basis as:

$$|\psi\rangle = \alpha_1|0\rangle + \alpha_2|1\rangle + \cdots + \alpha_d|d-1\rangle \tag{7}$$

under the normalization condition $\sum_{i=1}^{d} |\alpha_i|^2 = 1$, and amplitudes α_i are, of course, complex numbers.

After vector states defining, we can introduce the way of carrying out calculations in quantum computing. The most popular method is constructing circuits of quantum gates which transform input states. A quantum gates are operators which affect quantum states. These operators may be presented in a matrix form. If we want to transform x-qudit state $|\phi\rangle$, of the freedom level d, we need an operator which can be described by a unitary matrix U sized $(d^x \times d^x)$. This operation is mathematically expressed as multiplying the matrix U by the vector $|\phi\rangle$:

$$U|\phi\rangle = |\gamma\rangle. \tag{8}$$

The state $|\gamma\rangle$ is the output state (transformed input state $|\phi\rangle$).

The first solution that we utilize – the variational quantum circuit – is designed for qubits, and needs parameterized rotation gates, and controlled phase-changing gates. Let us express the gate of rotation about y-axis by an angle θ as:

$$R_y = \begin{pmatrix} \cos\frac{\theta}{2} & -\sin\frac{\theta}{2} \\ \sin\frac{\theta}{2} & \cos\frac{\theta}{2} \end{pmatrix}. \tag{9}$$

The controlled phase-changing gate is denoted by the symbol CZ and matrix:

$$CZ = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}. \tag{10}$$

One can observe that if the transformed state is one of the vectors from the two-qubit standard basis, then the sign (i.e. phase) of the second qubit is changed only for the initial state $|11\rangle$.

Once we transform the quantum state, we would like to read the result, so we have to perform an operation called a quantum measurement. There are different approaches to this problem what may be found in Nielsen et al (2000). We only recall that we use the von Neumann's measurement in this work.

Data Preparation

We solve the classification task with two quantum circuits. The first one is so-called variational circuit and was presented in the article by Wecker et al (2015). The second is the SWAP-test described in the book by Aimeur et al (2006). Both approaches need input data preparation, because data has to be transformed into quantum states. Before the quantum normalization, in both cases, the data is classically normalized what is widely applied in machine learning methods. This step helps standardize data. We know that in our data set different numerical types appear (real numbers, integers, Boolean values) what is unwelcome during the learning process because some variables x_i ($i = 1, \dots, n$) may have the stronger influence on the result (y_1) just because they obtain wider range of values. Let us mark the number of observations in the data set as m and the number of single observation as j ($j = 1, \dots, m$). Therefore, for each j-th value of variable x_i, we calculate normalized values $\bar{x}_{i,j}$:

$$\bar{x}_{i,j} = \frac{x_{i,j} - \min\{x_i\}}{\max\{x_i\} - \min\{x_i\}}. \tag{11}$$

The markings $\max\{x_i\}, \min\{x_i\}$ denote the highest and the lowest value of variable x_i, respectively.

After the above procedure of normalization for each variable, we have to apply the quantum normalization in order to obtain correct quantum states of our experiments. The quantum normalization is performed within each observation (the number of quantum states is equal to the number of observations). Now, for j-th observation, n amplitudes $\alpha_{i,j}$ have to be calculated:

$$\alpha_{i,j} = \sqrt{\frac{\bar{x}_{i,j}}{\sum_{k=1}^{n} \bar{x}_{i,j}}}. \tag{12}$$

In case of the variational circuit, we have x input qubits what means that the initial quantum state has 2^x amplitudes. We construct the consecutive states for experiments by filling normalized quantum states with $(2^x - n)$ zeros for states which may be omitted.

The states transformed by a circuit in the SWAP-test are qudit states. Generally, the freedom level d of the used qudits is equal to the number of variables in a decision task, so we introduce the normalized observation directly to one of the circuit's inputs.

Classifying Quantum Circuits

Variational Quantum Circuit (VQC)

The VQCs, constructed as it is shown in Fig. 1, are utilized in machine learning (see: Mitarai et al (2018)) and quantum neural networks (like in Macaluso et al (2020)). Because of small number of needed qubits, few types of used gates, and not many layers of gates (the depth of the circuit), one can expect that the experimental implementations of quantum machines, e.g. IBM, Rigetti, could solve classification tasks with the use of VQCs in the short-term future.

Fig. 1: The general scheme of a VQC used in the first experiment. The input vector is a state $|\psi\rangle$ describing states of four qubits q_0, q_1, q_2, q_3. The symbol R_y refers to one-parameter rotation gates (the learning process is a proper selection of these parameters' values). The CZ gates are presented as two dots connected with a line. The accuracy of classification rises if the number of basic layers increases - e.g. repeating four, five times the operation expressed as the basic layer intensifies the accuracy. The readout of the final quantum state needs the measurement M, and further processing of the obtained result

To construct the VQC, we need rotation gates R_y and phase changing gates CZ which are responsible for the entanglement of particular qubits. Each i-th rotation gate R_y owns parameter $\theta_i \in [0,2\pi]$ which describes the angle of the performed rotation.

The proper selection of θ_i values determines the success of the whole classification process. At this point, we have to apply the supervised learning methods.

The mentioned learning process is consistent with the description given in the article by Schuld et al (2020). However, we have to specify the steps performed in the classical part which is depict in Fig. 2. After quantum circuit execution, we obtain a quantum state which is defined by a function r. The value of function r, when we perform measurement operation on qubit s, may be specified as:

$$r(\psi,\theta) = \sum_{l=2^{n-1}+1}^{2^n} \left|(U(\theta)\psi)_{l|s}\right|^2, \text{where } |\psi_s\rangle = |1\rangle. \tag{13}$$

The expression $(U(\theta)\psi)_{l|s}$ points out the l-th element of the state vector which describes the quantum state after the operation $U(\theta)$ and the measurement on the qubit s. Naturally, the experiment's result is the statistics r, so the circuit operation and the measurement have to repeated to calculate the probability of obtaining state $|1\rangle$ on the s-th qubit ($|\psi_s\rangle = |1\rangle$). During the learning process, the expectation value is useful what is broadly described in the article by Schuld et al (2020).

Fig. 2: The scheme of the learning procedure in the VQC. The first stage is the conversion of classical data to the quantum states (marked as $|\psi\rangle$ in the picture). The circuit is prepared with the initial values of parameters θ. The consecutive vectors $|\psi_j\rangle$ are processed by the circuit, and after each vector, we analyze the results (classical part). The calculation of the cost function E allows to determine a new set of parameters θ. The circuit's parameters are updated, and the next state $|\psi_j\rangle$ is transformed. The whole process is repeated until a proper accuracy will be achieved

The value of r is necessary to calculate a cost function value E. If the number of observations is L, the function E is a sum of the squares of the absolute deviation, calculated for the result of circuit execution, given by the function r:

$$E(r(\psi,\theta),C) = \frac{1}{2}\sum_{l=1}^{L}|r(\psi_l,\theta_l) - C_l|^2, \qquad (14)$$

where C contains the class labels for the samples represented as $|\psi_l\rangle$. The above cost function is the standard least-square criterion in an optimization process. The update of parameters θ may be successfully realized with the gradient methods. In this work, we utilize the Powell method described in the article by Powell (1964). The selection process of θ parameters may be realized on a classical machine because of relatively low number of qubits but it could be also performed on a quantum device.

SWAS-Test

The SWAP-test is one of the most basic quantum circuits which may be used in the field of machine learning and data classification. The SWAP-test was originally designed for qubits. The realization of this solution as circuit use only two Hadamard H and one Fredkin $CSWAP$ gate (information about mentioned gates may be found in the textbook by Nielsen and Chuang (2000)). The idea of the SWAP-test is the quantum realization of the Fidelity measure calculation which, in the case discussed in this paper, is based on scalar product of two vectors, and determines these vectors' similarity. It should be pointed out that the quantum circuit does not return the exact value of the Fidelity measure but the value between $\frac{1}{2}$ and 1 for qubits (if the value is one, then vectors are the same; the lower value we obtain, the more vectors differ).

The simplest realization of the SWAP-test assumes that the Fidelity measure may be calculated by the quantum circuit shown in Fig. 3. The basic case concerns the circuits for qubits but this solution may be generalized to qudits. In this work, we utilize seven-dimensional qudits, and the circuit's construction remains the same. The value of the Fidelity measure is approximated by the probability of measuring the state $|0\rangle$ on the first qudit, what may be expressed as:

$$P(q_0 = |0\rangle) = \frac{37}{49} + \left(\frac{12}{49}|\langle d_i|v_c\rangle|^2\right). \qquad (15)$$

The above equation also shows the range of values which may be obtained, and it is $\left[\frac{37}{49}, 1.0\right]$.

Fig. 3: The three-qudit quantum circuit realizing the SWAP-test. The state $|d_i\rangle$ is the i-th tested sample, the state $|v_c\rangle$ represents the classifying vector supporting the classification of the input sample. The vector $|v_c\rangle$ stays unchanged for all samples $|d_i\rangle$. The result is the probability of measuring state $|0\rangle$ on the first qudit, i.e. $P(|0\rangle)$

The idea of utilizing the SWAP-Test (ST) is to determine the classifying vector v_c which is represented by the quantum state $|v_c\rangle$. Next, for each sample d_i, we execute the ST for input states $|d_i\rangle$ and $|v_c\rangle$. The obtained probability distribution for particular samples and their classes should belong to the given intervals:

$$ST\left(d_{i_0}, v_c\right) \in \langle a_0, b_0\rangle, \quad ST\left(d_{i_1}, v_c\right) \in \langle a_1, b_1\rangle, \tag{16}$$

where d_{i_0} and d_{i_1} stand for the i-th sample from class zero or one, respectively.

For the sake of classification simplicity, we can assume that intervals $\langle a_0, b_0\rangle$, $\langle a_1, b_1\rangle$ are separate (there are no elements which belong to both intervals). However, if the distribution probabilities are contained in groups or continues intervals, e.g. the interval $\langle a_1, b_1\rangle$ belongs to $\langle a_0, b_0\rangle$, it is still possible to correctly classify the samples, what is shown in Fig. 4.

Fig. 4: Exemplary probability distributions for the ST. The case (A) depicts the classification result for separate intervals – the black dots represent samples from a class zero, and the white ones from a class one. The case (B) shows situation when the probabilities corresponding to class one, lie inside the interval for a class zero.

Numerical Experiments

The experiments were conducted on a data set containing 80 input-output pairs. Let us choose an exemplary vector X:

$$[840000,100000,6,10000,1,1,0], \tag{17}$$

to show the result of the classical normalization:

$$[0.13553114,0.05319149,0,0.02,1,1,0] \tag{18}$$

and the final vector's form as amplitudes of a quantum state:

$$[0.24771309, 0.15518527, 0, 0.0951578, 0.67286728, 0.67286728, 0]. \tag{19}$$

The VQCs used in this work has three and four input qubits, so in the superposition equation for the initial state, we have 8 and 16 amplitudes – first seven amplitudes obtain values from the twice normalized vector, and other amplitudes are filled with 0 values. In the case of the SWAP-test, the qudits with $d = 7$ are used.

The implementation of the VQC was realized with the use of lastly presented Qibo package presented in the paper by Efthymiou et al (2020). This solution allows conducting numerical experiments in Python's environment. The data set was divided to the training, and the validation set. The quality of classification is expressed in percentage terms. The experiments are conducted in different settings which include changing: the number of basic layers, and the number of qubits in the circuit (three or four). The classification results are shown in Table 1.

The problem, we have been analyzing, has seven variables, so it seems that the three-qubit circuit should solve it. However, adding an extra qubit allowed us to gain a better accuracy for the circuit with smaller number of layers. If we look at Table 1, we can see that the circuit with one basic layer classifies samples more efficiently if it has four qubits. Increasing the number of basic layers to four, causes very high quality of the classification.

Table 1: The obtained accuracy of the classification realized with the VQCs of different layers number. The number of used layers is given in the first column. Accuracy, separately show for the training and validation sets, indicates the percent of properly classified samples

Layers	Accuracy for 3 qubits		Accuracy for 4 qubits	
	Training set	Validation set	Training set	Validation set
1	76.25%	72.25%	87.50%	89.25%
2	91.25%	92.00%	91.25%	92.00%
3	95.00%	96.25%	97.50%	98.00%
4	96.25%	96.50%	98.50%	99.00%

In the case of the SWAP-test, very high accuracy was obtained what is shown in Table 2. The SWAP-test is dependent on the test vector values. The four different vectors were used in the experiment, and we can propose a vector which gives 100% effective classification.

The form of the test vectors, before normalization, is:

$$\begin{gathered} v_0 = [0,4,0,0,0,0,8]^T, \\ v_1 = [1,5,1,1,5,1,9]^T \text{ and } vn_1^1 := -vn_1^1, \\ v_2 = [4,5,1,9,2,1,2]^T \text{ and } vn_2^1 := -vn_2^1, \\ v_3 = [1,0,0,5,7,1,6]^T \text{ and } vn_3^{1,4,6} := -vn_3^{1,4,6}. \end{gathered} \tag{20}$$

The v_0, v_1, v_2, v_3 are column vectors, and T means the transposition. The extra expressions, like $vn_2^1 := -vn_2^1$, denote adding minus to the vector's elements pointed by superscripts what is executed after the normalization process. The vector v_c is used as one of the initial states in the SWAP-test, so has to be normalized according to Eq. (12), just like observations are transformed to quantum states.

Table 2: The classification results for the SWAP-test in context of vectors determining adhesion of a sample to one particular class. The meaning of data in consequent columns is: Vector points out the vector v_c utilized during the classification; P.of.C1, and P.of.C2 are the probability intervals for the first, and the second class; C.C1, C.C2 show the numbers of correctly classified samples to both classes; Total contains the number of all samples

Vector	P.of.C1	P.of.C2	C.C1	C.C2	C.C1	C.C2	Total
			Training set		Validation set		
v_0	0.755-0.758, 0.81-0.84	0.758-0.81	28	52	25	55	80
v_1	0.755-0.757, 0.80-0.87	0.757-0.80	36	44	35	45	80
v_2	0.755-0.761, 0.789-0.856	0.761-0.789	39	41	39	41	80
v_3	0.755-0.761, 0.790-0.818	0.761-0.790	40	40	40	40	80

Table 2 shows that the proper selection of the test vector, e.g. v_3, leads to 100% correct data classification. Naturally, the vector's distance from samples of both classes should be the same, what allows separating elements of classes like it is depicted in Fig. 4.

Conclusions

In this paper, we have presented the results of conducted numerical experiments in which known from the literature approaches to solving the two-value classification task were used. For both the VQC and the SWAP-test, we have obtained a very high quality of classification, what is significant especially in the context of utilized circuits' simplicity.

In the case of VQC, we profit from the existing solutions, but the presented approach for the SWAP-test contains our contribution in the form of circuit generalization for qudits (originally, the SWAP-test was presented only for qubits). The data utilized in the experiment was gathered by employees of debt collection department in the actual pharmaceutical wholesaler.

The presented results, and the recent achievements described in the articles Moll et al (2018), Pérez-Salinas (2020), lead to the conclusion that in the nearest future, real quantum devices shown in IBM (2020) and Rigetti (2020) will be able to work as the classifying systems.

Abstract

The purpose of this empirical study is to assess the impact of three active labour market measures addressed to companies who employ graduates of education institutions or unemployed persons over 45 years old or with only 3 years left before retirement. We focus on the impact of these measures upon employment a year and a half after the completion of the measures and of their conditionality. In order to quantify the impact of these active labour market measures we rely on counterfactual scenarios, survey data and matching techniques. Empirical evidence for the case of the Romanian labour market is provided. Our findings highlight positive effects of such active labour market measures upon employment on the short-run, as our estimations support the hypothesis that the employment rate among the beneficiaries of these active measures are higher compared to similar individuals who did not benefit from these measures.

Keywords: Active Labour Market Measure, Impact Assessment, Employment, Counterfactual Scenario.

Introduction

At macroeconomic level, the adoption of public policy decisions must often be supported by impact studies and scenario analysis to ensure a documented and sustained decision-making process that is backed up by scientific arguments. In this respect, impact assessments, usually based on a mix of qualitative and quantitative methods, become a real necessity.

Assessing the impact of a public policy involves a process that consists of a sequence of logical steps, meant to establish the evidence in favor of or against the adoption of a policy. In case of a policy that is to be adopted, the assessment is referring to its potential impact (ex-ante evaluation), while in case of a policy that has already been adopted and implemented, the assessment focuses on the effects attributable to that policy (ex-post evaluation).

Quantifying the impact of a specific public policy can be achieved by means of quantitative analysis that allow for the impact of the change attributed solely to the interventions to be estimated. This impact is defined as a net effect of the intervention and differs from the gross observable effect, since the intervention might not be the only factor generating the outcome. As the net effect cannot be observed, the challenge for the assessors is of estimating the counterfactual effect, this being the effect that would have been noticed in the absence of the intervention. The counterfactual scenario underlying the evaluation aims to estimate what would have happened in the absence of the intervention. As the answer to this question is unknown, it is necessary to apply special statistical techniques.

The challenge of a credible impact assessment is how well the counterfactual analysis is designed. The basic idea of the method is to construct two groups of similar units in observable characteristics, with the only difference that those in the treatment group had access to the intervention, while the control group units did not receive that treatment. Thus, the difference between the measured results of the two groups of units will indicate the net impact of the intervention.

In this paper we study the impact of three active labour market policies (ALMP), consisting in subsidies granted to companies who employ graduates of education institutions or unemployed persons over 45 years old or with only 3 years left before retirement. We focus on the impact of these measures upon employment on the Romanian labour market a year and a half after the completion of the measures and of their conditionality. Empirical evidence for the case of the Romanian labour market is provided.

According to Law no. 76/2002, art. 85, employers who employ unemployed people over the age of 45 years for a minimum period of 18 months were entitled to benefit for one year of a monthly amount equal to the value of the social reference indicator for each person employed. When employing graduates of educational institutions, the companies were exempt from paying the contributions to the unemployment insurance budget for those graduates, while also receiving for a period of one year a monthly amount equal to:

(a) the value of the social reference indicator at the time of employment, for lower secondary school graduates or schools of arts and crafts;
(b) 1.2 times the value of the social reference indicator, at the time of employment, for graduates of higher secondary education or post-secondary education;
c) 1.5 times the value of the social reference indicator at the time of employment for graduates of higher education.

A revised version of this law that came into force on October 23rd 2013 no longer allows for the exemption from paying the contributions to the unemployment insurance fund. Instead, it keeps a simplified version of the provision referring to the monthly amount received by the employers for a period of 12 months (18 months for people with disabilities) that was then fixed at 900 Ron/month for all graduates, regardless of their education level.

In order to measure the impact of these measures upon employment in Romania, we conducted a counterfactual analysis using the propensity score matching method (PSM). For this purpose, micro-data was required. However, since the availability of such databases is rather scarce and no administrative datasets are open access to academic and research environment in Romania, we made use of survey micro-data. The survey was conducted by the National Institute for Scientific Research in the Field of Labour and Social Protection (INCSMPS) in October 2014 among both beneficiaries and non-beneficiaries of these measures. Even though the dataset might not accurately reflect the current economic context affected, for instance, by the COVID-19 pandemic, we accept such biases and pursue our aim of bringing empirically based evidences on the effects of subsidies addressed to employers of graduates or of unemployed persons over 45 years old. Since the current literature review on this topic is rather scarce, as we are unaware of any existing empirical study discussing the effectiveness of these particular types of measures, we believe that we can fill in the gap by investigating it and highlighting some particularities for the case of Romania.

The novelty of the paper is twofold. On the one hand, it is relevant in terms of methodological approach, as it brings insights on how to conduct such counterfactual impact assessment with limited access to administrative data. On the other hand, we share some insights on the effectiveness of such active labour market measures dedicated to employers in order to stimulate employment on the labour market. Even though the study can only provide insights upon the effectiveness of such measures for a single country case and a given period of time, we believe it brings added value to the current labour market program evaluation literature, not only by providing some general conclusions on labor market policy implications, but also because such an assessment could be informative for policy design.

Active labour market measures have been in the center of attention for both researchers, economists and decision makers due to the fact that high unemployment are problems that many European countries are facing and need to be tackled (Popescu and Lazar, 2015). Among those problems, a special focus must be given to young population, as the unemployment rates are higher for this age group and also because they are more vulnerable to demand-side risks, as the recent global financial crisis demonstrated (Caliendo and Schmidl, 2016). Previous research studies (Drăgoiu and Velciu, 2010; Militaru, 2015; Zamfir and Mocanu, 2016) underlined the fact that effective programs and investment in human resources can contribute to economic recovery. In this respect, active labour market policies have proved

to be an important tool in the fight against unemployment (Lehmann and Kluve, 2010; Pirciog et al., 2015; Popescu and Roman, 2018). Through an efficiency analysis, Roman (2008) proved the fact that active labour market measures are more efficient than passive ones. Moreover, Kleuve (2010) showed that active labour market programs are widely used in European countries. Using a meta-analysis based on a data set of 137 program evaluations from 19 countries, the study concluded that it is almost exclusively the program type that seems to matter for program effectiveness. Blasco and Rosholm (2011) consider that the weak results concerning the effectiveness of some programs come from the fact that their positive outcomes are off-set by the low transition into employment during participation to programs (the "lock-in" effect). In their study on the effects of intensified ALMP using data from an experiment in two Danish counties they concluded that their effects are beyond the short-run, and that policy beneficiaries have greater average post-unemployment employment. Vooren et al. (2018) showed that some ALMP (subsidized labour and public employment programs) have negative impact on the short run, and turn positive after 12 or 24 months after implementation. Still, there are also studies like McKenzie (2017) that show that for developing countries the positive impact expected by both policy makers and beneficiaries of active labour market policies is much higher than their effect and advocate for policies that help firms in creating jobs. Therefore, the conclusions of the studies concerning the efficiency of ALMP in different economies are mixed depending on the type of policy applied, the time effect that is being investigated and also on the economy's characteristics, or as Pignatti and van Bell (2018)[1] say there is very little evidence to show that policies who work well in one labour market context can be easily translated to another context.

Pervious empirical findings for the case of Romania indicate that ALMP have, in general, positive effects on the labour market. For instance, Rodriguez-Planas and Jacob (2010) estimated the effects of four active labour market measures implemented in Romania in the late 1990's, using follow-up survey data and propensity score matching techniques, and showed that training and retraining, self-employment assistance and relocation services were beneficial in improving participants' incomes, while public employment did not. In 2015, Roman and Popescu (2015) estimated the effects of training on the Romanian migrants' income. By taking into consideration data of Romanian migrants worldwide, their research underlined that Romanian migrants had registered increased earnings after attending training at destination. In a more recent study, Popescu and Roman (2018) found that training measures in Romania have a positive, but modest impact upon employability in Romania. More precisely, participation in training programs increases employment chances by 15%, being most successful for women and for people living in urban areas.

Impact assessment of active labour market measures on employment is still of high interest, due to current economic context and significant need of relevant public measures. This study is meant to provide insights on the impact upon employment a year and a half after the end of implementation of three active labour market measures dedicated to stimulate employers to employ unemployed people.

The paper is organized as follows. The next section is dedicated to data description and the methodological approach, while the main findings are presented in section 3. The paper ends with some concluding remarks.

Data Description and Methodology

In order to evaluate the impact upon employment of the three active labour market measures dedicated to stimulate employers to employ unemployed people a year and a half after the completion of the measures, a quasi-experimental approach was applied. In order for the survey to be conducted, the National Agency of Employment (NAE) database was used to randomly select individuals that were registered as unemployed right before the implementation of these measures. The treatment groups were made up of a total sample of over 713 intervention beneficiaries, divided in three sub-samples as presented in Table 1. A single control group was built to serve all three counterfactual scenarios, as it consisted of 251 respondents who did not benefit from any of the three measures. Therefore, the difference between each treatment group and the control group consists in the fact that each treatment group benefitted from one of the three active labour market measures, while the control group did not.

[1] These two authors study the interdependence between between active and passive labour market policies and stress the important effect of their interaction.

Table 1: Sample sizes for each active labour market measure

Active labour market measure	Profile of the beneficiaries	Sample size
Subsidies for employers who employ unemployed persons over 45 years old	urban male over 45, with medium education level	154 treated and 251 non-participants
Subsidies for the employers who employ unemployed persons with only 3 years left before retirement	urban male over 45, with low education level	125 treated and 251 non-participants
Subsidies for employers who employ graduates of education institutions	young urban female, with high education level	183 treated and 247 non-participants

Source: authors' own computation based on survey data

The propensity score matching method (PSM) was applied distinctly for each labour measure using STATA 16 software. We first estimated probit models to predict each individual's chances of receiving interventions through the public subsidies programs. In that respect, we built a binary treatment variable, which took value 1 in case of benefitting from a measure and 0 otherwise. Once the balancing property of the models was checked and the propensity scores of each individual were estimated, a non-parametric method for matching the treated with the untreated units was used based on the propensity scores.

We matched the treatment and the control groups, using a set of covariates that describe the relevant background information for each individual. In this set we included both socio-demographic characteristics and economic variables. We chose the variables that were mentioned as relevant in previous empirical studies on this topic and also in accordance with the applicable economic theory. We considered the following covariates, taking into consideration the individual characteristics and coding them in different sub-categories, as follows:

a. Socio-demographic characteristics

- Age: between 15-24; between 25-44; between 45-64; over 65;
- Gender: Male; Female;
- Residence area: Urban; Rural;
- Region: Bucharest-Ilfov; North-East; North-West; Centre; South; South-East; South-West; West;
- Level of education: Low level of education; Medium level of education; High level of education;
- Civil status: Married; Unmarried.

b. Economic variables

- Sector of activity: Services sector; Industry sector; Construction; Other sectors
- Years of work experience

The general form of the Probit model was:

Treatment = f (age, gender, civil status, region, education level, residence, sector of activity, work experience)

Four matching algorithms were tested, namely: the Nearest Neighbour Matching Method, the Radius Matching Method, the Kernel Matching Method and the Stratification Method. The model allowed us to assess the ex-post impact of the active measures upon employment in Romania, by quantifying the odds of a participant to still be employed one year and a half after the end of the measures' conditionality, as compared to similar individuals in terms of observable characteristics, but who did not benefit from the measure.

Main Findings

The purpose of this paper was to determine the effects (if any) on the Romanian labour market of three types of subsidies dedicated to stimulate employers to employ unemployed people. In order to quantify the impact of these active labour market measures addressed to companies who employ graduates or unemployed persons over 45 years old or with only 3 years left before retirement, a propensity score matching technique was applied.

The results of the PSM technique that were statistically significant are summarized in Table 2, where the net impact was computed as the average treatment effect on the treated (ATT). This estimator indicates the impact of the measures after computing the differences between the average outcomes of the two groups matched.

The degree of satisfaction of the treated group upon the effectiveness of these public active measures was also quantified through a self-evaluation process. For that, the beneficiaries were asked to subjectively evaluate the impact of those active measures, considering their ability/ inability to find a job in case of not benefitting from the measure.

Table 2: Impact of active labour market measures

Active labour market measure	Self-assessment of the impact	Net impact one year and a half after the measure's conditionality ended
Subsidies for employers who employ unemployed persons over 45 years old	43%	12%
Subsidies for the employers who employ unemployed persons with only 3 years left before retirement	66%	-18%
Subsidies for employers who employ graduates of education institutions	25%	16%

Source: authors' own computation based on survey data

In terms of self-assessment of the ALMP impact, one can notice that all three public active measures were appreciated for their positive effects upon the chances of the unemployed persons to find a job. Among the three public active measures under discussion, the subsidies for the employers who employ unemployed persons with only 3 years left before retirement was the most appreciated one. Approximately 66% of the beneficiaries shared the opinion that they would not have found a job without attending this measure. However, in terms of net impact at one and a half year after the end of the measure's conditionality, the counterfactual impact assessment indicated a negative effect of the measure. More precisely, our findings suggest that the employment rate among the beneficiaries of this active measure was actually 18% lower compared to similar individuals who did not benefit from the measure. However, this negative impact must be interpreted with caution, because at the time the survey was conducted, 74% of the beneficiaries of the measure retired early, changing their status from employed to inactive.

When being asked to subjectively evaluate the impact of the measure providing subsidies for employers who employ unemployed persons over 45 years old, 43% of the beneficiaries shared the opinion that they would not have found a job without attending this program. In terms of net impact, the counterfactual analysis pointed out that the employment rate among the beneficiaries of this active measure was 12% higher compared to similar individuals who did not benefit from the measure. These findings indicate that the subsidies offered for employers who employ unemployed persons over 45 years old were rather effective in reaching the purpose to reduce the unemployment level in Romania. Keeping in mind the fact that actually, the unemployed persons over 45 years old were the most numerous among the sub-groups of beneficiaries of active labour market measures in Romania in that period, these results are rather relevant in terms of policy implications.

Regarding the graduates whose employers were subsidized, about three quarters were employed at the time the survey was conducted, that is 1 year and a half after the end of the employer's obligation to keep them employed. About 25% of the beneficiaries of the measure consider that they would not have found a job if they had not benefited from the intervention. Compared to the self-assessed impact of the measure, the counterfactual analysis indicated a slightly lower level of the net impact, which is not surprisingly after all, when considering that, in general, self-evaluation might generate biased results. However, the statistical evaluation of the net impact suggests that the employment rate among the graduates who benefitted from this measure was 16% higher compared to similar graduates who did not benefit from the measure. This positive result is not surprising as wage subsidies are known to be very good performers among the ALMP for youth, increasing their employment level in all circumstances, except bad economic conditions, as shown by Caliendo and Schmidl (2016) in a study reviewing multiple evaluation studies in European countries.

Among the three public subsidies dedicated to stimulate employers to employ unemployed people, our findings suggest that the active measure dedicated to graduates of education institutions was slightly more effective in terms of net impact upon employment in Romania. These findings could play an important role in public budgeting and in the labour market policy making process, as it brings insights regarding the effects upon employment that can be attributed to each active measure in particular.

Active policies are only some mechanisms among many others, such as unemployment insurance policies (passive policies), wage policies, policies concerning the safety of employment, policies on wage-setting mechanisms and policies concerning social dialogue. The lack of a correlation of all the objectives of these policies may cancel or mitigate the partial positive effects obtained. Given the multitude of possible factors that may influence the results of implementation of some active measures, it is absolutely mandatory for any impact assessment to try to contextualize the best possible results.

Therefore, we decided to extend the impact analysis, by breaking it down on socio-demographic characteristics (gender, residence area, level of education and age groups) in order to emphasize the effectiveness of each measure at the level of some specific sub-groups.

Several logit models were then estimated on each of the following sub-groups of individuals: male versus female, urban versus rural, low, medium and high level of education, distinct age groups (under 25; 25-45, over 45 years old). The output variable was the occupational status of the respondents, while the explanatory variables were the covariates: sex, age groups, marital status, levels of education, residence area and the "*treatment*" binary variable.

Valid econometric models were estimated in relation to LR test and pseudo R^2 and also with statistically significant coefficients. A particular attention was paid to the significance of the "*treatment*" variable, which indicates the chances of a beneficiary of a certain measure to find a remunerated job at the time of the survey, compared to those of a non-beneficiary of the measure, with the same characteristics. The following conclusions were drawn from such sensitivity analysis, as presented in Table 3.

Table 3: Degree of effectiveness of active labour market measures

Active labour market measure	Degree of effectiveness of the measure
Subsidies for employers who employ unemployed persons over 45 years old	Has stronger effect on rural female over 45 years old, with medium education level
Subsidies for the employers who employ unemployed persons with only 3 years left before retirement	Has stronger effect, in general, on male over 45 years old.
Subsidies for employers who employ graduates of education institutions	Has stronger effect on rural male with high education level

Source: authors' own computation based on survey data

Conclusions

The purpose of this paper consisted in estimating the impact of three active labour market measures in Romania, addressing companies who employ graduates of education institutions or unemployed persons over 45 years old or with only 3 years left before retirement. We focused on the impact of these measures upon employment a year and a half after the completion of the measures and of their conditionality. In order to quantify the impact of these active labour market measures we applied a counterfactual impact assessment using survey data and matching techniques.

Even though all three public active measures were subjectively appreciated for their positive effects upon the chances to find a job, we bring empirical evidence to support the fact that the employment rate among the beneficiaries of at least two measures - those dedicated to graduates and to unemployed persons over 45 years old- were higher compared to similar non-treated individuals.

The findings of this research underline the utility of the active labour market measures concerning subsidies given to employers who employ graduates or unemployed persons over 45 years old and confirm the fact that this kind of programs have an effect in encouraging employers to hire more graduates and unemployed persons over 45 years old.

Among the three public subsidies, we found that the active measure dedicated to graduates of education institutions was slightly more effective in terms of net impact upon employment. In terms of gender differences, we notice that the active measures dedicated to graduates and to people who have 3 years up to retirement proved to be more effective among men, while the effects of the measure offering subsidies to companies who employ unemployed persons over 45 years old was felt more strongly among women.

These findings could play an important role in public budgeting and in the labour market policy making process, as it brings insights regarding the effects upon employment that can be attributed to each active measure in particular. As policy recommendations aimed at increasing the efficiency and effectiveness of active labour market measures, at strategic level, we emphesize the need for conducting periodic assessment of the impact of active measures, as well as periodic studies and forecasts on short and medium term of the labour demand.

Moreover, at active labour market measure level, we believe that better profiling of the persons looking for a job before being recommended for a certain measure could improve the outcomes of the program. Such impact evaluation studies, with findings similar to those that were briefly presented through this paper, could actually support the design of effective and evidence-based public policies.

Abstract

The IBCS® notation standards are relatively new but more and more popular tool used worldwide in business reporting practice. The efficacy of the IBCS® standards have not been yet scientifically analysed and quantified on a group of managers. The purpose of the planned research is to fill this gap by indicating real behavioral impact on decision-makers who are using conventional reports and those prepared with the IBCS®. The paper starts with a brief introduction to idea of notation standards. Then, the notation standards in business communication in the context of the IBCS® are discussed. The next part of the paper presents the idea of planned research in the light of decision-making theory. The last part is devoted to a brief summary.

Keywords: Notation Standards, IBCS®, Business Communication, Accounting.

Introduction

The musicians need a consistent notation system to quickly interpret music. In everyday life, standards simplify decision-making, allow to work more efficiently, and often even improve the quality of life. Well-known examples of standardization include: writing (standardized in the form of the Latin alphabet, as well as e.g. the Cyrillic, Chinese and Arabic alphabets), music (musical notation), traffic (traffic signs) as well as electricity (electric circuit plans) (Zebra BI d.o.o., 2020). Notation standards are helpful and commonly used in various disciplines, not only in music, cartography and engineering, but also in mathematics, computing, physics, chemistry, biology, sport, etc. (Hichert & Faisst, 2014).

In the area of accounting which is known as language of business, standards are commonly used. A form of communication here are first of all various types of financial reports. Financial statements which are final product of financial accounting are intended for external users, that's why the need for their standardization is widely recognized. The result of standardization process are i.e. International Financial Reporting Standards and US Generally Accepted Accounting Principles. The aim of those standards is to build one approach to complex business operations. They generally don't take into consideration the way of visual data presentation. On the other hand the form of controlling reporting is shaped internally in each company. That's why, when we are talking about reporting, both internal and external, it is common to use various layouts of reports, presentations or visualizations, even within one company. This affects both the readability and comparability of presented data.

When people design a business report or presentation, they usually follow their own intuition, logic, or observe how others do it. Although there are several guidance in the field of information visualization in general to amplify cognition (Schelkle, 2017). Until recently, there was any initiative to establish a generally accepted notation for business communication. The International Business Communication Standards (IBCS®) are the first framework that provides practical guidance for the design of business reports and presentations. The released Version 1.0 of the standards was adopted in 2015. The current version 1.1 was published in 2017. Now, the Standards are increasingly

recognized by industry (Proff & Schulz, 2016: as cited in Schelkle, 2017) and popular in the German-speaking countries. When assessing the idea of the IBCS®, the most important is it's real impact on human behavior.

Notation standards in business communication in the context of the IBCS®

In 2004, Hichert initiated work to standardize the way analysts and controllers present data in their reports, presentations and dashboards (Zebra BI d.o.o., 2020). In the work on the International Business Communication Standards were also involved the IBCS Association and authorities in the visualization field: Brinton, Few, Minto, Playfair, Tufte and Zelazny (Zebra BI d.o.o., 2020). Importantly, the Standards were developed on the basis of scientific, experimental and practical experience.

The IBCS® provide practical guidance for the proper conceptual, perceptual and semantic design of business communication. For the purposes of the Standards, business communication is understood as materialization (e.g. paper, screen views) of quantitative information for analytical and reporting purposes. It means the organization of business communication into products (e.g. reports, presentations, interactive analytic applications, statistics), consisting of pages (e.g. slides, screens) comprised of objects (e.g. text, charts, tables) with specific elements (e.g. columns, axes) and general elements (e.g. titles, comments) (Hichert, Faisst & Members of the IBCS Association, 2017).

The intention of the IBCS® is to use the same expressions and the same visualizations for the same content. The standards of the visual language are comprised of three pillars (based on Hichert's success rules):

- conceptual rules – concern the issue of using an appropriate storyline to clearly relay content;
- perceptual rules – indicate which visualizations should be used in a given case;
- semantic rules – present a uniform notation (IBCS Notation), which covers actual standardization of terminology, analyses, descriptions, dimensions and indicators used in business communication (Hichert et al., 2017).

Therefore, the IBCS® cover seven thematic blocks:

- convey a messages (say);
- organize content (structure);
- choose proper visualization (express);
- avoid clutter (simplify);
- increase information density (condense);
- ensure visual integrity (check);
- apply semantic notation (unify) (Hichert et al., 2017).

The IBCS® implementation is based on three preconditions, which include a clear concept with a set of rules, appropriate software and the right management (Zebra BI d.o.o., 2020). It is worth emphasizing that the software plays a key role in solving problems with business communication. The appropriate software makes the charts compatible with the IBCS®. As of today, 12 software products have been certified by the IBCS Institute.

While the benefits of notation standards in music, engineering and many other disciplines are obvious, it seems to be different in business communication. The research showed that visualization of business information is often not properly applied in business reporting (Schelkle, 2017). The standardization may improve the effectiveness and efficiency of reporting, but it requires adjustment to the individual circumstances of the organization.

Szarska (2018) presented the results of the research conducted by a research group at the University of Applied Science Upper Austria, which showed that the effectiveness through the implementation of standardized reporting increases after five weeks significantly, and the users needed 30% less time to analyse information. Zelga (2018) claimed that by applying global reporting notation standards in accordance with the concept of the IBCS®, a manager needs only one glance to be able to make decisions or draw conclusions for the future. This reduces the time taken to understand management information.

According to Hichert and Faisst (2014), the implementation of notation standards in business communication increases transparency by better comprehension and greater credibility. Taking into account the stages of the process to support decision making, Hichert and Faisst (2014) indicate three types of benefits:

- improved quality of the deliverables;
- reduced reaction time;
- reduced costs.

To confirm these theses, the authors refer to many positive opinions of the managers regarding the implementation of the IBCS® in their organizations (Faisst & Subirats, 2017).

The efficacy of the IBCS® have not been yet scientifically analysed and quantified on a group of managers. The effects of the Standards on reading-time and decision-making quality was measured in an eye-tracking and laboratory study on a group of 90 students with a background in business or IT at the Technische Universität München (Freyer, Linde, Schulz & Proff, 2020). None of the previous research have covered implementation of the IBCS® in Polish companies.

Study of the efficacy of the IBCS®

Each human activity and the activity of individual organizations is based on the continuous making of decisions and decisions (Ściborek, 2003, p. 25). According to the literature on the subject, decision-making is a process that consists in recognizing and choosing a specific course of action, which is to lead to the solution of a specific decision problem (Stoner, Freeman & Gilbert, 2001, p. 238).

Social science has developed two scientific approaches to decision theory that actually interpenetrate one another. They include the approach (Bolesta-Kukułka, 2003, p. 123):

- rationalist-normative (prescriptive), consisting in recommending universal recipes that people should follow in their actions;
- behavioral (descriptive), presenting how people act in reality.

The rationalist-normative approach, which is based mainly on indications resulting in large part from logic, mathematics and statistics, includes logically derived from a prioritized norms of rationality: conditions, rules and recommendations that must be followed so that decisions are made fully consciously and reasonably. If, in fact, there are deviations from these principles in the behavior of decision-makers, they are explained by errors in thinking resulting from the imperfection of human reason (Grzesik & Karaś, 2014, p. 20). In turn, the behavioral approach presents the actual behavior of decision-makers, which do not always coincide with the recommendations of rationalist-normative models. Such deviations are frequent and therefore difficult to interpret as a negative phenomenon. As part of the discussed approach, the authors of the recommendations not only describe the decision-making behavior, but also try to discover the reasons for the identified deviations. In behavioral models, attention is focused primarily on describing and explaining real decision-making processes that actually run differently than the norms contained in rational models (Grzesik & Karaś, 2014, p. 20+).

An exceptionally interesting and important area of research on decision-making is Judgment and Decision-Making research in accounting. It is a rapidly developing area of research in accounting literature (JDM) [see (Bonner 1999; Ashton & Ashton 2007; Luppe & Favero 2012; Schiller 2013)]. JDM researchers strive to measure the effectiveness of people in the context of making judgments and decision-making, as well as to identify determinants of high and low quality of the processes (Bonner, 1999, p. 386).

The purpose of the planned research is to analyze real differences in perception of business accounting reports prepared in conventional way and with usage of IBCS® guidelines.

The subject of the research is the population of managers from companies listed on polish Warsaw Stock Exchange.

Methodology includes an eye-tracking and laboratory study of specially prepared business reports which includes: annual external financial reports and monthly reports which covers area of selling, purchases, costs, cash flow and HR data.

Summary

The popularity of the IBCS® standards increases but there is only one research which aim was to analyze reading-time and decision-making quality of reports. The authors of this short paper want to fill this gap by preparing research in the same methodology as German researchers. The subject of the prepared research are managers from companies listed on polish Warsaw Stock Exchange. Our proposed research has limitations, which at the same time, are indications for expanding the research in this area. The findings may be useful for all the managers and scientists interested in reporting and decision-making area.

Abstract

The article contains the author's position on the key issues of understanding the tax management methodology. The author reveals the relationship between taxation and the economic system of the state in its broad sense. The author reveals the influence of deviations from the classical directions of the development of scientific cognition on the practice of tax management.

Keywords: Tax Management, Science, Methodology.

Introduction

Modern publications on taxation issues contain various terms and definitions of tax processes and their results.

However, most authors focus on the description of the rules for calculating a tax base and an amount of tax payments without the extremely necessary analysis of the predetermination of taxes by the condition of production factors (direct and indirect dependence) and the existing system of managing economic and financial processes [1].

On this basis, we will examine the theory of the subject, which promotes understanding of the relationship between taxation and the economic system of the state in its broad sense.

Theoretical and Literature Review

In modern studies, the word combination "theoretical and methodological propositions" is often used, which indicates that their authors ignore the classical propositions of the methodology of science as such [2].

The methodology, which includes a set of methods of speculative learning and their implementation in practice, serves as the basis for the development of the concept of management of any sector of activity of the economic entity in specific business conditions (object of management).

For the practical implementation of the concept, a development strategy for an object of management should be created. The starting point for its development is methodological principles. Therefore, from the standpoint of scientific theory, the development of an economic (financial, tax, etc.) strategy of a company should be based on a complex of methodological principles and a set of tools for implementing these principles in real practice.

Methodological principles are time-proved postulates of the movement of the economic sphere in an ascending spiral. New scientific knowledge is growing, based on the postulates of the classics of economic thought. Different branches of economic science, based on such principles, supplement them with their own (specific) ones. Scientific

Cite this Article as: Tatyana V. FEOKTISTOVA and Yuri N. VOROBEV " Methodology of Tax Management in The Economic System of The State" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

ideas can be specificated and revised, but at the same time we understand that there is continuity in the development of knowledge, deviation from which is fraught with being pushed to the sidelines of global progress [3].

For example, the science of taxation is based on Adam Smith's principles, which are rightly considered methodological, starting, basic. Modern tax management supplements these principles with new ones adapted to a specific space and time, since it is difficult to manage without knowing the specificity of the object of management, its location and other characteristics.

The foregoing words indicate the importance of scientific knowledge accumulated by society, the need for an accurate understanding of the essence of concepts and definitions. Clearly defined boundaries in which consciousness tries to identify the essence of a process, object or any other observed phenomenon, which are comprehended, allow to give them science-based definitions.

Having defined examined object, you can move on – develop a concept for managing it, consider alternatives for implementing the conceptual foundations of managing an object, compare these alternatives with each other from the point of view of adequacy to the conditions of space and time, and choose the most appropriate option. Legislative base and methodologies for the implementation of legitimate regulation will be prepared for this option. Therein lay the cause of the importance of methodological principles for improving methods of managing business practice in any of its segments (financing, taxation, etc.).

The tools for implementing a particular conceptually determined strategy are a set of methods, i. e. clearly defined algorithms for achieving the goal, a description of step-by-step progress toward the intended goal. Such methods take into account all sectoral specificities of the financial and economic activities of companies.

The results of the study and discussions

Choosing a strategy is a rather complicated process if the company's activities are multisectoral. The development of company's strategy for tax liability management takes one of the central places in the company's financial strategy.

Because of the relative novelty of the term "tax management", let us express our own position regarding its content.

Tax management, being one of the component parts (functional target sets) of the financial management system, consists of the same elements: planning taxes and payments; their regulation in case of deviation from the outlined plans; tax bookkeeping; accounting (drawing up declarations); analysis of the status of tax obligations according to the criteria of completeness and timeliness of execution; tax supervision. We should note that, instead of the term "tax management", it is fully justified to use in tax practice such a traditional and familiar to users concept as "tax liability management." Both of these terms presuppose developing a tax strategy basing on the state of the economic environment, its spatial characteristics and motive forces [4].

The extreme mobility of legal regulation of taxation, its contradictoriness and lack of proper connection with the provisions of civil, economic, budgetary law, as well as a number of other significant shortcomings, determine the presence of high tax risks in the relations between taxpayer and tax authorities. Tax risk is, first of all, an actual or estimated by calculation loss in profit (tangible or monetary) caused by a business transaction [5].

Minimizing tax risks requires a wide range of theoretical and practical knowledge, which a tax manager should have. At the same time, it sometimes becomes impossible to minimize tax liabilities due to the lack of a deterministic connection between the instruments of the state tax policy (the choice of the main lines of development of tax policy, changes in taxation elements, etc.) and factors of economic growth [6].

We consider the deterministic analysis of the dependence of various types of taxes and payments on the state of the basic factors of production and all elements of the economic policy of the government in (credit and monetary, financial, tax policy, etc.) to be the basic method of tax management, as well as financial management. It should be noted that deterministic analysis is carried out in the system of corporate tax management, while it is not carried out

in the system of state tax management. The taxation system is developing in a fragmented way by correcting the deficiencies in the provisions of the Tax Code of the Russian Federation which were revealed in court proceedings on the merits of tax litigations. Of course, such a situation cannot smooth out the acuteness of objective contradictions in the tax interests of taxpayers and the budgetary interests of federal and regional bodies of power and administration [7].

As practice shows, the tax managers of large Russian companies have a wide choice of analytical methods, many of which can be attributed to deterministic analysis. We will consider only some of them.

Expert methods presuppose using methods of logical analysis, they are characterized by a certain subjectivity. They include methods of expert assessments, scenarios, comparison, various psychological, morphological methods, methods of constructing indicator systems, analytical tables, etc. Methods based on strict formalized analytical dependencies are more accurate. The most well-known in this group are the following:

1) methods of factor analysis;

2) methods of economic statistics;

3) mathematical-statistical methods;

4) methods of economic cybernetics and optimal programming;

5) econometric methods;

6) methods of research of operations and decision theory [8].

Unfortunately, because of their complexity, the fifth and sixth groups of methods are not widely used in tax liability management even in large companies, however some of their elements are used in planning and analytical work (methods of the theory of production functions and network planning, construction of tree of objectives).

There are three types of basic models: descriptive (used in financial analysis and based on information from accounting (financial statements)); predicative (used in forecasting the financial activities of the organization); normative (based on a comparison of actual results of activities with normative results, they can be used in internal financial analysis, management accounting, budgeting).

Thus, to ensure so called “sure choice” in relation to principles, models, including tools for analytical learning of business situations and respective tax consequences, it is necessary to have a clear idea of not only the essence of the tax strategy as a whole, its main trends, but also of the basic method of tax management [9].

Conclusion

The main task of tax management is developing strategic taxation guidelines at macro, meso and micro levels of the economy. The application of financial analysis methods for tax liability management should be based on interconnected basic conceptions: cash flow and temporal value of monetary resources.

The loss of profit risk should be assessed on the basis of economic methods grounded on the assessment of imputed costs using a profitability indicator and assessment of the value of consumption expenses and income of business entities. All these methods of scientific cognition are based on using invariable elements of a systematic approach to the object of research.

Abstract

Success of an enterprise depends on its employees' human capital. This article investigates the influence of employees' education on their human capital formation. The relationship between the quality of education and employment opportunities for graduates is assessed by the number of the employees working in their field of studies. The following assumptions are being investigated: the quality of education affects the ability to utilize the acquired human capital in the labor market of Ukraine; easy access to higher education in Ukraine creates a surplus in the labor market of specialists; receiving education abroad is a competitive advantage in the labor market in Ukraine.

The data from 481 respondents' (age ranges 18-60 years old and working in industry) questionnaires has been analysed. Evidently, there is a strong link between the quality of education and the ability to use a person's human capital accumulated during their studies. There is no link between the availability of education, which leads to oversaturation of the labor market with professionals in certain fields and the possibility of using human capital. Nevertheless, there is a shortage of highly qualified specialists in engineering industries in Ukraine today. Similarly, there is a strong link between indicators that characterize the attractiveness of education abroad and the ability to use human capital accumulated during training, and the attractiveness of obtaining specific social capital, namely experience in foreign companies and relationships. This indicates that engineering education obtained in Ukrainian universities, according to respondents, is quite competitive with similar education abroad.

Keywords: Human Capital, Human Resources, Educational System, Industrial Sector of Ukraine.

Introduction

An enterprise reaches their success when an optimal combination of the employees' abilities, skills and knowledge is taken as a basis to form a human capital. This aspect is achieved by assessing the quality of education of the graduates. The relationship between the quality of education and employment opportunities for graduates is assessed by the number of the employees working in their field of studies. Formation of the human capital, assessed from the quality of education standpoint, is best reflected in the performance of industrial enterprises, as it requires the most specialized approach and a clear identification of the required specializations.

To assess the quality of education, it is advisable to consider the system of higher education, which is an important element in training professionals in all areas, and industry in particular. The optimal indicator is the number of higher education graduates working in the field of their degree. In Ukraine's labor market this indicator is weak as the number of employees who work in the field of their degree is very low.

The article examines the impact of education quality on the person's ability to use the human capital accumulated during their studies in Ukraine. Presence of a significant negative relationship between the employment rate in the field of their degree and the assessment of the education system quality in Ukraine indicates the relationship between investment in quality education and the possibility of return on investment by the bearer of human capital.

Cite this Article as: Yevhen REVTIUK and Yuliia VORZHAKOVA "Functioning of the Education System and Efficiency of Investing in Human Capital on the Example of the Industrial Sector of Ukraine" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The negative relationship between the employment rate in the field of their degree and the allegation that limited educational opportunities due to reduced numbers of scholarships reflects the recently emerged belief in Ukrainian society that a quality education cannot be free. The analysis of indicators that characterize the attractiveness of studying abroad in comparison to studying at Ukrainian universities reflects the belief that foreign experience could become a competitive advantage when applying for jobs, as well as achieving specific social capital by students. There is a negative significant relationship between the employment rate in the field of their degree and the respondents' age, which may indicate a reduction in the disparities between the demand for industrial specialists and their training within the education system of Ukraine.

Literature Review

In modern literature, the relationship between education and the formation of human capital is widely discussed. Getting a degree requires an investment of both time and money as well as a person's effort, which is quite similar to investing in the means of production. After all, the productivity, and hence the income, of a person with better skills and the ability to generate more added value will be higher. This phenomenon was noticed in the middle of the 20th century and has led to the idea of the possibility to invest in human capital (Schultz, 1961) and the emergence of the human capital theory, wherein the researchers tried to find a rational explanation for the economic efficiency of such investments (Becker, 1964). Therefore, human capital is the knowledge and skills which are the components of human resources. This means that the knowledge that the workforce will receive is provided through training. In this case, education is very important in terms of accumulating human capital. Another reason which highlights the importance of education is the people's ability to increase their productivity (Karaçor et al., 2017).

There are different approaches to determine the magnitude of human capital. Thus, in the study of human capital and its impact on performance, the following indicators were used: characteristics of education, usually the number of years of study (Bassanini and Scarpetta, 2001; Bils and Klenow, 2000; Pritchett, 2006), secondary education Bassanini and Scarpetta, 2001; Martins and Pereira, 2004), education costs (Hicks, 1980; Karaçor et al., 2017). In addition, researchers point out that the formation and effective use of human capital also depends on the characteristics of the education system (Fasih et al., 2012). At the same time, Lucas (1988) proposed a mathematical model that describes the processes of human capital formation, taking into account the activities of the educational sector.

As result, most researchers consider the education system as a tool for human capital formation and, consequently, a source of economic growth. In this case, the accumulated human capital in the education system increases labor productivity and, consequently, leads to a higher level of cumulative supply and demand in the markets (Hanushek et al., 2008).

Thus, human resources in the economy are growing both due to population growth and the growing share of human resources among the population. However, it is the growth of qualifications or quality of human resources, which are formed as a result of education, both in universities and directly at the place of work, leads to the accumulation of human capital in the country (Kucharčíková, Tokarčíková and Blašková, 2015). In other words, human capital can be expressed as the sum of knowledge and skills acquired by the workforce.

Empirical findings demonstrate a positive correlation between the wages and the level of education (Martins and Pereira, 2004). At the same time, the level of acquired education has a positive effect on the country's economic growth (Devarajan, Swaroop and Zou, 1996; Fasih et al., 2012; Karaçor et al., 2017). However, researchers note significant differences in the return on investment in human capital, which are caused by the level of the country's development, the quality and the field of education (Martins and Pereira, 2004) (for example, in OECD countries, income from investment in human capital is lower than in countries from the others groups (Karaçor et al., 2017).

Several fundamental studies indicate that education is important both for an investment in human capital and for promoting research and development. The implementation of the technologies in the early stages of education is important not only for subsequent employment, but also for further development in higher education for innovation (Vandenbussche, Aghion and Meghir, 2006). Investments in human capital (eg, spending on education and training) can have a more lasting impact on economic growth if high skills and training are combined with more intensive research and development and faster rates of technological progress (Bassanini and Scarpetta, 2001). Given the latest trends in society and entry into Industry 4.0, the assessment of human capital necessarily considers a combination of the quality of higher education and the employment opportunity in the field of studies. Rafiq et al. (2019) emphasizes

that during the transition to Industry 4.0, the nation's development focuses on the quality of education, where education is seen as a remedy for addressing issues related to human capital development. The assessment of the impact of human capital on youth unemployment shows that higher education institutions play a role in the relationship between skills and successful human development in the field where one works and have studied (Torul, 2020).

Although there is a consensus among researchers on the importance of economic investment in human capital, the effectiveness of such investment will largely depend on a number of specific factors such as the quality of the education system, the chosen field, changes in the sectoral structure of the economy, and abilities of the person to apply their knowledge during their career cycle. Nevertheless, in our opinion, the main factor that influences the possibility of returning investment in human capital at the individual level is the efficiency of the education system. At the same time, important factors are both the quality of the acquired knowledge and the conformity of the acquired specialty with the demand for special human capital in the labor market.

Background

Ukraine inherited from the Soviet Union a powerful branched education system with an advanced infrastructure at the time. After the proclamation of Ukraine's independence, the development of higher education system in the country has begun with the revitalization and implementation of the best achievements and practices of the education systems from Soviet union and European countries. The mid-90s are characterized by strong legislative support for the education sector, when a number of documents (the State National Program "Education. Ukraine of the XXI century " (1992), the Law of Ukraine" On Education" (1993), the Law of Ukraine "On Higher Education" (2002), the new Law of Ukraine "On Higher Education" (2014),) aimed at further development of the higher education system were adopted. Joining Ukrainian higher education system to the Bologna process in 2005 was a very important step, which has led to the integration of the Ukrainian higher education system into the European one. The lengthy integration process was aimed to be achieved in 2010, but unfortunately, has not been fully completed. For example, the transition to two-cycle studies has not been completed yet. There is also a low level of mobility of students and teachers. The autonomy of universities is still insufficient. There is a decrease in the number of classroom teaching and an increase in the hours for self-study (which often turns into an imitation of independent work, inevitably affects the quality of students' knowledge and causes the gradual decline in the competitiveness of domestic education).

Currently, 70-80% of secondary education graduates enter higher education institutions (HEIs). Prior to the introduction of the compulsory external independent evaluation (EIE) this figure even exceeded 80% (although no more than 50-55% of young people graduate as a result of dropout). In 2000, 50% of the secondary school graduates entered higher education, in 2017, according to statistics, in Ukraine 79% of secondary education graduates were studying for a university degree. 60% of the students were on the government scholarship, 20% were self-funded, and 20% were funded by private company's funding schemes.

Considering all of the above, we made the following assumptions: 1) the quality of education affects the ability to utilize the acquired human capital in the labor market of Ukraine; 2) easy access to higher education in Ukraine creates a surplus in the labor market of specialists, which reduces the opportunity to realize the human capital gained during training throughout their careers; 3) obtaining education abroad is a competitive advantage in the labor market in Ukraine, as the foreign education is considered to be better.

Methodology and Results

The study uses the data of a survey on the quality of education conducted by the Razumkov Center in late 2019. The questionnaire consisted of a series of questions which would allow us to assess the effectiveness of the Ukrainian education system. We selected 481 responses from respondents who indicated industry as their main place of work. The answers to the following questions were taken into the analysis: 1) "How would you assess the quality of education in Ukraine in general?"; 2) "How would you generally assess the accessibility of higher education in Ukraine?"; 3) "Why would a person, in your opinion, pursue a higher education? (several answer options) "; 4) "Do you work in a field of your higher or vocational degree?"; 5) "Professionals of which field would be able to find a well-paid job easier in the Ukrainian labor market? (several answer options) "; 6) "What would you need to do in a first place to secure a well-paid job after graduation?"; 7) "What would you find attractive in following education

abroad? (several answer options) ”as well as 8) age and 9) gender of the respondent. The SPSS software was used for statistical analysis. The information was coded based on the answers to 4 questions and labeled as follows: 1- the respondent works or worked in the field of their studies; 0 - the respondent has never worked in the field of their studies. Similarly, for multiple choice questions the answers were labeled as follows: 1- the respondent chose this answer; 0 - the respondent did not choose this answer. We rejected the answers of those respondents who reached retirement age (60 years and older), given that these individuals were educated in the Soviet Union education system. The main statistical characteristics of the information are given in the appendix.

A variable that indicates whether the respondent works / worked in the field of study or not was used as a dependent variable in the analysis. At the first stage, the relationship between this variable and the answers of the respondents was analysed.

Fig. 1: Average value of the respondents` answers for the question “How would you assess the quality of education in Ukraine in general?”

Thus, 41.88% of people who work or have worked in the field of their studies, rated the education system in Ukraine at the level of "High" and "Very high", as opposed to 22.83% of those who have never worked in the field (Fig. 1). Similarly, 23.83% and 35.87% of respondents in both groups rated “Low” and “Very low”, respectively. The identified difference can be explained by the fact that persons who could not find employment in their field blamed the quality of the education system for their unemployment.

Fig. 2: Average value of the respondents` answers for the question “How would you generally assess the accessibility of higher education in Ukraine?”

Access to education was assessed by both groups of respondents as follows: 37.94% of people who work or have worked in their field of study rated the education system in Ukraine as fully accessible, as opposed to 29.9% of people who have never worked in their field of study. At the same time, according to people who have never worked in the field of their studies, the reduction of academic scholarships is the more important reason for limiting the availability of education (31.96% as opposed to 21.28%).

Fig. 3: Average value of the respondents` answers for the question "Why would a person, in your opinion, pursue a higher education?"

Regarding the reasons that motivate people to get a degree, more than half of the respondents believe that education is a valuable investment. However, only 30.93% of respondents who have never worked in the field, and 39.94% of the respondents associate education with the opportunity to get a high-paying job, 30.9% and 24.1% of respondents, respectively - with the opportunity to find an interesting job, which is negatively characterizes the effectiveness of the education system in Ukraine. A quarter of respondents (25.77% and 29.08%) believe that getting a degree helps to accumulate their own social capital. Thus, the assessment of the effectiveness of investment in education is not very high among the respondents, which, again, may indicate the unsatisfactory quality of the education system in Ukraine.

Fig. 4: Average value of the respondents` answers to the question "What do you need in the first place to find a good job after graduation"

Opinions of the respondents have divided about the reasons for securing a well-paid job after graduation. Thus, people who did not work in the field of study, to a greater extent believe that personal connections (42.27% vs. 21.99% of answers) and money, and therefore bribes (27.84% vs. 18.09%) play an important role in getting their first job. On the other hand, people who work or have worked in the field of study more often noted the high level of knowledge (26.6% vs. 10.31%) and the ranking of the university where they studied (25.53% vs. 19.59%) as an advantage.

Fig. 5: Average value of the respondents` answers to the question "What is attractive about studying abroad?"

Notably, the respondents in both groups have similar answers about the advantages of getting a degree abroad. Firstly, it is an opportunity to get employment abroad (77.32% and 62.41%, respectively, among people who have never worked, and worked or are working in the field). In the opinion of the responders, recognition of diplomas in other countries (32.99% and 42.2% of respondents, respectively) and high quality of education (39.18% and 33.33%, respectively) are quite significant advantages. On the other hand, mastering new technologies (10.31% and 14.54%) and communication experience (10.31% and 18.09%) are not considered as an important advantage.

To better understand the impact of education quality indicators on a person's ability to use the human capital accumulated during training, the correlation coefficients between the following factors were calculated: 1) employment of the person in the field of study (0 - never worked, 1 - works or worked); 2) personal assessment of the quality of the Ukrainian education system (1 - very high, 2 - rather high, 3 - medium, 4 - rather low, 5 - very low); 3) assessment of the availability of higher education in Ukraine by statement of full availability for all fields (0 - no, 1 - yes); 4) assessment of access to higher education in Ukraine by statement of limited availability due to the high cost of education (0 - no, 1 - yes); 5) assessment of the availability of higher education in Ukraine by statement of limited availability due to the reduction of public procurement (0 - no, 1 - yes); 6) assessment of the availability of higher education in Ukraine by statement of limited availability due to the reduction of academic scholarships (0 - no, 1 - yes); 7) What would help to do in a first place to secure a well-paid job after graduation? (1 - have a good education, high level of knowledge, 0 -other answer options); 8) Attractiveness of studying abroad by statement of the opportunity to get employment abroad (0 - no, 1 - yes); 9) attractiveness of studying abroad by statement of the worldwide recognition of the diploma (0 - no, 1-yes); 10) attractiveness of studying abroad by statement of high quality of education (0 -no, 1-yes); 11) attractiveness of studying abroad by statement of the ability to stay abroad after graduation (0 - no, 1- yes); 12) attractiveness of studying abroad by statement of gaining experience of international communication and contacts (0 - no, 1-yes); 13) attractiveness of studying abroad by statement of training on modern equipment (0 - no, 1-yes). As control variables we used 14) age of the respondent (1 -from 18 to 24 years old, 2 - from 25 to 36 years old, 3 -from 37 to 45 years old, 4 - from 45 to 60 years old) and 15) gender of the respondent (1 - female, 0 - male). Descriptive statistics of the data used in the analysis are shown in Table 1.

The results of the correlation analysis are shown in Table 2. Firstly, it should be noted that there is a significant negative relationship between the employment rate in the field of study and the respondent's assessment of the quality of the education system in Ukraine. This confirms our previous assumption that those who think their education is better have a better chance of being employed in the field of their education and therefore, utilize the human capital they have accumulated during their studies. In addition, there is a close positive relationship between employment and quality education as a competitive advantage when getting a first job. The discovered fact indicates the existence of a connection between investments in quality education in Ukraine and the possibility of return on investment by the bearer of human capital. Thus, it can be argued that our first assumption has been confirmed.

Table 1: Descriptive statistics for variables used in the study

Variable	Description	N	Minimum	Maximum	Mean	Std. Deviation
Work	Employment rate of the person in the field of study	379	0,00	1,00	0,7441	0,43696
Q	Quality of the education system	425	1	6	2,80	1,109
AvEd1	Assessment of the availability of higher education: fully available	481	0	1	0,34	0,473
AvEd2	Assessment of the availability of higher education: - limited availability due to the high cost of education	481	0	1	0,30	0,460
AvEd3	Assessment of the availability of higher education: limited availability due to the reduction of public procurement	481	0	1	0,35	0,477
AvEd4	Assessment of the availability of higher education: Limited accessibility due to the reduction of academic scholarships	481	0	1	0,27	0,445
SW	Thing you need to find a well-paid job after graduation	481	1	6	2,61	1,323
EA1	Attractiveness of studying abroad: opportunity to get a job abroad	481	0	1	0,62	0,485
EA2	Attractiveness of studying abroad: worldwide recognition of the diploma	481	0	1	0,44	0,497
EA3	Attractiveness of studying abroad: : high quality of education	481	0	1	0,34	0,475
EA4	Attractiveness of studying abroad: the ability to stay abroad after graduation	481	0	1	0,16	0,369
EA5	Attractiveness of studying abroad: gaining experience of international communication and contacts	481	0	1	0,20	0,402
EA6	Attractiveness of studying abroad: : training on modern equipment	481	0	1	0,38	0,485
AGE	Age	481	1	4	2,84	1,063
SEX	Sex	481	0	1	0,34	0,473

Among the group of indicators that characterize the availability of higher education, there is a significant negative relationship between the employment in the acquired specialty and the statement about the limited opportunities for education due to the reduction of the number of scholarships. This phenomenon can be explained by the fact that in recent years Ukrainian society has become convinced that a quality education cannot be free. At the same time, receiving government scholarship, even though its amount is below the minimum subsistence income, is considered rather than as a factor contributing to the availability of education. Thus, there is no strong evidence to support the second statement.

Among the selected indicators which characterize the attractiveness of studying abroad in comparison to studying at Ukrainian universities, a negative close connection was found only with the answer "Gaining experience in international communication and contacts." This can be explained by the fact that for a long time Ukraine remained a relatively closed country, whose residents faced significant obstacles when traveling abroad. However, additional prospect for people who had international experience arose when the foreign companies started opening their branches in Ukraine. Among those who were unable to utilize their human capital accumulated during their studies, there was a belief that such an experience could become a competitive advantage when seeking employment. Third assumption was confirmed only for the part of specific social capital, whereas other factors showed no statistical significance.
There is no significant relationship between gender and work experience in the field of study. Instead, there is a negative relationship between the employment by field and the age of respondents, which may indicate a reduction in the disparities between the demand for industrial specialists and the training of specialists in the Ukrainian education system.

Conclusions

Human capital is one of the key factors of economic growth in the introduction of Industry 4.0, the formation of which is primarily the education system. At the same time, the acquired level of education does not guarantee a return on investment in human capital of individual education, because the latter depends on a number of exogenous and endogenous factors such as a person's career path, their desire to work in the field of study, the availability of suitable jobs in the labor market, and education. Such diversity of factors creates obstacles for researchers to assess the effectiveness of investing in human capital.

In this study, the efficiency of human capital use was operationalized through an indicator that demonstrates the experience of the employee in the field of study. Based on the results of a survey on the quality of education among people working in industrial companies in Ukraine, the relationship between respondents' assessment of the domestic education system, the importance of knowledge quality for the first job, access to university education, and attractiveness of education abroad has been investigated.

The identified trends indicate that there is a strong link between the quality of education and the ability to use a person's human capital accumulated during training. On the other hand, the assumption that there is a link between the availability of education, which leads to oversaturation of the labor market with professionals in specific fields and the possibility of using human capital. In our opinion, this result can be caused by the limitations of the dataset as only the answers from the responders working in industry were taken in the analysis. At the same time, there is a shortage of highly qualified specialists in engineering industries in Ukraine today. Similarly, a study of indicators that characterize the attractiveness of education abroad found a strong link between the ability to use human capital accumulated during training and the attractiveness of obtaining specific social capital, namely experience in foreign companies and relationships. This indicates that engineering education obtained in Ukrainian universities, according to the respondents, is quite competitive with similar education abroad.

This study, however, has a few important limitations. The experience of working in the field of study was chosen in order to assess the effectiveness of the human capital use accumulated during training. Unfortunately, there was no information available about the length of respondents' employment, which did not allow us to conduct a more in-depth analysis. At the same time, we assessed our data fairly assertively, believing that if a person did not work in the field of study, they were unable to use the human capital accumulated during training. Another limitation was the use of survey data from respondents working exclusively in industrial enterprises, which limited our analysis to a narrow and specific sector of the labor market. Despite these limitations, the proposed study characterizes certain trends in the processes of human capital formation in Ukraine, which should be investigated further.

Summary

Social media has quickly become the most essential communication and information-sharing tool in the daily lives of millions of people around the world. In a social network there are members who disseminate information and others who evaluate and repost it. This makes it possible to disseminate the maximum of information in a very reduced time and cost. The first source members of information are called "influencers". Detecting influencers is very important and useful in different areas. In marketing, for example, influencer detection lowers the cost of advertising by paying a small number of members to share positive opinions about a particular product. In This context we are interested in this social media marketing tool, namely influencers. More objectively and more concretely, we focused and focused on the role of the gender of followers in their responses to recommendations of a commercial type on the social network Instagram. To do this, we first carried out an exploratory study. Thus, we built a detailed review of the literature on the subject and conducted a quantitative study in order to understand and interpret certain phenomena and behaviors of followers on Instagram.

Keywords : Influencers, Consumers, Social networks, digital transformation

Introduction

We live in a digital, virtual and digital world in which consumers do not see the people they are talking to. Today it is accessible and very easy to connect and connect with a large number of people, and we consumers can send messages. Internet users expect brands to speak with them rather than for them and to provide them with inspiration and emotion.

With the advent of web 2.0, a participatory web, and social networks, digital opinion leaders - more commonly known as digital influencers - have arrived and appeared in a variety of fields. The web and social networks have become places of exchange between brands and consumers in a few years, but also between consumers themselves. Among these consumers, people have managed over the years to stand out by obtaining a certain skill and expertise and to emerge and stand out as opinion leaders, now called digital influencers or e-influencers. Unlike traditional opinion leaders who communicated with those around them directly, face to face, or indirectly, using word of mouth, digital influencers initially used social media such as than blogs, then, secondly, various social networks such as Instagram, Facebook, Twitter and YouTube. Influencers represent a new type of independent third-party endorser, that is, a new type of 'independent approvers' who shape and shape audience attitudes through blogging and the use of other social media.

Influencers, whether they are tweeters, instagrammers, consumer-actors, youtubers, want to offer their community authentic content, real experiences in order to share their expertise and passions.

The big challenge for brands is certainly not compensation, but it's building trust.

Relationships remain capital in the partnership and collaboration with influencers and this must be sustainable and above all based primarily on trust. Brands must put themselves in the shoes of influencers and be at their disposal and listening to them in order to offer them real content that meets their needs and communication operations that allow

them to create valuable and quality content. The best content is that which will be picked up and transmitted thanks to the best interpersonal skills and trust.

Issue :

What is the main role of an influencer on social networks ? and how important is influencer credibility and the trust established between followers and influencers on consumers' buying decision ?

Literature Review

Définition of the influencer

The term influencer refers above all to an individual with whom one associates a power and a power of influence, that is to say "a capacity of persuasion and of action on other individuals". This notion also combines the terms of prescriber or opinion leader. The term influencer was mentioned before the arrival of social media and networks, but these have changed the factors that define an influencer. Before the digitalization phenomenon, opinion leaders or prescribers were mainly politicians, celebrities and journalists who, through their fame, enjoyed the credibility that resulted from their status. Their influence was propagated through traditional media such as television, the press and radio or even the cinema. Today, social networks have enabled these personalities (politicians, journalists, celebrities) to transform or transpose the offline influence they enjoyed, on social networks where they will acquire a community of subscribers and where their opinion goes. count thanks to the fame that they enjoyed and were already enjoying. However, following the democratization of social networks, Internet users have shown and developed their network and have become influential only through their activity or the popularity they have acquired through a blog or through a buzz effect. They bring together and bring together a large audience and represent digital influencers, i.e. online influencers

"An influencer or thought leader can be defined as someone who is present in a significant and regular way on a number of social networks. He often participates in one or more blogs. It regularly delivers content to its community which over time grows and becomes loyal. An individual can be defined as an influencer if he brings together different characteristics such as: notoriety on digital platforms, A significant media presence, A concrete prescription capacity, A position of opinion leader and finally Editorial credibility

It is interesting to discover that the consumer does not have the same perception of the influencer, because for him 4 definitions stand out:

- The influencer is someone who has at least 10,000 followers
- The influencer is someone with whom brands interact to promote their products / services and messages
- The influencer is someone who shares information about the products they like
- The influencer is an expert in his field

The appearance of the digital influencer

The web and social networks are places of exchange transactions between consumers and brands, but also between consumers themselves. Among these consumers, there are people who emerge as 2.0 opinion leaders, now called "digital influencers" or "e-influencers". Indeed, bloggers can be seen as digital influencers, equivalent and similar to the offline opinion leaders of the "two-step flow" theory. These influencers can play the role of message mediators and convince communities in the digital environment, where messages can be distributed easily and quickly with a potentially viral effect. But concretely, what is a digital influencer? “Anyone - celebrity (actor, musician, etc.), reality TV star, model, reporter or blogger - with a prominent voice in media, primarily on social media and who receives reputation and generates notoriety through views of its content and of its commitment to the same content in a meaningful way for itself and the other people it mentions ”. Digital influencers are more prevalent via social media and blogging, if we think of their online social contacts, compared to traditional thought leaders who communicate face-to-face with their peers. Additionally, the ease of access and convenience along with the low cost of social media has made the contact process simpler and easier.

An influencer in a social network

The influence on social networks is a remarkable phenomenon not only from the point of view of the transmission of information, but also from the point of view of controlling the envy of other users. Especially in the field of politics and marketing. Influencers are also referred to as today's opinion leaders. To define an influencer, many authors have their own definitions. Watts and Dodds [define an influential person or opinion leader as a person who is part of a minority and who activates and exercises some influence over a large number of people. Detecting **influencers provides an impression and significant value in practice.**

To begin with, the term "influencer" refers to digital opinion leaders who, through an Instagram post or a YouTube video, influence the buying behavior of more people than many magazines combined.

Consult, share or discuss on social networks: a practice anchored in the daily life of Moroccan Internet users

Influencer Marketing has quickly found a place of choice among the levers that help companies gain visibility and develop their sales. It is mainly based on the prescribing power of influencers which is part of a true sales cycle today. The influencer who is at the center and plays the role of brand prescriber, must be given a certain credibility or even the ability to "relate". Social networks are mainly Instagram, Snapchat and Twitter. Advertising through an influencer followed by more than a million subscribers guarantees you, like digital, a quantifiable return on investment. Above all, it allows you to address a “generation Y” of young people.

Types of influencers

There are 3 main segments of influencers. Most influencer marketing programs will engage with individuals that fall into each of these 3 categories.

LEVEL 1 : MACRO OR CELEBRITY :

Traditional influencers who have long been recognized offline, such as journalists, analysts, politicians or celebrities. They generally have engaged and large audiences. No more fun, we now move on to the influencers who weigh in the game. From the top of their community of 100,000 to 1 million followers, these influencers undoubtedly boost a brand's visibility. They don't usually get to this level just because of their pretty little faces. Most of them benefit from the influence of a blog or even a YouTube channel. Others manage to break through without all of that, but they have an innovative concept that sets them apart from the competition.

LEVEL 2 : MAGIC MIDDLE :

Online community leaders, such as industry and subject matter experts. In a specific context These individuals can have more influence than certain media or macro influencers, who often involve their own opinion by listening to these level 2 influencers. Typically, they have smaller audiences, create expert content and generate high engagement rates

"And this is also the first advantage of a nano-influencer for a brand: its low cost. This type of influencer is also differentiated by its authenticity. The content creator baby is a Mister Everybody. If one user decides to follow him rather than another, it is sure that he is genuinely interested in what he is saying and has something new. Also, a nano-influencer usually doesn't do this for the money but out of passion. So, he shares his reviews with his followers like a friend or family member would. Consumers trust it and will therefore be more apt to like and comment. These content creators are, in this sense, strategic assets for low-budget brands wishing to improve their image and boost their sales ”

LEVEL 3 : MICRO INFLUENCERS :

The micro-influencer is the cut above. He has more visibility and above all knows all the inner workings of Instagram. Thus, it is able to produce very good quality content that highlights your brand and engages its community. Its asset: greater visibility than other types of influencer and 60% more engagement compared to macro-influencers and celebrities. Thanks to Instagram's niche community, brands can reach new target audiences. They thus boost their conversion rate and benefit from an interesting ROI.

Quite clearly, micro influencers usually represent fans, local experts, very active members of communities who interact with other fans and generate reviews within their groups. These people will have small but very engaged audiences. A group of micro-influencers can have as much impact as a macro-influencer.

The role of influencers

Following trendsetters makes it possible to predict changes, transformations and possible developments in expectations focused on a product or service, and to gain responsiveness.

Customer relationship, E-reputation: influencers, representatives of their community, can increase and strengthen consumer loyalty to a brand, and save time in the launch and improvement of a strategy adapted customers.

Product launches are the times when the role of influencers is the most important to promote them. Brands no longer hold sole responsibility for the image they wish to convey.

Followers are the target of almost all digital communication campaigns. They are also the main motivation for influencers, whose job it is to create valuable content for their followers.

Hashtag, that little hash placed in front of words or phrases on social media, is one of the most important building blocks for engagement. This symbol allows users of social networks to interact on topics. It creates the link between followers and influencers.

Brands and influencers looking to differentiate themselves to make their content stand out, use hashtags in the hope of increasing interactions on their products and services.

It is very important to establish lasting relationships with influencers, based on mutual trust, interactions and collaborations.

However, Influencers claim a large number of followers whose volume can sometimes reach close to millions.

The prescribing role of influencers :

Like opinion leaders, social media influencers have a prescribing role with the people who follow them, who turn into real an intention to buy and then translate into an act of purchase.

"Purchases that generate satisfaction, Acts of purchase that also arouse satisfaction since 76% of people who have bought a product after reading content published in a post on social networks by influencers, say they are satisfied. There is a minority of people who say they have been disappointed. The act of purchasing is more important for people who follow the beauty world (87%), the automotive world (87%) and the fashion world (86%), but also from people who primarily expect news on brands and products from influencers (82%). This prescribing power acts by recovery, since 64% of Internet users who follow an influencer recommend products and brands after having read content published by influencers or else they write a good comment. Overall, 70% of people who follow an influencer have already purchased or recommended a product after reading good reviews about that product. This allows us to consider that these people who have gained in notoriety thanks to social networks and which we now call "influencers" ... effectively influence the consumers who follow them.

Effective promo codes

It is desirable and desirable to note that 41% of Internet users who follow influencers declare to have already used during the last twelve months, "a promotional code or a reduction and a reduction proposed by an influencer. Also, if a third party follows influencers to get discounts, they are more likely to use them (44%), ultimately a sign of the effectiveness of the exposure of the content disseminated with a promotion code. Promotional codes are not the only lever to use, however, since despite everything, 75% of people who follow influencers say they have bought the product after reading the content posted on social networks. This shows once again that the real impact and the real influence can only be obtained by the distribution of quality content in line with the expectations and desires of Internet users, and not only by the distribution of a promotion code. ". If the latter generates lower sales than the content itself, it nevertheless makes it possible to monitor the sales generated from the content disseminated by influencers on e-commerce sites.

Influencers and trust

The topic of trust and influencers is at the heart of the existing debate or one of the most important points in influencer marketing. “A study was done to find out if there is a relationship between the credibility of influencers and the trust of subscribers.

• 44% of women believe it is necessary to see or test the product or service used to trust the publication of influencers.

• 41% of men place expertise as the main factor in trusting influencers.

Authenticity is the number one reason to trust an influencer

• 43% of respondents cite authenticity as the main factor.

Personalization is a key factor

• 66% of respondents say that influencer content should relate to the focus of followers. "

• How can you trust an influencer in the end?

First, "a brand will have an interest in weighing the utility and value of its product and minimizing the risks as much as possible. She will not submit a risky product to an influencer. Second, and this is the essential point for the influencer, it will be out of the question to say that a product is better or magical or to use a term that puts the product in orbit, if that is wrong!

Why ? Because it will no longer be just the brand that will be incriminated but also the influencer. And if the influencer is discredited for lying or being too positivity about a product, their online reputation will go down the drain. Outside an influencer no longer wants to take a risk whose goal of losing his influence, which he took years to gain.

The relationship of proximity and trust between influencers and followers:

Influencers are present on different exchange platforms such as social networks which are often the relays of a blog site. Thanks to their presence on various communication channels, they can reach a larger audience and be close to and listened to their subscribers. In the case of a trip, an influencer will be able, thanks to the different functionalities offered by social networks, to submit different content: texts on Facebook, behind the scenes on Snapchat, photos on Instagram, videos on YouTube ... subscribers find themselves throwing themselves into the daily life of the influencer and will increase and improve with him a feeling of closeness. The success of an influencer represents the strength of the connection he has with his community. For Bruno MALTOR, travel blogger, the important thing is to keep your originality, show humility, transparency and be easy and accessible to improve cohesion with your community. The stronger the bond created, the more apt followers will have to follow the recommendations made by an influencer. Influencers know the expectations and expectations of their audience, they will produce content of greatness and value that enters the interests of their subscribers. Thus, there will be a certain homogeneity between the influencer and his subscribers because they will come together around a common system of values.

Research hypotheses

H1: On a social network, engagement and trust are two determining variables in the influence that a social network can have on the consumer.
H2: The credibility of influencers can have a positive impact on the trust established between followers and influencers.
H3: Reviews and comments on social media can have a positive impact on a user's choice of social media (eg choice of travel destination).
H4: The promo code is a very effective trend that can have a positive impact on the choice of followers (ex: buying clothes).

Empirical study

Introduction

In this research work we seek to offer a better vision of social networks, to understand the motivations and reasons that push users of social networks to follow influencers, thus we wish to provide a better understanding of the major role that an influencer can play in through posts on Instagram and videos on youtube to encourage subscribers to make a purchase decision or book online in case of travel. finally we seek to understand the perception of users of social networks towards the credibility of influencers

First, we will outline our methodological choice and the research method adopted, we based it on a quantitative survey.

So we will try to find a relevant answer for our research problem, and to measure the significance of our hypotheses presented in the conceptual framework.

However, we will dwell a little on the one-dimensional, two-dimensional and multidimensional analysis and the results from the data processing software "SPSS".

Method of sample selection

This study was carried out by the administration of a questionnaire which was distributed by internet.We then target a large target of respondents of about 100 people whether they are young people who are still studying or elderly or young people who work in different professions, we preferred to distribute the questionnaire online and not face to face given the importance of the users of this communication platform.

Method of data collection and processing

To produce the knowledge of our research, we opted for a quantitative approach by administering the questionnaires. This allowed us to question individuals by first defining the terms of responses through the chained questions. It is a very efficient information gathering tool as it allows the processing of large samples and the establishment of statistical relationships or numerical comparisons.

For the quantitative study: we use the statistical method, in order to know the relationship between our dependent variables, and the independent variables.

This method then allows us to test all the hypotheses of the research, using the SPSS software, and we will retain a value of 95% as the risk threshold.

Quantitative Analysis

One-dimensional analysis

1. **Gender of influencers :**

We note that more than half of about 59.18% of followers follow female influencers while 27.55% follow women and men equally while 11.22% of followers are mainly interested in content from men, however, a minority of followers (2.04%) follow families.

2. . Persons contacted before making a purchase :

After the analysis carried out through the SPSS software, it was found that 32% of people contact their families before making an act of purchase, while 31% of people contact their friends to make a purchase, while 16% of people use influencers through Instagram posts and video content posted on youtube before making their purchases, yet a minority of people who contact professionals in the field to make a purchase

3. Reasons people follow influencers :

From this analysis, we found that there are many reasons why followers follow influencers, 70.41% of followers follow influencers for tips and ideas, while 22.45% of followers do this out of simple curiosity while a minority of them follow their people to find out about their daily lives.

Two-Dimensional Analysis

1. The effect of belonging to a socio-professional category on the frequency of online reservations

This study allowed us to note that 12% of the people questioned in our sample are students, they affirm that the degree of online reservation is occasional, while 7% of the people questioned in our sample are mainly intellectual executives and professions higher, this professional category books online all the time. Yet 4% of people who are unemployed do not book online.

2. The effect of the gender of social networks on the credibility of influencers

Through this study, we found that 30% of respondents trust Instagram and say why not give credibility to influencers and trust them, while 7% of respondents trust Instagram more and say that you absolutely have to trust influencers.

3. The effect of belonging to a socio-professional category on the reasons which push subscribers to book online:

Through this study, we found that 23% of students book online because of the speed and ease of use, while 7% of students book online because of the easy comparisons of offers between agencies on the internet, yet 3% of those questioned are people who work in intermediate professions, this category books online because of preferential rates on the internet (promotions).

Multidimensional analysis : Principal correspondence analysis :

At the beginning, we chose a few variables from our quantitative study for our map.

Projection of the variables on the factorial plane

The correlations of the variables with the components:

The first axis represents the first component, it can be interpreted as being the reasons that push consumers to follow influencers, whether they are bloggers, instagrammers and youtubers, while the questions relating to the reasons that push people to follow influencers and the reasons for booking online are linked to several factors such as belonging to a socio-professional category.

So, we can name axis 1: types of social networks used

While axis 2: reasons to follow influencers

While axis 3 represents the reasons for booking and not booking online.

Regarding the projection of individuals on the map of individuals, we found that the majority of respondents state that this is a strong correlation between variables, which leads us to say that there is a strong relationship between belonging to a socio-professional category and online booking since we found that senior managers, students and doctoral students are more likely to book online than other socio-professional categories, those who lead to the conclusion that people who do not have a good grasp of new information and communication technologies have difficulty booking online. However, we have seen that there is still a relationship between the type of social network used and the reasons that lead consumers to follow influencers, since the most used and well-known social network by influencers is Instagram, so this allows us to conclude that in the social network Instagram, among the reasons that push consumers to follow influencers in the first place is to get ideas and advice on different fields, fashion, beauty, travel

Discussion of the results of the quantitative analysis

Our quantitative study focuses on the description of the perception of social network users towards the major role of influencers who can have a direct impact on the purchasing decision of consumers, we defined a sample of 100 people, the questionnaires were completed via the Internet on the social network Facebook. This study allowed us to start by developing a unified varied analysis which consists of measuring the variables separately through descriptive techniques, the objective of which is to describe each variable in order to subsequently generalize the result.

From this analysis we found that the majority of people interviewers say that among the reasons people follow influencers is to get ideas and advice, yet people reach out to their families, friends and influencers to ask their opinion about a purchase before making it, while the socio-cultural level and belonging to a conscious and intellectual socio-professional category is one of the main reasons that push subscribers to book in line.

However, the majority of social media users trust Instagram and say that influencers should be trusted absolutely, after developing the varied united analysis, we believe it is important to perform the two-dimensional analysis, according to this analysis, we were able to conclude that students and executives who have a certain intellectual level are more likely to book online than other socio-professional categories, and the results of this two-dimensional analysis assert that influencers should be trusted and Grant them great credibility. However, we have found it useful to carry out a multidimensional analysis, to bring out the links between the different variables, the dependent and independent variables in order to be able to detect causal possibilities between the different variables.

Through this analysis we notice that this is a strong correlation between the different variables, we can conclude that the type and the credibility of the social network used and the belonging to a well-determined socio-professional category among the factors that drive consumers to follow these people and book online.

Conclusion

Based on the results presented in the literature review, we built an idea about the role of influencers and the factors that drive people to follow influencers, as well as the reasons for booking online and the credibility of the influencer. and its impact on the relationship of trust established between the influencer and the subscribers. In the context of the hypotheses presented in the literature review, quantitative research would be necessary to test the proposed hypotheses in order to confirm or reject them. The main objective of our study is to answer the problem and identify the elements that push consumers to follow influencers on social networks and the major role of the trust established between the influencer and the subscribers so that the influencer can acquire real credibility.

This study is not unanimous but makes some very useful recommendations for the future.

First, belonging to an intellectual socio-professional category is among the reasons that push consumers to book online (either booking a trip or buying something after reading a good comment on social networks or seeing a post on Instagram published by an influencer you like), second, the trust relationship established between the influencer and their followers can have an impact or an influence on the purchasing decision of consumers.

. Additionally, when the consumer is subject to an unknown brand, the engagement with that brand is also influenced by the type of argument presented by the influencers, in other words, when the influencer promotes an unknown brand with solid and original arguments, the commitment to this brand will be even higher.

Finally, we must not forget that an influencer creates a community thanks to his domain

Expertise and this is an element that should not be overlooked for future studies.

Abstract

Tourism is one of the most developing economic sectors, one of its developing forms being pilgrimage tourism. Pilgrimages and visits to sacred monuments are among the oldest forms of travelling, which have been developing for over a thousand years. In this report we analyse the positive and negative marketing aspects of this form of tourism for a selected monument – bazilika Navštívení Panny Marie na Svatém Kopečku (the Basilica of the Visitation of the Virgin Mary on the Holy Hill) near the town Olomouc, which is on the list of cultural monuments of the Czech Republic. The conclusions summarize the results of the analyses and generalize them for practical application in the frame of pilgrimage tourism. Selected conclusions may be generally applicable in order to increase the tourism of the area with a minimum of negative impacts, which may be an accompanying phenomenon of increasing tourism.

Keywords*:* Pilgrimage Tourism, Marketing Analyses, Marketing Mix, Strategy of Further Development.

Introduction

Tourism is currently influenced by many factors. Several works dealt with the influence of economic factors on tourism. For example, Jeřábek (2019) investigated the effects that the real exchange rates, incomes and travel cost have on inbound tourism demand (tourist arrivals). Tourism is one of the most growing economic sectors in the world and one of the forms of tourism is pilgrimage tourism. Pilgrimages and visits to sacred monuments are among the oldest forms of travelling, which have been developing for over thousands of years. Pilgrimage tourism, in a narrower sense, means travelling to visit a sacred place at a time when one of a number of specific religious events or pilgrimages is taking place there. In a broader interpretation, it is a synonym for the term sacred, religious or church tourism and is also one of the least studied forms of tourism. Exploring the economic impacts of tourism in the context of specific regions has been an important area of interest for tourism research for many years Amaro a kol. (2018),

Cite this Article as: Pavel Tvrzník, Zdeněk Málek , Katarína Mrkvová, Miroslav Fišera, Zdeněk Konečný and Darina Eliašová" Marketing and Management Analysis of Pilgrimage Tourism in A Selected Area in The Czech Republic" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Málek et al. (2017), Jeřábek et al. (2018). Tourism has been identified as a catalyst to stimulate economic growth, increase the viability of underdeveloped regions and improve the living standards of local communities Geary (2018), Lukášková et al. (2018).

The paper deals with the importance of pilgrimage tourism with its positive and negative impacts on the selected region and the selected sacral monument. The presented results represent a partial part of the comprehensive research project in the field of pilgrimage tourism, the aim of which is a comprehensive analysis of the economic impacts of pilgrimage tourism within the selected monuments in the Czech Republic.

Literature Review

Religious travelling has been associated with humanity since ancient times, and its origins have been inherently linked to faith. In the beginning there is a pilgrimage as a religious manifestation where the pilgrim is considered a tourist with religious motivation Digance (2003), Turner and Turner (1987). In a broader sense, religious tourism is any journey motivated solely or partly by religious reasons Rinschede (1992). In the last decade, traditional pilgrimage destinations have also become multifunctional tourist destinations Kaufman (2005), attracting their visitors to their architectural, cultural or artistic value Hughes et al. (2013), Fernándes (2010), Geary (2018), Ramírez and Fernández (2018). In general, tourist motivation is diverse; this means that tourists have multiple motives to travel in one trip Uriely et al. (2002). An estimated 300 to 330 million tourists travel annually for religious reasons, with a total tourist expenditure of approximately 18 billion dollars per year (OMT 2014). This fact represents a significant opportunity for the development of many destinations. Academics pay particular attention to the study of motivations, interests and spiritual or cultural needs offered by religious centres Rinschede (1992), while for policy makers, both at regional and national level, pilgrimage tourism represents a significant opportunity to increase employment Egresi el al. (2014). The aim of this paper is based on the strategic analysis to point out the importance of pilgrimage tourism with its positive and negative impacts for the region, respectively for the given sacral monument – bazilika Navštívení Panny Marie na Svatém Kopečku (the Basilica of the Visitation of the Virgin Mary on the Holy Hill). In 1995, the Church of the Visitation of the Virgin Mary was elevated by Pope John Paul II. to the basilica minor.

Data and Methods

In terms of methodology, the SWOT method of strategic analysis was used, which was primarily intended for the evaluation of company management.

The SWAT analysis of strengths and weaknesses, opportunities and threats was applied both in terms of location and to a specific sacral monument. The individual factors that were analysed are arranged in a so-called SWOT matrix (Kotler (2007).

a) Strengths – these are internal factors that increase the market position and the company has an advantage over the competition. This includes, for example, a price advantage, a strong brand, the ability to innovate products, etc.
b) Weaknesses – this includes factors in which the company is weak. These are, for example, the bad position of the company, high costs, lack of distribution channels, etc.
c) Opportunities – these are possibilities that can be used by the company and thanks to them the growth of the company would increase. The company must first identify them and only then it can use them.
d) Threats – these are negative factors that mean obstacles to the company´s activities. The company must respond to these factors to eliminate or minimize them.

The data were drawn from primary and secondary sources. The result is the presentation of the SWOT analysis, which should predict the direction of further development of the region and selected sacral monuments, but above all to become an inspiring source of information for further increase of pilgrimage tourism in the Czech Republic.

Results and Discussion

The prerequisite for tourist use is the availability and level of services provided, as well as information that serves as a basic impetus for choosing a destination. Determining the right strategy is essential for the development of tourism in the area. It is necessary to use the existing potential of tourist destinations and services, thus achieving a state where Olomouc will be perceived as a creative, experiential place for a holiday of Central European importance.

SWOT analysis of the town of Olomouc:
Strengths – location of the city, main transport routes, resulting from accessibility, public transport, cultural and

historical sightseeing tourism, UNESCO monument, Flora Olomouc Exhibition Centre, church tourist potential, cycling tourism.
Weaknesses – tourists stay only for one day, parking capacity of the Flora Olomouc Exhibition Centre, lack of perception of the city, awareness of the region, a small offer of pilgrimage tourism packages.
Opportunities – growing interest in local gastronomy, interest in beer tourism, mini-breweries, development of bike paths, creation of interconnected packages, more intensive cooperation within the region, development of current tourist destinations associated with urban and sightseeing tourism, culinary tourism, creating programs for autumn and winter.
Threats – decay of historical monuments, short terms of visitors´ stay, nowadays there is also a threat of a pandemic.

When evaluating the development of attendance of the Olomouc region given in the table 1 there is a noticeable year-on-year increase of 9% on average.

Table 1: Development of attendance in the Olomouc region

Years	2014	2015	2016	2017	2018	2019
Visitors	487 641	547 538	600 106	658 059	700 112	761 433
Non residents of which	226 028	243 774	244 696	269 853	288 271	292 709

Source: ČSÚ

Olomouc is a natural centre of the region with an important monument – sloup Nejsvětější Trojice (the Holy Trinity Column), which is listed on the UNESCO list. Other important religious monuments include, for example, Arcibiskupský palác (the Archibishop´s Palace), which is still the centre of the spiritual administration of Moravia. It is also possible to visit the Cathedral of St. Wenceslas. The most famous churches include the church of St. Moritz, the church of Our Lady of the Snows and the church of St. Michael. The baroque basilica of the Visitation of the Virgin Mary on the Holy Hill, one of the most famous places of pilgrimage in the Czech Republic, has a very dominant effect. Other important monuments are for example the oldest Moravian monastery Hradisko or the Jesuit boarding school, which today, however, already serves as a university art centre. The main reason for visiting the town of Olomouc remains knowledge associated with visiting tourist attractions, historical and architectural monuments – this is the main reason for visiting foreign tourists in 70% of respondents. Only 30% of Czech respondents stated tourist attractions and historical monuments as the main reason for visiting the town. The most visited tourist attractions in Olomouc include the historical centre around the Upper Square, the Town Hall with the Astronomical Clock and the Holy Trinity Column. This was stated by 80% of surveyed domestic and foreign tourists Hamřík et al. (2018). An important factor for the economy of tourism in a given locality is the length of stay, which is one of the basic indicators for evaluating the attractiveness of a given locality, resp. of the town of Olomouc. Graph No. 1 shows the share of the stay length of Czech and foreign tourists. Czech tourists prefer to stay in Olomouc for only one day, namely 55% of the total number of respondents, while foreign tourists stay in Olomouc for more than one day, namely 35% of the total number of respondents Hamřík et al. (2018)

Graph 1: Length of stay in Olomouc (in percentages)

Source: ČSÚ

SWOT analysis of the pilgrimage site of the Visitation of the Virgin Mary on the Holy Hill Strengths of the place of pilgrimage – in 2018 it was declared a cultural monument of the Czech Republic, in 1995 it was promoted to a basilica minor, part of the pilgrimage route, built tourist facilities, open daily, barrier-free access, transport accessibility, updated website, proximity to the ZOO, guide service, nature trail Svatý Kopeček (the Holy Hill), within the site you can visit other places of pilgrimage, such as the Cathedral of St. Wenceslas in Olomouc, the Church of Our Lady of the Snows in Olomouc, the Church of St. Michael in Olomouc, the Church of St. Moritz in Olomouc and the Holy Trinity Column, a UNESCO World Heritage Site.

Weaknesses of the place of pilgrimage – photographing and filming the interior of the basilica Visitation of the Virgin Mary on the Holy Hill is possible only with the consent of the Strahov Monastery and the spiritual administration. The tours take place only in Czech, in exceptional situation also in English. Other negative sides are also small cooperation with the travel agency, paid entrance fees even out of season, insufficient parking capacity during the main tourist season.

Opportunities of the place of pilgrimage – not only the support for the development of pilgrimage tourism from the point of view of the European Union, but also the support from the national, i.e. the Czech Republic point of view. It can be financial contributions, organizing various events to raise the profile of the place of pilgrimage and the development of tourism. Cooperation with churches of other countries within Europe and thus the creation of preconditions for the interest of foreign visitors, for a visit to a pilgrimage monument, can be considered as another opportunity for the place. A prerequisite for greater attendance at the pilgrimage site is the organization of cultural events in the Czech Republic.

Threats of the place of pilgrimage – the biggest threat is insufficient funds obtaining for the necessary repairs of the building, or expansion of the area, building the necessary structure of services, etc. The safety of visitors and guides, who could possibly lose interest in visiting the pilgrimage monument, is closely connected with this threat. This would be associated with the decline of tourism or the outflow of visitors abroad for other pilgrimage monuments.

Svatý Kopeček (the Holy Hill) is one of the most important tourist destinations in the town and in the region. However, it is also an important starting or ending point for walks and hiking and cycling activities in the surroundings of Olomouc. Graph No. 2 shows that the number of visitors to the basilica makes up 5% of the total number of visitors to the region.

Graph 2: Number of visitors to the basilica out of the total number of visitors to the region

Source: own survey

Graph No. 3 shows an increase in the number of visitors to the pilgrimage site, which amounts to 3-4 thousand visitors year-on-year, while the interest in paid tours has been declining by about 500 people year-on-year since 2016.

Graph 3: Number of people interested in a paid inspection

Source: own survey

An important factor for the development of tourism is the availability and form of information provided throughout the Olomouc region. Visitors to the town prefer electronic information sources, regardless of whether they come from the Czech Republic or from abroad. Internet search engines are an essential elements in obtaining information about the town, according to 40% of the respondents. 23% of the respondents used the town´s promotional materials for their decision to visit Olomouc, and only 7% of the respondents used the accommodation facilities´ websites. In the questionnaire survey, 20% of the respondents refer to the recommendation of a visit from friends and only 7% of the respondents refer to the recommendation of travel agencies Hamřík et al. (2018).

To increase the number of visitors to sacred monuments, the priest´s personal recommendation will continue to be an

important source.

Conclusion

Our analyses show an increasing interest in the Olomouc region. Parking is a problematic area from the point of view of tourist ratings, which is an almost limiting factor even in the case of a place of the pilgrimage and ZOO.

The most visited attractive places include the narrowest part of the historical centre around Horní náměstí (the Upper Square), the Town Hall with the Astronomical Clock and the Holy Trinity Column, the Basilica of the Visitation of the Blessed Virgin Mary on Svatý Kopeček the Holy Hill, both for Czech and foreign tourists. They prefer electronic information sources when searching for information.

In order to support the extension of the length of stay, it would be appropriate, in addition to the services provided, to offer ready-made packages that will become a marketing incentive. The creation of new tourist packages, together with the modification of the existing ones, will be a motivating component for the length of stay. However, the creation, editing and promotion of travel packages do not only concern accommodation facilities, but also sport opportunities, cultural and spiritual experiences, which are gaining in popularity due to the hectic times.

Promotion before important events, many tourists are aware of which, is of great importance. The aim to the promotion is to attract new tourists to the area. The advertising campaign should be understood as a continuous process of reaching potential tourists and attracting them to the diverse range of tourist activities that the area abounds in, thus increasing the overall interest in tourism.

A major weakness of the pilgrimage site is the lack of cooperation with travel agencies. From the above overview, it is clear that the biggest problem of pilgrimage tourism in the Czech Republic is its insufficient promotion. It is necessary to focus on the widest possible target group and the development of promotion and information of potential tourists, with the proviso that pilgrimage tourism is not just a matter of believers. A necessary prerequisite is the readiness of the monument (facilities, parking sites, guides, websites) for increased tourism. The basic precondition for the application of the above conclusions is the understanding and interest of the part of the owner of the monument and, above all, the common support and promotion of pilgrimage tourism in the Czech Republic and abroad. The weakest aspect of the Basilica of the Visitation of the Virgin Mary on Svatý Kopeček (the Holy Hill) near Olomouc can be considered the absence of a guide who would make an explanation of the basilica in English. Fulfilling this aspect would increase the growth and interest of visitors from abroad.

The findings show that pilgrimage tourism will continue to develop. Travel agencies, together with cities and owners of sacred monuments should understand that common promotion is a key prerequisite for the development of tourism. The question of further research is what is the interest of the church and what would be the potential effect of the development of pilgrimage tourism to “unprepared” places of pilgrimage, and how to set the limit of sustainable development without negative impacts.

Prospects for Application of Risk Management Method to Implement Merger and Aquisition

Yulia VERTAKOVA
Southwest State University, Kursk, Russia, vertakova7@ya.ru

Inga VSELENSKAYA
Southwest State University, Kursk, Russia, ingachka28@mail.ru

Abstract

Automated methodology of risk management in strategy implementation mergers and acquisitions is a well-developed model that can potentially be an effective instrument in the process of leveling the risks of mergers and acquisitions. This fact necessitates approbation of this method and an analysis of its advantages and disadvantages with the identification of prospects for the practical application of the method.
In this article, the process of approbation of the method of risk management of mergers and acquisitions is carried out, the shortcomings of the method are revealed and the ways to eliminate them and improve the application were proposed.

Keywords: mergers and acquisitions, risk management of mergers and acquisitions, risk management method, method automation, method testing.

Introduction

The developed and automated risk management method with the selection of the most adequate risk management instruments for each stage of the implementation of a merger and acquisition transaction, proposed by I.V. Vselenskaya in her article "Development of a risk management model for a merger and acquisition transaction" serves as the basis for the formation or improvement of internal management of the company participating in the transaction, a new or existing model of an effective risk management process, which will be able to reduce time and labor costs, as well as obtain other positive effects, that will lead to an increase in the efficiency of management of mergers and acquisitions.

However, to achieve this effect, it is necessary to approbate this method, to critically analyze its advantages and disadvantages.

Short Literature Review

This article will test the risk management model proposed by I.V. Vselenskaya in her article "Development of a risk management model for a merger and acquisition transaction" (Vselenskaya , 2019).

The first stage of model testing is the identification of the stage of the transaction, since each of the ten stages of a merger and acquisition transaction has its own set of characteristic risks (Vertakova et al, 2020).

Determining the stage of the transaction is most conveniently done according to the algorithm for forming a transaction, developed by Vselenskaya I.V. (Vselenskaya , 2019).

For purposeful, most effective risk management, the characteristic risks are ranked within each stage according to the level of significance in descending order.

As part of the development of a risk management model, each risk is assigned by its own unique number from R1 to R51.

Cite this Article as: Yulia VERTAKOVA and Inga VSELENSKAYA“ Prospects for Application of Risk Management Method to Implement Merger and Aquisition ” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In addition, each risk needs its own relevant instruments to manage it. So, the stage of integration procedures has its own set of risks:

- The risk associated with a lack of resources for the transaction;

- The risk of slowing down the integration process and failure to fulfill its plan;

- The risk of a decrease in the productivity of employees of the target company, a drop in work discipline;

- The risk of rupture for relationships with counterparties: customers and suppliers;

- The risk of underestimating the complexity of building an effective corporate governance system in the merged company;

- The risk of failure to achieve integration goals due to the dependence of the target company on large customers;

- Risks of having duplicate contracts with suppliers (Plotnikov et al, 2019).

Each risk has two key characteristics: the likelihood of risk occurrence (measured from 0 to 1) and potential losses (measured in c.u.).

Within the framework of an automated risk management model, it is necessary to assess these key characteristics for each risk of a specific stage.

After introducing the probability of occurrence of risks and potential losses from them, it is necessary to enter the maximum value of potential losses, which will be located along the horizontal axis on the "risk map", which clearly illustrates the risks of the considered stage of the merger and acquisition transaction.

After entering all the input parameters, by pressing the button "Show risk map", a "risk map" appears, on which the entered risks are marked with black dots, as well as the zones of criticality of these risks.

When the user hovers over any point that denotes a particular risk, a callout appears on the map with the risk number in order (from R1 to R51), the name of the risk, the probability of its occurrence (from 0 to 1), losses (in c. u.) and a relevant instrument for its management, which allows you to visually and quickly see what measures need to be taken to manage the risks under consideration.

Results and Discussions

We are testing the risk management method using the example of a merger and acquisition of Expobank and Kurskprombank. On January 21, 2020, Expobank and Kurskprombank announced the beginning of the integration process and launched a reorganization procedure in the form of a merger.

The choice of this transaction was due to the regional aspect, the relevance of the transaction, as well as the availability of accessible and reliable information in open regional sources.

Deal mergers and acquisitions of Expobank and Kurskprombank are currently at the stage of successful completion of integration procedures[1]. The presence of the completed stage of integration gives grounds for a comparative analysis of the real results of the transaction, obtained in practice, and the results of applying the developed methodology of risk management.

Within the framework of an automated risk management model, we will assess the key characteristics for each risk in specific stage.

[1] Expobank completed integration with Kurskprombank. URL: https://www.finanz.ru/novosti/aktsii/ekspobank-zavershil-integraciyu-s-kurskprombankom-1029035526 (In Russian). (The date of access 23.08.2020)

The sufficiency of Expobank's resources to conduct a transaction can be assessed by comparing the amount of financial resources required, that is, the cost of the transaction, and the amount of availability of financial resources in the form of company's free funds before the transaction.

According to the consolidated statement of financial position of Expobank as of 31.12. 2019, cash and cash equivalents amounted to 18,543,227 thousand RUB.

The cost of the transaction is not disclosed in open sources, but it can be estimated. According to the demand for the repurchase of equity securities of the joint-stock company, the purchase price of one ordinary share of Kurskprombank was 104,27 rubles as of 31.12.2019[2]. The number of Kurskprombank shares acquired by Expobank is 87.2%. The total number of Kurskprombank shares as of 31.12.2019 was estimated at 31,5 million shares. The calculation of the transaction value is presented in Table 1.

Table 1: calculation of the transaction value Expobank and Kurskprombank

Price shares (rubles)	Number of shares (in million pcs.)	Share of acquired shares (%)	Transaction value (in million rubles)
104.27	31.5	87.2	104.27*31.5*87.2/100=2864.1

Source: by authors

Consequently, the cost of the transaction can be estimated at 2864.1 million rubles or 2.9 billion rubles.

This estimate is confirmed by data from periodicals, the Kommersant newspaper, according to which the transaction amount could have amounted to around 2.4 billion rubles [3].

The amount of available funds, equal to 18,543,227 thousand rubles, is 6.4 times higher than the need for funds for the transaction, which indicates the minimum risk of lack of resources for the transaction, therefore, we estimate the probability of this risk at 0.05.

The integration process can be slowed down for external and internal reasons. External reasons include the situation of the coronavirus pandemic, which creates forced delays, increases administrative and bureaucratic barriers. According to open sources, coronavirus reduces the number of mergers and acquisitions and negatively affects the entire market[4]. As for internal reasons, integration can be hampered by disagreement and lack of interest in the transaction of any of the parties. The merger of Kurskprombank, according to experts, will help Expobank strengthen its corporate business and take a strong position in the Chernozem region.

In turn, for Kurskprombank, this deal will unlock its potential and strengthen its market positions and product line for the experience and technological platform of Expobank.

Since both parties benefit from the transaction, this risk for internal reasons can be considered rather low, and for external reasons - high, therefore, in general, the risk of inhibition of the integration process can be assessed as above average at the level of 0.65.

After the transaction is completed, Expobank wants to preserve the team and business model of Kurskprombank, which means that no layoffs and worsening conditions for employees are expected, therefore, the risk of a decrease in the productivity of employees of the target company and a drop in work discipline can be assessed below average, at the level of 0.25.

[3] Expobank acquired 87.2% of Kursk Industrial Bank. URL: https://tass.ru/ekonomika/6403745(In Russian). (The date of access 23.08.2020)

[4]Coronavirus cuts down on corporate mergers and acquisitions and negatively affects the market IPO. URL: https://zen.yandex.ru/media/id/5d6de4bfc6e2a400adda0a5f/koronavirus-sokrascaet-korporativnye-sliianiia-i-pogloscenii-i-negativno-vliiaet-na-rynok-ipo-5e83c1627aa354744888a855 (In Russian). (The date of access 24.08.2020)

The risk of breaking customer relationships can be considered high, at 0.75. The high risk is due to the fact that the Expobank brand is unknown in the Chernozem region, which may cause mistrust among individuals - Kurskprombank's clients, most of whom were people of retirement age.

In addition, despite the fact that all agreements remain unchanged, the presence of large borrowers in the regional market of Kurskprombank's presence determines the presence, albeit insignificant, of the risk of failure to achieve integration goals due to Kurskprombank's dependence on large clients.

Thus, a major client of Kurskprombank was, for example, OOO "Nipromtex" (Zheleznogorsk)5. Therefore, this risk can be estimated below average, at 0. 30. According to the Information on the qualifications and work experience of the Expobank management, most of the management positions are held by highly qualified, professional specialists with extensive experience in the area related to their responsibilities, therefore, such specialists are adequately able to assess the complexity of building an effective corporate governance system in the merged company, and the risk underestimation of this complexity can be estimated below average about 0,35[6].

Due to the fact that Expobank was not represented in the region of Kurskprombank presence, the risk of duplicate contracts for both banks is minimal, and can be estimated at 0,02.

Losses from all types of risks are assessed as much as possible, thereby considering the most pessimistic forecast.

The maximum losses that Expobank is expecting to incur can be judged by the cost of the transaction and all the costs associated with its execution. According to the expert opinion, the costs of connecting a bank are compared with the costs of opening a new branch that is similar in its capabilities, location, and specialization of activities and nature of services7. The opening of a similar branch of the bank in the Chernozem region can be estimated at 1,85 million rubles8, and Expobank merges 32 branches of Kurskprombank. Thus, the calculation of the maximum potential losses from the Expobank and Kurskprombank transaction is presented in Table 2.

Table 2: Calculation of the maximum potential losses from the Expobank and Kurskprombank deal

Transaction value (mln. rubles)	Branch opening cost (million rubles)	Number of branches Kurskprombank	Costs for the transaction (million rubles)	Maximum losses (million rubles)
2864.1	1.85	32	1.85*32=59.2	2864.1+59.2=2923.3

Source: by authors

Realization of the risk of lack of resources for the transaction will lead to maximum losses in the amount of total costs of the transaction, that is 59.2 million RUB.

Slowdown of the integration process and failure to fulfill the plan of integration procedures will lead to insignificant losses in the form of payment of fines and late fees. We estimate them at 0,5% of the transaction value9, that is, 0.005 * 2864.1 million rubles = 14.3 million rubles.

Realization of the risk of a decrease in the labor productivity of Kurskprombank employees, a fall in working discipline will maximally lead to the costs of hiring new personnel, their training, which, according to experts, may amount to 170.4 million rubles.[10]

The rupture of relations with the former clients of Kurskprombank will lead to significant losses, which can be assessed as strong, since the share of retirement age clients is high, which is explained by the presence of a large number of pension programs, and pensioners personify Kurskprombank as a reliable bank directly connected with the region of presence in the city of Kursk. Let us estimate the losses as a maximum in the amount of the total amount of Kurskprombank's deposits before the transaction, that is, in 2045.3 million rubles.[11]

As a result of underestimating the complexity of building an effective corporate governance system after the merger of Kurskprombank, losses in the amount of payment for third-party services for organizing corporate governance in the new company may arise. According to expert estimates, these services amount to about 0.1 million rubles for one branch. Therefore, for 32 branches – 3.2 million rubles.[12]

The presence of large clients, in connection with which the integration goals may not be achieved, can lead to potential losses in the form of the departure of these clients and the withdrawal of all deposits in Kurskprombank in the amount of 2826.5 million RUB.[13]

As for the losses from duplicate contracts, they are minimal and equal to the costs of renewal of contracts, which can be estimated at about 0.1 million rubles. The values of probabilities and losses are briefly presented in Table 3.

Table 3: probability of risk and loss for the Expobank-Kurskprombank transaction

Stage	№	Risks	The likelihood of a risk	Losses (in million rubles)
Integration procedures	R_{36}	The risk associated with a lack of resources for the transaction	0.05	59.2
	R_{37}	The risk of slowing down the integration process and failure to fulfill its plan	0.65	14.3
	R_{38}	The risk of a decrease in the productivity of employees of the target company. a fall in work discipline	0.25	170.4
	R_{39}	Risk of breaking customer relationships	0.75	2045.3
	R_{40}	The risk of underestimating the complexity of building an effective corporate governance system in the merged company	0.35	3.2
	R_{41}	The risk of failure to achieve integration goals due to the dependence of the target company on large customers	0.30	2826.5
	R_{42}	Risks of having duplicate contracts with suppliers	0.02	0.1

Source: by authors

As a result of the introduction of the maximum value of potential losses, the program automatically divided the horizontal axis into five equal parts, according to which losses from 0 million rubles to 584,66 million rubles are

estimated as minimal, from 584,67 million rubles to 1169,32 million rubles as weak, from 1169,33 million rubles. up to 1,753,98 million rubles. as average, from 1,753.99 million rubles up to 2338,64 million rubles as strong, from 2338,65 million rubles to 2923,3 million rubles as maximum.

The “risk map” of the deal between Expobank and Kurskprombank at the stage of integration procedures is as follows (Figure 1).

Fig. 1: "Risk map" of the transaction between Expobank and Kurskprombank at the stage of integration procedures

Source: by authors

According to Figure 1, insignificant risks are located in the green zone, namely, the risk associated with a lack of resources to conduct a transaction, and the risks of having duplicate contracts with suppliers.

The most critical risks are the risk of rupture of customer relationships and the risk of failure to achieve integration goals due to the departure of large Kurskprombank customers, since they are located in the orange zone. These risks require the most attention and priority management, since this transaction has no risks in the red zone.

The program allows you to visually see what measures need to be taken first. So, when you hover the cursor over a point corresponding to one of the two most critical risks, namely the risk of breaking relationships with customers, an offer appears with a relevant tool for managing this risk - the development of customer retention measures.

At the stage of integration procedures, the deal between Expobank and Kurskprombank did not actually encounter the risk identified according to the risk management methodology, since after the merger of Kurskprombank, the most important task for Expobank is the retention of each client. All the terms of cooperation remained the same as before the integration, the level of service, tariffs, and contracts[14]. Other theoretical risks of the Expobank-Kurskprombank deal did not materialize in reality.

This fact confirms the presence of the identified most critical risk and the effectiveness of the methodology in determining the relevant tools for managing it.

[14]“Expobank" and "Kurskprombank" decided to integrate. URL: https://46tv.ru/novosti/jekonomika/124747-jekspobank-i-kurskprombank-prinjali-reshenie-ob-integracii.html (In Russian). (The date of access 25.08.2020)

However, the approbation of the automated risk management methodology also revealed some shortcomings of the model.

First, the model does not provide the ability to perform a comparative analysis of risks that are in the same area. It is not always possible to clearly determine the proximity to the next most critical risk zone. The accuracy of this definition is insufficient. Therefore, in the process of making a decision on the priority of risk management measures that are in the same zone, it is necessary to take into account the level of their significance, assessed according to the methodology of the Vselenskaya I.V.[15].

In other words, in each zone, first of all, take measures to manage the most significant risk, regardless of the place it occupies in the zone.

Thus, the priorities of risks at the stage of integration procedures of the Expobank-Kurskprombank transaction, excluding and taking into account their level of significance, are as follows (Table 4).

Table 4: Risk ranking at the stage of integration procedures of the Expobank and Kurskprombank transaction, taking into accounts the zone and level of significance

Stage of risks	Zone	Without regard to the level of significance	Given the level of significance
The risk associated with a lack of resources for the transaction	dark green	6	6
The risk of slowing down the integration process and failure to fulfill its plan	yellow	3	3
The risk of a decrease in the productivity of employees of the target company, a fall in work discipline	light green	5	4
Risk of breaking customer relationships	dark orange	1	1
The risk of underestimating the complexity of building an effective corporate governance system in the merged company	light green	4	5
The risk of failure to achieve integration goals due to the dependence of the target company on large customers	dark orange	2	2
Risks of having duplicate contracts with suppliers	dark green	7	7

Source: by authors

Thus, we see that the list of risk priorities has changed, albeit insignificantly: the risk of a decrease in the productivity of employees of the target company, a drop in work discipline should be highlighted to earlier than the risk of underestimating the complexity of building an effective corporate governance system in the merged company, based on its significance level.

This fact suggests that the level of significance must be taken into account when determining the measures necessary to carry out within the framework of risk management in the implementation of a merger and acquisition transaction.

Secondly, the most significant drawbacks of the model include the subjectivity of assessing the likelihood of risks and losses from them, which entails the need to attract qualified professional experts in the field of mergers and acquisitions to assess them, which is associated with additional financial costs.

[15] Vselenskaya I.V. Characteristic risks of a merger and acquisition transaction // Management consulting. 2019.No. 9.P. 106-120 (In Russian)

Thirdly, the model needs to take into account the specifics of the industry. So, for example, in the considered case we are talking about the banking sector, in which there are no providers of banking services and contracts with them, which makes it difficult to assess risks.

Conclusion

The developed automated risk management model in the implementation of mergers and acquisitions is almost universal tool for managing risks arising in integration processes.

Approbation of the model has proven its effectiveness when comparing the theoretical results of applying the risk management model and real results mergers and acquisitions in practice.

However, in the process of approbation, some shortcomings of the model were revealed: the lack of consideration of the level of significance of the risks under consideration when prioritizing in risk management tools, the subjectivity of the assessment of key characteristics of risks, and the lack of consideration of the specifics of the industry in which mergers and acquisitions are carried out.

In general, taking into account the listed shortcomings and the proposed improvements, the risk management model can be considered effective.

Abstract

Nowadays, the challenge of having sustainability in the path of the growth and development for enterprises has become more complex due to the complication of the business environment correlated with organizational systems along with technologies and socioeconomic fluctuations. Moreover, in the rise of these complexities, the demand for new knowledge-based approaches and innovative methods to control the hurdles is vital for the management sectors to provide solutions and surpass the complications in the total function of organizations and corporate businesses. Therefore, to continue the assessment of the organizational sustainable development, In this article, the research focus on analysing the underlying nature of complexity based on the system thinking in order to present a dynamic solution-based approach to reduce complexity issues inside the organization systems by proposing an effective model for enterprise sustainability via growth and development. The structure of the model expands on a regular basis by assessing growth and development along with disorder and order in a systematic manner inside the organization. Moreover, the research presents the model as an instrument for the managers to observe the progression/regression in the enterprise to chart a path toward sustainable growth and development. Consequently, the research forwards to develop, test, and verify the model as an alternate path for finding a solution for the current issues of corporate management, organizational behavior and modern management systems connected with sustainable growth and development along with the information complexity in the condition of an enterprise.

Keywords: System thinking management, Sustainable growth and development, Organizational sustainability, Management system.

Introduction

The forms of macro and micro economic activities are taking shape based on the data and information analysis, and hence the global powers are competing over the amount of data collection storage which will give them the power to apply strategic approaches toward the future to control the mass population in a wrong way. Meanwhile, management systems are transforming distinctively over the enhancement of the technology, which evoke a demands for innovative approaches via optimizing management processes in the hands of humans as elements rather than Artificial Intelligence (AI). The forms of business transformation, are totally effected by advanced Information and Communication Technology (ICT) along with the modern feature of technology enhancement such as AI, which represents the complexity of the systems inside the organizations that are growing too fast-forward. Due to these effects, there is a need for an essential solution requirement to balance between the advancement of technology in favor of humanity, not the machines.

At the corporation level, the power of synthesis and analysis are vital for any management sector due to the platform of planning and decision making at strategic, tactical, operational levels. In the meantime, the tools which are using by managers are important, and it has to give them the proper leverage to observe and act in an appropriate time. However, the complexity of the information should not be overloaded in the process of analysis in which cause chaos and disorder in the outcome of processes (Bertalanffy L., 1968, p.41). These massive expansion of data, will increase the complication of the global enterprises transaction, mainly in economic and business terms. Therefore, the complexity arisen by the effect of ICT and in the near future by Internet of Things (IoT) needs to be controlled and simplified as soon as it's possible.

Cite this Article as: Behnam POURAHMADI and Joanna KAŁKOWSKA "Management System Dynamic – Alternative Model for Management System" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Sustainable development is another criterion that has a node connected to the upcoming challenges for enterprises, in a way that staying out of the border of it will bring many consequences. Altogether, Sustainability is one of the most important aspects in any form of business along with continuous improvement to reach a positive stage in growth and development inside and outside of the structure of the enterprises. Moreover, the sustainable development criterion is showing the global system of economic, social, environmental are totally interconnected and there should not be a jeopardize for the future by the present actions. Therefore, maximizing profit in the present should not compromise the future for the next generations, which emphasizes the value of having an equilibrium by a degree of sustainable growth and development with more order and less disorder. The importance of corporate management relation with the sustainable development criterion is becoming more significant, due to the policies of the United Nation in the business environment (Business, United Nation Main Website).

Meanwhile, there are pioneers in the criteria of organizational sustainability such as Peter Senge, Michael Porter, Paul Hawken which has contributed valuable methods to regulate the sustainability in the system of organizations and corporations at different levels. However, yet we are facing global issues in terms of cohesion in sustainability as a unified concept, which by the COVID-19 pandemic, many aspects of the current issues have risen profoundly. Therefore, one of the key aspects of this research is to propose an alternative approach to synthesis the knowledge behind the criteria of sustainability with management and organization systems.

Aim of the Research

The aim of the research is to proposing an innovative systematic model for the management based on the system thinking from the second law of thermodynamics to management system and organizational sustainability. The objective of the model is to perform as a sustainability equalizer for managers from any levels within an organization. The model emerges to observe and improve the performance of facilities in the criteria of growth and development with lower disorder and higher-order to finally reach sustainability in the path of growth and development.

The methodological approach on this research is systemic and it is set to withdraw a start line from the core aspect of the system's life cycle, which is time and entropy that have been chosen by the works of Stephen Hawking and Peter Atkins, also these concepts from authors perspective are linked to the system thinking and management criteria by the works of *Russell Ackoff*, that in the future will connect it to the works of *Jay W. Forrester* and *Peter Senge* in the system dynamics and the fifth discipline.

Also, there are methods to measure management performance correlated with sustainability which is Performance Measurement and Management Systems (PMMS). However, there is a need for more work in the process to evolve this method to combine more with IT systems and enhance its functionality (Libetruth T., 2017).

In a research study by Mossel, Rijnsoever, and Hekkert (2017), they suggest that the researcher rendering their finding in the compound of different theories to adjust their awareness for finding the proper theory for the transition toward sustainability (van Mossel A., van Rijnsoever F., Hekkert P. M., 2017).

For achieving a regular sustainable enterprise, there is a need for a new model to function as a sustainability equalizer for layers of information in the cycle of the management system dynamics of the corporate business, due to organizing more order and reduce omissions. The enterprise as a dynamic system has a considerable effect to its surrounding and if the system that lose its perception over the functionality of its entity as a whole inside the existence environment and damage its core, then it will finally eradicate its own existence (Ackoff, 1999, p.19). Nevertheless, there should be an equalizer platform for the whole functionality of the enterprise from the cause and effect of the outsight perspective.

The entropy and information inside a system

The system definition come from many perspective. According to Ackoff they can be classified in many different ways eg. by size, discipline, location, and by function (Ackoff, 1999, p.21). In a general explanation, a system can be the sum of some elements that work together as a whole or vice versa, for a purpose. Meanwhile, the nature of our existence is system based along with time. Based on system thinking the relation between the information and entropy has an attachment with the management and organizations due to the systematic nature of the enterprises onward to the business economy. In the historical background, there was a consideration on the research study by Von Bertalanffy (1968), *the general system theory* in which brought a productive perspective to the scientific practices (Von Bertalanffy, 1968).

In the corporate management, the control of almost all sectors is under the command of the managers in different types, which are systematically interconnected onward to applying strategies for the whole organization. Moreover,

the organization as whole in any enterprise has fluctuation of data transaction which bring us back to system criteria and how a system works.
In the system thinking approach, there are difference between analysis and synthesis, in the book by Ackoff (1999) describe the difference in following steps:

The difference of analysis and synthesis come from the first action which in analysis we separate parts to smaller segment and will continue as long as possible to reach to the most minimum levels and at the end we aggregate the results and define the outcome. Meanwhile in synthesis we consider the part as a segment of a bigger whole and assess the outcome base on the whole picture, and the same goes for understanding the behavior of parts (Ackoff, 1999, p.11).

The information measurement had an obstacle due to the definition and the elements of calculation and quantification until creation of the information theory, which had an impact on the formulizing the information in communication platforms and it provide deep analytical method to observe the transaction of information in the communication channel by introducing advanced models (Floridi L., 2010, p.6). However, this was a start for more complexity in the technology development.

According to Floridi, ICT have brought a profound change to the world in a straightway (Floridi, 2010). In one way, ICT has brought a lot of benefits and opportunities to the people welfare, education, prosperity, knowledge next to enhancing economic and science advantage. On the other way, ICT brings tremendous risk by increasing the complexity of the global problem in a serious way. As an analogy information society is considering as a tree in which has been reached to the highest level of branches which has more chaos and uncertainty, lack of balance than its ethical and cultural root (Ackoff R., 1999, p.22).

The concept of thermodynamic has been emerged during the 19 century due to the development of industrial proficiency. Particularly, steam engine development that had a significant impact on the progress of the industrial evolution in time. The father of thermodynamics known as Nicolas Leonard Sadi Carnot a French military scientist and physicist, on his published book as *Reflection on the motive power of fire* in 1824 (Atkins P., 1994). Sadi Carnot's effort was to develop a successful theory of the maximum efficiency of heat engine, due to the importance of steam engine performance in the competition of the industrial countries in his time era.

The laws of thermodynamic consist of four laws, which start by the zeroth law: the concept of temperature, the first law: the conservation of energy, the second law: the increase in entropy, and the third law: the unattainability of zero (Atkins P., 2010). Altogether, the laws of thermodynamics have the proficiency to incorporate with many aspects of science. Particularly, the management system dynamics, organizational behavior, and ICT science due to the works of theories such as *general system theory* and *information theory* in which, had an indication of the second laws of thermodynamics as the entropy. Moreover, this criterion has a designation to management science and its related protocols due to the systematic nature of the management and corporation cycle in business, thus, it will lead us to the laws that define the natural behavior of a system, which entropy is the most important one. However, in a deep interpretation of the four laws of thermodynamic, all aspect of it could be interconnected with management and organization science.

The second law of thermodynamics, entropy, is famous among various scientific fields which provided plenty of definitions in the variable scopes. Furthermore, the entropy provides exposition that why any change in any system takes place in nature (Atkins P., 2007, p. 50). Consequently, the second law can imply the criteria of management system dynamics, organizational behavior, and sustainable growth and development, etc. the interdependency of the systematic works of managers inside the enterprise as an organization is correlated to entropy in the processes and the outcomes due to its consistent nature. The description of the process comes from the fabric of a general system due to its lifecycle and timeline in figure 1.

Fig. 1: The description of the entropy and information inside a system

source: own study

First of all, in the book by Hawking (1988) the arrow of time is one way forward and this is a fact for all existed systems in the world. Second, the entropy coexists next to the time and it has a direct connection with the arrow of time, so both of them work together (Hawking S., 1988). Moreover, in the natural world, since the entropy of a system increase by passing time, the entropy moves forward to create more disorder spontaneously (Atkins P., 1994). However, the function of entropy is far beyond this simple definition and it has vast interpretation to move energy from one system to another. Furthermore, the information and data can be comprehended as a unit of transaction in a system that can act similarly as a thermal unit in thermodynamic due to its function, which means by increasing information, the entropy will increase spontaneously.

In this research, the proposed model for the sustainability of the enterprises in growth and development emerges out of the concept of time and the second law of thermodynamics, and it has the potential to illustrate a relative proportion of a systematic view from the status of the enterprise in management and organization sciences. In addition, entropic approaches through the course of the management and organization studies have been conducted, in a way to compound the second law of the thermodynamics with these criteria to conclude a method to measure the total entropy of the organization. Therefore, the research toward entropy conducted due to organizing more structure toward the information circulation in management systems and organizations. Due to the relation of the entropy and information, there is a significant impact on the process of management inside the organization. The demand for information is vital to increase the quality of decision making. Moreover, information as one of the key resources has a direct connection to the entropic level of the organization (Markina I., Dyachkov D., 2014). However, the scope of entropic approach toward socioeconomic environment has not been specific enough to cover the technical terms in condition of the systematic approaches (Markina I., Dyachkov D., 2014).

Model

The conception of the research model exist in the course to propose a multidimensional instrument to define sustainability toward growth and development for the organization, and also provide a vision for the managers to implement proper strategies and stabilize the condition of their sectors. The framework of the research model has been demonstrated in figure 2 to show the structure of the sustainability equalizer as the research model.

Fig. 2: The framework of the model,

source: own study

Furthermore, one of the main objective of the research model is to develop a degree of sustainable growth and development as a resolution for the issues which has close encounter with the systematic problems. Therefore, managers can have a better outlook on the performance of their team and also implements strategies to maintain the growth and development in a sustainable manner toward the effectiveness and productive work, which in figure 3 the ideal process is demonstrated to show the conception of the model.

Fig. 3: The conception of the model, source:

own study

In accordance with the model functionality, the model consists of two parts. First, the matrix to identify the current position of selected sector in the path of growth and development. Second, is the process horizon which defines the effects of the information inside the matrix of growth and development as a lever of control upon the transformation of the work and entropy process, (Figure 2). Moreover, in the both structure of the model, the design emerges from the literature review perspective over the system thinking, entropy and information along with sustainable development. Therefore, time is a base in the both forms as it has a cohesive connection to all elements of the model as well. Concurrently, to explore all aspects of the model in more detail, each element will be discussed separately to express the connection to the aim of the model.

The arrow of time

Time is one way forward and every process in the system of nature has the attachment to it (time is the fuel of the universe engine). Everything has a timeline, and hence from the time passage, the transformation will take shape. Based on the literature review, in the book by Hawking (1988) on the second law of thermodynamics, one of the bonds to the time is entropy that defines which bypassing time the entropy of the universe system will increase (Hawking S., 1988). Similarly, the procedure of growth is interdependent to the time process. Therefore, in comparison to a systematic environment, the growth could be positive or negative in the direction of time passage (Atkins P., 2007, p.55).

The Growth

Growth can be defined as the increase in the variety of terms and conditions in the passage of time, which can be a process to increase mass or size. Furthermore, growth has a direct connection with time, and hence the process of growth occurs in the passage of time. In accordance to the literature review on the system thinking section, growth is the measure of efficiency (Ackoff R., 1999, p.10).

The Development

Development is a process that has connection to growth and it can be unified by the growth toward progress. Therefore, development can be a boost with growth to increase productivity and effectiveness. In accordance to the literature review on the system thinking, development is the measure of effectiveness in the management and organization system (Ackoff R., 1999, p.10). The development element inside the model has four-stage along with the process of growth and it is interconnected to the passage of time. Therefore, development can merge at a low or high level with growth in which the result together can achieve different levels of sustainability.

The Sustainability

Based on the United Nation Brundtland Commision in 1987 definition, sustainability is "meeting the needs of the present without compromising the ability of future generation to meet their own needs" (Academic impact, United Nation Main Website). Therefore, based on the second law of thermodynamics in the literature review, to maintain a sustainable process, it needs to be adjusted in a way to reduce entropy and increase the work (Atkins P., 2007, p.78). Sustainability in this model is the result of effectiveness and efficiency in one unified intersection. Consequently, there will be a scale of instruction that can lead to a degree of sustainable growth and development by the management sector.

Furthermore, in continue to explore the process horizon as the second part of the model, all elements of this part will be discussed to express the relation to the aim of the model.

The Disorder

The disorder can be defined as perplexity and disorganization in the function or pattern of a system (Bertalanffy L., 1968, p.159). In accordance with the literature review, the second law of thermodynamics, the disorder has a relation with the increase of entropy, which by the increase of entropy, the disorder will increase as well to a higher state (Atkins P., 2007, p.50). Therefore, there is a connection with the passage of time and entropy with the disorder in a system. However, next to entropy in the process of transformation there is the *work* process as well, which in return can create more order and effectiveness. In the research model, the disorder, in the management and organization system is an element that can lead toward losing sustainability. This process will result in degrading the procedure of growth and development to the lower level. Additionally, it can lead the system to chaos and collapse at a higher level.

The Order

Order can be defined as an arrangement of things in a pattern of harmony in a system. It can provide a sequence of alignment in the process of a system (Bertalanffy L., 1968, p.208). Furthermore, the order in a sequence of harmony can produce accuracy as the result of systematic work. Unlike the disorder, the order has no direct connection with entropy and time. In accordance with the research model, based on the *work* process, through the management and organization system, the order is an element that can maintain sustainability and support the procedure of growth and development to upgrade toward higher levels. Therefore, in the model, the process horizon will provide a scale in the production of work in information transformation.

The Information

The information and data are the most valuable assets for any business organization in a way to consume and produce it matters the most. However, the information has the capacity to be in a clear and conductive state or result in a polluted and overloaded state. Based on the literature review, the reason why information has been chosen in process horizon lays in the analogy that in an organization system, the information can almost act similarly as a heat element in thermodynamic state, which it means by the increase of the information in an organization system, the entropy and disorder will increase as well (Bertalanffy L., 1968, p.150). Similarly, the information can be comprehended as the artery of data transactions among departments of an organization in the procedure of growth and development, and

hence the element of information is considered as a factor in the transformation of processes inside the process horizon. All in all, the elements of the model together shape a platform for synthesis and analysis toward the intersection of growth and development, next to the process horizon of the order and disorder of information in a sustainable manner.

The function of the model incorporates with the result in one framework, and also give an outlook to the managers to act accordingly to the requirement to improve the scales by applying strategies and methods to their department, and hence they can be aware of changes by continues assessment due to functionality of this model. Therefore, the management will have an instrument to transform the organization of the enterprise toward sustainability and maintain it.

The main four-elements of the model which altogether result in sustainability, has categories to collect data from the organization according to their classifications. Moreover, each element has four-parameter. Similarly, For providing a test example for the model the scale could divide into four numerical percentages accordingly with the parameters. Hence, the numerical percentage will be made from 25%-50%-75%-100% in which provide measurable range by the result of the survey on a linear scale to calculate the answers as an identified percentage. This process will provide transformations from the result of the survey to input data for the model which interconnects the percentages to the parameters. Altogether, extracting raw data from the test survey based on the answers of the participants will be measured on a linear scale, also the data will transform to the result as percentages, and hence the input data get provided for the model.

1. Development
    - Knowledge Acquisition 25%
    - Knowledge Maturation 50%
    - Wisdom Evolution 75%
    - Effectiveness 100%

Each stage in this part depict the level of the development which can been considered for the hypothetical organization. However, these variables can adjust in the definition according to the organizational system priorities.

2. Growth
    - Formation 25%
    - Innovation 50%
    - Amplification 75%
    - Efficiency 100%

Each stage of growth is connected to the timeline and it also has variables to propose the categories of growth in the lifecycle of the chosen organization. Also, the same proposition goes for the disorder and order.

3. Disorder
    - Low level of information complexity flow
    - Medium level information complexity flow
    - High level information complexity flow
4. Order
    - Low level of work flow
    - Medium level of work flow
    - High level of work flow

According to the description of the model, in the first step, the depiction of the matrix of for growth and development is showing in the figure 4. Also, in the second step, the depiction of the process horizon is showing in the figure 5. Moreover, these two figure are the fundamental character of the model. All in all, both representation conclude the sustainability equalizer in one framework (Figure 2).

Fig. 4: The matrix of the growth and development

source: own study

In figure 4, the matrix of growth and development has four stages for growth and development. Also, in figure 4, the intersection between two elements are the nodes which connect the stages of growth and development. In addition, the line of proportion is showing the ideal direction toward growth and development in a sustainable manner. The process horizon is the second part of the model in which after the identification of the intersection, the process will zoom in into the node to control and observe the order and disorder in which it has explained in the figure 5.

Fig. 5: The conceptual model of the process horizon

source: own study

The process horizon in figure 5, is the most important part of the research model in terms of information effect in the process of producing work by the transaction of the information in the structure of the system. It has been shown that both negative and positive information injection into the system can cause consequences in saturation and collapse. However, in the negative injection, the procedure is different than the positive side due to the synthesis of the effect in the result of the system, which is not functional in this criteria. Therefore, the main model only focuses is on the information positive transformation in the system to synthesis the dynamic of transformation. The essence of the model is relying on the sustainability equalizer toward growth and development, and it has ability to transform information effectively to knowledge-based arrangement.

Conclusion and future works

The objective of the paper has been conducted in the direction to propose a model for sustainable growth and development as an initiative platform. In this research, the methodology was a systematic compound of the second law of thermodynamics, system theory (system thinking), information, and sustainable development criteria along with organizational behavior and management system to create a sustainability equalizer. Furthermore, the model has more potential to evolve in the future, and also has the capacity of complexity reduction which by diminishing the

disorder in the process horizon, the complexity of information processes will reduce and more order takes place. Moreover, in the model, the complexity via the information which rises to a higher level in the process of growth and development can be controlled in a way to create more work along with the upgrade of the levels of productivity. Therefore, inside the model, the control of information and complexity can be achieved in the processes based on the management control of the system.

According to the articulation of the complication issues that comes from the technology advancement and information overload in the structure of the corporate facilities and organizations, along with the importance of the management control toward the path of growth and development, the result of the research was affirmative due to the test which provide a path to reduce complexities augmentation in a sustainable platform. It can be concluded, the model has the potential to utilize as a multidimensional instrument as a sustainability equalizer for the managers.

The future work of the research is to continue the enhancement of the model in a comprehensive technical approach in functional terms, specifying all details by standardization of all parameters and define strategies for different conditions from regression to progression. Additionally, all core elements will be specialized in an advanced way, and also there will be defined methods for leading toward an upgrade to fulfill all aspects of sustainable growth and development in a system based manner. The model can use platforms such as business intelligence (BI) or AI algorithm to extend its ability toward measuring progression/regression in positive technical terms in the future via equilibrium with technology.

Abstract

It is customary to pay considerable attention to safety issues at the enterprises characterized by harmful and dangerous productions. The labor protection system, existing in the Russian Federation, imposes specific, sometimes strict requirements on economic agents. Nevertheless, the rate of occupational injuries in our country is higher than in industrialized countries. As entrepreneurs consider the costs of occupational protection inevitable, they seek to improve their operational efficiency by reducing these costs and economizing. The authors of this article consider such an approach to be outdated. The article describes the mechanism of improving operational efficiency of the company by means of transition to "smart" labor protection process management which increases its safety.

Keywords: labor protection, operational efficiency, costs, personal protective equipment, "smart" management, digitalization.

Introduction

Advanced technologies are conquering new spheres of human acitivities – from everyday life to the most complex productions. At the same time, the problem of labor protection at the enterprise in its broadest meaning has not become irrrelevant. It is often when the management of the company believes that the costs of labor safety and labor protection are generally unproductive, just increasing the prime costs and have to be tolerated solely by virtue of the current norms of Russian legislation. In this case, the operational efficiency decreases, and the localization of labor-intensive industries in the countries with "preferential" legislation seems to be an optimal management decision. However, as we see it, it is not entirely correct. The experience of Vostok-Servis-Kuzbass LLC clearly shows that the use of information technologies in VMI (Vendor Management Inventory) supply chain management systems as well as in training and knowledge verification enables to reduce industrial enterprise's total costs on PPE (personal protective equipment) by 40%, while the costs of training, knowledge verification, briefing and giving access to upcoming production tasks can be reduced by 20-30%.

Methods

This study of the experience of Vostok-Servis-Kuzbass has been carried out by using the methods of systemic, logical, and comparative analysis. The findings will be used in the management activities of the company itself as well as at new partner enterprises in case of the further spread of the practice described.

Results

Vostok-Servis-Kuzbass LLC is the organizational part of Vostok-Servis federal holding and has been supplying overalls and personal protective equipment (hereinafter – PPE) to industrial enterprises of Kuzbass and neighboring regions for over 25 years. The market the company operates in is highly competitive from suppliers and is characterized by strong bargaining power of buyers. The clients of the company are the enterprises of basic sectors of industry, such as coal, metallurgical or chemical sectors. Moreover, the climatic conditions of the region leave their

traces on the requirements for PPE, which predetermines the need to ensure not only competitive price level, but the quality of products as well.

One of the main problems of the region in the field of labor protection is the industrial injuries. A sad axiom, known to every resident of Kuzbass since their childhood, says: “Every million tons of coal mined to surface takes one life of a miner”. According to the figures given by Kuzbass regional office of the Fund of Social Insurance of the Russian Federation, the level of industrial injuries in Kemerovo region is significantly higher that the averege level for the Russian Federation (see figure 1 below).

Figure 1: The dynamics of industrial injuries (severe accidents and fatalities) in the Kemerovo region

The authors consider digitalization of business processes relating to labor protection at the enterprises of basic sectors as one of the possible ways of solving this complex problem. The real minimization of the opportunities for human influence in the cases when there is a choice between the fulfilment of the production plan and the safety of continuing the production process will reduce the level of industrial injuries, including the severe accidents and fatalities.

The other significant problem concerning the labor safety system is the so-called “industrial necessity” of maintaining the quantities of residues of overalls and PPE in the warehouses of an enterprise [2]. Such necessity is due to the fact that it is impossible to predict with 100% certainty what type or size of overall or PPE may be required at a particular moment, as there is a natural movement of workforce, and despite the established standards on wear and tear, it is often when the PPE is replaced as a result of its becoming unusable. On the contrary, there are situations when the wear period has come to an end, but the PPE is still suitable for use; but since there is no control other than warehouse accounting, the worker is given a new pack set of overalls, while the old one – being absolutely suitable for use – is transferred to employee’s household for their personal use. [3], [7] Such a transfer of income in favor of the employee is not taken into account and forms the employer’s transactional costs, which the latter cannot even estimate. Moreover, discovering the defects in the supply of overalls is possible only when a set has been already handed to the worker. And if there is a defect in the warehouse stock, there has to be a stock to replace it.

The authors have analyzed the situation in the Kemerovo region concerning the procurement of overalls and PPEs for enterprises. The results of the analysis are summarized in table 1. There are 52167 enterprises and organizations in Kuzbass. They employ 780983 people in total. The share of those employed in hazardous and dangerous productions is about 34% or 267433 people. 65% of employees (507638 people) are in need for overalls. On average,

the annual cost of PPE given for one employee is 10570 roubles per person for those employed in dangerous or hazardous productions and 1350 roubles per person for those working under normal conditions. Thus, we can see that the annual volume of the PPE market in Kuzbass should be at the level of 3,132 billion roubles. Therefore, it can be said that the level reflects the socially necessary costs on PPE in the region per year. At the same time, the analysis of actual purchases clearly shows that the figures are incomparably higher.

The structure of employees	Number of employees	Average annual costs of procuring PPE per one employee, rub	Socially necessary costs on PPE	PPE actual purchase volume (by enterprises), roubles	Overexpenditure on PPE, roubles
Total number of employees in Kuzbass	780983				
Employees working on hazardous productions	267433	10500	2 808 046 500	4 071 667 425	1 263 620 92
Employees working under normal labor conditions in need for PPEs	240205	1350	324 276 750	502 628 963	178 352 213
Total number of employees in need for PPE	507638	6170	3 132 323 250	4 574 296 388	1 441 973 138

The source: summarized by the authors

As follows from Table 1, the difference (overexpenditure) between the necessary and actual costs of the enterprises of Kuzbass on purchase of overalls and PPE is 1,44 billion roubles. This is the amount of truly non-productive costs that the enterprises incur managing their business processes of labor safety. At the end, these costs are paid for by either the end consumers, or the employees when they buy the consumer goods based on the products manufactured by their enterprises, or the owners of the enterprises, missing profits when their products are exported and the price is quoted on world and regional trading platforms. The latter is applicable to coal, coke, fertilizers, the products of metallurgy, etc.

The way out of this situation, as authors see, is the widespread implementation of information technologies for supporting managerial decisions in order to ensure “smart” labor safety process management at the enterprise. By this category, we mean such management, which increases the quality of labor protection and operational efficiency at the same time. The quality of the labor protection will be characterized by the indicators reflecting the level of industrial injuries, the average number of days of incapacity for work per employer, employees’ satisfaction with their work conditions and employees’ motivation to work safely. A number of other indicators reflecting the instructions of control and supervisory authorities (Rostechnadzor, labor inspectorate, etc) can be added as well. [4] As concerns the increase of operational efficiency of the enterprise, we, first of all, see the possibilities of digitalization in such a type of chain supply management, which minimizes enterprise’s inventory balances, implements the principles of economical production and limits the costs only to those that are truly necessary for the end buyers.

The specialists of Vostok-Servis-Kuzbass LLC have developed and launched online service which, in our opinion, solves all the above problems. This product of the company is given the trade name “Abie”.

Its concept is based on three principles:

- Twenty-four-hour online availability for the user;

- Named data fixation;

- Real-time display and analysis of the situation.

The basic element of this system is a personal professional card containing information from the HR department about the employee as well as actual data on four main areas of labor protection (see figure 2): *working conditions* (the result of assessing negative factors at the workplace), *protective equipment* (the data on the state of PPE in production

and the terms of their renewal), *health* (the result of medical assessment of employee's state of health), *knowledge and skills* (the result of daily testing on safety and labor protection).

Figure 2: The schematic diagram of working functionality of Abie online service

This data is collected in cloud storage and is protected similarly to online banking data. The system analyzes the incoming information, conducts calculations and represents them in the personal professional card in an easy-to-understand graphical and tabular form. Data summary from personal cards is generated in thematic reports on labor protection at the enterprise. As a result, the system allows creating objective criteria for assessing the personnel and their motivation towards labor safety. The employee is able to verify his level of professional training and his safety personally.

The advantages of the Abie system, that affect the operational efficiency of the enterprise directly, include:

- High accuracy of planning and accounting the labor protection budget;

- 100% efficiency of spending;

- Zero balance of PPE on the balance of the enterprise;

- The absence of any restrictions on the number of suppliers of PPE and overalls;

- The absence of any need for arranging individual contact briefing (with a specialist of labor protection department or a foreman) on safety in case of routine work;

- Reducing the cost of periodic medical assessments with synchronous increasing the level of ongoing monitoring of the employee's health.

Thus, the Abie digital service allows carrying out "smart" management of business processes in the field of labor protection, considerably reducing occupational injuries and increasing operational efficiency of the company.

The use of the Abie online service is the most beneficial for the enterprise when the PPE supply management is processed on VMI model (Vendor Management Inventory – the stock is managed by the supplier). This model has been known since the beginning of 1990s and is used in many companies from Fortune 500: Wal-Mart, Procter & Gamble, Gilette, Mediamarkt. In the Russian market it is used by such companies as Coca Cola, Metro, Real, Wimm-Bill-Dann, etc [5, 6]. Its meaning lies in the fact that the supplier takes over the PPE stock management at the consumer enterprise. In this case, the supplier has access to the information on the consumer's stock and creates purchase orders for him.[7] By means of the Abie online service, the PPE supplier creates an accurate picture of the

needs of each employee of the enterprise for PPE, and combining and structuring the needs of several consumer enterprises, the PPE supplier will be able to optimize the delivery of necessary PPE on time and in full compliance with both nomenclature and the range of overalls and PPE. To describe such a model, one can use the category "Collaborated Forecasting, Stock and Replenishment Planning" or joint forecasting with suppliers and distributors as well as planning of stocks and their replenishment.

Conclusions

At present, 82 enterprises of Kuzbass with a total of 80 000 people have switched to the Abie system. Among them, there are such well-known companies as Evraz, SDS Azot, OF Raspadskaya, Sibugelemet, etc.

The transition to "smart" labor protection process management at Kuzbass enterprises will allow reducing industrial injuries, increasing the number of days of employees' working capacity, improving the quality of working conditions and personnel's motivation to safe work. By increasing the operational efficiency of the enterprise through reducing the remains of PPE in warehouses, timely receipt of necessary resources, reducing labor costs for training, testing knowledge on labor protection and issuing access to necessary productional operations, the Abie system is able to bring a cumulative economic effect in the amount of up to 1,4 billion roubles per year just within one constituent entity of the federation.

Intelligent System Support Potential in Manufacturing Process Management

Fredrick MUMALI and Joanna KAŁKOWSKA

Poznan University of Technology, Faculty of Engineering Management
Poznan, Poland
Email: joanna.kalkowska@put.poznan.pl

Abstract

Manufacturing enterprises are under constant pressure to deliver quality products at the right to meet the highly dynamic needs of their customers. Given the increasingly stiff competition from both national and international enterprises on the market, manufacturing managers have no choice but to optimize their processes to increase productivity, flexibility, and responsiveness. This paper attempts to show that deploying intelligent support systems in managing manufacturing processes is crucial for the survival of manufacturing enterprises and ensuring growth and sustainable development. The study focuses on the current research related intelligent decision support systems, genetic algorithms, and artificial neural networks and how they can help optimize manufacturing processes. Manufacturing enterprises are under constant pressure to sustain growth and development in increasingly competitive business landscapes. Enhancing productivity and flexibility in manufacturing requires rapid decision-making for optimal outcomes. A review of existing works of literature identifies the significant role of a robust decision support system in process optimization. The study establishes that genetic algorithms provide better tools for strategic decision-making and hold great potential for solving process optimization challenges. Moreover, a review of existing literature on artificial neural networks present them as essential tools for decision-making through their capacity to generate optimal outputs in process optimization. The observations emphasize the ability of artificial neural networks and genetic algorithm in enriching decision support systems capable of optimizing manufacturing processes. The study shows the need for further studies on unified techniques and methodologies of their implementation in manufacturing processes.

Keywords: Intelligent support, artificial neural networks, genetic algorithms, manufacturing processes.

Introduction

The primary purpose of the manufacturing process is to transform ideas into valuable products. Planning plays a critical role in achieving the objective of manufacturing by ensuring timely, comprehensive, and cost-effective implementation of the processes. Time, quality, and cost play a significant role in the optimization of manufacturing processes and are dependent on each other (Sauer et al., 2007). A similar observation emphasized that planning is a crucial link that defines in great detail the process for transforming raw materials into desired valuable forms (Halevi, Weill, 2012). Therefore, to produce a product in the preferred form, quality, and at the right time, requires comprehensive planning and management of the processes involved.

Manufacturing process management entails activities such as selecting and sequencing of operations and activities involved in transforming raw materials into finished components. Process planning involves detailing the activities and functions to manufacture a product successfully. As such, it includes the selection of processes and operations, determination of parameters and specification of quality assurance criteria, in addition to a significant amount of decision-making (Phanden et al., 2019, p. 2). Production process planning involves a substantial amount of human information and processing and decision-making (Gasser et al., 2010). Significantly, the management of manufacturing processes implies adding value within the organization in its objectives to transform raw materials into desired products.

Production technology and management have undergone three essential revolutions that include mechanization, electrification, and automation (Danielis et al., 2014; Zhu et al., 2013). Consequently, the dynamism of the changes in technology has necessitated the need for devising mechanisms to address organizational complexity. Ensuring success and competitiveness is becoming increasingly difficult for manufacturing companies in today's globalized world. Manufacturing enterprises operating locally and globally, continue to face stiff competition. Globalization,

coupled with revolutionary technological development on unprecedented scales, has significantly impacted the business landscape as demonstrated by an ever-increasing and highly competitive business environment across different industries.
The manufacturing industry, in particular, faces a growing diversity in customer preference combined with stiff competition between manufacturers. The success and competitiveness of many manufacturing enterprises significantly rely on their efforts to modernize their manufacturing processes to incorporate faster, quality, and efficient decision-making practices. As such, there is a need to improve productivity, quality, and cost-efficiency to meet these challenges. Present optimization methods focus on existing processes in connection with lean manufacturing methods whose objective is to eliminate waste. Furthermore, this approach has a lot of potentials but is not sufficient as it only improves process flows while overlooking among others, the resources performing the processes (Klocke et al., 2014). Thus, a gap exists in process optimization methodologies.

Knowledge engineering tools are among the resources required for the preparation and management of manufacturing processes. The fourth industrial revolution has ushered an age of intelligent manufacturing characterized by cutting-edge support technologies that increasingly feature real-time decision making and precise engineering methods. The objective of decision making in manufacturing process management is to find an optimal decision from a pool of different possibilities. Its essence is the optimization of the processes. Knowledge is undoubtedly the most significant resource for the transformation of enterprises. The manufacturing process is currently both dynamic and intensive (Li et al., 20117). As such, human experience on its own is incapable and prone to errors.

The development of knowledge engineering tools and intelligent systems has resulted in the design and development of complicated means to support different phases of decision making. Such means hold the potential to improve the speed, accuracy, and quality of decisions made by human capabilities. A decision-making support system is a system designed to interactively provide support throughout the decision-making processes (Phillips-Wren et al., 2006). The use of intelligent system support as a decision-making aid tool has brought remarkable improvements in various fields, including service and healthcare industries, among others. The article presents the evolution and application of intelligent systems and knowledge engineering tools in production planning. Related recent research works are analyzed to provide a comprehensive understanding of theoretical and practical advances in the use of intelligent systems and their potential in improving decision-making to enhance productivity, flexibility, and responsiveness in manufacturing processes.

Manufacturing Processes, Productivity and Flexibility

In the modern economic context, manufacturing means the transformation of raw materials into components and products of higher value through several processing steps and operations. In their original state, natural materials have less economic value and importance to consumers. Thus, manufacturing adds value to the raw materials by altering their properties into goods of desired forms that are valuable. These can be consumer goods, capital goods, and industrial goods. Consumer goods include items that are valuable to end users, whereas capital goods are those utilized to increase the productive capacity of enterprises such as equipment and machine tools.

Manufacturing companies of all kinds are under constant pressure to sustain a positive growth not only quickly but also cost-effectively. The sweeping transformations occurring in the manufacturing sector worldwide require decisions that used to take weeks or even months in the past to be timely and within hours if not minutes. Every decision makes concerning the manufacturing process must consider possible consequences to the enterprises and be made quicker than ever before. Consequently, the management objectives have grown to responding to market opportunities faster than competitors and maintaining a sustainable growth rate in a highly competitive business environment.

Productivity is significant for the long-term economic growth of an enterprise. As such, it remains one of the critical factors in sustaining competitiveness and development. Prokopenko and International Labour Office defined productivity as the efficient use of resources such as capital, materials, energy, and information in the manufacturing of goods. In manufacturing, a more productive process is one that takes less time to achieve the desired outcome. The fundamental concept of productivity is always the relationship between quality and quantity of products manufactured and the number of resources utilized in the process (Prokopenko, 1987). Higher productivity is equivalent to greater efficiency of manufacturing processes. For a company to be profitable and sustain its development, manufacturing must proceed at the highest productivity possible.

Flexibility is an essential aspect of manufacturing. The concept and importance of studying flexibility in manufacturing were introduced by Gerwin (Gerwin, 1993) in his observation on the need for decision-makers to leverage research on strategic aspects of manufacturing flexibility. Due to globalization, the business landscape has become more competitive. Manufacturing companies are increasingly faced with an increase in customization,

constantly changing consumer preferences and uncertainty. Consequently, manufacturing flexibility is increasingly becoming a necessity for survival (Boyle, 2006). Closely related to and resulting from flexibility is responsiveness. Responsiveness implies the speed at which an enterprise reacts to changes in its environment (Koren, 2010). In manufacturing process management, responsiveness describes two things. First, the speed at which manufacturing managers react to the dynamics of the business landscape and second, the rate at which high-quality decisions are made and executed for optimal outcomes. At the enterprise level, responsiveness describes the speed in taking advantage of the new market opportunities.

Manufacturing flexibility has a multidimensional nature and lacks sufficient measurements, which makes it a complex undertaking. Among the best practices proposed by Boyle on flexibility is the need for manufacturing managers to identify the different flexibility forms in connection with mobility, range, and uniformity as well as understand the potential of manufacturing flexibility to occur at various organization levels (Boyle, 2006). Implementing all required flexibilities is limited by the lack of sufficient resources, which puts immense pressure on decision-making to ensure optimal results.

Intelligent Decision Support Systems

An intelligent system is a collective term that describes knowledge-based systems, computational intelligence together with their hybrids. Such systems have made it possible to confront a large number of problems effectively. Intelligent Systems include expert systems, artificial neural networks, and genetic algorithms.

Incorporating intelligence elements in decision support was inevitable. As such, several scholars have widely studied intelligent decision support systems. Cheung, Leung, and Tam focused on the use of intelligent decision system support (IDSS) for network planning (Cheung et al., 2005). One of the significant observations noted by the authors was the limited use of IDSS. The study proposed the use of IDSS alongside an expert system (ES) to offer guidance during the decision-making process. According to this, the previously under-researched aspect of Fuzzy Logic and IDSS had become popular as the popularity of case-based reasoning diminishes. Due to the rising use of IDSS, the researchers added data mining as one of the aspects of intelligent system support with potential in production planning.

In terms of production planning to support systems that predict customer value, a study by Chan and IP (Chan, IP, 2011) focused on a dynamic approach to support systems to predict customer value in new product design. One of the key findings of this study is that decision-makers can use an active system to support confidence in the product. The authors observed that these dynamic systems could help companies develop competitive products that enhance sustainability and business growth. These findings align with previous research by Gao, Shang, and Kokossis (Gao et al., 2009), which examined the applicability of an agent-based system for supporting decisions in a chemical production company.

Felsberger, Oberegger, and Reiner (Felsberger et al., 2016) disputed the potential of intelligent system support in production planning as a function of management. They noted that the prospect of big data offers new insight for innovation on intelligent system support and decision making in the form of evidence-based decision-making. Moreover, they argue that data analysis is the significant impact of intelligent systems. Their study disputes the ability of intelligent systems to be used in production planning as a function of management but offers new avenues for the adoption of these systems in manufacturing processes (Felsberger et al., 2016). In turn, Guo et al. (Guo et al., 2009) focused on operative efficiency when using intelligent systems. The authors noted that operative efficiency depends on many factors among them the status of the machine, negligence, operator, and relearning and highlights the need for more research on the effect of these aspects on production control decision making.

Moreover, while intelligent manufacturing has gained pace, it is the need to develop and operate smart manufacturing systems on a different layer. There is a need for intelligent workshops, intelligent manufacturing units, and innovative manufacturing models (Li et al., 2016). Taking into account the above, Antosz, Pasko, and Gola (Antosz et al., 2019) focused on the possibility of using these intelligent systems in supporting decision making for effective implementation of lean manufacturing. They mentioned the possibility of using intelligent methods in the production process to achieve lean outcomes. However, they also underscore the need for more research on the application of intelligent systems.

Genetic Algorithms

The study of the genetic algorithm traces its origins to Holden (Holden, 1975) in his attempt to solve optimization problems. Since its introduction, the concept of a genetic algorithm has been studied widely by various scholars. Genetic algorithms describe intelligent methods that utilize computing power to simulate the process of natural

evolution with a purpose of finding specific patterns from a given set of data (Turban et al., 2005). The genetic algorithm provides a tool for seeking the best alternatives among strategies and processes to get optimal outcomes and can be understood as a standard metaheuristic method for optimization, used for solving various problems such as scheduling in manufacturing systems (Vlasic et al., 2019). Genetic algorithms have the potential in an enterprise's optimization problem with limited information (Rooyani, Defersha, 2019). Thus, in the digital era characterized by huge volumes of data, genetic algorithms present the best tools for optimization.

The notion of the population is a significant concept of genetic algorithm. A community of solution candidates is used in determining the most optimal solution. For this reason, a population of the candidate is at the core of genetic algorithm operations. As an iterative operation, executing a genetic algorithm involves an initial community of randomly generated potential solutions, also referred to as chromosomes. A generation refers to each iteration and involves examining and assigning fitness values to individuals of the chromosomes. A new population is formed by first selecting individuals followed by creating offspring candidates. The next generation of parents is developed from the offspring candidates. Therefore, an individual is expected to be chosen based on their relative performance within the population. Through operators such as crossover and mutations, genetic algorithms are used to produce new solution candidates and enable the selection of the optimal one. Crossover involves a combination of parts of parents to form one or two solution candidates termed as offspring. By contrast, mutation involves arbitrary alteration.

Operators such as crossover and mutation are inspired by natural genetic variation and selection. Iterations in genetic algorithms lead to the creation of generations until an acceptable solution is reached. As a stochastic iterative algorithm, generic algorithms lack convergence assurance. As such, termination occurs when the best solution is reached or after getting a maximum number of generations. Thus, genetic algorithms allow continuous learning by acting as a tool for generating new strategies from the previous ones in an attempt to find a better fit (Passos & Barrenechea, 2019). Li, Huang, and Niu noted that the solution candidates that form the generation are generated based on the evolutionary experience of parent solution populations. As such, population diversity is strengthened (Li, Huang, Niu, 2016).

Several studies demonstrate the enrichment of decision support systems by genetic algorithms. Mourtzis, Doukas, and Psarommatis noted the widespread adoption of genetic algorithms in tackling manufacturing network-related problems. They tackled design manufacturing network issues related to mass customized products by using a comprehensive search method, genetic algorithm, and the search algorithm. Moreover, genetic algorithm methods result in high-quality solutions, and their combined performance remained superior compared to intelligent search methods (Mourtzis et al., 2013). Yilmaz Eroglu and Kilic developed a decision support system for assisting managers in improving enterprise innovation and used the Hybrid Genetic Local Search Algorithm as the engine and determinant of significance degrees and succeeded in deploying the developed genetic algorithm in the strategic decision-making process within the innovation management context (Yilmaz et al., 2017). Jawahar and Subhaa utilized a genetic algorithm based intelligent support system on enhancing design decision making in a cellular manufacturing system (Jawahar, Subhaa, 2017). In turn, Musharavati and Hamouda proposed a modified genetic algorithm for solving the hard optimization problem presented by a manufacturing process planning involving multiple parts productions (Musharavati, Hamouda, 2011). Based on the simulation results, the proposed altered genetic algorithm was highly effective.

Artificial Neural networks

Artificial neural networks refer to computation networks designed to simulate the decision-making process that occurs in neurons of the biological central nervous system. Artificial neural networks are mathematical inventions that draw upon the research of biological systems (Graupe, 2019). Constructing artificial neural networks imitates a natural brain's distributed method of computing. Having machines that mimic the computational power of the brain was the motivation behind artificial neural networks. A neural network is made up of a group of artificial neurons. Together, they form a physical system with the capacity to collect, store, and utilizing knowledge based on experience and observation. The human brain learns through processes such as modifying synaptic links between neurons (Graupe, 2019).

Similarly, artificial neural networks change their forms based on input and output information flow when learning. Furthermore, Turban, Aronson, and Liang argue that artificial neural network improves their performance by learning from experience. Unlike experts who might be unwilling to share decision knowledge, artificial neural network's learning phase ensures the system is capable of identifying patterns and rules from experience and historical data (Turban et al., 2007).

Neural networks can engage in logical reasoning (Holden, Kryukov, 1991). Based on this assertion, the neural network can be said to possess the ability to learn an algorithm without having complete information about it. Canz

and Jagdale studied the application of the machine learning concept in decision making using an artificial neural network to predict the process parameter (Canz, Jagdale, 1995). Cho and Leu highlighted several manufacturing processes where artificial neural networks are applied. These include machining processes, where an artificial neural network can use vibration, temperature, and other data to predict the equipment's life or failure (Cho, Leu, 1998).

Artificial neural networks learn the relationship between input prototypes and expected outcomes (Cho, Leu, 1998). Yildirim demonstrated the use of artificial neural networks in modelling multi-objective optimization problems in a manufacturing system to assist managers in managing production plant capacities (Yildirim et al., 2006). Thus, the networks can generate optimal outputs based on what (Sudha et al., 2016) explored the use of artificial neural networks in process parameter optimization. The authors noted that various enterprises face the challenge of optimizing input parameters to attain the desired value. The authors established that predictions enabled by the artificial neural network in the parameter process optimization act as useful guidelines for decision-makers (Sudha et al., 2016). Recent works show the potential of artificial neural networks in nanomanufacturing (Almakaeel, Albalawi, Desai, 2018) and 3D printing (Yadav et al. 2020). Rodríguez et al. focused on the use of intelligent systems to support production planning using machine learning (Rodríguez et al., 2019). One of the significant observations from this study is the use of machine learning in processing real data and applying the information in the decision-making process. Rodríguez, González-Cava, and Pérez present a methodological solution based on fuzzy logic, built-in machine learning. They observed that full development and utilization of Fuzzy logic is an essential step towards automation as these systems can imitate the human decision-making process (Rodríguez et al., 2019).

Conclusion

A literature review of decision support systems and intelligent systems - artificial neural networks and genetic algorithms, reveals that these tools have massive potential in the implementation and management of manufacturing processes. Although decision support systems have been in use for decades, their effectiveness is enhanced when combined with intelligent systems such as artificial neural networks and genetic algorithms. The combination results in a robust and comprehensive smart decision system capable of helping managers make a high-quality decision in the shortest time possible.

Whereas the decision support systems help managers to store, process, and retrieve data and use it to make better decisions, artificial neural networks make it possible for the decision support system to learn by storing input and output and modifying the layers of the interconnected neurons. When making decisions, the closest outcome to the output fed into the system is selected. As such, artificial neural networks provide optimized solutions among the variety of possible solutions a manufacturing process manager needs to choose.

Similarly, genetic algorithms hold great potential in enriching decision-making models and systems. Unlike artificial neural networks, genetic algorithms, begin with a pool of potential iterated solutions, and the process only terminates when the best candidate is found. Besides, operators such as crossover and mutations generate new and better solution candidate offspring, which are again iterated to find the most optimal solution to a given problem. Given the increase in the amount of data available for managers to base decisions on, genetic algorithm holds the potential to not only optimizes solutions but also enrich the choices of known mutations and crossover operators.

As noted in the literature review, there is a substantial potential of intelligent support systems in managing manufacturing processes by supporting managers in making decisions that ensure optimization of the methods, which plays a vital role in preparing the enterprise to meet customers' needs while sustaining its growth and competitiveness. In particular, artificial neural networks and genetic algorithms can enrich existing decision-making tools, turning them into intelligent support systems.

Although progress has been made concerning intelligent decision support tools and systems, there is still a gap of knowledge and data on important aspects such as methodologies and models of integrating decision support systems with artificial neural network and genetic algorithms. The impact of intelligent systems such as artificial neural networks and genetic algorithms have been studied in isolation. As such, further coherent research is required to establish the methodologies of intelligent support systems that combine decision tools and intelligent technologies based on artificial neural network and genetic algorithms as a unified system. Specialized research is also needed on the impact of the developed methodologies on different manufacturing industries and scenarios.

Abstract

In Portugal, audit quality control is imposed on all audit firms. This requirement aims to improve the quality of the audit, and the decision-making process of stakeholders, who use the Audit Report.
This article aims to analyze the results of the quality control of the audit, carried out in Portugal, using the content analysis technique of the Audit Quality Control Reports, issued between 2009 and 2019, by the Order of Statutory Auditors. The results indicate that, in horizontal control, there are deficiencies in the internal quality control systems, in the human resources used, and in the fulfillment of ethical requirements. In turn, in the vertical control, there are deficiencies in the execution of the audit work and the audit reports. This study, in addition to being innovative, contributes to raising awareness among audit professionals about the importance of quality audit practice.

Keywords: Audit Firms; Audit; Quality Control; Audit Quality Control Reports.

Introduction

According to Rijwani and Rajpurohit (2017), auditing plays an important role in the financial reporting process, as it assures its credibility. Reinforcing this idea, Xalmuratovich, and Turdimuratovna (2020) refer that auditing is a necessary and important tool for the economic development. Baffa (2017), also, states that the role of auditing is to improve the quality of financial statements. However, the audit can only exercise its role effectively when it is performed with quality.

The quality control of the audit is defended by Kothari et al. (2012), Stewart (2012), Baylon et al. (2013), Carson et al. (2013), Saha and Roy (2016), Tapang, Kankpang, Inah, Bessong, Uklala (2020), and Aobdia (2020), given that, according to these authors, the quality of the audit improves after supervision. Coelho (2010) also states that audit quality control is essential, as it aims to ensure that all audit firms carry out the audit following the ethical and technical requirements of the profession. Reinforcing this idea, Saha and Roy (2016) state, that quality control of the audit has become extremely important in today's corporate environment in the backdrop of accounting irregularities and audit failures leading to corporate demise. These provide reasonable assurance of compliance with applicable regulation and issuance of the appropriate report by the engagement team.

In Portugal, all audit firms are subject to internal and external quality control. Internal audit quality control is of the responsibility of audit firms and external audit quality control is of the responsibility of the Securities Market Commission (SMC) and the Order of Statutory Auditors (OSA). Focusing on external control, this article aims to analyze, using the content analysis technique, the results of the quality control of the audit carried out in Portugal between 2009 and 2019.

This article, in addition to this introduction, includes a chapter on audit quality control and another on the empirical study, ending with the conclusions, limitations of the study, and clues for future research.

Quality control of the audit

The quality of the audit essentially depends on compliance with legal standards. However, Houshmand and Mahdavi (2012) consider that the auditor's qualities, together with continuous training, are also fundamental to the quality of the audit. Frederick and Libby (1990) and Carcello et al. (1992) also highlight knowledge and experience as relevant elements for the quality of the audit. Felo et al. (2003), Alsaqqa and Sawan (2012), Babatolu et al. (2016), Kuntari et al. (2017), and Abdul-Rahman et al. (2017) list not only personal requirements but also aspects such as the size and image of the audit firm, as well as the fees charged by the audit firm, as important characteristics for the quality of the audit.

As mentioned, the quality of the audit is a relevant factor for the success of this activity, and it is necessary to implement adequate quality control systems. Therefore, under the International Standard on Auditing (ISA) 220 - "Quality control for an audit of financial statements", and the International Standard on Quality Control (ISQC) 1 - "Quality controls for firms that perform audits and reviews of financial statements, and other assurance and related services engagements" and the Statute of the OSA, all audit firms are required to quality control of the audit.

The purpose of audit quality control, according to article 3 of the Quality Control Regulation, is to verify that the audit standards have been met and that the audit reports are following the conclusions drawn. This control also aims to assess whether the technical and human resources used, the internal quality control system implemented, and the fees charged are adequate, given the nature and size of the work carried out.

In Portugal, since 2016, the SMC has been responsible for the quality control of audit firms that audit entities of public interest. The remaining audit firms are subject to quality control exercised by OSA, within the scope of the SMC's final supervision. OSA attributes to the Quality Control Commission the competence to propose the annual quality control plan to be carried out and to promote its execution. It should be noted that a public draw is held annually, in which the audit firms subject to quality control are drawn, ensuring that all will be subject to control every 6 years.

The Annual Audit Quality Control Report, resulting from quality control, is divided into two types: horizontal control and vertical control. The horizontal control corresponds to the global assessment of the activity, namely, the analysis of issues related to personnel, such as independence, training, ethics and deontology, adequacy of resources used, and evaluation of the internal quality control system implemented. In turn, vertical control concerns the work performed, the quality of the documentation, the reporting of reservations and emphases, and the fees charged. The results of each control are classified as follows:

- **Without anything special to mention** it is not necessary to make changes and/or the analysis of the dossiers was considered adequate to support the opinion issued;
- **With less relevant observations and recommendations:** there are observations that audit firms should consider;
- **With relevant observations and recommendations:** some observations require the immediate intervention of audit firms, to overcome the deficiencies detected;
- **With the unsatisfactory result:** detection of deficiencies and insufficiencies, which prevent the issuing of opinions;
- **Canceled:** situations of proven absence of activity, death, or cancellation of the activity;
- **Controls not completed:** not approved until the date of the issue of the report.

According to article 21 of the Quality Control Regulation, if the quality control has been concluded with relevant observations, the audit firm must adopt these recommendations within 12 months. The Quality Control Committee will follow up on the suggested recommendations.

Empirical Study

Research Methodology and Sample

The purpose of this article is to analyze the results of the quality control of the audit carried out in Portugal, between 2009 and 2019. Specifically, it is intended to identify the main deficiencies pointed out in the quality of the audit. For this, the content analysis technique will be used, as according to Severino (2007), this methodology allows us to treat and analyze information from documents. This type of methodology describes, analyzes, and interprets the messages of all forms of discourse, seeking to interpret their meaning.

Therefore, the Audit Quality Control Reports, published annually by the Quality Control Committee, on the OSA website, referring to the period between 2009 and 2019, which comprise eleven reports, will be analyzed. The number of audit firms and dossiers subject to quality control, in the period under study, is shown in table 1.

Table 1: Audit Firms and Controlled Dossiers

	Number of Audit Firms	Number of work files
2009	127	191
2010	85	152
2011	82	185
2012	81	184
2013	82	219
2014	104	204
2015	115	204
2016	98	200
2017	78	109
2018	72	106
2019	63	92

Source: Own elaboration based on OSA data (2009-2019)

According to table 1, between 2009 and 2019, 987 audit firms and 1846 work files were subjected to quality control, resulting from the audits carried out. It should be noted that, in 2017, the number of auditing firms and controlled dossiers decreased, given that as of June 30, 2016, the quality control carried out by the Quality Control Committee covers only audit firms that do not carry out auditing public interest entities.

Results and Discussion

Horizontal Control

The results of the horizontal control, carried out between 2009 and 2019, are shown in table 2.

Table 2: Result of Horizontal Control

	Nothing special to mention	With less relevant observations	With notes of relevance	Unsatisfactory results	Canceled	Not completed
	%	%	%	%	%	%
2009	60%	35%	2%	-	3%	-
2010	56%	32%	5%	4%	4%	-

2011	50%	28%	17%	2%	2%	-
2012	37%	38%	19%	-	6%	-
2013	34%	41%	16%	2%	5%	1%
2014	52%	32%	12%	1%	3%	1%
2015	63%	25%	7%	3%	1%	1%
2016	76%	19%	2%	1%	1%	1%
2017	69%	21%	9%	-	1%	-
2018	52%	24%	24%	-	8%	-
2019	55%	19%	19%	6%	2%	-

Source: Own elaboration based on OSA data (2009-2019)

The results of the horizontal control, shown in table 2, reveal that more than half of the controlled audit firms obtained the classification "With nothing special to mention", which means that the majority of the audited firms inspected to comply with the auditing standards.

The second most attributed classification was that of “Observations of less relevance”, especially in 2013. However, this classification does not require interventions in audit firms. Next comes the classification "Observations and recommendations of relevance", which implies immediate intervention by audit firms. However, the percentages are not significant. Although there is a decrease in the quality of the audit in 2018 and 2019, this would not be expected, given that the new audit standards, applied since 2016, aim, among other things, to improve the independence and quality of the audit. Controls with “Unsatisfactory Results” were also completed, with minimum percentages. In these cases, it is not possible to issue an opinion and, therefore, these processes are usually referred to as the Disciplinary Council. The years 2012 and 2018, although with reduced values, stood out with lawsuits canceled, motivated by the proven absence of activity, death, or cancellation of the activity.

Table 3: Deficiencies in Horizontal Control

	2009	**2010**	**2011**	**2012**	**2013**	**2014**	**2015**	**2016**	**2017**	**2018**	**2019**
Internal quality control system	-	36%	50%	54%	36%	43%	41%	24%	42%	50%	60%
Ethics, deontology, and independence	-	13%	13%	5%	14%	11%	14%	21%	14%	10%	12%

Others		15%	19%	25%	12%	14%	12%	20%	19%	-	-

Source: Own elaboration based on OSA data (2009-2019)

As can be seen in Table 3, in 2009, it was not possible to identify the deficiencies pointed out in quality control. In the following years, it is observed that the biggest deficiency pointed out in the audits is in the internal quality control system, essentially in 2019.

The deficiencies of the internal quality control system refer to the lack of its implementation and monitoring, as well as to the lack of uniformity in the application of the system among the partners. In addition, it was found that, in many cases, the Manual of the internal quality control system is not detailed, nor does it specify the procedures, with the aggravation of not carrying out independent reviews by another auditor.

These results lead us to conclude that the audit firms do not adopt the policies and procedures to ensure the quality of the audit, as provided for in ISA 220 and ISQC 1.

Regarding ethics, deontology, and independence, the deficiencies are due to the inadequacy of fundamental principles, provided for in the Code of Ethics, as well as the absence of procedures to guarantee independence. These results corroborate the opinion of Bekiaris and Tasios (2012) and Houshmand and Mahdavi (2012), who state that the attributes of the auditors and compliance with ethical principles influence the quality of the audit.

The deficiencies pointed out to independence reveal that the auditors are not adequately complying with the independence that is required in the Code of Ethics and the Statute of the OSA. The studies by Aderin et al. (2013) and Enofe et al. (2013) concluded that when the auditor's independence increases, the quality of the audit increases. In the wake of this thought, Villacorta (2010) states that if the auditor is not independent, his opinion will not be more reliable than the financial statements prepared by the entity. This means that auditors are only able to properly serve stakeholders if they maintain a position of independence (Serra, 2013).

The deficiencies in human resources are due to the inadequacy and excessive subcontracting of technicians who are not subject to the rules of independence and professional training of OSA. It is, therefore, necessary to improve recruitment processes and invest in continuing professional training, as, as Frederick and Libby (1990), Carcello et al. (1992), and Felo et al. (2003) refer, the auditor's knowledge and experience are important factors for the quality of the audit.

In the Transparency reports, deficiencies are because some relevant aspects are not properly identified, and described. It should be noted that, in 2018 and 2019, the Transparency Report was not considered, but weaknesses in fees, training, and mechanisms to prevent money laundering and terrorist financing were considered.

The deficiencies called "others" relate to other errors observed, which affect the organization and functioning of the audit firm and the training of auditors.

Vertical Control

The vertical check focuses on the audit files, to verify that they are prepared correctly and that they are following the audit standards. The conclusions of the vertical control, carried out between 2009 and 2019, are shown in table 4.

Table 4: Result of Vertical Control

	Nothing special to mention	With less relevant observations	With notes of relevance	Unsatisfactory results	Canceled	Not completed
	%	%	%	%	%	%
2009	32%	50%	15%	1%	2%	-
2010	43%	35%	16%	3%	3%	-
2011	51%	31%	13%	4%	1%	-
2012	49%	36%	11%	2%	3%	-
2013	47%	32%	16%	1%	2%	-

2014	46%	31%	18%	1%	3%	1%
2015	55%	28%	13%	2%	1%	1%
2016	68%	21%	10%	-	1%	1%
2017	53%	37%	9%	-	1%	1%
2018	34%	34%	24%	8%	1%	-
2019	32%	27%	33%	9%	5%	-

Source: Own elaboration based on OSA data (2009-2019)

The results of the vertical control coincide with the results of the horizontal control, as most of the dossiers obtained the classification of "Without anything special to refer" or "with observations and recommendations of less relevance". The dossiers that required follow-up actions in the following period represent insignificant values, except for 2018 and 2019. Once again, it appears that the quality of the audit decreases in the years 2018 and 2019.

The dossiers with “Unsatisfactory results” disclosed minimum percentages in the vertical control, even less than in the horizontal control, in which some of them were subject to disciplinary proceedings imposed by the Disciplinary Council.

Table 5: Shortcomings / Shortcomings in Vertical Control

	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Work planning and documentation quality	-	18%	6%	4%	21%	16%	19%	16%	27%	14%	16%
Execution of work in key areas	-	62%	58%	52%	35%	35%	32%	32%	39%	35%	28%
Report	-	7%	22%	34%	27%	27%	25%	38%	22%	52%	48%
Fees charged	-	8%	4%	8%	6%	11%	12%	4%	9%	2%	2%
Others	-	5%	10%	2%	11%	11%	12%	10%	3%	2%	2%

Source: Own elaboration based on OSA data (2009-2019)

The results of the deficiencies pointed out in the vertical control are mirrored in table 5. As we can see, in 2009 the results of the deficiencies detected in the vertical control were not disclosed. In the following years, the main deficiencies are related to the execution of the work and the reporting of reservations and emphases.

The deficiencies in the execution of the audit work present very relevant values and are due to deficiencies in the audit documentation and the audit tests performed. When the auditor does not obtain sufficient and appropriate audit evidence, he/she is unable to issue an opinion with a reasonable degree of certainty, increasing the risk of the audit and, consequently, the risk of the Audit Report being distorted. These results reveal the non-compliance with ISA 500 - “Audit Evidence”.

Regarding the report, there was a lack of consistency with the conclusions drawn in the audit work and omissions in the disclosure of the Audit Report. These results lead us to affirm that the legal provisions are foreseen in article 45 of the Statute of the OSA and ISA 700 - “Forming an opinion and reporting on financial statements”, ISA 701 - “Communicating key audit matters in the independent auditor's report”, ISA 705 - “Modification of the opinion in the independent auditor’s report”, and ISA 706 - “Emphasis of matter paragraphs and other matter paragraphs in the independent auditor's report” is not being properly complied with. These results are, in a way, worrying, given that the Audit Report is a crucial document for users of financial information (Butler et al., 2004). Furthermore, Lin et al. (2011) refer that the Audit Report is an indicator of the quality of financial information. Mulyadi and Budiawan (2018) add that the Audit Report provides additional information on the financial statements for decision-making. Therefore, the fact that the Audit Report has omissions or opinions that are not properly supported can lead to poor decision making by the stakeholders, and the public interest of the audit is subverted.

Although not very relevant, vertical control discloses deficiencies in work planning and in the quality of documentation, namely in the assessment of the audited entities internal control system, as well as in the definition of audit risks, necessary resources, fees, and audit tests to be used. The deficiencies in the audit planning also demonstrate the non-compliance with ISA 320 - "Materiality in the planning and performing audit", which addresses the materiality and risk of the audit. The respective conclusions reveal a lack of organization and efficiency in the audit work, consequently, a lack of quality in the audit.

As can be seen in Table 5, the percentage of deficiencies identified in fees is reduced. Even so, fees continue to be charged with abnormally low amounts, decreasing the quality of the audit, as these are associated with less profound audit tests. Consequently, Martinez and Moraes (2014) state that the quality of the audit work may be impaired with the application of abnormal fees. Babatolu et al (2016), Kuntari et al. (2017), and Abdul-Rahman et al. (2017) also revealed that the fees received by the auditor have a significant positive effect on the quality of the audit.
The deficiencies detected and which are called "Others" are related to other errors found in the planning, execution, and conclusions of the auditors' work, including their opinions.

Conclusion

The audit must be carried out with quality and according to the auditing standards. As such, professional audit bodies have imposed quality control, both internal and external, on audit firms.

In the scope of external quality control, this article aims to analyze the results of the quality control of the audit carried out in Portugal, considering the Audit Quality Control Reports, issued between 2009 and 2019.

The results indicate that, in horizontal control, there are deficiencies in the internal quality control systems, in the human resources used, and in the fulfillment of ethical requirements, mainly, independence. In the vertical control, there are deficiencies in the execution of the audit work and the reporting of emphases and reservations. Given these results, audit firms must implement adequate internal quality control systems and invest in qualified human resources and continuous training. It is also imperative to improve the drafting of the Audit Report, essentially, because this is the output of the audit and is a vehicle for information between the auditor and stakeholders.

Despite the deficiencies pointed out, most audit firms and dossiers subject to quality control disclose satisfactory results or with observations with minimal relevance. Over the years, there has been a slight improvement in horizontal control and vertical control about unsatisfactory results or with relevant observations, except 2018 and 2019. Even so, the Quality Control Committee, in the 2019 report, states that the audit firms are sensitized to accept, in a collaborative way, the execution of quality control actions of their structures and their work dossiers, showing improvements in the consistency of the documentation of their work and the objective and impartial judgment of the quality of the work developed.

In developing this article, there were some limitations, particularly the 2009 Audit Quality Control Report, which did not allow us to identify the deficiencies pointed out in the quality controls. Even so, we consider that this study, in addition to being innovative, contributes to raising awareness among audit professionals about the importance of quality audit practice.

In the future, it would be interesting to conduct a study on the perception of audited entities and different stakeholders regarding the quality of the audit and its supervision.

Abstract

The aim of the article is to compare two approaches to measuring the quality of international trade data. The specificity of these data lies in registering them in two sources, in the countries of trading partners. The authors study data discrepancies in transactions concerning the intra-Community exchange. Information about the size of this exchange is registered in the EU's Intrastat system. A specific transaction is listed in one country as an intra-community supply of goods (ICS) and in the other country as an intra-community acquisition of goods (ICA). The compilation of this information indicates an asymmetry of data. The size of this asymmetry informs about the quality of statistical data. An important issue is the proper way of measuring this quality. In the literature, the approach using value indicators prevails, while the approach using quantity, expressed by weight of goods, is omitted. The authors conducted an empirical study in order to compare two variants of determining the aggregated data quality index. The example concerns Poland's transactions by commodity groups (CN chapters) with EU Member States (aggregation by country). The numerical example uses COMEXT data on intra-Community trade in 2017 provided by Eurostat.

Keywords: Intra-Community Trade, Asymmetry Data, Indicators of Mirror Data Quality

Introduction

Reliable statistical data is the basis for all kinds of economic analyses carried out at the national level or at the level of the European Union and the world. The public statistics services (Eurostat, national statistical offices) constantly carry out activities aimed at increasing quality, extending the scope or improving access to data. We live in times of intensive growth in the amount of collected data, Big Data analyses are being developed, including changes in the way very large data resources are collected and processed, but it's still the reliability of information that remains a fundamental aspect.

The specificity of international trade data is their bilateral nature. They are recorded in two sources. This way of collecting information makes it possible to compare the figures describing the same transaction and to identify possible discrepancies. Of course, the fact that the figures from the two registers do not fully overlap is explained by reasons such as variable exchange rates, ways of settling the costs of transport and insurance of goods, lack of obligation to register transactions by some contractors. Therefore, many researchers emphasize that a certain extent of asymmetry of international trade data is acceptable. Attempts were made by Morgenstern (1963), Federico and Tena (1991), Ferrantino and Wang (2008) to establish this acceptable range of data discrepancies. They also provide some guidance on assessing the quality of mirror data. Existing literature offers a variety of methods to study the quality of foreign trade data with different spatial and temporal ranges. The Authors of this article have also undertaken research in this area (Markowicz, Baran, 2019a, 2019b, 2020). The presented considerations explore the possibilities of analyzing data asymmetry based on value – using the value of realized transactions, as well as in quantitative terms - using information about the weight of sold and purchased goods. The second aspect we focus on is the type of indicators used in the evaluation of data discrepancies. We prefer an aggregated index. It uses the sum of absolute differences of mirror data, which makes it impossible to balance positive and negative differences between

Cite this Article as: Iwona MARKOWICZ and Paweł BARAN " Use of Intra-Community Acquisition's Value and Quantity for Calculating Mirror Data Asymmetry in International Trade" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

information from two sources. Aggregation can be done by country or commodity group. In this article, the survey of data quality was carried out by commodity groups with aggregation by EU Member States. The EU's Combined Nomenclature (CN) was used as a commodity classification, broken down by chapters (the survey covered 96 chapters). The numerical example concerns intra-community supplies of goods from Poland (data for 2017 from the Comext database). The analysis is an illustration of the problem of the mirror data asymmetry under consideration, so the time range is not important in this case. Newer data is already available at the time of writing, however, it should be taken into account that the database is still a work in progress. The work to complete the information is carried out by both Eurostat and Intrastat data units in the Member States even after publication. Therefore, considering the possible corrections of data after the so-called reconciliation rounds, slightly older data of higher quality were selected.

The aim of the article is to compare two approaches to the quality of international trade data. The authors conducted an empirical study to compare two variants of determining the aggregated data quality indicator. The example concerns Poland's transactions by commodity groups (CN departments) with European Union Member States (aggregation by country).

Literature Review

The literature review confirms that the observation of data asymmetry in foreign trade has been interesting both from statistical and fiscal perspective. Therefore, research in this area have methodological (ways of measuring the asymmetry of mirror data) as well as practical results (improvement of statistical data reliability and the possibility of detecting tax irregularities).

Although data asymmetry in foreign trade was observed earlier, Morgenstern's work (1963) was one of the first attempts to thoroughly investigate differences in data on exports and imports between several huge economies. He proposed tools to study both absolute and relative differences for the whole of a country's foreign trade as well as some indicators to study individual pairs of countries.

Methods for studying differences in mirror data proposed in the literature on the subject can be split into two main groups; techniques to study country-to-country (one-to-one) or country-to-countries (one-to-many) relations. Research on trade between pairs of countries includes Morgenstern (1963), Parniczky (1980), Ferrantino and Wang (2008), Guo (2010), Hamanaka (2012), Carrere and Grigoriou (2014). An absolute difference between the declared values of exports and imports in the trading partner countries, the relative growth, and data asymmetry indices were used. Several works focus on the analysis of differences in data on trade between a country and a group of countries (Federico, Tena, 1991; Hamanaka, 2012).

So far no universal methodology has developed to test the quality of mirror data, which would be accepted by all researchers in the area. There has been a discussion on this subject in the literature for many years. Morgenstern (1963) concluded that, with large differences in foreign trade figures, mirror data should be considered unreliable. Federico and Tena (1991) view it differently. They state that methods used earlier only check on the 'accuracy of geographical data'. According to these authors, data aggregation mostly eliminates this problem, and a better check on the reliability of the aggregated data is to compare the sum of the trade values of a country and the sum of the respecting flows recorded by the partner countries. They claim that the reliability of the data results mainly from differences in the method of accounting for transportation costs while all the reasons for data discrepancies can be divided into three groups: unavoidable (CIF and FOB, i.e. exclusion/inclusion of transportation costs), structural (different criteria for compiling statistics) and actual errors (data differs from actual flow). The errors include declaration errors due to negligence or fraud (errors may relate to weight, value, goods classification) as well as those made by statistical offices (estimation of official prices, exchange rates). E.g. lack of registration due to smuggling is often cited as the cause of data errors (Federico, Tena, 1991; Fisman, Wei, 2004; Javorcik, Narciso, 2008). Research by other authors focuses primarily on the ratio between CIF/FOB based values (Tsigas et al. 1992; Carrère, Grigoriou, 2014). These studies support the statement that the differences in mirror data are mostly due to differences in the treatment of transport and insurance costs.

Previous proposals for methods of mirror data quality measuring consist of indices of intensity and if aggregation was used, it concerned goods or countries, but when adding together the values of exports and imports (and not differences between them) separately which causes balancing of positive and negative differences and affects the measured data

quality. Measuring differences between mirror data on international trade is a task that several authors have also approached using econometric modelling (e.g. ten Cate, 2007; Ferrantino et al., 2012).

Such analysis, both with the use of data quality indices and econometric models, may support the work whose main objective is not the assessment of data quality itself, but the use of data for econometric modelling of international market phenomena, e.g. using spatial models (LeSage, Llano-Verduras, 2014). The results of modelling depend on the quality of the data used and in that respect maintaining high data quality depends on proper quality measures.

Data and Methodology

As mentioned above, discrepancies in mirror data on intra-EU trade (and more broadly international trade) are a sign of the quality of statistical data. The problem is the right way to measure the quality. In the literature there are some methodological guidelines. However, there is no ready-made solution to this problem. The authors have decided to complement the value-based approach used in the literature with a quantity-based approach. Therefore, the study used two aggregated data quality indices. The first one is based on transaction values and the second one on data concerning the weight of goods. The conclusions of numerous studies highlight the shortcomings of the analysis of international trade data in the value of goods. These usually include: variable exchange rates and taking into account transport and insurance costs. The use of data on the weight of goods is free of these defects.

In the study we used four indicators of mirror data quality – aggregated value-based index (1) and aggregated quantity-based index (2) based on traded commodity mass, complemented with two new measures: weighted aggregated value-based index (3) and weighted aggregated quantity-based index (4). We define aggregated value-based data quality index for exports (of commodity group *k*; here: CN chapter) given by:

$$ {}_{wZ}W_E^{AU}(k) = \frac{\sum_{i=1}^{n}\left|{}_{wk}E_{AB_i} - {}_{wk}I_{B_iA}\right|}{{}_{wk}K} \tag{1} $$

where:

${}_{wk}E_{AB_i}$ – declared value of exports (of commodity group *k*) from country *A* to all the other countries of a group under examination (here: to the whole EU),
${}_{wk}I_{B_iA}$ – declared mirror value of acquisitions of goods (of commodity group *k*) shipped from country *A* to all members of the group, as reported by the receiving countries,
${}_{wk}K = \sum_{i=1}^{n}\frac{\left({}_{wk}E_{AB_i} + {}_{wk}I_{B_iA}\right)}{2}$ – a hypothetical true value of the above said exports (of commodity group *k*) averaging the data reported by all sides.

A similar formula (2) provides us with a similar index using commodities' weight (quantity) instead of the value, which will later be referred to as an aggregated quantity-based data quality index (for commodity group *k*):

$$ {}_{mZ}W_E^{AU}(k) = \frac{\sum_{i=1}^{n}\left|{}_{mk}E_{AB_i} - {}_{mk}I_{B_iA}\right|}{{}_{mk}K} \tag{2} $$

where:
${}_{mk}E_{AB_i}$ – declared quantity of exports (of commodity group *k*) from country *A* to all the other countries of a group,
${}_{mk}I_{B_iA}$ – declared mirror quantity of acquisitions of goods (of commodity group *k*) shipped from country *A* to all members of the group, as reported by the receiving countries,
${}_{mk}K = \sum_{i=1}^{n}\frac{\left({}_{mk}E_{AB_i} + {}_{mk}I_{B_iA}\right)}{2}$ – a hypothetical true quantity of the above said exports (of commodity group *k*).

In addition to the above, we propose modified versions of (1) and (2). Here, we take into account weights of individual observations. The weights are equal to the share of a given group of goods in the total value (or quantity) of intra-Community supplies from Poland to the EU. We use following formulae (for commodity group *k*; here: CN chapter):

- aggregated value-based data quality index weighted with exports share

$$ {}_{wZ}^{*}W_E^{AU}(k) = \frac{\sum_{i=1}^{n}\left|{}_{wk}E_{AB_i} - {}_{wk}I_{B_iA}\right|}{{}_{wk}K} \cdot {}_{w}L(k) \tag{3} $$

where:

$_{w}L(k) = \frac{\sum_{i=1}^{n} {}_{wk}E_{AB_i}}{\sum_{k=1}^{p}\sum_{i=1}^{n} {}_{wk}E_{AB_i}} = \frac{{}_{wk}E_{AU}}{{}_{w}E_{AU}}$ – share of value of goods from a given commodity group *k* in exports total,

- aggregated quantity-based data quality index weighted with exports share

$$ {}_{m}^{*}{}_{Z}W_{E}^{AU}(k) = \frac{\sum_{i=1}^{n}\left|{}_{mk}E_{AB_i} - {}_{mk}I_{B_iA}\right|}{{}_{mk}K} \cdot {}_{m}L(k) \tag{4} $$

where:

$_{m}L(k) = \frac{\sum_{i=1}^{n} {}_{mk}E_{AB_i}}{\sum_{k=1}^{p}\sum_{i=1}^{n} {}_{mk}E_{AB_i}} = \frac{{}_{mk}E_{AU}}{{}_{m}E_{AU}}$ – share of quantity (weight) of goods from a given commodity group *k* in exports total.

In order to illustrate the declining influence of successive commodity groups with ever smaller shares of total trade between a pair of countries, indices (1) and (2) can also be compared, which are aggregated as follows. The first value is the index (1) calculated for the commodity group with the largest share in trade. Then we create an index calculated for the first two commodity groups next for the three commodity groups with the largest shares in total trade and so on. Aggregation in this way makes it possible, among other things, to indicate at which number of aggregated commodity groups the indicator does not differ significantly from the target value.

The numerical example contains Poland's exports by commodity groups (CN chapters) to the EU Member States (aggregation by country). The research was conducted in two parts. First we used value-based approach and then repeated the analysis in quantity-based approach. Each part was conducted according to the following stages:

1) Ordering of commodity groups (CN chapters) according to shares (value or weight) in exports total from Poland to EU countries.
2) Determining the aggregated data quality index (formula 1 in the first part and formula 2 in the second part) for one, two, three, ..., ninety-six CN departments, respectively. Aggregation takes place at the level of the whole EU, and therefore the absolute values of differences between the mirror data for each pair of countries (Poland – *i*-th EU country) are summed up. Such aggregation makes it possible to take into account all the differences in data, without balancing the positive and negative values.
3) Selecting the thirty most important groups of goods (in terms of shares in exports from Poland) and calculating for each of them an aggregated data quality
4) Calculating indices weighted by the shares (in value or weight) and sorting them from the highest values, i.e. from the lowest data quality.

The study designed in this way was to answer the following research questions:

- How does the value of the aggregated mirror data quality indicator change as more product groups are added (by export share)?
- What is the quality of data for the thirty CN chapters of greatest importance for Poland's intra-Community supplies of goods?
- How will the order of the CN chapters according to data quality change after weighting the indicators with total export shares?
- Will identifying commodity groups with the lowest data quality (which should be given special attention) in the two parts of the study (value-based and quantity-based approach) give similar results?

Research Results

The study was conducted in stages, as described in the previous chapter. Data quality indicators were determined for commodity groups and aggregated across EU countries. The classification according to the EU Combined Nomenclature (CN) was adopted as a division into commodity groups. This classification distinguishes chapters of goods numbered as follows 1, …, 76, 78, …, 99 (no. 77 isn't currently in use). Our study excluded two chapters; namely 98 (complete industrial plant) and 99 (special combined Nomenclature Codes) due to lack of transactions recorded. This means our study reflects Poland's trade in goods broken down into 96 chapters.

In the first part, data on the value of transactions of goods export from Poland to EU countries in 2017 were used. Commodity groups were ranked according to their share in total Polish export. The index (formula 1) for the chapter with the largest share was calculated, and then the index values were calculated after adding another chapters (Fig.

1).It turned out that already for the first department the quality index was 0.1528. Adding the next three chapters to the analysis resulted in a significant decrease in the index value and adding the next ones – its increase (diminishing). It can be concluded that the quality of total data is most affected by the chapters with the highest export value. Then, adding more groups only slightly changes the value of the indicator. This suggests that the improvement of data quality depends to a large extent on the reduction of mirror data discrepancies in some commodity groups. It is these groups that the activities of statistical and tax services should focus on.

Fig. 2 shows the values of the aggregated index (formula 1) for the 30 most important CN chapters (with the chapter number), while Fig. 3 shows the values of the index including weights (share of a given chapter in the export of goods from Poland) (formula 3). The final result of the first part of the survey is the ranking of CN chapters according to their importance in the study of the quality of data on trade between Poland and EU countries. The chapters are presented from the most important (Fig. 4), which in this case means a combination of a large difference in mirror data and a large share of trade.

Fig. 1: Values of the data quality index as a function of the number of chapters included, starting with the most important ones (chapters with the largest share in Polish exports) - value-based approach (in the order of shares)

Fig. 2: Data quality index values for the 30 most important CN chapters – value-based approach (by department number)

Fig. 3: Data quality index (weighted with shares) values for the 30 most important CN chapters – value-based approach (by department number)

Fig. 4: Ordered data quality index (weighted with shares) values for the 30 most important CN chapters – value-based approach (by department number)

The second part of the study was conducted in the same way and concerned the quantitative approach. Therefore, data expressed in quantity (mass) of goods were used here. Next, the values of the index (formula 2) for a growing number of chapters with the largest share in exports (Fig. 5), the value of the aggregated index for the 30 most important chapters of the CN (Fig. 6), the value of this index including weights (Fig. 7) and the ranking of CN chapters according to their importance in the study of data quality (Fig. 8) are presented.

Fig. 5: Values of the data quality index as a function of the number of chapters included, starting with the most important ones (chapters with the largest share in Polish exports) - quantity-based approach (in the order of shares)

Fig. 6: Data quality values for the 30 most important CN chapters – quantity-based approach (by department number)

Fig. 7: Data quality index (weighted with shares) values for the 30 most important CN chapters – quantity-based approach (by department number)

Fig. 8: Ordered data quality index (weighted with shares) values for the 30 most important CN chapters – quantity-based approach (by department number)

Conclusions

As we can see from the above charts, index values calculated in the value-based approach weighted with shares in value and index values obtained differ significantly. The values of quantity-based indices often exceed the values of value-based indices, which may result from a value-oriented definition of statistical thresholds. Although the values of quantity-based indices are higher, they are still more stable with respect to the number of commodity groups taken into account. The ordering of chapters is different in these two cases and there is no clear indication which one should be chosen. E.g. in the former case, attention should be paid first of all to chapter 87 (vehicles other than railway, their parts and accessories), and in the latter case to chapter 27 (mineral fuels, mineral oils).

The use of purely value-based or purely quantity-based approaches seems inadequate and leaves lots of interesting cases of the opposite approach unobserved. Therefore, the authors propose to conduct such data quality analysis in

two complementary approaches, taking into account data expressed in value of goods and expressed in mass of goods. This approach can be considered comprehensive.

Abstract

In Poland, after the accession to the European Union in 2004, an obligation to submit Intrastat declarations exists. The obligation applies to entities dealing with intra-Community trade in all EU countries. Statistical data are collected in individual countries (Intrastat system) and then transmitted to Eurostat. These data are symmetrical and often inconsistent. For example: there is a difference between two sets of data – data on intra-Community supply of goods (ICS) sent from Poland and data on intra-Community acquisition (ICA) coming from Poland (mirror data). The authors examine these differences broken down by Combined Nomenclature chapters and by trade partner countries. The aim of the article is to show how the selection of one of the above-mentioned data sources may influence the results of the analyses. The research was conducted on the example of Poland's trade with the EU Member States turnover. The ordering of EU countries according to the turnover and classification of countries according to the structure of goods (CN nomenclature chapters) in the scope of ICS-ICA (Poland-EU countries) and comparison of the results of the classification in time were carried out. We prove that ICS and ICA data from 2017 are more similar in structure to ICS and ICA data from 2016 respectively than to their mirror dataset from the same year.

Introduction

Intrastat system was introduced in the area of the European single market on January 1, 1993. It's main task is to record and collect data on intra-Community trade. It was also adopted by Poland and all new EU Member States after their accession took place.

Each entity carrying out intra-Community supply of goods (ICS) or intra-Community acquisition (ICA) is obliged to submit Intrastat declarations to the local customs or fiscal authorities or statistical office. In Poland, the receiver of the data in the Regional Office of Tax Administration (IAS) in Szczecin. There, a data set is created for Statistics Poland. The data, appropriately adjusted (according to Eurostat methodology), are transferred to the European Statistical Office (Eurostat) and become a part of Comext database. These data are adjusted on a monthly basis as a result of collecting some of the required data after the reporting deadline and after the estimations designed to match data from different countries are made. The need for data correction results from the differences between the information concerning the same transactions but received from two sources (countries). Although these are called mirror data, they never fully overlap. Differences between sets of data are partly explained by objective factors such as variable exchange rate, including transportation costs into the value of transaction by one of the sides and several categories of errors in declarations.

Polish system of foreign trade statistics is based on the methodology of the UN Department of Statistics, CN Combined Nomenclature (8-character) and the geonomenclature developed by Eurostat based on ISO 3166 standards. Foreign trade turnover is calculated on the basis of customs documents (trade in goods with non-EU countries) and Intrastat declarations (intra-Community trade in goods). The correctness of the Intrastat declarations is ensured by the possibility to compare the data with the data coming from the VAT declarations on intra-Community acquisitions and deliveries. Foreign trade turnover is compiled according to the 8-digit CN Combined Nomenclature, which is

Cite this Article as: Paweł BARAN and Iwona MARKOWICZ" Analysis of Intra-Community Foreign Trade of Poland on the Basis of Mirror Data" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

based on the six-digit HS Harmonized Commodity Description and Coding System and is the basic classification of goods in foreign trade. The CN nomenclature is subject to annual reviews and modifications.

The discussion on the regulation of trade and value added tax system of the European Community has been going on for many years (MacLean 1999, Hart 1994). According to the European Commission (2015), two fundamental issues related to the current tax system were identified. These are: the additional obligations and costs associated with the payment of VAT by businesses trading across borders and the significant number of VAT fraud in the EU through fraudulent transactions such as MTIC (Missing Trader Intra-Community, carousel fraud). It should be stressed that generating reliable foreign trade data is extremely important, but there are many reasons why it is not easy (Markowicz, Baran 2019a).

Taking into account public statistics, in the initial period of Poland's existence in the EU, total imports of goods exceeded exports in the net balance of foreign trade. In intra-EU trade, the value of purchased goods also exceeded the value of deliveries to EU countries. The values of exports and imports are similar starting 2013. On the other hand, supplies and purchases of goods in intra-EU exchange became equal as early as in 2009, and since 2012 the balance of Polish trade with EU countries is both positive and increasing (Fig. 1).

Fig. 1: Polish foreign trade turnover in total and with EU countries (values of imports and ICA given by country of dispatch) in the years 2004-2018 (million EUR)

Source: GUS, SWAID, Foreign trade turnover by groups of countries.

It should be emphasized that many economic studies, which are the basis of knowledge about intra-Community trade and foreign trade in general, are based on public statistics. Therefore, the quality of these data is of huge importance in both the study of the current state and the forecasting of numerous economic phenomena.

The aim of the article is to indicate the impact that the choice of one of the mirror data sources may have on the results of the analyses. The differences are shown on the examples of ranking the EU countries according to the trade turnover with Poland, and of clustering the EU Member States according to the structure of trade in goods varying within the pairs ICS vs. mirror ICA (goods shipped from Poland to the other EU countries) and in time. The importance and benefits of foreign trade of countries are treated, for example, by works: Helpman (1999), Rymarczyk (2012), Salamaga (2017). The authors are interested in the study of asymmetry (research methods, causes) in intra-Community trade data (Baran, Markowicz, 2019).

The aim of the article is to indicate the impact that the choice of one of the mirror data sources may have on the results of the analyses. The differences are shown on the examples of ranking the EU countries according to the trade turnover with Poland, and of clustering the EU Member States according to the structure of trade in goods varying within the pairs ICS vs. mirror ICA (goods shipped from Poland to the other EU countries) and in time.

Statistical Data and Research Methodology

The data used in the survey are derived from Eurostat's Comext database. On the one hand, the values of intra-Community supplies of goods from Poland in 2016 and 2017 broken down by countries and chapters of the CN was analysed. These are the values declared by Polish entities and adjusted by Statistics Poland according to the methodology provided by Eurostat. On the other hand, the values of acquisitions from Poland to all other EU countries, declared by contractors of Polish entities and again adjusted by national statistical offices, are examined. These values differ to some extent, but it turns out that the differences between ICS and mirror ICA are large, both positive (advantage of values in Polish declarations of goods export) and negative (advantage of values in declarations of goods import from Poland to EU countries) only for a number of chapters. The statistical data used (for 2016 and 2017) are old enough to be considered reliable. More recent data are already available, but we know from experience that they are still updated during the so-called reconciliation rounds.

There are numerous reasons for the differences between ICS and the mirror ICA including introduction of thresholds above which entities are obliged to submit declarations (different for export and import and in different EU countries), hiding transactions from taxation, declaring fictitious transactions (tax carousels) as well as plain errors in declarations (wrong commodity codes, wrong transaction values).

The study consisted of several parts:

1. Ordering the EU countries according to the value of turnover with Poland to show differences between ICS and mirror ICA in 2016 and 2017,
2. Clustering the countries of Poland's trade partners according to the structure of goods deliveries (ICS) and mirror purchases (ICA) from Poland in 2016 and 2017,
3. Similarity analysis between different groupings in pairs:
   - ICS 2016 vs. mirror ICA 2016 (mirror data compared),
   - ICS 2017 vs. mirror ICA 2017 (mirror data compared),
   - ICS 2016 vs. ICS 2017,
   - Mirror ICA 2016 vs. mirror ICA 2017.

A data unit (an object) in the survey is a vector containing all the information about the ICS from Poland to a specific Member State. Its characteristics (variables) are the shares of individual CN chapters in total trade. Another, more complex approach, in which exports from many countries (i.e., data matrix) are taken as data units, was presented by Salamaga (2017) in a paper in which he compared the full structure of foreign trade of 18 EU member states. A different approach to differences (changes) in structure is presented by Landesmann (2000), who refers to structural changes in two ways: changes in the structure of data (production, employment, exports, etc.) and changes in the way variables are interrelated. This approach to structure comparison was inadequate for the purpose of our study.

In this paper we attempted to group EU Member States as destinations of Polish foreign trade. In order to separate groups of countries with a similar structure of goods purchased in Poland, a hierarchical clustering of buyers' countries was applied. The advantages of agglomerative methods include a single calculation procedure, presentation of the results in the form of a classification sequence, and the possibility of graphical presentation that indicates the order of merging objects in the classes (Gatnar, Walesiak, 2004). In the following analysis the Euclidean distance, min-max feature scaling and the Ward method are used. More about the methods and assumptions of object classification can be found in the papers: Anderberg (1973), Kaufman and Rousseeuw (1990), Gordon (1999), Jajuga and Walesiak (2000), Walesiak and Dudek (2010), Markowska et al (2016).

Before the agglomeration procedure was launched, the data were pre-processed – both raw data, i.e. concerning the recorded ICS volumes, and data describing the structures (where values in the rows of the matrix are shares adding up to 1) were normalized. Such a non-classical approach has been applied due to the fact that the shares of particular commodity groups (CN chapters) in the structure of trade with different countries vary significantly: the shares of some chapters are even several orders of magnitude higher than another. Therefore, the use of non-standardized data makes the countries in which only a few largest shares of commodity groups are equivalent look falsely similar. The additional normalization of the columns of the data frame highlights the similarities covering specific trade, e.g. niche products, characteristic to some directions.

Research Results

The research was conducted in three stages. The first stage included ordering the EU countries (27) according to the volume of trade in goods with Poland. Total turnover values were used here, without taking into account commodity groups. It turns out that the order of Poland's trade partner countries established on the basis of ICS and mirror ICA values is not the same (Fig. 2 and 3). Therefore, even simply determining the significance of particular directions of export from Poland, we encounter methodical problems connected with the selection of statistical data.

Fig. 2: Ranking of EU countries in terms of value of turnover with Poland: export from Poland (ICS; list on the left) and mirror import from Poland (mirror ICA; list on the right) in 2016
Source: own study based on COMEXT database

The biggest differences in the results of the ranking, i.e. in determining the importance of individual trade partner countries of Poland in 2016, are for Sweden and Greece, whose positions are higher when considering the values declared by Polish businesses and lower when considering the values declared by partners in these countries (Fig. 2). For some countries, however, the position is higher in the ranking based on the mirror data.

In 2017 we notice slightly smaller changes, but among the countries that have a higher position on the side of Polish ICS, we can still observe Sweden, Greece and Ireland. On the other hand, Spain, Slovenia and Croatia are among the countries that gain ranking positions using mirror data the same way they did in previous year (identical change, from places 8, 23 and 24 to 7, 21 and 22). One possible explanation is that there are permanent causes for inconsistencies in trade data with these countries.

Fig. 3: Ranking of EU countries in terms of value of turnover with Poland: export from Poland (ICS; list on the left) and mirror import from Poland (mirror ICA; list on the right) in 2017

Source: own study based on COMEXT database

The second stage of the study included a hierarchical clustering of Poland's trade partner countries according to the commodity structure of supplies (ICS) and mirror acquisition (ICA) from Poland in 2016 and 2017. The results of the grouping procedures are presented in Fig. 4-7. The obtained groups of countries only partially overlap. Particularly important are the differences in the results concerning the same year and obtained for the mirror data sets. Considering the results for 2016 (Fig. 4 and 5), depending on the choice of the linkage level, it is possible to establish from 3 to 6 groups, with the most obvious division into 4-5 groups in case of data concerning ICS and 6 groups for the case of mirror ICA. In case of the analysis for 2017 data, 5 groups were created for the data concerning the ICS and 6 groups for the mirror ICA. Individual groups both in 2016 and 2017 only partially overlap. It proves the unequal commodity structure declared by Polish and foreign trade partners.

Source: own study based on COMEXT database

Fig.7: Grouping of EU countries by commodity structure (CN chapters) ICA from Poland (contractors' declarations) in 2017

Source: own study based on COMEXT database

For comparison, we quote the results of the study, presented in the paper by Baran and Markowicz (2018). The data on Polish ICS to each of the EU countries in 2016 were confronted with the data on mirror ICA values, thus obtaining a vector of data discrepancies by commodity groups. As a result of comparing the structure of such vectors with a simple structure similarity index (Chomątowski, Sokołowski, 1978) a matrix of similarities was obtained and the results were interpreted. Among the most similar structures of discrepancies in exports originating in Poland were the pairs like Greece and Cyprus (W_{ij} = 0.55), then Estonia and Latvia (W_{ij} = 0.49), Cyprus and Malta (W_{ij} = 0.49), and Greece and Croatia (W_{ij} = 0.48). Croatia and Sweden were indicated as countries quite similar to many others in terms of the structure of improperly reported exports or imports from Poland, while the structure for Bulgaria was the least similar to other structures. However, these are results based on data on discrepancies in the declarations, the data were not standardised, so the similarity was de facto determined on the basis of a small number of the largest commodity groups (e.g. in the case of Greece and Cyprus, these were chapters 85 – electrical machinery and equipment and parts thereof and 89 – ships, boats and floating structures). There was also a grouping of EU countries presented based on the commodity structure of Polish trade (Baran, Markowicz, 2018). A standard procedure was decided upon – raw data on the size of the ICS in particular directions broken down into CN chapters was standardized and then an agglomeration procedure was performed. Such an approach did not give satisfactory results, because the normalization of the columns of the observation matrix kept the information about the relative volume of trade in goods. The countries were therefore divided into three groups, which can be described as "the largest trade partner – Germany", "countries with large trade with Poland", "other countries". A proper algorithm that circumvents the above mentioned shortcomings must therefore take into account the relative importance of countries in certain commodity groups trade.

The third stage of the study concerned the analysis of similarity between groupings in the following pairs: ICS 2016 vs. ICA 2016 (its mirror data), ICS 2017 vs. ICA 2017 (again mirror data), ICS 2016 vs. ICS 2017 (data from the same source, delayed one year), ICA 2016 (mirror acquisitions to supplies originating in Poland) vs. ICA 2017 (data from the same source, delayed). The correlation between the groupings of Poland's trade partner countries was examined using Baker's Γ index (Baker, 1974). The results obtained (Table 1) indicate greater similarity of groupings obtained in different years for the same type of data (ICS 2016 and ICS 2017 and ICA 2016 and ICA 2017) than for mirror data from the same year (ICS and ICA in a given year). This result is surprising. It is also confirmed by the Bk index (Fowlkes, Mallows 1983), which was calculated as a function of the number of classes changing from 2 to *n*–1 (Fig. 8). Higher values mean similar groupings. Higher values of the index confirm the similarity of the groupings for ICS in both years and for ICA in both years, while lower values occur when comparing mirror data from the same year.

Table 1: Correlation between dendrograms (index Γ Baker)

Correlation	ICS 2016	ICA 2016	ICS 2017	ICA 2017
ICS 2016	1	0.3537	0.7796	0.2484
ICA 2016	0.3537	1	0.3753	0.7128
ICS 2017	0.7796	0.3753	1	0.2674
ICA 2017	0.2484	0.7128	0.2674	1

Conclusions

The study shows that there are large differences between the values of turnover declared in Poland (ICS; goods shipped from Poland) and those collected from declarations from other EU Member States (ICA; goods originating from Poland). These differences concern the total turnover as well as the structure of trade in goods. Researchers must be cautious about the data collected from statistical declarations made by companies in a given country, because their reliability is questionable. Mirror datasets contain a relatively huge amount of data not contained in their counterpart. The article points out some differences in the results of the analyses conducted using data from two mirror sources. Differences may occur both in ordering the countries according to the value of turnover as well as in clustering the countries according to the structure of trade exchange. According to the authors, the research on comparability of data concerning intra-community (and foreign trade in general) should be continued. The authors plan to carry out further research in order to develop the research framework for mirror data analysis. In applications, analyses should be carried out as widely as possible, paying particular attention to the various results obtained by selecting only one of the mirror data sources.

Acknowledgment

The work is a part of a project financed within the framework of the program of the Minister of Science and Higher Education under the name “Regional Excellence Initiative” in the years 2019–2022; project number 001/RID/2018/19; the amount of financing PLN 10,684,000.

Abstract

The Durability Key Life testing is an essential step in determining the expected life of a vehicle. It increases repeatability and reduces risk exposure by detecting defects at an earlier stage in the vehicle development process, whether of the full-vehicle, subsystem or component level is tested. The paper presents the characterization of the Accelerated Durability Key Life Test method and post-test measurements made after testing, applied on the automotive side doors, aiming to support the evaluation of the real-life of a vehicle component at an accelerated pace. The main objective of the paper is to validate the design of automotive components, by using the Key life test method and related test measurements required by the working procedure. The paper intends to highlight possible failure modes and the factors that contributed to it. Thus, the paper presents the detailed process of the key life test method and the measurement results of gap and flushness, torque and shut speed of the side doors. Following the results, the need to meet customer expectations in terms of quality, durability and reliability of the Key life test has increased.

Keywords: Accelerated Durability, Reliability, Key Life Test, Methods, Side Doors, Validation.

Introduction

The focus of this paper is to review the theoretical background and discuss the pros and cons of commonly used Accelerated Durability demonstration test methods. Durability is the ability of an object (material, subcomponent, component or whole machine) to perform a given function under given conditions of use and maintenance until reaching a limiting state. The measurement of durability consists of its length of time (hours, months or years) or its volume of work.

Key Life testing of vehicles and vehicle components is necessary for manufacturers during the research and development process as well as for validation and certification. Tests of a vehicle's durability are used for determining the expected lifetime by simulating environmental conditions. The expected lifetime is then simulated in a compressed manner, where the vehicle undergoes a long-term test, while normally being controlled by an automatic driving system.

Accelerated Durability Testing based on a combination of many types of accelerated tests (field, laboratory, multi - environment, mechanical, electrical etc.) integrated with safety and human factors helps to solve the identified problems. The simple definition of Accelerated Durability Testing technology is a "complex" composed of specific testing methodologies, equipment and usage that influence accurate prediction and successful accelerated development of product quality, reliability, durability, maintainability, availability and supportability.

In this paper we described the concept of the Key Life Test method for determining and measuring the current performance of a side door system, to validate the developed automotive product.

According to Ronald H. Salzman and Scott L. Ciemniecki (1997), a Key Life Test is an accelerated test designed to detect a major component failure and the main objective of this type of testing is the development of a model to improve quality by designing reliability into the product. Similar ideas are found at the authors Francis G. Pascual and Luis A. Escobar (2006), Yung-Li Lee (2015), Lev M. Klystin (2012).

Stuart Lebowitz and Craig T. Hodorek, (1996) said in his work that the main purpose of this approach is to keep with corporate objectives to increase customer satisfaction of long-term reliability, accelerated testing and relating more accurately testing results to the real world appears essential. Similar ideas had the authors Andrew W. Bur, Peter P. Dierauer and Lamar F. Ricks, (2003).

Analysis of the Current Situation

A successful product design development process needs to serve as the foundation of how a company will develop products that will delight its customers and improve their loyalty by providing value through optimization of quality and durability. Therefore, it should be prevented precisely the actions that lead to delays in development, time to market and increase costs related to:

- Design time and result
- Customer satisfaction and expense
- Maintenance frequency, cost and access
- Warranty costs and recalls
- Degradation of product/process over time
- Failures during time intervals and warranty periods
- Quality requirements and analysis
- Product safety
- Human factors

During the design and manufacturing process, one evaluates the quantitative characteristics of product quality, reliability, durability and maintainability [Nae I. & Severin I., Lascu E.a.o., Vizireanu E. & Severin I., Severin I. a.o, Mitrache I. a.o, Stinga F. a.o].

Necessary tests are selected to verify and validate the characteristics of these parameters. The tests are planned to control, review and document the following requirements:

- Test plans or specifications identify the product being tested and the resources being used to define test objectives and conditions, to identify the parameters to be recorded and to determine the relevant acceptance criteria.
- Test procedures describe the method of operation, the performance of the test and recording of the results.
- The correct standard configuration of the product is submitted for the test.
- The requirements of the test plan and the test procedures are observed.
- Acceptance criteria are met.

Measurement, analysis and improvement include:

- Design verification (including durability, maintainability and safety)
- Process control
- Selection and inspection of key characteristics
- Process capability measurements
- Statistical process control
- Inspection - matching the sampling rate to the criticality of the product and to the process capability
- Failure modes and effects analysis.

The quality control process consists of the measurement of parameters during design and manufacturing, comparison with drawing requirements, evaluation of measured values, calibration and the determination of criteria and methods needed to ensure that operation and control of the processes are effective.

Key Life Tests of side doors for Automotive Product Development

In product development, the design validation is mainly based on physical Key life tests (KLT), as a trial to satisfy the product durability requirements. A typical side doors physical key life test takes about 60 days, as well as significant costs associated with prototypes, facility, re-tooling and manpower.

There are also many additional pre- and post-key life test tasks to be performed for a physical key life test, such as fabrication of test Rig (support structure), building up side doors structure, pre-test measurement for side doors gap and flushness, torque measurements, check arm, door opening efforts and set-up of cycling; post-durability gap and flushness, torque measurements, check arm, door opening efforts, inspection, engineering report etc.

A delay from any suppliers or customers will put the whole Rig and doors assembly prototype on-wait and thus increase the development time and cost. Moreover, each Side door project involves, several physical tests (Accelerated Environmental Ageing, Resistance to Heat Ageing, Humidity testing etc.) during the product development process, for various reasons, such as component failures, re-design, re-validation, changes in designs, materials and / or suppliers.

Test Procedure Description

The Side doors Key Life Test procedure specifies the performance requirements and test methods for door locks and door retention components of vehicles. The procedure describes that the side door system has been subjected to a door slam durability test, which states: The side door system shall have a useful life of 10 years/240,000 km (150,000 miles) 84,000k slams. This will be demonstrated by completing the Side Door Key Life Test without any Functional or Attribute failures, as identified in the DVM (Design Verification Method - Document produced as part of an Engineering standard to ensure consistency of work) pass or fail criteria.

To validate Side Doors Key Life Test, the entire assembly of Rigs and doors are tested in a climate chamber, specially arranged and set, according to the working procedure, as shown in Fig.1 below:

Fig.1: Temperature cycling according KLT Procedure

Test Method Description

The Key Life Test shall be performed using the required design of side door system, verified by the test requestor(s), along with representative painted vehicle or buck, to evaluate the durability, fit and function of the systems.

In order to perform the test, the following aspects will be taken into account in order to carefully evaluate each detail:

Table 1: General requirements

Durability KLT	**To complete 84,000 cycles**	**Average**
Torque testing	Torque shall Not Fall Below 70% of Minimum Torque.	Nominal Torque (Nm): Hinge – 35 Nm Check arm body- 25 Nm Check arm door – 9 Nm Latch / Striker – 7 Nm to 25 Nm
Door hinge contribution to door cyclic drop off	The clamping fixture for the test shall be rigid enough to prevent the door locks or door hinges from sustaining extra local pressure during the test.	Drop Off 2.0mm Maximum
Side Door Slam - Open Durability	No functional failures after slam open cycles.	
Paint Protection From Door Slam Damage	No Paint Damage	
Door Opening Efforts	Measure Opening Efforts	The nominal speed - 0.88 m/s to 1.5Nm
To monitor the fender louvres during the side doors KLT	Remain functional	
Door Trim Panel KLT	To complete 84,000 cycles - examine for failures.	To perform half way for Side doors - 42, 000 cycles should be complete.
Outside Handle Release Efforts	Measure release Loads	25N to 60N
Outside Door Lock Efforts	Measure the Torque required to Lock and Unlock	0.1Nm to 1.4Nm
Outside Door Lock Key Insertion/ Extraction Efforts	Measure the Insertion/ Extraction Loads.	< 10N
Outside Handle travel	Measure the Outside Handle travel	
Inside Handle Release Efforts	Measure Opening Efforts	15N to 30N
Resistance To Door Slam Forces - Power Glass Adjustment	Work through KLT	

Equipment and facilities:

- All test equipment must have up to date calibration and certification.
- Environmental chamber, large enough to contain the door pillar with door subsystem, test rig or whole buck and the testing fixture. Test can also be performed on a whole vehicle if required, thus larger environmental chamber may be used.

- Force gauge or other mechanism to conduct the following load case measurements:
  - Peak effort to open (effort to unlatch push-push device).
  - Breakaway effort from full closed.
  - Breakaway effort from full open,
  - Peak effort to close (effort to latch push-push device).

- Programmable Logic Controller to actuate the pneumatic rig, and also provide closed loop control feedback via subsystem switches.
- The measurements will be performed as shown in Fig.1 above, in Measurement points. Measurements such as Gap and Flushness, presented in the results Table 4 & 5 below.
- The chamber must be capable of maintaining constant temperatures of -40 °C ± 2 °C and +82 °C ± 2 °C, with 85 % ± 5 % humidity at 40 °C ± 2 °C.

Fig.2: Automotive Door Slam - LHS Cyclic System

[https://www.encopim.com/driver-interface/automotive-door-slam]

The Fig. 2 describes the interior cycling method by which the side doors were cycled during testing, as follows: Once the door is closed, a micro-switch confirms the position and the door unlocks. A roller wheel was used to push the door into the fully open position by moving along the top roll area of the door card. Cylinder extension was attached to the interior rig assembling and was used to pull the door out of the fully open position; the door was then allowed to fall freely into the fully closed position.

Comments on Results

The application of Accelerated Key life test method will focus, as mentioned above, on the development of the following stages:

- The study of field conditions to determine the important parameters that are to be simulated in the laboratory
- Develop an accurate (by quality and quantity) simulation of the field conditions.
- Introduce accelerated durability testing, including the analysis and management of the causes of degradation (failures)
- Development recommendations for eliminating the causes of failures and degradation

- Make an accurate prediction of durability, maintainability and life cycle costs
- Accelerate the development of the product.

Thus, using the Key life test method and the related measurements, required according to the test procedure, the following resulted:

Shut Speed Measurements

The speed defined by the test procedure is the minimum identified shut speed plus 10% as shown in table 2:

Table 2: Shut speed

Temperature profile [°C]	Front Door [m/s]			Rear Door [m/s]		
	min	set	Interior	min	set	Interior
pre test	1	1.1	1.2	0.81	0.91	1.15
45/95	1.1	1.2	1.2	1	1.1	1.2
82	1	1.1	1.1	1.15	1.25	1.3
4	1	1.1	1.1	1.15	1.25	1.3
-4	1.05	1.15	1.25	1.15	1.25	1.3
-20	1.15	1.25	1.35	1.15	1.25	1.3
-40	Manual Cycling					
22	1	1.1	1.2	0.81	0.91	1.15

The nominal speed for Front Door is 0.88 m/s and for Rear Door is 1.08m/s (increased by 10%). The measurement of the door closing speed was measured with EZSpeed gauge. It is a compact unit system that mounts via a vacuum cup on the body. EZSpeed measures the speed of the door while closing and calculates the minimum closing speed.

Gap and Flushness Measurements

During final assembly verification, it is checked that the car's panels are joined correctly and adhere to strict dimensional specifications. Doors must lie flush with one another so that they do not pinch near the base. This requires highly accurate gauging of critical gaps or flushness and clearances.

Fig 3. Gap and Flushness measurement points (see details in Table 3)

The measurement methodology must be in accordance with the design criteria. This means that an instrument must have the flexibility to make several different types of measurements and the repeatability of the measurements must be in the

range of 0.20 mm, as seen in Fig.3.

Table 3: Gap and Flushness cut plane description

Cut Plane	Description
A	Front Edge below waist
B	Front Edge above waist
C1 / C2	Rear Edge below waist
D1 / D2	Rear Edge above waist
E	Top Frame Front
F	Top Frame Rear
G	Lower Front
H	Lower Rear

Exterior gaps can be as large as 4.0 or 5.0 millimeters and as small as no gap at all. The gap design can have square-edges or very large radii and the panels can be flat, curved or at a 90° angle to each other. Flush measurements are difficult because of the complex surfaces at the joints. The measurement instrument must be flexible in its methodologies to accommodate all of these features.

The Gap and Flushness test measurements results, required according to the test procedure are presented in tables 4 and 5:

Table 4: Gap measurements

Door Gaps	Right Hand Front Door				
	Start of Test [mm]	25% of Test [mm]	50% of Test [mm]	75% of Test [mm]	End of Test [mm]
B - Front Edge below waist	2.28	2.10	2.97	2.36	2.26
C1 - Front Edge above waist	2.90	2.90	3.05	3,43	3.55
C2 - Front Edge above waist	3.11	3.06	3.95	3.50	2.99
D - Top Frame Front	3.70	4.78	5.40	5.14	5.47
E - Top Frame Rear	2.23	2.41	3.42	3.20	3.19
F - Rear edge above waist	4.40	4.37	5.22	5.04	5.14

Table 5: Flush measurements

Door Flushness	Right Hand Front Door				
	Start of Test [mm]	25% of Test [mm]	50% of Test [mm]	75% of Test [mm]	End of Test [mm]
B - Front Edge below waist	-4.62	-5.40	-5.02	-5.50	-5.61
C1 - Front Edge above waist	0.11	0.41	0.48	0.41	0.40
C2 - Front Edge above waist	1.97	2.20	1.99	1.83	1.88
D - Top Frame Front	-0.06	-0.12	-0.15	-0.20	-0.18
E - Top Frame Rear	-2.40	-2.66	-3.19	-3.14	-3.50
F - Rear edge above waist	-1.92	-2.40	-2.74	-3.00	-3.30

Based on the results obtained in Table 4 & 5, the Key Life Test process was found to be a useful procedure for accelerated life. As can be seen in graphical form, in Fig. 4 & 5 below, the failure mode is insignificant, taking into account the lifespan of the side door.

Fig 4. Gap measurement results

Starting with the *Start of test* and ending with the *End of test* shown in Fig.4, all specimens measured similarly. The shape of the trends is similar in Fig 5, as well. The maximum change of the gaps is 0.75mm, accepted by the test specifications.

Fig. 5: Flushness measurement results

Certainly, the failures tended to occur at or soon after, the hot and humid cycles (40 °C ± 2 °C and +82 °C ± 2 °C), where plastic components traditionally struggle.

Torque measurements - Closing Module panel ('crack off' = anti-clockwise)

The method for determining indirect torque is the reaction force measurement method, where the force applied to the end of the lever arm is measured using a force transducer. Torque is then determined indirectly through measurement of certain auxiliary quantities in the drive train.

Fig. 6: LH Front door module plate positions

The torque checks showed the expected amount of torque relaxation, without fastener movement for all fixings on the module plate, resulting in a lower torque to undo than was applied in the first place, as shown in Table 6 below:

Table 6: Torque test results

Torque measurements	**Spec [Nm]**	**Set [Nm]**	**Crack off [Nm]**	**Retorque [Nm]**
LH Front closing panel Clockwise from top rear				
1	2.2	2.2	1.1	1.2
2	2.2	2.2	1	0.9
3	2.2	2.2	0.8	0.5
4	2.2	2.2	0.9	1
5	2.2	2.2	1	1.1
6	2.2	2.2	1	1.1
7	2.2	2.2	1	1.3
8	2.2	2.2	1.3	1.4
9	2.2	2.2	1.2	1.1
10	2.2	2.2	1	1.3

The graph in Fig.7 shows that the minimum requirement of 2.2 Nm was not achieved in any of the 10 measured positions.

Fig. 7: Graph of Torque results

The torque results, presented above, show the components failure mode and thus, the analysis and design improvement is necessary.

Conclusion

In order to control the Key life test, a thorough organization and knowledge of the technical elements underlying the test method is required. Accurate simulation of real - world conditions requires full simulation of the field input influences integrated with safety and human factors.

As a result of this study, the side doors key life test met the criteria according to test procedure. The measurement checks showed no particularly outstanding results. During post-test inspection, primarily it will look at torque relaxation at the hinges, physical inspections for cracks in stress areas (hinge, strut and latch) and general performance of the doors. With margin, flush and gaps measured before and after.

The tests are currently performed in automotive companies or in specialized technical laboratories. The tests are performed according to ISO / IEC 17025 - Testing and calibration laboratories and the working procedure of the Key Life test side doors system. The study aimed to analyze the results of the test method, in order to sustainably improve customer satisfaction. A similar test method can be applied to different components issued, but a thorough approach is needed to track and report relevant results.

Abstract

Educational institutions in recent years have followed a dynamic process of transformation and implementation of new technologies that are marked by flexibility and innovation in teaching methods. The use of educational games in higher education has roused the interest of researchers all over the world, as it is a tool that triggers the interest of students and represents an opportunity to encourage the participation and motivation in the teaching process while developing transversal competences. This work aims to analyse the use of educational games in South America, North America, and Europe in order to compare these experiences in different contexts in higher education. Through the analysis of the available literature, it is possible to obtain an overview of the reality and development of these practices and how they are meeting the needs of scholars in the face of the great diversity of the student population around the world. It also collects examples of successful development of Game based learning (GBL) in various fields of study and in the development of transversal skills.

Keywords: Game based Learning, Educational games, Gamification, Higher Education

Introduction

In recent years, all over the world, higher education has faced challenges to improve and innovate teaching practices to provide knowledge, develop skills and foster student engagement and participation in class. The aim of gamification is to offer the user an innovative experience through the use of game concepts and elements in an educative context. Gamification applications have been explored, and applied in a variety of different fields, including education, finance, health, and sustainability (Ibrahim and Ibrahim, 2020).

Different authors (Safapour, Kermanshachi and Taneja, 2019),(Hosseini and Mostafapour, 2019),(Kikot, Fernandes and Costa, 2015),(Kinio *et al.*, 2019),(Ibrahim and Ibrahim, 2020) demonstrate in their studies that GBL and gamification tools in higher education improves planning, problem-solving skills, creativity and intrinsic motivation to learn technical subjects. Moreover, at the end of a course that invest also in the development of soft skills and control of emotions, the student will be better prepared in the face of relationships and situations and will become a more productive individual and a successful professional (Almeida, 2020).

Cite this Article as: Jessica REUTER, Marta FERREIRA DIAS, Marlene AMORIM, Claudia VELOSO , Claudia FIGUEIREDO and Elisabete VIEIRA "Game Based Learning in Higher Education: A Multicountry Analysis" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

To obtain better results in gamification, it is important that the game design well-constructed, in order to promote motivation, social interaction and competition among the participants. Moreover, the range of options and autonomy of the participants are fundamental, as it is in "trial and error" that the student will reflect and experience the consequences of his choices and, within it, develop critical thinking (Gómez Contreras, 2020).

Game based learning practices consistent with the disciplines and learning levels of students, if implemented correctly, can be an effective tool for modern education. Together with traditional methods, students will learn and develop skills through mixed teaching methods (Hosseini and Mostafapour, 2019). The way games are taught and the guidance in instructional design have a great influence on the motivation, performance and success of this tool (Uukkivi, A., & Labanova, 2018).

In this sense, this work analyses the scenario of GBL building on a review of publications on the subject in Europe, North and South America, notably concerning the adoption and development of specific tools in higher education.

Methodology

In this study we conducted a descriptive literature review through the interpretative analysis of bibliographic documents (Schlagenhaufer, Amberg and Michael, 2015). This approach is a descriptive review methodology that involves the search of relevant documents in an area of interest through of the search of certain characteristics of the subject investigated.

Initially, the data selection was carried out on the scientific basis of Scopus and the Web of Science, with the key words: gamification or game-based learning or educational games. We then restricted the selection to research papers. In this collection of articles, we have selected only the experiences in Europe, North America and South America in the period from 2015 to 2020. Finally, we limited the selection for those articles applied to the specific context of higher education. At the end of this selection and after eliminating the duplicate articles, we were left with 82 articles that we proceed by reading the abstract and introduction to identify the affinity of the article with the aims of the study. In this analysis of the articles, we looked for those who conducted systematic and bibliographical reviews on gamification, game-based learning or educational games as well as those who reported the application of these strategies in higher education. In addition, we sought to analyse the convergences, divergences and complementarities between them. Finally, we retained 66 article type documents from 23 different countries in Europe, North and South America.

Results

In the 66 articles analysed in this study we are dedicated to understand experiences and examples of gamification in the defined countries. Regarding the number of publications per year, in 2015 we registered 5 publications, 2016 another 5, in 2017 there were 9 publications, in 2018 we registered 13, in 2019 we registered 20 and until August 2020 we selected 14 publications on the subject. This shows how much the subject has been gaining space with researchers in recent years.

In Table 1, we observe the areas of study and the types of GLB with the highest occurrence within each studied zone. We note that in Europe, South America and North America we have studies of the three main areas of study: exact sciences, human sciences and biological sciences.

In the fields of science where GBL's tools are applied, the most prominent areas are engineering, computer science, accounting, health sciences and foreign language. Moreover, the most common types of games in the application of this tool, which appear in all the documents analysed, are digital games, mobile games, escape room, board games, alternative reality games and Puzzles. It is important to highlight that most of the articles found in the area are about literature reviews, and therefore there is no application of the tool in a specific area.

Table 1: Summary of science fields and types of games by region

	Europe	N	South America	N	North America	N
Field of Science	Engineering	[10]	Accounting	[11],[7]	Health Sciences	[5]

In table 1, where figures refer to the authors: [5] (Kinio *et al.*, 2019), [10] (Ivanova, Kozov and Zlatarov, 2019), [11] (Alves, Silva and Damasceno, 2019),[12] (Grivokostopoulou, Kovas and Perikos, 2019), [13] (Kutun and Schmidt, 2018), [14] (Guerrero, 2015), [15] (Chrysanthou *et al.*, 2018), [16] (Rich *et al.*, 2019), [17] (Buckley and Doyle, 2016), [18] (zabala-Vargas, S., Ardila-Segovia, D., Garcia-Mora, L., Benito-crosetti, 2019), [19] (Brown *et al.*, 2018), [20] (Ferreiro-González *et al.*, 2019), [21] (Gonzalo-Iglesia, Lozano-Monterrubio and Prades-Tena, 2018), [22] (Corsi D., Dominguez F., 2019), [23] (Dubreil, 2020), [24] (Barr, 2018), [25] (Barr, 2017), [26] (Vélez *et al.*, 2019), [27] (Hernández *et al.*,2016),[28] (Gómez-Urquiza *et al.*, 2019), [29] (Esteves *et al.*, 2018), [30] (Rodriguez-oroz, D., Gómez-Espina, R., Perez, M., Truyol, 2019), [31] (Hosseini and Mostafapour, 2019), [32] (Welbers *et al.*, 2019), [33] (Turner *et al.*, 2018), [34](Vlachopoulos and Makri, 2017), [35](Hernández-Horta, Monroy-Reza and Jiménez-García, 2018), [36] (Fotaris and Mastoras, 2019), [37] (Torres-toukoumidis and Romero-rodríguez, 2018).

The Table 2 shows the number of publications in the 23 countries analysed. The countries with the largest number of publications on the subject are Spain and the United Kingdom in Europe, the United States in North America and Brazil and Colombia in South America. If we make an analogy with the expenditure on higher education in 2015, taken from the world bank (World Bank, 2020) in millions of dollars, we see that in North America the United States leads the rank, with more than 244 million spent on tertiary education, Canada and Mexico have more modest figures. For Europe, of the countries with selected GBL publications in our study, the highlights are Germany ($ 51,878 million), the United Kingdom ($ 34,639 million) and Spain ($ 16,352 million), and with the exception of Germany, these are the countries with the highest number of publications. In South America, among the countries selected with GBL articles, Brazil leads the top expenditure with the tertiary education (44,600 million), followed by Argentina (10,800 million) and Colombia (6,553 million). With the exception of Argentina, the South America countries are the ones where we find the largest number of publications in the area.

In table 2, where figures refer to the authors: [1] (Ibrahim and Ibrahim, 2020), [2] (Safapour, Kermanshachi and Taneja, 2019),[4] (Kikot, Fernandes and Costa, 2015), [5] (Kinio *et al.*, 2019), [6] (Almeida, 2020), [7] (Gómez Contreras, 2020), [8] (Uukkivi, A., & Labanova, 2018), [10] (Ivanova, Kozov and Zlatarov, 2019), [11] (Alves, Silva and Damasceno, 2019), [12] (Grivokostopoulou, Kovas and Perikos, 2019), [13] (Kutun and Schmidt, 2018), [14] (Guerrero, 2015), [15] (Chrysanthou *et al.*, 2018), [16] (Rich *et al.*, 2019), [17] (Buckley and Doyle, 2016), [18] (zabala-Vargas, S., Ardila-Segovia, D., Garcia-Mora, L., Benito-crosetti, 2019), [19] (Brown *et al.*, 2018), [20] (Ferreiro-González *et al.*, 2019), [22] (Corsi D., Dominguez F., 2019), [23] (Dubreil, 2020), [25] (Barr, 2017), [26] (Vélez *et al.*, 2019), [27] (Hernández *et al.*, 2016), [29] (Esteves *et al.*, 2018), [30] (Rodriguez-oroz, D., Gómez-Espina, R., Perez, M., Truyol, 2019), [31] (Hosseini, Hartt and Mostafapour, 2019), [32] (Welbers *et al.*, 2019), [33] (Turner *et al.*, 2018), [34] (Vlachopoulos and Makri, 2017), [35] (Hernández-Horta, Monroy-Reza and Jiménez-García, 2018), [36] (Fotaris and Mastoras, 2019), [37] (Torres-toukoumidis and Romero-rodríguez, 2018), [39] (Aoki, Fiuza and Lemos, 2018), [40] (Tenório *et al.*, 2020), [41] (Tenório *et al.*, 2019), [42] (Panosso, de Souza and Haydu, 2015), [43] (Bontchev *et al.*, 2018), [44] (Ardila-Muñoz, 2019), [45] (Arnseth and Silseth, 2018), [46] (Torres-Toukoumidis *et al.*, 2017), [47] (Romero and Kalmpourtzis, 2020), [48] (Jan *et al.*, 2015), [49] (Troussas, Krouska and Sgouropoulou, 2020), [50] (Kétyi, 2016), [51] (Lengyel, 2020), [52] (Vusić, Bernik and Geček, 2018), [53]

(Ranglund *et al.*, 2016), [54](Dias, 2017), [55] (Urh *et al.*, 2015), [56] (Carenys, Moya and Perramon, 2017), [57] (Muñoz-Merino *et al.*, 2017), [58] (De-Marcos, Garcia-Lopez and Garcia-Cabot, 2016), [59] (Ortiz-Colón, Jordán and Agredai, 2018), [60] (Sánchez-Mena and Martí-Parreño, 2017), [61] (Borrego *et al.*, 2017), [62] (Grivokostopoulou, Kovas and Perikos, 2019), [63] (Sánchez-Mena, Martí-Parreño and Aldás-Manzano, 2019), [64] (Mas-machuca, Jordan and Tresserres, 2019), [65] (Herrera *et al.*, 2019), [66] (Naik, 2017), [67] (Fotaris *et al.*, 2016), [68] (Coleman and Money, 2020), [69] (Computing and Services, 2018), [70] (Clarke *et al.*, 2017), [71] (Martin, Dennen and Bonk, 2020), [72] (Park *et al.*, 2020). Expenditures. M. $ taken from the world bank database. Variable: "Government expenditure on tertiary education, constant PPP$ (millions of US dollars)". In Bulgaria, Denmark and France data on tertiary education expenditure were not available.

Conclusion

The use of gamification and GBL in teaching seems to bring an enormous potential for teaching and developing skills in students. Several studies (Safapour, Kermanshachi and Taneja, 2019),(Hosseini and Mostafapour, 2019),(Kikot, Fernandes and Costa, 2015),(Kinio *et al.*, 2019),(Ibrahim and Ibrahim, 2020) showed that GBL and gamification tools in higher education increase creativity, problem-solving capacity and motivation to learn technical subjects as also as contribute to the development of soft skills and control of emotions so the student will be better prepared in the face of relationships and situations professional. In addition, to improve the interest and participation of students in class, the set of tools within gamification presents in itself an important challenge for the evolution of educators who need a constant update of their teaching methods in order to set ahead the perpetuation and transmission of knowledge. At the same time, it develops transversal skills in the students, preparing and helping them in the world of work.

In our study, we analysed the development of countries in relation to GBL publications. The United States and Europe have a wide range of studies on the tool. Although publications in higher education are still few, they undoubtedly

have been growing since 2017. In Eastern Europe and South America, studies using gamification tools and GBL in teaching and skills development practices are rarer.

Therefore, for the development of this tool would be a n interesting step for future studies with examples of gamification and GBL in South America and Eastern Europe.

Abstract

The effective functioning of small and medium enterprises in Ukraine is due to multifactorial impact formation of a competitive environment according to the deepening market relations. The approval of positive trends and the implementation of measures to improve business in the regions are directly dependent on the formation of purposeful, consistent and predictable state regulatory policy and actions of government and administrative bodies in the field of economic activity. At the same time, there are also ways to create a unique business environment and promote entrepreneurship at the local level. The experience of Ivano-Frankivsk city has shown high efficiency in the involvement of favorable geographical location, government interest and willingness to promote business development.

Keywords: Small and Medium Enterprises, Business Environment, Economic Development, Investment.

Introduction

Small and medium enterprises are the foundation of each market economy. In the current conditions of periodic financial crises, unstable socio-economic and political situation in Ukraine, the development and support of small and medium enterprises is important for the stabilization of the national economy as well as the solution of major social issues. Ukraine has strong enough capabilities to develop SMEs at the national and regional levels. However, Ukraine's economic insecurity leads to the fact that every crisis has an impact and leaves a negative impact on the country's economic growth.

The state of the market in Ukraine requires companies to form demand for their products not only to establish constructive relationships with customers, dealers and suppliers, but to build new investment-attractive areas, one of which in the last few years is the city of Ivano-Frankivsk in western Ukraine.

Richard Cantillon, Karl Marx, David Ricardo, Anthony Smith, Jean-Baptiste Say, Friedrich August von Hayek, Joseph Schumpeter and other prominent economists made a great contribution to the creation of theoretical foundations of entrepreneurship during the XVII-XX centuries. A large number of works and researches are devoted to small and medium business in modern economic theory. Small business remains the focus of researchers due to its economic and spatial manoeuvrability, flexibility of decision-making. Despite the significant amount of research on the activities of small and medium enterprises, the features of the development and functioning of small and medium-sized businesses in a particular region remain insufficiently studied. The example of the city of Ivano-Frankivsk is little studied in economic research and needs detailed analysis.

Cite this Article as: Yurii DRUK, Nataliya MARCHUK and Vasyl MARCHUK "Regional Features of Small and Medium Business Development in Ukraine (Ivano-Frankivsk City Example)" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The purpose of the study is to analyze the activities of small and medium-sized businesses in Ivano-Frankivsk based on the use of statistical methods, identify reasons for slowing down the functioning of SME, identify investment-attractive areas of Ivano-Frankivsk for its further development.

Main Text

Today, Ukraine is making significant efforts to create favorable conditions for doing business in all regions of Ukraine, which differ from each other in the priorities of socio-economic development, the availability of natural and human resources, labor skills, industrial structure and more. That is why each region is unique and has its own characteristics and competitive advantages.

The activities of small and medium-sized businesses are focused primarily on the local market and vitally depends on the conditions created for their existence at the local level. The development of small and medium business is one of the most important factors in solving socio-economic problems of the regions and improving their investment attractiveness.

The city of Ivano-Frankivsk (Stanislaviv - until 1939, Stanislav - until 1962) is one of the 24 regional centers of Ukraine. It is the administrative, economic and cultural center of Ivano-Frankivsk region, with a total area of 83.73 square km, with a population of over 250 thousand inhabitants. Ivano-Frankivsk City Council also consists of 5 villages that joined the city during the current administrative-territorial reform of decentralization. The city of southwestern Ukraine is located in the distance 150-300 km from the borders of Poland, Romania, Hungary, Slovakia.

The main characteristic of the economic complex of Ivano-Frankivsk is the diversified industry, which provides relative resistance to fluctuations in the economic situation in the country. The main sectors of the city's economy: food, engineering, production and distribution of electricity, gas and water, light and chemical industries, manufacture of wood products, printing.

Economic indicators characterizing the state of development of small and medium enterprises indicate the positive dynamics of growth of this sector and its share in the overall economic potential. The volume of products sold by industrial enterprises in 2019 in Ivano-Frankivsk is about UAH 11 768.7 million which is 356,6 milion EURO. This amount which is 86.2% of the volume of 2018 (Report on the Results of the Industrial Sector of Ivano-Frankivsk for 2019. [Online]. URL: http://www.mvk.if.ua/proms/52708 date of access: 12/09/2020). The decrease in sales was mainly due to the closure of production at Tyco Electronics Ukraine Limited according to the optimization of production in Europe carried out by the company. Another reason is the decrease in sales of Intelcom's products due to the expiration of supply agreements with the Russian Federation, as well as the oversaturation of the market with Chinese goods.

According to the official data, in 2018 Ivano-Frankivsk counted 16.8 thousand small and medium sized enterprises (including 129 medium-sized enterprises, 3.8 thousand small enterprises and 12.9 thousand individual entrepreneurs) but only three large-scale enterprises. Accordingly, 23.2% of the business entities were registered as legal entities, which is somewhat higher than Ukraine's average (19.3%). In 2018, the number of SMEs in Ivano-Frankivsk increased by 9% compared to 2017, which is 7.1 percentage points higher compared to the country's average (1.9%). This was primarily due to a 9.5% growth in the quantity of small businesses (the country's average reached 5.1%) and a 8.9% increase in the number of individual entrepreneurs (the country's average was recorded at 1.2%). In addition, the number of mediumsized enterprises increased by 4% (compared to a 7.5% at Ukraine's level). (Main Department of Statistics in Ivano-Frankivsk region, (2020), The number of enterprises in Ivano-Frankivsk city, [Online], [Retrieved October, 30, 2020], http://www.ifstat.gov.ua/)

Small and medium business is developing in almost all sectors of the economic complex of Ivano-Frankivsk city. The volume of products sold by industrial enterprises for the first half of 2020 in Ivano-Frankivsk is about UAH 5061.2 million which is 153,3 milion EURO. The share of sales of manufacturing enterprises is 39.8% of total sales. The largest share in the sales structure is occupied by the enterprises for the supply of electricity, gas, steam and air conditioning (57.8%). The largest share in the structure of the processing industry was occupied by machine-building enterprises (50.4%), the production of food, beverages and tobacco products (25.9%), the production of rubber and plastic products, other non-metallic mineral products (8.9%). In the volume of sold products of mining and processing industry by main industrial groups 51.3% were consumer goods of short-term and long-term use, 21.7% - investment goods, 27% - intermediate goods. (Report on the Results of the Industrial Sector of Ivano-Frankivsk for 2019, (2020), [Online], [Retrieved September, 12, 2020], http://www.mvk.if.ua/proms/52708)

The construction industry is developing rapidly in Ivano-Frankivsk city which is its characteristic feature. The total area of built residential buildings was 752 903 м2 which 186,3% of 2018 amount. (Main Department of Statistics in Ivano-Frankivsk region, (2020), The total area of residential buildings commissioned by cities of regional importance and districts in 2019. [Online], [Retrieved September, 10, 2020], http://www.ifstat.gov.ua/) The development of the construction industry is explained by systematic inflow of investments from workers from abroad. Ukrainians employed in temporary jobs in other countries invest their earnings in real estate and we can state that this creates economically unreasonable demand for real estate and high market prices.

There are numerous positive trends in the development of entrepreneurship in Ivano-Frankivsk in recent years. It is not only about the quantitative growth of small and medium-sized businesses, but also about the gradual reorientation to production, the introduction of new technologies, improving product quality, innovative development. Entrepreneurs today make up a significant part of the middle class and affect social processes. The total number of enterprises in the city of Ivano-Frankivsk in 2019 was 4 066 with 52 798 employees. (Performance indicators of enterprises by cities of regional significance and districts in 2019. Main Department of Statistics in Ivano-Frankivsk region. [Online]. URL:http://www.ifstat.gov.ua/ date of access: 23/08/2020). Disproportion in the total population and the number of employed persons can be explained by large volumes of labor migration abroad. There are no exact statistics of migration until the next all-Ukrainian population census is conducted (the previous one was held in 2001 and its data are no longer relevant). According to the State Statistics Service of Ukraine the estimate number from 1 to 4 million of Ukrainians work abroad every year but an unofficial sources state the number of 7 millions Ukrainians that are employed abroad in various spheres. Most people migrate from western Ukraine and Ivano-Frankivsk in particular due to the proximity of the border with the EU.

A popular form of management in the city as well as in Urkaine is an individual entrepreneur. This form of doing business attracts a more accessible registration procedure, less tax burden and lack of monthly reporting to government statistics. Simplicity, minimal costs for accounting and reporting procedures in this category

entrepreneurs give the opportunity to involve a significant part of the working population and develop their own business. As of January 1, 2019, 13 839 individual entrepreneurs were registered in Ivano-Frankivsk and this figure increased monthly until the beginning of the coronavirus pandemic. (Ivano-Frankivsk City Council, (2019), Socio-economic passport of Ivano-Frankivsk City Council, Ivano-Frankivsk: Misto NV, 4-8)

The growth of investment attractiveness of the city of Ivano-Frankivsk in addition to the proximity of borders with the EU, the availability of natural and human resources is also the development of modern urban projects with a high potential for investment. In 2014, a public restaurant Urban Space 100 was opened in Ivano-Frankivsk, which became a successful example of uniting socially active people around the idea of developing their city. The investors of the project were 100 residents of the city, and 80% of the restaurant's profit is directed exclusively to the implementation of public projects in Ivano-Frankivsk. Since the opening of Urban Space 100, 98 projects have been funded. The idea of a public restaurant attracted considerable attention to the city as a modern investment space and became a stimulus for the development of new projects.

In 2017, the project Promprylad Renovation was launched - an innovation center based on the old plant, which operates at the intersection of four areas of development of the region: the new economy and urban planning, modern art and education. This is an impact investment project, where investors simultaneously invest in the social impact on the region and receive a return on investment in the form of dividends. The amount of attracted investments as of September 2020 is $5 372 024 and is groving. This project made Ivano-Frankivsk a center for innovation and showed the city's potential for potential investors.

In 2018, Ivano-Frankivsk took first place in the ranking of transparency of the investment sector from Transparency International Ukraine within the Transparent cities program. Ivano-Frankivsk's best practice is the City Investment Portal, which contains all available information in Ukrainian and English on vacant land plots and production areas for the implementation of investment projects, as well as on successfully implemented projects. Foreign investors, Ukrainian enterprises and social departments of the city authorities included in this study evaluated 17 indicators that help determine the real transparency of investment in the economy, the presence of anti-corruption programs, conflicts of interest in city councils, tools and opportunities in the investment sector. (Transparency International Ukraine, (2020), Transparency rating of the 100 largest cities of Ukraine. [Online], [Retrieved September, 18, 2020], https://ti-ukraine.org/wp-content/uploads/2019/03/Rejtyng-prozorosti-mist-Ukrayiny-2018_1.pdf)

In September 2020, Ivano-Frankivsk became the best city in Ukraine for doing business according to Forbes Ukraine ranking. Ivano-Frankivsk received high scores on ten criteria: transparency of city authorities, business activity, Doing Business rating, purchasing power, transport links, security, education, perception of the city by residents, migration attractiveness and environmental situation. (Forbes Ukraine, (2020), The best cities for business, Forbes Ukraine №3 September, 114-120)

In 2020 Ivano-Frankivsk was recognized as the city with the most favorable business climate and effective economic governance together with other cities from different parts of Ukraine – Khmelnytsky, Lviv, Vinnytsia, Ternopil and Chernihiv. These are the results of the study "Ukrainian Competitiveness Index (ICM) 2019/2020", conducted by the "Competitive economy of Ukraine" program of United States Agency for International Development (USAID). In 2019-2020, the assessment included 24 cities, including the city of Kyiv and 23 cities-regional centres. According to this research, the strongest components of Ivano-Frankivsk city are low level of informal payments and corruption, strong leadership of municipal authorities, resources development, high compliance cost, transparency and data openness and access to public property. The weakest components are starting a business and support of innovations but these indicators are not at the low level. In particular, according to the survey data, the registration of a business in Ivano-Frankivsk in 2018-2019 took less time than on average in the country (4.9 days compared to 6.1 days). The surveyed business entities named the main barriers they face when doing business in Ivano-Frankivsk. According to the survey findings, three most important barriers included such factors as the lack of qualified workforce, high taxes, and low consumer demand. (NGO "Institute for Economic Research and Policy Consulting", (2020), Analytical report. Municipal Competitiveness Index. [Online], [Retrieved October, 30, 2020], http://www.ier.com.ua/files/Projects/2020/MCI/reports1/MCI_2019-2020_Part%202_Profiles_UKR.pdf)

Analyzing the development trends of small and medium business, we can conclude that in recent years in the city of Ivano-Frankivsk there have been positive changes. But the activities of small and medium enterprises in the city are

damaged by a number of negative factors, both specific to the Ivano-Frankivsk region and those that are common to Ukraine. These factors are:

- imperfection of normative-legal regulation of entrepreneurship
- insufficient development and effective functioning of the market infrastructure of business support
- administrative conditions for doing business and as a result of low innovation activity of small businesses
- limited access of entrepreneurs to financial and credit resources and their high cost
- complex system of state control in the field of economic activity
- insufficient effectiveness of the implementation of state regulatory policy
- low level of innovation in business
- unpreparedness of enterprises to work in quarantine conditions
- insufficient local authorities' efforts to protect the rights of small and medium-sized businesses and entrepreneurs during the COVID-19 pandemic.

Conclusions

Recently, there have been more and more discussions in Ukraine about supporting small businesses on national and local levels. The state as well as local authorities should first of all be interested in the development of small business, through which it is possible on a larger scale to fill the budget, create jobs and finally move from a commodity-type economy to an economy based on the functioning of small businesses. Studying the experience of Ivano-Frankivsk city showed that small business can take on the role of stimulator not only economic but also social development of the community. Favorable geographical location, government interest and willingness to promote business development have shown high efficiency and contributed to the creation of a unique investment environment for Ukraine. The economy of Ivano-Frankivsk city is characterized with quantitative growth of small and medium-sized businesses, the gradual reorientation to production, the introduction of new technologies, improving product quality and innovative development and the implementation of unique community projects.

The number of small and medium sized enterprises in Ivano-Frankivsk is somewhat higher than Ukraine's average and the city occupies leading positions in independent business environment rankings. Nevertheless, there are barriers to doing business in Ivano-Frankivsk such as the lack of qualified workforce, high taxes, and low consumer demand.

It is necessary to conduct an audit of business support infrastructure, identify potential key areas of business development in Ivano-Frankivsk to maintain the positive dynamics of economic growth. Authorities should also pay attention to the weaknesses of the business environment and anticipate the onset of risks.

Abstract

Disruptive sharing-economy technologies, unlike other innovations, follow a different version of the Hype Cycle. The traditional graphic model helps to predict the behaviour of collective expectations, supports entrepreneurial decisions and strategic investments. However, when applied to such collaborative solutions, based on the concept of sharing rather than owning, some steps seem to differ. In this paper, interesting findings came from applying a mixed-method approach and from a closer analysis of two innovative and disruptive sharing economy companies: Uber and Airbnb. Foremost, they presented two positive hypes on public expectations rather than one. Consequently, the companies also had to overcome two phases of disappointment. This finding indicates that predictions using the Hype Cycle, when applied to such innovations, may have to be revisited and consider a different pattern.

Keywords: Sharing Economy; Disruptive Technologies; Hype Cycle; Uber And Airbnb.

Introduction

During the past decade, innovative and disruptive technologies increased the popularity of sharing economy solutions. The idea of renting, swapping, or trading based on monetary or non-monetary transactions spread out through community-based online tools. Investors considered such innovations as "mega-trends", which could be lucrative and bring along major societal impacts (Hamari et al., 2016). In this context, two particular companies shined a spotlight on the idea of sharing while encouraging individual entrepreneurship: Uber and Airbnb. They became well-known symbols of new possibilities, as anyone could improve their income by taking passengers for a ride or by renting a spare room. Within their respective markets, each of these innovative platforms played a leading role in shaking up established industry structures (Skog et al., 2018).

The increased use of these platforms has also piqued the interest of competitors, investors, and scholars in analysing their development. They investigated the business model and possible effects on competitors, existing regulations, and general society (Cannon and Summers, 2014; Cohen and Sundararajan, 2015; Heinrichs, 2013). However, new innovations are influenced by a phase of increasing public expectations and by subsequent disappointment. This process, called the Hype Cycle, can impact the pace, direction, reputation, and amount of resources that are available for the development of a technology (Ruef and Markard, 2010). To the best of our knowledge no study analysed if these technologies have been hyped. Therefore, the intention of this research is to address this gap and investigate whether Uber and Airbnb, as sharing economy innovations, went through all the stages of hype and disappointment predicted by the hype cycle model and how has this occurred.

In order to do so, a mixed-methods approach was chosen, combining descriptive statistical analysis with content and sentiment analysis, and a history line. Finally, to verify similarities and differences the results were contrasted with the hype cycle model.

The paper is structured as follows: Sections 1 and 2 present the most important theoretical concepts that were used for the analysis. Section 3 summarises the methodology. Section 4 presents the results and discussion. Finally, Section 5 brings the general conclusions.

Innovation and Disruptive Innovation

The definition of innovation must include the creation of the new. This could be a process, reorganisation of production, development, or alteration of a product, or even an improvement of existing methods and instruments. Regardless of a type of solution that it brings, development of an innovation is always followed by degree of uncertainty. Either because there is no correct formula for its implementation, or because it is not possible to anticipate results from its application (Kline and Rosenberg, 2010).

An innovation may be pivotal for the growth of a business, increase of earnings, improvement in competitiveness or to answer customers' demands. It can also be a way to tackle globalisation and environmental changes (Baregheh et al., 2009). Innovation is then a way to create and, simultaneously, a capacity to change and adapt (Thompson, 1965). It is worth noting that the dimensions of innovation may vary from 'Incremental' to 'Radical'. This could, respectively, be perfecting or optimising something that already exists or presenting a complete novelty to the world. It may also go from a 'Component Level' which improves parts or components, to a 'System Level' which creates a whole new version of a product (Tidd and Bessant, 2018).

The present study focuses on disruptive innovations. Normally, performed by smaller companies with limited access to resources, such innovations can successfully challenge incumbent businesses, and improve products or services, even when they cannot achieve existing performances. Typically cheaper and simpler, such innovations are more efficient and convenient, which gives them the possibility to develop, meet standards of performance and displace established solutions. In other words, disruptive companies have a potential to impact the strategies of entire business models (Christensen et al., 2015).

Hype Cycle

The Hype Cycle model is often used by managers or scholars during the study of innovation development. It predicts five specific phases that innovations should overcome during their development. Such patterns are considered 'inevitable' and applicable to every innovation, regardless of the type of business or the kind of technology that is being introduced. For this reason, the graph is used as a tool that helps predict the future (Fenn and Raskino, 2008). Presented in Figure 1, the model considers the evolution of the expectations on the Y-axis and behaviour over time on the X-axis.

As indicated in Figure 1, this analysis starts with the 'Innovation Trigger' the first stage and breakthrough of a technology, when an idea spikes media interest, but it is still in an early stage of development. It might not yet be usable or even viable, however its existence brings excitement, and a buzz starts to build up around it.

The following phase is called 'Peak of Inflated Expectations', as success stories are more often brought to the public by the media, as well as some of its failures. The product/solution is still being adjusted, but investors and other companies are seeking to be a part of the movement before their competitors. There is a high excitement, along with the feeling that joining the trend is needed, not to be left behind.

Subsequently, comes the third phase or 'Trough of Disillusionment'. As the initial hope develops into impatience for results. Performance and implementation are not meeting the expectations and the adoption is slower than planned. Those issues drive a reduction in interest on the technology. Simultaneously, there is a rise in the number of less favourable stories in the media, highlighting the challenges more than the opportunities. Improvements in the early adopters' satisfaction appear as the only way to keep investments.

The following stage is titled 'Slope of Enlightenment', that is, when the benefits of a technology crystallise, and new products/services start reaching the market. It is possible to observe the innovation maturing, while the conservative organisations remain cautious.

Finally, public expectations stabilise in the fifth stage or the 'Plateau of Productivity', when the technology adoption takes off. This phase is characterized by a more clear and defined relationship between the innovative company and

its suppliers and providers. It is also when the solutions' importance in the market starts paying off and the adoption accelerates rapidly. The real-world benefits of the innovation are clearly presented and accepted (Fenn and Raskino, 2008; Van Lente et al., 2013).

Figure 1: Hype Cycle illustration, based on 'The hype cycle of innovation'
Source: Fenn and Raskino, 2008

It is important to stress that the Hype Cycle reflects a period prior to the widespread diffusion of new technologies. At a point when collective expectations can strongly influence the implementation through an inherent and elevated level of uncertainty. Furthermore, outcomes, performances and societal impacts in this phase are still somewhat vague and unclear. In this sense, the higher the expectations, the higher are the chances that a technology will obtain support and investments for development. This may be especially relevant to capture the attention of policymakers, who will also rely on credibility of expectations when making decisions and drafting policies (Kriechbaum et al., 2018).

In other words, the interplay of expectations at different levels, on the debut of a technology, influences the capacity of a field to cope with its hype and disappointment. High expectations of a bright future can have a positive impact on the development of an innovation by drawing new actors and investment into the field (Van Lente et al., 2013).

It is also relevant to notice that there is no measuring unit for capturing expectations. While in the financial market expectations flow can be seen and assessed and measured through by the changes in the stock market, in areas such as business and innovations those expectations levels are less clear, highlighting the need for performing an indirect analyses. (Fenn and Raskino, 2008).

Methodology

This research focuses on the study of hype and disappointment applied to disruptive sharing economy innovations. It proposes the analysis of Uber and Airbnb as case studies for being among the most popular symbols of sharing innovations. By drawing the evolution of collective expectations, during the development of each one of these companies, the aim is to verify whether the Hype Cycle steps are applicable to sharing economy solutions.

To perform this study, the research uses a mixed-method approach. One simple quantitative method, measuring the media's attention over time, and three qualitative investigations focusing on different aspects. First, a content analysis to categorise the mentioned topics of the journalistic texts. Second, a sentiment analysis to reveal whether the content published was positive or negative. Finally, a historical line of events enabled the comparison of main facts and background context to each identified stage of the companies' development, deepening the investigation.

The research relied on printed and online versions of The New York Times as a source for the extracted journalistic publications. Since there is no direct measure of capturing expectations, a common approach used by researchers in the study of the Hype Cycle is the use of media analysis. Expectations and disappointments are extracted from within the articles, as they are apparent through the manner information is presented to the public; through the what issues the article is focusing on; and through the choice of words and meanings that paint, indirectly, a picture of how the technology is seen in a given moment (Fenn and Raskino, 2008).

The choice of this specific newspaper is based on a previous research done by the authors Van Lente et al. (2013), who also investigated the Hype Cycle using mixed methods and specific study cases. The research reviewed two technologies with very different domains: voice over internet protocol (VoIP) and gene therapy and high-temperature superconductivity (HTS). The reading of news articles mentioning such technologies was the pillar for the hype investigation in both cases. In addition to that, The New York Times has a reputation for being the main driver in shaping other journalistic organisations' news agenda and legitimising the coverage of topics that otherwise would not have a national journalistic reach (Golan, 2006; Bryant and Oliver, 2009).

The time frame defined for this research is from the year of each company's creation to the 31st December 2018. That represents for Uber and Airbnb 9 and 10 years of history, respectively. As a starting point, the researchers identified all texts mentioning "Uber" and/or "Airbnb" using the newspaper online search tool, which provides subscribers with an access to all published material since 1851.

Sample Treatment and Analysis

Focused on finding all published content mentioning 'Uber' and/or 'Airbnb', the initial research identified 6'517 texts in the given timeframe. Following the methodology of content analysis proposed by Bardin (1977) in the book 'L'analyse de contenu', the sample was submitted to a process of pre-analysis. This implied the refinement of the data by disregarding texts that did not mention at least one of the companies in the title. Results with the following characteristics were also excluded:

1) Index pages: dedicated to list the summaries of different journalistic stories
2) Multimedia content: including videos, pictures, audios and other multimedia content
3) Book reviews: as they are not the target of this research
4) Pages presenting the full content of legal decisions, internal company emails and other documents obtained without a journalistic text alongside

After applying the mentioned criteria, the sample was reduced to 762 publications. From this total, Uber had most of the texts: 594, against 168 mentioning Airbnb. The development of those numbers is detailed by the quantitative analysis.

According to Bardin (1977), the following step to be performed is the 'encoding', that allows the categorisation and transformation of the raw data, which enables a more simple and statistical view of the content analysis is provided. In this step, 40 texts were chosen randomly from the sample and read in their entirety. During this reading, all the mentioned subjects were listed and grouped into more general topics. This process resulted in the creation of 10 main categories.

Essential for performing the content analysis, the creation of those categories enables the classification of the texts according to a set of defined codes, during the categorisation phase. This includes the reading of all the sample, composed by 762 texts, while attributing the number 'one' to each one of the mentioned categories. Due to this process, the understanding of the published news articles can be simplified, creating a path for their general interpretation. To be more specific and capture nuances in the journalistic speech, each category was duplicated, allowing to compute when it appeared connected to a positive or negative context.

1) App features and operation
2) Company development
3) Competition/Partners
4) Ethical behaviour
5) Price

6) Economic performance
7) Political / Legal aspects
8) Advantages / Drawback to drivers / house owners
9) Advantages / Drawback to users
10) Local/International agreements / Local/International conflicts

Based on Bardin's (1977) content analysis method, it was defined that each text equals one unit of analysed data. Also, that each text may include one or several categories, in either a positive or negative context. Each category could be marked only one time per text to indicate a positive mention and one time for having a negative mention. Non mention categories remained unmarked. Later, the results were grouped and displayed in a graphic form.

To add another dimension to the analysis of the texts, the researchers also conducted a sentiment analysis. This is an automated method based on machine learning that helps to identify the polarity of each article. By using this method, it was possible to determine whether a text could be considered positive, negative, or neutral. The results were also used to create a graphic that could be compared with the Hype Cycle model. The program selected to perform this analysis is called Monkeylearn, which can process a large scale of texts quickly. To perform the analysis, all the texts from the final sample were consolidated in a single Excel file, then submitted to the platform for processing the material and return the results.

Lastly, it was built a time sequence of the main events for each company, to help visualise what occurred during the development of each one of them. Those inputs later combined with other results bringing deeper insights for the analysis of the outcomes. This specific applied methodology is a simplified version of the one used by the authors Van de Ven and Poole (1990). The authors propose a sequence of analysis in longitudinal qualitative data. The method is susceptible to subjective judgments while defining the incidents and, therefore, does not represent the sum of all the occurrences present in the development of an innovation. It does, however, allow an overview of several main events over time. All the information used to build this history line comes from the companies' official websites or from publications made by The New York Times.

Results and Discussion

As indicated in the methodology, this research started with the identification of 6'517 results for published content about Uber and Airbnb by The New York Times, between January 1st, 2008 / 2009 and December 31, 2018. This data set was refined by the application of pre-defined inclusion and exclusion criteria, resulting in a final sample of 762 publications. From which, 594 were focused on Uber and 168 on Airbnb.

The light blue line on Figure 2 shows how the number of publications about Uber developed during time. The other curves detail the results obtained by the sentiment analysis. In red, for example, are all articles considered negative: a total of 346 publications, equivalent to 58,2% of the sample. The green line represents the articles considered positive: 230 journalistic articles or 38,7% of the total. The yellow line is used to visualise the 18 publications or 3% of Uber's sample considered neutral. Grey is the line representing the net results or, in other words, the difference between positive and negative texts found in the sample. With only one exception, in 2013, when this result was neutral, all the other years were mainly negative. Interesting to note that positive, negative, and net results present a similar evolution, having peaks in 2015 and 2017.

Figure 2: Sentiment Analysis by year for Uber

Airbnb's results are presented in Figure 3. The light blue line indicates the evolution of the analysed sample of journalistic texts, and the other curves the results obtained by the sentiment analysis. The green line shows clearly that most of the articles written about the company were considered positive; 93 out of 168 texts, or 55,3% of the total. Negative articles summed 74 or 44% of the sample, as presented by the red line. Only one text was neutral, 0,6% from the sample, as evidenced by the yellow line. In grey are the net results. This is the most irregular line, positive in 2011, 2013, 2014, 2016 and 2017; and negative in 2012, 2015 and 2018. It is worth noting that, despite initial disparities, the positive and net curves present similarities in their evolution, with peaks in 2014 and 2016.

Figure 3: Sentiment Analysis by year for Airbnb

Figure 4 presents the result of the content analysis made for Uber. The graph gathers the sum of times a category has been mentioned by year, including both: positive and negative citations. It is important to stress that, during the coding process, a single text could possibly include more than one category, and that each category could be marked up to one time when referred positively and up to one time when referred negatively. Figure 4 brings the sum of all those mentions, year by year, during the timeframe analysed. It also shows that some issues were prominently featured by the media. In Uber's case, among ten different categories, the most popular topics were: 'App's Features and Operations', 'Company Development', 'Political Decisions and Legal Aspects', and 'Local and International Agreements or Conflicts'.

Figure 4: Number of mentions per year by category for Uber

Figure 5 presents the evolution of the mentioned topics for Airbnb. The figure also indicates the sum of mentions, positive and negative, by category and year. Likewise, the categories 'App's Features and Operations', 'Company Development', 'Political Decisions and Legal Aspects' and 'Local and International Agreements or Conflicts', are also on the top of the list, as most frequently mentioned subjects.

Figure 5: Number of mentions per year by category for Airbnb

Finally, the methodology proposed the elaboration of a timeline indicating the main events during the development of Uber and Airbnb, as this overview gives a different perspective for the collected data. Each company was analysed individually, and the highlighted events were summarised below. Figure 6 presents the first part of Uber's history line, going from 2008 to 2013. This initial phase of the company was marked by the company's creation and development, especially in North American cities. In this period, Uber developed several popular marketing campaigns, and got involved in a negative polemic involving 'surge pricing', an increase in fare rate during demand peaks.

Figure 6: History of Events for Uber from 2008 to 2013

Figure 7 looks at the second part of the history line, the years between 2014 and 2018. During this period, the company had a significant capital increase, while heavily impacted by regulatory challenges and worldwide taxi-drivers' strikes against the spread of the technology. During this period, the company was banned from operating in several cities around the world, accused of having an 'aggressive global expansion plan' and critiqued for a policy based on 'asking for forgiveness and not for permission'. In 2014, Uber was featured in the headlines due to their hostility towards the press, when a senior executive assumed collecting private information from reporters that criticise the company, information that would be later publicly spread. In the same year, the media questioned the process of screening of drivers, following cases of passenger rape accusations. Uber's driver hiring model was also under the scrutiny, as it did not ensure basic rights. Other issues were revealed later in 2015, as hackers gained access to a massive amount of users' private data. In 2016, after investing billions of dollars to conquer the Chinese market, Uber retreated from its operation in the market.

In 2017, Google accused a former engineer of stealing trade secrets on autonomous vehicles and disclosing them with Uber's division in charge of developing a similar technology. In 2017, it was revealed that Uber used a program called 'Greyball' to deceive authorities worldwide and keep the platform running in cities where the service was officially banned. The company appeared in several other news articles due to internal discrimination and harassment complaints, ultimately resulting in the departure of the founder and chief executive, Travis Kalanick. In 2018, the new CEO Dara Khosrowshahi implemented several changes in Uber's management model and business culture. The year was also marked by a fatal accident when Uber's self-driving car collided with and killed a pedestrian in the United States during testing.

Figure 7: History of Events for Uber from 2014 to 2018

The first period of the timeline created for Airbnb can be found in Figure 8. It presents the events between 2008 and 2013 and includes the company's creation and the following strategy adaptation phase, which led to its successful growth in the number of users and cities in North America where the service was available. As the platform grew, several issues came to light such as cases of vandalised houses or stolen belongings. However, Airbnb's problems were amplified as hosts started being fined in New York City for illegal rent. A petition endorsed by Airbnb, requesting city legislators to adapt the local law, collected 50'000 signatures. The situation escalated when the city's attorney general required access to the hosts' information to identify illegalities.

Figure 8: History of Events for Airbnb from 2008 to 2013

The second part of Airbnb's history line, presented in Figure 9, shows that the company was able to expand and develop around the globe. The economic growth followed the same flow and in 2014 the company was worth 10 billion dollars. Back then, the company decided to cooperate with the New York State Attorney and provided some of the host's information. The data was used to produce a report indicating that almost three-quarters of the listings in the city were illegal. From then on, problems with city administrations started appearing in several different cities around the world. Airbnb started campaigns to convince politicians and legislators of the benefits of short-term rentals. However, legal restrictions imposed on Airbnb activities around the world still dominated the news, even over the years and the reduction in the volume of journalistic texts that feature the company. Other topics mentioned during this period were accidents involving Airbnb's users, such as a man that died when using a swing in the garden of a rented property; a badly injured user that was attacked by the host's dog or a 19-year-old man reported being

sexually abused by his host. The company also faced criticism after a report revealed widespread discrimination and racism on the platform.

Figure 9: History of Events for Airbnb from 2014 to 2018

Conclusion

This paper investigated the existence of hypes during the development of Uber and Airbnb, two popular and disruptive sharing economy companies. The research used mixed methods to analyse, using different angles and perspectives, published newspaper articles about the technologies during their development. The results indicated growth of expectations and disappointment which were later compared with the Hype Cycle model.

This combination of quantitative and qualitative methods revealed interesting findings. In the first place, the results of both study cases indicated the existence of two distinct peaks of hype. Consequently, there were also two instances of disappointment. That means, when comparing the findings to the Hype Cycle, neither Uber nor Airbnb followed the exact shape established by the model. What is also worth noting is that, besides presenting two hypes each, and being in two different industries, the timings when those spikes registered are consistent: founded in 2008, Airbnb had its first euphoria peak happening exactly one year earlier than Uber, established in 2009. This indicates that disruptive sharing-economy companies may follow an adapted shape of this graph and should be analysed by predicting the existence of more than one hype.

Following a closer look at the content analysis, it is possible to come to a conclusion that identified hypes for both companies happened when similar topics were brought by the media, such as ‘App features and Operations’, ‘Political and Legal aspects’, ‘Company’s development’ and ‘Local or International Agreements or Conflicts’. The euphoria and disappointment also correlated with the greater reach of the technology. As Uber and Airbnb expanded their operations, they also had to overcome numerous new barriers and challenges. Mainly linked to political and regulatory matters, that have proven to be fundamental dilemmas for their evolution. In contrast, the same growth had a positive connotation, and was frequently mentioned with optimism.

An obvious difference between the two companies is that most of the media coverage featuring Uber was of negative sentiment, while Airbnb, on the other hand, was featured in a more positive light. This becomes very evident when looking at the net results of the sentiment analysis. Such perspectives may have affected the public's opinions and expectations of these two innovations, and perhaps even influenced the use of each of the platforms. The assessment of this impact was not the focus of this study; however, it might be an interesting topic for future research.

Another possible venue for investigation stems from a limitation of this study. As defined in the methodology, the research relied on the data gathered and analysed from a single source: The New York Times. This may have created a bias, due to, for example, editorial orientation. New studies could address this problem by broadening the research by choosing more than one newspaper to compose the data source.

Lastly, when considering the descriptions of each one of the stages of the Hype Cycle, it is possible to say that Uber and Airbnb went through four of the pre-defined stages. However, none of the companies could fully complete the cycle, as they have not met all the criteria of the last phase, called 'Plateau of Productivity'. In this aspect, their tumultuous relationship with regulators all over the world may have prevented them from having a clear and defined relationship with suppliers and providers.

Abstract

The entrance of company into the regulated market for medical devices is associated with compliance with many regulations, ordinances and laws. On the other hand, the production and sale of medical devices is very promising, in all economic periods. In May 2021, Europe is facing a major change in the legislation on medical devices in the form of MDR Directive 2017/745, which has been developed to protect patients in order to increase their safety. This is undoubtedly the right and proportionate situation for society, but it involves high costs and investments for manufacturers. Companies are now faced with the question of what future economic result can be expected and what strategy to follow. The goal of this study is to suggest and specify steps of medical device development for economic evaluation and calculation of economic efficiency. For these purposes, a calculator that calculates economic efficiency indicators such as Return on Investment, Net Present Value and Breakeven Point, was made. It takes into account the new legislative conditions, and it also allows its users to set the risk class and other characteristics of the medical device. The study also contains demonstrated calculation of economic efficiency indicators for one case study.

Keywords: Medical Device; Development; Economic Efficiency; Investment.

Introduction

The entrance of company into the regulated market for medical devices is associated with compliance with many regulations, ordinances and laws. On the other hand, the sale of medical devices is very promising, in all economic periods. The market for medical devices must be regulated in order to ensure high patient safety. Emphasis is placed on preclinical and clinically evaluated medical devices to ensure that the manufacturer demonstrates not only efficacy but clinical safety when used on humans. All testing is very expensive, many tests are forced by the manufacturer in accredited laboratories and testing laboratories, however, in the end it is up to the manufacturer to decide whether the test results are acceptable and satisfactory. All this is complemented by the need to create technical documentation and ensure a product quality management system. All activities with regulatory affair medical devices are associated with high costs. At a time of changing legislative conditions, it is crucial, especially for small and medium-sized companies, to correctly set all the parameters of the company's operation so that they can survive on the European market.

Cite this Article as: Petra MARESOVA, Lukas PETER, Martin MATEJICEK, Jan MACI and Kamil KUCA "Development of New Medical Device – Investment Evaluation" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In 2021, Europe is facing a major change in the legislation on medical devices in the form of MDR Directive 2017/745, which has been developed to protect patients in order to increase their safety (Regulation (EU) 2017/745 of the European Parliament and of the Council of 5 April 2017 on Medical Devices, Amending Directive 2001/83/EC, Regulation (EC) No 178/2002 and Regulation (EC) No 1223/2009 and Repealing Council Directives 90/385/EEC and 93/42/EEC 2020).

Companies developing medical devices will be obliged to introduce clinical trials even in the lower classes of post-marketing risk. This is often described by companies as a fundamental problem in the development of future economic results. They are now faced with the question of what future economic result can be expected and what strategy to follow.

The topic of regulation of economic life is a very sensitive discipline with an overlap into various scientific disciplines and human activities, such as political economy, law, environmental sciences including engineering, urban planning, health policy services, etc. Regulations are also a significant socio-political force (Faulkner 2012). Regulation is also such a complex issue that it is possible to meet with the term or field of *„regulatory science“*. For example, the Food and Drug Administration defines regulatory science as *„the science of developing new tools, standards, and approaches to assess the safety, efficacy, quality, and performance of all FDA-regulated products“*. (FDA 2019).

While some regulations on the one hand, mean activity limitation, on the other hand also represent an opportunity for new business development - an opportunity for innovation (Maresova et al. 2020). Some innovations are ahead of regulation (technology-push innovation), others are driven by regulations (technology-pull innovation). As reported by Faulkner (2012, p. 390), technological innovations are commonly seen as the leading control, i.e., regulation lags behind innovation.

Therefore, our goal is to suggest and specify steps of medical device development for economic evaluation and calculation of economic efficiency. For these purposes, we created a calculator that will be publicly available on the internet. The calculation takes into account the new legislative conditions, and it also allows its users to set the risk class and other characteristics of the medical device. Knowledge of all necessary tasks and stages of development of these devices is a fundamental starting point for the design of the model of medical device development. The calculation will be demonstrated on a chosen case study.

For example, the user (company) will be able to answer the following questions:

- How will the company's economic result develop in the event of a transition to new legislation?
- How much would the company have to increase the price to cover the increased costs associated with the new legislation?
- When will the company reach the breakeven point under the new legislation?

Theoretical Background - Market Regulation and Innovation in the Field of Medical Devices

The goal described above is based on the topic of regulation of medical devices and the current change in European legislation, which is a discussed topic. The new legislation will enter into force in May 2021, so companies are preparing for it accordingly. The aim of regulation is to increase the quality of development, however, it entails increased costs, as will be shown later.

From the point of view of theory, many authors across disciplines comment on the topics or on the success of regulations.

Amable, Demmou, and Ledezma (2010) define three indicators of the degree of regulation. These indicators are intended to make it possible to compare the level of legislation in different countries. On the one hand, the authors of the publication mention that the negative impact of regulations increases in intensity as they approach the technological limit of production possibilities. On the other hand, according to their empirical tests, there are cases where regulation has a positive effect on industries close to the technological frontier.

Bourlès (2013) and Franco, Pieri, and Venturini (2016) examine the effects of product regulation along the vertical axis (see upstream regulation). Bourlès et al. (2013) using the endogenous growth model show that product upstream regulation (eg in services through licensing) limits efforts to improve downstream productivity. The degree of regulation was monitored according to OECD data base of regulation indicators. Franco, Pieri, and Venturini (2016) use econometric analysis to show that upstream product market regulation reduces the effectiveness of downstream R&D.

Regarding control of products in terms of environmental impact, Friedrich (2019) reported that in the initial phase of introducing the product on the market should be set lower standards. This would ensure the entry of a sufficient number of companies that enter the industry and will innovate the product with a view to increasing profits. This will have an overall positive effect on social welfare.

Erdman et al. (2013) connect the topic of innovation through big data and regulation in the medical device environment. The authors believe that the involvement of big data for simulations and modeling in the development of medical devices will reduce the number of animal and human trials required for proof of safety and efficacy as well as device testing cycles and product design cycles. Virtual prototyping should make future devices safer and more effective which should make it easier to meet regulatory requirements.

Lee and Kesselheim (2018) point out that the Digital Health Software Precertification (Pre-Cert) Program *"may reduce incentives for developers to study the safety and effectiveness of their software products before patients start to rely on them."* The program, on the one hand, speeds up some regulatory procedures and, on the other hand, introduces some confusion.

Methods

This chapter describes all the methods used in this study. It is also important to mention the fact that all primary data were processed in CZK. For the purposes of this paper, a conversion to EUR was performed according to the exchange rate as of September 18 2020, i.e., 1 EUR = 26.6895 CZK.

Design of the Study

To perform the calculation, certain input parameters have to be filled in. All input data are described below.

The calculation will compute the ROI (return on investment), NPV (net present value) and BEP (breakeven point) indicators.

Input Data

Table No. 1 represents the first of the three areas of monitored parameters that are supposed to be specified by user/company. All variables are related to the characteristics of the company and the intended markets, from which it is possible to outline an idea of the potential of the target market. These values are qualitative and serve to correctly interpret the calculated results in the context of company size, market position, business model, etc. However the demonstration of the calculator in this paper will not include an interpretation for case studies.

Table 1: Parameters related to company, product, and markets

Input information / question	Choice / value
Indicate the number of employees in the company.	0-10 10-50 50-250 250+
What type of medical device do you plan to develop and manufacture?	I Is Im

	IIa IIb III none
Is your solution innovative?	Yes No
Are you planning the IP of your solution - a patent?	Yes No Already have
Is your product demonstrably more effective than product of your competitors?	Yes No We don't have clinical records
What is your business model?	Self-payers Public health
What primary market are you targeting?	Czech Republic Western Europe Eastern Europe Other countries accepting CE
What percentage of market share do you hold?	%
What percentage of the market is occupied by your biggest competitor?	%

In the second specified area, there are individual stages of medical device development. The questions are aimed at determining the costs for individual phases. For a more precise determination, the individual activities that may belong there were specified for each phase.

Table 2: Phases and costs of medical device development

Input information / question	Value
1. Initiation phase	
Total estimated cost of the phase	EUR
Identifying customer needs	(Number of hours * price / hour) OR (EUR in case of outsorcing)
Description of functionality and advantages over the existing solution, decision on the type of medical device	
Verification of manufacturability	
Estimation of costs and revenues	
Other costs associated with the initiation of the first idea for a new product	
Total other overhead/indirect costs for the initiation phase	
2. Concept proposal	
Total estimated cost of the phase	EUR
Specification of strategy and development plan, market analysis and evaluation of product potential, estimation of time needed for development, provision of personnel security	(Number of hours * price / hour) OR (EUR in case of outsorcing)

Determination of product characteristics (product function, material requirements, etc.)	
Production specification costs	
Costs of decisions on the MP class and estimation of related legal and legislative acts	
Patent research for concept design	
3. Design and development	
Total estimated cost of the phase	EUR
Specification of development strategy and plan, costs and revenues, business plan	(Number of hours * price / hour) OR (EUR in case of outsorcing)
Detailed production plan, including the determination of materials	
Estimation of the total costs of testing and evaluation in relation to the considered type of medical device (PMFC, clinical trials, risk analysis aFMEA, dFMEA, creation of accompanying documentation, etc.)	
4. Verification and validation	
Total estimated cost of the phase	EUR
Design validation and certification	(Number of hours * price / hour) OR (EUR in case of outsorcing)
Testing costs not included above (biological evaluation, electrical safety, additional tests)	EUR
Clinical evaluation / test / study	(Number of hours * price / hour) OR (EUR in case of outsorcing)
Creation of a technical file	
5. Production	
Total estimated cost of the phase	EUR
Material	EUR
Production work of the team	(Number of hours * price / hour) OR (EUR in case of outsorcing)
Finalization of activities in relation to risk management	
Finalization of activities in relation to design validation and verification	
Reserve fund, costs associated with product risk insurance	EUR
Mass production costs	
Own production line	
6. Placing product on the market	
Total estimated cost of the phase	EUR
Patent application (European patent / Czech Republic, etc.)	EUR
Training of sales representatives and doctors	(Number of hours * price / hour) OR (EUR in case of

	outsorcing)
7. Parameters associated with the existence of the product on the market	
Total estimated cost of the phase	EUR
PMCF during the life of the product	EUR
Post Market Surveillance	(Number of hours * price / hour) OR (EUR in case of outsorcing)
Feedback evaluation, planning and setting changes	
Service costs	
8. Estimation of conformity assessment costs	EUR
Costs of conformity assessment before placing on the market	EUR
Costs of conformity assessment in the first year of sale	
Costs of conformity assessment in the second year of sale	
Costs of conformity assessment in the third year of sale	
Costs of conformity assessment in the fourth year of sale	
Costs of conformity assessment in the fifth year of sale	
9. Total estimated cost of production of 1 piece of MD	EUR/piece

All medical devices are divided into three risk classes, individual regulatory rules in individual countries can further specify these classes (only applies to medical devices outside IVD and pharmaceuticals). In the case of risk class I, the manufacturer is obliged to assess compliance with the essential requirements concerning MDD 93/42 / EEC in terms of safety himself. In the case of other risk classes, a conformity assessment body is required for this conformity assessment to allow the manufacturer to affix the CE marking jointly to the notified body and place the medical device on the market. In order to meet the essential requirements for medical devices resulting from MDD 93/42 / EEC, the manufacturer is obliged to prepare a complete technical documentation for the medical device and to ensure an adequate quality management system for medical devices based on ISO 13485 to declare not only that its medical device is but above all, it is safe, under defined production processes.

In relation to the risk class of the medical device, expert estimation of the costs of certification for 5 years of the product's existence after placing product on the market is included as a help for users, see Table No. 3. The estimate is based on company practice in the conditions of the Czech Republic.

Table 3: Certification costs - expert estimate of the costs of conformity assessment costs in the conditions of the Czech Republic (EU)

Risk class	1st year	2nd year	3rd year	4th year	5th year
I	2,248.07 EUR	2,248.07 EUR	2,248.07 EUR	2,248.07 EUR	2,248.07 EUR
Is	13,113.78 EUR	5,245.51 EUR	5,245.51 EUR	8,617.62 EUR	5,245.51 EUR
Im	13,113.78 EUR	5,245.51 EUR	5,245.51 EUR	8,617.62 EUR	5,245.51 EUR
IIa	19,483.32 EUR	7,868.26 EUR	7,868.26 EUR	14,488.45 EUR	8,617.62 EUR
IIb	20,607.35 EUR	8,617.62 EUR	8,617.62 EUR	14,237.81 EUR	8,617.62 EUR
III	22,480.75 EUR	9,366.98 EUR	9,366.98 EUR	14,987.17 EUR	9,366.98 EUR

To determine the return on investment, the key is an expert view and an estimate of the revenue side, where the following variables are monitored (Table No. 4).

Table 4: Expected renevues- quantifiable revenues and benefits throughout the life of the newly developed product

Input information / question	Value
Number of pieces sold per year	Count
Estimated sale price per piece	EUR/piece
Total revenue from licenses / patents	EUR/year
Total revenue from service activities	EUR/year

Calculation of Economic Efficiency

The following three indicators will be used to assess economic efficiency: ROI, NPV and BEP.

Return on Investment (ROI)

ROI is one of the financial indicators that measures the rate of return from a given investment. It is a ratio that measures the loss or gain from an investment in relation to its costs (Beattie 2020). It can be used both when calculating the potential of one investment and when comparing the return on several investments as well. ROI is expressed in percent.

$$ROI = \frac{Net\ return\ on\ investment}{Cost\ of\ investment} \times 100$$

Net Present Value (NPV)

According to Kenton (2020) NPV displays the difference between the present value of cash inflows and the present value of cash outflows for a period of time. NPV is a widely used ratio indicator in the field of investment planning to analyze the profitability of the projected investment. For calculating NPV, the following formula is used:

$$PV = \sum_{t=1}^{n} \frac{R_t}{(1+i)^t}$$

$$R_t = net\ cash\ inflows - outflows\ during\ single\ period\ of\ time\ t$$

$$i = return\ that\ could\ be\ earned\ in\ alternative\ investments\ or\ discount\ rate$$

$$t = number\ of\ periods$$

The discount rate can be defined as the interest rate provided by alternative investments of a similar magnitude and risk. However, there is no general rule that determines which interest rate to use. For the purpose of this study, a discount rate of 8 % is considered.

Breakeven Point (BEP)

The principle of breakeven point analysis is to determine the prices at which the product reaches the target profitability or when revenues exceed the costs of production and marketing. Popesko and Papadaki (2016) also calculate the value of the breakeven point, describing mainly the effect of margin settings. They define it as a unit contribution to the payment of fixed costs and the creation of profit, which consists of the difference between price and variable costs . The

breakeven point expresses how many unit contributions to be paid are needed to cover fixed costs - the calculation is described using the formula:

$$Breakeven\ point = Q(BEP) = \frac{fixed\ costs}{price\ per\ unit - variable\ costs\ per\ unit}$$

After reaching the breakeven point, the product brings a profit that increases with the volume of production until the maximum production capacity is reached.

Results – Medical Device Development

To demonstrate the functionality of the calculator, one company from practice, which operate in the field of medical devices, was contacted. Representative of the company filled in the input data, which specify the costs for individual phases of medical device development (Table No. 5), as well as the expected revenues for the product life cycle (Table No. 6). Specifically, company Tesla Medical s.r.o., which plans to launch a medical device with risk class IIa, was contacted.

Table 5: Phases and costs of medical device development – case studies

Total cost of each phase	Case study – risk class IIa
1. Initiation phase	8,055.60 EUR
2. Concept proposal	10,491.02 EUR
3. Design and development	26,227.54 EUR
4. Verification and validation	13,038.84 EUR
5. Production	2,397.95 EUR
6. Placing product on the market	149,871.67 EUR
7. Parameters associated with the existence of the product on the market	562,693.19 EUR
8. Estimation of conformity assessment costs	86,176.21 EUR
9. Total estimated cost of production of 1 piece of MD	374.68 EUR

From the input data it is clear that in this case study the most expensive phase is Parameters associated with the existence of the product on the market. In this case, most of the costs come from the PMCF (Post Market Clinical Follow-up) over the life of the product - 562,693.19 EUR. The second most expensive phase is Placing product on the market, and the third place is reached by conformity assessment costs.

Table 6: Expected renevues- quantifiable revenues and benefits throughout the life of the newly developed product

Input information / question	Case study – risk class IIa
Number of pieces sold per year	2,000 pcs
Estimated sale price per piece	2,248.08 EUR
Total revenue from licenses / patents	0 EUR
Total revenue from service activities	191,086.38 EUR

The monitored company does not plan to benefit from licenses and patents. The profit will come mainly from the sale of the product and then from service activities.

In the next step, economic efficiency indicators were calculated from the input data, namely Return on Investment (ROI), Net Present Value (NVP), and Breakeven Point (BEP). See Table No. 7.

Table 7: Case studies economic efficiency indicators calculation

Indicator	Case study – risk class IIa
ROI	191,4 %
NPV	2,285,792.14 EUR
BEP	715,417 pcs

In real cases, the obtained data must be interpreted in the context of the given market, position, size of the company, etc. The qualitative input data, which were listed in Table No. 1, are supposed to be used for this purpose. However, the demonstration of the calculator in this paper does not include an interpretation for case studies.

Discussion and Conclusion

In this study, steps of medical device development for economic evaluation were designed and specified. These phases serve as input data for the calculation of economic efficiency. The functionality of the calculator was demonstrated in a certain case study - the company Tesla Medical s.r.o., which plans to manufacture and sell medical devices with risk class IIa. The return on investment was calculated to be 191.4 % for the given situation. The Breakeven Point will be reached after the sale of 715,417 pieces of the product and the Net Present Value is 2,285,792.14 EUR. A discount rate of 8 % was considered for the calculation of the NPV.

Companies doing business in the field of medical devices are located in an environment that is associated with a large legislative burden. This is mainly due to the fact that the manufactured devices must meet health and safety criteria and must not pose any risk to patients or persons using these devices. This is undoubtedly the right and proportionate situation for society, but it involves high costs and investments for manufacturers. Companies in this sector should ensure compliance with current legal conditions and monitor their changes. Within the economic situation, they should regularly analyze variants of future development and calculate the suitability and return on intended investments. On the other hand, the production and sale of medical devices is very promising in all economic periods. This sector is stable even in times of crisis. The current situation regarding the COVID-19 virus, where the business in the medical device is thriving and still growing, can also be a proof.

At the moment, it is possible to proceed in accordance with MDD 93/42 / EEC in the case of clinical trials by comparing the equivalence of a medical device already on the market relatively easily. Perhaps it was just one of the reasons for the establishment of MDR 2017/745, which regulates certain obligations and specifies them for manufacturers. The new legislation will enter into force in May 2021 and it specifies more specifically the design of a clinical trial, where it will no longer be so easy for manufacturers to compare equivalence with the medical device referred to above and regulates the conditions under which the clinical trial must be conducted. It specifies and mandates the manufacturer to perform post marketing clinical monitoring to collect clinical data and to continually verify the effectiveness and safety of the medical device in particular.

The change in legislation in the area of regulating medical devices affects manufacturers, where Notified Bodies are also affected by the same legislation. It turns out that the NB will be reduced and those that remain will have to face increased demand for their services. This demand will not be able to be met immediately. Companies that are aware of this are starting to look for an alternative in a foreign NB, which is currently trying to obtain a notification under MDR 2017/745 or has already received this notification. However, this is associated with an increase in the cost of the conformity assessment process itself, ie certification. This change can be very critical for many small and medium-sized manufacturers.

The limit of this study is expert estimation of conformity assessment costs (Table No. 3), that is based on company practice in the conditions of the Czech Republic. This is because these costs may vary from country to country.

Acknowledgment

This study was made as a result of the implementation of the TAČR ETA project No. TL01000302, *"Development of medical devices as an effective investment for public and private entities"*, that was realized at the Faculty of Informatics and Management of the University of Hradec Králové in cooperation with the Technical University of Ostrava.

Abstract

Edible insects are generally high in protein and can be considered as meat substitutes. Nevertheless, in European countries edible insects' consumption is actually very low mainly due to food neophobia. The purpose of this paper was to explore the readiness of people to consume insects as an alternative protein source. An explorative study among 989 consumers was conducted using a questionnaire via the „google forms" and directly as the technique for data collection. Most of respondents do notice the need to search for an alternative source of protein and they are curious about eating a meal containing insects. Main factors that differentiate the opinions regarding eating edible insects as an alternative source of protein were: level of education, gender, age and the product's degree of processing. People with higher education see a greater need to look for alternative sources of protein than those with basic education. Additionally, men and young people indicate definitely greater desire to consume a meal containing insects than women or older respondents. Most people would be more likely to choose highly processed products. Integration of edible insects as an alternative source of protein into European food culture is possible as people are open and curious. Nevertheless, this process would need an encouragement of consumers using highly processed insects incorporated into ready-to-eat meals, because people seem not to be ready to eat insects in whole form.

Keywords: Insects, Protein, Alternative Source, European Consumers

Introduction

Food is one of the most important products for humans. Maslow in his pyramid indicated that only satisfaction of nutritional needs allows to appear those of a higher level. Although this hierarchy was described in 1943, access to food both today and in the future will remain a problematic issue on a global scale (Mikula, 2012).

From one year to another world's population is increasing. According to the forecasts of the United Nations Food and Agriculture Organization (FAO, 2009), in the year 2050, Earth will be inhabited by 9.1 billion people (Krzywiński and Tokarczyk, 2011,). It is 30% more than at present. The largest increase in the birth rate will take place in developing countries such as India and China (Krzywiński and Tokarczyk, 2011, Zielińska, Karaś and Jakubczyk, 2015). Larger population means increase in need for energy and thus also for protein intake.

Population explosion calls into question food security. This is a global problem, because difficulties in ensuring right amount of food in one country are rapidly becoming problematic in many others. The term „security" comes from the Latin se cura / sine cura and refers to a state in which care is lacking (Kowalczyk, 2016). Main factor,

The Case of Poland" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

which negatively influences future food security is declining area of agricultural land (Buczyńska and Szadkowska-Stańczyk, 2010). Attention should also be paid to the problem of constantly decreasing global water resources, which significantly contributes to the increase of costs and the difficulty of animal husbandry. Consequently there exists a real danger that conventional sources of animal protein, including beef, pork and chicken meat, may become insufficient. Edible insects are potentially environmentally friendly choice for future food systems. In comparison to livestock, rearing insects seems to be more environmentally friendly with regards to greenhouse gas production, water consumption and land requirement (Birgit et al, 2013).

Insects are a valuable source of both macro and micronutrients. Individual insect species contain from 5-77g protein / 100g, the developmental stage also affects this value.Insects' protein is of very high digestibility: 77-98%, thus it is comparable to the digestibility of egg white. In addition, it is complete protein that contains the right amount of exogenous amino acids, similarly to beef (Zielińska, Karaś and Jakubczyk, 2015).

Some species of insects are rich in lysine, tryptophan and threonine, which makes their protein complementary to many plant products that are deficient in these amino acids (Kourimska and Adamkova, 2016).

Currently, various species of insects are considered to be pests. Huge amount of money is spent to control these pests, while harming the natural environment with pesticides. We protect crops containing no more than 14% vegetable protein, while killing another source of food that can provide up to 75% of animal protein. The grasshopper *Phenarium purpurascens* in Mexico is considered a pest. However, the pattern of coping with him is completely different than in Europe. Insects are captured and used as food, thanks to which hundreds of families gain food (Premalatha et al, 2011; Aleksander et al,2017).

Research suggests that marketing activities should be aimed at reducing emotional barrier among consumers. Although the choice of food is a combination of many factors, not only sensual, but also situational, cultural, demographic or cognitive, increasing consumers' knowledge about food produced from insects may have a positive effect on readiness to consume it. Attitudes towards food containing insects differ not only between cultures of different continents, differences being noticeable even between European subcultures (Piha, et al, 2016).

Until December 31, 2017, consumers in Poland could have consumed insects only if they were bought abroad, or caught or raised independently. However, from 1 January 2018 insects were undoubtedly recognized as food, thus entrepreneurs who will request from the European Commission appropriate permission will be able to introduce insects as food to stores. There is also possibility of selling insects in shops without the authorization of the European Commission, then it must be proved that the consumption of a given insect has already occurred in the European Union and was a common phenomenon. The aim of this exploratory study was to understand the consumers' attitude to insects as an alternative source of protein.

Results and Discussion

Data Collection and Sampling

The survey was carried out with a questionnaire method among the residents of Poland using a questionnaire via the "Google Forms" portal and directly. The survey was conducted in December 2018. The questionnaire consisted of 13 questions and separate part concerning demographic background. The estimated time of completing the form was about 2 minutes.

Altogether 989 people participated in the study: 498 women and 491 men. Respondents were divided into four age groups: under 18, from 18-35 years, from 36-65 years, over 65 years. The size of individual groups is shown in Table 1.

Table 1: Sociodemographic characteristics

Category	Subcategory	Number of people	Percentage [%]
Gender	Woman (W)	498	50.4
	Men (M)	491	49.6
Age	<18 years	183	18,5
	18-35 years	635	64.2

	36-65 years	161	16.3
	>65 years	10	1.0
Education	Primary education	21	2.1
	Middle School	138	14.0
	National Vocational Qualification	52	5.3
	Secondary education	373	37.3
	Higher education	405	41.0
Material status	Bad	23	2.3
	Acceptable	323	32.7
	Good	511	51.7
	Very good	132	13.3

The largest group of respondents were people with higher education (41%). Less than 38% of respondents declared secondary education, 14% of had lower secondary education, while a smaller proportion own vocational (5.3%) and basic education (2.1%) (Table 1).

More than half of the respondents declared that had good financial status, less than 33% declared that it was acceptable. 14% of respondents believe that their material status is classified at a very good level, while only slightly more than 2% of them rated it as bad.

Consumers' attitudes towards insects as an alternative source of protein

Most of respondents asked if they notice the need to search for alternative sources of protein replied that rather yes. Only less than 5% of them claimed that they definitely do not see this kind of need. Comparing the answers by gender it can be concluded that this parameter was not influencing the consumers' attitude, the ration of yes/no answers being similar (Figure 1).

Fig. 1: Respondents' opinion towards the need to search for alternative sources of protein. Division of responses according to gender.

Visible factor that differentiates the opinions is the level of education. People with higher education see a greater need to look for alternative sources of protein than those with basic education (Figure 2).

Fig. 2: Respondents' opinion towards the need to search for alternative sources of protein. Division of responses according to the level of education.

A share of 62.7% of respondents declared that they have already heard about the concept of entomophagy (yes 62.7%, not 37.3%.) which is in line with previous findings from Hungary (Attila et al, 2017). The majority of respondents (55.8%) belonging to the group of people with vocational education answered that they have not heard of entomophagy before. The highest awareness of this phenomenon was registered in the group with higher and secondary education (Figure 3). Considering the current state of knowledge it has been concluded that better education can lead to better acceptance of entomophagy among consumers and also reduce prejudice and negative attitude of the public towards the consumption of edible insects (Sogari, 2015).

Fig. 3: Awareness of respondents about the existence of entomophagy. Responses according to their level of education.

People who declared their knowledge of the entomophagy were asked to indicate the source, from which they found out about it. Definitely the most frequent answer was the Internet: 42.8% of the respondents chose it, the second most popular answer was television: 25.7% chose it. The distribution of other answers is visible in the Figure 4. In addition, respondents had the opportunity to indicate their own sources: 13 people indicated the classes at the university, 8 terrarium exchange, 7 work, 6 books and 2 people heard about edible insects in radio.

Fig. 4: Places from which the respondents learned about insects edible.

A proportion of 31.6% of respondents who know the concepts of entomophagy declare that they have already eaten edible insects. In this group there are almost twice as many men as women (Figure 5). Similarly: respondents who answered „yes" to the question whether they would like to try a meal containing insects constituted 33.3% of surveyed people, 23.3% of them are men. In addition, 21.3% of those, asked about the same, answered „rather yes" and here the gender ratio was much more balanced: 9.6% constituted women and 10.7% men. People who definitely would not like to try a meal containing insects constituted 19% of the respondents, of which 13.8% were women (Figure 6). Men indicate definitely greater desire to consume a meal containing insects than women, which is in line with other author's results (Hartmann et al, 2015).

Fig. 5: Percenta.ge of respondents who have already consumed an insect meal. Responses divided according to the gender.

Fig. 6: Percentage of respondents showing a willingness to taste a meal containing insects. Responses divided according to the gender.

Participants of the study who answered the above question „yes, rather yes, neither yes nor no" were asked to indicate factors that would encourage them to ingest insects. Definitely the factor that would have the greatest impact on the decision to consume this type of meal is curiosity (30.8% of answers) and departure to places where insects are traditional food (21.2% of answers) (Figure 7). Some authors also suggested that it does exist an increasing curiosity towards the practice of entomophagy and willingness to try new products containing edible insects (Balzan et al, 2016; Yen, 2009). The respondents had also opportunity to indicate their own reasons: 3 people would choose such a meal because of their nutritional values, 2 because of large amount of meat usually consumed and another 2 because of the desire to diversify the diet. Individual people indicated being a vegetarian and also promotional campaign was emphasized as an important factor.

Similar factors were indicated in the study conducted within Hungarian consumers, who highlighted that insect-based food might attract them as they seek new food choice options and intend to reduce meat intake (Atilla et al, 2017). On the other hand people are not convinced of the additional health benefits of the consumption of insects in comparison to meat. Perceived nutritional value is not the most important barrier that needs to be overcome (Verbeke, 2015).

Fig. 7: Percentage share of factors encouraging the consumption of edible insects.

Each of the participants was asked to determine the probability of eating the products containing insects of different degrees of processing in a hunger situation and the lack of availability of other protein sources. At the beginning respondents were asked about willingness to eat a meal containing raw insects. A share of 27.9% of respondents claim that they would definitely not have eaten such a meal, slightly more women than men answered that answer. However, in the group 13.7% of people who would eat such a meal (answer „yes"), as many as 11.2% are men, and only 3.5% are women. Male gender manifests a definitely greater willingness to consume raw insects (Table 2).

In the situation of limited access to food, over 50% of respondents, including 21.1% of women would eat a meal containing ground and thermally treated insects. In addition, almost 25% of respondents indicated the answer: rather yes. Only 8.5% of people participating in the study would definitely not have eaten such a meal (Table 2). Attitude of people under 65 to this type of dishes is very similar: most of them chose the answer „yes" or „rather yes". People over 65 were slightly more skeptical: responses „yes" and „rather yes" constituted only 40% out of all answers given by this group of age (Table 3).

Table 2: Percentage of respondents declaring willingness to eat insects depending on their form of processing in conditions of hunger and lack of availability of other protein sources with regard to gender

		Yes	Rather yes	Neither yes nor no	Rather no	No
1		Raw insects				
	W	3.5%	7.7%	8.9%	11.3%	15.1%
	M	11.2%	8.8%	8.1%	10.8%	14.6%
2		Insects thermally treated and given in their entirety				
	W	11.9%	14.0%	6.4%	9.9%	8.2%
	M	24.9%	14.0%	3.8%	3.8%	3.1%

3		Ground insects subjected to thermal treatment				
	W	21.1%	14.9%	5.3%	4.1%	5.0%
	M	30.8%	9.6%	3.5%	2.1%	3.5%
4		Insects as an addition in the form of flour				
	W	24.3%	15.1%	3.6%	2.8%	4.6%
	M	32.4%	9.0%	3.7%	1.5%	3.0%
5		Insects in the form of a protein isolate				
	W	23.9%	12.8%	5.3%	3.4%	5.0%
	M	32.9%	9.4%	3.1%	1.2%	3.0%

Analyzing this question in terms of the age of respondents, it can be seen that younger people more often indicate answers yes, or rather yes than in the case of people at more advanced age. 80% of respondents over 65 years of age would definitely not eat a meal containing raw insects (Table 3).

On the question of the probability of eating a meal containing whole heat-treated insects, 36.8% of people answered yes, and 28% rather yes, as in the previous question, in the group of people who chose the first option there are more than 2 times more men than women (Table 2).

Percentage distribution of individual answers in each age group shows a tendency that with the lower the age there is a greater willingness to try an insect meal. However, in this case, up to 40% of people over 67 said that they would rather eat the meal (Table 3).

Table 3: Percentage of respondents declaring willingness to eat insects depending on the form of processing in conditions of hunger and lack of availability of other protein sources in particular age groups

		Yes	Rather yes	Neither yes nor no	Rather no	No
1		Raw insects				
	>65	0.0%	0.0%	0.0%	20.0%	80.0%
	36-65	13.5%	15.3%	17.2%	27.6%	26.4%
	18-35	16.3%	14.5%	16.1%	22.5%	30.6%
	<18	11.5%	25.1%	20.8%	16.4%	26.2%
2	Insects thermally treated and given in their entirety					
	>65	0.0%	0.0%	40.0%	10.0%	50.00%
	36-65	30.4%	27.3%	13.0%	14.3%	14.9%
	18-35	37.8%	27.6%	9.8%	12.8%	12.1%
	<18	41.0%1	29.0%	9.3%	14.8%	6.0%
3	Ground insects subjected to thermal treatment					
	>65	20.00%	20.0%	30.0%	20.0%	10.0%
	36-65	49.7%	25.8%	11.3%	2.5%	10.7%
	18-35	52.3%	25.1%	7.4%	6.8%	8.5%
	<18	54.60%	21.30%	10.40%	7.1%	6.6%

4		Insects as an addition in the form of flour				
	>65	40.0%	60.0%	0.0%	0.0%	0.0%
	36-65	51.6%	27.3%	6.8%	3.7%	10.6%
	18-35	57.0%	23.6%	6.9%	4.9%	7.6%
	<18	60.70%	20.80%	9.8%	3.3%	5.5%
5	Insects in the form of a protein isolate					
	>65	40.0%	60.0%	0.00%	0.0%	0.0%
	36-65	48.4%	24.8%	10.6%	5.6%	10.6%
	18-35	57.2%	20.5%	8.5%	5.2%	8.7%
	<18	63.40%	24.0%	6.60%	2.2%	3.8%

Another question addressed to respondents concerned the desire to ingest insects in the form of flour in conditions of absence of other sources of protein. As in previous questions, men are more likely to eat insects, however, the total number of people who answered „yes" is higher than in the previous question and is 56.6% of all respondents. The amount of people who replied that they „definitely would not" and „rather would not" eat is adequately 3% and 1.5% (Table 2).

Again, the highest percentage (60,7%) of responses „yes" was in the group under 18 years old; slightly less - 57% was in the group of 18-35 years and 51.6% among people aged 36-65, but in the two last groups, more people answered „rather yes". As a result: the total percentage of respondents answering „yes" and „rather yes" in each of the three groups discussed above reached a very similar level around 80%. On the other hand, respondents over 65 years old in 40% chose the answer „yes", the remaining 60% of people from this group indicated the answer: „rather yes" (Table 3).

The last question concerned whether in the case of hunger and the lack of availability of other sources of protein people would be willing to eat a meal containing insects in the form of a protein isolate. A share of 56.7% of respondents answered that yes, 32.9% of them were men. The answer „rather yes" was indicated by 22.2% of the respondents, which together with the group of people who chose the variant „yes", gave 78.9% of all answers. Only 8% of respondents would definitely not eat insects in the form of an isolate, 5% of this group were woman as presented in Table 2.

Other authors' studies indicate that consumers' positive intention to eat insects strongly depends on the form and appearance of the products. Insects can be either visible or unrecognizably processed as ingredients. It is certain that food acceptance is influenced by visual appearance and food texture (Logue et al, 1981). Therefore it can be concluded that the perception of eating an insect-based food (i.e. cricket flour in bakery products) is not the same as the perception of eating a visible insect (i.e. a whole cricket). It appears rational to grant that the invisible insect inside a processed food might have more positive acceptance (Tan et al, 2015).

With increase of the respondents age, the share of people choosing answer „yes" and „rather yes" drops. The exception is the group of respondents aged over 65, where the answer „rather yes" was chosen by almost 60% of respondents. Comparing the results of groups: under 18, 18-35 and 36-65 it can be noticed that the number of people undecided is growing with age (answering: neither yes nor no) and those who choose „rather no" and „definitely not" (Table 3).

Similar research was carried by Hartmann et al (2015) among residents of Germany and China. Results revealed that Asians show greater readiness to ingest insects and most of the respondents said they had eaten insects before. Germans would be more likely to use highly processed products, while in China the readiness for consumption did not differ significantly due to the degree of processing. In the Western Europe countries the majority of people refuse the idea of eating insects, for mainly cultural reasons and generally not regarding it as food (Sogari et al,

2017; Tan et al, 2016). Other studies indicate that the most common reason for refusing to taste an insect-based product is the disgust factor (Sogari, 2015).

Conclusion

This study presents an insight on attitudes of entomophagy acceptance as source of protein among Polish consumers. On the basis of consumer surveys it can be concluded that a large number of people perceives the need to look for alternative sources of protein. For the most of the respondents the concept of entomophagy is known but the percentage of people who have already eaten insects is low. The gender is an important factor in determining the willingness to eat a meal with insects, also differences are noticeable between different age groups. Attitudes to meals containing insects are also determined by its degree of processing. It is similar result to the study carried among German consumers: most people would be more likely to choose highly processed products. Men indicate definitely greater desire to consume a meal containing insects than women. The age of respondents is a factor that impacts consumers' openness: people of older generations have much more prejudices to entomophagy than those of the younger ones. It may be due to the fact that older people are more accustomed to the traditional cuisine and they cannot imagine introducing a revolution into their diet like eating insects. Among Polish consumers, meals containing insects in a highly processed form - for example protein isolates, have a greater chance to gain popularity than unprocessed ones. The target group should be young generation because of their greater openness to the new products.

Abstract

In this time of health crisis, it is important to make adjustments of resources encountered in many areas dealing with logistical issues by minimizing the costs of transportation and maximizing the satisfaction and preferences of patients in the field of Home Health Care. In this paper, we deal with the vehicle routing problem with time windows, precedence, and synchronization constraints along with staff lunch break requirements combined with the scheduling and planning matter. Oftenly, patients whom are not requiring anymore staying at hospital are needed to leave their spot to another critical case, but need further treatment that can be done at home. Caregivers are assigned to perform special care to needy patients depending on their demands by taking into consideration temporal constraints such as time windows, preferences of patients, precedence, synchronization and more importantly the issue of caregivers' lunch breaks which give a realistic aspect to the problem.

A caregiver (vehicle) is assigned to a patient (customer) to perform a number of given cares with multiple options according to the customer wishes like time windows requirement often specified by the patient, the precedence constraints are usually done if a specific care must be done before another and could involve more than one caregiver and must have at least one lunch break per day and it is not always taken at a fixed time of the day and must be flexible to maximize the satisfaction of customers' demands.

To solve this problem, a mathematical model of the problem is described as a Mixed Integer Linear Programming (MILP) and a method based on a Greedy Randomized Adaptive Procedure (GRASP) is proposed. At the end of the paper, results are shown on a benchmark derived from the literature.

Introduction

Over the years, the number of diseases has increased significantly meaning the average number of patients per one hospital bed have ascended thus the need of giving care to sick people in their homes have become crucially needed. It is very important to cite that pandemic (SAR-COV-19) (Euchi., 2020), have led to prioritize the necessity of moving patients from their homes or vice-versa much needed. Due to these circumstances, challenges have arisen a lot for conducting researches in the field of operations researches and decision support in this field. Coordinating either human and resources is the core to provide an optimized planning in order to reduce/minimize the costs while maximizing the quality of home health care services for both working staff (Lunch Breaks, Preferences…) and patients (Time Windows, Preferences, Precedence…).

In this paper, we propose an adaptation of the vehicle routing problem with the windows, synchronization, precedence and lunch breaks constraints. This problem consists of looking for a set of routes performed by a fleet of vehicles (regarded as caregivers) to serve a set of customers (patients) in a predetermined geographical area, respecting a certain availability in the most effective and efficient manner. A service that the home health care facility provides must occur within a determined and accurate time and can require the intervention of one or many

caseworker either at the same time (simultaneously) or in a specific order (precedence) which means that a customer (patient) must be ensured two or more services in a row (not at the same time). On the other hand, after a certain amount of working time by the caregiver, it is mandatory to have a break time to eat and rest. The lunch break generally has a time windows (e.g.: 13:00-14:00) and a period of time (e.g.: 45 min). In our study, all those prerequisites enforce the collaboration and coordination of many caregivers to achieve the desirable objectives which lead us to consider the problem as an alternative of the vehicle routing problem with time windows called VRPTW-SPLB for the Vehicle Routing Problem with Time Windows, Synchronization, Precedence and Lunch Break constraints.

Literature Review

This section illustrates the state of the art of the vehicle routing problem (VRP) encountered in the home health care sector (HHCS) viewed as a combinatorial optimization problem in the field of Operation Research. The philosophy derived from this type of problem is that the transportation and carriage of people (elderly/disabled/critical state), and medical devices delivery to customers' (patients') homes must occur with a time interval mostly known as time windows (VRPTW) is the essential and classical form to initiate the solution. A lot of scientists working on this field start from this initial point to carry on many variation of this problem itself. To illustrate all this, a classification according to two clusters has been done:

Pick-up and Delivery Problems

This cluster tackles the matter of delivering/picking-up patients or goods from a site A to a site B as explained in (Diabat el al., 2016),(Zhang el al., 2018), in the same line (Liu el al., 2013), (Coppi el al., 2013) and (Ceselli el al., 2014) were interested in solving problems of transporting medical devices and medicines to customers' (patients') homes and collecting drugs, samples that are no longer used by patients. Others such as (Shuang el al., 2019), (Alkaabnech el al., 2020) looked into this problem as a variation which considered heterogeneity of a fleet of vehicles which means that vehicles can deliver or collect on the same path, some customers may require several visits in the same time windows and several depot can be found, thus dividing deliveries between vehicles can occur. Another interesting case was introduced by (Rousseau el al., 2003) whom works on a Dial-a-Ride problem (DAR) where customers (patients) demands one or more particular services before the transportation can be done.

Planning and Scheduling Problems

This cluster tackles the matter of allocating missions to a set of caregivers according to a specific planning and visits schedules. A lot of works have been conducted on this area, (Bertels el al., 2006) that considered the allocation of nurses whose professional qualifications and skills vary along with (Bredström el al., 2007, 2008), (Braysay el al., 2009), (Bredström el al., 2007) and (Rasmusen el al., 2010) whom have opted to give a set of skills to each of the staff (caregivers) such as sex gender, medical expertise, spoken languages… From what was said, restrictions have been set to decide objectively according to the caregiver skills the actual and profitable assignments to each patients' needs and demands. To illustrate and to give a clear idea, each caregiver from their initial depot (start point) are required to visit patients according to the type of care suitable for the patient within a specific time windows, each care type have a certain amount of time (duration) not to exceed and a type of skill.

Before moving on, taking caregivers desires and needs into consideration is essential for the service quality of tasks performed. Hunger, thirst, fatigue, day-off, vacation and much more needs cannot be neglected. Likewise a care is given by a caregiver to a patient within a certain time windows, lunch break also have a specific time windows with a limited duration. (Yuan el al, 2015) have considered lunch break as a stochastic service time meanwhile (Liu el al, 2016) included it as a requirement (constraint). Many recent works dealing with lunch break in the Home Health Care Services have allowed it on the condition that shift length is longer than a predetermined time either without considering time windows (patients are visited at any time) or at a fixed time. (Trautsamwieser el al., 2014) allowed taking break on the condition that the successive working time prescribed for the caregiver is surpassed.

After reviewing some of the past works on this theme, we observed that most used methods for solving such problems is the Mixed Integer Programming which is considered an exact method such as the branch-and-cut-and-price used by (Bredström el al., 2008), (Rasmusen el al., 2010) without including lunch break requirement for the working staff (caregivers), meanwhile (Yuan el al., 2015) and (Liu el al., 2016) included lunch break constraints. Approached methods commonly known as meta-heuristics are most suitable for dealing with this type of problems

and are mainly based on Large Neighborhood Search and Local Search as seen in (Rich., 1998), (Rousseau el al., 2013) and (Lin el al., 2019).

Problem Description

This paper addresses a variant of the vehicle routing problem with time windows, precedence and synchronization constraints along with staff' lunch break requirement in the Home Health Care System.

The VRPTW-SPLB can be considered as a graph G= (V, E) where V is a node-set V= NUD where N = {1… n} corresponds to a group of customers (patients) and D = {c, f} are nodes where c is the initial depot (center) and f the final depot. M denotes as a margin (edge) set where each margin m = [i, j] is linked to a travel cost C_{ij} and a travel durationT_{ij}. S denotes as a set of services where the initial depot (center) c offers a choice of multiple services S = {1…s} to customers (patients). A customer i demands a subset of services ensured by a set $S_i = \{s \in S: e_{is} = 1\}$ where e_{is} matches 1 if a patient I requires services ∈ S, and 0 if not. For each service s provided to a patient i is associated a time duration d_{is} and a time window $[a_i, b_i]$; where a_i is the earliest service start time and b_i the latest service start time of patient i. K is the set of vehicles available at the initial depot (center) c and for each k ∈ K an availability time window $[\alpha_k, \beta_k]$ where a vehicle k can only leave the depot c at α_k and must return to the final depot f at β_k. To assure the preference of each vehicle k, a number Prf_{ik} is associated to the vehicle k and denotes the non-preference of customer (patient) i to the vehicle (caregiver) k.

For the sake of this study, we suppose that k ∈ K accomplishes a unique service s. y_{ks} equals 1 if vehicle k offers the service s, 0 otherwise (∀ k ∈ K, ∀ s ∈ S).

P denotes the lunch break and has a duration L and a time window $[w_p, z_p]$ as put by (Cheng and Rich, 1998). g_{ik} equals 1 if the caregiver uses his/her break at patient i before service completion and 0 otherwise, g'_{ik} equals 1 if the caregiver uses his/her break at patient i after service completion, 0 otherwise. st_{ik} is the service start time of caregiver k at patient i and st_{pk} is the lunch break time start of the caregiver k. For the sake of simplicity, we write $k \in K_s$ if y_{ks}=1 and $s \in S_i$ if $e_{is} = 1$.

For customers (patients) whom are demanding more than one service either in a specific order or simultaneously, we define for each patient i ∈ N a $slot_{isr}$ as the time separating the time start of service s and service r demanded by patient i where services s and r have to be provided in a given order (service s before service r).

This problem formulation considers the minimization of the sum of non-preferences of patients towards caregivers and total travelling time by shortening to the maximum the total travelled distance overall.

(Ait Haddadene el al., 2016) and (Labadie el al., 2014) have conducted similar studies but did not consider caregivers' lunch break requirement. This kind of problem is known to be an NP-hard problem. For the first resolution, we will use the Mixed Integer Linear Program (MILP) considering the binary and real variable decision respectively as follows:

- x_{ijk}=1, if k ∈ K travel from i to j, 0 otherwise
- st_{ik} infers to the start time of service at node i if customer (patient) i is visited by vehicle (caregiver) k.

To generalize the constraints of time in this formulation, we presume that all the requested services by patients are asked independently from the initial depot (center) c and their duration is 0 (D_{cs} = 0, ∀ s ∈ S).

Mathematical Formulation

The MILP corresponding to our formulation is as follows:

$$min \sum_{i\epsilon V\setminus\{f\}} \sum_{j\epsilon V\setminus\{c\}} \sum_{k\epsilon K} C_{ij}\, x_{ijk} + \sum_{i\epsilon N} \sum_{j\epsilon V\setminus\{c\}} \sum_{k\epsilon K} Prf_{ik}\, x_{ijk} \qquad \textbf{(1)}$$

Subject to:

$$\forall k \in K\,, \sum_{j\epsilon N} x_{cjk} = 1 \qquad \textbf{(2)}$$

$$\forall k \in K, \sum_{j \epsilon N} x_{ifk} = 1 \quad \textbf{(3)}$$

$\forall h \in N, \forall k \in K,$

$$\sum_{i \epsilon V \setminus \{f\}} x_{ihk} = \sum_{j \epsilon V \setminus \{c\}} x_{hjk} \quad \textbf{(4)}$$

$\forall i \in N, \forall s \in S,$

$$\sum_{j \epsilon V \setminus \{c\}} \quad \sum_{k \epsilon K_s} x_{ijk} = e_{is} \quad \textbf{(5)}$$

$\forall k \in K,$

$$\sum_{i \in V} g_{ik} + \sum_{i \epsilon V} g'_{ik} = 1 \quad \textbf{(6)}$$

$\forall k \in K, i \in V,$

$$g_{ik} + g'_{ik} \leq \sum_{i \epsilon V} x_{ijk} \quad \textbf{(7)}$$

$\forall k \in K, j \in V,$ $\quad st_{pk} + L.g_{jk} \leq ts_{jk} + (1 - g_{jk}) z_p$ **(8)**

$\forall k \in K, i, j \in V,$

$$st_{ik} + (T_{ij} + d_{is})(x_{ijk} + g_{jk} - 1) \leq st_{pk} + (2 - x_{ijk} - g_{jk}) b_i \quad \textbf{(9)}$$

$\forall k \in K, i, j \in V,$

$$st_{pk} + (L + T_{ij})(x_{ijk} + g'_{ik} - 1) \leq st_{jk} + (2 - x_{ijk} - g'_{ik}) z_p \quad \textbf{(10)}$$

$\forall k \in K, i \in V,$

$$st_{ik} + d_{is} g'_{ik} \leq st_{pk} + (1 - g'_{ik}) b_i \quad \textbf{(11)}$$

$\forall i, j \in V, \forall s \in S: s \in S_i \cup S_j, \forall k \in K_s,$

$$st_{ik} + (T_{ij} + D_{is}) x_{ijk} \leq st_{jk} + b_i (1 - x_{ijk}) \quad \textbf{(12)}$$

$\forall i \in N, \forall s \in S_i, \forall k \in K_s,$

$$a_i \sum_{j \in N} x_{ijk} \leq st_{ik} \leq b_i \sum_{j \in N} x_{ijk} \quad \textbf{(13)}$$

$$\forall k \in K, \quad \alpha_k \leq st_{ck} \leq \beta_k \quad \textbf{(14)}$$

$$\forall k \in K, \quad \alpha_k \leq st_{fk} \leq \beta_k \quad \textbf{(15)}$$

$$\forall k \in K, \quad w_p \leq st_{pk} \leq z_p \quad \textbf{(16)}$$

$$\forall i, j \in V, \forall k \in K, \quad x_{ijk} \in \{0,1\} \quad \textbf{(17)}$$

$$\forall i \in V, \forall k \in K, \quad g_{ik}, g'_{ik} \in \{0,1\} \quad \textbf{(18)}$$

$$\forall i \in V, \forall k \in K, \quad st_{ik} \in \{0,1\} \quad \textbf{(19)}$$

The objective function **(1)** is to minimize the total travelling time and the sum of non-preferences. Constraints **(2)** and **(3)** ensure that each vehicle must leave initial depot and return to it. Constraint **(4)** secures the continuity and constancy of the routes while constraint **(5)** ensures that the demands of customers (patients) are provided and executed. Constraint **(6)** assures that every one of the caregivers takes a break in the route, meanwhile constraints **(7)** affirm that the caregiver k uses his/her break at patient i on the condition that the patient i is visited by this caregiver. Constraints **(8)**, **(9)**, **(10)**, **(11)** assert the accurate start times of breaks utilized by caregivers before and

after services in customers' (patients') homes. Scheduling permitting the consistency between the durations of visits is maintained by constraint **(12)**. Constraints **(13)**, **(14)**, **(15)**, **(16)** guarantee the respect of patients, caregivers and breaks time windows. Constraints **(17)**, **(18)** and **(19)** define the nature of the decision variables.

Just to note that lunch breaks are not depending entirely on the time duration of the route, and a lunch break can be taken and utilized if the duration of the route outpaces and exceeds α_p. It is also permissible to take a lunch break at the end of a route even if the time window of the lunch break is not yet covered.

Resolution Approach

(Féo el al., 1995) introduced a method called Greedy Randomized Adaptive Procedure (GRASP) which enables to construct at first an initial solution *Res* by the mean of a randomized parallel constructive heuristic (RP) that aims to offer a feasible solution working as a start point of the resolution process, however it could lead to an unfeasible solution, which take us to consider the use of an Insertion Procedure (IP) to fix the solution. After this step, we improve the solution by using a Local Search (LS). This process is replicated a certain number of times given an *IterMax* by the loop For. At each iteration a new solution replaces the current one if it is considered to be better, then the new solution is considered as the current solution.

GRASP Algorithm

```
begin
    X* ⟵ +∞
    for NbIter ⟵ 1 to iterMax do
        Res ⟵ RP ()
        if (Res unfeasible) then
            Res ⟵ IS (Res)
        Res ⟵ LS (Res)
        if (X (Res) ≤ X*) then
            Res* ⟵ Res
            X* ⟵ X
```

Constructive Heuristic

Randomized Parallel Constructive Heuristic (RP) is suggested to produce a primary solution. Each available vehicle has an opened route, subsequently these routes are connected to customers (patients) randomly and chosen in parallel manner, then inserted by applying the finest insertion procedure. We suppose these variables:

- i: The recent node visited by a vehicle k,
- $EarliestDate_{ij}$: The earliest appointment on which the vehicle (caregiver) k leaving the node i might be at the customer (patient) j,
- $LatestDate_{ij}$: The latest appointment when the vehicle (caregiver) k leaving the customer (patient) j may be at the customer j,
- $LowerBound_{js}$&$UpperBound_{js}$: The lower and upper bound that guarantee the homecoming to the depot s in their respective time windows.
  $EarliestDate_{ij} \leq b_j$ & $EarliestDate_{ij} \leq w_p$
  $LatestDate_{ij} \geq a_j$ & $LatestDate_{ij} \geq z_p$
  $LowerBound_{js} \leq st_{jk} \leq UpperBound_{js}$
  $LowerBound_{js} \leq st_{pk} \leq UpperBound_{js}$
  To those four expressions ensure that a patient j is eligible to be candidate for a tour *tr* under the condition of finishing the visits of patient i by caregiver along with his/her lunch break. If not, the list of all candidates is shrunk to keep only the candidates served by the vehicle. For a

synchronized visit asked by a customer (patient) for the first time, the service start time is set for its double visits.
When there are no customers (patients) left to add to a vehicle (caregiver) k as a result of time windows, the algorithm ceases. After the completion of this step, we could still have an unfeasible solution, thus the need to construct and develop an Insertion Procedure (IP) in order to repair the available unfeasible solution.

Insertion Procedure

If the solution provided by Randomized Parallel Constructive Heuristic(RP) is not feasible, the Insertion Procedure comes into play by considering that all patients have not been visited by the RP Procedure. This insertion benefits the inclusion of customers (patients) in the best location in any available route. This insertion advantage the minimization of extra costs and feasibility of timing/temporal constraints.

Local Search

GRASP involves five classical neighborhood in Vehicle Routing Problem included under the Local Search procedure and are summoned in the subsequent order:

1. Migration applied for a unique route; a patient is altered from a current location to another in the same path way,
2. Migration applied on various routes; a patient is altered from a current location to another in the same path way,
3. 2-swap moves performed within a singular route; two patients affiliated to a similar route are swapped;
4. 2-swap moves performed within various routes; two patients affiliated to two different routes are swapped;
5. 2-opt moves performed on a singular route; two non-successive boundaries (nodes) are removed and replaced by new ones.

The primary feasible move is applied and the moves are perceived as successive. When there are no moves which can improve the solution, the search terminates.

Numerical Results

(Bredström el al., 2008) proposed a set of instances to test the proposed model. A clustering of three distinct categories is set up to validate the proposed study, this benchmark contains three parameters; the number of customers is equivalent to patients in our case, the number of vehicles equivalent to caregivers and are grouped according to this scheme:

- 18 clients (patients) with the use of 4 vehicles (caregivers),
- 45 clients (patients) with the use of 10 vehicles (caregivers),
- 80 clients (patients) with the use of 16 vehicles (caregivers),

To incorporate the notion of synchronization, we opted to deal with a range number linked to synchronization from two to four, the lunch break for the sake of generalization is always taking after performing successfully a service s. Time windows is grouped by small, medium and large. In our case, we put the limit to not exceed at most two requested services.

The first implementation that considers the mathematical model was done by CPLEX Studio version 12.10, and the meta-heuristic and heuristic part were implemented using Python 3.8. The hardware specifications of the machine used to generate the solution is as follows: 2.4 GHz Intel Core i7-5500 CPU with 8GB of RAM, functioning under Windows 10 Home. As explained before, GRASP method requires two additional parameters to function properly, *iterMax* and the maximal candidates' size *Ncand*. After many tests and launches done, we found that the suitable values set to these two parameters are 100 for *iterMax* and 5 for *Ncand*. We launched the algorithm a number of 8 times.

Table I: MILP Solutions

Instance	Objective	CPU(ms)
18_4_s	62.25	930
18_4_m	60.13	1956
18_4_l	49.59	2812
45_10_s	-16.65	4012
45_10_m	-50.14	5236
45_10_l	-98.64	7054

As shown from the results of Table (I) and Table (II), the instances are referred in column 1; where the first value indicate the number of patients, the second one the number of caregivers aka vehicles and finally the indexes s and m and l refer to the time windows width respectively(small, medium and large). To make it clear, we take 18_4_s where 18 indicate that there is 18 customers (patients), 4 indicates that there is 4 vehicles (caregivers) and s design that the width of the time window is small. The other two columns refer respectively to the objective function value for the best feasible solution achieved in both tables and the final column refers to the running time obtained after the completion of the running process (given in milliseconds).

Table II: GRASP Solutions

Instance	Grasp	CPU(ms)	Gap(%)	Average Cost
18_4_s	71.12	1145	14.24	71.46
18_4_m	70.45	1298	17.16	71.12
18_4_l	50.2	2512	1.23	49.68
45_10_s	97.69	4150	686.72	125.35
45_10_m	31.87	8925	163.56	33.74
45_10_l	-51.03	15305	48.25	-46.05
80_16_s	-104,32	22531		-89.24
80_16_m	-117.32	22460		-94.98
80_16_l	-130.64	23102		-96.23

The gap percentage value of column 4 of Table (II) is calculated according to a formula shown as follows:
$\text{Gap} = ((\text{Grasp} - \text{Objective}) \times 100) \div \text{Objective}$

Where Grasp corresponds to the value of column 2 in Table (II) and Objective corresponds to the value shown in column 2 of Table (I). Column 5 of Table (II) refers to the average cost' solution after running the process 8 times. It is obvious that for the MILP solutions provided by the CPLEX solver are only feasible for small instances with a reasonable running time, where on larger instances; the time of computation is increasing remarkably. We also notice that when time windows' width becomes larger, computational time grows considerably. CPLEX solver is limited and cannot solve instances of 80 clients and above. Meanwhile the GRASP algorithm shows some extent of efficiency and offer solutions somehow on a reasonable scale.

Conclusions and Perspectives

As explained throughout this paper, we somehow approached a realistic aspect of the vehicle routing problem in the home health care sector by adding the lunch break requirement along with temporal, synchronization, and

precedence constraints. We presented two types of resolution method, an exact one (MILP) and an approximate one (GRASP). The experiment conducted was done relatively for 9 instances derived from the benchmark introduced by (Bredström el al., 2008) where the MILP showed its effectiveness only on small instances, where the GRASP method can optimally solve up to 80 customers (patients) relatively in an acceptable time. It is good to note that this kind of problem is an NP-Hard one and its computation time grows in parallel with large instances.

For future works, it is preferable to introduce more constraints such as customers' preferences in order to render the problem to be more complex. The use of mixed heuristic and meta-heuristic algorithms can prove to be a good alternative to improve the solution already found. Also, this problem can be extended to handle the overall waiting times in order to minimize it.

Abstract

This study concern about untapped market and lower market share of takaful compared to conventional insurance and how social media marketing could shed some problems by influencing purchase intention of takaful. The purpose is to examine the determinants of attitude towards takaful, and purchase intention. This is a quantitative research. Five variables identified in this study namely: *social media marketing, sharia compliance in social media marketing, sharia compliance in product, attitude* and *purchase intention*. Purposive sampling technique was used in this study and analysis of data from the results of a survey of 156 muslims using Structural Equation Modeling (SEM) analysis and Lisrel program. The eventual result of regression analysis showed that social media marketing and sharia compliance in product had a positive impact on purchase intention through an intermediary attitude towards takaful. While sharia compliance in social media marketing has proven to have a negative impact on attitudes towards takaful among muslim customers in Indonesia. Analysis and findings show that there are significant intention in the muslim community in Indonesia to purchase takaful. The results of this study provide which new strategies to takaful operators to implemente social media marketing strategies to intensify consumer awareness towards takaful products. This study examines purchase intentions and the role of social media marketing in the takaful industry, which is still limitedly discussed in previous studies.

Keywords: Social Media Marketing, Sharia Compliance In Social Media Marketing, Sharia Compliance In Product, Attitude, Purchase Intention, Islamic Insurance, Takaful.

Background

Insurance as practiced by conventional insurance companies has been discussed by many Islamic scholars at the international level, among others at the Islamic Economic Congress in Mecca (1976), the Great Ulama Unity Council at Saudi Arabia (1977), and Majma'al-Fiqh al-Islam al-Alami (Union of Fiqh Ulama World) in Mecca (1979 and 1985) (Perwira, 2019). These conference states that conventional insurance is haram. Then they make an ijma' that insurance on the basis of helping each other (ta'awuni) is an insurance that is permisible in Islam.

Takaful, stemming from the Arabic verb kafal, meaning to take care of one's needs, is descriptive of a practice whereby participants in a group agree jointly to guarantee themselves against loss or damage (Wahab et al, 2007). For example, in Indonesia, According to Law Number 40 of 2014 concerning Insurance, the definition of sharia insurance is a collection of agreements, which consists of agreements between the sharia insurance company and policy holders and the agreement between the policy holders, in order to manage contributions based on sharia principles in order to help and protect each other by:

Cite this Article as: Dini Amalia Putri, Nurwahidin and Hardius Usman "The Effect of Social Media Marketing on Purchase Intention of Takaful in Indonesia" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

1. provide reimbursement to participants or policyholders because loss, damage, costs incurred, loss of profit, or legal liability to third parties that participants may suffer or policy holders due to an uncertain event; or
2. provide payment based on the death of the participant or payments based on the participant's life with benefits the amount has been determined and / or based on the results of fund management.

Global takaful industry is increasingly every year. According to Islamic Financial Service Industry Stability Report (2020) in 2018 total contribution of Takaful reached USD 27.07 billion, growing 3.2% from 2017. Total of Takaful asset has only reached 1.1% of total assets of Islamic economy. Its assets is expected to increase to USD 48.1 Billion in 2025 (Imarc, 2019). In Indonesia Takaful has double up its asset from Rp 22.4 trilion in 2015 to Rp 45 trilion in 2020 (Indonesian Islamic Insurance Association, 2020). However this numbers does not show its best potential.

Therefore, insurance, especially takaful operators should take an innovative way to enlarge takaful market. Takaful operators need to adopt a new marketing strategies in order to create a demand for takaful products.

The lack of awareness, knowledge, and exposure to takaful have direct impact on purchase intentions towards takaful. This is in accordance with the Otoritas Jasa Keuangan (OJK) report that said insurance literacy index in Indonesia was only 15.76 percent in 2016.

Indonesia, which consists of thousands of islands, presents its own challenges in literacy efforts and access to insurance. Technological improvements will open new insurance distribution and communication doors through digital channels rather than conventional ways, as it will open up new markets that have been constrained by distances.

In recent years, there has been a change in the market along with the emergence of the digital world. This changes was welcomed by Indonesian. Data from We Social in Jan 2020 showed the number of Indonesian internet users reached 175.4 million people or 64% of the total population. With 160 million people of them actively used social media and spent average 3 hours and 26 minutes on social media.

According to a survey conducted by Daily Social Research entitled Insurance Technology Research 2019, 69.4% of respondents were familiar with the term insurtech and 83.9% of respondents had bought insurance through insurtech. The majority of respondents 41.46% of respondents notice insurtech through social media.

Daily Social Research with Mandiri Capital conduct another survey about Insurtech in 2020. It said in that survey that consumers who have used insurtech services showed satisfaction with the products and services that they are using.

Social media are used to connect and share many things, such as experiences, reviews and information to their "connections". That information is a useful source, which might influence consumer decision making.

One of the main aims of using social media for promotion and communication is to shape the consumer’s decision-making process (Tuten and Solomon, 2018). Therefore, this study attempts to predict the customer’s purchase intention for the takaful that are promoted using social media.

Literatur Review

Social Media Marketing

Social media is a computer-mediated interactive technology that facilitates the creation and sharing of information, ideas, career interests, and other forms of expression through communities and virtual networks (Kietzmann et al., 2011). Kaplan and Haenlein (2010) propose the following categorization of various social media services: blogs, social networking sites (eg Facebook), collaborative projects (eg Wikipedia), content communities (eg YouTube), virtual social worlds (eg Second Life), gaming world virtual (e.g. World of Warcraft).

Social media marketing is understanding how technology makes it easier for people to connect socially with their social networks and how businesses can benefit from that understanding (Bashar et al., 2012). Balakrishnan et al. (2013) explained that online marketing communications, specifically, E-WOM, online communities, and online advertising are effective in promoting brands and products through corporate websites and social media platforms and then consumers provide feedback through social media to increase purchase intention. It was further found that brand awareness and image mediate the influence of social media marketing on purchase intention. Many studies (Kosarizade and Hamdi, 2015; Akhtar et al., 2016; Laksamana, 2018) shows that there is a positive relationship between social media marketing and purchase intention. Based on the above, the following proposition is proposed:

H1 : there is a significant relationship between social media marketing and muslim's attitudes towards participate in takaful

Religiousity Aspek and Behaviour

Tylor (1871) define culture as complex whole which includes knowledge, belief, art, morals, law, custom, and any other capabilities and habits acquired by man as a member of society. Culture can have impact on how's people words, act or behave. Consumer makes decisions based on a lot of priorities, including personal beliefs, peer group influences, social status, economic status, cultural affinity, and other environmental variables (Goodhope, 2013). Many studies shows that culture influences buying habits and behaviours of consumers (Shaw and Clarke, 1998; Liu et al., 2001).

According to Kotler (2000), religion is a part of culture that can shape people's behaviour. As we discuss Islamic insurance and our subject is muslim, its only right that we added Islamic value on to this study.

Islamic financial products must be within the limits of sharia rules. Takaful is a brand that identifies and differentiates whether an insurance is managed with sharia principles or not. Takaful has a different concept from conventional insurance, where it is not presence of elements of gharar, usury, maishir, etc. The concept used by Takaful is in accordance with Islamic values that should be held by a muslim.

Based on research findings (Johan et al., 2017; Dusuki and Abdullah, 2007; Metawa and Almossawi, 1998; Wilson and Liu, 2011) found that sharia compliance/ religious value/ Islamic norm/ Islamic faith has a significant relationship with interest in Islamic financial products.

Apart from the products offered, in order to met the Islamic value, companies also need to pay attention to how the product is marketed, such as not making a promotion contain elements of fraud, vilify others, promote something that the product doesn't actually have.

Sharia compliance in product and social media marketing are needed to explain how will the effect of implementing sharia will influence muslim consumers interest in takaful.

Hence, the following propositions about the expected relationships are made:

H2 : there is a significant relationship between sharia compliance in social media marketing and muslim's attitudes towards participate in takaful
H3 : there is a significant relationship between sharia compliance in product and muslim's attitudes towards participate in takaful

Theory of Reasoned Action

The theory of reasoned action proposed by Fishbein and Ajzen (1975) is the most basic and influential theory of human behavior. In a theory of reasoned action, behavior is determined by two unique factors namely attitudes and subjective norms. Attitude towards behavior measures the extent of a person have favorable or unfavorable evaluations of ones behavior referred to, while subjective norm measures the influence of others with respect with behavior.

Ajzen and Fishbein (1980) said to be able to fully understand deeply about the factors that influence behavior, we need to look at the beliefs held by individuals both about themselves and their environment. This study only used attitude as a variable because attitudes are relatively difficult to change and make people behave relatively consistently against an object and consumer's attitude can be an accurate control over purchasing behavior (Dharmmesta, 1998) also can influence individual mindsets in decision making. The better attitude towards a particular product or service, the more likely that person is to buy or use a product or service (Rahim and Amin, 2011).

The above discussion leads to the following hypothesis:

H4 : there is a significant relationship between muslim's attitude towards takaful and purchase intention towards takaful.

Research Methods

This study use structural equation modeling (SEM) analysis. The analytical tool used is Lisrel-SEM. The population used in this study is Indonesian muslim's. Purposive sampling technique was used in this study with the condition that he/she has ever followed / sought information from social media of takaful operators, has social media and knows about takaful but have yet used it. This requirements is enforced so that respondents can make an assessment of marketing on social media, takaful compliance with sharia rules and attitudes towards takaful as a material consideration of purchase intention.

The distribution of questionnaires (Likert scale) online through Google Form is done through social media. The questionnaire were requested to answer questions relating to the degree of social media marketing, sharia compliance in social media marketing and sharia compliance in product on their attitude toward takaful and intention on takaful participation, on a five-point Likert scale, ranging from "strongly agree" to "strongly disagree". All items intended to measure the variables in this study were taken from previously validated instruments and modified so that the focus was on takaful participation. The construct of social media marketing was measured with scales from Kim and Ko (2012), while sharia compliance in social media marketing and product was measured with scales from Othoman and Owen (2002). Attitude was assessed with measures reported by Siaputra and Isaac (2020).

To find out how social media marketing affects interest in Islamic insurance, the author uses a two-stage SEM process approach (two step SEM process), with the following steps (Suwandi, 2019):

1. Good of fit and construct validity of the measurement model proposed to be tested, using Confirmatory Factor Analysis (CFA)

2. Test structural theory. After a satisfactory measurement model obtained
3. The CFA model is then modified based on the nature of the relationship between constructs
4. The end result is a determination of the structural model to use test the hypothesized theoretical model
5. Formulate conclusions and provide some input and suggestions. The research results will be presented in advance as a whole then continued with the discussion.

Research Results and Discussion

From a total of 604 questionnaires distributed and collected, 156 questionnaires were found complete according to the research criteria. This study uses the estimation method of deep unweighted least squares (ULS) Structural Equation Modeling (SEM) to process and analyze relationships among the variables of this study using.

Preliminary Model

The first step in forming the initial model without any modification or change and carry out the process of assessing all the observed variable data that has been obtained must be processed first using SEM.

Table 1: Standarized Loading Factor, T-Value

Construct	Code	Standarized Loading Factor	T-Value	Construct	Code	Standarized Loading Factor	T-Value
Social Media Marketing	M1	0.89	13.96	Sharia Compliance of Product	P1	0.91	21.00
	M2	0.70	7.82		P2	0.94	24.88
	M3	0.85	11.53		P3	0.91	22.30
	M4	0.67	7.14		P4	0.84	13.07
	M5	0.70	9.71		P5	0.71	7.61
	M6	0.69	8.43	Attitude	A1	0.93	
	M7	0.74	11.54		A2	0.79	7.07
	M8	0.80	9.78		A3	0.93	10.40
	M9	0.78	11.36		A4	0.90	6.76
Sharia Compliance of Social Media Marketing	S1	0.90	19.34		A5	0.91	9.18
	S2	0.93	15.74		A6	0.91	10.08
	S3	0.74	8.53		A7	0.89	8.60
	S4	0.80	10.68	Purchase Intention	I1	0.86	
	S5	0.83	14.06		I2	0.87	10.10
					I3	0.94	14.15
					I4	0.83	6.84

The test results show that almost all of the Preliminary Modeling indicators have good (ideal) validity and are significant. Only 2 indicator (M4 dan M6) is below the ideal limit of 0.70 but is far above practically significant.

Structural Equations

Attitude = 0.303*Social Media Marketing - 0.222*Sharia Compliance of Social Media Marketing + 0.848* Sharia Compliance of Product , Errorvar.= 0.233 , R^2 = 0.767

(0.101) (0.191) (0.158) (0.0765)
3.009 -1.163 5.373 3.042

Purchase Intention = 1.004*Attitude, Errorvar.= -0.00887, R^2 = 1.009
(0.0637) (0.0316)
15.770 -0.281

However, from the structural equation above we can see that there has been a Heywood case on this preliminary model. In order to eliminate Heywood case, this modeling must go through modeling evaluation with using Confirmatory Factor Analysis (CFA) exogen and endogen var.

Confirmatory Factor Analysis (CFA) Exogen and Endogen Var

In CFA exogen process we drop 4 variables with the lowest validity, namely: M4, M5, M6, M9 in order to have a fit model. After CFA exogen dan endogen been done, it appears that all indicators of exogen and endogenous variables have an ideal loading factor > 0.70 and significant with a T-value > 1.96. The process continues with preparing the Final Structural Model by combining the valid exogenous with endogenous CFA var.

Final Structural Model

Determination of the final structural model by determining the relationship from one construct to another based on a theoretical model proposed. To do that this study combines the results of testing using only valid variables of CFA Exogenous and Endogenous.

Table 2: Construct Reliability, Avarege Variance Extracted, Standarized Loading Factor, T-Value

Construct	Code	Construct Reliability	Average Variance Extracted	Standarized Loading Factor	T-Value
Social Media Marketing	M1	0.8979615	0.533667	0.92	13.47

Table 3 show the Good of Fit from Final Structural Model

Table 3: Good of Fit

No	GOF	Rule of Thumb	Test Value	Conclusion
1)	DOF	Positif (*over identified*)	292	*Overidentified*
2)	*Chi-square*dan*P*	Nilai(χ^2)kecil dan P > 0.05	335.527 (P = 0.0404)	good fit
3)	Normed *Chi-square*	(χ^2)/ *df*≤ 3	335.527/292= 1.15	good fit
4)	GFI	GFI≥ 0.90 = *good fit*	0.99	good fit
5)	RMSEA	RMSEA ≤ 0.08=*good fit*	0.0310	*good fit*
6)	SRMR	SRMR < 0.1	0.061	good fit
7)	AGFI	AGFI≥ 0.90 = *good fit*	0.98 8	*good fit*
8)	NFI	NFI≥ 0.90 = *good fit*.	0.982	*good fit*
9)	CFI	CFI > 0.90	0.998	*good fit*
10)	NNFI	NNFI≥ 0.90= *good fit*	0.997	*good fit*
11)	PNFI	The higher the better	0.882	*good fit*

Based on the data in Table 2 and 3, it can be concluded that the structural model studies have excellent compatibility (GOF). Combined reliability test results for each latent variable (Composite Reliability or also known as Construct Reliability (CR)) show that all latent variables have a good combined reliability (good reliability) past the minimum threshold of 0.70. As for the value of Average Variance Extracted (AVE), which shows convergent validity, also shows that the five latent variables have good convergent validity and value past the minimum limit of 0.50. Thus, the final structural model has good reliability. Overall, the assessment results prove that final structural model has a very good GOF, ideal validity, significant and reliable.

From structural equations below can be interpretate that the coefficient of determination for each the equation is as follows:

For the endogenous construct of Purchase Interest the value of R2 is obtained = 0.959.

This value can be interpreted that 96% of the total variation of the variable latent Purchase Interest can be explained by the structural equation and the remaining 4% is explained by other variables outside this study. As for the endogenous construct of Attitude, the R2 value is obtained = 0.704 means that 70.4% of the total variation of the Attitude variable can be simultaneously explained by Social Media Marketing, Sharia Compliance in Social Media Marketing and Product, and the remaining 29.6% is explained by other variables outside of this study.

Structural Equations

Attitude = 0.277* Social Media Marketing - 0.223*Social Media Marketing Compliance to Sharia + 0.862*ShaProd, Errorvar.= 0.243, R^2 = 0.757

(0.102) (0.177) (0.152) (0.0657)
2.716 -1.258 5.666 3.697

Purchase Intention = 0.994*Attitude, Errorvar.= 0.0118 , R^2 = 0.988
(0.0560) (0.0311)
17.763 0.379

All the results of hypothesis testing are briefly presented in the Table 4.

Table 4 : Coeficient Value and Hypothesis Testing

Hipotesis	Variable Relation	Coefficient Value	*T-value*	Conclusion
1	M➔A	(+)0.277	2.716	The M variable has a positive and significant effect on A
2	S➔A	(-)0.325	-1.258	The S variable has a negative but not significant effect on A
3	P➔A	(+) 0.862	5.666	The P variable has a positive and significant effect on A
4	A➔ I	(+)0.994	17.763	The variable A has a positive and significant effect on I

Hypothesis 1 states that social media marketing has a positive and significant effect on attitudes towards Takaful. The relationship between social media marketing and attitudes towards Takaful has a P value = 0,000 with a path coefficient (β) of 0.277 and a statistic of 2.716. Based on this value, a decision was made to accept H1 or reject H0, so that hypothesis 1 of this study is supported by the data. The conclusion is that social media marketing has a positive and significant impact on attitudes.

Hypothesis 2 states that sharia compliance in social media marketing has a positive and significant effect on attitudes towards Takaful. Table 3 shows that the relationship between sharia compliance in social media marketing and attitudes towards Takaful has a P value = 0.000 with a path coefficient (β) of 0.325 and a statistic of -1.258. Based on this value, a decision was made to reject H1 or accept H0, so that hypothesis 2 of this study was not

supported by the data. The conclusion is that sharia compliance in social media marketing has a negative but not significant effect on attitudes.

Hypothesis 3 states that sharia compliance in product has a positive and significant effect on attitudes towards Takaful.The relationship between sharia compliance in product and attitudes towards Takaful has a P value = 0,000 with a path coefficient (β) of 0.862 and a statistic of 5,66. Based on this value, a decision was made to accept H1 or reject H0, so that hypothesis 3 of this study is supported by the data. The conclusion is sharia compliance in product has a positive and significant effect on attitudes.

Hypothesis 4 states that the attitude towards Takaful has a positive and significant effect on Takaful purchase intention.The relationship between attitudes towards Takaful and Takaful purchase intention has P values = 0,000 with a path coefficient (β) of 0.994 and a statistic of 17.76. Based on this value, a decision was made to accept H1 or reject H0, so that hypothesis 4 of this study is supported by the data. The conclusion is that the attitude towards Takaful has a positive and significant influence on the Takaful purchase intention.

General Discussion and Practical Implication

The initial aim of this study was to see how social media marketing can influence muslim intention to participate in Takaful. A number of studies have confirmed that social media marketing is closely related to consumer attitudes. Research by Ko and Kim (2011) found that marketing on social media affects consumer attitudes towards purchasing Louis Vuitton. The conclusion of research on the effect of social media marketing is corroborated by other previous research conducted by (Rudiyanto, 2018; Sallam and Algammash, 2016; Moslehpour et al., 2020). Takaful industry needs to increase demand for their products in order to enlarge market share. New innovative strategies should be implemented to intensify consumer awareness towards takaful products. Due to Indonesia's geographical conditions, takaful literacy using the latest technology must be used. Social media is an effective choice for takaful operators because its large number of users in Indonesia. The information from the literacy activities might influence consumer decision making.

Furthermore, Muslims are consumers who obey the rules of their religion, this obedience itself depends on the level of religiosity and knowledge. One of the things to consider is the influence of religion on individuals behaviour. Consumers will have a positive attitude towards company that offers familiar religious values (Mokhtar, 2016). Marketers need to observe the cultural traits, environment, norms, beliefs, and values of a particular country or region to gain an understanding of whether promotion will be considered ethical, as it will effectively win the hearts of consumers and creating market charisma (Haque et al., 2010).

Promotional activities that are in accordance with Islamic values will form a more positive attitude towards brands and an intention in purchasing. However, according to Islam and Alam (2013), a deceptive and unfair promotion has occurred. Another study by Kadir dan Al-Aidaros (2015) found that Malaysian advertising was not significant for Malaysian respondents in terms of cultural, control and emotional factors from an Islamic perspective. The reason given for this finding is that of audiences prefer western culture which is not Islamic and that advertising agencies fail to follow Islamic principles. It is important for insurance operators to make their social media a pleasant place for consumers to share and receive information from companies and fellow consumers. More attention needs to be paid by takaful operators to make promotional activities on social media in accordance with Islamic values.

Other factor that should take into consideration in order to understand muslim attitude toward takaful is product compliance with sharia rules. Based on research findings (Johan et al., 2017; Dusuki and Abdullah, 2007; Al Nemer's, 2015) compliance with sharia rules was significantly related to interest in Islamic financial product. Building consumer trust means making consumers confident that sharia insurance products and services can meet

consumers needs to comply with Islamic principles. More recent studies about sharia compliance is from Usman et al (2020) about sharia hotels states that Muslim tourists who have high importance of sharia compliance present a more positive assessment of of sharia products and will feel the need has been met. Takaful operators must continue to maintain Islamic values in the making of each product, because it is the basic differentiator of takaful products from conventional in.

The theory of reasoned action states belief is considered as the background for a person's subjective attitudes and norms and ultimately determines interests and behavior. A better attitude increases the likelihood of consumers buying or using the product or service. Several studies discuss how demand for takaful is influenced by attitudes and purchase intention (Rahim and Amin, 2011; Husin and Rahman, 2014; Shabiq and Hassan, 2016). This study suggests that higher awareness, knowledge or exposure will have positive attitude and purchase intention.

The proposed model contains only three factors – social media marketing, social media marketing compliance with sharia rules, product compliance with sharia rules – that are expected to have a direct effect on attitude and intention to purchase takaful. Thus, there is the prospect for other variables on intention to purchase takaful. Hence, the paper pointing the importance of social media marketing and product compliance with sharia rules that influencing potential consumer attitude and intention towards purchasing takaful product. While social media marketing compliance with sharia rules didn't significantly impact consumer attitude and purchase intention toward takaful.

Abstract

While blockchain is an emerging technology that has exponential interest, the literature shows limited real-world examples of blockchain applications that have been applied in developed countries and there is no evidence of its adoption in Middle Eastern hospitals, especially in Saudi Arabia. Before adopting any new technology, it is necessary to know the extent of user acceptance of the technology. This study will investigate the factors that influence the adoption of blockchain technology in Saudi hospitals. The aim of this study is to develop a framework for blockchain decision-making in hospitals to provide a systematic approach to blockchain adoption that takes different perspectives into consideration. The framework developed is based on Technology-Organisation-Environment (TOE) framework and seeks to help healthcare decision-makers by covering three categories of blockchain adoption: technological, organisational and environmental. The implications of this study will contribute to both theory and practice.

Keywords: Blockchain, Adoption, Acceptance, TOE framework.

Introduction

Blockchain is simply a time-stamped group of immutable data records that is handled through a group of computers that are not owned by a central authority (Sharples and Domingue 2016). Cryptographic principles are used to provide security to these blocks of data (i.e. block) and to keep them bound to one another (i.e. chain) (Swan 2015). Healthcare is one industry that can gain significant benefits from blockchain technology. There are several areas of the healthcare system where blockchain technology can be used as it offers accessibility and security. In a study carried out on patient privacy and data security, it was found that there was at least a single security violation in the last two years in 94% of the hospitals (Patil and Seshadri 2014). Using blockchain in pharmaceutical industries helps in the fight against counterfeit medicines (Mettler 2016). It will improve medical record management and insurance claim procedures while increasing the pace of clinical/biomedical research (Kuo et al. 2017).

Before a new technology is adopted, it is critical to determine if users will accept the new systems/applications/services, and if the new system is compatible with the existing systems. To comprehend if an organisation will adopt a technology, the factors that will have an influence on the adoption process need to be identified. This study proposes a conceptual framework to enhance blockchain adoption in healthcare, which could be utilized by governmental hospitals in Saudi Arabia as well as in private hospitals. This study will investigate IT professionals' points of view on the following three dimensions: technological, organisational and environmental to find which factors will impact blockchain adoption in healthcare. This study explicitly aims to explore the main factors affecting the adoption of blockchain technology in Saudi hospitals. The research question for this study is formulated as follows in order to fulfil this objective: "What are the main factors affecting blockchain adoption in Saudi hospitals?". Understanding these factors in a better way may help in making sure that blockchain technology, which is still in its initial stages, is implemented in a way that is acceptable to healthcare organisations, so as to promote the meaningful use of the technology.

Research Framework

There are several factors in developing countries that can have an influence on the effective adoption of blockchain technology. Determining the theoretical perspective that was used to formulate the research hypothesis and model is critical. Different theories were taken into account when choosing the most appropriate theory as the basis of the study. Very limited research has been conducted that examines the adoption of blockchain technology. The TOE framework was used in some of these studies as the most relevant and widely used theory as presented in Table 1.

Technology-Organisation–Environment framework (TOE)

Tornatzky et al. (1990) formulated the TOE framework to analyse organisational level adoption of different information system/information technology services and products. The theoretical foundation of the model is solid, and it is capable of being used in IT adoption (Oliveira and Martins 2011). Its key objective is to determine technological, organisational and environmental perspectives that have an effect on the adoption of the latest IT systems in organisations (Tornatzky et al. 1990). The TOE framework will be used in this study by applying it to the context of Saudi Arabia to comprehend blockchain technology adoption in Saudi hospitals.

Research Model and Hypothesis

Technological Context

The features of technology are explained by the technological dimension, comprising the functionalities, equipment, expenses and techniques for technology adoption (Tornatzky et al. 1990, Oliveira and Martins 2011). Because blockchain has only recently been introduced, the factors that have an impact on its adoption have not been well identified so far. Hence, it is important to assess a variety of factors. With respect to the technology context, a variety of perceived technological factors are considered to be pertinent to the adoption decision (Rogers 1995). There are various perceived technological factors that have either a positive or a negative impact within the TOE framework. These are complexity, relative advantage and compatibility.

Complexity

Complexity is the extent of the apparent intricacy and difficulty associated with the comprehension and utilization of a certain innovation (Tornatzky et al. 1990). It is imperative that new technologies are user-friendly in order to increase the adoption rate. Because of the perceived levels of complexity and the inadequate business use cases, many larger companies and SMEs have rejected the use of blockchain (Clohessy and Acton 2019). This suggests that complexity functions as a barrier in the adoption of blockchain. There is a negative relationship between an

innovation's perceived complexity and its adoption (Holak and Lehmann 1990, Abbas et al. 2017). Thus, the proposed hypothesis is:

H1: Complexity has a negative influence on blockchain adoption in healthcare.

Relative Advantage

Relative advantage is defined as "*the degree to which an innovation is perceived as being better than its precursor"* (Rogers 1995). In this study context, relative advantage refers to the degree to which blockchain technology is believed to be better in comparison with its predecessor for healthcare organisations. The higher the perceived advantage of blockchain technology (such as security, fast transactions, immutability, etc.) to an organisation, the greater the possibility of the organisation adopting the innovation (Clohessy et al. 2019). To ensure that adoption is successful, key stakeholders should acknowledge the relative advantage of the technology. Thus, the proposed hypothesis is:

H2: Relative advantage has a positive influence on blockchain adoption in healthcare.

Compatibility

Compatibility is defined as *"the degree to which an innovation is perceived as consistent with the existing values, past experiences, and needs of potential adopters"* (Rogers 1995). The adoption decision of an organisation is affected by compatibility. The lack of compatibility between new technologies and the prevailing principles and practices being followed in the workplace will affect the adoption (Kwon and Zmud 1987). It was asserted by Tornatzky et al. (1990) that the perceived high compatibility of the innovation with the existing technologies of an organisation may have a positive impact on the adoption process. A significant factor pertaining to the adoption of health data standards in hospitals in Saudi Arabia was compatibility (Alkraiji et al. 2013, Alharbi et al. 2016) and this had a positive impact on adoption. Thus, the proposed hypothesis is:

H3: Compatibility has a positive influence on blockchain adoption in healthcare.

Organisational Context

Descriptive measures regarding the organisation, for example management structure, scope and size fall under the organisational context (Oliveira and Martins 2011). Organisations personally and independently regulate their internal factors known as organisational factors. These factors greatly affect the process of decision-making (Oliveira et al. 2014). It is expected in this study that top management support, hospital size and hospital readiness will be the key factors in the adoption of blockchain by Saudi hospitals.

Top Management Support

Top management support is described as the views of the management regarding technological initiatives, their involvement in those initiatives, as well as the degree to which technological growth is encouraged by top management (Kulkarni et al. 2017). A significant part is played by top management in the adoption of the innovative supply chain management of small and medium enterprises using blockchain technology (Nayak and Dhaigude 2019). Top management support plays a vital role in the adoption of blockchain as there may be a need to introduce new regulatory requirements (Castaldo and Cinque 2018). Thus, the proposed hypothesis is:

H4: Top management support has a positive influence on blockchain adoption in healthcare.

Hospital Readiness

Having particular organisational resources in hand to adopt blockchain technology is referred to as organisational readiness (Iacovou et al. 1995). When an organisation shows greater willingness to adopt a new technology, it is more likely that the management and staff will be supportive of change, and display a cooperation and supportive attitude (Wang et al. 2010). In a study carried out by Clohessy and Acton (2019), it was shown that if IT infrastructure is easily accessible and there are adequate economic and human resources, then such conditions have a positive impact on the company's intention to adopt blockchain technology. Thus, the proposed hypothesis is:

H5: Hospital readiness has a positive influence on blockchain adoption in healthcare.

Hospital Size

Organisational size refers to the measure of various factors that bring about innovation, such as overall resources, slack resources, the technical capabilities of employees and organisational structure (Rogers 1995). A significant determinant of blockchain adoption is organisational size (Tapscott and Tapscott 2016). Therefore, hospital size has a significant effect on the decision to adopt innovative technology (Chang et al. 2007). It has been indicated in previous studies that organisational size has a positive impact on the willingness of an enterprise to adopt new innovative IT (Clohessy and Acton 2019, Damanpour 1992). Thus, the proposed hypothesis is:

H6: Organisational size has a positive influence on blockchain adoption in healthcare.

Environmental Context

The distinctive features of the external world where the organisation performs its business is known as the environmental context (Alharbi et al. 2016, Lian et al. 2014). Organisational environment can support or restrict an organisation in adopting innovation (Rogers 2003). External factors such as government or competitors will have an impact on the use of blockchain technology in the field of healthcare. There are two factors in this research framework that are related to blockchain adoption, government regulations and external pressure.

Government Regulations

Government regulations or particular applications that may be prevented can hamper the adoption of blockchain (Janssen et al. 2020). To supervise and regulate the industry for compliance, new rules and policies may need to be devised (Crosby et al. 2016). Technologies like blockchain should be regulated by governments, which should simultaneously work in cooperation with the community, instead of serving like a strict legally binding authority (Tapscott and Tapscott 2016). Healthcare providers' decisions to adopt new technologies can be influenced by government laws and policies (Yusof et al. 2008). Chang et al. (2007) indicated that government policy has a positive effect on hospitals seeking to adopt a new technology. Thus, the proposed hypotheses are:

H7: Government regulations have a positive influence on blockchain adoption in healthcare.

External Pressure

The pressure imposed by competitors, trading partners and the government on the organisation is known as external pressure (Duan et al. 2012, Chwelos et al. 2001). One of the external pressures is competition which plays a very important part in driving organisations to adopt IT innovations (Lumsden and Gutierrez 2013). Organisations usually try to adopt the most recent technologies so that they can increase their market share, decrease costs and ensure more effective service delivery (Low et al. 2011). A positive relationship between external pressure and cloud computing adoption in the healthcare sector in Saudi Arabia has been identified (Alharbi et al. 2016). A positive impact may be exerted by external pressure from IT vendors, or when governmental regulation is mandatory (Alharbi et al. 2016, Low et al. 2011). The Saudi government may also exert pressure on Saudi healthcare organisations, as it is seeking to generate a digital transformation in the country in accordance with the 2030 vision (Khan 2016). Thus, the proposed hypothesis is:

H8: External pressure has a positive influence on blockchain adoption in healthcare.

Based on proposed hypotheses, our conceptual research model is presented in

Figure 1.

Figure 1: Conceptual research model.

Hypotheses will be tested to study the way the constructs in the framework are related to each other. Therefore, the primary method will be used to determine the effects of the constructs is the quantitative method.

Conclusion and Future Direction

Blockchain adoption in hospitals is still in the stage of rapid development and requires its own theoretical foundation for business value and risk identification (Woodside et al. 2017). The results of this study will play a part in filling the gap in knowledge and the unavailability of a predictive framework to identify the blockchain adoption intent of hospitals. To the best of our knowledge there is no research examining blockchain adoption in healthcare in developing countries such as the case in Saudi Arabia. This study conceptually identified the key factors as being the most influential in the previous studies are extracted and classified into the three contexts on the basis of the TOE framework, technological, organisational and environmental. The conceptual research model and the identified variables will be evaluated in Saudi Arabia to understand the adoption of blockchain technology by healthcare IT professionals. The Saudi government and/or decision makers will benefit from this study by obtaining an improved understanding of the advantages and challenges of blockchain adoption in healthcare. Healthcare organizations will also benefit from this research by acquiring a better comprehension of how the technology can be applied in the context of Saudi Arabia.

The Main Financial Instruments in The Context of The Digitalization of The Economy at Small and Medium-Sized Enterprises

Olga Viktorovna Dyatlova

PhD in Economics, Associate Professor, Federal State Budgetary Educational
Establishment of Higher Education "Russian State Social University" (4, bldg 1, Vilgelma Pika Str., Moscow)
E-mail: diatlova-60@mail.ru; djatlovaov@rgsu.net

Annotation

In this article, the author substantiates, presents the main aspects of the analysis of financial instruments. This is a rather complex set of measures that takes into account both external and internal factors. During the study, the current regulatory framework for financial instruments was analyzed, and measures were proposed to improve the analysis procedure.

Keywords*:* basic financial instruments, recognition, assessment, impairment, determination of fair value, derecognition, disclosure of information in the statements.

Introduction

Today, among the scientific business, academia and at the government level, you can often hear the expression "digital economy", or, as it is more customary to call, information-type economy.

In the context of the digitalization of the economy, information, being the most valuable resource, is formed, stored, transmitted and processed through information and communication technologies (ICT).

At the first stage of the emergence of the digital revolution, a transition was made to the beginning of the automation of technologies and business processes. Then the Internet was created, which opened up almost limitless possibilities and cellular communication appeared. The worldwide spread of the Internet contributed to the development of social networks and instant messengers (Gusareva, Tsaritova, Dyatlova 2019).

During the transition to the digital economy, one of the urgent problems of managing the socio-economic development of enterprises was the use of basic financial instruments in small and medium-sized enterprises (Stepanov A.A., Stapanov I.A., Savina, 2018).

All this requires the study of modern forms of organization and management of basic financial instruments based on the introduction of information and digital technologies.

Methods

The methodology for studying the main financial instruments in the context of digitalization is based on the concepts of innovative development at the stage of formation of an information-digital method of production and consumption (Savina, Stepanov I.A., Stepanov A.A. 2018).

The subject of research is social and managerial relations regarding the formation of the main financial instruments at small and medium-sized businesses.
In the process of preparing the article, concepts of special techniques and methods of economic analysis were used, these include traditional methods of quantitative analysis, economic and mathematical methods and heuristic and expert methods of qualitative analysis and others (Barilenko, 2021).

Results

Russia, like no other major state in the world, went through fateful milestones; revolutions, numerous large and small wars, and global changes in its economic, political and territorial structure, which led to its ups and downs (Dyatlova, 2003).

In the context of an intensifying competition, an important factor in increasing efficiency and ensuring the leadership of enterprises, is the effective use of their production potential (Savina, Stapanov 2019).

One of the most important conditions for the correct functioning of enterprises in the conditions of the formation of market relations, is the skillful management of their finances. At the same time, the main task of financial management is the effective management of the main financial instruments, as well as the development of an effective credit policy within the enterprise (Dyatlova, 2013).

A financial instrument is a contract that gives rise to a financial asset for one entity and a financial liability or equity instrument for another. Each company has financial instruments, it can be cash, accounts receivable and payable, bank loans (O. V. Dyatlova, 2019).

There are various concepts of the socio-economic nature of financial instruments. For example, (M.A. Vakhrushina, L.A. Melnikova, N.S. Plaskova, 2006) (M.A. Vakhrushina, 2014) consider "financial instruments" a complex concept, its constituent parts are as assets and obligations. In the Russian practice such a merger, where a single term is applied to property and obligations, does not exist.

In accordance with the position (V.G. Getman, 2018) the rules on financial instruments available to almost all SMEs enterprises are reflected on complex instruments that not every sme-related company has..

The concept of "financial assets" is broader than "financial investments". According to any of the Russian documents, there are no rules for accounting for many financial transactions, such as futures, options, swaps and others. There is no concept and accordingly the procedure of accounting for complex financial instruments in accordance with the position of scientists (I.I.Proskurovskaya, 2007) (O.E.Nikolaeva, T.V.Shishkova 2001).

According to the main principle of IFRS - prudence - the carrying amount of assets should not be overstated, and liabilities understated. In the works of the authors (L.I.Ushvitsky, A.A. Mazurenko), such concepts as "impairment of assets" and their application for all assets, except for those for which the relevant standards provide special requirements for the recognition and assessment of impairment, were considered.

Analysis of various scientific views allows us to conclude that financial instruments should be understood as a contract, as a result of which financial assets arise from one organization and financial liabilities from another.

The concept of "financial instruments" is complex and reflects firstly, a concept as "assets"; secondly, a concept as "liabilities"; thirdly, an orientation towards a specific intended target result of the activities of small and medium-sized businesses (Sushchina, Dyatlova, 2020).

Discussion

In accordance with modern scientific concepts, the following financial instruments belong to the main ones: cash, debt instruments, loan obligations, investments in unconverted ledated shares and ordinary shares without the right to sell back (Dyatlova, 2011).

A debt instrument is classified as a major instrument if the following conditions are met simultaneously:

1. The income of the holder of the instrument represents: either a fixed amount of income; or income with a fixed rate over the life of the instrument; or variable rate income; or income, which is a combination of such fixed and variable rates, if they are positive;

2. Under the terms of the agreement, the holder cannot fail to receive the principal amount and interest accrued for the current or previous periods;
3. Contractual provisions allowing early repayment of a debt instrument or presentation of it for early repayment do not depend on the occurrence of any future events;
4. No conditions affecting yield or maturity.

The main financial instruments include cash; demand deposits and term deposits (bank accounts); commercial bills held; accounts receivable and payable on loans, accounts and bills; bonds and similar debt instruments; investments in non-convertible preference shares and non-puttable ordinary and preference shares; obligations to receive a loan if the obligation cannot be settled in cash (Dyatlova, 2017).

The most common fixed assets and liabilities are presented in Table 1.

Table 1: The most common major financial instruments used by SMEs

Assets	Commitments
Trade receivables	Trade payables
Bills receivable	Bills payable
Receivables	Accounts payable
Organizations should	The organization should

Source: compiled by the author

An entity shall recognize financial assets or a financial liability only when it is subject to the contractual provisions of the instrument.

With regard to the issue, recognition as an asset or a liability of receivables and payables occurs at the time the enterprise enters into a contractual relationship that gives the enterprise legal rights. Failure to recognize a financial asset or liability is a firm agreement to buy or sell goods.

Considering the valuation, we can say that for all major financial instruments the rules of the IFRS for SMEs govern the use of amortized cost. The instruments listed above as an exception to the amortized cost measurement rule, when their fair value cannot be measured reliably, are measured at cost less impairment. Thus, financial instruments are measured at fair value only if it can be reliably determined (Dyatlova, 2015).

Consider examples of calculating amortized cost. Suppose on January 1, 2020. The enterprise took a loan from the bank for a period of four years in the amount of 49 million rubles. Under the terms of the agreement, the principal amount and remuneration (interest) are payable at the end of the fourth year in the amount of RUB 71.741 million, which corresponds to a 10% rate. The interest rate is in line with the market rate for similar four-year loans. The loan is initially recognized in the amount of RUB 49 million. The amortized cost calculation is presented in table 2.

Table 2: Calculation of amortized cost

Period	Debt at the beginning of the period, million rubles	Interest (at a rate of 10%)	Debt at the end of the period, mln rubles
January 1 - December 31	49	4,9	53,9
January 1 - December 31	53	5,39	59,29
January 1 - December 31	59,29	5,929	65,219
January 1 - December 31	65,219	6,522	71,741

1st jear	2nd year	3rd year	4th year

Source: compiled by the author

In accounting, this will be reflected in the Debit account. "Cash (financial asset)" 49 million rubles. Credit account "Bank loan (financial liability)" 49 million rubles.

Interest is accrued annually, which is reflected by the entries: Debit account. "Interest expenses" 4.9 million rubles. Credit account "Bank loan" (financial liability) 4.9 million rubles.

Consider a second example: January 1, 2020. The company took out a loan worth 900 million rubles, the transaction costs amounted to 40 million rubles. The annual remuneration is 50 million rubles. over three years (due December 31st). The loan must be repaid on December 31, 2020. In the amount of 1,021.792 million rubles. Loan terms correspond to market conditions. The interest rate on this financial asset is 8%. The amortized cost calculation is presented in table 3.

Table 3: Calculation of amortized cost

Period	Debt at the beginning of the period, million rubles	Interest (at a rate of 8%)	Payment, million rubles	Debt at the end of the period, million rubles
January 1 - December 31	940	75,2	(50)	965,2
January 1 - December 31	965,2	77,2	(50)	992,4
January 1 - December 31	992,4	79,392	(50)	1021,792

1st year	2nd year	3rd year

The revision of the estimated payments or receipts requires an adjustment to the carrying amount of the financial instrument to reflect the revised estimated cash flows. Restatements of the carrying amount are performed using the original effective interest rate of the financial instrument to determine the present value of estimated future cash flows. The adjustment is recognized in profit or loss as income or expense on the date of the revision.

Having analyzed the impairment of assets, it can be said that at each reporting date the entity is required to analyze whether there is objective evidence of impairment for any financial asset measured at cost or amortized cost. If objective evidence of impairment is identified, an impairment loss should be recognized immediately in profit or loss (Dmitrieva, Dyatlova 2017).

An entity shall conduct an impairment test for each equity instrument, regardless of its significance, on a case-by-case basis.

An entity shall assess other financial assets individually or group them for impairment testing based on the level of credit risk.

An impairment loss for an instrument measured at cost less impairment is measured as the difference between its carrying amount and the best estimate of the amount the entity would receive for it if it were sold at the end of the reporting period.

An impairment loss for an instrument measured at amortized cost is measured as the difference between its carrying amount and the present value of estimated cash flows discounted at its original effective interest rate.

If the impairment loss decreases in a subsequent period due to an improvement in the situation that existed at the time the loss was recognized, the entity is required to reverse the previously recognized impairment loss. The amount of the reversal is recognized immediately in profit or loss.

Recovery is performed in one of two ways:

- right when the financial asset increases;
- indirectly when the estimated reserve account is adjusted.

A reversal of an impairment loss must be made in such a way that the carrying amount of the financial asset does not exceed the carrying amount at which the asset would have been measured in the absence of a previously recognized impairment.

In order to determine fair value, a valuation technique should be based as much as possible on market data and at least on data from the entity itself. A valuation technique provides a reliable estimate of fair value when it adequately reflects the market's expected valuation of an asset and the inputs reasonably reflect market expectations and the inherent risk / reward ratio of the asset. The preferred valuation method is recognized by market participants as providing the most reliable price estimates.

The fair value of assets that do not have a quoted market price in an active market are reliably measured. If the range of values of potential estimates of the fair value of assets is small enough or it is possible to reasonably estimate the likelihood of different estimates within this range for its further use in determining the fair value.

An entity should not measure an asset at fair value if the range within which the fair value estimates are reasonable is significant and the probabilities of different estimates cannot be reasonably estimated.

When the source of data for a reliable measurement of an asset at fair value disappears, the carrying amount determined based on the last reliable measurement of the asset at fair value at the closing date is recognized as its new cost. Subsequently, the entity shall measure the cost of such an asset at that cost less impairment losses until a source of data exists to reliably measure fair value.

Consider the conditions for derecognition of a financial asset:

a) the contractual right to the cash flows from the asset is exercised or expired;

b) the asset is transferred to another organization;

c) the entity has transferred control of the asset to another entity, but has retained some of the risks and is able to receive consideration for the transferred asset.

In the case of option (c), the entity must not only derecognize the financial asset, but also separately recognize any rights or obligations associated with it.

The carrying amount of the transferred asset is allocated between the retained and transferred rights and obligations based on their relative fair values at the time of the transfer. Newly created rights and obligations should be measured at their fair value at that date. The difference in value between the compensation received and the values, whose recognition was deactivated in accordance with this paragraph, and the values newly recognized, are included in profit or loss during the transfer period (Barkhatov, Bukhareva, Gorodetskaya, Dyatlova, et al. 2017).

If, despite the transfer of the asset, the transferor retains significant risks and rewards, the transferor continues to recognize the transferred asset in full and also recognizes a financial liability for the consideration received. Offsetting such an asset and a liability is prohibited. In subsequent periods, the gains from the transferred asset and the expense of the financial liability should be recognized in full.

If a debt or equity instrument is transferred, the accounting for that financial asset by the transferee and the transferor will depend on:

1) whether the receiving party has the right to sell or repledge this security;
2) the fact that the transferring party fulfills its obligations.

When both conditions are met, the transferor should continue to account for the collateral as its asset, and the transferee should not account for the collateral as an asset. The transferor should reclassify such an asset in its statement of financial position as pledged and present it separately from other assets. If the receiving party has already exercised its right and sold the collateral pledged to it, it must recognize:

- proceeds from sale; and
- a fair value obligation to return that collateral.

When only the first condition is met, the transferor should derecognize the collateral and the transferee should, if it has not sold the collateral, recognize it as its asset by initially measuring it at fair value. If it sold the collateral, then derecognize its obligation to return the collateral.

An entity derecognises a financial liability only if it is extinguished.

If an existing borrower and lender exchange financial instruments whose terms differ materially, the original liability must be completed and a new financial liability must be recognized. When the terms of an existing financial liability, or part of it, change significantly, the entity is also required to record the extinguishment of the original financial liability and recognize a new financial liability.

Conclusion

The main directions of the formation and use of basic financial instruments in the information-digital economy should be, first of all, improving the forms of organizing business processes and information and digital technologies.

As a result, the spread of digital technologies was able to change not only economic processes, but also the very way of life of society. Today it is becoming more and more informational. The development of the information society is closely related to the construction of a digital economy and general robotization. The main requirements for society and characterizing it are changing the nature of work and employment, as well as increasing general requirements for the level of education and professional qualifications.

The generalization of the best domestic and foreign experience in the effective organization and use of basic financial instruments showed that the analysis is carried out using various indicators, on the basis of which a conclusion is made about the state of the main financial instruments in small and medium-sized businesses. An entity shall

recognize in profit or loss the difference between the carrying amount of a financial liability extinguished or transferred to another party and the consideration paid, including any non-cash assets transferred or liabilities assumed.

During the period of digitalization, the very nature of labor and labor relations is changing (Shpilina, Dyatlova, 2015). Increasingly, business processes go online, and this applies to all spheres of society.

Abstract

The aim of the paper is to show the importance of knowledge components in knowledge-based organizations in the context of DSS system implementation. The paper is based on a literature review and describes the primary attributes of the DSS, KM, and DDMKCC model paradigm, with a special focus on knowledge-based process management. The paper delivers a case study of BI system implementation for knowledge component improvement within the DDMKCC model. The case study is based on a Polish IT company. The study supports the thesis that BI systems can siginficantly help improve and develop the knowledge component in knowledge-based organization.The results highlights the background for a new methodology for implementing the knowledge component in hybryd DSS in DDMKCC models. Owing to the literature review and the ongoing research, the paper concludes that the use of BI systems can largely enhance the development of the knowledge component in DSS environments. Future efforts should concentrate on the use of AI and Big Data software to improve human-computer interaction in creativity support, modeling and simulation contexts, further exploring different approaches and applicable technologies: Big Data, mobile technologies, etc. Advanced computer algorithms have already proven to be capable of delivering better decisions than human decision makers, hence more and more of them are finding multiple applications in effective business solutions.

Keywords: Decision Support Systems (DSS), Knowledge Management (KM), DDMKCC Model.

Introduction

The paper presents the idea of new role of knowledge management (KM) in context of DSS (Decision Support System) systems implementation in knowledge-based company. The new role of knowledge in management and organization is closely connected with some changes in implementation process in/for organizational decision support systems (Young, 1988). The basic scope of the paper is to show the importance of knowledge components in knowledge-based organizations in the context of DSS system implementation based on BI system implementation for future DSS implementation methodology. The background of the paper is focused on the literature review to show the DSS paradigm and KM paradigm, and the DSS Meta-Design Methodology with knowledge components in DDMKCC model. The background showed the new role of DSS in knowledge-based organization with the idea of double-loop pattern of knowledge development in/for DSS (Stanek, Sroka, 2000).

The improvement of knowledge component presented in theoretical background was verified in case study based on BI system implementation in chosen knowledge-based company. The paper delivers a case study of BI system

Cite this Article as: Stanisław STANEK, Anna SOŁTYSIK-PIORUNKIEWICZ and Marian SZARY "The Implementation of DSS in Knowledge-Based Organizations – the New Role of Knowledge Components in DSS Meta-Design Methodology" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

implementation for knowledge component improvement within the DDMKCC model (Sprague, Carlson, 1982), (Sprague, Watson, 1996), (Sroka, Stanek, 2011). The case study is based on a Polish IT company. The study supports the thesis that BI systems can significantly help improve and develop the knowledge component in knowledge-based organization.

The case study showed the implementation of knowledge management system in organization: there are some key problems in implementation of such a system with too many reports, unrevealed facts, and time lost on digesting reports and messages. Is there a way to eliminate these? The research results analyses gave the way to eliminate the basic problems and showed the concept of smart reporting system implementation due to changing knowledge workers expectations.

The paper is divided into five chapters. The introduction describes the aims and the thesis of the paper with paper methodology. The second chapter is based on literature review and showed the background of DSS systems development with aspects of current knowledge management in organization. The third chapter described the research methods with the case study and the research thesis was verified. The fourth chapter showed the research results, and the paper is concluded in chapter five with some new ideas for the further research.

Background

DSS paradigm and KM paradigm

Even today data remain one of the most important business resources, playing a major role in each and every company. Their actual value, however, depends on how they are used, therefore a company pursuing its business goals needs to collect information from best available sources and transform it into knowledge. Well-prepared information can be used to improve the decision-making process in an organization. This process is fundamental to making an organization more competitive. Decisions can be categorized as structured, semi-structured, and unstructured. Structured decision problems have a well-known optimal solution and do not require computerized decision support. For instance, a decision problem involving the choice of the shortest route between two geographical points can be solved analytically and there is usually no need to deploy any dedicated systems to help make the right decision. On the other hand, unstructured decision problems have no agreed-upon criteria or solutions, relying critically on the decision maker's preferences. Between these two types of decision problems – structured and unstructured – there lies a wide strand of semi-structured problems. This is the case of a lot of business decisions that may have some agreed-upon parameters but their solution mostly involves the human factor and relies on human preferences. The processing of semi-structured decisions requires a combination of analytical methods and user-machine interaction to develop alternatives based on pre-defined criteria and to eventually reach the optimum solution. To this end, specialized IT systems called decision support systems, group decision support systems (Shishany, Kharabsheh, Adams, 2017) and intelligence decision support systems (Skulimowski, 2011), (Turban, Aronson, 2001) with agent systems (Padgham, Winikoff, 2004) are used.

Decision Supports Systems (DSS) are computer-based information systems designed to help managers select one of many alternative solutions to a problem. In a large and sophisticated DSS it really is possible to automate some of the decision making processes and to speedily analyze an enormous amount of information. Such systems help corporations increase their market share, reduce costs, increase profitability, and enhance quality. Yet, what plays a crucial role in a decision making process is the nature of the problem itself. A DSS is essentially an interactive computer-based information system involving an organized collection of models, procedures, databases, software, communicators, devices, and people, that helps decision makers solve unstructured or semi-structured business problems. The key features of DSS are as follows:

- DSS are able to handle huge amounts of information stored in databases or data warehouses.
- DSS can obtain and process data from many different sources and in multiple formats.
- Using DSS companies can easily create reports tailored to the user's needs.
- For data presentation, DSS use both textual and graphical techniques, such as trendlines, tables, charts, etc.
- DSS perform complex, sophisticated analyses and comparisons using advanced software packages.
- DSS can project or indicate the consequences of individual choices.

A schema, or general design, of a decision support system is shown in Figure 1.

Figure 1: A Decision Support System – a schema.
Source: (Davenport, Prusak, 1998), (Davenport, 1994), (Duhon, 1998).

The Data Management component consists of all databases containing data relevant for a specific context and is managed by the so called database management system (DBMS). The database management subsystem can be interconnected with the corporate data warehouse – a repository for relevant corporate decision-making data.

The Model Management component gives users access to a plenty of models that can assist them in the decision making process. The model base can include a model base management (MBMS) software that coordinates the use of models in a DSS. This latter component can be connected to an external data storage.

The Knowledge Base subsystem can support any of the other subsystems or act as an independent component. It provides intelligence to augment the decision maker's own. It can be interconnected with an organization's knowledge repository termed as the organizational knowledge base.

The User Interface component, also known as the dialog management facility, allows users to interact with the system in retrieving information. It works chiefly through action language – that alerts the DSS to what is necessary for effective system operation and imports the required data – and presentation language that transforms and delivers results to users.

Knowledge Management (KM) is a discipline that has developed in the wake of increasing use of computer technology. Probably the most commonly cited definition is that "[it] is a discipline that promotes an integrated approach to identifying, capturing, evaluating, retrieving, and sharing all of an enterprise's information assets. These assets may include databases, documents, policies, procedures, and previously un-captured expertise and experience in individual workers." (Duhon, 1998) It focuses on the various stages of managing information and allows people and machines to act efficiently.

Today, hardly any company can work without a well-developed knowledge management system. Perhaps it could be stated that there have always been some systems for information management, therefore what is now called Knowledge Management merely helps standardize and enhance the process. The goal is, anyway, to develop or bring together the right tools, structures, policies, cultures and people in an effort to refine organizational learning and knowledge storage and transfer by embracing a rich variety of short- and long-term factors.

To apply Knowledge Management principles in the real world, e.g. in a business environment, a knowledge management system can be used that deploys a set of software modules controlled through a single central user

interface. It may include mining important data, processing it to the expected format, and creating electronic documentation in the form of e.g. reports provided to entitled recipients.

DSS Metadata Methodology

The human-computer interaction in decision support systems (DSS) is focused on speeding up the learning process of the user (Klein, Methlie, 1995). A well-designed DSS is one that supports knowledge management in an organization. Since it is a natural property of knowledge that it evolves continuously, a DSS that is not capable of evolving with the knowledge may not at all bring the expected benefits to the organization. The meta-design approach has had its advocates who undertook to further develop it (Duhon, 1998), (Hevner, Hatterjee, 2010), (Sobolewska, 2020), (Sprague, Carlson, 1982). Due to the volatility and change dynamics of the design space, frequently coupled with a need for organizational change entailed by IT deployment, an integration of current trends in system design and organizational change occurs (Fry, 2009). Meta-design methodology provides a higher-level abstract rules supporting the working methodology framework used in the DSS development process. Meta-design literature supplies a variety of such rules, some of which deserve to be underscored (Hevner, Hatterjee, 2010), (Fischer, Giaccardi, 2004) :

- developing socio-technical environments that support and empower users to engage in the process of system development not only at design time but also at use time,
- embodying the human ability of autopoiesis in projects for which the "designing the design" process is a first-class activity,
- supporting social creativity by providing the technical and social conditions for the exchange of ideas during workshops, discussions, debates, brainstorming, co-creation sessions and other forms of intense collaboration,
- combining art and design in the processes of self-realization,
- use of meta-analysis for comparing, combining, synthesizing, summarizing, specifying, and generalizing of previous studies.

Dan Power (Power, 2002), (Power, 2013), (Power, 2003) perceives the following advantages of employing the architecture approach within DSS projects: better collaboration, easier planning, implementation and integration with other systems, and an augmented ability to evaluate technology. Clyde Holsapple, one of the fathers of the DSS concept, commented (Burstein, Holsapple, 2008), (Holsapple, 2008) that "DSS architecture does not define what DSS is; rather, it functions as an ontology that gives a common language for design, discussion, and evaluation of DSS." This perspective on DSS corresponds with Lambert's opinion that "the architectural design should set a common level of understanding among technical, non-technical and management participants." Suresh Basandra (Holsapple, 2008), on the other hand, believes that "system architecture is the process of partitioning a software system into smaller parts." The above insights bring us to Holsapple's (Holsapple, 2008) definition of the DSS architecture: "DSS architecture is a general framework that identifies essential elements of a DSS and their interrelationships." Sprague and Carlson (Sobolewska, 2020) proposed the Data-Dialog-Modeling design paradigm as a DSS architecture.

The evolution of DSS meta-design methodology revolves around six components. Ensuing research endeavors (Sobolewska, 2020), (Sprague, Carlson, 1982) and business studies (Turban, Aronson, 2001), (Twardowski, Wartini-Twardowska, Stanek, 2011) contributed extensions of DDM paradigm into the DDMKCC Model (Sprague, Carlson, 1982).

Figure 2: Overview of the DDMKCC Model with a Knowledge-Centric Component.
Source: (Sprague, Carlson, 1982), (Sprague, Watson, 1996), (Sroka, Stanek, 2011).

The DDMKCC solution includes six, rather than three, components: (1) data (DaC), (2) dialog (DC), (3) modeling (MC), (4) knowledge (KC), (5) communication (CC), and (6) creativity(CrC). The existing evolution trends include innovative solutions (data fusion, BI) to produce new DSS characteristics, such as situational awareness, cognitive bias, etc.; interface agent (personal assistant, avatar) technology and ergonomic design of the human-machine dialog as a challenge for the user interface subsystem; combining heterogeneous models (a hybrid model) in such a way that their concerted actions produce synergy and increase overall applicability.

The positioning of DDMKCC with a knowledge-centric component (Figure 2) as a DSS meta-design methodology provided an opportunity to revisit the perception of the knowledge component, focusing attention on its role. Now, with the proliferation of BI systems and the Big Data approach, DSS meta-design methodology strongly emphasizes the knowledge component.

The concept of Business Intelligence systems encompasses issues related to the presentation of corporate data in the form of intelligible and transparent reports delivered to decision makers. As a result, key organizational decisions can be made at a faster pace without having to employ a number of analysts to read information from a large number of diverse sources, e.g. from different transactional systems that do not integrate with one another.

The BI system is describe as the processes, technologies and tools needed to turn data into information and information into knowledge and knowledge into plans that drive profitable business action. BI encompasses data warehousing, business analytics and knowledge management. From another point of view BI system is defined as the knowledge gained about a business through the use of various hardware/software technologies which enable organizations to turn data into information.

Based on widespread definitions and relevant literature sources, the goals that the Business Intelligence systems are supposed to achieve can be summarized as follows:

- automation of business operations;
- informing decision-makers;
- accelerating and improving decision making;
- optimizing internal business processes;
- increasing operational efficiency;
- driving new revenues;
- gaining competitive advantages over business competitors;
- identifying market trends;
- spotting business problems that need to be addressed.

The basic functionalites are to provide historical, current, and predictive views of business operations, to use data that has been gathered into a data warehouse, to work from operational data, and to support reporting, with interactive "slice-and-dice" pivot-table analyses, visualization, and statistical data mining. The functionality of BI system is connected with iformation gathering from an internal and external sources of company. The source of all information that is processed and analyzed by the Business Intelligence system is collected in a core of each system – the data warehouse (DW). The DW stores information from a variety of sources, such as spreadsheets, text files, and transactional databases. As BI systems were created to develop reports supporting corporate decision makers, they must be capable of analyzing data from finance, accounting and sales departments. Therefore, the data warehouse primarily sources information from transaction systems, e.g. financial and accounting systems, such as MRP, CRM, etc. Since BI systems are targeted at data visualization and analysis, they can be also fed by: GIS (Geographic Information System) designed for visualization of geographic data; EIS (Executive Information System) – a type of management information system that facilitates and supports senior executive information and decision-making needs; MIS (Management Information System) – systems designed to support the management of enterprises (Morawiec, Sołtysik-Piorunkiewicz, 2020). EIS provides easy access to internal and external information relevant to organizational goals. It is commonly considered a specialized form of decision support system (DSS).

New Role of DSS in Knowledge-Based Organization

In today's organizations, structured business processes and decision problems are just the tip of an iceberg (Sobolewska, 2020), (Szelągowski, 2019). The increasing prevalence of dynamic semi-structured and unstructured processes shifts attention to Adaptive Case Management (ACM) (Svenson, 2010) founded on effective collaboration of knowledge workers. It is therefore knowledge workers and their performance that has arisen – as predicted by Drucker (Drucker, 1999) – as a key challenge for businesses. The methodology underpinnings for learning and knowledge acquisition by knowledge workers have been addressed by prior DSS studies (Moore, Chang, 1983), (Nonaka, Takeuchi, 1995), (Osuszek, Stanek, 2015), (Stanek, 2010), (Stanek, 1998), (Stanek, 1999), (Stanek, Sroka, 2000), (Stanek, Twardowska, Twardowski, 2013), (Twardowski, Wartini-Twardowska, Stanek, 2011). What is at stake here is consistent support involving respective components of the extended DDMKCC paradigm:

- The need to enhance analytics (DaC) relates to the metaphor of "blind surgeons" – former stakeholders in a business process who performed their roles while being oblivious of the prevalent trends (Van der Aalst, Weske, Grünbauer, 2005), as opposed to knowledge workers who are increasingly aware of recent developments (with data warehouses, machine learning, Big Data, and Data Lakes on hand) and empowered to revise processes as they go.
- Effective and intuitive human-machine dialog (DiC) is key to making the most of the available technologies, i.e. of computers linked to increasingly standardized ecosystems/platforms and supported by advanced artificial intelligence, visualization and augmented reality tools.
- A knowledge worker who can perform simulations employing an array of computerized models (MC), standardized notations (BPMN, CMMN, UML, EPC) and software applications (Pegasystem, IBM Case Manager, Apian, Tibco) is increasingly aware of the decision context and capable of assessing the relative outcomes of available alternatives.
- Learning processes drawing on a variety of technologies (BI, knowledge portals) fuel the conversion of data into meaningful information (KC), trigger knowledge development and validation as well as the creation of meta-knowledge and parameter-based scenarios for future use (cf. Figure 3).

Figure 3: The double-loop pattern of knowledge development in/for DSS.
Source: (Stanek, 2010); (Stanek, 1998).

- It is within communication processes (CC), whether face-to-face or indirect, that team projects are executed, group decision-making takes place, relationships are established and nurtured, and knowledge is disseminated (outdated and falsified). The immense number and diversity ofavailable tools will suffice alone to mark the significance of this component. Relevant experiences can be sought in the application of agile technologies and SMAC systems (Social Media, Mobile, Analytics & Big Data, Clouds).
- Creativity and innovation (CrC) represent knowledge workers' most valuable potential that can be supported and developed using the latest methodologies and technologies (Remy, Vermeulen, Frich, Biskjaer, 2020), (Sroka, Stanek, 2011).

Based on the data accumulated, cleaned and loaded into the organizational data warehouse, the reporting system creates reports or computes indicators that can be used by decision makers (e.g.KPI – Key Performance Indicators). Further, the information feeds hypotheses that are set forth and validated. In the next step, with time elapsed and increasing experience, an organizational knowledge base is built, forming a repository of know-how unique to the organization, accounting for its market position and competitive advantage.

Business Intelligence systems continue to be a very important group of analytical systems and are likely to remain in use for a long time. However, over time and with increasing volumes of information being processed, they tend to turn into completely new types of analytical AI-driven solutions. The curent studies showed the context of AI usage for knowledge workers (Greiner, Jovy-Klein, Peisl, 2020)

In our case study, this trend in the evolution of BI systems is outlined on the example of an intelligent reporting system.

Big Data are made up of information generated by users of web portals, sourced from Internet transaction data and scientific outcomes (biological, astronomical, physical measurements, etc.), contributed by robots searching the Internet (Web mining, Web crawling), etc. Most Big Data have a non-relational structure and are chiefly composed of text and images, but they can also include metadata or graphical data tracing connections between websites, and other similar input. Hence, no specific data model is assigned to the concept of Big Data. The most important features of Big Data are very well characterized by the 5 Vs, where the successive Vs stand for: Volume – huge volume, Velocity – high-rise speed, Variety – diversity of structure and content, Veracity – reliability and accuracy, Value – actual value for decision making processes.

The implementation of DSS systems involves a number of technological and organizational aspects relating to business process management. In recent years, systems capable of processing very large data sets – Big Data – have gained an important position, responding to the need for tackling an increasing volume of more and more complex data coming in diverse, non-standard formats that cannot be stored in traditional databases or data warehouses. This

requirement implies the use of Big Data systems that can, automatically and in real-time, download, process and analyze huge collections of petabytes of data characterized by great diversity and high variability in time.

Under one of the Big Data definitions proposed by V. Mayer-Schönberger and K. Cukier (Mayer-Schönberger, Cukier, 2014) this term includes whatever can be implemented on a large scale and cannot be implemented on a small scale in order to acquire new knowledge or create new value that will change markets, organizations and relations between governments and citizens, etc. The above definition portrays Big Data as a revolutionary and innovative concept that will alter the functioning of contemporary and future enterprises, institutions and workplaces, and that will be reflected in all facets of human life.

The revolutionary and innovative nature of large data set processing has also been noticed in Poland. The Center for Digital State Studies has brought attention to the linkages and impacts between Big Data or social media and such technology trends as the Internet of Things or mobile solutions.

This new type of systems involves a different approach to data being processed. In setting the standard for analyzing large data sets, Schönberger and Cukier (2014) stress that, with Big Data, precision and accuracy are no longer the key criteria, given the diverse and unstructured nature of data being processed; it will mostly suffice to indicate the general trend of change.

According to e.g. Schönberger and Cukier (2014), and already cited by Morawiec and Sołtysik-Piorunkiewicz (2020), in processing large data sets one should move away from searching for causality in favor of discovering relationships. For its operation, Big Data relies on specific algorithms, such as Map-Reduce or Apache Hadoop, and statistical languages such as R, Python or Matlab (Morawiec, Sołtysik-Piorunkiewicz, 2020).

The Research Method

This chapter delivers the case study of BI system implementation in an IT company for the sake of refining the knowledge component in line with the DDMKCC model.

The case study of Business Intelligence system implementation involves CONSORG SA. This joint-stock company boasts nearly 30 years of market presence and, throughout the period, has conducted a number of IT and consulting projects for many major Polish companies. Its business profile encompasses design, implementation and oversight of IT solutions, as well as business process optimization and management support services. CONSORG specializes in the implementation of modern IT solutions in the field of budgeting and controlling as well as supporting the management of capital groups, with particular emphasis on the issues of consolidation of financial statements. In these cases the previous DSS research studies were condacted in CONSORG as well (Stanek, Twardowska, Twardowski, 2013), (Twardowski, Wartini-Twardowska, Stanek, 2011). The study is focused on an in-company BI system implementation process at CONSORG SA and describes the subsequent stages of the process.

System implementations in the IT industry owe their unique character to the environment and the way in which they are performed. IT companies tend to not use so much the services of external companies to deal with all of the software development and implementation process, instead relying on their own resources and handling the entire process on their own. For this reason, the process differs from what is the usual practice in other industries. As a rule, system implementations performed in IT companies take less time and expenditure because they do not involve intermediary or service companies; in addition, businesses dealing with IT implementations on a daily basis will already have relevant insights into customers' requirements, valuable links with software suppliers and, in most cases, ample experience with business-to-business collaboration and project management.

Taken together, the factors mentioned above seem to support the hypothesis that it is in IT companies that the knowledge component can be and should be improved in the first place.

The analytical system implemented at CONSORG SA was primarily addressed and tailored to needs of top managers, project managers, department managers (in many cases being the same people acting in different roles), and the sales personnel. The system was expected to enable these actors to monitor project implementation processes on a continuous basis, controlling deviations from plan and analyzing time spent on projects. For top managers solely, the system was supposed to provide reports on budget performance, support strategic decision

making, and facilitate projections into future developments based on financial result forecasts for the following reporting period.

CONSORG SA's system draws on Microsoft technologies and products from the MS SQL Server family, such as OLE DB and Analysis Services – for data analysis, or ASP.NET – for data presentation and visualization. Microsoft SQL Server ranks among most advanced database solutions available in the market and has been a market's favorite for years. Bundled with analytics tools, it can effectively work with large sets of diverse data and can serve as a platform underpinning an organization-wide analytical system.

SQL Server supports the R language, a leading data science and analysis solution attuned to the prevalence of Big Data, recently upgraded to provide better data security through the incorporation of such encryption and security technologies as:

- Always Encrypted – for encryption of data at read and save time, requiring client applications to run the dedicated Always Encrypted driver for data decryption;
- Row-Level Security – a service protecting records in data tables from being modified by any users other than those specifically authorized to do so;
- Dynamic Data Masking – making it possible to hide some sensitive data from unauthorized users.

Other functions in the SQL Server provide further facilities relating to data access, analysis and reporting (e.g. automated KPI calculation or R Language integration), making it a powerful technology that comes in handy in a wide array of environments.

OLE DB (Object Linking and Embedding Database) is a collection of COM (Component Object Model) objects that makes it possible to retrieve data for various sources. The OLE DB interface aims to provide all database applications with a single method of accessing data from diverse sources. At the same time, OLE DB represents a beta version – an in-development implementation – of the Microsoft-made ODBC (Open Database Connectivity) standard that can handle, alongside SQL queries, requests in other query languages, as well as queries involving non-relational databases and other data sets, such as spreadsheets and object-oriented databases.

Analysis Services form part of the Microsoft SQL Server and are included in the SQL Server Data Tools (SSDT) alongside Integration Services interfacing between data and Report Services – the latter reporting data analyses to Azure cloud services. SQL Server Analysis Services (SSAS) is capable of multidimensional data modeling, including (since 2012) tabular modeling and integrating with Power Pivot. In the BI solution being implemented, SSAS is responsible for generating OLAP cubes from diverse-source data fed into the system and for processing MDX (Multidimensional Expressions) queries built automatically via a graphical interface. For its operation, Analysis Services depend on the DAX (Data Analysis Expression) language – a collection of function libraries employed in calculating KPIs or creating calculated columns. DAX also includes a number of statistical, logical and filtering functions.

In addition, ASP.NET is used as a comprehensive solution for website development in presenting data analyses. A variety of .NET Framework is utilized in the system for website design and web application development. ASP.NET is open-source software consisting of three component frameworks geared to web application development: Web Forms – a drag-and-drop tool for dynamic website design; ASP.NET MVC – a solution based on the Model View Controller template for use in web application design and mobile application design (e.g. for Android) allowing users unfamiliar with the .NET language to easily develop applications; ASP.NET Web Pages – an integration tool that combines HTML code with cascaded style sheets (CSS) and database layers.

Prior to the BI system implementation, the company's IT infrastructure was made up of a financial and accounting system and Impuls Evo software by BPSC S.A.

The new BI system was aimed to add the following functionalities:

- A chart of accounts on top of financial and book-keeping records from which to retrieve data for financial analyses and forecasts built using MS Azure and MS Power BI architecture.
- Doc Studio – a data collection system for project planning and assessment of time consumption.

The in-design BI system thus consisted of four main components, i.e. webStudio, deskStudio, xlStudio, and wordStudio, is targeted at different users: the tools of webStudio as a web application designed for key users and/or top managers, because of management portal where data are presented in the form of transparent managerial dashboards; the deskStudio tools for analytical teams, allowing them to create complex reports and present them in the form of charts; the xlStudio tools for budgeting departments staff, helping them enter data from Microsoft Excel spreadsheets into budget forms; and the wordStudio tools for faculty users, generating reports in the form of Microsoft Word documents that can be circulated among the company's employees.

The subsequent stages of the BI system implementation process were designed with flowStudio, etlStudio, and calcStudio. These subsystems making up the Business Intelligence solution were being discussed. The flowStudio tools were using for planning and supervising group work, supporting the execution of business processes and enabling analysis of deviations from plan. The etlStudio tools were important due to ETL proces. The ETL creator have beed used in analytical processing of data and allows users to save these data in a data warehouse. The calcStudio auxiliary tool was used to help generate billings and to create a billing matrix through input filtering and transformation.

Arguably, the key system components are the webStudio and deskStudio applications. webStudio is an analytical tool based on OLAP architecture, relying on a multidimensional model (MOLAP) for its operation. Its role consists in creating reports from aggregated warehouse data coupled with data from transaction systems and data entered by users. The program is able to generate parameterized and fully scalable reports for a single user as well as for user groups – in the form of interactive tables, dashboards or key indicators. The application uses the ASP.NET web technology for data presentation.

deskStudio is an analytical tool based on OLAP architecture, largely similar to webStudio. It is a desktop application that uses the OLE DB interface as the source of data for processing and Analysis Services to process data in the form of OLAP cubes. It includes pivot tables functionality for ad hoc analysis. The application is utilized by the company's analytical team to launch budget performance forecasts, as well as to analyze returns on future projects and analyze the impact of changes and deviations from plan on ongoing projects.

The company's analysts have thus been given the possibility of visualizing data contained in the warehouse in tabular form, exporting data to Microsoft Excel or Microsoft Word (they can be read in real time using the xlStudio and wordStudio add-ons described in the following sections), creating advanced MDX queries (used in Analysis Services for data management) as well as of writing their own scripts in programming languages supported by the Analysis Services platform (C#, Visual Basic).

Other reports generated in the Business Intelligence system include a tabular presentation of the company's sales, linked to information on deviations from plan and next-period forecasts; a presentation of revenues from sales as a line chart to depict budget performance or as a bar chart to illustrate operating profit; as well as presentation of deviations from plan in the form of dashboards and matrix charts.

The Research Results and the Limitation Problems

The case study of DDMKCC model based on BI systems implementation in IT company showed some problems of knowledge management in organization. Too many reports, unrevealed facts, and time lost on digesting reports and messages – these are the key problems that most knowledge workers struggle with on an everyday basis. Is there a way to eliminate these? The research results analyses have the answer for smart reporting system implementation.

The rapidly changing economic conditions and the uncertainties around the COVID-19 pandemic have put businesses in a stint of profound transformations. The business models they have been pursuing are heavily based on data analysis, and the quantity of data has been growing exponentially. Given the excess of information and reports to be analyzed, they need better ways to handle the incoming data and timely make key business decisions. It is smart reporting* that might bring the much-desired solution to the problem.

A smart reporting system should be able to eliminate or mitigate at least some of the weaknesses of traditional reporting. Hence, to be able to reduce the amount of redundant information, the system must know what should be reported and how to make the data more meaningful and intelligible. In addition, it ought to be capable of tailor the

visualization option to best suit each user's preferences and to offer the optimum path for analysis that will engage the user in the problem rather than walk him through irrelevant facts. Finally, it might be a good idea to make sure that the reports come at the right time, bringing alerts to a minimum.

While it may seem obvious, the question is: how can the system know what should be reported, and what should not? The answer is in making assumptions on the following three areas:

- Analyzing the problem context, where the context is found in the knowledge base;
- Analyzing the relationships – links to the knowledge base;
- The choice of alerts, if applicable – alerts may be indicative of threats as well as of opportunities.

What a smart reporting system must be able to do is screen a collection of available data for items that should be reported, whether indicative of threats or opportunities. It is basically up to the knowledge base designer to decide what kind of information will be interpreted as reportable. The system can accommodate any number of knowledge bases that may operate standalone or in conjunction, while linkages among them may be based on data types (where an analysis entails mining a dedicated knowledge base) or on sharing a common data source (where a data item triggers an analysis in other independent knowledge bases). Depending on the designer's choices, reported data items (signals) can be grouped and filtered e.g. by weight. They can also become a starting point for a more in-depth analysis.

Knowledge required to identify problems is stored as a set of business rules that are processed via the open-source engine called Drools – a Business Rules Management System (BRMS). Besides the basic business rules engine (BRE), it comprises a web development and rules management application (Drools Workbench).

The business rules engine includes connectors enabling it to access data from independent sources, such as databases and data warehouses, spreadsheets, etc., to process mathematical models, or to incorporate artificial intelligence mechanisms, such as fuzzy logic and learning systems.

Self-service BI is among the top five BI trends of 2020, hence emphasis was placed by the authors throughout the research process on ensuring that users (designers) can create their own business rules. To this end, a proprietary business rules editor was developed that makes it possible for designers, using the original Drools format, to compose new rules, whether in text form, much the same way they would in natural language, or in graphical form.

In addition to business rules, knowledge bases designers can define visualization rules. As a result, they can influence the way the system will display specific types of information. They can choose to just define a number of individual signals as well as to build signal groupings and develop complete managerial desktops geared to viewing these. Whichever approach they choose, however, they will never be able to predict the actual configuration of signals generated from a knowledge base. It is the system itself that has to make sure that the data are presented in a manner that not only makes sense to the user but also supports horizontal (across the problems identified) and longitudinal analysis (in-depth to understand the underlying factors). This means that, for example, where too many incoming signals are identified as presentable to the user, they should be split into a number of desktops (views); where the system encounters presentable data lacking visualization rules, it will follow its internal rules to automatically generate visualizations, e.g. it may use a line chart to present a time series. Further, the system will attempt to suit the choice of visualization techniques to the user profile, so the same data may be presented differently to different users.

At the same time, smart reporting may work in a way that resembles classic reporting, i.e. it has to be initiated by the user who either wishes to explore a particular area (whether a single knowledge base or a number of interlinked knowledge bases) or requires comprehensive information on existing problems (which results in throwing up all available analyses).

The reporting function may also run in a continuous mode, even if, for the sake of smooth performance, it will probably not be able to work with all available data sources, instead being plugged into a so called data stream, e.g. a transactional system, to monitor records and capture irregularities. If this is the case, reporting is mostly confined to conveying brief messages to the user (by e-mail, via a messaging service, etc.), whereas detailed reports are not delivered unless the user initiates the process. The parctical example of solving the problem based on knowledge

management in the organization is tarrting in the field of budgeting and controlling as well as supporting the project management.

Conclusions

The paper highlights the new role of DSS in knowledege-based organizations and the concept of Meta-Design Methodology for knowledge management. The extensive literature review performed, the case study conducted, and the research work involved have led the authors to advocate the thesis that the use of BI systems can effectively support the development of the knowledge component in DSS environments. Future efforts should focus on the use of AI and Big Data software to improve human-computer interaction in creativity support, modeling and simulation contexts. More specifically, researchers need to further explore applicable approaches and AI technologies for optimum performance. A central dilemma is likely to be whether computers should think and act like men, or whether they should be based on rational thinking. As we are all aware, human decisions can be biased by emotions, so even if we try our best to be objective, we will never be so.

One more thing we must realize is that giving more power to machines will always raise fears among people – that machines, once beyond human control, might take over our world and destroy mankind. To mitigate the fears, it should be said, in the first place, that we have not even begun to understand what human consciousness is, so there is way to go before we can put anything like it in computers. Second, we already are governed or tracked by machines in many areas of our lives: computerized systems help us pick a movie, decide if we get a loan, test our health condition, or predict our purchasing decisions to make sure the right products are in stock.

Advanced computer algorithms have already proved to be able to deliver better results than humans and are becoming more and more common in business applications. Importantly enough, they do not threaten to immediately rid people of their jobs; more likely, they are going to change our world the way that the Industrial Revolution did. As AI grows into new subdomains – Virtual Reality, Expert Systems, Natural Language Processing, Deep Learning, Neural Networks, Speech Recognition – additional skills and an increasing number of knowledge workers will be needed.

* The solution is an outcome of the research and development project entitled “The Development of Advanced Smart Algorithms for Context-Based Selection and Visualization of Content Reported”, conducted by CONSORG and co-funded by the European Union under the RPO WSL Program for 2014-2020.

Abstract

Elderly people, as a group of mobile device users, differ significantly from other age groups. Acquiring knowledge of how they look at specific issues can be helpful in the process of designing the devices and applications themselves. This article deals with broadly understood security, which concerns the device itself and the way it is used. The group of seniors was asked to answer six basic questions in this area. These questions concern, among others: the importance of data on the device, the way the device is unlocked and the question about receiving SMS notifications and links in the context of phishing. The responses received and their discussion suggest that not all users of mobile devices in this age category are aware of the threats awaiting them.

Keywords: Smartphones, Elderly People, Security.

Introduction

Mobile devices are commonly used in the modern world. The use of smartphones can be very challenging, especially for older people, which may have issues with using them. On the other hand, it is a fact that the societies of highly developed countries are aging, and the number of seniors grows quite quickly. Demographic forecasts confirm this, among other, for European countries (De Wulf (2020)). This means that the challenges of how seniors interact with new technologies will become more and more significant factor in the very near future.

One of the most critical issues regarding the use of mobile devices is security. This can apply to both the device itself and the way it is used. The problem is more complicated than it appears. Nowadays, having confidential data stored on mobile device is connected with potential attacks allowing the acquisition of such data for further use of it (for example to transfer money via electronic banking). This issue also applies to seniors, and due to their age and often less experience in using of mobile devices, they are more susceptible to this type of attack. So-called grandchild trick fraud is worth mentioning here, which is an attempt to extort money by pretending to be a close person of a senior. Such an attack was viral in

Cite this Article as: Arkadiusz BANASIK, Adrian KAPCZYNSKI and Marcin LAWNIK "Initial Research on Security Aspects of Mobile Devices Used by Elderly People - Polish Case Study" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Poland, for example, where many seniors were deceived in this way (Europol (2014)). Accessing the senior's mobile device may additionally make this attack credible. Therefore, new challenges appear here, which include, among others, the challenge of how to adopt older people to mobile devices and services (Mallenius et al. (2007)) as well as the challenge of appropriate interaction between them and the mobile devices (Leme et al. (2014), Kapczynski and Lawnik (2020)). Smartphones are also used in case of supporting frailty assessment (Fontecha et al. (2013)) or a source of alert informing about falls (Martín et al. (2011)).

As one can see, the challenges of using mobile devices by older people is widely described and examined in scientific publications. It also offers a variety of issues connected with older people, technology, and their matching. Moreover, understanding how seniors operate can help create better hardware and applications that run on it. Some of the currently available solutions may turn out to be unnecessary, and perhaps there will be a need to introduce new solutions.

The article is based on results of own research survey performed among older people from Poland. The research questionnaire consists of six questions which address security aspects of use of mobile devices by elderly people:

- Importance of data stored on mobile device;
- Access control to mobile device;
- Emergency actions programmed on mobile device;
- Phishing on mobile device;
- Localization of mobile device in case of loss;
- Unwanted links on mobile device.

All above mentioned issues are a part of the survey, which results are presented in the article.

The article contains an introduction presenting aspects of older people and mobiles, than related works containing a review of other views on the given topic. The third part of the article includes a description of the methodology of the survey and the obtained results. The final part consists of conclusions containing the authors' opinions and findings on the presented topic.

Related Works

Mobile devices are a part of everyone's life. The use of them is a common practice in our lives. The researchers from Brasil noticed that people over sixty years old are an increasing group of users of smartphones (Leme et al. (2014)). Also, some research was done in Iraq concerning the positive or negative consequences of their abilities (Mohammed et al. (2016)). A similar study focused on both seniors and young people was conducted in Finland (Oksman (2006)). That is one of the recognized aspects of a combination of elderly users and their mobile devices.

Another approach is connected with the attitude towards developing and integrating of a personalized system for mobile devices for elderly people (AlRazgan et al. (2012), Fang and Chang (2016), Mallenius et al. (2007)).

The most important papers are focused on a combination of monitoring of health and disabilities of older people by using mobile devices (Fontecha et al. (2013), Martín et al. (2011), Sendra et al. (2012), Sendra et al. (2014)). Some aspects are focused on a way of health aging (Helbostad et al. (2017)) and virtual communities to the elderly support (Camarinha-Matos et al. (2001)).

Another aspect of surveys made is generalized security issues connected with older people (Mallenius et al. (2007)), also associated with privacy and hypermedia in case of information provision (Fink et al. (1997)). It is also known that the Internet of Things (IoT) is connected with security problems (Azimi et al. (2017)).

Another research direction is related to secure older people as novice users of mobile devices (Cook et al. (2011)). The similar context is shown in (Azuddin et al. (2014)). The problems are shown in connection with user interface (Warpenius et al. (2015)) and the applications (Holzinger et al. (2007)). It is also connected with communication system for older people as users of mobile devices (Mikkonen et al. (2002)).

The other research approach is related with touch-based interfaces (Häikiö et al. (2007)). That provides another aspect, i.e., pattern lock, which is also recognized in literature in the context of older people and disabled people (Kocejko and Wtorek (2012)). It is a significant factor that provides security in context of: access control to buildings (Bo et al. (2014)), electronic payment systems (Kwong (2013)) or mobile authentication (Ehatisham-ul Haq et al. (2018)). There are interesting research projects which are connected with user authentication of mobile devices by using pattern lock (Bier et al. (2018)) or biometrics (Sae-Bae et al. (2012)).

Above mentioned pattern-lock issue is connected with user authentication methods for mobile and online services (especially elderly users). It is a novel approach presented in (Blanco-Gonzalo et al. (2015), Ahmed et al. (2017), Renaud (2006), Garner et al. (2016)).

All above mentioned works are connected with security challenges, which should be treated from different points of view, including ethical aspect, technical aspect and usability aspect. That provides many questions that users should answer to cope with mobiles and their services on a daily basis. Moreover, it is also connected with users' abilities and disabilities, including those associated with the age. According to those arguments, the authors provided a case study based on Polish elderly people, which shows their attitude toward security aspects of mobile devices.

Preliminaries Methodology and Results

The study was conducted in the form of a questionnaire on an adequately selected target group. The question concerned several aspects related to the safe use of mobile devices. A detailed description of the target group and the questions themselves can be found below.

Group of users surveyed

The surveyed group of users are seniors aged 55 and over who use mobile devices on a daily basis. Their exact age and gender structure are shown in Figure 1. The figure shows that the majority of respondents are men aged 66-75. Such a selection of the research group is appropriate for the intended purpose of security analysis in mobile devices.

Fig. 1: The age structure of the surveyed participants

Issue 1: There is data on my phone that is important to me.

Fig. 2: Results for the first question about the data stored on the mobile device

The first question asked concerned about the data that is available on the mobile device. The surveyed group was asked if the data was important. The results can be seen in Figure 2. The vast majority of respondents answered this question in the affirmative (only a few people chose other options). It means that the vast majority of respondents are aware that a personal mobile device is not only an ordinary electronic gadget but also a database containing valuable data for them. These data may concern, for example, the contacts themselves but also multimedia files created with such a device (photos and videos). Besides, nowadays, mobile devices are often used as tools supporting electronic payments and, if such a device is used by inappropriate people, they can be used to steal money. This issue will become more and more critical over time, and undoubtedly the data stored on personal devices will become incrementally important.

Issue 2: Unlock the phone by entering: a complicated PIN, entering an unlock pattern or submitting biometric data

Fig. 3: Results for the second question on how to unlock your mobile device

The second question was about the ways one unlocks the mobile device. The respondents were asked whether they use PIN codes, patterns, or biometric methods of unlocking the device. The results can be seen in Figure 3. They show that only half of the respondents answered the question in the affirmative. The others either do not use these methods of unlocking the device or perhaps they did not fully understand the question (selecting the answer: I have no opinion). Nevertheless, such a combination of answers seems surprising, the more so as in the first question, the vast majority stated that their mobile device stores valuable data. Undoubtedly, the most convenient form of unlocking a mobile device for a senior would be a biometric method. It does not require memorizing complicated patterns or a sequence of numbers. However, such a method may seem less secure for an older person, and the device's configuration may be more complicated in this case. When creating new applications and devices dedicated to seniors, it may be worth putting more emphasis on this issue.

Issue 3: In an emergency (e.g. after passing out) my phone is configured to trigger an emergency procedure

Fig. 4: Results for third question about emergency situation

The third question concerned emergencies in which a mobile device can send a special alert informing other people. The respondents were asked if their device was configured so that it could send an appropriate signal in such a situation. The survey results are presented in Figure 4. They show that only some of the respondents have their mobile devices configured in this way. This situation may come as a surprise because this possibility of informing other people in emergencies is dedicated to this age group of users. Such a small percentage of affirmative answers may result from the observation that not every senior can adequately configure their mobile device. Perhaps a more comfortable configuration of the device in this direction would allow a larger group of people to take advantage of this useful functionality.

Issue 4: A phone call or a short text message informing about the necessity to contact the bank will arouse my suspicion in the first place

The fourth question was about phishing. The respondents were asked whether the situation of receiving a message about contact with the bank would raise their suspicions or not. The results can be seen in Figure 5. More than a half replied that such information would cause fear in them. However, it is disturbing that a total of about 30% of respondents answered that such a situation did not seem suspicious to them. Perhaps it is a matter of the fact that some banking services, such as transactions, are reported in the form of text messages. Nevertheless, it means that in the case of phishing, there is still a lot of work to be done to increase the awareness of users (rather than just seniors) of the risks it brings. This issue is all the more important as the attacks of phishing confidential data or even financial means are more and more sophisticated, and, seemingly, a sheet of a text message can lead to severe consequences. Such a text message may also be about the attack on the grandchild mentioned in this article.

Fig. 5: Results for the fourth question about receiving suspicious messages asking the user to contact the bank

Issue 5: My phone is prepared for work in such a way that it has mechanisms to locate it in case of theft or loss

Fig. 6: The results for the fifth question about the issue of the location of the

mobile device in case it is lost or stolen

The fifth question was related to the situation in which the user of the mobile device is unable to locate it in the event of loss or theft. The results are shown in Figure 6. More than half of the respondents replied that their mobile devices are properly configured for this situation. This means that the issue of losing or theft of a mobile device is not so important to the other half or they are not aware that there are mechanisms to prevent this type of situation. Perhaps a more straightforward configuration of a mobile device or better integration with other smart band devices would allow for broader use of this functionality by the elderly.

Issue 6: When I receive a link to a website sent by the instant messenger, I open it without fear, because clicking on such a link is not associated with any danger

Fig. 7: The results for the sixth question about the awareness of threats related to instant messaging

The sixth question was again about phishing, but this time in the form of a link to a website. The results are shown in Figure 7. For 15% of respondents, a situation in which they get a link to a foreign site seems unlikely. Such a percentage may seem relatively small. However, considering the multitude of such attacks that try to extort confidential or identity-stealing data, it is very dangerous. The more that attacks of this type are more and more sophisticated. Moreover, not only extortion attempts, but also classic problems related to the risk of installing malware are implemented in this way. As in the case of SMS messages from the bank, the issue of raising the awareness of seniors should be intensified when it comes clicking links to other websites.

Conclusions

The article shows and discusses the issue of broadly understood security regarding the use of mobile devices by seniors. The questions asked concerned, among other things, phishing (text messages from the bank or clicking on links) or the device itself (whether the device is valuable from the side of the data it contains or how to unlock it). The survey results show that in some matters, the awareness, in this case of seniors, is not yet optimal, and further efforts can be made in this regard. Besides, the interview conducted in this way may be helpful in designing mobile devices because some of the questions concerned technical aspects.

Simulation Techniques in Automation of Criminal Procedure - Towards Industry 4.0

Dariusz PIERZCHALA

Faculty of Cybernetics, Military University of Technology, Warsaw
Poland, dariusz.pierzchala@wat.edu.pl

Abstract

The Polish criminal procedures involves many steps, phases and stages and creates very complex processes that are composed of multiple sub-processes and activities. Nowadays, the participants of the criminal procedure are limitedly provided with modern IT, thus there is an urgent need for methods and tools to optimize process and minimize delays, shorten queues of pending cases and reduce (or even eliminate) the number of human errors. However, the guiding assumptions are: elimination all reasons that might weaken the access of citizens to judiciary system, as well as make hard to keep the guarantee of "equality before the law". These objectives are consistent with the principles of Industry 4.0, especially simulation based knowledge acquisition, machine learning and robotic process automation. The simulation method has been applied for verification of usefulness of proposed automation with QR Code and RFID tagged documents. The original simulation software allows conducting the experiments in a short period of time for numerous testing scenarios. Moreover, during the experiments the simulated events and resources (people, tools) are integrated with real devices in order to gather data about their reliability and performance. We propose two-way analysis of the criminal procedure: modelling and simulation of the process similarly to Business Processes Modelling (BPM), which forms the basis for measuring and assessing an effectiveness, and optimization based on hybrid models and methods: GAN/GERT with queuing theory and optimization. The practical result of this work is the workflow system extended with the business process simulator.

Keywords: Criminal Procedure, Court Automation, Event Simulation.

Introduction

In the last two decades, technological advances have been extremely rapid and have significantly changed human life. Industry 4.0 is becoming more and more the reality for many companies around the world, what also applies to the developing European countries of the Central and Eastern Bloc, in particular Poland. More than 90% of the managers, who took part in the global survey of the consulting company Deloitte, indicate In a research study by Deloitte (2020) that the digital transformation is the highest strategic goal of their organization. The fourth industrial revolution should increase efficiency and bring savings even more evidently. However, there are also many challenges and problems. The first one is cybersecurity - Industry 4.0 increases the possibility of cyber attacks. The second is unfavourable social reactions, related to the influence of automation on the labour market. The third is the concern that intelligent robots will replace the human factor at work resulting "technological unemployment". The fourth is the risk of over-subordination to robots and their still very limited intelligence and perception.

According to Bowles (2014), the percentage of automation professions in Europe ranges from 45-60%, and especially southern Europe is more vulnerable to the wave of automation. The conclusions of the discussion at the 2016 World Economic Forum in Davos about the consequences of Industry 4.0 show that up to 7 million jobs could be at risk in the next 5 years.

There is no turning back in the economy of countries from technological and organizational changes related to Industry 4.0. It is also clear that it will have an increasing impact on other dimensions of human life, such as education, travel, medicine etc. According to the author's opinion also the judiciary, as a particularly sensitive area

Cite this Article as: Dariusz PIERZCHALA "Simulation Techniques in Automation of Criminal Procedure - Towards Industry 4.0" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

of state functioning, can and should be subject to changes imposed by Industry 4.0, notwithstanding with special caution and prudence. The proper functioning of the judiciary - the third power - is crucial for all countries. Although the new century has brought significant positive changes stemming from the advances of IT technology (for instance the simplifying and accelerating many official procedures), there is still an urgent need for innovation of judicial system in the areas: organizational, legal (formal) and technology. Replacing people with artificial intelligence of software machines creates an opportunity to relieve the burden on people, reduce delays in processes, objectify judgments and reduce error rates.

According to the different social research, judicial system is criticised by many Polish citizens (following a research study by Beldowski et al (2010) it was even approximately 40%). In particular, there have been criticized delays of criminal cases. Currently in Poland, the participants of the criminal procedure (i.e. judge, secretary, sites) are provided with modern IT limitedly. Although IT tools for case-management are reported in more than half the courts there are rather stand-alone non-integrated programs and that solutions applies to administrative courts mostly (e.g. electronic files are available in 10% of courts).

A very recent fact that may have an impact on acceleration of the automation of courts and the criminal procedures are phenomena similar to Covid-19. The impossibility of typical and "normal" functioning of courts based on traditional techniques and tools, resulting from the limitations of the coronavirus epidemic, including the limitation to a physical meeting during hearings of both parties, may result in acceleration of the process of computerization of courts. Solutions such as videoconferencing (in UK, the HMCTS enables all parties to take part remotely in a criminal hearing using video platform) and remote participation of the parties in the trial, electronic application offices (Polish abbreviation: ePUAP), information portal of the courts are already quite common. However, in a media space it is a common opinion that automats and artificial intelligence can analyse cases and generate a decision for a judge only in simple cases. In complex cases, the robot adjudicating on other cases raises understandable objections – AI methods should support processes and procedures, but should not replace the judge. It is definitely important to enable the criminal justice system to operate both efficiently and primarily: fairly. In the context of a criminal procedure, that is sensitive to errors in actions and procedures, the focused action of the authorized entities and actions limited by time (the passage whereof becomes a factor undermining to a great extent the basic level of its objectives: the completion of the case in a "proper time") are required.

These subject issues have appeared in research carried out around the world since the early 1990s. In many works, efforts have been made to assess the functioning of judicial systems: Posner (2005) mentioned that it is an analysis of the work of courts from the economic point of view, in In the books by Rosales-Lopez V. (2008) and EC (2012) that are statistics and forecasts, while in Beldowski et al (2010) there are opinion-based evaluation of courts. The paper presents an extended approach based upon the earlier researches conducted with cooperation with the District Court in Bialystok, Poland - case study sourced from the court following a research study by Pierzchala et al (2014).

There are known useful approaches that allow modern organizations and businesses to operate effectively according to Industry 4.0. For the proper analysis of a criminal procedure and then the construction of supporting software tools (for workflow management and simulation) there is crucial to adapt a modern methods to criminal process specification (e.g. queueing systems, simulation models, business process modelling, machine learning, robotic process automation). Advances in the criminal process should be obtained by an analysis of the current status, identification of possible places to cover with AI and possible actions to automate with software robots, and the prospective changes necessary and possible to applying. If we treat criminal procedure in terms of business processes, the selected problems can be solved with the use of tools for process modelling and simulation, which will form the basis for assessing the effectiveness and finally optimization. Elimination or reduction of “bottlenecks” in that process, identifying how to redefine and reorganize the process, indicating the time and resource savings is possible to be made after identifying the real causes of problems. Simple examples are the complaints that are allowed by criminal code to submit on almost every stage of the proceedings. The other one is a necessity to service formal defects in criminal process documents (writs, letters, briefs etc.) – it creates an opportunity for machine learning methods. Due to lack of data, simulation and synthetic data generators can be used. Before implementing any changes in the existing system, their effectiveness and usefulness should be examined, also with simulation techniques.

Modelling of The Criminal Procedure

The background

In Poland, the Constitution provides for dualism of the judiciary's authority – the justice system is composed of courts and tribunals. Currently, there are almost 380 common courts in Poland - one “supreme (highest)” court, more than 10 appeal courts, 45 district courts and 321 regional courts. Regional courts are courts of the first instance - they handle most cases within jurisdiction that covers an area of several Communes. District courts have a function as both first and second instance courts – they handle serious cases and appeals within jurisdiction of several district courts. Dubois et al (2013) mentioned in that structure there are ~10,000 professional judges working in courts: ~7,000 at first instance, ~3,000 at second and less than 200 at highest instance. According to general statistics, more than 90% cases are proceeded by courts of first instance. Among different cases a weight of criminal ones is special, so due to the facts the role of criminal departments in district courts is really important.

The Polish criminal procedural law is a set of legal norms regulating the criminal process, defined as a set of regulated activities aimed at detecting, judging and possibly executing a punishment and protective measures for a crime and its perpetrator. We can also try to define the concept of a criminal trial by a number of activities carried out by preparatory and judicial authorities. In that meaning the criminal procedure involves many steps and stages that at the most general level are: Criminal investigation, Grand Jury proceeding and Execution of sentence. More detailed, there exists the following steps: Reporting of the Crime, Pre-arrest Investigation, Arrest, Arrest and Booking Process, Post-arrest Investigation, Decision to Charge, Filing the Complaint, First Appearance, Preliminary Hearing and/or Grand Jury Proceeding, Arraignment on the Information or Indictment, Pre-trial Motions, Plea Bargaining and Guilty Pleas, Trial, Sentencing, Appeals and finally Post-conviction Remedies. The space of is perceived as discrete and depending on goals it can be divided into different number of levels leading to complex processes that are composed of multiple sub-processes and activities. Each one is optional and can run according to various alternative paths thus a procedure can finish without executing all steps.

If we treat the criminal procedure in terms of formal models (e.g. business processes or stochastic processes), the selected problems can be solved using tools for modelling and simulation. Thus, M&S constitutes the basis for optimization, reorganization of the criminal procedure and assessment of both improvement of efficiency and savings - in sense of time and resources. To achieve this objective we proposed in a research study by Pierzchala et al (2014) the approach based on repeating iterations in cyclical activities: (1) modelling of a courts’ structure and organization, the environment and the activities in the criminal procedure; (2) study the quantitative characteristics describing courts and the current criminal procedure; (3) reorganization (optimization) in the direction of improvement; (4) development and implementation of computer systems supporting the courts; (5) re-modelling, study characteristics, verification and correction of direction of the proposed changes and modifications.

Business Process Modelling of a criminal procedure

The main objective of BPM is to adopt organizations to the needs of their customers and to define an intended model of functioning. BPM cover the interlinked stages of activity i.e. the identification, analysis & modelling, simulation, implementation, launching and monitoring - which is also the main elements of a typical life cycle of business processes. Assumption is that the processes should be continuously improved on to ensure their accuracy, the ability to better achieve its goals. The are many advantages, despite a solid effort required to implement and maintain such an approach.

Fig 1. Schema of "business process model" life cycle. Source: own preparation.

According to BPM notation, every step is so called process (at the top level) and subprocess (the subordinated levels), which leads to decomposition to more complex model with more specific tasks. Main area of our interest is judicial criminal proceeding, which is the second step. Figure 2 shows its diagram at a higher level.

It begins with the bill of indictment by the prosecutor. The case documents, especially indictment, are then verified by the president of the Criminal Department. This step is a complex subprocess called "Indictment verification" during which formal verification is performed and reporting judge is chosen.

Fig. 2: The first (higher) level of judicial criminal proceeding. Source: own preparation.

If any formal problems with indictment occurs, subprocess called "120 KPK" (120 paragraph of the Code of Criminal Procedure) is started, which means all formal defects should be resolved by prosecutor or indictment will be rejected. After "Indictment verification" step is completed the reporting judge has all the case files. In the next step, which also is subprocess, these documents are verified by judge and decisions including use of detention for the accused, discontinuance of the proceedings or going for trial are made. Depending on this decisions next steps are trial or session concerning the discontinuance of the proceedings (from which case also can go to trial step or sentencing step). Like steps before, trial is also a complex subprocess with multiple different paths, but unlike them it cannot be supported by BPM system. The last step, which is also subprocess, is sentencing. It is quite complex because events such as appeal or objection can occur. Diagram in Figure 1 may not look as complicated as the judicial criminal proceeding really is. In fact, there are four levels of subprocesses and some of them are executed more than once. For example diagram for process "Indictment verification" contains fourteen tasks and more than ten alternative paths. What more, two of those tasks are complex subprocesses. One is mentioned earlier, "120 KPK" step and the other one is complaint handling process. Both are used many times in further steps of judicial proceeding process. That is the most complex and time consuming part of this process. One of the main goal of modelling and simulation is to verify what is the impact of pessimistic paths on time of execution and cost of whole judicial proceeding. The analysis of procedural activities in a criminal department of a district court has finished with number of such diagrams, which became the basis for the design of computer support system, quantitative analysis and optimization.

To model, analyse and simulate criminal process we can use formal models and methods dedicated for analysis of complex operations (processes, projects). Following models and methods it may be considered: queuing theory, CPM (Critical Path Method), PERT (Program Evaluation and Review Technique), GAN (Generalized Activity Network), GERT (Graphical Evaluation and Review Technique). Each of them has advantages and disadvantages, for instance CPM and PERT methods have limitation to acyclic structure of projects and, in general, they are deterministic.

In this paper we propose to use a method based on stochastic model of the complex activities where time-dependency could be modelled using a stochastic PERT model. As a complex activities we understand operations that contain many related actions. Relations between actions mean a time sequence and reflect influence of one action on the another. Looking at "120 KPK" step and the other one is complaint handling process. Both are used many times in further steps of judicial proceeding process. Complaint handling is particularly complex. It contains seventeen tasks and more than twelve different paths and, what causes most problems, loops (decisions made during complaint handling also may be subject to complaint). We define complex activities as the following network $S_p=\langle G,\Phi,\psi\rangle$, where:

- $G=\langle A,E\rangle$, G –Berge's graph without loops:
  - A – set of graph nodes, where a node is related to one *action* of complex activities, $A=\{a_p,1,2,..a_k\}$; nodes represent some tasks that should be completed in order to obtain assumed effect;
  - E - set of graph edges – edges define the time and causal sequence of actions;
- $\Phi=\{f\,|f:A\rightarrow R\}$ – family of functions defined at graph nodes;
- $\Phi=\{\tau_{min}, \tau_{max},\tau_p\}$ is defined by:
  - the shortest time needed to complete tasks connected with action *a*;
  - the longest time needed to complete tasks connected with action *a*;
  - the most probable time needed to complete tasks connected with action *a*;
- Ψ – family of functions defined at graph edges.

Similarly to a research study by Najgebauer et al (2018) time duration of a path from the node *i* to the node *j* (the length of this path) can be computed as a sum of times $\tau_E(a)$ for subsequent nodes of the path and $\tau_E(a)=1/6*(\tau_{min}(a)+4\cdot\tau_p(a)+\tau_{max}(a))$. Further, based on this assumptions the following (and others) characteristics are computed:

- Expected duration of the tasks leading to the achievement of the node (action);
- The earliest possible moment of starting the implementation of tasks leading to the achievement of the node;
- The earliest possible moment of starting the implementation of the actions leading to the achievement of the node without delaying the implementation of the entire process (the shortest time distance from the starting node);
- The earliest possible moment of completing the actions leading to the achievement of the node;
- The latest possible moment of completing the actions leading to the achievement of the node, not causing a delay in the implementation of the entire process;
- Probability of reaching the node in less than the 'worst' time, taking into account the impact of achieving the previous nodes (calculated for the worst time of the implementation of tasks leading to the node);
- Probability of achieving a node in less than 't', taking into account the impact of achieving the preceding nodes;
- Probability of reaching the node, taking into account the impact of achieving the preceding nodes;

- Variety of random variable of time needed to complete tasks necessary to reach the decision point (e.g. normal distribution).

In compliance with the model it has been developed software package to model and simulate complex activities, similarly to model processes using notation similar to BPMN. There are embedded different characteristics of complex operations.

Simulation Method for Verification of Usefulness of Automation

Criminal procedure life cycle, similarly to BPM, follows the steps outlined at Figure 1. That cycle depends on correctness of modelling and simulation as well as reliable statistics gathered during execution. Thus, there is an obligation to develop adequate software tools for simulation analysis of effectiveness of the criminal process, which will help finding reasons of problems and allow for proceeding optimization. Generally, we focus on problems such as congestion, the high cost and delay of procedures elimination or reduction of "bottlenecks" in processes, suggestion of redefinition and reorganization processes as well as the time and resources saving, etc. Although simulation is very suitable the formal way is adopt hybrid models and methods: stochastic PERT with queuing theory and discrete-event agent-based simulation. Finally, the simulation method has been applied for verification of usefulness of proposed automation. Moreover, during the experiments the simulated events and resources (people, tools) are integrated with real devices in order to gather data about their reliability and performance.

The Pert package has the basic classes responsible for the creation and calculation of network functions/characteristics (described in nodes and arcs). Characteristics are positive real numbers representing time and probability. It contains methods dedicated to, among others, detecting cycles in the graph, searching for the shortest and longest path, calculating the time of starting and ending the activity and estimating the probability of successful completion of the activity (defined as a node). Both known algorithms (Dijkstra algorithm, Depth-first Traversal) as well as heuristic algorithms, which are our own elaboration, were used.

Fig. 3: The structure of simulation software package. Source: own preparation.

The original Java-based discrete simulation software package (named *DisSim*) has been developed in order to facilitate creating constructive simulation software – both discrete and quasi-continuous as well as hybrid. DisSim is "light-weight" solution, which are built from the scratch and customized to the needs of the end users. DisSim is an object paradigm based package and consequently, the basic entity is an simulation object with its attributes.

Similar objects create classes. At any time *t* of the simulation time each measurable feature of the criminal process is represented by an ordered quadruple: <*object, attribute, value, time*>. For each object class there are defined: the state vector with attributes and either the events or periodically executed equations that change the values of attributes (and finally a state of the process).

ProcessModels package contains generic models of heterogeneous devices that is the crucial part in building application for criminal procedure simulation. The key feature of the software is the ability to change object's behaviour and to modify actions of the process without changing any compiled line of code (even during running simulation). We propose the way based upon Groovy/Python scripts and DisSim classes to serve them. These highlighted reasons prevailed for the decision to use the original DisSim package in order to implement simulation models specified for criminal procedure domain. Each modelled component is independently constructed by a dedicated factory whose member is the script interpreter. By changing the script's contents it becomes possible to alter device's behaviour without changing programme code. The package simulation forms some kind of library the content of which is successively developed (new models of devices, new behaviour algorithms).

Following action "120 KPK", we should emphasize that almost every decisions made during judicial proceeding may be subject to complaint, what increases complexity of whole process dramatically. Steps responsible for handling defects and complains might be performed in other parts of judicial proceeding - they form so-called pessimistic paths. That is the most complex and time consuming part of this process. One of goals of modelling and simulation is to verify what is the impact of pessimistic paths on time of execution and cost of whole judicial proceeding. However, the main goal is to optimize process operations in such a way as to minimize delays, shorten queues of pending cases and reduce the number of human errors.

The other issue, which many courts face, is limitation on providing rapid access to court documents. Process automation helps reducing the amount of time and manpower required to perform repetitive tasks. The success of software algorithms of robots depends on the correct and high-performance operation of the supportive devices. After deep analysis it has been proposed to implement QR-code and RFID tags for documents. The tagged document does not differ much from a traditional document – in the case of QR-code it is small rectangle while the size of the RFID tag is getting smaller to approximately 10 square centimeters. The flow of paper documents in courts is connected with the registration of many important legal records or personal documents, judgment, statements, administrative decisions, etc. Even though traditional documents notably frequently replaced by electronic equivalents, paper is still required from the formal point of view. The main issue concerning the examination of the characteristics of the document flow processes is to define the capacity and reliability properties on the support system implemented in the courts. Especially, in preparatory proceedings at initial phase of the criminal procedure where time plays a major role. The equipment necessary for the correct identification and management of tagged documents are as in a research study by Pierzchala et al (2017): entrance sluice with the RFID antennas, cabinets with the RFID antennas, reading tunnel, tray reader and dedicated software integrator. The entrance sluice registers the document in/out flow, the cabinet with the RFID antennas is specialized storage space for the documents required during criminal procedure. Both the reading tunnel and the tray reader is used for registering tagged documents.

Fig. 4: The of simulation software package GUI. Source: own preparation.

In the real circumstances, the examination of such complex environment (people, procedures, devices and prospective automation robots) would be time consuming. From a statistical point of view, it would take "many many" days to collect a sufficiently numerous set of data as well as significantly varying court cases. Carrying out a series of simulation experiments allows to collect dataset and finally to estimate the statistics on: queues before service nets, partially and completely realized tasks, resource usage, bottlenecks, expected delays or probability of completeness of a case in a given time. The time inside the developed simulator can flow at a rate of 1:1 with astronomical, or it can be repeatedly accelerated, therefore the simulator can immediately imitate thousands of the events related to the documents' inflow and events related to documents' flow between court's offices. Each event generate a message directed to the server in the form of XML with the coded information about action performed on a document. The Groove scripts simplify creating messages and sending them to the target end-point of the service on the server. Simulation experiments are conducted based on scenario which describes types of events (types of actions in court), duration of actions, period between events and sequences of related events. Every simulated queue of documents is modelled in a form of a group object with a discipline (e.g. FIFO) and a theoretically unlimited capacity (in practice: the maximum value a computer can achieved). A station inside a simulated queuing network represents a person (judge, clerk, chairman, secretary) and is modelled as an simulation agent characterized by a random service time (a random variable with value set by software random generator of any distribution). It is very important that the parameters are not homogeneous in time. It conducts towards a multidimensional stochastic process consisting of the events (understood as a state change in the simulation model). In a simulation experiment a number of requests to a court with a given distribution of interval is generated and the random path executions of each criminal case are simulated. Thus, the software generators of pseudo-random numbers were implemented. In order to adequately create random values, a set of empirical distributions were created (after the measures have been taken in the court). Subsequently, the Bayesian network was built to reflect the complex relationship between the submitted cases and the duration of actions.

Conclusion

The Polish criminal procedures creates very complex processes and there is provided with modern IT limitedly. The requirements, such as elimination all reasons that might weaken the access of citizens to judiciary system, as well as make hard to keep the guarantee of "equality before the law", are consistent with the principles of Industry 4.0. We propose two-way analysis of the criminal procedure: modelling and simulation of the process (which forms the

basis for measuring and assessing an effectiveness) and robotic process automation based on QR Code and RFID equipment.

The simulation method has been applied for verification of usefulness of proposed automation. During the experiments the simulated events and resources are integrated with real devices in order to gather data about their reliability and performance. Increase the effectiveness of criminal justice is possible via changes in both organizational and procedural way, as well as through the IT technologies supporting the processing of information at any stage of a criminal proceeding. There is very crucial to treat automation as a powerful solution, however using carefully in a right way.

Finally, the rules of criminal procedure are constantly evolving thus in contrast to most of existing simulation tools the proposition has a capability to modify simulation events or activities with programming Groovy scripts even after building a closed ready-to-use software.

Knowledge-Based Engineering Approach for Facilitating Weld Design with The Support of Machine Learning

Abstract

Nowadays, the development of new structures is carried out by reusing the engineering knowledge that is encompassed in virtual prototypes. To facilitate this process, most recent product development software benefits from a wide range of parametric design capabilities. From this perspective, a cross-linkage can be achieved between various disciplines, allowing engineers to adjust full scale projects by modifying desired specifications. Even so, such capabilities are limited when designing welded connections, considering the rigid boundaries of Computer Aided Engineering simulation models. To overcome such issues, the present paper proposes a new approach that makes effective use of machine learning for improving the modeling of engineering knowledge. At first, a sensitivity study is conducted on a specific welded structure. By adjusting candidate parameters, the mechanical behavior of the assembly can be evaluated. The results achieved are stored in a dataset that is further used to develop regression models based on neural networks. To this end, a generalized structural behavior is achieved, allowing engineers to predict the performances of welded joints without explicitly updating simulation models.

Keywords: Weld Design, Simulation, Machine Learning

Introduction

In the book published by Bennett (2013), electric welding is regarded as one of the most widespread fabrication processes, whereby two or several metallic parts are fused together at their original boundary surfaces by means of heat, pressure or a combination of both. In all major industrial fields, welded joints represent critical locations in the load path of an assembly. From this perspective, Piscan et al (2012) highlights the need for a careful evaluation of the static and dynamic criteria to ensure the safe and reliable operation of such structures. A recent study by Dubovska et al (2014) emphasizes the proliferation of weld design modules in most virtual prototyping software to assist engineers in deciding the optimal technological parameters. Such tools also benefit from knowledge-based systems technologies, thus allowing the cross-linkage between design disciplines. In this regard, the drawings that resemble welded joints are completed with the support of Computer Aided Design (CAD). On the other hand, the transfer of the resulting continuous models to Computer Aided Engineering (CAE) analysis systems is described in Kiani et al (2015). The process is deployed for evaluating the mechanical behavior of the structure at both junction and assembly levels. Parameters belonging to the two different environments can be interconnected as part of Product Lifecycle Management (PLM) systems. Furthermore, the paper by Nosenzo et al (2014) brings into discussion the advantages of using metamodeling as a convenient way of linking the resulting set of parameters with other sources of knowledge (i.e. economical evaluation or sustainable product development software). Even so, the effective parameterization of CAE simulation models for welded assemblies represents a challenging perspective. This is mainly due to the tight requirements of the mesh generation process, whereby even minor changes to the location of the nodes or the number and types of elements can cause high stress peaks and subsequent singularities. From this perspective, the cross-linkage of the disciplines associated to the weld design process is limited to the modeling and capture of engineering knowledge, the reuse of CAE simulation models demanding most of the time additional user input. To overcome such issues, the present paper proposes a Knowledge-based engineering (KBE) approach that makes effective use of machine learning for predicting the mechanical behavior of welded assemblies by learning and generalizing from sensitivity studies. In the first stage, a set of candidate parameters that influences the behavior of welded joints is chosen. A range of design points is decided for analyzing the influence of these parameters on the static or dynamic behavior of both parts and their junction area. The results are stored in a dataset that is further used for developing a machine learning regression

model. A case study regarding the weld design of an electronic enclosure from the heavy equipment industry is completed to prove the given concepts.

Knowledge-based engineering in Weld Design

Any KBE approach comprises three layers of abstraction: knowledge modeling, capture and reuse. The implementation of such concepts in weld design is achieved at a minimal level by interconnecting CAD and CAE environments. In this way, the modeling of knowledge is carried out by defining the parameters that are governing the definition of the geometry in conjunction with the specification of the welded joints. The resulting model is further transferred to CAE environments, being used as a reference for developing the mathematical representation of the load paths. In this stage, the initial set of geometric parameters are correlated with specific simulation ones, allowing CAD-CAE cross-linkage. In the next stage, the knowledge captured is stored at enterprise levels, allowing its successful reuse in future projects (Figure 1).

Fig 1. A holistic overview of KBE in weld design

The process involves the definition of the boundary edges based on an initial 3D model of the assembly. In these locations, a detailed representation of the optimal weld configuration is achieved. A set of parameters is defined to allow the adjustment of the geometry and subsequent weld specifications. The resulting model is transferred to the CAE environment. In this stage, the topology is simplified to facilitate the definition of assembly connections by imprinting the edges of the welded joints. The definition of the mesh is completed in the next stage to divide the continuous model in smaller domains by discrete elements. This step represents an essential one in all CAE projects, demanding most of the times several topology adjustment loops. Loads and Boundary Conditions (BCs) are applied to materialize the behavior of the assembly during its life cycle. The resulting digital representation of the simulation model is transferred to a solver. In accordance with the analysis type, the solver assembles the equilibrium equations of the problem and generates result files that are further interpreted for verifying the integrity of the structure. Improvement loops are conducted if errors are identified in the simulation model. In contrast with the CAD environment, the CAE one is characterized by several adjustment and improvement loops. From this perspective, the correlation between mesh and geometric parameters is limited, considering that a single mesh approach satisfies a single weld connection definition. Figure 2 – a illustrates an idealized scenario where two plates are linked together by a bar which materializes a spot welding area. When adjusting geometric parameters such as the thickness of the plates, the number of welded points increases or decreases. In this case, two scenarios are the most common: the distortion of the nodes found in the proximity of the bar to accommodate another one (Figure 2 – b) or the addition of elements to increase the number of nodes and allow the connection to be satisfied (Figure 2 – c).

Fig .2: Limiting aspects of weld connection adjustment

In any of these cases, the quality criteria of the elements found in the junction area is impacted. This results in a different stiffness behavior of the weld connections. Subsequently, unsatisfactory results can be achieved. From this perspective, KBE in weld design is only limited to the storage of CAD - CAE models.

Proposed Approach

The proposed approach consists of 5 stages that support the knowledge modeling process. Their description is performed below:

• *Definition of candidate parameters:* in this stage, a selection of geometric parameters is performed by considering those having a significant influence on the mechanical behavior of the welded joints and subsequently, the entire assembly. For example, the length of a part influences the welding pitch, which has a direct consequence on the load distribution in the structure. In accordance with the mesh generation strategy, the selection of parameters can be distinguished as flexible (or parameters that have no influence on the number of elements or position of the nodes) and rigid ones (or parameters that cause the initial mesh to change).

Identification of rigid parameter rules: once rigid parameters are adjusted, user input is required in the CAE environment to fix mesh issues. Even so, such corrections can be accomplished within specified ranges. For example, increasing the number of spot weld points up to a certain value can be completed with a single update of the mesh.

• *Sensitivity study:* the aim of the sensitivity study is to identify the relationship between the candidate parameters and the mechanical behavior of the assembly. For example, a gradual decrease of the thickness of the welded parts results in an increase of the stress in the junction area. As a consequence, the safety factors of the assembly decreases.

• *Dataset development:* the results of the sensitivity study are stored in a dataset comprising the candidate parameters as features and the results of the sensitivity study as labels (or regression targets). Feature normalization is applied. On the other hand, the rows from the dataset that indicate no significant increase of the labels in conjunction with the features are removed. The dataset is divided in training and validation sets for further use in the machine learning process.

• *Development of sequential regression model:* the dataset is further used for developing a neural network with a simple stack of layers with the support of a machine learning library. From the knowledge of the authors, the simplest representation of a sequential model having 2 hidden layers and using the hyperbolic activation function between them provides best results for this type of problem. The RMSprop can be used as optimizer, the typical loss function being the mean squared error.

Case Study

A case study is provided regarding the knowledge reuse for developing a lighter electronic box structure in the heavy equipment industry. For this purpose, the influence of the welded joint on the natural frequencies of the assembly requires evaluation. In this regard, the vibration modes are found in a close relationship with the changes in mass and boundary conditions. Figure 3 depicts the third vibration mode of the assembly, together with details regarding the parts and the way the junction between them is defined. The simulation model is completed using ANSYS Workbench CAE interface.

Fig. 3: Example of the 3rd vibration mode and details regarding the analyzed junction

The candidate parameters and their relationship are decided in conjunction with the requirements of the modal analysis. From this perspective, the geometric characteristics of the assembly and their subsequent weld specifications (i.e. material thickness and corresponding weld throat) have a direct influence on the mass and BCs of the structure.

In total, the developed dataset consists of 128 rows, corresponding with the sensitivity study that was carried out by adjusting the candidate parameters individually and by combining them. Manufacturability constraints were added to limit the range of possible solutions. The labels correspond to the six vibration modes of the assembly. In the next stage, the neural network was developed by using TensorFlow with Keras machine learning library. Training of the model was performed by using early stopping option to avoid over fitting. A total of 25 training epochs were completed. Figure 4 depicts the predicted and simulation frequencies for an arbitrary selection of candidate parameters. The mean absolute error of the predicted values is estimated at +/- 0.85 Hz which proves a reasonable accuracy for such types of problems.

Fig. 4: The prediction accuracy of the model for an arbitrary set of parameters

Conclusions

Weld design represents an extension of virtual prototyping technologies that allows engineers to address the full scale design and simulation problems of welded parts. The process does not fully benefit from Knowledge Based Engineering approaches, considering the adjustment and improvement loops that coexist in Computer Aided Engineering environments. To overcome such issues, the present paper proposes a machine learning approach that makes effective use of results derived from sensitivity studies for generalizing the mechanical behavior of assemblies. The wide scale implementation of the given concepts involves additional stages for extending the

generalization abilities of the machine learning procedure. In this way, predictions can be performed at product rather than assembly levels.

Aknowledgement

This work was financed by the Politehnica University of Bucharest under Grant 457/GP/06.08.2020 with the support of the Project “Inginer prin Europa”.

Abstract

Paper aims to develop an effective method of objectifying the effects produced by the electromagnetic radiation of the mobile phone on living human tissues. The research hypothesis was that radiation caused using mobile telephone is not harmless and causes various effects on the human body, some immediately visible, others with long-term impact. First part of the paper presents the main short and long-term problems that this type of radiation can have. There were presented and described, using the operating parameters of the phone, the specific examination conditions and the experimental plan. Results were presented according to their relevance, respectively regimes and duration of operation, showing the objective effects it induces in human tissue. These were highlighted by visualizing of the immediate thermal effects of mobile phone radiation on the human user. In addition, the simulation showed that these effects are not only superficial but also have an impact on the brain at depths distribution of the thermal field in the area of incidence of the waves with the skin on the human scalp. In order to predict the profound effects of the temperature observed outside, the penetration that the thermal field can have through its three components encountered in its propagation was simulated with specialized software: epithelial tissue (skin), bone (skull box) and brain. It can be stated that the technique and experimental method used allow, with a very high degree of confidence, the highlighting of up to 7-8 mm.

Keywords: Mobile Phone Radiation, Infrared Thermography, Human Tissue.

Introduction

Mobile phones are the main tool for communication today. There are a lot of mobile phone types in use. The global trend is growing, which means that an increase in the number of users switching to smartphones is expected.

In most cases, a user holds the phone directly in contact with the head and earlobe. This practice can cause side effects caused by its radiation in the contact areas and adjacent areas. The health risks associated with prolonged use of mobile phones have been discussed in literature are somewhat confusing, if not contradictory. Mobile phones generally have a dual influence on human tissues, which correspond to both thermal and non-thermal models.

Thermal effects include both the interactions of magnetic and electric fields, by the impulse transmitted by the photon to the living cell and by the reorientation of the dipoles that are formed from the substances contained in the tissues. Unlike other diagnostic methods such as mammography, radiography, tomography and other diagnostic methods, thermography does not submit the body of any stress such as radiation, pressure in contact with various materials, intravenous injections, etc. That is why it is a very comfortable procedure that does not pose any risk to human health and can be performed at any time without side effects in a research study by Bauer et al (2018). Thermography of human tissue is based on the detection of increased emissivity of the areas involved, due to its activation by electromagnetic fields, Forouharmajd et al (2018). Also, by detecting changes in blood activity, infrared thermography can identify the presence of a tumor in the early stages, whose size is not large enough to be observed by physical examination or radiography, Omranipour et al (2011). The problems related to the influence of electromagnetic fields on living beings are intensively studied and very present in the literature, but the variability of the results obtained is very high and therefore the subject creates many controversies. The results of studies made on rodent's have shown that the threshold at which exposure disrupts the learned behavior of subjects is between 2.5 and 8 W/kg SAR (specific absorption rate) throughout the body, with a temperature rise of about 1 °C. Deficiencies in the performance of a previously learned behavior occur after long-term exposure to electromagnetic fields of 2.45 GHz at SAR at an exposure of 2.3 W/kg body. The blood-brain barrier, which prevents large molecules from passing through the cerebrospinal fluid in the blood, could be susceptible to high-frequency electromagnetic fields. It has been reported an increased blood-brain barrier penetration for anesthetized rats after low exposure to 1.2 GHz pulsed or continuous wave fields, Neves et al (2015). Thermal effects are considered to be the main factors affecting the physiological processes in the human body due to the conduction of heat from other neighbor tissues, through the phenomenon of conduction, convection through the blood and radiation from the surrounding tissues, Berz et al (2007). The effect of heat on living things is not always uniform and dependent on heat intensity, stimulus duration and external stimulation environment, Hildebrandt et al (2010). Heat generation in human tissues according to the mechanisms described above, its accumulation is amplified due to the appearance of a disequilibrium between heat generation and heat dissipation. Thermal effects can cause disruption of cell function and development, Usamentiaga et al (2013).

Materials and Methods

GSM (Global System for Mobile communication) is a mobile digital network, widely used by mobile phone users in Europe and other parts of the world, Freeman et al (2005). GSM uses a variant of TDMA (Time-division multiple access) and is the most widespread of the three digital wireless telephony technologies: TDMA, GSM and CDMA. GSM digitizes and compresses the data, then sends them a channel with two other data streams, each in its own time interval. It operates in either the 900 MHz or 1,800 MHz frequency bands. HSPA (High speed packet access) is a third generation (3G) mobile broadband communications technology [8]. The term HSPA refers to two specific protocols used in tandem packet access, HSDPA and HSUPA. HSPA networks provide a maximum of 14.4 megabytes per second [Mbps] of transfer per cell. An improved version of high-speed packet access technology, known as Evolved HSPA, provides a transfer rate of 42 Mbps per cell. By using two-cell deployment and multiple inputs as well as multiple output architectures, HSPA + networks can reach a maximum speed of 168 Mbps. The International Telecommunication Union recognized HSPA + as a fourth generation (4G) technology in December 2010. For experiments he used an IPHONE SE mobile phone coupled with a wooden spacer with a thickness of 8 mm (both thermal and electromagnetically inert insulator), attached to the phone, to avoid direct contact between the phone and the person head. This eliminates the conduction of local heating of the mobile phone during operation, remaining to be observed on the human user, only hurts the thermal effects produced by the electromagnetic radiation of the antennas. During the measurements, the phone had the following services that emit electromagnetic waves: GSM 800 MHz communication service (the human volunteer was engaged in conversation), bluetooth communication service; wireless communication service, 400 mobile internet service on the frequency of 2600 MHz. Four human volunteers from the caucasian race were used in experiments, two females, two males, aged between 28 and 32 years, weighing between 68 and 85 kg and height between 1.69…1.82 m. The experimental plan involved the continuous recording of infrared thermography images of the human subject while using the mobile phone at different time periods: 0.5; 10; 20; 30; 40; 50 min. The experiment was repeated 10 times and the measured values were mediated and presented to the tables. The camera used for the recordings was the FLIR T440 type. The test took place in the non-destructive defectoscopy laboratory of the Faculty of Industrial and Robotic Engineering of the University Polytechnic of Bucharest between 17.02.2020 - 20.02.2020, 4:00 PM to 8:00 PM, in conditions of relative humidity of 57% and ambient temperature of 22 °C. The emissivity of human skin was taken from the literature between 0.96-0.98, depending on the human subject analyzed. Examination

distance 1.5 meters, the angle of incidence being perpendicular to the examined surface being ± 15 °. Of interest is the temperature difference recorded as a thermal effect on living human tissues of electromagnetic radiation. To confirm the temperature in the head area it was recorded using an electronic thermometer. With the help infrared thermography camera, the target was fixed in the same area and from the adjustment of the parameters (emissivity coefficient, reflected temperature, humidity), the aim was to obtain a value identical to the measured one. For each situation included in the experimental plan, an infrared thermography image was taken in normal incidence on the examined surface of the subject. The images were processed in the specialized software Flir Tools in order to identify the maximum temperature in the layout area of the mobile phone. Areas of investigation were drawn to cover the surface of interest and the results obtained regarding the value of the maximum temperature recorded were presented, as average values, tabular.

Results and Discussions

Specific problem that needs to be solved is to highlight the immediate effect of electromagnetic radiation on tissues, in particular the effects on mobile phone users. From the study of literature it was found that electromagnetic radiation creates the following types of effects: thermal effects (tissue heating); magnetic effects (deflection of charge, orientation of magnetic dipoles); the introduction of very low currents into the conducting tissues and into the nerve pathways (which have chemical mediators that conduct the electric current). By the infrared thermography method used in the experiments, only the thermal effects of the electromagnetic radiation from the use of the mobile phone could be observed (figure 1). It can be seen that at the initial moment, in the area of interest, marked with a circle on the image, the maximum temperature is 35.2 ℃, at 10 min there is an increase in maximum temperature in the selected area accompanied by an increase in temperature on the cheek. The subject in the phone area (lighter, white, in the image). Finally, after 50 min of continuous use, the thermal imprint of the phone can be clearly seen on the cheek, as well as the increase of the maximum temperature in the investigated area to the value of 39.9 ℃.

a) b) c)

Fig 1. Thermograms recorded at different time periods: a) the beginning of the experiment; b) after 10 min of use; c) after 50 min of use

The nominal results of the measurements obtained, reported as average values, are presented in Table number 1.

Table 1: Maximum average temperature recorded on the examined area

Time[min]	Maxim temperature [°K]
0	308.35 °K
5	309.15 °K
10	309.15 °K
20	310.15 °K
30	310.25 °K
40	310.25 °K
50	311.05 °K

From the graph it was observed that the highest thermal effect caused by electromagnetic radiation is recorded in the first 5 min (figure 2) of using the phone with a growth rate of 37 % followed by a constant evolution so that in the next few minutes, to make a new jump of about 29 %. In the area of use between 20 and 40 min, the observed thermal effects represent an increase of only 3.7% of the total, with practically a new landing area. Finally, the last 10 minutes bring a new increase of approximately 29% of the total increase of 2.7 °C that was observed throughout the examination period. To determine the continuous evolution of the temperature at any time t_i, the MATLAB program and polynomial interpolation were used, to approximate the intermediate values. The results obtained are shown in figure 3.

Fig. 2: Temperature change during phone use

Fig. 3: Continuous representation of temperature evolution by polynomial interpolation

The effect of depth penetration of electromagnetic energy was simulated on a specialized program using finite element analysis theory. The thermal effects of electromagnetic radiation can be important at depths of up to 5-6 mm inside the skull, noting that the decrease in simulated temperature values is almost exponential (figure 4).

Fig. 4: Simulation of thermal effects inside the skull after 50 min of using the mobile phone

Conclusions

Through the present study, with the help of infrared thermography and using an appropriate experimental plan, the immediate thermal effects resulting from the use of the mobile phone by a human subject were observed. The way in which the surface thermal effect propagates inside the skull was also investigated, being made simulations with the help of a specialized software. It was found that the local surface temperature generally increases by a value of about 3 degrees Celsius in all subjects examined in the immediate arrangement of the telephone antennas, while the theoretical penetration of these immediate thermal effects can reach a depth of 6-7 mm inside the skull. It should be noted that this study only highlighted the immediate thermal effects of electromagnetic radiation from mobile phones, but they represent only a part of their total. For a further development of research, it can be considered to continue the study in a multidisciplinary team composed of doctors and engineers in order to present in parallel the values of physical quantities measured with pathological effects likely to occur in the medium and long term.

Abstract

Tradicionalmente el desempeño de las empresas ha sido valorado en función de los resultados económicos de la misma, de manera que la obtención de unos niveles de beneficios positivos y crecientes se consideraba que reflejaban el buen hacer de la entidad. Sin embargo, en los últimos años se asume que no solamente es recomendable centrarse en los aspectos puramente económicos de las organizaciones, sino que también habría que valorar cuáles son los efectos de las actuaciones de la empresa desde el punto de vista medioambiental y social. En el presente trabajo se pretende analizar el desempeño o *performance* de la empresa para un sector o grupo de organizaciones que se consideran como conscientes de los diferentes efectos o impactos generados por sus actuaciones. Son las empresas que pertenecen a la órbita de la Economía del Bien Común. El objetivo del trabajo consiste en evaluar en qué medida la *performance* de estas empresas es diferente del resto de las empresas de la economía española, y qué papel juegan en su evolución los ratios financieros más comunes, el tamaño, y el sector al que pertenecen, así como la influencia de la vertiente de género, todo ello mediante la metodología del análisis factorial.

Palabras clave: Performance, Economía del Bien Común, Género, Tamaño, Rentabilidad, Riesgo

Introducción

La evolución de la sociedad en los últimos años ha dado lugar a un incremento de la toma de conciencia de que la economía tradicional no responde a las necesidades actuales al no considerar habitualmente la evolución del entorno social y medioambiental. Como consecuencia, en varios países han ido surgiendo diferentes movimientos sociales que presentan una visión alternativa de las relaciones económicas, una querencia por los aspectos medioambientales derivados de las actuaciones de los agentes económicos y una preocupación por paliar las carencias sociales que se derivan de las actividades habituales que tienen lugar en la sociedad. Son las llamadas economías alternativas.

En este marco se sitúan diferentes modelos alternativos entre los que se encuentra la Economía del Bien Común (EBC). Este modelo sigue los criterios de sostenibilidad formulados en su día por el informe "Nuestro Futuro Común", más conocido como Informe Brundtland, que definió el desarrollo sostenible como la satisfacción de «las necesidades de la generación presente sin comprometer la capacidad de las generaciones futuras para satisfacer sus propias necesidades" (Informe [1]. Así pues, este informe permitió el cambio del objetivo básico de las economías al

[1] Informe «Nuestro futuro común» de 1987, Comisión Mundial sobre el Medio Ambiente y el Desarrollo.

Cite this Article as: Amparo MASET-LLAUDES, David CABEDO, Iluminada FUERTES and José Miguel TIRADO "Performance, Economía del Bien Común y Género: Análisis Factorial para las Empresas Españolas" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

pasar del crecimiento meramente económico al desarrollo sostenible, concepto que se va a basar en tres pilares fundamentales: además del económico, pasan a considerarse los aspectos sociales y medioambientales para determinar cuál va a ser la evolución de las diferentes economías en el futuro.

La EBC va a permitir, precisamente, evaluar cuál es el desempeño de las organizaciones desde el punto de vista social y medioambiental, mediante un instrumento que permitirá a las entidades no solo determinar su situación en estos campos, sino también cuáles van a ser los aspectos a mejorar en el futuro. Este instrumento es el Balance del Bien Común (BBC), que se va a basar en la Matriz del bien común (MBC). Esta consiste en una tabla de doble entrada en la que aparecen los *stakeholders* de las organizaciones, y un conjunto de cuatro valores de la sociedad tales como dignidad humana, solidaridad y justicia social, sostenibilidad medioambiental y transparencia y participación democrática. Este instrumento nos permitirá llevar a cabo un informe valorativo del nivel de cumplimiento de cada empresa.

Tomando esto como base, en el trabajo que aquí se presenta se pretende analizar si la performance de la empresa puede afectar a la probabilidad de que una empresa pertenezca a la EBC. En este sentido se han agrupado las distintas variables que forman parte de aquella utilizando el análisis factorial previamente al estudio de dicha probabilidad, al que se ha incorporado la vertiente de género representada por el/a gerente o director/a de las empresas analizadas.

La estructura del trabajo que aquí se presenta es la siguiente: tras esta introducción, se definen la performance de la empresa, para seguir con el análisis empírico, que se dividirá en el análisis factorial, que permitirá agrupar las diferentes variables económico-financieras, en la elaboración de distintos modelos logit basados en dichos factores. En el último apartado se presentan las conclusiones alcanzadas, las limitaciones del trabajo y las futuras líneas de investigación.

Performance Y Género

A la hora de estudiar la situación económica de la empresa, es determinante analizar cuál es la estrategia más adecuada para mejorar su competitividad, situación en los mercados y eficiencia. Tradicionalmente, las medidas utilizadas para ello son cuantitativas, y se han centrado en los ratios económico- financieros de las empresas, a las que se suelen añadir otras variables que ofrecen información alternativa, tales como el tamaño de la empresa o el sector al que pertenecen.

En términos generales, la *performance* de la empresa se ha convertido en un medio que ofrece información sobre aspectos financieros y no financieros de las entidades, capturando diferentes perspectivas de las mismas, normalmente a través de variables que pueden ser extraídas directamente de las cuentas anuales de las empresas o calculadas directamente con la información ofrecida por las mismas. En la práctica, el estudio cuantitativo de la *performance* de la empresa se realiza a través de los ratios económico-financieros.

En el trabajo empírico que se desarrolla a continuación, se considera la utilización de las diferentes medidas de la rentabilidad (económica, financiera y de la inversión) como un reflejo adecuado del desempeño o *performance* de la empresa, tomando como base a Murugesan *et al* (2016), Shook (2005) y Aragón y Sánchez (2005). A estos ratios se les han incorporado una serie de variables adicionales como son el tamaño de la empresa y el apalancamiento financiero, a las que se han añadido el ratio corriente, y una variable representativa del género del gerente de la empresa (Florio & Leoni, 2017).

En el grupo de las rentabilidades se ha considerado conveniente introducir la rentabilidad financiera, a pesar de las dudas aportadas por autores tales como Bititci et al (2013) y Hagel, Brown y Davison, 2010, que señalan una serie de inconvenientes presentados por esta medida cuando se trata de analizar la performance de pequeñas y medianas empresas, en las que la rentabilidad de los propietarios representada por esta medida no es probablemente tan básica como en empresas de mayor tamaño.

A pesar de ello, puede considerarse que existe un cierto consenso sobre las medidas de la rentabilidad de la empresa que son más adecuadas para reflejar el desempleo de la misma, pero se considera que esta variable debe verse complementada con los aspectos que reflejan el riesgo de la empresa y que en este trabajo vienen representados por el ratio corriente y el ratio de liquidez de las empresas ((Sharpe, 1975; Watson y Robinson, 2002).

Sin embargo, existe una variable de aspecto cualitativo que podría aportar más información a la situación económico-financiera de la empresa, sobre todo a la hora de realizar análisis empíricos que permitan estudiar las relaciones entre las diferentes variables. Se trata de la inclusión de la vertiente de género, que aporta una nueva perspectiva al incluirla en los análisis económico-financieros tradicionales.

Aunque los efectos derivados de la inclusión de la variable género en los análisis de la *performance* financiera de la empresa no son concluyentes (Terjesen et al, 2009), su inclusión en este estudio obedece a la intención de dilucidar qué importancia puede tener a la hora de analizar la probabilidad de que una empresa pertenezca a la EBC, y si existe relación entre dicha variable y la rentabilidad y el riesgo de este tipo de empresas.

Analisis Empirico

Metodología

El objetivo del trabajo consiste en evaluar en qué medida existen diferencias entre las empresas de la economía del bien común y las empresas que no pertenecen a este grupo, respecto a la *performance* de la empresa. En concreto, si la *performance* de la empresa afecta a la probabilidad de las empresa de pertenecer a la EBC. Para ello se va a realizar, en primer lugar, un análisis factorial con el fin de agrupar las variables que reflejan la *performance* de la empresa en grupos con características comunes. En segundo lugar, se procederá a realizar una serie de análisis de regresión con el objetivo de determinar en qué medida los diversos factores hallados en la etapa anterior afectan a la probabilidad de que las organizaciones pertenezcan al grupo de empresas de la economía del bien común.

Muestra

La muestra que se va a utilizar en este trabajo está compuesta de 60 empresas. Ésta se divide a su vez en dos submuestras: por una parte, empresas que se pueden considerar como pertenecientes a la EBC, y por otra, un grupo de empresas que a partir de aquí llamaremos "espejo", dado que cuentan con las mismas características que aquellas referentes a tamaño (medido por el número de trabajadores) y sector CNAE de pertenencia. Se considera que las empresas de la primera submuestra, aunque no pueden ser consideradas como empresas sociales dado que pertenecen a distintos sectores de la economía, sí que podría considerarse que cuentan con ciertos niveles de conciencia social. Al estar dentro de la órbita de la EBC y haber elaborado un BBC debidamente auditado por un auditor del BC reconocido oficialmente, implica que sus directivos podrían ser conscientes de que los efectos de las actuaciones de sus empresas van mucho más allá de los puramente económico, considerando también las implicaciones sociales y medioambientales al encontrarse ambos aspectos reflejados en los diferentes índices que conforman la MBC, y por ende, el BBC.

Habría que señalar que las metodologías aplicadas al estudio que aquí se presenta y la validez de los test aplicados y de los resultados obtenidos se basan en una muestra de tamaño considerado pequeño a nivel estadístico, aunque se han aplicado técnicas específicas desarrolladas para muestras inferiores a 50 elementos, incluso inferiores a 30 elementos en el caso de análisis para las submuestras de tipos de empresas.

Variables

Las variables que aparecen en la muestra son las siguientes:
EBC: pertenencia de las empresas a la economía del bien común
GEN: si la empresa está dirigida por una mujer
AT: tamaño de la muestra medido por el activo total de la empresa
INCN: tamaño de la muestra medido por el importe neto de la cifra de negocios de la empresa
ROA: rentabilidad de los activos
ROE: rentabilidad de los accionistas
ROI: rentabilidad de la inversión
CURR: current ratio
LIQ: ratio de liquidez

Como puede observarse, para reflejar la performance de la empresa se han utilizado tres variables referentes a la rentabilidad de la misma (ROA, ROE y ROI), y dos variables adicionales que de laguna manera reflejarían el riesgo

de la organización a corto plazo (current ratio y ratio de liquidez). Por otra parte, del listado de variables a utilizar en el análisis, la primera de ellas (EBC) será considerada como variable dependiente por lo que no será tenida en cuenta en los cálculos realizados en el análisis factorial. También se excluirá del mismo la variable que refleja las variables que reflejan el género del director-gerente-propietario de la empresa. Por otra parte, también en este trabajo se incluye el tamaño de la empresa como uno de los determinantes de la performance, característica que se verá reflejada en las tres variables tradicionales utilizadas para medir el tamaño de la empresa: el número de trabajadores, el activo total y el importe neto de la cifra de negocios., aunque viene siendo la primera de ellas la más comúnmente utilizada en los estudios realizados sobre *management* de la empresa (Rahman, 2001).

Resultados

La parte empírica de este trabajo corresponde, en una primera etapa, a la realización de un análisis factorial con el fin de evitar posibles problemas de correlación entre las variables independientes. Si en lugar de variables usamos factores, podremos incluir todas las variables consideradas en el modelo evitando problemas de multicolinealidad.

En primer lugar, habría que comprobar si los datos a utilizar son buenos candidatos para agrupar las variables en factores y así poder aplicar el análisis factorial. Para ello se realiza la siguiente prueba:

Tabla 1: Prueba de KMO y Bartlett

Prueba de KMO y Bartlett		
Medida Kaiser-Meyer-Olkin de adecuación de muestreo		0,6
Prueba de esfericidad de Bartlett	Aprox. Chi-cuadrado	357,669
	gl	21
	Sig.	0

Fuente: elaboración propia

Como se puede observar, el valor del KMO es mayor que 0,5, y la significatividad menor del 1%, por lo que los valores que tenemos son buenos candidatos para que las variables se agrupen en factores.

La realización de una serie de análisis factoriales nos va a permitir delimitar cuáles serían los factores a tener en cuenta a la hora de utilizarlos como variables independientes en las regresiones logísticas. Estos análisis vienen reflejados en la tabla que aparece a continuación:

Tabla 2: Análisis Factoriales

Modelo	Variables independientes	Factores	Número de factores	KMO	Sig	% de varianza explicada	Muestra
1	Nº trabajadores, AT, INCN, Género, EBC, ROA, ROE, ROI, Current ratio, Liquidez, Solvencia, Apalancamiento	Rentabilidad / Solvencia (3 variables) / AT, INCN / GEN, EBC / Nº trabajadores	5	0,539	Si	81,598%	Total
2	Nº trabajadores, AT, INCN, ROA, ROE, ROI, Current ratio, Liquidez, Solvencia, Apalancamiento	Rentabilidad / Solvencia (3 variables) / AT, INCN / Nº trabajadores	4	0,591	Si	82,475%	Total
3	Nº trabajadores, AT, INCN, ROA, ROE, ROI, Current ratio, Liquidez, Solvencia	Rentabilidad / Solvencia (3 variables) / AT, INCN / Nº trabajadores	4	0,616	Si	89,773%	Total
4	AT, INCN, ROA, ROE, ROI, Current ratio, Liquidez, Solvencia	Rentabilidad / Solvencia (3 variables) / AT, INCN	3	0,619	Si	87,924%	Total
5	AT, INCN, ROA, ROE, ROI, Current ratio, Liquidez	Rentabilidad / Solvencia (2 variables) / AT, INCN	3	0,600	Si	94,050%	Total
6	AT, INCN, ROA, ROE, ROI, Current ratio, Liquidez	Rentabilidad / Solvencia (2 variables) / AT, INCN	3	0,584	Si	95,489%	Hombres
7	AT, INCN, ROA, ROE, ROI, Current ratio, Liquidez	Rentabilidad / Solvencia (2 variables) / AT, INCN	2	-	-	87,094%	Mujeres

Fuente: elaboración propia

Para determinar qué análisis factorial habría que considerar a la hora de realizar las regresiones logit, nos basaremos en los resultados obtenidos en el KMO y en el porcentaje de varianza explicada. Como puede observarse en la tabla, conforme se van eliminando variables explicativas se observa, en general, tanto un incremento en el KMO como en el porcentaje de varianza explicada. Finalmente se ha optado por elegir el modelo 5 ya que, aunque el KMO disminuye ligeramente, esta disminución se compensa con un importante aumento en el tanto por ciento de varianza explicada.

En el modelo 5 aparecen claramente 3 factores:

F1: factor que recoge información sobre la rentabilidad de la empresa
F2: factor que recoge información sobre la solvencia de la empresa
F3: factor que recoge información sobre el tamaño de la empresa

Con respecto a los análisis logit, a los tres factores considerados y que recogen información sobre la *performance* de la empresa se va a añadir la variable que refleja la perspectiva de género como variable independiente, y la variable que va a reflejar la pertenencia o no a la economía del bien común, como variable dependiente. Los resultados de la estimación de los modelos logit realizados con los factores anteriores y la variable de género, aparecen en la tabla siguiente:

Tabla 3: Análisis logístico

Variables	Modelo 1	Modelo 2	Modelo 3	Modelo 4
GEN	0,594			
	(0,838)			
F1	-9,719	-9,242	-3,180	-1,739
	(0,038)*	(0,015)*	(0,024)*	(0,030)*
F2	599,057	562,541	323,977	-0,241
	(0,052)**	(0,015)*	(0,023)*	(0,298)
F3	-16,868	-15,864	-9,447	
	(0,068)**	(0,031)*	(0,053)**	
Constant	114,674	108,073	64,610	-0,773
R2 Cox & Snell	0,645	0,644	0,593	0,334
R2 Nagelkerke	0,860	0,859	0,790	0,445
*Significativo al 5%				
** Significativo al 10%				

Fuente: elaboración propia

Como se ha comentado, las regresiones logísticas calculadas contienen las variables explicativas formadas por los factores calculados en la etapa anterior y la variable de género. Dichos factores han sido calculados ex-profeso para cada uno de los modelos considerados, que son los siguientes:

Modelo 1: regresión realizada con los tres factores y con la variable de género
Modelo 2: regresión realizada con los 3 factores y sin la variable de género
Modelo 3: regresión logística realizada solo para la submuestra de hombres (modelo 6 de los análisis factoriales)
Modelo 4: regresión logística realizada solo para la submuestra de mujeres (modelo 7 de los análisis factoriales)

A la vista de los resultados que aparecen en la tabla anterior, puede afirmarse que los test que valoran el ajuste de los modelos son en general elevados, excepto para la submuestra mujeres, que corresponde al modelo con peor ajuste de los calculados. Se trata pues de modelos perfectamente válidos a la hora de explicar la probabilidad que tienen las empresas de pertenecer a la órbita de la EBC.

Con respecto al papel que juega el género sobre la probabilidad de que una empresa pertenezca a la categoría de empresas del bien común, cabe comentar que el efecto de que el director o gerente de una empresa sea una mujer, afecta de manera positiva a la probabilidad de que una empresa se sitúe en la órbita del bien común, sin embargo, esta variable ha resultado no ser significativa.

Conclusiones

En el presente trabajo se pretende analizar si las variables financieras de las empresas, identificadas estas en grupos tales como la rentabilidad, el riesgo y el tamaño, esto es, la *performance* de la empresa, tienen algún efecto a destacar sobre la probabilidad de pertenecer al área de la EBC. Para ello se ha realizado un análisis factorial sobre una muestra de empresas que abarca tanto a aquellas que han realizado el balance mencionado, como un grupo de empresas similares llamadas espejo (por compartir con las primeras características como tamaño y código CNAE). Una vez obtenidos los factores, se han llevado a cabo una serie de análisis logit que han permitido explorar de qué depende la probabilidad de que una empresa pueda ser considerada como una entidad de la Economía del Bien Común.

A las vista de los resultados, puede afirmarse que, en general, en todos los modelos estimados, el factor que refleja la rentabilidad de la empresa afecta de manera negativa a la probabilidad de pertenecer a las empresas de la economía del bien común, así como el factor que refleja el tamaño de la empresa. Sin embargo, el factor que refleja la solvencia de la empresa afecta positivamente a la probabilidad de que la empresa pertenezca a la economía del bien común.

Una variable adicional considerada en este análisis es el género del/a gerente de la empresa, lo cual implica la utilización de un nuevo enfoque en los estudios sobre la economía del bien común, dado que no se suele contemplar habitualmente la vertiente de género en este tipo de estudios. En este sentido, cabe destacar que mención aparte merece el grupo de empresas que se encuentran dirigidas por mujeres. En este caso solamente se obtuvieron dos factores de entre todas las variables independientes incluidas en el análisis factorial: los que reflejan la rentabilidad y el tamaño de la empresa, aunque este último no ha resultado ser significativo. A diferencia de lo que ocurre con el resto de modelos, su coeficiente ha resultado ser negativo, lo que podría llevar a deducir que cuando una empresa está dirigida por mujeres, su tamaño afecta negativamente a la probabilidad de pertenecer a la economía del bien común.

Finalmente, las empresas dirigidas por mujeres, tradicionalmente tienen un mayor nivel de deudas (están más apalancadas), probablemente por la desconfianza tradicional de las entidades financieras a la hora de conceder préstamos. Como consecuencia, se trata de empresas con unos menores niveles de rentabilidad y mayores niveles de deuda.

Es decir, a modo de resumen, se podría afirmar que:

- A mayor rentabilidad, generalmente menor probabilidad de pertenecer a la economía del bien común.
- A mayor tamaño, menor probabilidad de pertenecer a la economía del bien común, excepto para el grupo de empresas con mujeres directivas, en las que no se ha considerado este factor.
- A mayor nivel de los indicadores de solvencia, mayor probabilidad de pertenecer a la economía del bien común, excepto para las empresas con mujeres directivas, en las que, a mayor nivel del factor solvencia, menor probabilidad de pertenecer a la economía del bien común.

Podría afirmarse que la *performance* de la empresa afecta a la probabilidad de pertenecer a la EBC, sin embargo el tipo de efectos sobre dicha probabilidad son más bien ambiguo, dado que los diferentes componentes tienen unos efectos diferentes(al aparecer la variables independientes con distintos signos) sobre la probabilidad estudiada. En este sentido habría que señalar que la inclusión de otras variables que reflejaran aspectos adicionales de la *performance* de la empresa, así como la realización de un análisis adicional desde el punto de vista del sector de pertenencia de las empresas de la muestra, el nivel educativo del gerente, la antigüedad de la misma, y completar el análisis de la vertiente de género introduciendo una nueva variable que refleje el género de los trabajadores y no solo del directivo/a, podrían contribuir a dilucidar con más detalle cuáles son los principales determinantes y cómo afectan a la probabilidad de pertenecer a la EBC.

Agradecimientos

Esta investigación ha sido realizada con el apoyo del Plan de Promoción de la Generalitat Valenciana (Resolución 19 de diciembre de 2020, del conseller de Economía Sostenible, Sectores Productivos, Comercio y Trabajo, por la que se efectúa la convocatoria anticipada de ayudas destinadas a la promoción de la economía sostenible en la Comunidad Valenciana para el ejercicio 2020. Abstract

Sanitation and clean water are crucial because they directly relate to human health and well-being. The sanitation and clean water condition in Indonesia, especially in rural areas, is still not optimal. One of the obstacles faced in implementing the sanitation and clean water program in Indonesia is related to funding. Therefore, a potential source of funding is needed that can finance sanitation and clean water. One of these potential sources of funds is zakat, infaq, alms, and waqf (ziswaf). Also, there is an MUI fatwa that allows the utilization of ziswaf for sanitation and clean water. This study aims to determine the strategic priorities in utilizing ziswaf for sanitation and clean water from the regulator's side by using the Analytic Network Process (ANP) approach. The results of this study indicate that the priority of ziswaf utilization strategy for sanitation and clean water is the synergy between central and local governments, promotion related to sanitation and clean water, and improvement of supporting infrastructure. This research contributes to providing policy advice to parties related to the utilization of ziswaf for sanitation and clean water in Indonesia.

Keywords: Sanitation, Clean Water, Ziswaf, Promotion, Infrastructure, Synergy

Introduction

Sanitation and clean water are essential aspects of the realization of environmental health, which then impact individual health, where individual health plays an essential role in achieving prosperity. Several previous studies related to the impact of sanitation and clean water conditions on health include Andrés et al.(2017). They stated that sanitary conditions could affect the prevalence of diarrhea in children. Regarding clean water, research conducted by Komarulzaman et al. (2017) suggests that households that use tap water have a lower risk of diarrhea in children. Meanwhile, households that use open containers for water storage have a higher risk of diarrhea in children (Otsuka et al., 2019).

Poor sanitation and clean water not only affect the health aspect but can also hurt the economic aspect. Therefore, sanitation and clean water are among the issues raised in the Sustainable Development Goals (SDGs), a global development agenda agreed upon by UN member countries. Prabowo et al., (2016) stated that poor sanitation's economic losses reached 56 trillion / year. These losses include lost income due to absenteeism, decreased tourist visits, medical expenses, and raw water treatment. Besides, poor sanitation and clean water also account for a loss of 2.3% of Indonesia's GDP.

The number of destructive impacts caused by inappropriate sanitation and clean water makes the issue of sanitation and clean water not to be ignored. Then, sanitation and clean water are also closely related to the Human Development Index (HDI). Increasing the feasibility of sanitation and access to drinking water at the individual, household, and community levels can reduce community-based figures and increase life expectancy. That will indirectly affect the HDI because in calculating HDI, there is a component of life expectancy.

The condition of the feasibility of sanitation and clean water in Indonesia is still low. That can be seen based on data from the Central Statistics Agency per 2017 that Indonesian people who have access to sanitation and clean water are

Cite this Article as: Rika Yulita AMALIA, NURWAHIDIN and Nurul HUDA "Strategies for Optimizing Ziswaf Utilization for Sanitation and Clean Water in Indonesia" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

still below 100%, namely 67.89% and 72.04%. Even though in this regard, the government is targeting Indonesia can achieve 100% access to sanitation and clean water by 2019. These targets are contained in the National Medium Term Development Plan (RPJMN).
The Indonesian government, non-governmental organizations (NGOs), and various parties have made efforts to address sanitation and clean water problems. Various government programs are the Community Based Water Supply and Sanitation Program (PAMSIMAS), the Drinking Water Grant Program conducted by the Ministry of Public Works and Public Housing (PUPR), and the Community-Based Total Sanitation (STBM) carried out by the Ministry of Health. Apart from the government, similar programs are also carried out by other institutions, such as the water credit program, a micro-credit through financial institutions to improve sanitation and clean water infrastructure.

According to research conducted by Wardiha & Putri (2018), efforts to improve access to sanitation and clean water face various obstacles, including behavior, habits, public knowledge of sanitation that still needs to be improved and the economic level of the community and the availability of funds to support programs sanitation and clean water programs.

In this regard, there are potential sources of funds that can be used to improve access to sanitation and clean water, namely zakat, infaq, alms, and waqf funds (ziswaf). That is based on the fatwa of the Indonesian Ulema Council (MUI) number 001 / MUNAS-IX / MUI / 2015 regarding the utilization of zakat, infaq, alms, and waqf assets for the construction of clean water and sanitation facilities for the Indonesian people. In the fatwa, it is explained that the utilization of ziswaf for the construction of clean water and sanitation is permitted provided that there is no urgent need for the mustahiqs, and the benefits from the construction of these facilities are for the public interest.

Whether ziswaf is used for sanitation and clean water provides an excellent opportunity for Indonesia to increase sanitation and clean water for the community. Besides, the Indonesian government, represented by Bappenas (National Development Planning Agency), also supports the program to realize the SDGs goals related to sanitation and clean water. That is evident by the existence of an agreement in the form of MoU, which was signed jointly between Bappenas and various institutions related to the utilization of ziswaf for sanitation and clean water.

Therefore, the right strategy is needed to utilize ziswaf for sanitation and clean water to have a significant impact on the community in increasing access to sanitation and clean water and can produce results that are as expected.

This study aims to determine strategies that can be carried out to optimize the utilization of ziswaf for sanitation and clean water. As far as the authors observe, research related to strategy to optimize the utilization of ziswaf for sanitation and clean water is still very limited. In previous research such as that conducted by Huda et al. (2014), Alam (2018), Rusydiana & Devi (2018), and Hasim et al. (2016), the main focus is related to the factors that affect the collection and utilization of zakat, infaq. , alms, or waqf in general or with different objects of utilization. As for the research conducted by Herlinda (2018), Trijunianto (2016), Odagiri et al., (2017), and Elisa & Paul (2010), the main focus is related to factors that affect the provision and sustainability of clean water facilities government programs and their source of funds do not come from ziswaf.

This research is expected to provide benefits for various parties interested in utilizing ziswaf for sanitation and clean water in Indonesia, such as the government as a policymaker and the Ziswaf Management Institute as a direct implementing program. Besides, this research is also expected to provide knowledge and descriptions related to ziswaf for sanitation and clean water for academics or society in general.

Literature Review

Zakat, Infaq, Sadaqah, and Waqf (Ziswaf) are sources of social finance in Islam. Zakat can be interpreted as a certain number of assets required by Allah to be submitted to the rightful people (Qardhawi, 2011). The basic principle of zakat is an excess of wealth owned by a person in which rights over others, to be distributed for people in need. Then, regarding the distribution of zakat, it has been regulated in the Al-Qur'an Surah At-Taubah verse 60.

Infaq is a voluntary expenditure made by a person as much as he wants. In contrast to zakat, there is a nishab or a specific limit on whether wealth is obliged to zakat or not; in infaq, there is no nishab (Sumadi, 2017).

Almsgiving has a broader meaning than zakat and infaq. Almsgiving can be interpreted as all kinds of forms of goodness done by confirming the existence of a reward from Allah for kindness (Saprida, 2015). Almsgiving and infaq have the same meaning. The difference between the two is if infaq is closely related to the matter, while alms concerns all things, including non-material things (Sumadi, 2017).
Waqf can be interpreted as providing permanent assets for socio-religious purposes such as donating a plot of land to be built for a mosque or to be used as a public cemetery (Mardani, 2012).

Sanitation and Clean Water

Sanitation and clean water are among the goals of the Sustainable Development Goals (SDGs). Sustainable Development Goals (SDGs) is a global development agenda endorsed by UN member countries in 2015, including Indonesia (Hoelman et al., 2016).

According to the World Health Organization (WHO), the definition of sanitation is a method for collecting human feces, urine, and public waste in a hygienic manner and does not have a negative impact on human health (Huuhtanen & Laukkenen, 2006). Lapid (2012) states that a sanitation system's primary objective includes protecting human health, minimizing environmental degradation and depleting resources, and maintaining long-term social acceptance. Minister of Health Regulation No. 416 of 1990 concerning requirements and control of water quality states that clean water is water used to meet daily needs where the quality meets health requirements and can be drunk if it has been cooked. Quddus (2014) states that the requirements for clean water quality are by the provisions of the WHO, the Department of Health, or the United States Public Health Association (APHA); water suitable for human life is determined based on physical, chemical, and bacteriological quality requirements.

Ziswaf for Sanitation and Clean Water

In Indonesia, ziswaf utilization for the development of sanitation and clean water is allowed as long as it does not violate Sharia's principles. This is based on the Fatwa of the Indonesian Ulema Council (2015) Number: 001 / MUNAS-IX / MUI / 2015. The fatwa explains that the utilization of ziswaf for the development of clean water and sanitation is permitted. There is no urgent need for the mustahiq (for zakat), and the benefits from the construction of these facilities are for the public interest. Even in the fatwa, the MUI also recommended that the Amil Zakat Institution in Indonesia distribute zakat in the provision of clean water and facilities to answer the community's needs.

In the implementation of ziswaf utilization for Sanitation and clean water in Indonesia, Bappenas (National Development Planning Agency), BAZNAS (National Zakat Agency), BWI (Indonesian Waqf Board), and MUI (Indonesian Ulama Council) have also agreed in the form of an MoU to provide support. The Clean Water and Sanitation program as an effort to realize the SDGs goals related to Sanitation and clean water.

Ziswaf Utilization Strategy for Sanitation and Clean Water

Strategy comes from the Greek strategos, which means "general." Strategy in the military sense is planning and directing combat on a broad scale. In context, a strategy is the initiation of action to achieve goals more quickly (Steiss, 2003). Steiss (2003) also states that there are three essential components in strategic management, namely, strategic planning (effectiveness), resource management (efficiency), and control and evaluation (accountability). This research focuses on strategic planning to identify the best specific actions needed to achieve organizational or institutional goals and objectives.

Ziswaf utilization to improve access to sanitation and clean water facilities requires synergy from various related parties. Nurbaiti & Bambang (2018), in their research, stated that external factors that affect community participation in sanitation and clean water programs are the roles of village governments, community leaders, local governments, non-governmental organizations (NGOs).) and the assistance team or facilitator.

The utilization of ziswaf for sanitation and clean water, which involves the Zakat Management Institution (LPZ) or BAZNAS as an institution that has a source of ziswaf funds, of course, requires synergy with other parties such as local governments, communities or other Zakat Management Institutions (LPZ) so that ziswaf for sanitation and clean water can be more optimal.

Among the strategies that can be taken to improve sanitation and clean water is carrying out health promotion. Cairncross & Valdmanis (2006) stated that the promotion of hygiene practices, including the use and maintenance of appropriate sanitation facilities, is an intervention that can be carried out by the public sector. These efforts can improve sanitation and clean water access and are an appropriate intervention for the health sector. People's mindset must change so that their behavior also changes because all behavior is based on processes in people's minds, one of which is by activating their knowledge (Mosler & Contzen, 2016).

Promotion is also needed to increase ziswaf collection, a source of funds that can be used to improve access to sanitation and clean water. The optimal collection of funds will have an impact on its utilization. Hudzaifah, (2019), Zen & Setiadi, (2018) said that among the factors that influence someone to do zakat, infaq, alms, and waqf (ziswaf) is to continue to invite and the community regarding ziswaf or promotion. Nurhasanah & Suryani (2018), in their research, stated that socialization, education to the community regarding ziswaf also needs to be improved either by the government or other elements of society. That is important given the considerable potential of ziswaf in Indonesia and has a significant influence on reducing poverty.

Limited infrastructure is a problem the Indonesian people face in accessing sanitation and clean water facilities Qamaruddin et al., (2017). The infrastructure in question includes public and necessary infrastructure such as roads, bridges, and others. Bosch et al. (2013) stated that in the slum and informal settlements that accommodate the urban and suburban poor, they are often geographically isolated, unhealthy, and lack the necessary infrastructure and services. So that people cannot access clean water and proper sanitation. Besides, remote rural areas and the lack of public infrastructure and communication infrastructure often hamper assistance because it is quite expensive (Bosch et al., 2013). Therefore, infrastructure is an important matter that needs attention to improve access to sanitation and clean water.

Research Methodology

This research is a study that explores strategies related to the utilization of ziswaf for sanitation and clean water using the Analytic Network Process (ANP) approach. This type of research is a combination of qualitative (in-depth interview) and quantitative research.

The data used are primary and secondary. Primary data is obtained directly by interviewing experts, practitioners, and academics who understand the research topic. The secondary data were obtained from previous literature reviews. In research using the ANP method, the data processed is in the form of research variables from experts on the problem used as the object of research on a numerical scale.

The number of informants in this study consisted of 6 people who were experts, practitioners, and academics from various institutions in Indonesia, including Bappenas, Puskas BAZNAS (National Zakat Board), Indonesian Ulema Council (MUI), Indonesian Waqf Board (BWI), and Amil Institute Zakat (LAZ).

ANP problem solving depends on alternatives and existing criteria. Saaty & Vargas (2006) suggests that the ANP analysis technique uses pairwise comparisons of alternatives and project criteria. There are three underlying axioms. This axiom serves to prove that a proof can be seen as accurate without the need for proof. Ascarya (2005) states that the three axioms include:

1. Reciprocal. The purpose of reciprocal is where if there are two things being compared, for example, X and Y, then the importance value of X has an importance level of 6 times more important than Y. Y has an expected value compared to X, namely Y is equal to 1/6 of X.
2. Homogeneity. This axiom states that there is not too broad a difference between the criteria being compared. Because if the comparison is too large, it can have an impact on more significant misjudgment. The ranges used in ANP are 1 to 9.

3. Each criterion and component used in a hierarchical network framework or feedback can represent the existing conditions.

The research process in the ANP method is divided into three phases, namely the model construction phase, model quantification, and synthesis and results in the analysis (Ascarya, 2005), which can be described as follows:

1. Model Construction Phase
   This phase begins by constructing an ANP model that is compiled based on theoretical or empirical review literature. It provides questions or discussions with experts and practitioners of ziswaf for sanitation and cleans water through in-depth interviews (Ascarya, 2005). Interviews are needed to examine in-depth information related to problems in research. The construction phase of the model is the stage of developing the research model.
2. Model Quantification Phase
   The next stage of quantification of the model is to use the questions in the ANP questionnaire in the form of pairwise comparison between the criteria to find out which is more dominant and how big the difference is through a numerical scale (scale 1 - 9.5). The numerical scale used is a translation of the assessment variable. After the questionnaire is made, then the next is the survey of respondents. Respondents will be asked to determine priorities, or most have the most influence on the problem (Tanjung & Devi, 2013).
3. Result Analysis Phase
   Before analyzing the data processed, it is necessary to validate the data. Validation is done by a consistency test (Huda et al., 2017). Consistent data are those that have a consistency ratio (CR).

Results and Discussions

Based on the results of interviews and studies from various literature, it is known that the conceptual model or framework that can be formulated for ziswaf utilization strategies for sanitation and clean water in figure 1.

Figure 1: Conceptual Framework

Synergy from various parties, including the central government, local government, the Ziswaf Management Institute (LPZ), the Indonesian Ulema Council (MUI), and the local community, is needed in optimizing the utilization of ziswaf for sanitation and clean water. That is because the ziswaf utilization program for sanitation and clean water is a program that involves various fields, namely health, social, and religion.

Promotions related to ziswaf as sources of funds and promotions related to the importance of sanitation and clean water also need to be carried out. Ziswaf promotion is needed so that ziswaf fund collection can be more optimal so that the funds that can be utilized and distributed can be more optimal. Besides, Indonesia's ziswaf potential is excellent and influences various problems such as poverty, economy, social, and health. Likewise, the promotion of the importance of sanitation and clean water, people who know and are aware of the dangers of poor sanitation and clean water will more easily change their behavior. That will positively impact community acceptance related to sanitation and clean water assistance, which will also impact improving access to sanitation and clean water, public personal health, and environmental health.

Infrastructure is also an important matter that needs to be considered to improve sanitation and clean water access. Therefore, supporting infrastructure such as roads, bridges, and others is needed so that sanitation and clean water assistance can be more optimized.

The criteria and sub-criteria for the strategy are in the table 2.

Table 2: Criteria and Sub-Criteria

Criteria	Sub-criteria	Source
Synergy	1. Synergy between central and local governments	Informant (2019), Lubis & Latifah (2019)
	2. Synergy between Ziswaf Management Institute or Lembaga Pengelola Ziswaf (LPZ) in program harmonization	
	3. Synergy between local governments, Ziswaf Management Institute or Lembaga Pengelola Ziswaf (LPZ), Indonesian Ulama Council or Majelis Ulama Indonesia (MUI), and local communities	
Promotion	1. Organizing a national campaign for ziswaf	Informant (2019)
	2. Promotion of behavior change among vulnerable groups	
	3. Widespread socialization of the harmful impact of sanitation and improper clean water	
Infrastructure	1. Use of appropriate technology	Informant (2019)
	2. Sanitation and clean water infrastructure budget for remote areas	
	3. Improvement of supporting infrastructure	

Result of Geometric Mean and Inconsistency

The geometric mean calculation results show that all informants, on average, provide an assessment of the criteria related to ziswaf utilization strategies for sanitation and clean water with answers ranging from important to very very important (score 5-9). This shows that the informants agree or agree that the criteria and subcriteria that are compiled are relevant in optimizing the utilization of ziswaf for sanitation and clean water.

Inconsistent values from all clusters for all informants have met the criteria, namely less than 0.1 or 10%. All informants' entire inconsistency ratio value is in the range of 0.0000 - 0.0769, which is below 0.1 or 10%. That shows that the value of the inconsistency ratio is consistent. The priority weighting of the existing criteria can be used as a basis for interpreting the results of the study's analysis.

Strategies Priority Results

Based on the results of the pairwise comparison calculation, it can be seen that the priority in the ziswaf utilization strategy for sanitation and clean water is a synergy that reaches 44.91%. Then the second priority in the strategy is promotion, which is equal to 30.21%. The third place is infrastructure, which is 24.87%. That can be seen in the chart 1.

Chart 1: Priority Strategy

As for the more detailed, priorities based on the sub-criteria in the conceptual model are in the table 3.

Table 3: Priority Strategy of Criteria and Sub-Criteria

No	Criteria	Sub-criteria	Percentage
1	Synergy	1. Synergy between central and local governments	0.38918
		2. Synergy between local governments, Ziswaf Management Institute or Lembaga Pengelola Ziswaf (LPZ), Indonesian Ulama Council or Majelis Ulama Indonesia (MUI), and local communities	0.34541
		3. Synergy between Ziswaf Management Institute or Lembaga Pengelola Ziswaf (LPZ) in program harmonization	0.265408
2	Promotion	1. Organizing a national campaign for ziswaf	0.353936
		2. Promotion of behavior change among vulnerable groups	0.332114
		3. Widespread socialization of the harmful impact of sanitation and improper clean water	0.313948
3	Infrastructure	1. Use of appropriate technology	0.430436
		2. Sanitation and clean water infrastructure budget for remote areas	0.33813
		3. Improvement of supporting infrastructure	0.231432

Based on the table above, it can be seen that in the synergy criteria, the priority sub-criteria is the synergy between the central and local governments, then the synergy between the local government, LPZ, MUI, and local communities

as well as synergy between LPZ in program harmonization. In this regard, Hudaefi (2019) states that:

> "Bandung City, which is regional government regulation, has been proven numerically to realize the potential (ziswaf). So the government issued a rule that the State Civil Apparatus (ASN) in Bandung must pay zakat to BAZNAS. Finally, zakat's potential increased from say per month to less than 400 million, to three billion. It's pretty big, and we have the data on it. If we look at it from one case, yes, how to increase this potential, it must be encouraged by the local government ".

Besides, regarding local government, Hudaefi (2019) also said that:

> " Concerning practitioners, practices, all regional governments must be more aware and collaborate with the local BAZNAS. And with other stakeholders. So that the implementation of clean water and sanitation is accomplished, there must be ".

With the synergy between all parties involved in utilizing ziswaf for sanitation and clean water, the opportunity for optimal utilization of ziswaf for sanitation and clean water will be even more excellent. If the government or regulators are directly involved, ziswaf collected potential will be even more significant. That will impact the potential for more optimal ziswaf utilization, both in terms of coverage and effectiveness. Therefore, the priority strategy that must be implemented in optimizing ziswaf utilization for sanitation and clean water is the synergy of the various parties involved.

Furthermore, related to the promotion or holding a national campaign related to ziswaf, this is the following research conducted by Lubis & Latifah (2019) that the current Islamic economic movement is still partial and focuses on commercial finance only. That makes the ziswaf collection not yet optimal so that it affects the ziswaf utilization, which is not optimal either. Therefore a strategy is needed, one of which is to hold a national campaign to carry out ziswaf.

Then related to outreach to vulnerable groups and widespread outreach regarding the lousy impact of sanitation and clean water, Prihannande (2019) states that "We also approach schools, we are constantly provoking this." That shows that promotion or outreach should be carried out extensively to vulnerable groups and strategic development, such as educational institutions.

Holding a national campaign to carry out ziswaf, promoting behavior change to vulnerable groups, and widespread socialization of the adverse effects of sanitation and clean water implies that what is being done is an educational pattern. Besides, the effect of the excellent promotion will have an impact on public perceptions. It can then impact changes in people's mindset and behavior, both related to ziswaf and sanitation and clean water.

The third strategy is related to infrastructure, namely the use of appropriate technology, the need for financial support from the government for remote areas to build sanitation and clean water infrastructure. Then it is also important to improve the infrastructure to support access, such as roads, bridges.

Conclusions and Suggestion

After all stages of the research have been carried out, it can be concluded that the priority strategy related to the utilization of ziswaf for sanitation and clean water is synergy. There is a synergy sub-criteria between the central government and regions, the synergy between local governments, LPZ, MUI, and local communities, and synergy between LPZ in program harmonization.

Based on the results of the research that has been done, the suggestions or recommendations of this study are

1. It requires synergy from various parties such as the central government, local communities, and institutions related to ziswaf for sanitation and clean water. Besides, increased promotional activities related to sanitation and clean water or the utilization of ziswaf for sanitation and clean water. It is also necessary to improve supporting infrastructure facilities so that ziswaf distribution for sanitation and clean water for people in need can be done quickly.
2. This study has many limitations; one of them is a scope of research that is too broad, not specific in an area. The output of this study only describes in general, does not accommodate or describe specific problems or solutions, considering Indonesia is a vast country diverse regional cultures, and each region has its character. Therefore, in subsequent studies, it is recommended to research the same theme in a specific area.

Abstract

The aim of this study was to investigate the relationship between job characteristics in terms of job demands and resources, work stress, and cyberloafing among Polish information technology (IT) professionals. We gathered data in an online self-report survey from 426 IT employees. The results indicated that Polish IT workers engaged in cyberloafing at a moderate level. Likewise, they reported low to moderate level of job demands, higher than average job resources and work stress level as below average. Our findings further demonstrate that job demands and resources relate to cyberloafing directly and *via* stress-related symptoms. Specifically, job demands (i.e., work pace, quantitative and cognitive demands) and job resources (i.e., influence, justice, and employee mutual trust) were directly related with cyberloafing. Quantitative and cognitive demands, and job resources (i.e., meaning at work and possibilities for development) were related to cyberloafing through stress symptoms. Our study explains potential mechanisms underlying the relationship between specific job characteristics and cyberloafing among IT professionals and contributes to the growing body of research on cyberloafing as a stress coping strategy. The current results suggest that in order to maintain employees' well-being, human resources managers shall address job characteristics, which may intensify work stress and cyberloafing.

Keywords: cyberloafing, job characteristics, work stress, psychological well-being, IT professionals.

Introduction

In this paper we intend to explain a potential mechanism underlying the relationship between job characteristics identified as job demands and job resources, intensity of stress symptoms, and cyberloafing among Polish IT professionals. We present a hypothetical model depicting various links among the selected variables, which we will next have verified empirically. In the Introduction, we present all analyzed phenomena we and explain the relationships between them: We will have focused on (1) cyberloafing, its prevalence and potential impact for organizations, work and well-being or employees, (2) stress as commonplace job attribute, and (3) job characteristics in terms of job demands and job resources. Further, in the Method section we present the study methodology, procedure, relevant variables and measures, as well as the measurement model followed by pertinent statistical analysis. Next, in the Results section we will have described in detail the results of the analysis. Lastly, the elaborate Discussion, together with practical implications and study limitations, and Conclusions will have been presented.

Cyberloafing at work

One of the contemporary problem organizations are highly concerned with is wasting company resources due to overuse of the internet and mobile technology for non-work activities. The misuse of cybertechnologies, called cyberloafing is defined as "voluntary acts of employees using their companies' Internet access for non-work-related purposes during working hours"; and "a counterproductive work-place behavior resulting in production deviance" (Lim, 2002; p. 677). Another term "cyberslacking" is used as the extension of typical counterproductive workplace behavior that involves distraction and putting off work to 'surf the Internet' for non-work purposes (O'Neill et al., 2014). Individuals engage in cyberloafing irrespective of the organization type or job position, simply because they have access to multiple information technology devices to engage in these behaviors (Mercado et al., 2017). According to AMA 2019, nearly 45% employees admitted to use internet as the number one medium to waste time at work (email, IM, online polls, interactive games, message boards, chat rooms, etc.) and engage in cyberloafing for one to two hours daily. Cyberloafing apparently disturbs efficient use of organizational resources, which ultimately may result in decreasing the competitive status of the organization (Liberman et al., 2011), and can cost organizations as much as $85 billion dollars (Zakrzewski, 2016).

Since the advent of new technologies organizational systems have been forcing intense time and effort demands on employees, who often are connected to their employers 24/7. They get equipped with devices that enable them to stay online, and be ready to act whenever employer decides it is necessary. This hyper-connectivity may blur the purposes of using new technologies (Kuschnaroff and Bayma, 2014). In other words, the boundaries between time at work and time off work are not clear any more. Thus, cyberloafing might not even be recognized by employees as a genuine problem or they diminish its seriousness through neutralization technique (Cheng et al., 2014; Lim, 2002).

Research demonstrates that cyberloafing may be considered as work distracting activity that undermines timely task completion and goal achievement (e.g. O'Neill et al., 2014) as well as a form of counterproductive work behaviors (Lim, 2002; Mercado et al., 2017) that negatively impact job performance (Liberman et al., 2011; Sao et al., 2020). Other research indicates that heavy internet use or cyberloafing serves as a coping strategy to alleviate work stress (Henle and Blanchard, 2008; Lim and Chen, 2012; Quinones and Griffiths, 2017). Work-related negative affect, stress, fatigue, emotional exhaustion and burnout may result in browsing activities, social networking or gaming as a respite from these negative experiences. It appears that cyberloafing as a stress relief strategy helps to protect or recover weakened resources when employees experience frustration and distress at work. Relationship between cyberloafing and stress is by no means straightforward. Cyberloafing may also become a source of stress-related consequences, such as low satisfaction, frustration due to unfinished tasks, distraction, and even ill health (e.g. Kim and Christensen, 2017).

Job characteristics in the IT industry

According to the Job Demands-Resources (JD-R; Bakker and Demerouti, 2007) model, job characteristics were divided into two fundamental categories: demands and resources. Job demands are defined as those features of the job that involve continuous physical and psychological effort associated with physiological and psychological burden (Schaufeli, 2017). Examples of job demands are workload, pressure for professional development, role conflicts or job insecurity. Job demands may lead to burnout and consequently to lower workability health-related absenteeism, or lower job engagement. Job resources relate to job aspects that increase the likelihood of achieving work goals, help to develop professionally, and reduce negative effects of job demands. Examples of job resources include job autonomy, organizational justice, management and peer support. Job resources can lead to higher job satisfaction, work engagement, or great job performance (Bakker and Demerouti, 2014). The JD-R model has been acknowledged as a theoretical and practical framework that explains mechanisms underlying relationships between job characteristics and negative work outcomes like counterproductive work behaviors, as well as positive outcomes, such as high job performance (Balducci et al., 2011). Literature is not consistent in explaining how job characteristics related to cyberloafing. There are accounts of work underload (Hensel and Kacprzak, 2020; Metin et al., 2016; Pindek et al., 2018), role ambiguity and role conflict (Henle and Blanchard, 2008), emotional demands (Quinones and Griffiths, 2017), and workplace aggression (Andel et al., 2019) that relate to cyberloafing. Other predictors of cyberloafing from job resources include job autonomy (Metin et al., 2016;

Mercado et al., 2017), opportunity for development (Metin et al., 2016), meaningfulness at work (Jia et al., 2013), organizational injustice (Kim et al., 2016; Lim, 2002), and trust (Liberman et al., 2011).

The exploration of the relationship between different job characteristics and cyberloafing seems to be exceptionally important for information technology (IT) profession (Kim and Christensen, 2017; Salanova et al., 2002). Research have suggested that IT profession abounds in a variety of job demands. These include high pressure to keep up-to-date with new technological developments, fluctuating requirements, work overload, role conflicts, as well as low autonomy and fairness of rewards. Accumulation of these demands may lead to experiencing high stress at work and burnout (Koay et al., 2017; Maudgalya et al., 2006; Shih et al., 2013; Shropshire and Kadlec, 2012; Syrek et al., 2013). Studies also emphasize ill-health, negative attitudinal behavior (i.e., low work engagement, poor satisfaction) and various unproductive or counterproductive behavior such as conflicts, procrastination at work, sabotage, theft, and high turnover as an outcome of high job demands (Lim, 2002; Salanova et al., 2002; Shih et al., 2011). Therefore, in agreement with Kim and Christensen (2017) professionals are particularly at risk to engage in cyberloafing, since IT job is on one hand highly demanding and on the other hand relates to permanent interaction with computers, employee's autonomy and reduced monitoring from supervisors or peers. The round-the-clock access to Internet may prompt IT employees to treat cyberloafing as an effortless escape when things at work get psychologically and physiologically overwhelming. As trivial as it sounds, IT companies do acknowledge rising complexity of demands employees need to face, but also, they are highly concerned with rising cyberloafing activity, which may undermine IT workers' job performance.

Present Study

To the best of our knowledge, there research on job characteristics and cyberloafing among Polish IT professionals is sparse. Therefore, we aimed at identifying job characteristics (i.e. job demands and resources) and work stress among Polish IT professionals, as well as the extent to which they engage in cyberloafing. Following the JD-R model (Bakker and Demerouti, 2014), the assessed job characteristics were considered as three categories: (1) job demands, (2) task resources, and (3) organizational resources (Berthelsen et al., 2017). Drawing on the previous findings, we assumed that in the Polish IT organizational environment job characteristics in terms of demands and resources as well as cyberloafing would be determined as high. The second aim of this study was to investigate the association between job characteristics (i.e. job demands and resources) and cyberloafing, as well as the mediating role of work stress in this relationship. The hypothesized model of tested relationships is presented in Fig. 1. We expected direct negative relationships between task and organizational resources and cyberloafing (H1). Next, we hypothesized that associations between job demands and cyberloafing are positive and are mediated by stress symptoms (H2).

Fig. 1. Hypothetized model of the relationships between job characteristics, stress symptoms, and cyberloafing.

Method

Participants and Procedure

The sample consisted of 426 IT professionals from Poland, employed as programmers (48%), software developers (24%), network, database or web administrators (22%), and other IT job positions (6%). There were 153 women and 273 men, aged from 25 to 55 years. The employees' mean work experience was 9.65 years (SD = 9.74). Participants have been recruited via e-mail using a snowball procedure from Polish (47.7%), international (38.5%), and own companies (13.2%). The study was conducted online and respondents participated anonymously and voluntarily, and provided informed consent before they completed all self-reported measures.

Measures

Job characteristics. In this study we used the Copenhagen Psychosocial Questionnaire (COPSOQ II; Pejtersen et al., 2010) in the Polish adaptation (Baka, 2019) to measure various job characteristics in terms of job demands and resources (Bakker and Demerouti, 2014). Following Berthelsen et al. (2017) recommendations, we measured: (1) *job demands* (i.e., work pace, quantitative demands, cognitive demands and emotional demands, role conflicts, job insecurity), (2) *task resources* (as influence, possibilities for development, variation, meaning at work), (3) *organizational resources* (i.e., justice, mutual trust between employees, trust regarding management, recognition), and (4) *stress symptoms* (i.e., stress, burnout, somatic and cognitive stress symptoms). All subscales consisted of 3 or 4 items. Each of these subscales consisted of 4 items on 5-point scale (1 – *very little* to 5 – *very much*) or on the scale (1 – *at all* to 5 - *all the times*). The reliability of these measures in this study were satisfactory (Cronbach α = .69 - .85).

Cyberloafing. Participants' cyberloafing was measured with the 4-item subscale of the Polish version of the Procrastination at Work Scale (PAWS; Metin et al., 2016). An example item is "I do online shopping during work hours". Items are scored on a 7-point Likert scale ranging from 1 – *never* to 7 – *always*. The internal consistency of the cyberloafing measure in this study was acceptable (alpha = 0.78).

Results

Job characteristics, work stress, and cyberloafing among IT professionals

First, we examined the level of IT job characteristics among IT professionals. As shown in Table 1 and Fig. 2, IT job demands were perceived by Polish workers as below average, whereas task and organizational resources were assessed as higher than average. Polish IT professionals have reported various stress symptoms as below average. The t-test results showed significant gender differences in cyberloafing, in all task and organizational resources, and two job demands (i.e., cognitive demands and role conflict).

Table 1: Mean and standard deviation for cyberslacking and job characteristics among IT professionals

	Total sample ***N* = 426**		**Women** ***n* = 153**		**Men** ***n* = 273**		***t*(424)**

Burnout	2.68	.89	2.64	.81	2.70	.93	-.37

Note. $^{*}p < .05$, $^{**}p < .01$.

As depicted in Table 1 and Figure 2, men declared higher tendency to cyberloafing than women. Compared to men, women declared higher level of role conflicts, and perceived their work as less cognitively demanding. Men perceived influence, possibilities for development, variation, and meaning at work as higher than women did. Moreover, there were significant gender differences in the perception of availability of organizational resources. Compared to men, women assessed that trust in coworkers and in management, recognition, and organizational justice were lower. Also, men tended to engage in cyberloafing more often than women. However, we did not find significant differences between men and women in respect of job demands and stress-related responses.

Fig. 2. Differences in cyberloafing and job characteristics between women and men.
Note. CB = Cyberloafing; QD = Quantitative demands; WP = Work pace; CD = Cognitive demands; ED = Emotional demands; JI = Job insecurity; RC = Role conflicts; IN = Influence; PD = Possibilities for development; VA = Variation; MW = Meaning at work; TE = Mutual trust between employees; TM = Trust regarding management; JU = Justice; RE = Recognition; ST = Stress; SS = Somatic stress symptoms; CS = Cognitive stress symptoms; BU = Burnout.

Effects of job characteristics and work stress on cyberloafing – mediation model

In the next step we ran the two multiple linear regression analyses in order to determine the predictive power of demographic variables and job characteristics on work stress symptoms and cyberloafing (Table 2). In the first step we entered sex and age as demographic variables, and in the second step we introduced all job characteristics. Age, but not gender, turned out to be a significant predictor of cyberloafing among IT workers.

Within job demands, work pace, quantitative and cognitive demands were significant predictors of stress symptoms and cyberloafing. Moreover, influence, trust regarding management, and organizational trust (as job resources) were significantly associated with cyberloafing. In addition, stress, burnout, and cognitive stress symptoms have shown significant, but weak relationship with cyberloafing. There were no effects of the remaining demands (i.e., emotional demands, role conflicts, job insecurity), work organization and job content aspects (i.e., possibilities for development, variety, meaning at work), and organizational resources (i.e., mutual trust between employees and recognition) on cyberloafing.

Table 2: Effects of job characteristics on stress symptoms and cyberloafing

Note. $N = 426$. $^{*}p < .05$, $^{**}p < .01$, $^{***}p < .001$.

In the next step, on the basis of regression analyses results we have developed a structural model, in which all significant predictors of cyberloafing were included. The job characteristics, in terms of demands and resources, as predictors and stress symptoms as a mediator in the prediction of cyberloafing have been patterned. Therefore, the empirical model consisted of nine observed variables (job characteristics and cyberloafing) and one latent variable with four stress-related variables)[1]. This model was tested using the maximum likelihood estimation method, with AMOS software (IBM SPSS AMOS 24.0). According to Kline (2011), the model is well fitted to the data, if fitness parameters meet following criteria: χ^2/df is between 2-3; root mean-square error of approximation (RMSEA) is below 0.08, standardized root-mean square residual (SRMR) is near 0 whereas comparative fit index (CFI), Tucker-Lewis index (TLI), goodness-of-fit index (GFI), and adjusted goodness-of-fit index (AGFI) are above 0.90. The results of this analysis indicated that the measurement model provided an excellent fit to the data (χ^2= 81.93, df = 37, χ^2/df= 2.21, RMSEA = .070, SRMR = .046, CFI = .96, TLI = 0.96, AGFI = .97). All path values between variables are statistically significant.

[1] Due to high intercorrelations between stress-related variables (above .60), we decided to include them despite non-significant effects on cyberloafing.

Fig. 3. A structural model of the relationships between job characteristics, stress symptoms, and cyberloafing among IT professionals.
Note. Path values are presented as standardized regression coefficients.

As depicted in Fig. 3, low work pace, low cognitive demands, and high quantitative demands (considered as job demands) were directly associated with low cyberloafing. In addition, cognitive and quantitative demands were related to cyberloafing through stress-related symptoms. In the tested model there were revealed direct associations of job resources, as high influence at work, high organizational justice, and low horizontal trust (between employees), with high tendency to cyberloafing. Moreover, we have found significant effects of task resources (such as possibilities for development and meaning at work) on cyberloafing mediated by work-related stress. All job characteristics included in the measurement model were significantly intercorrelated.

To examine the mediating effects of job characteristics on cyberloafing through stress-related symptoms, we performed indirect effect analysis using the bootstrapping method with 10,000 re-samples and 95% bias-corrected confidence intervals (BC 95% CI; Hayes, 2013). There were observed four indirect effects of quantitative demands (effect = .09, boot *se* = .04, boot 95% CI [.04, .18]) and cognitive demands (effect = .10, boot *se* = .04, boot 95% CI [.03, .19]), meaning at work (effect = -.07, boot *se* = .03, boot 95% CI [-.13, -.03]), possibilities for development (effect = .05, boot *se* = .03, boot 95% CI [.02, .12]) on cyberloafing *via* stress-related symptoms. All indirect effects are significant, because the bootstrapped CI does not contain zero (Hayes, 2013). Overall model explained 26% of the variance.

Discussion

First, we explored job characteristics, work stress symptoms, and cyberloafing among IT professionals. Our findings demonstrated that IT workers in Poland generally declared moderate level cyberloafing (i.e. non-work-related Internet use during work). However, increasing number of global and national surveys report that cyberloafing tendencies are on the rise among general population of employees, including intensive-knowledge workers and IT professionals (AMA, 2019; Hein, 2016; HRK, 2020; IT community at Poland, 2020). The latest data from amanet.org show that on average

employees spend around 2 hours on the internet for non-work activities each day. Given our results, cyberloafing phenomena among IT professionals in Poland shall be further monitored. Worth noticing and important for this study is that men were more likely to engage in cyberloafing than women, but the differences were negligibly significant. This finding is in line with previous research suggesting that men are more likely to engage in cyberloafing than women (Andreassen et al., 2012; Hensel and Kacprzak, 2020; Lim and Chen, 2012; Vitak et al., 2011).

Our results also revealed that job demands in the Polish IT industry are rather moderate. Cognitive demands were assessed by IT workers as higher than average, which resonates with a long-standing view of the complexity and dynamics of IT profession (Maudgalya et al., 2006). Polish IT workers have assessed quantitative and emotional demands as slightly below average. This result may be a function of relatively young workforce employed in the IT industry and possible high skills at handling workload and keeping emotions in check. Work pace, job insecurity, and role conflict have been declared as slightly lower than average. While perception of having a secure job corresponds with common knowledge of a good standing of IT industry in terms of employability, declaration of a lower than average work pace and role conflict seems interesting. It might be that IT professionals are used to certain high tempo at work, so they take it for granted and declare that it is just fine as it is. The lower than average role conflicts however might reflect the desire to present oneself as having things under control. In general, it seems that elevated cognitive demands are the salient challenges for Polish IT workers. There were no significant difference between men and women in the perception of job demands except of higher role conflicts among women. Task resources (i.e., development, variation, influence and meaning at work), and organizational resources (i.e., mutual trust among employees, trust regarding management, justice, and recognition) were also perceived relatively optimistically. On the one hand, it can suggest that Polish IT professionals rate themselves as not overburdened by work and with sufficient resources to draw from, on the other hand these results, again, might have been contaminated by the social desirability bias. Generally, among Polish IT professionals, women declared lower level of task and organizational resources available to them than men. These results resonate with other research, which shows that even if the knowledge and expertise is leveled between men and women, the letter feel inferior and underappreciated by their employers (e.g. Kim et al., 2016; Lim, 2002). It is thus possible that women, when faced with stressful work events, would be replenishing their resources from rather deficient reservoir in comparison to men. Lim and Chen (2012) explain these differences between men and women within the framework of conservation of resources theory (Hobfoll, 1989), which informs that resources are valuable assets for individuals. IT male professionals are considered savvier than women in the domain of cybertechnology. They can thus resort to stress-reducing behaviors through the use thereof, and replenish their resources quicker and with greater ease than women (Lim and Chen, 2012). This assumption is in line with studies informing that men's attitude towards cyberloafing is more positive than women's (Andreassen et al., 2014), and men engage in cyberloafing if it helps to reduce stress.

There is a general consensus in the literature that IT profession is marked by one of the highest levels of stress and burnout (e.g. Shih et al., 2011), and associated with increasing market pressure, ever higher time pressure, blurred boundaries between family and work life, e.g. Maudgalya et al., 2006, Shropshire and Kadlec, 2013). Interestingly, but opposite to aforementioned data, in our study Polish IT workers reported relatively low level of various stress symptoms. This corresponds to one survey reports (e.g. The Workforce View in Europe, 2019), however vast majority of findings provide data on very high stress levels among IT professionals (e.g. HRK, 2020). We think that in our study social desirability bias embracing self-deception and impression management has interfered with yielding genuine responses. Apparently in a study by (Akbulut et al., 2017), social desirability bias was positively related to cyberloafing most probably due to commonly accepted view that cyberloafing is an organizationally undesirable behavior.

The results of this study demonstrated significant relationships between job characteristics (in terms of job demands and resources), stress symptoms and cyberloafing in a structural model of direct and mediated associations. Firstly, our results revealed direct relationships between job characteristics (in terms of job demands, job resources) and cyberloafing. Interestingly, low cognitive demands and slow pace at work were directly negatively associated with cyberloafing. Possibly, when IT workers are not stimulated enough at work or pressed by deadlines they resort to cyberloafing. In the circumstances of low cognitive demands and slow tempo at work they might engage in cyberloafing for variety of reasons e.g. as a time filler, stimulation, or leisure. In fact, this explanation is in line with previous research (e.g. Metin et al., 2016; Pindek et al., 2018) and may especially be true among IT professionals, who are recognized for high intelligence, intrinsic motivation and desire to learn and develop. Our study also revealed positive direct link between quantitative

demands and cyberloafing, which corroborates with studies concluding that employees who are overwhelmed with work may engage in heavy internet use (Quinones and Griffiths, 2017). It is possible that excessive workload may yield behaviors related to retreating or escaping towards activities that are associated with pleasure or stress relief. In sum, the relationships between organizational demands and task demands and cyberloafing are not obvious and predictable. The complexity of the links between various job characteristics and cyberloafing most probably stems from the interplay between situational factors, particular profession demands, and personal characteristics. These interactions lie beyond the focus of our study; however, we find it important to address it in future research. Task and organizational resources, such as influence, justice and mutual trust between coworkers were also directly related to cyberloafing, thus partially supporting our Hypothesis 1 (H1). Influence at work directly related to high cyberloafing. This result supports Garrett and Danziger (2008) findings that cyberloafing is pretty common amongst educated managers and professionals since they are less restricted in regulating their schedules, work, and other activities. Also, meta-analysis by Mercado et al. (2017) has revealed that autonomy, a concept related to influence, has been positively related to cyberloafing. The non-work cyberactivity does not necessarily jeopardize task completion or job performance; it might as well occur for educational purposes. Perception of influence similarly to feelings of being autonomous has a potent positive effect on expert workers in terms of job satisfaction, reduced strain effects, learning motivation, and better performance (e.g. Shih et al., 2011; 2013). We would not encourage however to draw simplistic conclusions as to the relationship between influence and cyberloafing. As shown by Metin et al. (2016), autonomy was negatively correlated with cyberloafing both, directly and indirectly via boredom. Somewhat counterintuitive and in contrast with other empirical results (e.g. Kim et al., 2016; Lim, 2002), positive perception of organizational justice and cyberloafing are positively interrelated in our study. It may be that having recognized that one's effort and work outcomes are appreciated and distribution of resources is just and fair, IT professionals may feel empowered to allocate their personal resources (e.g. mental focus) into non-work activity in the cyberspace. Again, the outcome of this behavior does not necessarily harm the company as portrayed by an example of Atlassian company (Tay, 2014), which yields the most creative IT solutions when the employees are granted one day per month of control-free activity. Lastly, our study shows that low mutual trust among co-workers results in more frequent cyberloafing. Good part of a positive, up-beat and stimulating work atmosphere relates to interpersonal trust. Peer support may enhance employees' well-being (Liberman et al., 2011). The relationship presented in the current model may inform that employees resort to internet during work hours when they feel they cannot depend on their peers, for example to get help in resolving a work-related issue. In a situation of low employees mutual trust, cyberloafing may be a form of positive, quasi-professional interactions or simply a breather from the dullness of isolation experienced due to low confidence in coworkers.

Results of this study provides further insight into relationship between job demands and resources, work stress, and cyberloafing. Specifically, our findings revealed that within IT profession high job demands, i.e. quantitative and cognitive demands lead to increased stress-related responses, which enhanced cyberloafing. This result supports our Hypothesis 2 (H2). It corresponds to other findings, which showed that job demands increase stress reactions (e.g. Shih, 2011; 2013) and emphasize the key role of stress and strain in cyberloafing (e.g. Andel et al., 2019). As detailed in the IT sector reports (HRK, 2020) high stress is deeply rooted in the IT profession. Likewise, ample research confirms the relationship between stress and detrimental individual and organizational outcomes (Koay et al, 2017; Maudgalya et al., 2006; Shih et al., 2013; Shropshire and Kadlec, 2012; Syrek et al., 2013). So, for IT professionals when high workload increases distress it may provoke cyberloafing, which most probably reflects coping with stress related to cognitive and quantitative job demands. In addition, two task resources, i.e. low meaning at work and high possibilities for development were also related to cyberloafing *via* increased stress responses. Low meaning of work may create boredom and become stressful to IT professionals who are recognized for their mental agility, cleverness, and creativity. Probably, meaningless tasks lead to cyberloafing as a way of getting some intellectual stimulation or recreation. Non-mediated relationships of the same direction between job meaningfulness and cyberloafing have been earlier discovered by Jia et al. (2013), so has boredom been related to cyberloafing (e.g. Pindek et al., 2018). Possibly then, our findings indicate that when the task is low in meaning it may prod employees to engage in cyberloafing as a strategy to relief stress associated with boredom. Ample possibilities for development may also intensify stress-related responses, which then increase cyberloafing. Possibilities for development might be perceived by IT workers rather as employer's expectation to further educate and advance and as such could be subconsciously sensed as pressing demands for more highly challenging work. As mentioned earlier, quantitative and cognitive demands yield stress-related responses, which lead to intensive internet use as a way to reduce negative impact of stress (Quinones and Griffiths, 2017; Kim and Christensen, 2017). In sum, our

results are consistent with previous findings, which show that high demands and low resources may lead to cyberloafing as cyber-counterproductive reactions to stress (Balducci et al., 2011; Quinones and Griffiths 2017). Thus, stress symptoms shall be considered as influential reactions, which explain the associations of quantitative and cognitive job demands and task resources, i.e. low meaning at work and possibility for development with cyberloafing.

This study contributed to the growing body of research on the prevalence of cyberloafing in IT profession among Polish employees, specific job characteristics such as cognitive and quantitative demands, job resources in terms of possibility for development, employees mutual trust, and stress as predictors of cyberloafing. Also, worth emphasis is that we have conducted our study among IT professionals, the knowledge workers with constant access to computers who operate in a very demanding industry. Our study helps to recognize that among IT professionals not only job demands but also job resources may become a contributing factor to various forms of stress symptoms, which then may provoke cyberloafing. The results further support the stream of research, which considers cyberloafing as a form of coping and stress relief strategy (e.g. Andel et al., 2019) as opposed to counterproductive work behavior (e.g. Lim, 2002).

Practical Implications

For management practice, interesting facts arise from our findings. First not only task-based demands but also relational deficiencies (e.g. low mutual trust) may induce IT workers to engage in cyberloafing which is probably a means to diminish both, task based and relational stress. This result could serve as a valid cue for managers to embrace cyberloafing as one of the methods to maintain employees' well-being. Therefore, preventing employees from spending personal time online may be a short-lived strategy. Second, this study demonstrated that besides job demands particular job resources, such as possibilities for development may also relate to higher cyberloafing. Hence, managers shall also focus their attention on other than commonly recognized individual and organizational causes of cyberloafing. It seems that IT profession is truly a unique one in terms of perception of potential job demands. Third, there are differences in respect of the extent to which men and women engage in cyberloafing and its organizational antecedents. Since women think that task and organizational resources do not benefit them as much as they benefit men, managers shall effortfully consider these inequalities. Expert employees shall have an equal opportunity to expand their capabilities, men and women alike. These inequalities may create a tangible loss for an employer when good portion of expert workforce is not able to fully unveil its potential. It can be a difficult task for the management to disentangle the roots of stress-inducing job characteristics. In view of this difficulty, we recommend that organizational decision-makers first investigate the perceptions regarding the key aspects of the job for each employee. This could provide initial information needed to understand the reasons of cyberloafing. Then, engaging in monitoring the quality and quantity of tasks and projects assigned to the employees would help to take care of their overall wellbeing. Proactive approach in this process may include offering the tools and information to prevent the negative impact of stress, and crafting assignments compatible with each employee emotional and cognitive capacity. Particular steps that shall be undertaken by the management could include employing employee-oriented style of managing, initiating coaching sessions, supporting employees in stress-relief education, or simply assigning time for chatting. The inevitable rise of new and ever more sophisticated mobile technology shall only become yet another trigger to keep in touch with real persons and be aware of their perspective and needs to fulfill the role of valued employees.

Limitations

We acknowledge some limitations of this study. First, we used cross-sectional data to conduct our analyses. Thus, any inferences on the causal effect cannot be drawn. Future research shall employ longitudinal approach to study the linkages between job demands and job resources and cyberloafing. The universality of the results is limited. However, IT professionals in large part, work remotely for international organizations, so the study results may at least partially be used for comparison purposes. Third, this study lacks information on important behavioral measures, such as time and frequency of non-work-related activities in the workplace, which would enable to draw more comprehensive picture of cyberloafing. Also including broader set of cyberloafing behaviors would have been beneficial for deeper understanding of the phenomenon. Lastly, results of our study might have been contaminated by social desirability bias (Akbulut et al.,

2017), since responses to central aspect of IT job, i.e. stress and its components were slightly lower than average. It is a common bias among employees whenever they rate themselves on behaviors, which might be seen as inappropriate.

Conclusions

Currently, personal use of cybertechnology during work is an irreversible phenomenon. The more intense work requirements the less time and energy remains at employees' discretion to take care of simple but important personal matters (e.g. paying bills, respond to e-mails, or connecting with family members), watch news, relax, or even advance in education. However, using new technology devices may be quite alarming whenever employees abuse company's time and other resources (e.g. computers) for non-work cyberactivity. Some workers do not even acknowledge that, for example, watching adult sites during work might incur costs of legal issues, upon the costs of lost company time and productivity. Cyberloafing shall not however be perceived as entirely negative phenomenon. So far, ample research has confirmed that it may provide learning opportunities, relief from stressful events at work or mental break. Our research delivers further understanding of possible organizational and personal factors, which may predict cyberloafing. Results show that both, task and organizational demands, may directly encourage cyberloafing. Also, they may generate higher stress-related responses, which then would prompt workers to resort to cyberloafing, most probably for stress relief purposes. Our study demonstrated that cyberloafing may occur not only in relation to negative work experiences, such as high job demands and intense strain, but also when an employee enjoys influence over her job and thinks highly of company's justice standards. Inevitably the nature of cyberloafing is complex. Employers and employees shall thus acknowledge that cyberloafing may be predicted by job demands and job resources alike, and that work stress is an influential motivator to engage in cyberloafing.

A Nonparametric Efficiency Perspective on the Quality of Air and Traffic Safety in European Cities

Associate Professor, PhD, Bucharest University of Economic Studies, Department of Economic Informatics and Cybernetics, Bucharest, Romania, anamaria.aldea@csie.ase.ro

Abstract

Environment, traffic, and its effects are indissolubly linked, usually evolving in the same direction: a strategy to reduce traffic effects will also entail a minimization of the impact on the environment, leading to a better quality of air. The definition and measurement of these concepts contain a note of subjectivism by the authors, all approaches being strongly influenced by the selected variables. The modern lifestyle together with the recent major geophysical events made 2010s the hottest decade recorded in history and 2010 was only the first hottest year during this period. In this context, the purpose of this study is to analyze and classify 112 European cities based on 2011 data using non-parametric techniques, investigating the situation at the beginning of 2010s decade. This paper shapes two models that follow two different dimensions (air quality and traffic safety) across two directions: output-oriented and hyperbolic. Following the efficient and inefficient classification, we benchmark the cities with the purpose of illustrating the characteristics of efficient ones and how inefficient cities should reduce the harmful impact on the environment by improving their efficiency score. The difference between the two categories of cities is mainly determined by size – a low population implies fewer cars, therefore safer traffic, and a smaller environmental footprint.

Keywords: Nonparametric Efficiency; European cities; FDH.

Introduction

Growing urbanization and mass industrialization have led to an economic growth directly proportional to environment degradation. From industries to households, every part of our society depends on energy nowadays, but most of the energy is generated by burning fuels. Therefore, people heavily harm the environment and the according consequences have started to be visible. Global warming is an alarming phenomenon worldwide and more people are becoming worried about its long-term effects.

Urban agglomerations cover the most common and complex problems: intense traffic, pollution, demographic changes, etc. The interest for this topic is rising, as the regional authorities have become aware of these issues during the last years. Planners are often struggling with the need of finding solutions to environmental and social issues while conceiving medium and long-term development plans.

The modern lifestyle together with the recent major geophysical events made 2010s the hottest decade recorded since 1880, according to the National Oceanic and Atmospheric Administration. 2010 was only the first hottest year during this period. The decade had no less than eight of the 10 hottest years ever recorded, the remaining two positions in this top 10 being 2005 and 1998. In this context, the current study has an objective to investigate the situation in 2011, considering that the impact of 2010's hottest temperature should already be noticeable during the subsequent year.

This study aims to analyze the efficiency of 112 European cities based on 2011 data using nonparametric techniques. The models based on the situation in many urban agglomerations illustrate how European cities behave according to the two dimensions analyzed: air quality and traffic safety. Efficiency scores were obtained in R, as well as the efficiency frontiers.

Clearly, European metropolises such as Paris, London or Rome have a very harmful impact both on the environment and society. Developed cities prove serious issues not only on traffic management, but also on the quality of air, both being more difficult to control and maintain as the city size increases. In this regard, smaller-sized cities such as Basel, Geneva (Switzerland) or Münster (Germany) are leading, where any measure of minimizing the traffic or the carbon dioxide emissions has a direct and rapid harm reduction effect.

The ecological aspects of intense urbanization represent a wider field of research in the literature. With its technological advance and massive industrialization, China has been extensively analysed from an ecological point of view, even by using nonparametric DEA techniques (Zhang et. al, 2008; Yu, Wen, 2010; Huang et. al, 2014; Yin et. al, 2014; Lu, Lo, 2007). Approaches differ from using classic Banker-Charnes-Cooper (BBC) and Charnes-Cooper-Rhodes (CCR) models and Malmquist Index (Yu, Wen, 2010) to constructing more complicated functions for assessing the efficiency, but most studies only implement DEA techniques, irrespective of their nature, to classify cities, regions or provinces in China (Yin et. al, 2014; Zhang et. al, 2008).

Ecological efficiency has also been previously analysed in European cities. A recent study attempted to produce an index of scores from several DEA models that classifies 116 Italian cities whose general behaviour claims that ecologic inefficiency increases with the size of the city (Lo Storto, 2016). The same pattern was analysed for 81 provinces in Turkey considering two inputs (water resources, ecological budget) and six outputs (solid waste, number of persons using sewerage services, number of persons drinking potable water, maximum concentration of PM_{10}, maximum concentration of SO_2), integrated into different models (Üstün, 2015).

The main findings of this analysis reveal that medium-sized cities or provinces (below 1 million inhabitants) behave better than big cities and mega-cities, as larger cities have heavy industries, which drastically reduces their environmental sustainability. Gross Domestic Product growth per capita implies an expansion on the economic scale and leads inevitably to an increase in resource consumption and, implicitly, to higher pollution. But same GDP growth can lead to higher investments in research and development. Advanced technologies tend to improve pollution control and resource efficiency, leading to a higher level of environmental sustainability and to a smaller environmental footprint.

The current paper opens with a *data description* section, illustrating both the choice of variables and the dataset, continues with the *research methodology*, summarizing a few nonparametric estimators employed in the analysis, resumes further a set of *main findings* and closes with the *conclusions* to be withdrawn from this analysis.

Data Description

People release carbon dioxide through the breathing process. The bigger the city population, the higher the CO_2 emissions. But the natural carbon dioxide produced by living beings represents only a small part of total emissions, the majority being generated by burning fossil fuels for various usages, from heavy industrial processes to personal cars. Considering this assumption, a first model was built, entitled *quality of air*, whose objective is to minimize the carbon dioxide emissions.

The influence of cars on the carbon dioxide emissions raises another issue: what if the numbers of cars in a city increases at the same time with the urbanization level? Congested traffic illustrates another problem that cities and megacities are facing nowadays. With the increase in the number of partners involved in traffic, the risk of injury is also rising. On the other hand, the chances of road accidents are even greater as the infrastructure is precarious. Under these assumptions, the *traffic safety* model was proposed for the analysis, whose objective is to minimize the deaths in road accidents.

Each model requires a set of inputs and a set of outputs. Modelling the quality of air considers a single output, CO_2 emissions (Y_1), which is generated by 4 inputs: Population (X_1), Total area (X_2), Private cars registered (X_3) and Municipal waste generated (X_4). The traffic safety model uses as inputs Population (X_1), Total area (X_2) and Private

cars registered (X_3), while the output is the Number of deaths in road accidents (Y_2). All indicators were provided from Urban Audit (Eurostat database) and OECD Metropolitan database, according to year 2011. A summary statistics of the indicators is illustrated in table 1.

In the classical approach, inputs need to be minimized and outputs maximized. Both current outputs, CO_2 emissions (Y_1) and Deaths in road accidents (Y_2) cannot be maximized, as their nature is harmful. Using undesirable outputs involves either using those outputs as inputs or processing these variables through a decreasing monotone transformation to allow their maximization (Fare et al, 1989). Instead of using the initial variables Y_1 and Y_2, the monotone transformations $y_1 = 1/Y_1$, $y_2 = 1/Y_2$ respectively were used as outputs in the models previously set.

Table 1: Summary statistics

Category	*Variable*	*Minimum*	*Maximum*	*Mean*	*Standard deviation*
Inputs	Population (X_1)	166,135	9,545,591	1,008,592	1,374,139
	Total area (X_2)	18	2,654	451.6	427
	Municipal waste (X_3)	61	3,561	334.6	404.2
	Private cars registered (X_4)	57,814	2,739,129	330,398	403,329
Undesirable Outputs	CO_2 emissions (Y_1)	0.9	75.1	9.1	11.6
	Deaths in road accidents (Y_2)	1	351	28	43

Drawing the efficiency frontier requires a single input and a single output. In this regard, a dimension reduction method was performed on the dataset. We employed the approach introduced by Mouchart and Simar (2002), that avoids the curse of dimensionality, which can bias the efficiency estimators. This method creates aggregated variables, inputs or outputs, as linear combinations of the standardized variables. Principal components analysis provided us the set of weights that allowed aggregating the original inputs into a linear combination of inputs, for each model. Correlations between the aggregated inputs and the original ones are showed in table 2, proving their high dependency with the original variables.

Table 2: Correlations between the aggregated inputs and the original inputs

	Population (X_1)	*Total area (X_2)*	*Municipal waste (X_3)*	*Private cars registered (X_4)*
Aggregated input (M1)	0.938	0.826	0.937	0.840
Aggregated input (M2)	0.947	0.842	–	0.844

The analysis was performed using R version 4.0.2 (2020) and multiple packages: *stats*, *ggplot2*, *dplyr*, *FEAR*, *reshape2*, *viridis*.

Methodology

Data Envelopment Analysis (DEA) is a nonparametric technique for estimating production frontiers and a robust tool for benchmarking production units with respect to those frontiers. The concept was introduced by Charnes, Cooper, Rhodes (1978), extended by Banker, Charnes, Cooper (1984) and many others, evolved from linear programming to the probability theory and many approaches are currently under development.

Nonparametric methods have the advantage that they do not need to assume a particular mathematical form or shape for the production function. Two nonparametric estimators are available: DEA and FDH (Free Disposal Hull), both of them being robust estimators, but sensitive to outliers. Whereas DEA has a convexity assumption for the feasible production possibility set, FDH avoids this constraint, allowing only levels of input and output actually attained by individual produces.

Efficiency analysis implies an input vector $x \in \mathbb{R}_+^p$, and an output vector $y \in \mathbb{R}_+^q$. In academic literature, the *production set* is referring to the achievable combinations of input and output:

$$\psi = \{(x, y) \in \mathbb{R}_+^{p+q}, \text{where x can produce y}\} \tag{1}$$

The attainable set ψ is unknown, only a sample of units being observed:

$$\chi_n = \{(x_i, y_i), i = \overline{1, n}\} \tag{2}$$

The units that produce maximum output using minimum input are the optimal combinations, which compose the *efficiency frontier*:

$$\partial\psi = \{(x, y) \in \psi, (\theta x, y) \notin \psi, \forall\, 0 < \theta < 1 \text{ and } (x, \lambda y) \notin \psi, \forall 0 < \lambda < 1\} \tag{3}$$

which envelops the entire dataset. All decision-making units positioned along this frontier are considered technically efficient, whereas the points below the frontier are technically inefficient.

Färe (1985) proposed simultaneous changes in inputs and outputs, introducing a *hyperbolic measure of technical efficiency*, later developed by Wilson in 2011 and defined as:

$$\gamma(x, y) = \inf\{\gamma > 0 \mid (\gamma x, \gamma^{-1} y) \in \psi\} \tag{4}$$

Deprins et al (1984) suggested to measure the efficiency of a specific unit relative to the free-disposal hull (FDH) of the observations:

$$\widehat{\psi}_{FDH}(\chi_n) = \left\{(x, y) \in \mathbb{R}_+^{p+q} \,\middle|\, y \leq y_i, x \geq x_i, (x_i, y_i) \in \chi_n\right\} \tag{5}$$

Recent studies of many have extended the probabilistic approach of those estimators. This study employs nonparametric frontiers and their statistical properties as described by Simar, Wilson (2000). Suppose a random pair (X, Y) is extracted from the density $f(x, y)$ of the production set ψ, the common distribution of (x, y) can be described as following:

$$H_{XY}(x, y) = P(X \leq x, Y \geq y) \tag{6}$$

which defines the probability that decision-making unit to be dominated by another unit that produces at least the same output as , but without using a higher input than . This can be decomposed as:

$$H_{XY}(x, y) = H_{Y|X}(y|x) \cdot F_X(x) \tag{7}$$

if $H_{Y|X}(y|x) = P(Y \geq y \mid X \leq x)$ exists, where F is the repartition function $F_X(x) = P(X \leq x)$.

Thus, the hyperbolic measure of technical efficiency becomes:

$$\gamma(x, y) = \inf\{\gamma > 0 \,|HY|X(\gamma x, \gamma^{-1} y) > 0\} \tag{8}$$

The idea behind hyperbolic efficiency is to search for attainable pairs by reducing the input with γ, simultaneously with amplifying the output with γ^{-1}, those combinations being placed on a hyperbolic path.

Results

The first model follows the impact of human activity on the environment. People have a fairly large impact on the environment through their daily modern activities. As the population of a city grows, the impact on the environment will intuitively grow, consequences being largely negative. The initial purpose of this model was to minimize the amount of carbon dioxide emitted into the atmosphere, but the undesirable feature of this output required a monotone transformation (Fare et al, 1989), which has become the new output of the model.

Figure 1: FDH Efficiency frontier for Model 1 - Quality of Air.

The average efficiency estimate value for model 1 is 26%, dividing the dataset in 39 low efficiency cities (35% of the entire dataset) and 73 high efficiency cities (65% of the cities analysed). The differences between low and high efficiency cities are summarized in Figure 2. The mean efficiency estimate for the first group reaches 50%, whereas for the second group it goes down to only 12%.

One could notice significant differences in both input and output variables between those two groups in Figure 2. As the city size increases (in terms of population and total area), both the amount of municipal waste and the number of private cars registered will increase. This growth generates more carbon dioxide released into the atmosphere, leading to a lower efficiency score. Also, the bigger the city, the more difficult it is to manage all its dimensions in order to minimize the carbon dioxide emissions.

Figure 2: Summarizing differences between low and high efficiency cities in Model 1 - Quality of air.

Basel behaves extremely well considering the quality of air, being positioned on the efficiency frontier, as shown in the figure 1. In 2011 Basel was fuelled with 100% renewable energy and another Swiss city, Geneva, had the same

percentage at about 80%. In addition, Basel has the largest green roof area per capita in the world, due to numerous subsidies granted to install such roofs. These factors have a strong influence in minimizing the carbon dioxide emissions, driving Basel to be the best city according to model 1.

Figure 3: Distribution of high and low efficiency cities by country, based on Model 1 – Quality of air.

At the opposite pole, some of the worst quality of air cities are Berlin, Madrid, Rome, Barcelona, Hamburg, Milan, and Paris. They all have major issues in managing carbon dioxide emissions, both due to crowded population and heavy traffic. Low efficiency cities are typically large cities, generating massive amounts of carbon dioxide due to various factors. All inputs have large values for these cities, which determines low efficiency estimates, below the dataset average.

The second model, entitled *traffic safety*, emerged from the previous model which tracks the effect of people, cars and municipal waste on the air quality. When the number of cars in a city increases, traffic becomes heavier, traffic jams appear every day and traffic safety is compromised. The number of deaths in road accidents is used as a measure of traffic safety, an indicator also employed as undesirable output, similarly to the previous model.

The average efficiency estimate obtained for model 2 is about 29%, which reveals 40 cities with high efficiency and 72 with low efficiency. The average number of deaths in road accidents is only 8 for high efficiency cities and reaches 37 in the case of low efficiency cities. A lower population involves a lower number of cars and implicitly, fewer casualties in road accidents.

Basel is positioned on the efficiency frontier, with a maximum efficiency estimate of 100%. It is a city with an outstanding transport infrastructure, concerning not only the public transportation, but also bicycles and pedestrians. Its comprehensive public transportation system offers a variety of transfer connections and has a popular reputation for punctuality. Most parts of the city can be easily and conveniently reached by alternative means of transportation, leading to the conclusion that cars aren't essential here. In this context, there are plenty of households that do not own a private car.

Figure 4: FDH Efficiency frontier for Model 2 - Traffic safety.

Münster and Karlsruhe are two cities from the efficiency frontier that behave exemplary. The main reason that determines the efficiency of German cities is the strict driving license system, which manages to produce very good drivers. German roads are extremely well maintained, being regularly inspected for discovering and correcting any type of irregularities. Cars are also subject to periodic and thorough inspections every two years to check and maintain their technological safety. With this context in mind, it is not surprisingly that Germany has many high efficiency cities when referred to the traffic safety model.

Figure 5: Summarizing differences between low and high efficiency cities in Model 2 - Traffic safety.

According to model 2, some of the cities with the poorest traffic safety are Berlin, Madrid, Rome, Paris, Milan, Barcelona, Hamburg, Budapest, and Naples. Congested traffic is a common issue across these megacities, which significantly decreases the traffic safety and also increases the number of casualties and deaths in road accidents. As

in the previous model, the group of low efficiency cities includes many big cities, in terms of both population and area, leading to a high number of cars, which drives a congested and unsafe traffic. The existence of many traffic arteries and many road users leads to an increase in the number of accidents, driving unfortunately an elevated number of deaths. Therefore, in such cases traffic safety is extremely difficult to achieve and monitor.

Figure 6: Distribution of high and low efficiency cities by country, based on Model 2 – Traffic safety.

Investigating both models in parallel reveals high efficiency cities across both quality of air and traffic safety. A few of them are worth mentioning, such as Basel, Geneva (Switzerland), Saarbrücken, Freiburg im Breisgau and Munster (Germany). At the opposite pole, low efficiency cities with respect to both models are the greater cities included in the analysis: Paris, Madrid, Berlin, Milan, Barcelona, Rome, Vienna, Budapest, Amsterdam.

Conclusions

Urbanization and mass industrialization have led to a more developed society that is directly proportional to the degradation of the environment. The effects of global warming are both noticeable and alarming across all countries, being due to various human activities that range from heavy industries to the recent dependency of personal cars.

The purpose of this paper was to analyse the efficiency of 112 European cities using nonparametric techniques, across two dimensions: air quality and traffic safety. Findings revealed that small-sized cities behave better, minimizing their carbon dioxide emissions and number of deaths in road accidents. Cities with a low population release less carbon dioxide into the atmosphere, both due to their respiration and waste generation. Besides, a small population involves a smaller number of cars, reducing simultaneously the traffic and its impact on the environment.

Basel (Switzerland) is a worthy example, classified as high efficiency with a maximum efficiency estimate in both models. This city behaves excellent at managing to minimize both greenhouse gas emissions and the harmful traffic effects by granting green roof subsidies, using full renewable energy and continuously encouraging its inhabitants to use alternative means of transportation.

A phenomenon that should be studied in correlation with the effects of traffic and the quality of air is represented by the technological advance. New technologies allow the construction of electric cars, which replace the combustion system with electricity, dramatically reducing gas emissions only by replacing classic cars with electric cars. This measures also applies to the traffic effects, both by reducing noise pollution and by improving safety of passengers and road users by using smart systems.

Future directions of research imply improving the models by applying more complex techniques and extending the dataset with other countries and a different timeframe. Both quality of air and traffic safety are aspects that describe the quality of life, which could be further investigated by including an extended set of variables that describe the economic and social development. An interesting direction could be studying the level of education in parallel with the two dimensions already analysed and determining the correlation between education and air quality and traffic safety, as well as the meaning of this relationship.
