As announced in our previous works, this paper is part of a larger research that deals with sustainable development and environmental protection. For a government to make decisions about the supply and financing of public goods according to the criteria recommended by economists requires that it have lots of difficult-to-acquire information, and can involve equity questions as well as efficiency questions. As such, this paper shows that government intervention offers the possibility of realising efficiency gains, by eliminating or mitigating situations of market failure. First we discussed that many environmental resources are not subject to well-defined and clearly established property rights. As we shall demonstrate, efficiency gains may be obtained if government can create and maintain appropriate institutional arrangements for establishing and supporting property rights as the basis for bargaining. However, we shall also see that the scope of this kind of government action to correct market failure is limited to cases where non-rivalry and non-excludability are absent. Many environmental problems do involve non-rivalry and non-excludability.

Keywords: Allocation, Economic Efficiency, Environmental Services, Market Economy, Public Goods.

Introduction

An allocation of resources is said to be efficient if it is not possible to make one or more persons better off without making at least one other person worse off. Conversely, an allocation is inefficient if it is possible to improve someone's position without worsening the position of anyone else. A gain by one or more persons without anyone else suffering is known as a Pareto improvement [Buchanan, 1962; Mock, 2011; Wu *et al.*, 2016]. When all such gains have been made, the resulting allocation is sometimes referred to as Pareto optimal, or Pareto efficient. A state in which there is no possibility of Pareto improvements is sometimes referred to as being allocatively efficient, rather than just efficient, so as to differentiate the question of efficiency in allocation from the matter of technical efficiency in production.

Hence, in a previous research [Bulearca and Popescu, 2019], we laid out the conditions that characterize an efficient allocation. In that paper, we showed that, given 'ideal' circumstances concerning institutions and behavior, a system of markets would produce an efficient allocation. We noted that the ideal circumstances are truly ideal, in that they do not describe any actual economy. Actual market economies depart from the ideal circumstances in a variety of ways, and the allocations that they produce are not efficient.

Economists use welfare economics theory [O'Connell, 1982; Mäler, 2011; Bernheim, 2008; Feldman, 2008; Deardoff, 2014] to identify 'market failures' – situations where actual circumstances depart from the ideal – and to recommend policies to correct them so that actual economies perform better in relation to the objective of efficiency [Howarth, 2012]. Much of environmental and resource economics is welfare economics of this sort. It is concerned with identifying and

correcting market failure in relation to the services that the environment provides to the economy.

The existence of markets for environmental services

To recapitulate from our previous paper [Bulearca and Popescu, 2019], we have seen that for markets to produce efficient allocations [Howarth, 2012], it is necessary that:

1. Markets exist for all goods and services produced and consumed.
2. All markets are perfectly competitive.
3. All transactors have perfect information.
4. Private property rights are fully assigned in all resources and commodities.
5. No externalities exist.
6. All goods and services are private goods. That is, there are no public goods.
7. All utility and production functions are 'well behaved' [Perman *et al.*, 2003].
8. All agents are maximisers [Perman *et al.*, 2003].

Clearly, #1 here is fundamental. If there are goods and services for which markets do not exist, then the market system cannot produce an efficient allocation, as that concept applies to all goods and services that are of interest to any agent, either as utility or production function arguments. Further, #4 is necessary for #1 – a market in a resource or commodity can only exist where there are private property rights in that resource or commodity.

We can define a property right as: a bundle of characteristics that convey certain powers to the owner of the right [Hartwick and Olewiler, 1986]. These characteristics concern conditions of appropriability of returns, the ability to divide or transfer the right, the degree of exclusiveness of the right, and the duration and enforceability of the right. Where a right is exclusive to one person or corporation, a private property right is said to exist.

In our previous papers [Neagu *et al.,* 2017, 2019a, 2019b; Bulearca and Popescu, 2019] we provided a classification of the services that the natural environment provides to economic activity [Mas-Colell, 2013]. Let us now briefly consider the different classes of service distinguished there in relation to the question of the existence of private property rights. Where these do not exist, market forces cannot allocate efficiently. If efficiency is the objective, some kind of public policy intervention is required. Our remarks here are intended only to provide a general overview, as a guide to what follows in the rest of this paper. The details of any particular case can be quite complicated.

In regard to the provision of inputs to production, natural resources, we made two major distinctions – between flow and stock resources, and, for the latter, between renewables and non-renewables. Generally, there are no private property rights in flow resources as such. Individuals or corporations do not, for example, have property rights in flows of solar radiation. They may, however, have property rights in land, and, hence, in the ability to capture the solar radiation falling on that land. To see the complexities that can arise, note that in some jurisdictions a householder may be able to prevent others taking action which reduces the light reaching her property, though this may depend on the nature and purpose of the action. Deposits of nonrenewable natural resources are, generally, subject to private property rights. Often these reside ultimately with the government, but are sold or leased by it to individuals and/or corporations. The problems arising from the non-existence of private property rights are not central to the economics of nonrenewable resources.

They do, on the other hand, feature large in the renewable resource economics literature. Many, but not all, of the biotic populations exploited by humans as hunter–gatherers, rather than agriculturists, are not subject to private property rights. The standard example of the case where they are not is the ocean fishery. Where private property rights are absent, two sorts of situation may obtain. In the case of 'open-access resources' exploitation is uncontrolled.

The term 'common-property resources' is used whenever some legal or customary conventions, other than private property rights, regulate exploitation of the resource. Whereas an open-access regime definitely will not promote exploitation that corresponds to efficiency, a common property regime may do so given the appropriate conventions and regulation. Much of the modern fisheries economics literature, as will be seen in a future paper, is concerned with the

design of systems of government regulation of common property that will promote behavior consistent with efficiency on the part of the private agents actually exploiting the fishery.

The second class of environmental service that was distinguished was that of receptacle for the wastes arising in economic activity. Generally, for most of history and for many wastes, the environment as waste sink has not been subject to private property rights, and has been, in effect, an open-access resource. With increasing awareness of the problems of pollution arising, states have moved to legislate so as to convert many waste sinks from open-access resources to common-property resources.

Much of the research is about the economic analysis that is relevant to the public-policy questions arising. What is the level of pollution that goes with efficiency? How should the behavior of waste dischargers be regulated? We shall introduce the basic ideas involved here later in the future works, when discussing 'externalities'.

The case of the amenity services that the environment provides is rather like that of flow resources, in that the service itself will not generally be subject to private property rights, though the means of accessing it may be. Thus, for example, nobody can own a beautiful view, but the land that it is necessary to visit in order to see it may be privately owned.

Private property rights in a wilderness area would allow the owner to, say, develop it for agriculture or extractive resource use, thus reducing the amenity services flow from the area, or to preserve the wilderness. While in principle the owner could charge for access to a wilderness area, in practice this is often infeasible. Further, some of the amenity services that the area delivers do not require access, and cannot be charged for by the owner. The revenue stream that is available under the preservation option is likely to understate the true value to society of that option. This is not true of the development option. In this case, a decision as between the options based on market revenues will be biased in favor of the development option, and the operative question in terms of market failure is whether the existing private property rights need to be attenuated, so as to secure the proper, efficient, balance between preservation and development. This sort of issue is dealt with in a future paper.

The life-support services provided by the natural environment are not subject to private property rights. Consider, as an example, the global atmosphere, the carbon cycle and the climate system. Historically, the global atmosphere has been a free-access resource. As briefly discussed in the previous already mentioned papers, anthropogenic emissions of carbon dioxide have increased atmospheric concentrations of that greenhouse gas. The consensus of expert judgement is that this has affected the way that the global climate system works, and that unless action is taken to reduce the rate of growth of anthropogenic carbon dioxide emissions, further change, on balance harmful to human interests, will occur. Given this, most nations are now parties to an international agreement to act to curb the rate of growth of carbon dioxide and other greenhouse gas emissions. This agreement is discussed in future papers. It can be seen as a first step in a process of transforming the global atmosphere from a free-access to a common-property resource.

Public Goods

One of the circumstances, noted #6 in the listing above, required for it to be true that a pure market system could support an efficient allocation is that there be no public goods. Some of the services that the natural environment provides to economic activity have the characteristics of public goods, and cannot be handled properly by a pure market system of economic organization. So we need to explain what public goods are, the problems that they give rise to for markets, and what can be done about these problems.

What are public goods? This turns out to be a question to which there is no simple short answer. Public goods have been defined in different ways by different economists. At one time it was thought that there were just private goods and public goods. Now it is recognized that pure private and pure public goods are polar cases, and that a complete classification has to include intermediate cases. It turns out that thinking about these matters helps to clarify some other issues relevant to resource and environmental economics.

There are two characteristics of goods and services that are relevant to the public/private question. These are rivalry and

excludability. What we call rivalry is sometimes referred to in the literature as divisibility. Table 1 shows the fourfold classification of goods and services that these two characteristics give rise to, and provides an example of each type. Rivalry refers to whether one agent's consumption is at the expense of another's consumption. Excludability refers to whether agents can be prevented from consuming. We use the term 'agent' here as public goods may be things that individuals consume and/or things that firms use as inputs to production. In what follows here we shall generally discuss public goods in terms of things that are of interest to individuals, and it should be kept in mind that similar considerations can arise with some inputs to production.

Table 1: Characteristics of private and public goods

	Excludable	Non-excludable
Rivalrous	**Pure private good** Ice cream	**Open-access resource** Ocean fishery (outside territorial waters)
Non-rivalrous	**Congestible resource** Wilderness area	**Pure public good** Defence

Source: Authors own assumptions.

Pure private goods exhibit both rivalry and excludability. These are 'ordinary' goods and services, the example being ice cream. For a given amount of ice cream available, any increase in consumption by A must be at the expense of consumption by others, is rival. Any individual can be excluded from ice cream consumption. Ice cream comes in discrete units, for each of which a consumption entitlement can be identified and traded (or gifted). Pure public goods exhibit neither rivalry nor excludability. The example given is the services of the national defence force. Whatever level that it is provided at is the same for all citizens of the nation. There are no discrete units, entitlement to which can be traded (or gifted). One citizen's consumption is not rival to, at the cost of, that of others, and no citizen can be excluded from consumption.

Open-access natural resources exhibit rivalry but not excludability. The example given is an ocean fishery that lies outside of the territorial waters of any nation. In that case, no fishing boat can be prevented from exploiting the fishery, since it is not subject to private property rights and there is no government that has the power to treat it as common property and regulate its exploitation. However, exploitation is definitely rivalrous. An increase in the catch by one fishing boat means that there is less for other boats to take.

Congestible resources exhibit excludability but not, up to the point at which congestion sets in, rivalry. The example given is the services to visitors provided by a wilderness area. If one person visits a wilderness area and consumes its services – recreation, wildlife experiences and solitude, for example – that does not prevent others from consuming those services as well. There is no rivalry between the consumption of different individuals, provided that the overall rate of usage is not beyond a threshold level at which congestion occurs in the sense that one individual's visit reduces another's enjoyment of theirs. In principle, excludability is possible if the area is either in private ownership or subject to common-property management. In practice, of course, enforcing excludability might be difficult, but, often, given limited points of access to vehicles it is not.

The question of excludability is a matter of law and convention, as well as physical characteristics. We have already noted that as the result of an international agreement that extended states' territorial waters, some ocean fisheries that were open access have become common property. We also noted above that a similar process may be beginning in respect to the global atmosphere, at least in regard to emissions into it of greenhouse gases. In some countries beaches cannot be privately owned, and in some such cases while beaches actually have the legal status of common property they are generally used on a free-access basis. This can lead to congestion. In other countries private ownership is the rule, and private owners do restrict access. In some cases where the law enables excludability, either on the basis of private ownership or common property, it is infeasible to enforce it. However, the feasibility of exclusion is a function of technology. The invention of barbed wire and its use in the grazing lands of North America is a historical example.

Satellite surveillance could be used to monitor unauthorized use of wilderness areas, though clearly this would be expensive, and presumably at present it is not considered that the benefit from so doing is sufficient to warrant meeting the cost.

In the rest of this paper we shall consider pure public goods, which we will refer to simply as 'public goods'. As noted, we will be returning to a detailed consideration of open-access resources, and common-property resources, at several places later in the paper. The next paragraphs consider some examples of public goods an then look at property rights in relation to biodiversity, and the arising implications for incentives regarding conservation and medicinal exploitation.

The classic textbook *examples of public goods* are lighthouses and national defence systems. These both possess the properties of being non-excludable and non-rival. If you or I choose not to pay for defence or lighthouse services, we cannot be excluded from the benefits of the service, once it is provided to anyone. Moreover, our consumption of the service does not diminish the amount available to others. Bridges also share the property of being non-rival (provided they are not used beyond a point at which congestion effects begin), although they are not typically non-excludable.

Many environmental resources are public goods, as can be seen from the following examples. You should check, in each case, that the key criterion of non-rivalry is satisfied. The benefits from biological diversity, the services of wilderness resources, the climate regulation mechanisms of the earth's atmosphere, and the waste disposal and reprocessing services of environmental sinks all constitute public goods, provided the use made of them is not excessive. Indeed, much public policy towards such environmental resources can be interpreted in terms of regulations or incentives designed to prevent use breaking through such threshold levels.

Some naturally renewing resource systems also share public goods properties. Examples include water resource systems and the composition of the earth's atmosphere. Although in these cases consumption by one person does potentially reduce the amount of the resource available to others (so the resource could be 'scarce' in an economic sense), this will not be relevant in practice as long as consumption rates are low relative to the system's regenerative capacity.

Finally, note that many public health measures, including inoculation and vaccination against infectious diseases, have public goods characteristics, by reducing the probability of any person (whether or not he or she is inoculated or vaccinated) contracting the disease. Similarly, educational and research expenditures are, to some extent, public goods.

As regarding *property rights and biodiversity*, we may argue that among the many sources of value that humans derive from biological diversity is the contribution it makes to the pharmaceutical industry. This is examined in a volume which brings together a collection of papers on the theme of property rights and biological diversity [Swanson, 1995a]. For the purposes of our analysis, we summarise here some of the central issues raised there.

Swanson begins by noting that the biological characteristics of plants (and, to a lesser extent, animals) can be classified into primary and secondary forms. Primary characteristics concern the efficiency with which an organism directly draws upon its environment. But another set of characteristics – secondary characteristics – are also of great importance in the survivability of an organism within its environment. To survive in a particular ecological complex, an organism must be compatible with other living components of its environment. The secondary metabolites which plants develop are crucial in this respect.

Two things are virtually certain. First, a large number of substances are being, or have been, used in specific cultural contexts without their usefulness having become generally known. Secondly, we have only begun to scratch the surface of the range of possible uses that the biosphere permits. Our collective knowledge encompasses only a small part of what there is to know. All of this suggests that the conservation of biological diversity is of enormous value. This was recognised in the 1992 Rio Convention on Biological Diversity, which stated that biological diversity must be conserved and cultural/institutional diversity respected. Yet the institutional arrangements we have in place are poorly designed to conserve that diversity. Swanson [1995a, 1995b] focuses on the role that property rights plays. The nub of the problem is that the system of property rights which has been built up over the past 100 years rewards the creators of information in

very different ways.

A system which rewards people who create useful information by granting them exclusive rights to market products that incorporate that information is of immense value. Intellectual property rights, in the form of patents and the like, give market value to information, and create incentives to search for and exploit more information. However, Swanson points out that not all forms of information have such market value. In particular, the existence of biologically diverse ecosystems creates a reservoir of potentially useful information, but no system of property rights exists which rewards those who build up or sustain biodiversity.

What is needed, therefore, is a property rights system that brings the value of biodiversity back into human decision-making. So-called 'intellectual' property rights should be generalised to include not only intellectual but natural sources of information. Put another way, it is *information* property rights rather than just *intellectual* property rights that should be protected and rewarded. An ideal system would reward any investment that generates information, including that which is produced naturally.

Public Goods and Economic Efficiency

For our economy with two persons and two private goods, we found that the top-level, product-mix, condition for allocative efficiency was:

$$\text{MRUS}^{\text{A}} = \text{MRUS}^{\text{B}} = \text{MRT} \tag{1}$$

which is equation MRUS = $\frac{P_X}{P_Y}$ [Bulearca and Popescu, 2019] written slightly differently. Hence, for a two-person economy where *X* is a public good and *Y* is a private good, the corresponding top-level condition is:

$$\text{MRUS}^{\text{A}} + \text{MRUS}^{\text{B}} = \text{MRT} \tag{2}$$

We have shown that, given certain circumstances, the first of these will be satisfied in a market economy. It follows that the condition which is equation (2) will not be satisfied in a market economy. A pure market economy cannot supply a public good at the level required by allocative efficiency criteria. A simple numerical example can provide the rationale for the condition that is equation (2).

Suppose that an allocation exists such that MRT = 1, MRUS^{A} = 1/5 and MRUS^{B} = 2/5, so that MRUS^{A}+ MRUS^{B} < MRT. The fact that the MRT is 1 means that, at the margin, the private and public commodities can be exchanged in production on a one-for-one basis – the marginal cost of an extra unit of *X* is a unit of *Y*, and vice versa. The fact that MRUS^{A} is 1/5 means that A could suffer a loss of 1 unit of *X*, and still be as well off if she received 1/5th of a unit of *Y* by way of compensation. Similarly, the fact that MRUS^{B} is 2/5 means that B could suffer a loss of 1 unit of *X*, and still be as well off if he received 2/5 of a unit of *Y* by way of compensation.

Now, consider a reduction in the production of *X* by 1 unit. Since *X* is a public good, this means that the consumption of *X* by both A and B will fall by 1 unit. Given the MRT of 1, the resources released by this reduction in the production of *X* will produce an extra unit of *Y*. To remain as well off as initially, A requires 1/5 of a unit of *Y* and B requires 2/5 of a unit. The total compensation required for both to be as well off as they were initially is 1/5 + 2/5 = 3/5 units of *Y*, whereas there is available 1 unit of *Y*. So, at least one of them could actually be made better off than initially, with neither being worse off. This would then be a Pareto improvement. Hence, the initial situation with MRUS^{A}+ MRUS^{B} < MRT could not have been Pareto optimal, efficient.

Now consider an initial allocation where MRT = 1, MRUS^{A} = 2/5 and MRUS^{B} = 4/5 so that MRUS^{A}+ MRUS^{B} > MRT. Consider an increase of 1 unit in the supply of the public good, so that the consumption of *X* by both A and B increases by 1 unit. Given MRT = 1, the supply of *Y* falls by 1 unit. Given MRUS^{A} = 2/5, A could forgo 2/5 units of *Y* and remain

as well off as initially, given *X*A increased by 1. Given $MRUS^B = 4/5$, B could forgo 4/5 units of *Y* and remain as well off as initially, given *X*B increased by 1. So, with an increase in the supply of *X* of 1 unit, the supply of *Y* could be reduced by 2/5 + 4/5 = 6/5 without making either A or B worse off. But, in production the *Y* cost of an extra unit of *X* is just 1, which is less than 6/5. So, either A or B could actually be made better off using the 'surplus' *Y*. For $MRUS^A + MRUS^B >$ MRT there is the possibility of a Pareto improvement, so the initial allocation could not have been efficient.

Since both $MRUS^A + MRUS^B <$ MRT and $MRUS^A + MRUS^B >$ MRT are situations where Pareto improvements are possible, it follows that $MRUS^A + MRUS^B =$ MRT characterizes situations where they are not, so it is a necessary condition for allocative efficiency. In the case of a private good, each individual can consume a different amount.

Efficiency requires, however, that all individuals must, at the margin, value it equally. It also requires, see equation (1), that the common valuation, at the margin, on the part of individuals is equal to the cost, at the margin, of the good. In the case of a public good, each way, it is *information* property rights rather than just *intellectual* property rights that should be protected and rewarded. An ideal system would reward any investment that generates information, including that which is produced naturally.

It is ironic that the 'success' of modern scientific systems of medicine may be contributing to a loss of potentially useful information. Swanson points to the fact that knowledge which is used with demonstrable success in particular cultural contexts often fails to be widely recognized and rewarded. The difficulty has to do with the fact that this knowledge is not codified in ways that satisfy conventional scientific standards. However, individual must, by virtue of non-rivalry, consume the same amount of the good. Efficiency does not require that they all value it equally at the margin. It does require, see equation (2), that the sum of their marginal valuations be equal to the cost, at the margin, of the good.
Markets cannot provide public goods in the amounts that go with allocative efficiency. In fact, markets cannot supply public goods at all. This follows from their non-excludability characteristic. A market in widgets works on the basis that widget makers exchange the rights to exclusive control over defined bundles of widgets for the rights to exclusive control over defined bundles of something else. Usually, the exchange takes the form of the exchange of widgets for money. This can only work if the widget maker can deny access to widgets to those who do not pay, as is the case with private goods. Where access to widgets is not conditional on payment, a private firm cannot function as it cannot derive revenue from widget production.

Given that the direct link between payment and access is broken by non-excludability, goods and services that have that characteristic have to be supplied by some entity that can get the revenue required to cover the costs of production from some source other than the sale of such goods and services. Such an entity is government, which has the power to levy taxes so as to raise revenue. The supply of public goods is (part of) the business of government. The existence of public goods is one of the reasons why all economists see a role for government in economic activity.

Given that it is the government that must supply a public good, the question which naturally arises for an economist is: what rule should government follow so as to supply it in amounts that correspond to efficiency? In principle, the answer to this question follows from equation (2). In a two-person, two-commodity economy, the efficient level of supply for the public good is the level at which the sum of two MRUSs is equal to the MRT between it and the private good. Actual economies have many individuals and many private commodities. The first point here presents no difficulty, as it is clear that we simply need to extend the summation over all MRUSs, however many there are. As regards the second, it is simply a matter of noting that the MRT is the marginal cost in terms of forgone private goods consumption, so that the rule becomes: supply the public good at the level where the sum of all the MRUSs is equal to the marginal cost. Now, it follows from its definition that the MRUS is the same as marginal willingness to pay, MWTP, so this rule can be stated as: supply the public good at the level where aggregate marginal willingness to pay is equal to marginal cost.

Preference Revelation and The Free-Rider Problem

While the rule for the efficient supply of a public good is simple enough at the level of principle, its practical application faces a major difficulty. In order to apply the rule, the government needs to know the preferences, in terms of marginal

willingness to pay, of all relevant individuals. It is in the nature of the case that those preferences are not revealed in markets. Further, if the government tries to find out what they are in some other way, then individuals have (on the standard assumptions about their motivations and behavior) incentives not to truthfully reveal their preferences. Given that all consume equal amounts of a public good, and that exclusion from consumption on account of non-payment is impossible, individuals will try to 'free-ride' with respect to public goods provision.

To bring out the basic ideas here in a simple way we shall consider an example where the problem is to decide whether or not to provide a discrete amount of a public good, rather than to decide how much of a public good to supply. The nature of the problem is the same in either case, but is easier to state and understand in the 'yes/no' case than in the 'how much?' case. At issue is the question of whether or not to install street lighting. We will first look at this when there is no government. There are two individuals A and B. Both have an endowment of private goods worth mu1000. Installing the street lighting will cost mu100 (mu is the acronym for monetary units). The two individuals both have preferences such that they would be willing to pay mu60 for the installation of street lighting. The analysis that follows is not dependent on the two individuals being equally well off and having the same preferences, that just makes the story easier to tell initially. An obvious modification of the rule derived for the efficient level of provision of a public good derived above for the 'yes/no' situation is that the decision should be 'yes' if the sum of individuals' willingness to pay is equal to or greater than the cost. In this case it is greater: mu60 + mu60 = mu120.

Now, suppose that A and B agree to proceed in the following way. Each will independently write down on a piece of paper either 'Buy' or 'Don't buy'. If when the two pieces of paper are brought together, both have said 'Buy', they buy the street lighting jointly and share the cost equally. For two 'Don't buy' responses, the street lighting is not bought and installed. In the event of one 'Buy' and one 'Don't buy', the street lighting is bought and the individual who voted 'Buy' pays the entire cost. The four possible outcomes are shown in the cells of Table 2 in terms of the monetary valuations on the part of each individual, that of A to the left of the slash, that of B to the right. This is a 'game' with the structure often referred to as 'the prisoner's dilemma' because of the setting in which the structure is often articulated. A 'game' is a situation in which agents have to take decisions the consequences of which depend on the decisions of other agents.

Table 2: The preference revelation problem

		B	
		Buy	Don't buy
A	Buy	1010/1010	960/1060
	Don't buy	1060/960	1000/1000

Source: Authors own assumptions.

In the bottom right cell, the decision is not to go ahead. Neither incurs any cost in regard to street lighting and neither gets any benefit, so both are in their initial situations with mu1000. Suppose both responded 'Buy'. Then with the street lighting installed, as shown in the top left cell, the situation for both can be expressed in monetary terms as mu1010. Each has paid mu50, half of the total of mu100, for something valued at mu60, so gaining by mu10 as compared with the no street lighting situation. Suppose A wrote 'Buy' and B wrote 'Don't buy'. The lighting goes in, A pays the whole cost and B pays nothing. A pays mu100 for something she values at mu60, and goes from mu1000 to mu960. B pays nothing for something he values at mu60, and goes from mu1000 to mu1060. This is shown in the top right cell.

The bottom left cell has the entries of that cell reversed, because B pays the whole cost. Now, clearly both are better off if both write 'Buy' and the street lighting is bought. But, either will be even better off if, as in the bottom left or top right cell, they can 'free-ride'. For each individual thinking about what to write on their piece of paper, writing 'Don't buy' is the dominant strategy. Consider individual B. If A goes for 'Buy', B gets to mu1010 for 'Buy' and to mu1060 for 'Don't buy'. If A goes for 'Don't buy', B gets to mu960 for 'Buy' and to mu1000 for 'Don't buy'. Whatever A does, B is better off going for 'Don't buy'. And the same is true for A, as can readily be checked. So, while installing the lighting and sharing the cost equally is a Pareto improvement, it will not come about where both individuals act independently to serve

their own self-interest. What is needed is some kind of coordination, so as to bring about the Pareto improvement which is going ahead with the street lighting.

Given what we have already said about public goods, government would seem the obvious way to bring about the required coordination. It can, in principle, ascertain whether the installation of street lighting is justified on efficiency grounds, and if it is install it and cover the cost by taxing each individual according to their willingness to pay. However, in practice, given self-seeking individuals, the free-rider problem also attends this program. The problem comes up in trying to get the individuals to reveal their true preferences for the public good.

Suppose now that a government does exist, and that it wants to follow efficiency criteria. It knows that installing the street lighting will cost mu100, and that it should install it if total willingness to pay is equal to or greater than that. It does not know the preferences, in terms of willingness to pay, of the two individuals who, in this simple example, constitute the citizenry. The obvious thing for it to do is to ask them about it. It does that, stating that the cost of installation will be met by a tax on each individual which is proportional to their willingness to pay and such that the total tax raised is equal to the cost of installation. If each individual truly reports willingness to pay mu60, the street lighting will go ahead and each will pay mu50 in tax. This represents a Pareto improvement – see the top left cell in Table 2. The problem is that the incentives facing each individual are not such as to guarantee truthful preference revelation.

Given that tax liability will be proportional to stated willingness to pay, there is an incentive to understate it so as to reduce the tax liability if the street lighting goes ahead, and to get something of a free ride. In the example of Table 2, if B states willingness to pay as mu40 and A tells the truth, the street lighting will go ahead – stated aggregate willingness to pay mu100 – and B will pay 40%, rather than 50%, of mu100. If A also understates willingness to pay by mu20, the government's estimate of aggregate willingness to pay will mean that it does not go ahead with the lighting. The attempt to free-ride may fail if many make it.

The problem of securing truthful preference revelation in regard to the supply of public goods has been the subject of a lot of investigation by economists. It turns out to be very difficult to come up with systems that provide the incentives for truthful revelation, and are feasible [Deardoff, 2014; Brown *et al.,* 2015; de Man, 2016]. Here we will, in order to indicate the nature of the difficulties, simply note one idea that is intended to overcome the free-riding incentives generated by the system just discussed. There the problem was that an individual's tax liability depended on stated willingness to pay. This could be avoided by the government's asking about willingness to pay on the understanding that each individual would, if the installation went ahead, pay a fixed sum.

Suppose that the government divided the cost by the number of individuals, and stated that the fixed sum was mu50 per individual. For both individuals, true willingness to pay is mu60. Both have an incentive now to overstate their willingness to pay. Both value the street lighting at more than it is going to cost them so they want to see it installed. Both know that this is more likely the higher they say that their willingness to pay is, and that however much in excess of mu60 they report they will only pay mu50. In this case overstating willingness to pay produces the right decision. The street lighting should be installed on the basis of true aggregate willingness to pay, and will be installed on the basis of reported willingness to pay. If the lighting is installed, each individual is better off, there is a Pareto improvement.

Suppose, however, that A's willingness to pay is mu55 and B's is mu40. In that case, aggregate willingness to pay is mu95, less than the cost of mu100, and the street lighting should not be installed. In this case, on the understanding that each would pay a tax of mu50 if the lighting is installed, A would have an incentive to overstate her willingness to pay as before, but B would have an incentive to understate his. In fact, it would make sense for B to report willingness to pay as mu0 – if the lighting goes ahead he pays mu50 for something worth just mu40 to him, so he will want to do the most he can to stop it going ahead. Whether it does go ahead or not depends on how much A overstates her willingness to pay by. If A reports mu200 or more, despite B reporting mu0, the street lighting will be installed when on efficiency grounds it should not be.

Finally, this simple example can be used to show that even if the government could secure the truthful revelation of preferences, public goods supply is still a difficult problem. Suppose that A's true willingness to pay is mu60 and B's is

mu41, and that somehow or other the government knows this without needing to ask the individuals. The government has to decide how to cover the cost. It could tax each in proportion to willingness to pay, but given that A and B are initially equally wealthy in terms of private goods, this is in practice unlikely as it would be regarded as unfair. Taxing each at equal shares of the cost would be likely to be seen as the 'fair' thing to do. In that case, A would pay mu50 for a benefit worth mu60, and B would pay mu50 for a benefit worth mu41.

In monetary terms, as the result of installing the lighting, A would go from mu1000 to mu1010 and B would go from mu1000 to mu991. Since there is a loser this is not a Pareto improvement, though it is a potential Pareto improvement – we are into the domain of the Kaldor–Hicks–Scitovsky test [Scitovsky, 1976; Deardoff, 2014]. By looking at equally wealthy individuals, we avoided the problem that efficiency gains are not necessarily welfare gains. Suppose that the gainer A were much richer than the loser B. Then, the question arises as to whether gains and losses should be given equal weight in coming to a decision.

Conclusions

For a government to make decisions about the supply and financing of public goods according to the criteria recommended by economists requires that it have lots of difficult-to-acquire information, and can involve equity questions as well as efficiency questions.

In this paper we have shown that government intervention offers the possibility of realising efficiency gains, by eliminating or mitigating situations of market failure. First, many environmental resources are not subject to well-defined and clearly established property rights. As we have seen, efficiency gains may be obtained if government can create and maintain appropriate institutional arrangements for establishing and supporting property rights as the basis for bargaining. However, we have also seen that the scope of this kind of government action to correct market failure is limited to cases where non-rivalry and non-excludability are absent. Many environmental problems do involve non-rivalry and non-excludability.

In such cases, possible government interventions to correct market failure are often classified into two groups. So-called command-and-control instruments take the form of rules and regulations prohibiting, limiting or requiring certain forms of behaviour. Fiscal instruments – tax and subsidy systems, and marketable permits – are designed to create appropriate patterns of incentives on private behaviour. We have looked at taxation briefly in this paper, and we shall explore all of these instruments in depth in our future papers. As noted immediately above, another form that government intervention to correct market failure could take is providing information, or funding research activity that can increase the stock of knowledge. The arguments we have used so far in this paper have all pointed to the possibility of efficiency gains arising from public-sector intervention in the economy. But actual government intervention does not always or necessarily realise such gains, and may entail losses.

It would be wrong to conclude from an analysis of 'market failure' that all government intervention in the functioning of a market economy is either desirable or effective. First, the removal of one cause of market failure does not necessarily result in a more efficient allocation of resources if there remain other sources of market failure. We discussed this above, using the case of the polluting monopolist as an illustration. A second consideration is that government intervention may itself induce economic inefficiency. Poorly designed tax and subsidy schemes, for example, may distort the allocation of resources in unintended ways. Any such distortions need to be offset against the intended efficiency gains when the worth of intervention is being assessed. In some cases, the chosen policy instruments may simply fail to achieve desired outcomes. This is particularly likely in the case of instruments that take the form of quantity controls or direct regulation.

Many of the services that the environment provides involve some kind of market failure, and hence the levels of provision in a market system will not be those corresponding to allocative efficiency. Much of resource and environmental economics is about devising ways to intervene in the market system so as to promote efficiency in the use of environmental services. In this respect, in our future papers we shall introduce some of the basic ideas involved here. Firstly we shall apply the basic ideas to the problem of environmental pollution. Secondly we shall extend the basic ideas to cover intertemporal allocation problems, and then we shall look, mainly, at the welfare economics of the amenity services that

the environment provides. Finally other papers shall deal, mainly, with the economics of natural resources as inputs to production.

Abstract

The world has increasingly been establishing standards for industrial safety and health to improve level of occupational safety and health (OH&S) in the organizations. One of the most effective way to achieve this goal is to implement in the organizations OH&S management system (OH&SMS) based on the international standards. The purpose of this paper is to analyze the influence of OH&SMS on a safety status on the example of the construction company. The construction sector was chosen because in this area the greatest number of fatal accidents is recorded in Poland. Moreover the sector remains one of the most dangerous sectors all over the world. The research was carried on and based on the safety data obtained from the company and three surveys. The questionnaires were created to analyze the differences of OH&S levels in the company during three periods of the operation from 2005 to 2018. First period was connected with traditional safety management based mainly on safety regulations (2005-2007). The company during that time had not had any formal OH&SMS in place yet. The second period concerned the implementation of OH&SMS specification (2008-2009). The last period was associated with the implementation and certification of OH&SMS according to OHSAS 18001: 2007 standard (2010-2018). Now the company has been preparing for ISO 45001 to migrate from previous standard (2019-2020). The results of the analyses were referred on charts and tables to qualify a specific safety level expressed in safety indicators. Based on the surveys carried out, the authors identified the factors which have a decisive influence on the performance of OH&S in the company.

Keywords: safety, construction industry, occupational health and safety management systems

Introduction

The implementation of the OH&SMS in companies has been becoming more and more common. It ensures compliance with legal requirements, identification of existing hazards, risks and monitoring of working conditions. Companies try to implement OH&SMS in order to reduce the number of incidents, occupational diseases, accidents at work, and thus to improve work safety. The certification of OH&SMS also allows to achieve better competitiveness on the market (Yoon et al., 2011). In order to effectively manage occupational health and safety, it is worth using international standards. Currently, the latest standard in this area is ISO 45001: 2018 Occupational Health and Safety Management Systems - Requirements and guidelines for use. The International Organization for Standardization (ISO) published it on March 12, 2018. This standard replaces existing health and safety standards, such as OHSAS 18001: 2007 or Polish PN-N-18001: 2004. ISO 45001: 2018 is based on the directives of the International Labor Organization. After the publication of the new standard, the previous standard - OHSAS 18001, is valid for three years, i.e. until 2021. The surveyed organization currently has the OHSAS 18001: 2007 standard implemented. The purpose of the OHSAS 18001 Occupational Health and Safety Management System is, in particular, effective risk management, ensuring better communication within the organization and constant improvement of those areas that are responsible for safety, ensuring the improvement of the economic performance of the enterprise by reducing the number of accidents at work (OHSAS 18001, 2007). A thoroughly conducted analysis of the current OH&SMS in the company will allow to obtain a detailed view of the methods of risk management in the area of safety used so far

Cite this Article as: Tomasz EWERTOWSKI and Kinga KUBICKA " Impact of Occupational Health and Safety Management System on The Performance of Occupational Health and Safety in A Selected Construction Company – A Case Study" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

and obtain an answer which of the examined system elements had the greatest impact on the improvement of OH&S performance in the surveyed periods. Construction activity has made considerable breakthroughs in the past decades in the context of increases in development activities, state regulations, and public demand. At the same time, occupational health and safety issues have become a major concern to construction organizations (Rajaprasad. 2015). According to Statistics Poland in 2019 the construction organizations has recorded the greatest number of fatal accidents among all industry branches (stat.gov.pl, 2020). The company discussed in this paper belongs to the bigger international construction organization, that has branches not only in Poland but also around the world, incl. Europe and Asia. The company employs in Poland about 600 people. For the last 25 years, operating in Poland, it has cooperated with nearly 360 investors, thus implementing almost half a thousand construction projects. The company carries out construction projects in accordance with the principles of construction art, technical safety at work, using modern technologies and solutions. It specializes in the construction of cubature and infrastructure facilities. The company's offer includes mainly office, residential, industrial, public utility, commercial and entertainment facilities, as well as land and water construction works for large infrastructure projects. The organization is one of the signatories of the "Agreement for Safety in Construction" - an initiative of twelve general contractors, aimed at improving safety in Polish construction sector. It assumes the implementation of a number of projects introducing system solutions in the field of health and safety, including: common document templates, a model for confirming the professional qualifications of construction workers or periodic training. The agreement promotes a safety culture, makes people aware of the dangers of working on a construction site and, consequently, is to eliminate the risk. In the field of occupational safety management, one of the most important goals of the organization was the implementation in 2007 of the OH&SMS according to the OHSAS 18001 specification and obtaining the certificate of the Integrated Management System covering - quality, environmental protection and health and safety areas. Currently, the OH&SMS is certified annually. The company has been preparing to implement the new ISO 45001: 2018 standard.

Literature Review

In recent years, public awareness of work-related accidents has driven industries to focus on improving the occupational health and safety management. There are two main approaches to OH&S management. First, traditional approach is based mainly on OH&S government regulations (Marcinkowski, 2013). The company follows the rules, but it does not have a systematic structure to use all available resources in order to achieve goals associated with OH&S. The approach is based mainly on OH&S service and does not use a synergy effect of all resources. It uses traditional tools of OH&S management such as:

- OH&S supervision and OH&S service in the company,
- OH&S board in the company,
- Social labor inspection.

The result has been an uncoordinated approach to safety issues, exposing workers to higher levels of risks and hazards. The second approach as opposed to first one uses modern tools of OH&S management connected with risk management. Risk management is an integral part of OH&SMS. The purpose of OH&SMS is to provide a framework for managing the prevention of death, work-related injury and ill health. The goal of OH&SMS is the reduction of occupational injuries and diseases, including promoting and protecting physical and mental health (ISO 45001, 2018). An OH&SMS is based on the principle of the Deming Cycle (Plan-Do-Check-Act “PDCA”). In the systems thinking approach system must involve an understanding the interactions between people and all other elements, and use this as the basis for devising a system, which takes into account inter-related or coupled activities or entities (e.g., hardware, software, spaces, communities and people) with a joint purpose. Furthermore, a systems approach examines, accounts for and enhances the design of a system, and people’s interactions with it, rather than concentrating on an individual part of the entity (Wilson, 2014). The approach uses a synergy effect of all resources. Management systems are divided into formal and informal. The first of them is characterized by functioning on the basis of specific, written rules - the requirements of standards (standardized) or legal acts and other common documents (non-standardized). Informal systems are less common and are based on contractual principles (Borys, Rogala, 2007). The OH&SMS are usually based on the international standards. First standards and guidelines concerning OHS management were developed in the early nineties of twentieth century. In 1996, International Organization for Standardization (ISO) held a discussion inviting many nations to develop international OHSMS. Some of 33 representatives had participated in the discussion including 6 international organizations like ISO, ILO – International Labour Organization, governments, labor unions, employers, worldwide safety and health

administrations, and insurance institutes. In 1999, US Occupational Health and Safety Administration in cooperation with international certifying bodies from 15 countries on 3 continents published the Occupational Health and Safety Assessment Series - OHSAS 18000 (Vinodkumar and Bhasi, 2011). It includes two parts, 18001 and 18002. The standard was revised, and its latest version is BS OHSAS 18001:2007 “Occupational Health and Safety Management Systems” (Fernández-Muñiz, et al., 2012). The OHSAS 18001 is not accepted in some countries. They developed their own standards which were mainly modifications of “Guidelines on occupational safety and health management system” published by International Labour Organization. In Poland PN-N 18001:1999 standard was developed. It was one of the standards that were used instead of OHSAS 18001. PN-N 18001 was revised in 2004 (Kafel, 2016). Recently, new standard in this area is ISO 45001: 2018 Occupational Health and Safety Management Systems - Requirements and guidelines for use. The International Organization for Standardization (ISO) published it on March 12, 2018. This standard replaces existing health and safety standards, such as OHSAS 18001: 2007 or Polish PN-N-18001: 2004.

Organizations often take measures to improve the status of work safety. They realize that proper management is the most effective way to ensure a high level of OH&S for several reasons. Firstly, due to the obligation to comply with the legal regulations imposed on employers, secondly - social expectations, and thirdly - the possibility of obtaining positive economic effects for the organization. In addition, by implementing OH&SMS, the organization also gains an advantage on the market over others because having a certificate, which is often a requirement of customers. Successful introduction of the OH&SMS in the organization depends largely on the involvement of the top management. The basis of a well-functioning OH&S is "ensuring a wide cooperation of employees at the stage of designing, implementing and maintaining all elements of this system" (PN-N-18001, 2004). Employee participation allow to design better working conditions at all organizational levels and to identify problems that are important for safety management. Employers often lose the opportunity to gain knowledge on the subject of problems, by not consulting and ensuring employees' participation in matters of work safety. The main tasks of the OH&SMS include:

- determining which legal requirements are crucial for the organization,
- effective identification of threats and occupational risk assessment for workplaces,
- recording incidents and carrying out their analyzes (remember that accidents and incidents are caused by the same causes, hence it is so important to prepare a cause analysis to know where the problem is)
- setting health and safety goals and actions that will help in achieving them, and regular monitoring of the health and safety condition,
- implementation of internal audits and reviews of the management system, as well as corrective actions resulting from audit reports,
- developing a health and safety policy and appointing a person who supervises the functioning of the OH&SMS, i.e. the Management Board's Representative for OH&S,
- overseeing documents relevant to the OH&SMS (Marcinkowski, 2013).

There are many advantages and benefits of shaping work safety. It is important, first of all, for the employees themselves, as they are the most important link in the functioning OH&SMS due to the need to protect their life and health. Moreover, some surveys confirmed that the implementation of the occupational health and safety management system has a positive effect on the health and safety at work. They show that a better compliance with the requirements of the OH&SMS is generally associated with a lower accident rate ”(Dudka et al., 2001). The evaluation of the effectiveness of OH&SMS requires both monitoring of the implementation of the activities and their results. The indicators for assessing this effectiveness are set by each enterprise in relation to its needs and capabilities. Reactive indicators, such as the number of accidents at work or occupational diseases, turned out to be the most frequently used due to the fact that each organization has an accident register on the basis of which it is possible to determine progress in the form of a decrease in the number of accidents or their increase. However, they are not allow for a quick response to the occurring problems because it takes a longer period of time to come to a conclusion based on the accident rates that our OH&SMS is not effective.

The most standardized indicators are number of accidents and:

$$accident's\ frequency\ rate = \frac{number\ of\ accidents}{number\ of\ \text{employees}} x1000 \qquad (1)$$

$$accident's \text{ severity rate} = \frac{number\ of \text{ inability to work days}}{number\ of \text{ accidents}} \qquad (2)$$

In order to assess the effectiveness of occupational health and safety management, it is necessary to take into account the working conditions and activities that are implemented as part of OH&SMS, as well as their results. The indicators that characterize OH&SMS activities are generally defined in the planning process, which includes setting goals and plans for their implementation. In order to define the goals, the health and safety should be assessed in order to determine which areas require improvement. In addition, it is important to verify compliance with legal requirements. An appropriate action plan will allow the organization to achieve its goals. An organization can use simple tools such as "checklists of control questions" relating to the basic areas of OH&SMS, which include, among others, top management commitment, employee participation, occupational health and safety policy, communication, training, occupational risk management as well as monitoring and evaluation of operation. A detailed assessment of the health and safety management system in an organization should include such elements as:

- health and safety objectives;
- commitment of top management;
- informing top management about health and safety issues;
- information on health and safety to the public;
- procedures for the implementation of basic activities in the field of health and safety;
- health and safety planning;
- engaging employees in health and safety activities;
- evaluation of health and safety performance;
- monitoring of OSH functioning;
- implementation of a health and safety management system;
- requirements for functioning in the area of OH&S, set for subcontractors and subcontractors (Pawłowska, 2006).

Materials and Methods

The analysis in this paper is based on a case study in the polish construction company, belonging to a multinational corporation with headquarters in another country and several factories in other, mostly European and Asian countries. The company has an OH&SMS implemented since 2010, which is annually certified for compliance with the OHSAS 18001 standard. The purpose of the research is to determine how the method of OH&S management affects the OH&S performance in the organization. The study concerned the period of the company's operation from 2005 to 2018. According to fig. 1 the analysis was divided into three periods, additionally, the fourth period for the planned implementation of ISO 45001: 2018 was illustrated.

Figure 1: Research periods of OH&S management in the organization

Source: own elaboration

The authors used the principle of triangulation in the research. Triangulation uses evidence from different sources to corroborate the same fact or finding. The case studies drew on multiple sources of evidence. These included documents, archival records, statistics and three surveys. Statistical analysis included indicators such as:

- number, severity and frequency of accidents;
- number of reports of incidents;
- number of subcontractors' accidents.

Analysis of the internal documents and archival records of the organization included i.e .:
- health and safety analysis;
- analysis of accident and incidents reports;
- analysis of internal and external audits;
- internal procedures and instructions.

The data collection procedure was conducted in the period between November 18, 2019 and March 09, 2020. The surveys were directed at the management of the company. A survey conducted on a group of 15 managers who have been employees of the organization since at least 2005. Three respondents were associated with OH&S service, the rest (12) were site managers. The structure of the surveyed respondents is presented in Table 1.

Three surveys were conducted. The first one concerned the period when the organization had not yet operated the OH&SMS (2005-2007). The first questionnaire concerned the period consisted of 4 questions each rated on five-point Likert-type scales (presented in Table 2). The second and the third surveys had similar structure but concerned two different periods. These questionnaires consisted of 10 questions each rated on five-point Likert-type scales (presented for second period in Table 3 and for third period in Table 4). The second survey was connected with the period when the company implemented of the specification of the OH&SMS (2008-2009) and the third period concerned the period when the company implemented and certificated the OH&SMS according to OHSAS 18001: 2007 (2010-2018).

Table 1: Features of survey respondents

Characteristics		Job position				P*
		Site manager		OHS manager		
		N	%	N	%	
Gender	M	12	100	2	66,67	>0,2000
	F	0	0	1	33.33	
Age group	40-50	2	16.67	0	0.00	>0.9999
	51-60	6	50.00	2	66.67	
	60+	4	33.33	1	33.33	
job experience (years)	20-30	11	91.67	2	66.67	>0.3714
	31-40	1	8.33	0	0.00	
	40+	0	0.00	1	33.33	

Fisher exact test were performed to examine the statistical difference for the participant's demographic factors between site managers and OHS managers.

* p value by Fisher exact test.

The scoring of individual response results on seven-point Likert-type scales is as follows:

1. I strongly disagree - 1 point,
2. I disagree - 2 points,
3. I have no opinion - 3 points,
4. I agree - 4 points,
5. I strongly agree - 5 points

The collected data has been coded and checked for correctness and randomness of the answers given. The STATISTICA 13 program was used in the data analysis.

Results

The results were divided into two parts. The first one shows indicators for an analysis of the whole period of research (2005-2018) and the second one shows the indicators for an analysis of individual three periods.

Results of period 2005-2018

The whole period of research was presented by key OH&S indicators. Figure 2. illustrate number of accidents and accident's frequency rate during research period. A systematic decline in all these indicators was noticed. In 2017, the number of accidents slightly increased, but in 2018 it continued the previous downward trend. The number of accidents dropped from 8 in 2005 to 6 in 2018, and the accident's frequency rate, respectively, from 12.4 in 2005 to 10.0 in 2018. The decrease in both indicators is even more spectacular, counting from 2007, when the number of accidents was 21 and the accident's frequency rate was 24.82. Figures 3 illustrate accident's severity rate. The lowest accident's severity rate was 13.3 recorded in 2017 (96 days of inability to work for 7 accidents); while the highest was 121.3 in 2015 (364 days of inability to work for 3 accidents). The reason for such high rates was the high number of days of inability to work after minor accidents, not severe ones.

Figure 2: OH&S indicators during researched period.
Source: own elaboration based on materials obtained from the company

Figure 3: Accident's severity rate during researched period. Source: own elaboration based on materials obtained from the company

Results of individual periods

According to Figure 1 the results was divided into three periods:

Results of period 2005-2007

During this period, a very large increase in the number of accidents was recorded, from 8 accidents in 2005 to 21 accidents in 2007. The accident's frequency rate turned out to be equally growing, which in 2005 was 12.40; in 2006 - 12.43, while in 2007 the indicator was 24.82. The accident's severity rate reached 77.87 in 2005, turned out to be optimistic in this period; 47.7 in 2006 and 45.24 in 2007. When analyzing the causes of accidents that occurred in the period, it was noticed that the main causes of accidents were inappropriate human behavior, fall from a height, slip and improper use of machines and devices. Most of the accidents were caused by the employees not maintaining sufficient attention to the activity, especially during operation and within the workstation of the table saw, and improper storage of materials.

Figure 4. Causes of accidents at work 2005-2007

Source: own elaboration based on materials obtained from the company

Table 2 presents statements describing which of the mentioned factors had the greatest impact on the OH&S status in the organization in this period. The overall Cronbach's alpha coefficient of the survey was 0.63. But the item-total correlation varied.

Table 2: Internal consistency analysis results

No.	Rated Item	Mean	SD	Item-total correlations
1	low OSH culture in the organization and employees' lack of awareness of the risks	2.53	0.91	0.75
2	Lack of process of reporting near misses	4.27	0.88	0.68
3	lack of in-depth analyzes of the causes of accidents and no appropriate corrective actions	4.8	0.86	0.74
4	lack of appropriate OSH training	1.27	0.46	0.61

Results of period 2008-2009

In the second analyzed period the organization implemented the OHS Specification, transformed in the end of 2009 into the OHSAS 18001: 2007 standard, and a five-point occupational risk assessment. At the beginning of 2007, the first editions of procedures and instructions were published, while in 2009 the organization began to operate in accordance with the requirements set out in the specification, which initiated the implementation of processes, including risk management. Bearing in mind the implementation and functioning of the above elements, a systematic drop in accident rates was observed in 2007-2009 compared to the first analyzed period, i.e.

- the number of accidents from 21 accidents in 2007 to 16 in 2009;
- accident's frequency rate - from 25 in 2007 to 19 in 2009;
- the number of accidents for employees of subcontracting companies - from 6 in 2007 to 4 in 2009.

The accident's severity rate increased from 45.24 in 2007 to 54.81 in 2009. There were no fatal, serious or group accidents during this period. The main causes of accidents in that period are given in fig. 5.

Figure 5. Causes of accidents at work 2008-2009

Source: own elaboration based on materials obtained from the company

The number of incidents reported by employees was gradually increasing from 8 in 2007 to 18 in 2009. Table 3 presents statements describing which of the mentioned factors had the greatest impact on the OH&S performance in the organization in this period. The overall Cronbach's alpha coefficient of the survey was 0.75. But the item-total correlation varied.

Table 3: Internal consistency analysis results

No.	Rated Item	Mean	SD	Item-total correlations
1	health and safety goals	4.00	0.76	0.64
2	commitment of top management	3.1	0.96	0.43
3	informing top management about health and safety problems	1.6	0.74	0.53
4	information on health and safety to the public	1.3	0.46	0.68
5	procedures for the implementation of activities in the field of health and safety	3.93	0.88	0.56
6	occupational health and safety planning	3.33	0.62	0.65
7	engaging employees in OSH activities	2.0	0.76	0.58
8	evaluation of health and safety performance	3.52	0.92	0.51
9	monitoring the functioning in the area of OSH	3.2	0.86	0.57
10	requirements for functioning in the area of occupational health and safety, set for subcontractors and subcontractors	1.73	0.79	0.61

Results of period 2010-2018

In connection with the development of procedures compliant with the requirements of OHSAS 18001 in 2009, it was possible to fully implement it. Moreover, actions were planned and implemented consisting in effective risk management. At the beginning of the analyzed period, in 2010, 13 accidents were recorded, while in 2018 this number decreased to 6. The highest decrease in all indicators recorded in the period 2013-2016. In 2018, despite the low number of accidents, one serious accident and one fatal accident were recorded. The fatal accident was due to communication problems related to the language barrier and cultural differences between manager and the employee. A general systematic decrease in this parameter was visible after the implementation of the OHSAS 18001 standard in 2010. Even the latest increase in the indicators in 2016-2018 shows that this value is much lower than at the beginning of this period. The lowest severity rate was recorded in 2017, going to 13.3 (96 days of inability to work as a result of an accident at work out of 7 accidents); while the highest in 2015 going to 121.3 (364 days of inability to work for 3 accidents). In addition, the OH&SMS in the surveyed organization largely covered subcontractors with its activities. The results are visible in fig. 6 in the decline of the accident number both at the company and subcontractors.

Figure 6: The number of accidents for the company and subcontractors 2010-2018.
Source: own elaboration based on materials obtained from the company

The main causes of accidents in that period are given in fig. 7.

Figure 7. Causes of accidents at work 2010-2018.
Source: own elaboration based on materials obtained from the company.

The largest number of accidents in the analyzed period was caused by improper use of machines and devices. In terms of incidents, the number of reports varies from 8 reported incidents to 21, giving an average of 13 reports per year. The result is slightly better than in the period 2007-2009, where the average number was 12 per year. Table 4 presents statements describing which of the mentioned factors had the greatest impact on the OH&S status in the organization in this period. The overall Cronbach's alpha coefficient of the survey was 0.74. But the item-total correlation varied.

Table 4: Internal consistency analysis results

No.	Rated Item	Mean	SD	Item-total correlations
1	health and safety goals	4.00	0.76	0.51
2	commitment of top management	3.2	1.15	0.62
3	informing top management about health and safety problems	2.3	0.96	0.61
4	information on health and safety to the public	3.26	1.1	0.63
5	procedures for the implementation of activities in the field of health and safety	3.93	0.88	0.71
6	occupational health and safety planning	3.26	0.59	0.46
7	engaging employees in OSH activities	3.6	1.12	0.70
8	evaluation of health and safety performance	3.53	0.92	0.41
9	monitoring the functioning in the area of OSH	3.2	0.86	0.39
10	requirements for functioning in the area of occupational health and safety, set for subcontractors and subcontractors	4.10	0.70	0.45

Discussion

The implementation of the OH&SMS in the researched organization had a large positive impact on the OH&S performance at work. The research methodology used for the analysis allowed for a positive verification of the thesis. The authors used the principle of triangulation in the research. Multiple sources of evidence such as: documents, archival records, statistics and surveys confirmed similar facts and findings. Comparing accident rates from the period when the OH&SMS did not operate in the organization, a significant decrease in accident number was noticed in the subsequent years of the OH&SMS operation. These rates were reliable because there was no significant decrease or increase in the number of employees, construction sites or subcontractors. Despite the increase in the OH&S indicators in 2017, they were much lower than in 2007, when the organization had been preparing to implement the OH&SMS. Although no serious, fatal or group accidents were recorded in 2013 and 2015, the accident's severity rate was the highest in those years. The reason for such high rates was the high number of days of inability to work after minor accidents, hence it should not be assumed that these rates reflect the type of accident. The causes of accidents in individual periods indicate an increase in awareness among employees about hazards, taking into account the decrease in the number of accidents related to inappropriate behavior of an employee from 38.1% in 2007 to 27.77% in 2010-2018. This was an another evidence that the benefits of implementing the OHSAS 18001:2007 standard increased the awareness of hazards occurring at workplaces (www.pcbc.gov.pl, 31/01/2020). A great impact on the prevention of accidents and injuries is visible after the analysis of accident's rates. The implementation of analyzes of potential accidental events aimed at determining their causes and implementing corrective actions which support the prevention of similar events in the future. Thanks to the analysis of the causes of accidents, it is also visible that accidents caused by work at height, and consequently falls of employees from heights, classified as high-risk, significantly decreased from 23.82% in 2005-2007 to 11.11% of all causes in 2010-2018. Thanks to the implementation of corrective actions such a significant decrease in recurrent causes of accidents is visible. The above assumptions are confirmed in the survey, indicating the lack of in-depth analyzes of the causes of accidents and taking appropriate corrective actions as the main reason for the bad OH&S performance in 2005-2007. According to the respondents, also the lack of registration of reports of incidents had an impact on the OH&S performance in this period. The implementation of the Occupational Health and Safety Management System resulted in the commencement of processes of registering reports of incidents and their analysis. From 2007 to 2009, an increase in the number of reports of incidents was observed. It indicates an increase of employees' awareness. During the operation of the OH&SMS, an increase in the average number of notifications per year was recorded, which also indicates the benefits of implementing the OH&SMS in this area.

Since the organization has implemented risk management processes in the area of subcontractors' cooperation a decline of number of accidents has been noticed. The agreement the company with subcontractors provided guidelines and tools for effective risk management. Almost all respondents noticed that the requirements for subcontractors had a large impact on the OH&S performance during implementation of OH&SMS in the organization.

The fulfillment of the OHSAS 18001:2007 requirements gave the organization the possibility of effective risk management, which in turn contributed to the reduction of number, severity and frequency of accidents, increasing employee awareness of threats and their consequences. Additionally The organization got an increase in the number

of reported incidents and the benefits of the implemented corrective actions, contributing to the elimination of similar accidents in the future.

Thanks to all mentioned factors the organization can easier migrate to the new standard ISO 45001:2018.

Abstract

This article has as a starting point the definition of the evaluation of an educational system.Thus, severaldefinitions are presented and critically and comparatively analyzed. Based on these analyzes, we have developed a more complete definition that refers both to the four types of resources (material resource, financial resource, material resource and information resource), and to specific management activities. The article also presents and analyzes several parameters for evaluating the performance of educational systems. Among the parameters presented we mention: indicators of performance of the quality of the educational system (resources of the education system; participation; effectiveness and efficiency of education; completed levels and results of education); indicators for quantifying participation in education (participation at all levels of education); indicators for analysis and evaluation of the resources involved.

Keywords: Educational Systems; Management; Evaluation; Performance.

Introduction

The educational system is a complex one and of great importance. From this point of view, a periodic evaluation of it is necessary. It is useful to define the concept of evaluation in general and the one specific to educational systems in particular.

According to [1] there are several definitions of the evaluation of educational systems. Thus, [2] gives us the following definition. Assessment is a system of concepts, principles and techniques related to the measurement and appreciation of school results and the teaching process and the teaching process as a whole. This definition refers only to the teaching process. The educational system is wider, it also contains all the bodies that participate in the realization of education.

Another definition of the evaluation of the education system [3] provides that to evaluate means to state a value judgment, based on precisely established criteria, regarding a determined entity, in order to adopt a decision regarding

the improvement or future of this entity. This definition emphasizes criteria, rules on carrying out activities and making managerial decisions, so it refers more to the organizational system.

According to [4], the evaluation is the complex didactic act, integrated in the whole educational process, which ensures the highlighting of both the amount of knowledge acquired by the student and their quality, offering solutions to improve the teaching-learning act. This definition also refers only to the didactic (learning) process, to its quantitative and qualitative aspects.

Another specialist in the field [5] offers us the following definition. Evaluation is a complex process of comparing the results of the instructive educational activity with the planned objectives - evaluating the quality, with the resources used - evaluating the efficiency or with the previous results - evaluating the progress. This definition refers to the resources used, but without specifying their types. It also brings into discussion the dynamics of the educational system (evaluation of progress).

Another definition [6] provides that school assessment is the process by which useful information is delineated, obtained and provided, allowing subsequent decisions to be made. It refers to the informational resource (the process by which useful information is delimited, obtained and provided) and to the implicit managerial component (making subsequent decisions).

According to [7], evaluation is a process of measuring and assessing the value of the education system or part of it, the efficiency of resources, conditions and strategies used by comparing the results obtained with the proposed objectives, in order to make decisions for improvement. and improvement.

Parameters for evaluating the performance of educational systems

We can consider that no definition presented and analyzed previously is complete, because it does not refer to all types of resources involved in an educational system, namely: human resources, financial resources, material resources and information resources and the correlations between them.

Thus, we consider the following definition more complete and comprehensive. An educational system is the instructive-educational process in which four types of resources are involved (human resource, as the most important, financial resource, material resource and information resource, which governs the first three), a process that, in progress and dynamics to require periodic updates (upgrades) and evaluations by applying indicators and parameters of the qualitative and quantitative performance of the specific activities carried out.

Based on our definition, which we consider more complete (but not exhaustive), we propose the following scheme of the educational system (figure 1).

From the multitude of categories of performance indicators of the educational system, we will present and further analyze the following categories [8,9]:

Performance indicators of the quality of the educational system

- Education system resources (human, financial, material and informational).

Ensuring the qualitative and quantitative level of the four types of resources is of great importance for theperformance of the educational system at any level.

- Participation (gross, net and net adjusted rate of inclusion, etc.)

The level of participation in the educational process quantifies the subjects' interest in the educational system.

- The effectiveness and efficiency of education (repetition rate, school survival rate, efficiency coefficient, etc.).

  This parameter quantifies the existence and good use of the 4 types of resources.

- Graduated levels and results of education (results in national and international evaluations, graduation rate, employment rate of graduates of different levels of education, etc.).

  This indicator reflects the good completion and implementation through results of the educational process.

Fig. 1 : Theschemeofdefiningtheeducationalsystem

Another category of performance parameters of the educational system is represented by:

Indicators for quantifying participation in education

Participation at all levels of education: number of pupils / students, by levels of education; the share of pupils and students in the total population; gross enrollment rate at all levels of education; the specific school enrollment rate by age at all levels of education; school life expectancy for children aged3/6 years.

Indicators for analysis and evaluation of the resources involved

Indicators regarding human resources: the share of teaching staff in the total employed population; thenumber of teachers, by levels of education; the share of female teachers; the share of qualified teaching staff; the share of unqualified teaching staff; the share of teaching staff with full working time (full time); the share of part- time teaching staff; the share of educational units that function entirely with qualified teaching staff; the share of women with management positions (director); teacher student report; the average number of students per class; the share of educational units in which groups / classes with student numbers below the minimum / above the maximum in relation to the legal provisions operate; the share of groups / classes with students below the minimum / above the maximum in relation to the legal provisions.

Indicators regarding the financial resource: public expenditures for education, as% of GDP; public expenditures for education, as% of total public expenditures; public expenditure on education, as% of total expenditure on education; expenditures from the state budget per pupil / student; staff costs, as% of total education expenditures; expenses with professional training and teacher evaluation per student.

Indicators regarding the material resource: educational units (number of school units / institutions in pre-university and tertiary non-university / university education; number of educational units with teaching in minority languages, by teaching languages; number of educational units that provide mother tongue study, subjects Minority language and History and culture of minorities, number of educational units with simultaneous teaching classes, share of educational units with simultaneous teaching classes, number of units providing extracurricular educational activities, children's palaces, children's clubs, share of units of educational activities with students in school laboratories, the share of educational units that carry out practical training activities with students in school workshops, the share of educational units that have gyms, the average number of volumes and publications per student; the number of students returning to a computer; the share of secondary education units (middle school and high school) that use at least 15 computers in the activity with students; the share of pre-university education units with Internet access.

Conclusions

The qualitative and quantitative evaluation of the educational system has a special importance. The chronological definitions of the evaluation of the educational system offered by specialists in the field are elliptical, because many of them do not refer to the four types of resources (human resource, financial resource; material resource, informational resource) and / or specific management activities.

Among the parameters for evaluating the performance of educational systems, the following indicators have a significant importance: the indicators of the efficient use of the four types of resources within the specific activities carried out; indicators of participation in the educational system; indicators of the efficient implementation of the results of the educational systems.

Another aspect of the relevance of the increased importance of educational systems is that within the 3S concept (school, as education- streets, as infrastructure-hospitals, as health), the priority place is given to educational systems.

Abstract

After the Second World War, the population has increased more and more, from 3 billion in the ’60s to more than 7.8 billion today. In this case, the agriculture production has to be more efficient and more productive. Over time, the need to produce more and feed a growing population has led to the identification of new solutions to meet these challenges. Starting from this, the present study proposes to make an analysis regarding the dynamics of vegetable sector in the last decade, from the perspective of the conventional and ecological system, based on the importance that have been gained by the ecological products and also on the fact that ecological area increased by 70% in the recent years. In this sense, our study is concentrating on a few indicators provided by Eurostat and starts with the share of ecological surfaces at the EU level, which has increase from 4% in 2007 to 7% in 2017. Beside this, we analyze indicators between 2012 and 2019, such as cultivated areas and production, both for conventional and ecological systems, for the main agricultural crops. Mostly, our research has been based on a quantitative analysis and has highlighted that all the European countries are basing their production more and more on ecological agriculture.

Keywords: Vegetable Sector, Conventional Agriculture, Ecological Farming.

Introduction

Over time, the need to produce more and to feed a growing population has led to the identification of new solutions to meet these challenges. Thus, once entered into the modern era, the agricultural activity was transformed being focused on producing more, with a lower consumption of resources, while increasing the need to produce healthier food (Bostan, 2016). This is how very productive hybrids have appeared, which have gradually replaced local varieties, pesticides and fertilizers, which have helped farmers protect their crops from disease and pests, while fertilizers have helped to increase soil fertility.

Cite this Article as: Ruxandra-Florina TEODORESCU, Valentina Constanta TUDOR, Alina MARCUTA, Dorina MOCUTA and Dragos-Ion SMEDESCU“ The Dynamics of The Vegetable Sector from The Perspective of The Conventional and Ecological System” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Gradually, more and more farmers have replaced traditional agriculture with a modern practice, where chemicals represent the solution to all problems in the crop, except for the limitations imposed by climatic conditions, where irrigation systems have not been implemented (Kremen, 2012). Modern agriculture has seized much of the arable land available in Romania, but also at the level of EU (Hartvigsen, 2014). The need to produce more has prevailed at the expense of the need to obtain more environmentally friendly productions.

In the last decades, people have been more focused on eating healthy, all around the world and especially in countries with higher income, increasing the demand for safe and high-quality food (Sadilek, 2018). In this situation, agriculture must meet the twin challenge: the need to feed a growing population, with a rise demand for products with high-calories diets and meat, while simultaneously minimizing its global environmental impacts (Binta, 2015).

In recent decades, as concerns about healthy eating have intensified, there has been a renewed interest in producing healthier, more natural, environmentally friendly cereals, vegetables, fruits or milk and meat. The increasing demands of the consumer for such products have led to the resumption of the production process and to the transition, gradually to the traditional agriculture practiced in ancient times (FAO, 2020).

Materials and Methods

Starting from the UE28 level, the research is based on data provide by the European Statistics Office from the period 2012 till 2019. In order to achieve the results, we took in consideration the main vegetable crops, such as: wheat, barley, corn, rice, potatoes, sugar beet, rapeseed, sunflower, soy, hemp, tobacco and hops. In this sense, our study is based on a few indicators provided by Eurostat and starts with the share of ecological surfaces at the EU level, which has increase from 4% in 2007 to 7% in 2017. Beside this, we analyze indicators such as cultivated areas and production, both for conventional and ecological systems, for the main agricultural crops.

Results and Discussions

Among the most extensively cultivated areas in Romania are maize, wheat and sunflower (Tudor, 2013). In the case of the maize crop, at the level of 2019 an area of 2.65 million hectares was exploited, decreasing in comparison with the area cultivated in the year 2012. The area cultivated with wheat in 2019 was 2.09 million hectares, increasing by 4.7% compared to 2012, and in the case of sunflowers the cultivated area was 1.3 million hectares, increasing by 21.8% in comparison with 2012 (Table no. 1).

Table 1: Evolution of the cultivated areas at the level of Romania with the main plant crops in the period 2012-2019 in conventional system (thousands hectares)

Crop	2012	2013	2014	2015	2016	2017	2018	2019	2019/2012 %
Wheat	1.997,6	2.104,0	2.112,9	2.106,6	2.137,7	2.052,9	2.110,7	2.091,5	4,7

At the opposite, regarding the cultivated areas in Romania, between the analyzed crops, there is the cultivation of hops, tobacco and hemp. Hemp cultivation is exploited on restricted areas in certain favorable regions, therefore the area cultivated at the level of 2019 was only 270 hectares. And in the case of tobacco culture it is noted that it is exploited on small areas, where at the level of 2019 it was a little over 100 hectares. It is worth noting, however, the

reintroduction of hemp culture, so that if in 2012 this crop was not exploited, in 2019 the area exploited with hemp was 1.87 thousand hectares (Table no. 1).

Climatic factors play an extremely important role in determining high quantities, but also qualitatively (Powlson, 2016). We can notice, in the case of the maize crop, where the year 2018 was a really "good" one for this crop, registering a record in this respect, when a production of over 18.8 million tons was obtained, meaning an average production of 7.8 t / ha. The high yields this year determined the farmers that in 2019 maize will be grown on a larger area (2.65 million hectares, compared with 2.42 hectares) (Table no. 2.).

Table 2: Evolution of the productions obtained at the level of Romania in the main plant crops in the period 2012-2019 in conventional system (thousands tons)

Crop	2012	2013	2014	2015	2016	2017	2018	2019	2019/2012 %
Wheat	5.297,8	7.296,4	7.584,8	7.962,4	8.431,1	10.035,0	10.138,6	10.051,4	89,7

Source: Eurostat Database, 2020.

It should be noted that in the case of both wheat and maize, net yields were higher than those obtained in 2012. For example, in the case of wheat cultivation, the production obtained increased by more than 89% in 2019, compared to 2012, from a production of 5.3 million tons to just over 10 million tons. Also, in the case of maize, from a production of 5.9 million tons in 2012 to a production of 14.9 million tons in 2019, increasing by 150% compared to 2012 (Table no. 2.). In Romania, the arable area involved in ecological farming is quite small, occupying less than 200,000 hectares in 2017. Compared to the total area of the European Union, the area on which ecological farming is practiced in Romania represents only 3.5% of the total area. occupied by the ecological crops at the level of the European Union in 2017 (Figure no. 1.).

Figure 1: The total area occupied by ecological farming and land under conversion to ecological farming
Source: Processed data provided by Eurostat Database, 2020

In Romania, the arable area involved in ecological farming is quite small, occupying less than 200,000 hectares in 2017. Compared to the total area of the European Union, the area on which ecological farming is practiced in Romania represents only 3.5% of the total area occupied by ecological crops at the level of the European Union in 2017.

The areas occupied by ecological crops in Romania oscillate between 2013-2017, so that if in 2013 the area occupied by the ecological crops was 173,794 ha, in the period 2015-2016 the area was reduced by about 17,000 hectares, while in 2017 the area it registered an increase of almost 38,000 hectares compared to the area registered in 2016 (Figure no. 1).

According to a report of the European Parliament, most of the ecological agriculture in the intra-Community area is concentrated on pastures and meadows intended for the ecological growth of animals (45.1%) and on arable crops of cereals, fresh vegetables, green fodder and industrial plants (44 %).

The remaining 10.9% of ecological farming is focused on permanent crops of the type: fruit trees, shrubs, olive groves and vines).

Table 3: Evolution of the cultivated areas at the level of Romania with the main plant crops in the period 2012-2017 in ecological system (hectares)

Crop	2012	2013	2014	2015	2016	2017	2017/2012 %

According to Table 3.3. there is a decrease of the cultivated areas in an ecological system, so that in the case of wheat cultivation, if in 2012 were cultivated over 56 thousand hectares, in 2017 the cultivated area was only 45.7 thousand hectares, decreasing with over 18%. Also, a significant decrease was recorded in the case of maize crop that suffered a decrease of over 41% in 2017 compared to 2012, when cultivated over 33.7 thousand hectares (Table no. 3).

The most significant decrease was recorded in the case of potato cultivation, which from a cultivated area of 533 hectares in 2012, in 2017 the cultivated area was only 188, decreasing by over 64%. The only crops analyzed that registered an increase of the cultivated area, were the rice crop (29.5%) and the rice crop (49.4%) (Table no. 3).

Table 4: Evolution of the productions obtained at the level of Romania in the main vegetable crops in the period 2012-2019 in ecological system (tons)

Crop	2012	2013	2014	2015	2016	2017	2017/2012 %

Although the cultivated areas have decreased in the case of wheat and maize, we can see that the wheat production increased by 40%, from a production of 74 thousand tons in 2012 to a production of 104 thousand tons in 2017. Also, corn cultivation increased by 66.3% from a production of 40.3 thousand tons in 2012, to a production of 67.1 thousand tons in 2017, registering an average production of 3.4 t / ha (Table no. 4).

At the level of Romania, the area cultivated in the ecological system has values between 1 and 2%: in 2007 the area was 1% and at present the value reached is 1.93%.

Ecological farming plays a very important role for Austria, which owns 23.4% of the total cultivated area, at the level of the European Union, in 2017, being the first place after the share of the cultivated areas in the ecological system. Croatia, the last state to join the EU, has a cultivated ecological area of 6.5% of the total. At the same time, Bulgaria and Romania, which joined in 2007, have an area weight of 2.72% and 1.93% respectively in 2017 (Table 5.).

Table 5: The share of ecological surfaces from the total area cultivated at EU level (%)

The size of the ecological area differs considerably from one EU Member State to another. Four Member States accounted for more than half of the total agricultural land cultivated in 2017: Spain (16.6%), Italy (15.2%) France (13.9%) and Germany (9.1%), representing together 54.7% of the total EU-28 ecological area (figure 2.1.). In 2016, these four countries represented a similar weight, 54.4%.

Conclusions and Recommendations

Agriculture in the conventional system was widespread in Romania until 1989 (Stoleru, 2019). Today, it is unanimously accepted that this type of agriculture can affect the environment, especially if the different components of the agricultural technological system are applied without taking into account the local specific: climate, soil, relief, social and economic conditions, which determine the level of vulnerability or susceptibility to the different processes of chemical, biological, physical degradation of the environment.

In ecological farming the improvement of soil fertility is based on ecological fertilization, and in the conventional system the synthetic fertilizers are used, soluble (Peigne, 2018). Plant nutrition is indirect in the ecological system, and direct in the conventional system. Plant protection is preventive; based on combating causes in the ecological system, compared to the conventional system that uses curative methods; based on fighting symptoms (Des Roches, 2018). The growing demand for products from ecological farming has led to the creation of a set of rules that must be followed by each farmer who wants to move from conventional to ecological farming. Thus, there is a conversion period that varies depending on the type of products you want to get (Shaban, 2015). At European level, ecological products are easily identifiable on the shelf, with a distinct logo and guarantee that the product comes from a sustainable agricultural system, which respects the environment and animal welfare, but also includes all other stages of the supply chain with food.

The EU green market has been steadily expanding and is now worth around 30.7 billion euro a year. Although the EU's ecological farmland has expanded over the years, they use only 7% of the total agricultural area. The difference between demand and production is covered by increased imports.

Climatic factors play an extremely important role in determining high quantities, but also qualitatively. We can notice, in the case of maize crop, where the year 2018 was a really "good" one for this crop, registering a record in this respect, when a production of over 18.8 million tons was obtained, meaning an average production of 7.8 t/ha. The high yield from last year, determined the farmers to cultivate a larger area with maize in 2019, 2.65 million hectares, compared to 2.42 hectares in the previous year.

In Romania, the arable area involved in ecological farming is quite small, occupying less than 200,000 hectares in 2017. Compared to the total area of the European Union, the area on which ecological farming is practiced in Romania represents only 1.93% of the total area in 2017.

Acknowledgments

We thank the referees for all the data provided for this paper. The publication of this article was possible thanks to the sectoral project ADER 23.1.1: “Technical-economic basis of production costs and estimates regarding the prices of capitalization of the main plant and animal products, obtained in conventional system and in organic farming” Subcontract no: 23.1.1./2-03.10.2019 contracted with the Ministry of Agriculture and Rural Development.

Abstract

Testing the possibilities of using the standard apparatus of neural networks for predicting the indicators of socio-economic development of regions. The used methodology is based on the standard apparatus of neural networks included in the Statistica software products. Correlation-regression analysis was used as an alternative. The use of the apparatus of neural networks is due to the practical need to supplement the socio-economic processes used to predict the socio-economic processes in the territorial and functional subsystems of countries and macro regions. Expansion of the range of interconnections between systems of various levels required the expansion of methods for predicting the parameters of socio-economic processes. Results. Approbation of the standard apparatus of neural networks was carried out on the example of predicting the dynamics of one of the most significant indicators of socio-economic development of meso-level systems - the total fertility rate. The use of a fairly simple version of the apparatus of neural networks made it possible to establish a fundamentally different version of the dynamics of the predicted indicator, which differs from the expert and "trend" one. At the time of the calculations, the growth of the indicator values in the strategic planning documents of the model region and based on the analysis of the previous trend over a fifteen-year period was predicted. Neural network analysis made it possible to predict a decrease in the birth rate in the medium and long term as one of the possible options. In other words, a pessimistic variant of the development of the demographic situation in the region is not excluded.

Keywords: Neural Network, Forecasting, Region, Target Indicators.

Introduction

Currently, the use of neural networks has become quite widespread in various fields of knowledge, including for the purpose of predicting technical and technological, socio-natural, socio-economic processes. At the moment, the e-library information system alone contains more than 500 scientific papers devoted to forecasting problems in these areas. So, some authors consider the prospects of using neural networks to predict the volume of freight traffic (Yakupov & Rozhko, 2017). Other scientists assess the capabilities of the neural network apparatus in order to assess the quality indicators of dairy products (Melnikova et al., 2017). Some scientists propose the use of neural networks to predict electrical loads (Alferova & Trokhova, 2019). Other authors highlighted in their works the experience of neural network diagnostics of a number of diseases (Lazarenko & Antonov, 2017). A.V. Yakimchuk et al. assess the prospects for long-term weather forecasting using neural networks (Yakimchuk et al., 2015). In some cases, for example, in the works of S.V. Sholtanyuk, the prediction results are compared using alternative methods, including neural networks and correlation-regression analysis (Sholtanyuk, 2019). Until now, we have not been able to find thorough research in the field of strategic forecasting of regional socio-economic systems. Despite the adoption in 2014 of the Law on Strategic Planning, which provides for the establishment of indicators of the socio-economic development of territorial subsystems of the country until 2030 or 2035, forecasting methods have basically remained the same: strategic analysis, expert forecasts, correlation regression analysis, used and in

theoretical, in practical aspects[1]. The authors of this article have significant experience of their own in regional strategic planning and are familiar with the techniques of other expert groups. In theoretical terms, we, including in co-authorship, have proposed various options for analyzing and forecasting the development of regional socio-economic systems (Treshchevskiy, Papin & Penina, 2018; Bitarova et al., 2018; Treshchevsky et al., 2018; Lanskaya et al., 2018; Vertakova et al., 2019; Plotnikov et al., 2020).

A previous attempt to assess the possibilities of using a neural network apparatus for predicting the socio-economic parameters of a region was made by scientists (Azarnova, Treshchevsky & Papin. 2020). The calculation results showed that neural networks turned out to be "more careful" than experts - they predicted less pronounced dynamics. However, the use of neural networks for such an indicator as the gross regional product (GRP) is not of significant practical interest, since it is a kind of aggregator of socio-economic processes and, despite fluctuations associated mainly with strong crisis phenomena in certain years; it is predicted with high precision expert methods. More complicated and, accordingly, requiring the use of various methods, is the forecasting of particular indicators, which, at the same time, are of strategic importance for socio-economic systems of macro- and meso-levels. In this study, the total fertility rate was chosen as such an indicator. At present, significant organizational and financial resources of the federal center of Russia and regions of the country are directed to the growth of this indicator.

Materials and Methods

The information base for predicting the birth rate in the region was compiled by official statistics for a fifteen-year period (from 2005 to 2019). The period is sufficient to identify trends in interrelated indicators. The forecast horizon was eight years (from 2020 to 2027). This period was chosen in order to study the work of neural networks in long-term forecasting. The forecasting period is somewhat higher than the recommended one for correlation-regression analysis, but it is not yet clear for what period neural networks "work" correctly enough in predicting the parameters of socio-economic systems. Therefore, we decided to test their capabilities as long as possible.

To carry out the calculations, we used the MSExcel and Statictica 10 software products. The minimum number of hidden neurons on the inner layer is 4; maximum - 13; actual - 11, at the output of neurons - 1; networks for training - 100, for storage - 5, the output function is logistic.

Data for training and testing of neural networks were used for the period from 2005 to 2019 based on the materials of official statistics[2]. The results obtained with the help of neural networks were compared with the predicted values revealed on the basis of trends, as well as data from the “Strategy of socio-economic development of the Voronezh region for the period up to 2035”[3].

For the purposes of forecasting, in addition to the target, 13 more socio-economic indicators of the development of the region were used, including seven presented in the "Strategy - 2035". The selected indicators are theoretically related to each other and are presented in Table 1. In order to avoid the repeated use of long phrases describing the values of the indicators, the designations indicated in Table 1 are applied to them.

Table 1: Indicators used to predict the total fertility rate

Indicator name	Indicator designation
Total fertility rate, ppm	VAR 1
Population, thousand people	VAR 2
The share of the population with monetary incomes above the subsistence level,%	VAR 3
The share of the population with monetary incomes above the subsistence level,%	VAR 4
Employment rate,%	VAR 5
Total area of residential premises per 1 inhabitant, m2	VAR 6
Provision of preschool children with places in preschool educational institutions, number of	VAR 7

places per 100 children	
Crime rate (number of registered crimes per 100 thousand population)	VAR 8
Population of childbearing age (15-49 years), thousand people	VAR 9
The ratio of marriages and divorces (there are divorces per 1000 marriages)	VAR 10
Social payments in the region as a whole (benefits, social assistance and scholarships), thousand rubles / month	VAR 11
Average consumer spending per capita, thousand rubles / month	VAR 12
The share of families that have received living quarters, among families registered as needing living quarters,%	VAR 13
Termination of pregnancy (abortion), number per 100 births	VAR 14

The results of the analysis of relationships and their discussion

For the purpose of forecasting using neural networks, the coefficients of pair correlation were determined for all selected indicators (table 2).

Table 2: Coefficients of pair correlation between the analyzed indicators and the total fertility rate

Indicators	**Correlation coefficients between indicators and VAR1**	**Indicators**	**Correlation coefficients between indicators and VAR1**
VAR 1	1,000000	VAR 8	**-0,602435**
VAR 2	0,116804	VAR 9	-0,475681
VAR 3	**0,620412**	VAR 10	-0,072812
VAR 4	**0,593721**	VAR 11	**0,744713**
VAR 5	0,331562	VAR 12	**0,554007**
VAR 6	**0,527137**	VAR 13	**0,589813**
VAR 7	**-0,514924**	VAR 14	**-0,805274**

Note. The values of the correlation coefficients sufficient to determine the vector and the strength of the connection are highlighted in bold (according to the Chaddock scale, the strength of the connection varies from noticeable to high).

From the data presented in Table 2, it can be seen that a significant number of interdependencies are easy to interpret logically, on the basis of which tools should be developed aimed at increasing the total fertility rate. First of all, let us pay attention to the relationships that do not allow a double interpretation of cause-and-effect relationships. Either assumes that the dependent variable is the fertility rate. Thus, a direct relationship is demonstrated by “the share of the population with money incomes above the subsistence level”, “average per capita money incomes”, “the volume of social payments” of various kinds, not necessarily associated with stimulating the birth rate (benefits, social assistance, and scholarships). Consequently, one can expect an increase in the fertility rate due to a decrease in poverty and an overall increase in income. However, the latter is not obvious, if there is a qualitative change in the general level of income, the dynamics may worsen. The same should be attributed to the "total area of residential premises per 1 inhabitant".

The positive relationship between the birth rate and "the proportion of families who received housing, among families registered as needing housing", has rather the opposite meaning - the appearance of a child increases the chance of getting housing due to state programs. Let us turn to the indicators that have an inverse relationship with the birth rate. The inverse relationship between the fertility rate and the proportion of women who terminate pregnancy is quite logical.

An inverse relationship is noticeable between the target indicator and the “level of crime”, which obviously indicates a greater desire to expand the family in “calm” conditions.

Some relationships do not follow directly from causation and require some assumptions. Thus, the inverse relationship between the birth rate and “provision of preschool children with places in preschool educational institutions” is quite logical, if we assume that their construction and commissioning are planned without taking into account the upcoming demographic changes.

The almost complete absence of a connection between the target indicator and the “ratio of marriages and divorces” (correlation coefficient - 0.07) can also be considered logical if we recognize the typical practice of forming single-parent families.

It is difficult to interpret: there is a direct connection between the sought indicator and “consumer spending per capita” (correlation coefficient 0.55). At first glance, the inverse relationship between the fertility rate and “the number of population at childbearing age” contradicts logic (the correlation coefficient - 0.47, although it does not reach the value of 0.5, is still quite high). The logic of this connection is revealed only when comparing the dynamics of the size of this population group and the special fertility rate (calculated for women of fertile age) - this coefficient is growing much faster than the share of the population aged 15 to 49 is decreasing.

Neural network forecast of the indicator dynamics - calculation methodology and results

According to the training results, neural networks were obtained with a very high value of training performance (0.9466) and the maximum values of the test and verification (1.00). This indicates the ability of the neural network to accurately describe the patterns of a number of dynamics when predicting the birth rate. Based on the results of network testing, the most accurate of them was selected. The plotted error graph is close to the normal distribution. The scatter plot of the actual values used by the program to construct the regression equation demonstrated a high degree of connection between the target and test indicators of the total fertility rate. The results of calculating the squares of the residuals of the actual data and those derived by the neural network showed a satisfactory result (table 3).

Table 3: The squares of the residuals of the actual values of the key indicator change from those derived by the neural network

Years	The actual value of the key indicator	Key metric value inferred by the neural network	Residual squares
2005	8,200	8,383	0,033450
2006	8,400	8,419	0,000351
2007	9,000	9,035	0,001218
2009	10,400	10,323	0,005932
2010	10,200	10,731	0,282221
2012	10,900	10,546	0,125072
2013	10,700	10,590	0,012083
2014	10,900	10,781	0,014100
2015	11,100	10,907	0,037347
2017	9,600	10,319	0,516616
2019	10,786	10,395	0,152792

Table 4 shows the significance of the impact of each of the selected indicators (the indicator is considered significant if the value is greater than 1.0). It is worth noting three indicators, the rejection of which will have the strongest impact on the results of the forecast: "termination of pregnancy", "social benefits", "consumer spending on average per capita".

Table 4: Network sensitivity analysis

Indicator	Designation	Significance
VAR 14	Termination of pregnancy (abortion), number per 100 births	18,8050
VAR 11	Social benefits (benefits, social assistance and scholarships), thousand rubles	3,9212
VAR 12	Average consumer spending per capita, thousand rubles	1,8933
VAR 8	Crime rate (number of registered crimes per 100 thousand population)	1,4619
VAR 6	Total area of residential premises per 1 inhabitant, m2	1,2625
VAR 13	The share of families that have received living quarters, among families registered as needing living quarters,%	1,1660
VAR 4	Average per capita cash income, thousand rubles per month	1,0604
VAR 3	The share of the population with monetary incomes above the subsistence level,%	1,0407
VAR 7	Provision of preschool children with places in preschool educational institutions, number of places per 100 children	0,9960

Let us determine the initial results of predicting the indicator using data from strategic documents and building trends based on correlation and regression analysis (Table 5).

Table 5: The results of predicting the values of indicators used for the analysis

Indicators	Years						
	2020	2021	2022	2023	2024	2025	2026
VAR 1	10,9	10,9	11,0	11,0	11,1	11,1	11,2
VAR 3	90,9	91,6	93,3	93,6	95,3	95,4	95,5
VAR 4	36,2	38,9	41,9	45,2	48,6	52,2	56,1
VAR 6	30,7	31,2	31,7	32,2	32,7	33,2	33,8
VAR 7	63,3	63,5	63,7	63,9	64,0	64,5	65,0
VAR 8	1246,0	1239,0	1227,0	1220,0	1211,0	1203,0	1192,0
VAR 11	3458,4	3644,0	3829,6	4015,2	4200,7	4386,3	4571,9
VAR 12	31,0	33,0	34,9	36,8	38,8	40,7	42,7
VAR 13	3,3	3,4	3,4	3,5	3,6	3,7	3,8
VAR 14	36,0	34,3	32,6	30,9	29,2	27,5	25,8

Note. Rounding to tenths

Forecasted values VAR 3-4, VAR 6-8 are taken from "Strategy-2035", for VAR 1 and VAR 11-14 trends are built based on statistical data (Fig. 3, 4, 5, 6, 7).

The dynamics of the key indicator is best described by the power function with a 56.5% confidence level. The equation is:

$$У = 8{,}370X^{0{,}093} \quad (1)$$

X – ordinal number of the year in the analyzed period;

У – total fertility rate.

A graphical interpretation of the actual dynamics and trend is presented in Figure 1.

Fig. 1: Actual dynamics and trend of values of the total fertility rate in the region

Along the X-axis - calendar years; on the Y-axis - the values of the total fertility rate.

Despite the low correlation coefficient, the form of the equation and the value of the exponent of the independent variable less than 1.0 allow us to notice the positive dynamics of the total fertility rate with a decrease in its growth rates.

In all the equations below: X is the ordinal number of the year in the analyzed period; Y - the values of the corresponding indicators in units of measurement, presented in table 1. The calculation of the values of indicators associated with the birth rate by functional dependencies, showed their ambiguous "behavior" in the analyzed period.

Thus, the dynamics of the VAR 11 indicator is described by a linear trend with a probability of 92.9%, which indicates a potentially high accuracy of trend forecasting.

Equation (2) has the form:

$$У = 185{,}5941X + 488{,}867 \quad (2)$$

The ratio of the values of the free term of the equation and the coefficient in front of the independent variable demonstrates high growth rates of social benefits in the analyzed period. The presence of a linear relationship with a high correlation coefficient makes it possible to predict the preservation of the formed trend in subsequent years.

The dynamics of the VAR 12 indicator with an accuracy of 98.4% is described by a linear equation (3):

$$У = 1{,}94X - 0{,}028 \quad (3)$$

The ratio of the values of the free term of the equation and the coefficient in front of the independent variable allows us to assume stable, low growth rates of the indicator in the forecast period.

The dynamics of VAR 13 is unstable and is described by a power function with a correlation coefficient of 51.2%. Equation (4) has the form:

$$У = 0{,}093X + 1{,}763 \quad (4)$$

Fluctuations over the years in the analyzed period occur in the range from 0.5% to 6.0%. When predicting the impact of this indicator on the upcoming dynamics of the total fertility rate, it is necessary to take into account that its absolute values are small, therefore, it cannot be significant (which can be seen from the data in Table 4).

Dynamics of VAR 14, characterized by a power-law trend with a correlation coefficient of 0.96. The equation is:

$$y = 187{,}3x^{-0{,}58} \quad (5)$$

This is the most significant indicator that creates a very favorable situation for the growth of the total fertility rate that took place in the analyzed period. The values of the indicator decreased rather quickly until 2015. However, in subsequent years, the values stabilized, which indicates a low perspective for its further decline.

On the basis of the data presented above, the use of a neural network and the results of correlation-regression analysis, alternative forecasts of the dynamics of the total fertility rate in the region were obtained (table 6).

Table 6: Alternative forecasts of the dynamics of the total fertility rate (ppm)

Years	**Forecast using a neural network**	**Forecast by trend**	**Deviation (column 2 minus column 3)**
1	2	3	4
2020	10,3283	10,8515	-0,5232
2021	10,2768	10,9133	-0,6365
2022	10,2086	10,9719	-0,7632

2023	10,1461	11,0276	-0,8815
2024	10,0832	11,0806	-0,9975
2025	10,0057	11,1314	-1,1257
2026	9,8891	11,1800	-1,2909
2027	9,8037	11,2266	-1,4229

Graphical interpretation of the data in Table 6 is shown in Figure 2.

Fig. 2: Alternative forecasts of the dynamics of the total fertility rate (on the abscissa - calendar years; on the ordinate - the values of the fertility rate in ppm)

As can be seen from the above analysis, the data in Table 6 and Figure 2, the forecast based on a linear trend, characterized by a high level of reliability of the regression equation, and the neural network forecast differ significantly. In the first case, we observe, although not high, but positive dynamics, in the second - negative. At the moment, of course, it is impossible to draw a conclusion about the accuracy of each forecast, but the authors believe that the neural network forecast is more realistic, since it takes into account the dynamics of indicators associated with the target. A number of them will, as follows from the above analysis, have a negative impact on the growth of the total fertility rate. The performed calculations demonstrate, in the opinion of the authors of the article, good prospects for using the apparatus of neural networks, even in their simplest version, for predicting the socio-economic indicators of large systems (in particular, regions).

Conclusion

Theoretical developments in the field of the formation of the apparatus of neural networks have now moved into the plane of practical application in the analysis and forecasting of the development of socio-economic systems of various levels. The need for its application is due to the complexity of the relationship between individual socio-economic processes and their characteristics. Correlation-regression and expert analysis used in the process of forecasting socio-economic processes have practically exhausted the possibilities for improvement. This required the use of an apparatus to reveal hidden patterns in the relationship. In some cases, they are not obvious enough even at the qualitative level, and quantitative characteristics generally represent an almost in-soluble problem for experts, usually specializing in narrow areas of economic knowledge. A serious basis for the use of neural network analysis is the formation of a fairly reliable statistical base of socio-economic indicators of Russian regions, covering a period of 18-19 years, which, in turn, makes it possible to forecast for 4-7 years, depending on the statistical characteristics of the identified dependencies. The significant scale and inertia of regional socio-economic systems makes them very convenient models for testing the apparatus of neural networks.

Approbation of the standard apparatus of neural networks using the example of predicting the values of one of the significant indicators of socio-economic development of meso-level systems - the total fertility rate, made it possible to establish a fundamentally different variant of its dynamics, which differs from the expert and "trend"

one. For the purpose of strategic management of regions, it is advisable to use the results obtained to substantiate one of the development options, in this case - pessimistic.

Acknowledgment

The study was supported by the grant of the President of the Russian Federation for state support of the leading scientific schools of the Russian Federation NSh-2702.2020.6 "Conceptual foundations of a new paradigm of economic development in the era of technological and social transformation."

Abstract

The practical experience of foreign countries shows that the formation and development of partnerships between enterprises has a positive effect on the modernization of the economy and the harmonious development of the business environment. The transition to the knowledge economy and the stimulation of innovation require rethinking of the role of interaction between business structures in the field of small entrepreneurship. However, since there is a wide variety of tasks, goals, activities and business conditions for the participants in the relationship, it is important to study the process of interaction between business structures in the field of small business. The purpose of the article is to analyze the development problems of business structures in the context of transformation. As a methodological basis for the study, the authors used the methods of comparative, statistical and graphic-analytical analysis of the main indicators of the development of business structures. The study analyzes the dynamics of key indicators of the development of business structures in Europe and Russia, which makes it possible to assess the impact of small and medium-sized businesses on the economic development of countries. On the basis of the comparative analysis, the key problems in the development of small and medium-sized businesses in foreign countries have been identified. The programs of public and private financing of business structures in Russia and abroad have been analyzed. Measures to support and regulate the activities of business structures have been summarized, which allows taking into account the peculiarities of the functioning of small and medium-sized businesses in various economic spheres.

Keywords: Transformation, Small Business, Government Regulation

Introduction

The state should support social initiatives of business both materially and morally. The degree of compliance of corporate social investments with both the needs of the business itself and the interests of the country's development depends on the effectiveness of relations between the state and business.

The development of relationships between business and the state is a reflection of changes in economic relations in society. The main task here is the necessity to find forms of optimal and effective partnership between the state and private business to ensure sustainable socio-economic development of the national economy as a whole.

The main principle of applying the concept of the model of partnership between the public and private sectors of the national economy is that the state determines what services it needs, and private investors create supply that must meet the requirements of the state (Polozhentseva et al, 2017; Vertakova et al, 2016).

Cite this Article as: Yulia VERTAKOVA, Maria KLEVTSOVA, Yulia POLOZHENTSEVA and Alexandra CHULAKOVA " Development Problems of Business Structures in the Context of Transformation" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Thus, the model of partnership between the public and private sectors of the economy is considered as an integrated concept.

At the moment, there is a problem of increasing the level of cooperation between government and business structures. (Held, 1996). Relations between the state and business should be formed on the basis of mutual responsibility, which will ensure the harmonization of their interests in the direction of raising social standards, the level and quality of people's life. When choosing models of cooperation, it is necessary to take into account the peculiarities of the tasks facing society and business, the specifics of the functioning of entrepreneurial structures and their real possibilities of influencing the socio-economic development of the state. (Androsova, 2013). Government and business should be mutually responsible for the fulfillment of their obligations to society and citizens.

The authors suggest considering separately the listed structures within the framework of the study of the object of the research - the process of interaction between business structures.

1) Cluster formations are the most common form of interaction between business structures.

The creation of cluster formations in the economy has attracted considerable attention of many scientists for a long time.

2) The attractiveness of network structures is explained by very high production advantages, which mean the emergence of a network of interaction, and "collaborative networked organizations" that have different typologies, as evidenced by the typology of collaborative networks.

The network economy is a form of economic activity based on the information environment, the economic advantages of network forms are in the formation of more optimal communications than the market can do, simplification of optimal coordination in the face of changes, the importance of which cannot be fully conveyed or comprehended through price signals.

The mechanisms of network structures lead to an increase in the interest of collaborators in the use of "open concepts"; the center of interest is shifting from maximizing its internal profit to maximizing the productivity of the infrastructure as a whole.

So, the network economy as a product of the development of stakeholders of the productive forces, the active use of information technologies, a new form of organizing economic activity has undeniable advantages and certain limitations. The development of network forms of economic organization in the context of globalization causes the evolution of modern economic systems, opens up new opportunities for generating income and requires adequate mechanisms inherent in these forms of interaction between corporate and government structures, and their use in the interests of society.

3) The authors also consider the most common form of interaction between business structures - public-private partnership (PPP).

Investigating the problem of interaction between business structures, there are several approaches to defining the spheres and even the category of such interaction itself. The first thing that should be said about this is that “public-private partnership” is a concept that has recently become more widespread.

Gerrard M. B. (Gerrard, 2001) clarifies the purpose of the PPP mechanism by the state. To date, a number of authors have come to the general consensus that PPP is cooperation in the sharing of resources.

From the point of view of Budaeus D., PPP is a long-term cooperation between public institutions performing public tasks and private enterprises.

The state sector of the economy in PPP projects can be represented by central, regional and local executive authorities, depending on the scale of the project. Private sector can be represented by one or more private economic agents. In some cases, third parties may be involved in the preparation and implementation of PPP projects. One of the important tasks in the framework of PPP is such a coordination of the interests of the participants, which would allow each of them to realize their own needs with minimal losses and receive benefits.

Thus, all forms of relations between the state and business are between the state order and privatization.

Results

Analysis of the development of business structures in the context of transformation

Small and medium-sized enterprises play a fundamental role in investment and innovation in Europe. Despite macroeconomic problems such as weak domestic demand and economic uncertainty, they continue to be an integral part of the manufacturing sector.

Currently, around 162.8 million small and medium-sized businesses are registered around the world. In general, the average density of small and medium-sized businesses is at the level of 32.18 entities per 1000 people. The leaders of the countries with the highest rates of SME density are: the United States (89.96), Czech Republic (89.31), Liechtenstein (80.69), Iceland (79.20) and Portugal (78.70). There are approximately 28.7 million commercial SMEs, with approximately 18.6 million operating in emerging markets. Moreover, the main share of small and medium-sized businesses is made up of micro-enterprises; there are about 131.4 million of them worldwide. [1].

About 508.0 million employees work in small and medium-sized businesses, with about 231.4 million employees working in emerging markets. It is worth noting that in general, worldwide, according to the estimates of the International Labor Organization, small and medium-sized enterprises, on average, account for 37.5 percent of employment. The World Bank also estimated that small and medium enterprises in 104 developing countries accounted for 47.94 percent of employment.

Canada (85 percent), China (75 percent), Japan (60 percent), Ukraine (57 percent) and Lithuania (52 percent) are leaders in terms of the share of small and medium-sized businesses in employment.

The authors suggest considering the position of small and medium-sized enterprises in the four largest economies of the European Union: Germany, France, Spain and Italy. The economies of these countries account for more than 13 million small and medium-sized enterprises, representing more than 98% of all firms in 2014 and employing more than half of the workforce in these countries.

As such, in the future, international competitiveness and hence the long-term growth and prosperity of the four largest economies in Europe will depend largely on the viability of their micro, small and medium-sized enterprises (SMEs).

The authors analyze the dynamics of the number of small and medium-sized enterprises in Europe for the period from 2016 to 2018 (Table 1). For more informational content, the analysis will include the countries with the largest economies in Europe.

Table 1: dynamics of the number of small and medium-sized enterprises in European countries (2016-2018).

Country	2016	2017	2018	Absolute deviation of 2017 to 2016	Absolute deviation of 2018 to 2017	Growth rate of 2017 to 2016	Growth rate of 2018to 2017
Germany	2 179 097	2 182 416	2 486 635	3 319	304 219	100,1	113,9
France	2 877 989	3 012 369	3 183 959	134 380	171 590	104,6	105,6
Spain	2 382 328	2 352 275	2 374 429	-30 053	22 154	98,73	100,9
Great Britain	1 697 653	1 775 877	1 835 574	1 122	10 297	100,1	101,5
Total	22 303 139	22 529 983	23 653 265	226 844	1 123 282	101,0	104,9

Source: http://ec.europa.eu/

Based on the results of Table 1, it can be seen that, in general, the number of small and medium-sized enterprises in Europe is growing (in 2017, compared to 2016, by 226,844 units, or by 1%; and in 2018, compared to 2017, by 1,123,282 units, or 4.9%). Country analysis also shows an increase in the number of enterprises.

[1] Small and Medium Business in Europe / [Electronic resource] /http://www.smeeurope.eu/

So, for example, in Germany in 2017 their number was 2,182,416 units, which is 3,319 more than in 2016, or 1%. And already in 2018 the number of small and medium-sized enterprises reached 2,486,635 units, which is 304,219 thousand more than in 2017.

France is the leader in the number of small and medium-sized enterprises. In 2018, compared to 2017, their number increased by 171,590 thousand (or 5.6%), and amounted to 3,183,959 enterprises.

The authors further analyze the share of small and medium-sized enterprises in the total number (Table 5). Based on table 2, it is possible to conclude that the number of small and medium-sized enterprises in total has increased in recent years.

Table 2: the share of small and medium-sized enterprises in the total number of enterprises

Country	The number of enterprises in total 2016	Share of small and medium enterprises,%	Number of enterprises in total 2017	Share of small and medium enterprises,%	The number of enterprises in total 2018	Share of small and medium enterprises,%
Germany	2 189 737	99,51	2 193 135	99,51	2 497 694	99,56
France	2 882 419	99,85	3 016 705	99,86	3 188 138	99,87
Spain	2 385 077	99,88	2 354 948	99,89	2 377 191	99,88
Great Britain	1 703 562	99,65	1 781 894	99,66	1 841 715	99,67
Total	22 346 729	99,80	22 573 702	99,81	23 695 657	99,82

Source: http://ec.europa.eu/

In the period from 2016 to 2018, their share increased by 0.02%, and amounted to 99.82%. The largest share of the number of SMEs in the studied countries is observed in Spain (99.88%), as well as the share of SMEs above the average for European countries is observed in Spain (99.87%).

If we consider a wider range of time, we can observe that the number of small and medium-sized enterprises in Europe has almost doubled (Figure 1)[2].

At the same time, the number of small businesses in Italy, for the period from 2013 to 2018, increased by 142%. France is experiencing growth above the European average in the number of medium-sized enterprises (112%).

SMEs in the total number of employed in Europe accounted for 67% of the total in 2018, the relative contribution of small and medium-sized enterprises to the total number; this indicator varies significantly from country to country (Figure 1).

Fig. 1: The share of small and medium-sized enterprises in the total number of employed residents in 2018

The leader in this indicator among the countries with the largest economy in Europe is Italy. The share of workers in small and medium-sized enterprises there amounted to 80% of the total.

[2]Official site of Eurostat [Electronic resource]/ http://ec.europa.eu/

In Spain it is slightly lower - 73%. Germany and France are roughly at the same level 63% and 64% respectively. The UK has the lowest indicator for the number of people employed in the small and medium-sized business sector in Europe (54%).

Small and medium-sized enterprises make a huge contribution to the total value added. So in 2018, their share amounted, on average across the EU countries, to 58% (Figure 2).

Fig. 2: Share of small and medium-sized enterprises in total value added in 2018

Small and medium-sized enterprises play a very important role in all spheres of the world's economies. And their influence is growing every year. The authors suggest considering the dynamics of registration of small and medium-sized enterprises in the field of healthcare innovation and development of new medicines in Europe.

The Regulation on Participation of Small and Medium Enterprises was adopted to promote innovation and development of new medicines by small and medium enterprises. Its main goal is to provide financial and administrative assistance to micro, small and medium enterprises.

At the end of 2018 (Figure 3), the number of companies with the status of small and medium-sized businesses amounted to 1619, which is the highest indicator in the entire history since the emergence of the initiative for the participation of small and medium-sized businesses in the development of medicines. The number of small and medium-sized enterprises registered with the Agency at the end of 2018 was 15 times higher than in 2010 and increased by 24% compared to the previous year. Significant increases in 2015 and 2018 were associated with companies registering paid incentives and paid pharmacological incentives for MedDRA, respectively.[3].

Fig. 3: Number of registered companies from 2009 to 2018

[3] Official website of the European Medical Agency / [Electronic resource]/ http://www.ema.europa.eu/ema/

Since the launch of this project, the application process for SME status has been simplified in order to reduce the administrative burden on the applicant companies. An automated electronic declaration form for small and medium-sized businesses that calculates the number of personnel, annual turnover and the final balance in accordance with the ownership structure of the enterprise was launched in 2011. Countries leading in the share of small and medium-sized enterprises in innovation and medicine development in 2018 are the United Kingdom, Germany and France, followed by Italy and Spain.

In 2018, most of the registered companies were involved in the development of products for human use (76%), 5% developed both human and veterinary medicines, and 4% only veterinary medicines. Service providers for the pharmaceutical industry accounted for 15% of companies; most of them were regulatory consultants (86% of all service providers). Of these registered SMEs, 14% were created within the last 3 years (since January 2016). Most companies are privately owned, either by individuals such as founders or employees, or owned by private corporations through partnerships and holdings.

Venture capital funding is 7% of the equity capital of the companies. At present, the share of developed high-tech medicines by small and medium-sized enterprises is 7%. Also, one of the striking examples of support programs for small and medium-sized businesses is the KeyGene Company[4].

KeyGene's core activity is strategic and applied research into natural genetic changes in vegetables and other crops. It has 135 employees and is based in the Netherlands. Founded in 1989, the company strengthened its international activities in 2004, when the European Commission implemented a project to support small and medium-sized enterprises in international projects. During this period, the company established a subsidiary in the United States and began cooperation with a research institute in China. In addition, the company hired more employees from foreign countries and established English as the main internal language. KeyGene is currently receiving useful support for its international activities not only from its shareholders, but also from the Dutch embassies, as well as from the European Business Association. Moreover KeyGene participates in joint public projects funded by European research institutions. Internationalization has thus had a significant positive impact on companies: turnover, number of employees and number of patents have all led to strong growth.

Problems of small and medium-sized businesses in foreign countries and programs to support and regulate the activities of business structures

After two years of recession, the short-term outlook for European economies has improved. However, this picture hides a very heterogeneous environment in the four largest players, where the financial and economic crisis that began in 2008 has been felt at different levels of intensity.

In Germany activity recovered to pre-crisis levels in early 2012 and after two years of stagnation in 2012 and 2013 accelerated again in 2015-2018[5]. The labor market proved to be very resilient, with the unemployment rate reaching 6.7% at the end of 2018, the lowest level since German reunification. Spain and Italy, on the other hand, experienced a major double recession. The output began to fall sharply from mid-2011, when the sovereign debt crisis intensified. Tightening financial conditions and fiscal consolidation have seriously affected public and private demand. In Spain, suppressed domestic demand led to unemployment at 26% at the end of 2012.

However, in early 2013, Spain began to recover, pushing export growth. Domestic consumption accelerated in 2014[6], and high unemployment started to decline. At the same time, despite this, the recession has slowed down, Italian production continues to fall and unemployment continues to rise.

The French economy has taken an intermediate path. A strong recession in the economy at the first stage of the crisis and the release of the pre-crisis level reached in early 2011, as in Germany. However, this recovery quickly stopped and a long period of stagnation followed. 2014 was the third year in a row with near-zero unemployment growth, rising slowly but steadily[7].

Regardless of the speed of recovery in different countries, 2018 began with some positive news for the entire eurozone, encouraging hopes in the near future to break out of the long stagnation of the past years.

[7]Official site of the international financial agency / [Electronic resource] /http://www.ifc.org/

The sharp drop in oil prices will have a beneficial effect on household purchasing power, which can already be seen in the rebound in consumer confidence at the start of the 2018 survey, as well as on firms' production costs, generating more profits and investment. In addition, the depreciation of the euro affected the relief for the export sector.

In terms of recovery in consumption, the short-term outlook is much brighter for the European manufacturing sector today than a year ago. However, many problems remain unresolved. Difficult macroeconomic conditions have left their mark on the European manufacturing sector. Small and medium-sized enterprises, which are at the heart of its dynamics, have been particularly hard hit. Less diversified and more financially fragile, they were particularly vulnerable to weak demand conditions and, in many cases, face difficulties in accessing financial resources. This led to a decrease in their investment costs, and forced them to postpone particularly high levels of return, in yet risky projects.

In addition, the crisis has shown the need for many European economies to improve their competitiveness, especially in Italy, France and Spain.

All three countries have significant and strong export sectors that will benefit from competitiveness reforms as previous growth drivers, such as housing and civil construction, and consolidate their balance sheets. In addition to adjusting spending, strengthening the size of non-price factors such as quality, reputation, and innovation is important in the long term for economies for which external demand is an important component of GDP.

Many other issues need to be addressed in order to achieve a sustainable recovery, such as the continuing decline in leverage, the continued large reserve capacity that leads to weak inflation, and the persistence of financial fragmentation in the euro area despite recent significant improvement.

In any case, the present weakening of financial and economic conditions is an opportunity for European SMEs to address these problems. Stimulating investment strategies for small and medium-sized businesses, especially if they focus on innovation and growth, can contribute to strengthening competitiveness in the deflationary environment of the euro area.

The survey results show a rather contradictory picture of the current competitiveness of small and medium-sized enterprises in Europe. However, they transmit a clear signal. European small and medium-sized enterprises face stiff competition in world markets based on the prices of goods and services. They are unlikely to be able to compete with low-priced firms from emerging economies such as China and Brazil. Consequently, aspects such as quality, reputation and innovation will be critical for European SMEs to survive in a globalized world.

Eurostat personnel recently conducted a survey to assess the international competitiveness of small and medium-sized enterprises in ten industrialized and developing countries and compare them in terms of price, quality or innovativeness of their products and services (table 3).

Table 3: indicators for assessing the competitiveness of small and medium enterprises in ten industrialized and developing countries

Indicator	Great Britain	Brazil	The USA	Germany	France	Russia	Spain	China	Italy	Japan
Price	3,3	3,53	3,24	2,85	3,15	3,27	3,16	3,40	3,09	2,97
Quality	3,67	3,5	3,60	3,89	3,44	3,45	3,38	3,16	3,40	3,28
Innovation	3,49	3,43	3,47	3,42	3,22	3,12	3,23	3,11	3,22	3,00
Recognition	3,48	3,50	3,28	3,17	3,40	3,22	3,20	3,07	3,22	2,79
Delivery Time	3,43	3,51	3,19	3,75	3,24	3,30	3,30	3,31	3,25	3,31
Service level	3,58	3,36	3,53	3,85	3,34	3,30	3,27	3,09	3,11	2,87
Personnel	3,32	3,22	3,14	2,55	3,00	3,01	3,07	3,44	2,92	2,77
Total Level	3,47	3,44	3,35	3,35	3,26	3,24	3,23	3,23	3,17	3,00

To determine the firm's performance, representatives of the companies were interviewed and asked to rate their performance in comparison with their main international competitors in various aspects. Possible answers: 1 - much worse; 2 - slightly worse; 3 - similarly; 4 - slightly better; 5 - much better. The values displayed represent the weighted average of all surveyed companies in the country. The firm's productivity component indicator is calculated as a simple average of seven factors.

When it comes to pricing, only Brazilian and Chinese firms perceive themselves to be highly competitive in international markets. French, Spanish, Italian and in particular German small and medium-sized enterprises, on the contrary, perceive their price competitiveness as relatively weak. Russian firms, according to competitors' surveys, have a fairly good level of prices, quality, delivery time and level of service. The authors suggest referring to the World Bank's annual Ease of Doing Business report (Table 4)[8].

Table 4: Ease of Doing Business Rating

Country	Establishment of enterprises	Obtaining construction permits	Property registration	Access to credit	Taxation	Raiting
Germany	114	12	79	32	48	17
France	27	20	100	82	63	29
Spain	85	113	50	62	37	32
Italy	22	28	10	28	32	50
The USA	51	39	36	2	36	8

Source: http://doingbusiness.org/

France is ranked 27th in terms of ease of doing business, according to the World Bank. The state provides an enabling business environment with strong government institutions and a regulatory framework in line with European standards. The main French business sectors are electronics, transport, tourism, textiles, food processing and chemicals.

Starting a new company in France can be done quickly and easily. All formalities can be resolved in one place: Business Center. French law provides effective regimes for the protection of intellectual property, as well as specific tax incentives to create; storage; removal of IP and IT rights.

Companies in France are subject to corporate income tax at a rate of 34.43%. Foreign companies are also subject to limited liability tax on their French source of income. However, there are many favorable tax regimes applicable to companies belonging to the same group that comply with transfer pricing rules that follow OECD principles[9].

Any salaried employee must be declared to the local social security authorities within the 8-day period prior to commencement of the employment. Payment of wages is subject to social security contributions, which vary depending on the amount of wages paid and the nature of the employee's work. In addition, the French legal framework protects workers, as an employee can only be fired in very specific circumstances, and after the completion of a regulated process.

Spain is ranked 85th in the ease of doing business ranking. Small and medium-sized businesses across Spain have a lot of variance in regulatory practices depending on where they do business. Differences in implementation requirements at municipal, regional and national levels determine how easy it is to do business.

Except for construction permits, all regions are below the European average.

Italy takes the 22nd place in the Ease of Doing Business ranking. In Italy, the easiest way to deal with a construction permit and registration of property rights in Bologna, enforcement of a contract in Turin, and starting a business in Catanzaro or Padua. For cross-border trade Genoa is the best port.

Differences from one city to another can be very large. In the case of obtaining construction permits, the main delay in obtaining one depends on the municipality. In Catanzaro and Palermo, this step alone takes six months, while the same procedure takes half that time in Campobasso, Naples, and Potenza, and only one month in Milan.[10].

[8] Official website of the World Bank [Electronic resource]http://doingbusiness.org/

[9] Official website of the Organization for Economic Cooperation and Development / [Electronic resource]/ http://www.oecdru.org/

The legal environment for local entrepreneurs in Italy is improving and the pace of change is gaining momentum. Comparing Italy's performance from 2005, the global Doing Business report shows how much the regulatory environment has changed for the better.

Despite the good changes, problems still remain. Companies across Italy continue to face inefficient and time-consuming procedures that carry high costs, especially in areas such as obtaining building permits and enforcing contracts.

In the 2016 annual report of the World Bank the USA fell from seventh to eighth in the overall ranking. Just six years ago the US ranked fourth. The main fault lies with New York City's legal problems, as these ratings were derived from examining the conditions for doing business in the most economically important city in each country.

Tax reform was underway in the United States. There is widespread support for simplifying the US tax code for businesses by lowering rates while expanding the tax base by closing loopholes[11]. Due to this, it has become easier to pay taxes, and the United States is in the middle place among the OECD countries in terms of ease of paying taxes. Also, in the future, it is planned to introduce a state law that will equalize taxes between enterprises in different states, which makes the economy more efficient as a whole.

Nowadays, businesses are facing huge challenges, and small and medium enterprises are no exception. In addition to globalization, small and medium-sized enterprises face a number of other challenges, such as increasing digitalization, rising energy prices and an aging population, that require smart investment and innovation strategies. The computerization of manufacturing, or the fourth industrial revolution, offers many opportunities for small and medium-sized businesses that are willing to invest in process innovation, but poses a threat to enterprises that are defensive against it. Energy prices are still low, but the expected growth in the medium term could make investments in energy saving technologies irreplaceable.

This is especially true for small and medium-sized enterprises with energy-intensive production processes. SMEs also face demographic challenges. The average age of small and medium-sized business owners in Germany, for example, has risen from 45 in 2002 to 51 in 2018[12]. Older owners tend to invest significantly less in their firm. They are more focused on replacing investments than expanding production capacity.

This underlines the need for a comprehensive economic policy that encourages investment and innovation, including more indirect measures such as encouraging young talent and entrepreneurial successors of a company. European politicians have already realized this and have launched a series of initiatives to encourage investment and innovation across Europe. In this regard, the "Junker plan" is currently being implemented, which has a strong impact on the development of small and medium-sized businesses in Europe. The Junker plan is dependent on the European Fund for Strategic Investment (EFSI). EFSI supports strategic investments in infrastructure as well as financial risks for small businesses that the market cannot finance alone. Therefore, it finances projects with a higher risk profile in an effort to maximize the impact of public spending and unblock private investment. EFSI focuses its funding on infrastructure investments and innovation in small and medium-sized enterprises.

According to the European Commission, the EFSI is expected to allocate 315 billion euros to the real sector of the economy within three years (2015-2017), of which 240 billion euros is provided for long-term investments in infrastructure and 75 billion euros is planned for financing small and medium-sized businesses[13].

Also, at present, the countries of the European Union are implementing the "Horizon 2020" program. The volume of investments is about € 3 billion, which is being implemented in the period 2014-2020. The programs included in this project help small and medium-sized enterprises with high potential to develop innovative ideas for products, services or processes that are ready for global market competition.

During the first two years of implementation, more than 1200 SMEs received funding under the SME Support Program. Around 513 million euros have been invested in the success of innovative small and medium-sized

enterprises. By the end of 2020, the Horizon project will finance about 7500 new small and medium-sized businesses[14].

The program offers the following tools to support small and medium businesses:

- Business innovation grants for the purposes of technical and economic assessment: 50,000 EUR (one-time) in the project (70% of the total project cost);

- Business innovation grants for innovative development and demonstration purposes: an amount in the approximate range of 500,000 euros and 2.5 million (70% of the total project cost as a general rule);

- Free business trainings (optional) in order to support and strengthen the innovative potential of the firm and help in aligning projects with strategic business needs;

- Access to a wide range of innovation support services and easier access to venture funding to promote the commercial exploitation of innovation.

Conclusions

The practical experience of foreign countries shows that the formation and development of partnerships between enterprises has a positive effect on the modernization of the economy and the harmonious development of the business environment. The transition to the knowledge economy and the stimulation of innovation require a rethinking of the role of interaction between business structures in the field of small entrepreneurship.

However, since there is a wide variety of tasks, goals, areas of activity and business conditions for the participants in the relationship, it is important to study the process of interaction between business structures in the field of small business.

In world practice, within the framework of the concept of partnership models of the public and private corporate sector of the national economy, five basic models of cooperation have been formed.

The basic principle of applying the concept of the partnership model between the public and private sectors of the national economy is that the state determines what services it needs, and private investors create supply that must meet the requirements of the state.

Thus, the model of partnership between the public and private sectors of the economy is considered as an integrated concept.

At the moment, there is a problem of increasing the level of cooperation between the government and business structures. Relations between the state and business should be formed on the basis of mutual responsibility; it will ensure the harmonization of their interests in the direction of raising social standards, the level and quality of people's life.

Acknowledgments

The study was supported by the grant of the President of the Russian Federation for state support of the leading scientific schools of the Russian Federation NSh-2702.2020.6 "Conceptual Foundations of a New Paradigm of Economic Development in the Era of Technological and Social Transformation."

Abstract

The paper presents a discussion on the influence of implemented management systems such ISO 9001, ISO 14001 and ISO 45001 on risk-based thinking in organizations. The requirement to use a risk-based thinking in the organizations appeared with the entry into force of international standards based on so-called high level structure. Many organizations have introduced basic principles related to the identification of risks and opportunities resulting from the application of a risk-based thinking. However, in international ISO standards are included only requirements. This means that the management of an organization may use a risk-based thinking in various ways to identify risks and opportunities and appropriately manage areas where risks and opportunities emerge. The complexity of the methods of application depends on the organizational context, including the internal environment and maturity of processes and management system as a whole [Zhemchugova and Levshina, 2020].
The aim of this article is to show the influence of implemented management systems on risk-based thinking in organizations. This article indicates the requirements for the risk-based thinking as part of the quality, environmental and occupational health and safety management system. The possibilities of using the risk-based thinking in the organization within three areas of systemic management were presented.

Keywords: Risks, Opportunities, Risk-Based Thinking, Quality Management System, Environmental Management System, Occupational Health and Safety Management System.

Introduction

Risk-based thinking is an integral part of the functioning of organizations in all aspects of their operations, because in order to implement the strategy, all steps taken by the management of an organization are burdened with a certain degree of risk and opportunities that may be associated with the functioning and development of their business. Dynamically changing conditions of the economic environment and organizational context means that an appropriate approach to risk management is now crucial and constitute a determinant of effective management as such [Tchankova, 2002]. Top management of an organization focused on improving the performance of its activities shall demonstrate a commitment with respect to the risk-based thinking [Chiarini, 2017] and must be aware of a number of factors affecting the activities of the organization and leading to the occurring of both risks and opportunities. Organizational risk management must be incorporated into decision-making processes that generate value for organizations [Gallop et al., 2016]. Failure in considering risks in decision-making processes can have many negative effects, from losing a customer, through losing control over the organization, up to possible bankruptcy of the company [Falkner and Hiebl, 2015]. Therefor a lot of organizations have formed risk management departments to manage and control their threatening risks that they are exposed to [Samani et al., 2017].

Risk-based thinking has been used in management systems since the last revision of international standards (ISO). In previous editions of these standards, the concept of the risk-based approach was presented indirectly, e.g. by planning, carrying out management reviews, conducting preventive actions to eliminate potential non-conformities

Cite this Article as: Alina MATUSZAK-FLEJSZMAN and Beata PALIWODA "Influence of The Implemented Management Systems on Risk-Based Thinking in Organizations – A Review" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

and their consequences, analyzing non-conformities that have already occurred, and by taking actions to prevent the non-compliance from recurring. Currently, the requirements of the international standards for risk-based approach are firmly defined. Risk-based thinking enables the organization's management to identify factors that may cause deviations from the planned results of the processes and management system, introduce preventive oversight measures to minimize negative effects and make the most of the opportunities [ISO 9001:2015, point 0.1]. The volatility of the business environment is predictable to a varying degree and may affect the undertaken activities both positively and negatively. In order to maximize market opportunities and minimize threats, risk management takes place in every organization, implemented in a more or less formalized way in relation to the intuitive approach taking place in the activities of every human being [Zapłata, 2019]. Each of the ISO standards containing requirements for the application of a system approach to quality, environmental, and occupational health and safety management define the areas of risk-based thinking and related risk management to be applied in the organization.

The article aims to present the issues related to the application of risk-based thinking in a systemic approach to quality, environmental and health and safety management and to present the results of a pilot study conducted in organizations operating in Poland in terms of assessing the impact of implemented management systems on risk-based thinking.

Basic definitions in terms of risks and opportunities

The concept of risk is present in most scientific areas e.g. finance management [Mertzanis, 2014], project management [Ward and Chapman, 2003; Kutsch, 2008], investment management [Merková and Drábek, 2015], insurance [Willet, 1901], human resource management [Becker and Smidt, 2016], innovation management [O'Connor et al., 2008; Bowers and Khorakian, 2014], maths [Biagini et al., 2014] or quality management [Jedynak, 2017]. The interweaving of concepts, theories and measurement methods from various areas of science has made today's knowledge of risk interdisciplinary, which affects many different definitions of the term "risk". Cambridge Dictionary defines risk as "the possibility of something bad happening" [Cambridge Dictionary]. Another popular definition define risk as: "the measure of probability and the weight of undesired consequences" [Lawrence, 1976]. According to Campbell "risk equals expected damage" [Campbell, 2005]. Those definitions see risk in negative light, which is often treated as a threat. In the case of negative characterization of risk, it is referred to when there is a probability of a certain damage, loss or simply failure to implement the established assumptions. In such cases, risk is associated with the terms "threat", "danger", "loss" or "harm". Some other definitions put risk in neutral light e.g. "risk equals the product of probability and severity" [Wilson and Crouch, 1982]. In ISO 31000, risk is defined neutrally as [ISO 31000:2018]:

- uncertainty related to an event or action that will affect the ability to achieve goals,
- the chance that something will happen that will have an impact on the goals, expressed in terms of probabilities and effects,
- a combination of the probability of an event and its consequences.

Thus, risk can be defined as the uncertainty related to future events or the outcome of a decision leading to a loss or gain. On the other hand, in a neutral concept, risk can be both a threat and an opportunity. It appears when the results of a certain action are unknown to the interested party. Risk means uncertainty as to the future effects of certain decisions or events. These effects can be positive (chance or opportunity) and negative (threat). In this concept, risk is associated with the probability of both loss and profit. As part of the neutral approach to risk, there is also the concept of risk as the possibility of obtaining an effect other than the intended one, without assessing whether it is positive or negative [Jajuga, 2018].

Those definitions can be useful for risk management in organizations. Risk in management is usually analyzed in the organizational dimension. Therefore, the risk relates to management at any hierarchical level of the organization and may affect the functioning of the unit in the short, medium and long term. According to de Melo and de Medeiros risks are classified as follows: Strategic Risk, Market Risk, Compliance Risk, Operational Risk, and Reputational Risk [2020]. Additionally, risk relates to the organization's activities in three dimensions:

- strategic (risk related to the organization's strategy, organizational goals, fusions, mergers, acquisitions),
- tactical (risk related to undertakings, projects, product and service development),

- operational (risk related to routine activities).

It should be emphasized that, on the one hand, the risk may be a threat to the management of organizations, against which they take action to remove or minimize it, and on the other hand, the management of those organizations is aware of the positive role of the risk (so-called opportunity), which may bring greater benefits. In the ISO 9000:2015 standard, risk is defined as the impact of uncertainty on the objectives [ISO 9000:2015]. Defining goals allows for the identification of threats and assessment of the risks that may impact the achievement of goals.

Cambridge Dictionary defines as opportunity as "an occasion or situation that makes it possible to do something that you want to do or have to do, or the possibility of doing something" [Cambridge Dictionary]. In case of managing an organization, opportunities can be used to achieve benefits, both market and financial. Unfortunately, they are often confused with the strengths of the organization. In terms of strategic management, opportunities are factors outside the organization. The management of the organization has no direct influence on the opportunities, unlike the strengths, which mainly include the internal factors of the organization, having a positive impact on its functioning and the effects resulting from its activities.

Opportunities, unlike risks, are always positive, i.e. they can be used in the improvement of the organization's activities, its products or services. The management of the organization should be focused on looking for opportunities and use them to improve the performance of the organization in terms of quality, environmental protection and safety. Opportunities appearing in the organization's environment may lead to the adoption of new management techniques, methods and practices, introducing new goods and services to the market, entering new markets, acquiring new customers, retaining existing customers or returning lost customers and strategic partners, introducing new technologies, and also building partnerships and other desired opportunities beneficial for the current needs of the organization or its clients.

Risk-based thinking enables the management of an organization to take into account both risks and opportunities in making strategic, tactical or operational decisions that affect the functioning and improvement of business operations.

Risk-based thinking in the management systems

Quality, environmental and occupational health and safety management systems are based on a process and risk-based approach. However, is should be emphasized, that both the "process approach" and the "risk-based thinking approach" should be treated primarily as a requirement enabling a reliable analysis of the organization's activities, in particular in terms of quality, environmental impact and ensuring safe working conditions. It also should be remembered that the application of the process approach and the risk-based thinking approach ensures the stability of the functioning of processes. The improvement of those processes affects the effectiveness of activities and development of the organization and enables the management of the organization better understand and meet the needs and expectations of customers and other interested parties [Matuszak-Flejszman, 2019].

A risk-based thinking is a necessary factor in the effectiveness of a quality, environmental, and health and safety management systems. The concept of risk-based thinking was introduced to eliminate potential nonconformities, analyze existing nonconformities, and take actions to prevent reoccurrence. In order to meet these requirements, the management of the organization must plan and implement activities to eliminate risks and increase opportunities. The consideration of risks may include avoiding risk, taking the risk to pursue an opportunity, removing a source of risk, changing the probability or consequences, sharing the risk, or stopping the risk based on an informed decision. Opportunities, on the other hand, may lead to the adoption of new practices, the introduction of new products, the opening of new markets, the acquisition of new customers, building partnerships, the use of new technologies and other desired and real opportunities, taking into account the needs of the organization or its customers.

According to Zhemchugova and Levshina [2020] the risk-based thinking can be applied in any organization, irrespective of size and the sector profile, but the complexity of the methods of application depends on the environment of the organization, including the internal environment, and considering the maturity of its processes and management system as a whole.

Risk-based thinking in ISO 9001

Risk management is an essential element of effective quality management [Juhani and Kari, 2017]. The ISO 9001 standard contains many areas for the application of the risk-based thinking. As part of the requirement concerning the context of the organization, it is necessary to define the processes needed in the quality management system and their application in the organization, and to take into account risks and opportunities [ISO 9001: 2015, p. 4.4.1.f]. Actions related to risks and opportunities should be initiated at the time of planning the processes functioning in the organization [Medić et al., 2016]. Considering risks and opportunities when planning processes can help organizations in avoiding later expenses and the need to implement changes to existing processes.

In the leadership section, top management is required to demonstrate leadership and commitment to the quality management system by promoting the use of a risk-based thinking [ISO 9001:2015, p. 5.1.1.d] and to demonstrate leadership and commitment in the area of orientation on the customer by ensuring that risks and opportunities affecting the compliance of products and services and the ability to increase customer satisfaction are identified and addressed [ISO 9001:2015, p. 5.1.2.b].

Another area where the quality management system requires a risk-based thinking is risk and opportunity activities, where risks and opportunities should be identified after considering factors affecting the organization to ensure that the QMS can achieve its intended goals, increasing the desired effects, preventing and reducing the occurrence of undesirable effects, as well as continuous improvement. Actions related to risks and opportunities should be planned, and actions taken should be proportional to the impact on the compliance of products and services with the relevant requirements.

The results of the analysis and evaluation of relevant data and information from monitoring and measurement should be used to evaluate the effectiveness of activities taking into account the risks and opportunities. The management review should be planned by the management of the organization and conducted in terms of the effectiveness of the actions taken, taking into account the risks and opportunities. Moreover, in the event of non-compliance, including customer complaint, the organization should update the risks and opportunities identified when planning related activities.

Risk-based thinking in ISO 14001

ISO 14001 also requires the application of a risk-based thinking. In the ISO 14001 standard, the risk was presented in a negative connotation - related to the unfavorable development of the situation for the organization. Opportunities, on the other hand, are understood as chances for the development of a given situation favorable for the organization. Regardless of this, attention should be paid to the fact that the application of a risk-based thinking to the environmental management system is concerned with the risks and opportunities associated with the organization's activities and not with the environment as such.

When planning the environmental management system, the organization should identify risks and opportunities related to the its environmental aspects, compliance obligations and other factors and requirements defined in the context of the organization. It is necessary to ensure that systemic approach to environmental management in the organization allows to achieve intended result and prevent or limit undesirable effects. Moreover, it allows the continual improvement of activities, processes and products. It is required to create documented information on identified risks and opportunities, and then to plan appropriate actions relating to these risks and opportunities. Risks and opportunities are related to the identification of potential emergency situations, including those that may have an impact on the environment. In addition, as part of the management review, the organization's management should consider changes in risks and opportunities.

Risk-based thinking in ISO 45001

In the ISO 45001 standard containing the requirements for the occupational health and safety management system, the issues related to the application of the risk-based thinking appear more times than the requirements contained in the ISO 9001 and ISO 14001 standards. The ISO 45001 standard provides a broader view of issues related to risk, not only related to occupational risk, but also to the risk related to the functioning of the occupational health and

safety management system.

While planning an occupational health and safety management system, management of an organization should consider the context of the organization, stakeholders and the scope of the occupational health and safety management system, and identify risks and opportunities to ensure that the occupational health and safety management system achieves the intended results, prevents or reduces undesirable effects and constantly improves the effects of its activities.

When determining risks and opportunities associated with the occupational health and safety management system and its planned results, the management of the organization should take into account [ISO 45001: 2018, p. 6.1]:

- risks, including health and safety risks and other risks,
- health and safety and other opportunities,
- legal and other requirements.

Occupational health and safety risk analyses should consider hazards that:

- arise as a result of the activities of the organization,
- remain under its control and can affect both people working in the organization and people outside the organization (subcontractors, people visiting the organization),
- may affect employees who perform work outside the permanent location and over which the organization has no direct influence.

Possibilities of reducing risks associated with threats are related in particular to:

- eliminating threats and limiting occupational risk at the design stage,
- restrictions on monotonous or forced-speed work,
- application of new technologies,
- creating a high safety culture.

The organization's management in the planning process should identify and assess the risks and opportunities that are relevant to the planned results of the occupational health and safety management system and its processes. When analyzing threats in the effective system, the organization should first of all pay attention to the context of the organization, available resources, audit program, competences of people performing key functions, the commitment of the top management, the degree of consideration of the needs and expectations of interested parties, as well as the results obtained in the area of safety. Opportunities relating to the improvement of the system include, for example, increasing the visible support from the top management, improving incident investigation processes, increasing employee participation in activities related to occupational health and safety, benchmarking, as well as cooperation with other entities and forums focusing on occupational health and safety issues.

In case of planned changes, whether permanent or temporary, it is required to assess the risk or opportunity before implementing any change. The main goal of planning activities related to health and safety at work should be primarily to determine how to deal with risks and opportunities. Planning of activities should also take into account the status of current legal requirements and other specific standards relating to occupational health and safety, control hierarchy and results of the occupational health and safety [Kubista, 2019]. The organization should establish targets for the appropriate functions and levels to maintain and continuously improve the system. These goals should take into consideration the results of the risk and opportunity assessment. Planning of activities should focus at the best available practices and technology options in the organization, financial, operational and business requirements to achieve the health and safety objectives.

In accordance with the requirements of ISO 45001, the organization must establish, implement and maintain processes for the elimination and reduction of health and safety hazards in accordance with the following hierarchy of activities [ISO 45001:2018, p. 8.1.2]:

- eliminating the threat,
- replacement by less dangerous processes, operations, materials or equipment,
- application of technical control and reorganization of work,
- application of administrative control, including training,
- use of appropriate personal protective equipment.

As part of the activities aimed at controlling risks in the organization, it is necessary to establish, implement and maintain the processes necessary to prepare and respond to potential emergencies. In addition, the organization should establish, implement and maintain processes for monitoring, measuring, analyzing and evaluating activities, taking into account, inter alia, activities undertaken and actions related to identified threats, risks and opportunities.

As part of the management review, the management of the organization, as in the case of the QMS and EMS, should, consider issues relating to changes in external and internal factors that are relevant to the occupational health and safety system, including risks and opportunities, and information on activities, including trends in risks and opportunities.

Risk management according to ISO 31000

Risk management is the process of coordinated activities to direct and control an organization in relation to risk. In order to ensure effective risk management, the principles and guidelines contained in the ISO 31000 standard should be implemented in the organization. Any solution for the implementation of these principles can be used, but they are to contribute to the effectiveness of the management system and be understandable to users. The implementation of these principles is facilitated by the use of a risk management model based on a process approach, which is included in the ISO 31000 standard.

The risk management process should be an integral part of management and decision-making and integrated into the structure, operations and processes of the organization. It can be applied at strategic, operational, program or project levels [ISO 31000].

Important elements of the risk management process include defining the scope, context and criteria necessary to identify, analyze and evaluate risk. A very important element in ensuring the effectiveness of the risk management process is effective communication and consultation with risk users.

One of the key elements of the risk management process is its assessment, which is the overall process of risk identification, analysis and evaluation. A very important action when identifying the risk is to determine the source of the risk and to predict the potential impacts and consequences of this risk in individual areas of the organization. In order to identify risks well, each area should be analyzed in detail and the possible risks based on events that could disrupt the achievement of goals or contribute to the emergence of threats to the implementation of activities or processes in the organization are listed.

The next stage of the risk assessment process is its analysis. The risk analysis process aims to provide the data necessary to conduct a risk evaluation and to make decisions on how to deal with the risk. In this case, the risk analysis process should take into account the probability of consequences and the effects that may arise as a result of these consequences.

Third stage in the risk assessment process is a risk evaluation to compare the results of the risk analysis with the risk benchmarks for determining risk severity. A risk evaluation is performed to determine the risk acceptability level. It is intended to support management in making decisions on how to deal with risk in terms of its avoidance, acceptance, removal of risk sources, changing the probability of risk occurrence, changing the consequences or sharing the risk.

Risk treatment is an important part of the risk management process. After risk assessment the necessary steps for risk treatment should be carried out. Risk treatment involves an iterative process of [ISO 31000, p. 6.5.1]:

- formulating and selecting risk treatment options,
- planning and implementing risk treatment,
- assessing the effectiveness of that treatment,
- deciding whether the remaining risk is acceptable,
- if not acceptable, taking further treatment.

Each step of the risk assessment process should be properly monitored and reviewed to ensure the effectiveness of actions. The results of monitoring and reviews should be documented and reported to the risk users. Recording and reporting aims to [ISO 31000, p. 6.7]:

- communicate risk management activities and outcomes across the organization,
- provide information for decision-making,
- improve risk management activities,
- assist interaction with stakeholders, including those with responsibility and accountability for risk management activities.

Conclusions

The analysis of the literature has shown that risk-based thinking is used in many organizations, but the management of the organization implements it in different ways depending on the approach to identifying risks and opportunities and the areas in which those risks and opportunities may arise. There is no doubt that the top management of an organization focused on improving the performance of its activities should demonstrate a commitment to risk-based thinking and must be aware of a number of factors influencing the activities of the organization and leading to the risks and opportunities. Therefore, risk-based thinking and as a result organizational risk management should be integrated into management's strategic and decision-making processes.

The implementation and maintenance of the management system significantly influences the improvement of risk management activities. There is no doubt that risk-based thinking enables the management of the organization to identify factors that may cause deviations from the planned results of the processes and management system, to introduce preventive supervision measures to minimize negative effects and maximize opportunities. By applying risk-based thinking, the organization's management can reliably analyze quality, environmental and occupational health and safety activities, and then ensure appropriate supervision of these activities to minimize risks and increase opportunities. This, in turn, improves the effectiveness of activities and the development of the organization, as well as a better understanding of the needs and expectations of stakeholders.

Abstract

Nowadays, Breast cancer is a profoundly severe disease that many women have been diagnosed with in the past few decades. For starters, Breast Cancer is mainly the formation and grouping of some malignant cancerous cells inside the breast cells. Even though breast cancer is the second most cancerous disease that women get diagnosed with, Men also can get diagnosed with it, but it is not very likely. Breast cancer can be deadly if not detected quickly and in its early phases. Subsequently, scientists have been searching for a method to help them address this problem efficiently, and their studies lead them to machine learning. Recently, Breast cancer Prediction has been one of the most progressing topics in machine learning. In the proposed paper, we quickly disclosed and identified whether a tumor is benign or malignant with some features processing of our 2 benchmark datasets and classifying algorithms (KNN, decision tree, naïve Bayes). A malignant tumor is a cancerous tumor that spreads, and the benign is the tumor that does not spread and is not cancerous. To conclude, as for the first dataset, we found that the best algorithm was the IBK Accuracy of 95.43%. We found that the naïve Bayes algorithm proved better than the other algorithms for the second dataset due to its relatively good data71.67%.

Keywords: Malignant, Benign, Classification, and machine learning Algorithms

Introduction

In 2016, it was stated in the US reports that around 2,46,600 cases of women were diagnosed with breast cancer, and about 40,450 of these cases died (Ganggayah, 2019), which is nearly 16% of the number of diagnosed women. Therefore, this confirms the idea of breast cancer being fatal to women and booming in the last few years.

The structure of the breast is simply as follows, connective tissues, Glandular tissues, and Fat cells. The most important and prime parts in the female breast are the" lobules" which are the glands that produce milk, "ducts" which are the milk passages which connect between the lobules and the nipple, and the stroma which are fatty tissues and ligaments that surround the lobules and the ducts (Chaurasia, 2018). Breast cancer is an unusual and malformed growth and spread of cells that usually lies along the ducts and the lobules.

Over the past several decades, developments and advancements of multiple "machine learning(ML) and data mining(DM)" operating methods that have been made for the sole purpose of detecting and classifying breast cancer as it is inevitably a pervasive cause of death in both men and women (Abernethy, 2010). This paper will be using the WEKA tool to preprocess data and use some of the offered classification algorithms to analyze breast cancer detection and how reliable and accurate is using the previously mentioned tool in prediction (Kalmegh, 2015).

With the help of big data and its evolutions, scientists were able to store large amounts of data in the area of breast cancer and also be qualified and free to use this Data in classifying and training it to be a reliable model in breast cancer detection, relying on various attributes that lead to the tumor being malignant or benign with a high percentage of accuracy (Ganggayah, 2019; Agarap, 2017). There are 32 attributes in the first dataset and ten attributes in the second dataset.

Numerous algorithms are used for the classification and the forecast for breast cancer results. Three algorithms are going to be used and compared in order of performance levels and executability, which are the KNN, naïve Bayes, and Decision tree. These algorithms belong to the most crucial and significant algorithms in data mining within the research community (Ganggayah, 2019). We are aiming to assess the efficiency, proficiency, and efficacy of these algorithms according to their precision, reliability, and accuracy (Khurana & Verma, 2020).

The rest of the paper is described as follows: the paper's related work can be found In Section 2. The methodology is presented in Section 3. Section 4 shows a comparison between proposed algorithms and the experimental results. Finally, Section 5 shows the conclusions and future work.

Literature Survey

A considerable number of researchers have been developing and analyzing breast cancer detection systems. Some of their works and papers are going to be explained here.

Dhahri et al. (2019) constructed a method to point out whether the tumor is benign reliably (B) or malignant(M) using "machine learning(ML)" algorithms and genetic programming, their focus was on the feature extraction, segmentation of the images and information extraction.

Talukdar & Kalita (2015) were working on the WEKA tool, and they used two classification algorithms to analyze the data of breast cancer detection, J48 decision tree and ZeroR. These datasets were collected from online repositories that belong to actual patients of cancer.

Srikanth et al. (2019) brought their dataset from the UCI repository. They managed to experiment on the WEKA tool using the following classifiers. Machine learning algorithms, KNN, K-means, J48, NB, SMO, however, SMO algorithm has shown its potency and efficiency in breast cancer detection in best execution and blunder rates.

Asri et al. (2016) were aiming to experiment and analyze multiple classifiers with the help of the WEKA tool and UCI Wisconsin dataset, and they used the SVM, KNN, C4.5, NB algorithms, and the SVM algorithm has proven to be the best and the most effective regarding performance and error level.

Gayathri et al. (2013) wanted to compare the "machine learning(ML) algorithms" in detecting and prognosing breast cancer with the help of and using the relevance vector machine (RVM) and support vector machine(SRM), the artificial neural networks(ANN) that detects data using synapsis, and the RVM proved to be more effective and precise.

Agarap (2017) conducted an experiment using the Wisconsin diagnostic dataset and the ANN to compare between the SVM, linear regression, GRU-SVM, NN, MLP, softmax regression in detecting breast cancer best in terms of performance and error rating, he partitioned the data into 70% for training and the rest for testing, after all, the SVM proved to be the best.

Zhou et al. (2004) are going to create a website using python framework, flask, and with the help of WDBC dataset and six ML algorithms, RT, NB, KNN, ANN, Decision tree and SVM, by comparing them, she is going to deduct what is the best algorithm for breast cancer detection.

Eltalhi et al. (2019) used multiple data mining tools like WEKA, Tanagra, orange, c++ and Matlab, and several ML algorithms like DT, k-means, NN, NB to compare and experiment for the best detecting algorithm.

Chaurasia et al. (2018) used three data mining tools, NB, j48 decision tree, and RBF network, to compare them with 10-fold cross-validation on WEKA tool and the WDBC dataset for the best detection results and the naïve Bayes happened to be the perfect one throughout the whole experiment.

Ganggayah et al. (2019) wrote this paper on the investigation made to predict the survival rate of the breast cancer patient, they retrieved a large dataset through the university of Malaysia, then a prediction model was created using the decision tree, NN, random forest, logistic regression, SVM and extreme boost, then, the dataset was clustered, the random forest algorithm was better than the decision tree.

Many other researchers who are recognized in literature on Optimization and Metaheuristics algorithms and applications such as [Abd Elminaam, D.S.(2020)], [Elminaam, D.S.A.(2018)], [Elminaam, D.S.A . (2018)], [El-Ashmawi, W.H.(2019)] ,[Abd Elminaam, D.S.(2019)], and [El-Ashmawi, W.H.(2020)] studied the predictions pobems and its solutions. As a result of the collected information, we decided to combine all the features that the previous attempts worked on to enhance the expected results' efficiency.

Proposed Breast Cancer Detection System

The breast cancer detection system is fundamentally a medical diagnostic technique that uses numerical breast attributes that lead to a specific scenario when accumulated together, therefore predicting and predicting whether the tumor is malignant(M) or benign(B). In this experiment, we are going to start with preprocessing both datasets; then, we will begin with the classifying algorithms, KNN, decision tree, and naïve Bayes, and last but not least, we are going to compare the used algorithms in terms of best results in both datasets.

Dataset Description

At first, we downloaded the" Wisconsin breast cancer dataset (WDBC)" which is officially benchmark from the Kaggle website and UCI machine learning repository website. As a matter of fact, our first dataset mainly consisted of numerical attributes and only one nominal attribute, which states if the suspected tumor is benign(B) or malignant(M), and the second dataset consisted of nominal attributes. First and foremost, the first dataset contained the following 32 attributes and 569 instances: "id," concavity," area," smoothness," radius," diagnosis," perimeter," compactness," texture," fractal dimension," "symmetry," "concave points." Not to mention that for each image, the standard error (SE), mean and worst were calculated to guarantee strictly accurate results (Gupta et al, 2020).

Moreover, this dataset simply emphasizes on the projection of the signals and the identification of breast cancer. Furthermore, this dataset corresponds to supervised learning in which the only task that underlies it is the classification. Moving on to the next dataset which consists of 10 attributes and 286 instances, "age", "inv nodes", "tumor size"," node caps", "breast", "deg malign", "irradiate", "breast quad", "class". This dataset was also classified, and, in both datasets, we maintained the cross-validation folds to only 10, meaning that 90% of the specified data will be used for thorough training and 10% for testing.

Machine Learning Algorithms

K-nearest Neighbor Algorithm

The KNN algorithm (instance-based learning) is an ultimately convenient data mining method that allows us to utilize former data instances, for further clarification, with the presence of the known and agreed upon output values. It can forecast an anonymous output of a new instance (Asri et al, 2016). It uses the normalized Euclidean distance in calculating the distance between two points and is very active with large datasets because it compares the case of the new data with all the old data. It can guarantee an accurate prediction; that is why it is a lazy algorithm. Last but not least, we maintained the Euclidean distancing and changed the K, respectively.

$$\mathrm{d}(\mathbf{p},\mathbf{q}) = \mathrm{d}(\mathbf{q},\mathbf{p}) = \sqrt{(q_1-p_1)^2+(q_2-p_2)^2+\cdots+(q_n-p_n)^2} \qquad (1)$$

Decision Tree

The decision tree is also known as the Rept tree in WEKA (reduced error pruning tree) uses the regression tree mechanism in creating various trees in many different various iterations, afterward, it shows the representative tree that it has selected as the best chosen one from all the generated and originated trees and then prunes the tree with the mean square error method. It is a quick learner, and it creates the tree on the basis of gaining information or variance reduction (Talukdar & Kalita, 2015).the formula for decision tree as follows

Cite this Article as: Diaa SALAMA ABD ELMINAAM ,Shaza BAHNACY, Esraa HASSAN , Habiba TAREK, Mai HAZEM, Nura MOSTAFA and Lobna SHAHEEN "Breast Cancer Detection using Macchine Learning Algorithms" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

$$E(S) = \sum_{i=1}^{c} -p_i \log_2 p_i \quad (2)$$

$$E(T,X) = \sum_{c \in X} P(c)E(c) \quad (3)$$

$$\text{Gain}\ (T,X) = \text{Entropy}\ (T) - \text{Entropy}\ (T,X) \quad (4)$$

Naïve Bayes Algorithm

The naïve Bayes algorithm is based and hinged on the mathematical Bayes theorem. This algorithm contributes to the universal principle of classifying any feature is independent and individualistic of the other represented features. As well as the datasets that this algorithm classifies should be divided into a feature matrix and a response vector, which are the rows of the dependent vector and the class that states whether the action can be taken or not, the values should be independent yet equal, as the Data itself doesn't depend on each other. Still, they are all critical, therefore being all equal in importance. The NB algorithm is high-speed compared to different algorithms.

$$P(A \mid B) = \frac{P(B|A)P(A)}{P(B)} \quad (5)$$

Result and Discussion

The presented breast cancer detection system experimental outputs and results shall be looked over throughout this section. Moreover, the presented methodology was applied and executed in the WEKA Tool.

In the following table, the first dataset' results will be represented with the algorithms used.

Table 3: Results for The First Dataset

	IBK Euclidean dist. &K =1	**IBK Euclidean dist. & K=2**	**IBK Euclidean dist. & K=3**	**Naïve Bayes Algorithm**	**Rept Tree Algorithm**
Kappa statistic	0.9171	0.9032	0.9319	0.8418	0.8376
Mean absolute error	0.0405	0.0439	0.0492	0.0732	0.0984
Root mean squared error	0.1963	0.1689	0.1694	0.2648	0.2526
Relative absolute error	8.6513	9.3974	10.5225	15.6565	21.0341
Root relative squared error	40.591	34.9356	35.0346	54.7597	52.2483
Build time	0 seconds	0 seconds	0 seconds	0.04 seconds	0.07 seconds
Correctly classified instances	96.13%	95.43%	96.84%	92.62%	92.44%

From the table, it appears that the best algorithm was the IBK using Euclidean distance and K =2 because of its good results and the worst algorithm in detecting was the decision tree. Moving on to the second dataset for the comparison in the following table:

Table 4: Results for The Second Dataset

	IBK Euclidean dist. &K =1	IBK Euclidean dist. & K=2	IBK Euclidean dist. & K=3	Naïve Bayes Algorithm	Rept Tree Algorithm
Kappa statistic	0.2438	0.2079	0.2281	0.2857	0.1601
Mean absolute error	0.3257	0.333	0.3414	0.3272	0.3797
Root mean squared error	0.5101	0.4563	0.4477	0.2648	0.4652
Relative absolute error	77.8513	79.5848	81.5847	78.2086	90.7409
Root relative squared error	111.6114	99.8215	97.9585	99.1872	101.7845
Build time	0 seconds	0 seconds	0 seconds	0 seconds	0.02 seconds
Correctly classified instances	72.37%	73.42 %	73.77 %	71.67 %	70.62 %

The naïve Bayes algorithm proved that it is better than the other algorithms due to its relatively good data, and the REPT tree again proved to be not the best.

Conclusion

The purpose of this document was to reflect on how vital breast cancer detection because of its significant drawbacks when not treated in its early phases and compare between the three previously mentioned classification algorithms(KNN, decision tree, and Naïve Bayes) according to the precision, accuracy, and effectiveness. After experimenting on our two benchmark datasets with the WEKA tool, we finally came to the resolution that the first dataset worked best with the KNN algorithm using Euclidean distance and k=2 and the accuracy was95.43% and the worst algorithm in detecting was the decision tree with accuracy of 92.44%. As for the second dataset, it worked best with the naïve bayes algorithm with accuracy of 71.67% and the decision tree was the worst algorithm to detect breast cancer with accuracy of only 70.62%.

Abstract

Throughout our everyday lives, the importance of transport lies in facilitating people's movement or goods from one place to another. Transportation problems (TP) are not easy to fix. The choice of travel times and means of transportation has become confusing. Notably, during the periods of study and work in any city where the number of trips and congestion increases, especially at peak hours of the day. Transportation problems, therefore, cause waste of time, decreases efficiency, and dramatically adverse effects on society and citizens. Such issues include bus schedules, truck routing problems, truck transportation problems, problems with traffic management, and so on, causing air pollution, busy highways, and unsafe highways. There is much work to address these issues. In this paper, the proposed model offers a solution to solve transportation problems using a fuzzy logic technology with traffic simulation. The proposed system, based on the Fuzzy Expert System (FES) helps find the best road, the best time of the trip and avoids some traffic and transportation problems.

Environmental pollution is one of the most severe problems that threaten society. It affects the public health of citizens and the health of plants. Also, environmental pollution is leading to global warming. Vehicles exhaust is one of the most severe cases of environmental contamination. The increase in the number of vehicles and the rise in congestion increase the exhaust and pollution resulting. This paper focuses on measuring the exhaust of vehicles like CO2, CO, HC, NOX, and PMX using SUMO (Simulation of Urban Mobility). This research uses Sumo to extract real-time emission from cars over the trip on the network of routes and study the relationship between vehicle emissions and fuel consumption. Another point in this research is to measure the noise emission of the same vehicle.

Keywords: Transportation Problems (TP), Fuzzy Expert System (FES) IoT, SUMO, Noise Emission.

Introduction

From this section, input the body of your manuscript according to the constitution that you had. For detailed information for authors, please refer to Parra et al. (2014).

In the past few years, there has been a growing interest in solving traffic problems by establishing new roads or providing solutions to avoid congestion. That is considered one of the reasons leading to the rise of the economic situation, also providing a proper traffic system and control of car exhausts. The problem of transportation is a general problem that we aim to solve to save time and effort and reduce the expense of transferring things from one place to another. There are various transportation problems (Parra et al., 2014). like maritime transportation, air transportation, land transportation, rail transportation, space transportation, and intermodal transportation. These traffic classes have a generic name called transportation problems, which have resources, location, and transportation mode as TP's general parameter. Transportation problems' parameters are as the following: -

- *Resources*: The support of those components that can be shipped from sources to goals. Instances of variation assets are merchandise, apparatuses, individuals, payload, machines; associated assets incorporate vitality, fluids, and cash.

Cite this Article as: Diaa SALAMA ABD ELMINAM, Eman MAHMOUD and Rasha ORBAN"Modeling And Building Dynamic Transportation System Based on The Internet of Things" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

- *Locations*: The locations of purposes of supply, recollection, stop hubs, railroad stations, transport stations, stacking port, seaports, air terminals, refueling warehouses, or school.
- *Transportation modes*: The transportation modes are shipping a few assets to areas—the transportation modes such as street, water, air, rail, space, and cable.

The sources of emission which cause environmental pollutions can be classified into stationary and portable sources (Klein et al., 2015). Instances of stationary sources create warmth and vitality, such as focal warming frameworks and electrical power plants, and establishments where modern procedures occur. Versatile sources incorporate different transport methods such as traveler vehicles, heavy-duty trucks, inland conduit vessels, and flying machines, just as portable hardware with ignition motors, such as horticultural tractors forklifts.

Car exhausts cause two types of pollution, environmental pollution and noise pollution. Environmental pollution is the number of gases coming out of the car, such as carbon dioxide (CO2), carbon monoxide (CO), nitrous oxide (N2O), nitrogen oxides (NOx), methane (CH4), hydrocarbons (HC), and particulate matter (PM).

There is no method to avoid that kind of air pollution or any treatment for it in Egypt. Many researchers use IoT sensors to calculate the amount of that emission to tell the cars' owners with the ratio of their car exhaust. The cars' owners try to avoid increasing it because their government expects a fine on vehicles with higher emissions. Dealing with emission extraction through IoT requires working with sensors and other communication technology. However, in the real-world may be considered a challenge as it costs much money and lacks experience in using the internet (Gao et al, 2007).

This paper focuses on the issues of land transportation. Land transportation conveys assets over long, medium, and small good ways from areas to different areas utilizing routes by vehicle or comparative methods for land transportation. Working on land transportation as an intelligent transportation system means working with sensors and other communication technology (Gao et al, 2007). The proposed model works on the problem throw three main axes simulating traffic using SUMO, Fuzzy Logic expert system, and the combination between fuzzy logic and SUMO.

Simulation traffic using SUMO: Traffic simulation is one of the best ways to give solutions to traffic problems due to the difficulty of following the traffic in nature because of the high cost of the material and technology. So, SUMO is the solution of working on transportation with high accuracy as it provides making a network of real roads and works on it.

Fuzzy logic expert system: A fuzzy logic expert system gathers membership functions and rules used to think about data. In contrast to the conventional expert system, which is predominantly traditional thinking, a fuzzy logic expert system will deal with numerical processing. The rules in a fuzzy logic expert system are generally of a structure like (on the off chance that x is low, and y is high, at that point z = medium). Where x and y are input factors (names for realizing data values), z is a yield variable (a name for a data incentive to be figured).

The combination of fuzzy logic and SUMO: In this part, we take the output data of the SUMO as input data to the expert system (Corvid Exp. Sys.) to get the expected output, which considers our solution in the proposed model. SUMO executes XML sheets of the simulated network, and we convert it to rules which are considered an input to the corvid expert system tool. Corvid Expert System is a robust and extensively tested tool for developing interactive expert system applications.

Our research works in three main steps: Get Map from OpenStreetMap, Use SUMO, and analyze the results from SUMO. OpenStreetMap (OpenStreetMap, 2019) is an online site where the desired area is exported and used in SUMO.

Traffic simulation utilizing SUMO (Behrisch et al, 2011): Traffic simulation is perhaps the ideal approach to offer answers for traffic issues because of the trouble of following the traffic in nature on account of the material's significant expense and innovation. So SUMO is a suitable tool to deal with transportation with high precision as it enables making a system of open streets and chips away at it. The SUMO emission tool is used to get vehicles' exhaust then analyze it to study the relations between emissions and fuel consumption.

The rest of the paper is organized as follows; Section 2 provides traffic and transportation issues and some related work to handle them. Next, Section 3 presents the proposed model. Section 4 demonstrates the results and discusses them. Finally, Section 5 concludes the paper and future work.

Literature Review

It is no simple attempt to operate on traffic and transportation issues. It includes many challenging problems. Most research forms work on a smart transport network based on the Internet of Things (IoT), which costs a substantial budget to cover a large area. Some of them depend on SUMO.

(Eriksson et al. , 2008) developed one of the first road condition monitoring systems that detect and map road anomalies, such as potholes, using an accelerometer and GPS.

(Mednis et al., 2011) and (Ghose et al. , 2012) later boteloped road condition monitoring applications for a smartphone whithatnds sensor data to a remote server and alerts drivers of potholes in the road.

(Mohan et al. , 2008) developed a road and traffic monitoring system, named Nericell, which also employs smartphone sensors to detect certain conditions.

In addition to the driver behaviour monitoring feature, (Fazeen et al. , 2012) also added a road condition characterisation and mapping feature to their system that uses a smartphone's GPS and accelerometer.

(Zaldivar et al. , 2011) proposed using smartphones as an alternative on-board unit in vehicles to access information in the vehicle's electronic control unit (ECU) wirelessly. An ECU is typically accessed through an industry-standard on-board diagnostic connector, known as OBD-II. By connecting an OBD-II-to-Bluetooth adapter to the vehicle's controller area network (CAN) bus, a smartphone can access the bus via Bluetooth. Automatic accident detection is accomplished by using data obtained from the CAN bus together with the smartphone's GPS and accelerometer.

(Similarly, Yang et al. , 2013) developed a smartphone-based diagnostic system for hybrid electric vehicles that also accesses a vehicle's CAN bus through OBD-II.

The WreckWatch accident detection system developed by (White et al. , 2011) differs from the one developed by(Zaldivar et al , 2011) in that it detects accidents using only the accelerometer values from a smartphone, and not the values from a vehicle's ECU. In addition to the advantage of not requiring additional hardware, WreckWatch also requires no permanent GPS-connection, which dramatically reduces power consumption

(SignalGuru , 2011) , and (SignalGuru , 2011) is a service that uses smartphones to opportunistically detect traffic signals with their cameras and collaboratively share and learn traffic signal schedules. This enables Green Light Optimal Speed Advisory applications which provide drivers with the schedule of forward traffic signals, allowing them to avoid coming to a complete halt and thereby lowering their fuel consumption.

(Jam Eyes , 2012) [28] is an application that uses a smartphone's camera and wireless fidelity to detect vehicles around it in a traffic jam, in order to collaboratively calculate the length of a traffic queue.

Many other researchers who are recognized in the literature on Optimization and Metaheuristics algorithms and applications such as [Abd Elminaam, D.S.(2020)], [Elminaam, D.S.A.(2018)], [Elminaam, D.S.A . (2018)], [El-Ashmawi, W.H.(2019)] ,[Abd Elminaam, D.S.(2019)], and [El-Ashmawi, W.H.(2020)] studied the optimized solution for complex problems. As a result of the collected information, we decided to combine all the features that the previous attempts worked on to enhance the expected results' efficiency.

Proposed Model

The proposed model simulates transportation problems using SUMO (Simulation of Urban Mobility) (Behrisch et al, 2011). A fuzzy expert system using exsys corvid tool is used. It gives various solutions for different cases of road trips. The proposed method also introduces a new monitoring process that manages the real network traffic

from SUMO and the Traffic Control Interface (TraCI). Information about the vehicles can be obtained from the system, such as the minimum and the maximum speed for every car on the road, exhaust ratio of each car, and which lane on the network that the vehicle takes.

There are four main axes to implement a realistic simulation of the traffic and transportation system. They include traffic simulator, real roads network, real transportation data, and expert system advisor.

Traffic Simulator

SUMO (Behrisch et al, 2011) is an open-source microscopic traffic simulation package widely used in many transportation and vehicular networking projects (Sumo Projects, 2019). In SUMO, vehicle movement is mostly simulated using queue approaches, and a single car is moved between such queues. Also, SUMO offers great grained control over vehicles on the network via the TraCI. TraCI is a technique for interlinking road traffic and network simulators. It allows us to control the conduct of vehicles during simulation runtime. TraCI enables us to recover from vehicle speed and fuel utilization and manage their states such as speed and path evolving (TraCI, 2019). SUMO models driving practices practically with the goal that any significant level control direction would be executed in a manner that complies with severe physical restrictions to keep away from the crash or running the red lights. SUMO uses its NETCONVERT tool to import the OSM map and convert it to the network and keep in mind preserving the roads' features such as network structures, road grades, and estimated speeds, as illustrated in Fig. 1 and Fig. 2.

Fig. 1: Standard Sumo Network

Fig. 2 : Real-world SUMO Network

Fig. 3 shows the four phases of the proposed model. In phase 1, The OSM map is obtained from the OpenStreetMap site and exported to the PC to be used by SUMO. SUMO is an open-source little traffic recreation bundle that is

broadly utilized in numerous transportation and vehicular systems administration ventures (Sumo Projects, 2019). In SUMO, vehicle development is generally mimicked using line approaches. Single autos are moved between such lines. Likewise, SUMO offers extraordinary grained power over vehicles on the system through the Traffic Control Interface (TraCI). TraCI (TraCI, 2019) is a strategy for interlinking street traffic and test systems. It permits us to observe the lead of vehicles during simulation runtime. In this phase, we use the netconvert tool (Netconvert Tool, 2019) to get the sumo network.

Fig. 3 : The Proposed Model Phases

In phase 2, we have to organize trips in that area by identifying the zone of work using TAZ (Martı´nez et al, 2009). Then, identify the vehicles' sources and destinations in that zone by creating Origin-Destination (OD) matrix (Demand/Importing OD Matrices, 2019).

In phase 3, the dual router tool is used. It is an algorithm that imports different demand definitions and computes vehicle routes used by SUMO using shortest path computation. This phase's input consists of the network on SUMO (.net.xml file) and a configuration file that defines the trip's input and output, which contains the TAZ file and OD matrix.

Phase 4 Emission output (Simulation/Output/EmissionOutput, 2019) helps define each vehicle's exhaust, such as the amount of CO2, CO, Nox, fuel, electricity, and noise emitted by the car in the actual simulation step.

Real Roads Networks

To simulate traffic and transportation models, we can create a non-real transportation system and suppose the number of vehicles, information, and trips from node to the other. However, we work on a real road network imported from OpenStreetMap (OSM). The region of Benha city is determined, and the map is exported from OpenStreetMap (OpenStreetMap, 2019) as a (.OSM) file, as shown in Fig. 4. The NETCONVERT in (Netconvert Tool, 2019) is used to convert it to SUMO network to start work on it.

Fig. 2: Benha Map from OSM

To simulate realistic traffic on the sumo road network, we need a real dataset about the region we were imported from OpenStreetMap. Unfortunately, there is no real dataset in the specified area. So, Quadcopter is used for data gathering about Benha city. The collected data, such as the number of vehicles in the managed roads and the time of traffic conditions (Abdul Minaam et al, 2018).

Expert System Advisor

After representing the roads network for real traffic areas using SUMO and detecting and monitoring the traffic conditions in this area using Quadcopter, we can either obtain reports for decision-makers or collaborate with TraCI and SUMO on traffic management. Actually, in this paper, we prefer to help decision-makers using a fuzzy logic expert system (Goodarzi & Rafe, 2012). An expert system is like a computer application based on Artificial Intelligence (AI). The role of an expert system is to simulate the human expert in decision-making processes.

Fuzzy expert systems are a mix of input/output guidelines and rules that are utilized to coordinate certainties and data against the given rules (Abdul-Kader, 2009). A fuzzy logic expert system usually uses IF_THEN rules to think and judge on the processes. Fuzzy logic is a helpful technique for building up a specialist framework.

exsys corvid tool is used as an expert system. in this research, we divide the variables given to the corvid tool into:

- Static variables: such as the source, destination, and trip time.
- Numeric variables: the number of cars on the roads, cars' velocity, and amount of gas in the tank.
- Hidden variables: are the variables that fuzzy logic is dependent on, such as traffic conditions and favorite roads for cars in the network.

Finally, after getting the map from OpenStreetMap and convert it to the SUMO network, the proposed model depends on the output of SUMO as an input to the expert system. It converts the XML Sheets output from SUMO to a set of rules. Then, it fees them to the corvid expert system tool, as illustrated in Fig. 5, to get the desired output. The result of this expert system depends on the rules created on the corvid tool. The IF part depends on users' given data. The THEN part is calculated using fuzzy logic in the proposed system. Large positive confidence numbers express the desired results. Fig. 6 shows the probability of taking road1_conf = 80.0. The value 80.0 means that the best road the cars can take is road one and so on in the following results.

Fig. 5 : Examples of the Logic Rule Used in Fuzzy Logic Expert System

Fig. 6 : A Sample Run of Corvid Expert System

Result and Discussion

All results shown relate to one vehicle on its trip from edge to another edge on the network. Fig. 7 shows the percentage of exhaust carbon dioxide (CO2) in exchange for fuel consumption. It is advised to follow up on the use of gasoline while walking to avoid increasing the exhaust rate. Most of the previous research relied on showing the exhaust percentage only.

Fig. 8 illustrates the relationship between fuel consumption and carbon monoxide (CO). Fig. 9 shows the ratio of hydrocarbons (HC) exhaust; moreover, Fig. 10 clarifies the nitrogen oxides (NOx) exhaust.

Fig. 7: Fuel vs. CO2 emission

Fig. 8 : Fuel vs. CO Emission

Fig. 9 : Fuel vs. HC Emission

Fig. 10: Fuel vs. NOx Emission

Fig. 11 shows the relationship between the car's speed and fuel consumption. The car speed begins to increase with the increased use of fuel until the car reaches a fixed speed amount in which consumption increases at a lower rate from the beginning. The fuel consumption increases with a slight change in the car's speed, which indicates a factor affecting the vehicle's speed at the new lane on the network.

Fig. 12 describes the change in the car's location during the trip and the extent of the increased noise pollution. Figure 12 shows an increase in noise emission during the trip, which indicates the possibility of stopping the road during the journey, which suggests congestion in the places of increased noise pollution.

Fig. 13 proves the previous figure's authenticity when progress at the time of the trip has the potential for the road to be locked by congestion, which increases noise emission. Finally, Fig. 14 shows all exhaust from the vehicle through its trip vs. its fuel consumption.

Fig. 11: Fuel vs. Vehicle Speed

Fig. 12 Pos of a vehicle vs. noise emission

Fig. 13 Trip Time vs. Noise Emission

Fig. 14 Vehicle Emission

Conclusion and Future Work

Our proposed model works on traffic from a different perspective than all previous researches. We have combined traffic simulation with a fuzzy logic expert system that has enabled us to work on real traffic maps that we get from

OpenStreetMap. Then convert it to the SUMO network then assign it with real transportation data given from QuadCopter. Finally, save the simulation output to IF-THEN rules to be an input to the expert system.
Also, environmental pollution and noise pollution have a significant impact on the lives of individuals. We must follow them and extract information about them from vehicles on the routes. The SUMO is used to obtain data about the emissions, fuel consumption, trip time, and cars' speed to compare them to extract reports. In the future, we aim the fuzzy logic expert system works on the extracted data. In the future, we aim to manage traffic and transportation using SUMO and TraCI and develop the algorithms of vehicles' movements.

Abstract

Chronic Kidney Disease (CKD) is a global health problem with increased prevalence and occurrence, poor outcomes, and increased costs. The consequences of Chronic Kidney Disease (CKD) only include kidney failure and reduced kidney function complications. Current research indicates that early identification and diagnosis will eliminate or postpone some of those adverse effects. The use of technology is promising in this field, so we are using machine learning to help in the early recognition of CKD. We are using algorithms like Support Vector Machine (SVM), K-Nearest Neighbour (KNN), Decision Tree, and Random Forest comparing their results to achieve the maximum accuracy and having two different datasets "Pima Indians Diabetes dataset" and "Chronic Kidney Disease dataset," with varying numbers of the attribute (8 for the first dataset and 25 for the second dataset) and of course different attribute values. We are also training the machine on various percentages of training set size (70% and 80%) and test set size (30% and 20%). And different K values (1 and 3) for the KNN. In the end, we found out that by training the algorithm on 80% of the data in the "Chronic Kidney Disease" dataset and by using the Random Forest method, we could achieve an accuracy of 100%.

Keywords: Chronic Kidney Disease, Machine Learning Algorithms, Random Forest(RF), Support Vector Machine(SVM)

Introduction

Chronic kidney disease (CKD) is a type of disorder that affects the kidney structure and its function. (Levey & Coresh, 2012) It is a chronic disorder with significant consequences for the safety and healthcare budgets of patients. It can be triggered by high blood pressure, diabetes, and other diseases. (Pasadana et al., 2019) Risk factors for CKD are divided into factors that initiate and perpetuate, including genetic factors, ethnicity, socioeconomic factors, and age. Causes of CKD are too many, but diabetes mellitus is the most common. According to a published paper, early detection and characterization are critical factors in controlling and treating CKD (Rady & Anwar, 2019).

It is hoped that the number of patients with CKD in the end-stage will be reduced with early recognition and treatment. According to The NHS website, the symptoms differ between the initial stage and late-stage. Still, they are mostly poor appetite and weight loss, shortness of breath, swollen ankles/hands/feet, body tiredness, insomnia, skin itching, muscle cramps, and headaches (Song, HJ et al. 2007). Unfortunately, chronic renal disease is under-diagnosed and under-treated, partially because there is no consensus on identifying and classifying it. It is diagnosed if there has been evidence of kidney damage for a long time, mostly more than three months. Based on the glomerular filtration rate, it gets divided into five levels. To determine CKD prevalence, it has to be done by screening populations as it is asymptomatic, so the prevalence depends on the population studies that took place and the methods of screening used in it. To overcome the burden of CKD, it is important to identify which patients are most at risk in order to be able to screen and treat them early.

As machine learning advances its advantage toward solving global problems advances. Machine learning is used in many sectors, but the health sector has been one of the most benefited sectors with machine learning, as we can see

in the past few years all the improvement that has taken place.(Thomas, 2020) So we are going to use machine learning in our solution to detect CKD.

This paper compares using the following algorithms Support Vector Machine (SVM), Random Forest, Decision Tree, and K-Nearest Neighbors (KNN).

The rest of the paper is described as follows: the paper's related work can be found In Section 2. The methodology is presented in Section 3. Section 4 shows a comparison between proposed algorithms and the experimental results. Finally, Section 5 shows the conclusions and future work.

Related Work

Some related work in the same field is "Chronic Kidney Disease Prediction Using Machine Learning" by Priya & Kumar (2018). It was found out that the Decision tree method is more accurate than the naive Bayes method.

"A Machine Learning Methodology for Chronic Kidney Disease Diagnosis" by Jiongming Qin et al. (2019). Using the imputation of KNN, LOG, RF, SVM, and RNN, it was found out that it could achieve better output than the cases when using random imputation and imputation of mean and mode.

"Dietary prediction for patients with chronic kidney disease (CKD) by using machine learning algorithms to find blood potassium level" by Wickramasinghe et al. (2017). It was found out in it that the Multiclass Decision Forest algorithm gives the best results compared to the other classification algorithms by 99.17% precision.

"Biomimicry and Machine Learning in the Context of Healthcare Digitization" by Lee et al. (2019). It summarizes analysis done using Hancock's "Knowledge-Based Expert System" (KBES) on two datasets. Regarding the best diet to follow to reduce the CKD.

"Comparative Study of Chronic Kidney Disease Prediction using KNN and SVM" by Sinha & Sinha (2015). It was found in it that the ANN performance is better than the other algorithms.

"OF-KNN Technique: A Chronic Kidney Disease Prediction Approach" by Subhashini & Jeyakumar (2017). It was found in it that the OF-KNN gives a high classification accuracy rate.

Many other researchers who are recognized in literature on Optimization and Metaheuristics algorithms and applications such as [Abd Elminaam, D.S.(2020)], [Elminaam, D.S.A.(2018)], [Elminaam, D.S.A . (2018)], [El-Ashmawi, W.H.(2019)] ,[Abd Elminaam, D.S.(2019)], and [El-Ashmawi, W.H.(2020)] studied the predictions pobems and its solutions. As a result of the collected information, we decided to combine all the features that the previous attempts worked on to enhance the expected results' efficiency.

Proposed CKD Detection System (and dataset used)

WEKA has been used as a data mining tool in this experiment by authors to identify data, analyze and evaluate the prediction accuracy of K-nearest neighbor KNN, Decision tree, and Support vector machine SVM algorithms on two different datasets. This experiment has been tested on an HP Pavilion laptop running Linux operating system with Intel 8th generation core i5, 8GB RAM and NVIDIA GeForce GTX 1050 Ti GPU.

Proposed Algorithms

Support Vector Machine Algorithm:

SVM is for binary classification problems. In our case, the two classes have the disease or not (1,0); there are two types of linear and nonlinear SVM (Arora, 2020). A linear SVM is when the classes can be separated using a linear line called a hydroplane. The hydroplane, which has as much margin as possible between the hyperplane and any point within the dataset, is the one chosen.

Fig.1: SVM Algorithm

Nonlinear SVM is used when the data cannot be separated using a linear line, so kernels are used to map data into high dimensional space to classify and separate classes.

We used the SVM linear technique with our two datasets, and it showed the best accuracy in the Pima Indians Diabetes dataset in both the training % of 70 and 80.

K-Nearest Neighbour Algorithm:

The K-Nearest Neighbour (kNN) is widely used in classification problems, and it depends on K the closest number of neighbors for a given data. For example, we want to know the class of the star if K =2, then the nearest two neighbors are circles, so the star is more likely a circle.

Fig.2: KNN Algorithm

We used KNN with K=1 and K=3. It showed the worst results in the Pima dataset but showed relatively accurate chronic kidney disease data results.

Decision Tree Algorithm:

Decision Tree Algorithm is part of the supervised learning algorithms family; it classifies and solves the problem using tree view representation. Each leaf node is considered a class label, and each internal node is an attribute or feature. The decision tree algorithms showed better accuracy than KNN in the Pima dataset and showed almost 99% accuracy in the chronic disease dataset at a 70% training set.

Random Forest Algorithm:

Random Forest algorithm also belongs to the family of supervised learning algorithms. It ensembles several decision trees trained using the bagging technique to increase learning models, increasing the results' accuracy. Random Forest algorithms result in the creation of several decision trees. Each returns a result of the classification

of the input data. For example, if there are four decision trees, 3 of them classified the data as class X, and one tree classified it as class Y, then the result is that this data belongs to class X.

The Random Forest algorithm showed the best accuracy in the chronic kidney disease dataset with 100% accuracy. In the Pima dataset, it outperformed the KNN and decision tree algorithms.

Data Sets Description

Pima Indians Diabetes dataset (Pro, 2020)**:**

When it comes to type-2 diabetes, "Pima Indians of Arizona" have the highest prevalence and incidence of any type of it worldwide. The National Institute of Diabetes and Digestive and Kidney Diseases has a dataset we took as our first data set. It contains details on medical measures related to 768 people, 500 citizens with no diabetes problem, while the remaining 268 samples are diabetic. For healthy people, the class column in this dataset is set by 0 for diabetic patients by 1. There are eight attributes. (Şahan et al., 2005)

Chronic Kidney Disease dataset (Rubini, 2015)**:**

The dataset used to perform the research in this respect Manuscripts was collected from a UCI data collection. The dataset includes data of 401 people aged between two and ninety from the South of India. There's a total of twenty-four parameters, the majority of the clinical in nature and physiological. Table 2 details the Specific parameters. In the preprocessing, the missing data values were replaced by the column's average if it is numerical and replaced by the most repeated word if it is a string.

Results and Discussion

This research paper has been training each algorithm two times, with training data 70% and 30% for testing and the second time with training data 80% and 20% for testing.

Table 3: The Results of Pima Indians Diabetes Dataset

Algo / Training %	KNN K=1	KNN K=3	Decision Tree	Random Forest	SVM Type=linear
70%	73.4	73.4	75.2	77.8	80.8
80%	74.6	75.3	78.5	79.8	79.8

Table 4: The Results of Chronic Kidney Disease Dataset

Algo / Training %	KNN K=1	KNN K=3	Decision Tree	Random Forest	SVM Type=linear
70%	97.5	97.5	99.1	100	93.3
80%	97.5	96.2	91.2	100	90.0

Conclusion

This research aim was to clarify how chronic kidney disease (CKD) prediction happens. Here, the KNN algorithm is used with different values for K and also other used algorithms (Decision tree, SVM, and Random Forest) that aims to get as high accuracy as possible using different training percentages using two different datasets to check more and more and get higher accuracy through different pieces of training techniques and different percentages. It was concluded that the best accuracy found is 100% by using the Random Forest method by training the algorithm on 80% of the data in the "Chronic Kidney Disease" dataset we have.

Abstract

Firms need creative leadership to comprehend and respond to a dynamic and complex business environment. As such, leaders must possess creative competence and creative thinking skills to adapt and respond to complexity. Creativity in the workplace has become vital for organizational performance, success, and sustainability. This paper explores creative leadership and creativity using the literature review approach. We search for relevant articles using three keywords: ''leadership'' ''creative leadership'' and ''creativity''. Considering the role of leadership and creativity in promoting organizational outcomes, it is vital to X-ray these concepts. Drawing from historical data and findings from prior studies, it was observed that personality, leadership development program, and work environment foster creativity in organizations. Specifically, physical and cultural environments are important to support individual and group creativity in the workplace. The antecedent and consequences of creativity were discussed. The authors proposed some recommendations for managers and business leaders.

Keywords: Creative Leadership, Creativity, Workplace Creativity, Extroversion, Openness

Introduction

The challenging and ever-changing business environment call for creative leadership, creativity, and collaboration among divergent stakeholders. The leadership space continues to be very busy and complex. Organizational behaviour literature demonstrates that leaders influence followers' attitudes and behaviours (Çekmecelioğlu and Özbağ, 2016). Great leaders inspire others by providing answers to the questions; why, how, and what they do. Leaders inspire and motivate others towards achieving set goals. Arguably, people are inspired by ''why you do'' and not ''what you do'' as a leader. Leadership behaviour explains employee behavior, performance, and well-being (Kuoppala, Lamminpää, Liira and Vainio, 2008; Avolio, Walumbwa and Weber, 2009). Creative leadership is the ability to intentionally engage one's imagination to influence and guide a group toward a new goal and direction (Mumford et al., 2000; Sternberg, 2002). Creative leaders positively influence their workplace, community, school, and family. They proactively explore and exploit opportunities inherent in change. Complex, new, ambiguous issues can be solved by reshaping and reforming prior knowledge (Mumford et al., 2000). As such, creative thinking and creative problem-solving skills are needed to deal with complex issues. Changing technology, consumer preferences, and intense competition demand increasing organizational creativity. Creativity is the ability to develop new and useful ideas that foster entrepreneurship and business sustainability (Amabile and Khaire, 2008). Anderson et al. (2004) contend that creativity focuses on absolute, "true" novelty, that emanates from individuals or groups within an organization. This paper focuses on reviewing and discussing the concept of creative leadership and creativity using prior studies. This study enriches the leadership literature by informing academicians and practitioners of the importance of creative leadership and creativity in organizations. This paper is arranged as follows. In the following section, this paper presents an overview of the theoretical underpinning, leadership, leadership development, creative leadership, and creativity. Next is the methodology section. Finally, discussion, conclusions, and limitations, and suggestions for further study.

Theoretical Underpinnings

The five-factor theory of personality is considered as appropriate to explain creativity (e.g. Madjar, Oldham and Pratt, 2002; Gong, Cheung, Wang and Huang, 2012). The personality theory suggests that individual creativity depends on 5 factors; conscientiousness, openness, neuroticism extroversion, agreeableness (Heckhausen et al., 1989; Krueger and Heckhausen, 1993). Conscientiousness focus on competence, order, and dutifulness (McCrae and Costa, 1996), mature, wise, and responsible (Igier and Mullet, 2003) and academic achievement and workplace performance. Openness refers to fantasy, aesthetics, and feelings (McCrae and Costa, 1996) and experience, intellectual and experiential curiosity. Neuroticism factor refers to emotional stability. It connotes anxiety, anger, hostility, and depression. Extroversion suggests warmth, assertiveness, and gregariousness (Igier and Mullet, 2003). Agreeableness refers to trust, straightforwardness, and altruism (Igier and Mullet, 2003) and friendly and good-natured. Few studies used Five personality dimensions to explain creativity. These studies suggest that Five personality dimensions interact with contextual variables to empower or hinder creativity (e.g., George and Zhou, 2001; Baer and Oldham, 2006; Madjar, 2008; Baer, 2010; Raja and Johns, 2010). In the study of creative personality and creativity, Madjar, Oldham and Pratt (2002) submit that managers can nurture and foster creativity in employees who are not naturally creative. Gong, Cheung, Wang and Huang (2012) report that a proactive personality promotes creativity.

Understanding Leadership

Leadership has been conceptualized in different ways. The majority fall into four often contested typologies; position, person, result, and process (Grint, 2010; Northouse, 2015). Leadership as a position suggests leaders' positional power which allows them to achieve set goals. Leadership as a person connotes the personal traits and attributes of the leader. Leadership, as a result, focuses on the leader's performance in terms of the achievement of set goals. Leadership as a process emphasizes the process that occurs between leaders and their followers. Arguably leadership is a two-way process that involves an interactive and fluid relationship between the leader and the led. The concept of leadership is still evolving. Extant literature on leadership document characteristics of leaders (trait) (e.g Avolio, 2007), contingency or situational leadership (e.g. Stogdill, 1974), transactional leadership (Burns, 1978), transformational leadership (Burns 1978; AlimoMetcalf, Alban-Metcalf, 2005), distributed leadership (Hartley et al., 2008), entrepreneurship leadership (Gupta et al., 2004; Yang, 2008; Dover, Hariharan and Cummings, 2014; Rae, 2016). Entrepreneurial leaders influence others to leverage both opportunity-seeking and advantage-seeking behaviors (Ireland, Hitt and Sirmon, 2003; Vecchio 2003; Kuratko, 2007). Strategic leadership is a firm's capability that allows it to leverage important resources to achieve sustainable performance (Nwachukwu and Vu, 2020).

Leadership Development

Leadership development is an integration strategy that helps people understand how to relate with others, coordinate their efforts, build commitments, and create extended social networks by applying self-understanding to social and organizational imperatives (Day, 2001). Leadership development emphasizes developing a broader and collective framework in which leadership is developed in practice (Hernez-Broome and Hughes, 2004). It is a social process that involves everyone in the organization (Wenger and Snyder, 2000; Tichy and Cardwell, 2002) and focuses on creating relationships that will add value to the organization. Organizational attitude dimensions of influence include; positive peer group, supervisor, resources, challenge, mission clarity, autonomy, cohesion, and intellectual stimulation. Managing these influences requires developing creative leaders. In this context, organizations need to design and implement robust leadership development programs. The key component of leadership development programs includes coaching, accountability, change management, influence and negotiation, and communication. The following figure shows the important skills that leaders would develop from a robust leadership development program.

Figure of Key skills in Leadership Development Programme

Creative leadership

Extant literature has shown that creativity is central in leadership (Csikszentmihalyi, 2001; Sternberg, 2002; Sternberg, Kaufmann and Pretz, 2004). Sternberg et al. (2004) propose the concept of creative leadership. Sternberg (2002) notes creative leadership hinges on successful intelligence, practical, and creative intelligence. Successful intelligence focuses on recognizing and capitalizing on one's strengths to achieve success (Sternberg, 2002). Practical intelligence enables individuals to successfully align their environments to suit themselves. Creative intelligence enables leaders to develop a vision and to decide where they wish to lead others. The goal of creative intelligence is to convince others to support your unpopular ideas. Mumford et al. (2000) assert that creative problem-solving skills promote leadership effectiveness. It has been argued that creativity is an important aspect of leadership competence. Creative competence can be built by minimizing the fear of judgment, showing confidence to execute behaviors needed to achieve specific performance, and walking people through various steps and processes. Creative thinking is equally necessary to navigate a challenging business environment or to resolve complex problems. The manager who finds imaginative ways to improve business performance within a period of COVID 19 pandemic, the university teacher who finds a new way to teach and conduct examination for the student in the face of COVID 19 pandemic and organizations who must adapt to a new strategy because of COVID 19 pandemic all employ creative thinking to guide others toward achieving set goals. Leaders must keep abreast of significant events in the environment and emergent technologies that can be exploited (Byrne, Mumford, Barrett and Vessey, 2009). Indeed, creative leaders can leverage new opportunities in their environment to achieve success.

Amer, (2017) identifies the following art of creative leadership.

- ✓ Every team member is unique and diverse skills foster a good workplace.
- ✓ To keep team members engaged and willing to innovate, leaders create an atmosphere in which employees can communicate friendly, unafraid of criticism or attacks.
- ✓ Innovation is a mindset that improves over time and ideas can come from an unexpected place.
- ✓ Productivity (aim, target, and performance) matters more than long hours.
- ✓ A strong leader addresses a problem early before they cause disruption.
- ✓ Use evaluation tools, self-evaluation included.
- ✓ A strong leader turns negativity into positive energy.

- ✓ Kill your ego.
- ✓ To keep spirit and motivation up, a strong leader should encourage, instruct, and develop team members.
- ✓ A bad experience is a good opportunity to learn from negative experiences and change them into something good.
- ✓ Penalties are always an option.
- ✓ Leaders are role model

Creativity

Creativity involves introducing new techniques by individuals or a group of people in an organization to achieve better business outcomes. In light of innovation and globalization, firms need creative employees to compete in their respective markets. Employees with proactive personalities are more likely to make the constructive change (Zhou and George, 2001). Creativity involves primarily intra-individual cognitive processes (Rank et al., 2004) which focuses on idea generation. Creativity is encompassing and connotes opportunities to solve problems and to engage in breakthrough thinking throughout the organization (e.g. West, 1997). Creativity may depend on the employee or situation (Siddiqi and Qureshi, 2016). An employee's creativity is an individual who has skills and new ideas about his work and working style (Runco, 2004). Prior studies have shown that creativity contributes to organizational innovation, growth, and survival (Amabile, 1996; Madjar et al., 2002; Mandel, 2008), new product performance, and employee job performance (Zhang and Bartol, 2010b). Mumford et al. (2000) opine that creative problem-solving skills are important to leadership performance. Creativity can be at the individual, group, or organizational levels. Çekmecelioğlu and Özbağ, (2016) find a connection between followers' perceptions of transformational leadership and individual creativity. Arguably, creative people possess both physical and mental energy and are more productive. It has been argued that creative process engagement improves creative performance management. It highlights the extent to which individuals engage in creativity, including (1) problem identification, (2) information searching and encoding, and (3) idea and alternative generation (Zhang and Bartol, 2010; Zhang and Bartol, 2010b). Creative people have great respect for others who work in their field and recognize the impact of previous innovations on their work.

The work environment that stimulates/ hinder creativity

The environment fosters creativity based on specific creativity tasks. Leader promotes creativity by actively engaging in processes that may lead to creative outcomes (Zhang and Bartol, 2010a). The work environment that encourages creativity may support positive knowledge sharing among subordinates (Dunegan, Tierney and Duchonet, 1992). Empowering a work environment enables employees to achieve superior sustainable creative performance (Zhang, Sun, Zheng and Liu, 2019). Leader encouragement of creativity plays a vital role in conditioning the creative environment and motivating employees' creativity (Zhang and Bartol, 2010a). Sun, Xu and Shang (2014) assert that leaders who encourage creativity speed up innovative activities by assisting team members to understand external information. Zhang and Bartol, (2010a) opine that encouragement from leaders fosters a higher degree of creative process engagement. Arguably, organizations with an empowering work environment are more likely to have creative employees. The cultural environment plays an important role in enhancing creativity. Multicultural exposure and experience encourage creativity. Extant literature had focused on cultural differences in individual creativity. For instance, how task and social contexts moderate the relationship between individuals' cultural values (e.g., individualism/ collectivism, power distance, and uncertainty avoidance) and creativity (Erez and Nouri, 2010), culture moderates the impact of leaders, supervisors, co-workers, and social networks on creativity (Zhou and Su, 2010), culture and assessment of creativity (Hempel and Sue-Chan, 2010), and culture and the entire process of creativity (Chiu and Kwan, 2010), other culturally relevant variables such as race and ethnicity positively impact team creativity (Paulus and van der Zee, 2015). Culture affects how people express or assess creativity (Niu and Sternberg, 2001; Yi et al., 2013; Tang et al., 2015) and whether they perceive creativity as fixed or trainable (Karwowski and Tang, 2016; Tang et al., 2016). Creativity training should address the robustness of culture and differences between cultures by encouraging participants from different cultures to share their views on creativity and innovation (Tang, 2019). These studies lend credence to the positive influence of culture on creativity in different contexts. We reason that people with a larger primary social network are more creative. Accordingly, the more people interact with one another, the higher the chances of generating better ideas through knowledge and information sharing Additionally, an environment that allows teams to collaborate by sharing knowledge and ideas will achieve better creative performance. Efficient communication such as electronic brainstorming and writing promotes collaborative ideation (Paulus, Korde, Dickson, Carmeli and Cohen-Meitar,

2015). The immediate physical environment such as lighting, office ambiance, temperature, nature, and auditory/visual surroundings may foster or hinder creativity. According to Amabile and Gryskiewicz (1989) state that time pressure, too much evaluation, emphasis on maintaining the status quo, and too much organizational politics hinder creativity.

Methodology

Scholars use literature to lend credence to a variety of opinions and to manage the “diversity of knowledge" that is available (Tranfield et al., 2003). ProQuest and Goggle Scholar databases were searched for quantitative and qualitative articles. The search keywords typed into ProQuest and Goggle Scholar databases were “leadership” “creative leadership’’ and “creativity” only were included to enhance the validity and relevance of the study. The review included peer-reviewed articles published between 1978 to 2020. The inclusion of recent articles in 2019 and 2020 adds fresh and timely insights (Lim et al., 2020). In the final analysis, 66 articles were used for the review.

Discussion

The literature review focuses on three main areas. The first part of the review discusses leadership, leadership development, and creative leadership. The second area explores creativity and the last part discusses features of the work environment that stimulate and hinder creativity. Our review suggests that personality promotes individual creativity. Our literature review reveals that different leadership paradigm exists, and there is no best approach to leading. The leadership paradigm to adopt will depend on situations and contexts. We observe that issues such as coaching, accountability, change management, influence, and negotiation as well as communication must be incorporated in a robust leadership development program. Organizations need robust leadership development programs to develop and nurture creative leaders. This is important to enable them to cope and navigate the dynamic and uncertain business environment. To effectively weather the storm, firms need to create products and services that will satisfy and increase customers' patronage and enhance strategic performance (Nwachukwu and Chladkova, 2019). This demands creativity and creative leadership. Our review shows that creative leaders need creative competence and creative thinking. Because of COVID 19 pandemic, organizations need creative leadership to achieve superior business results. Given this, creative thinking and creative competence have become increasingly important for leaders and their firms. We observed that creativity promotes organizational outcomes such as innovation, growth, survival, new product development, and employee job performance. Strong leadership is essential for organizational creativity. Our analysis highlights the importance of the work environment in promoting creativity. The work environment may foster or restrict organizational creativity, individual, or group. The characteristics of a work environment that promote creativity are leadership, culture, physical work environment, adequate freedom, challenging work, appropriate resources, supportive supervisor, diverse and communicative co-workers, sense of cooperation, management that supports creativity. To stimulate creativity in the workplace, leaders must encourage knowledge sharing and collaboration among group members. Organizations should give attention to their physical environments such as lighting, office ambiance, temperature, nature, and auditory/visual surroundings. By doing so, employees will be motivated to think creatively and come up with robust ideas that will help the organization achieve its goals. A conducive physical environment is important for the health and safety of employees.

Conclusion

Creativity is a valuable workplace skill that is needed by all organizations, whether public or private, for-profit, or not-for-profit. Successful creativity needs a radical change in the way organizations to manage and generate ideas. Firms need competent managers and employees to achieve strategic goals and enhance strategic performance (Vu and Nwachukwu, 2020). The changing and unpredictable environment has made creative leadership an increasingly key resource for firms that want to remain competitive in the marketplace. This paper explores creative leadership and creativity using the literature review approach. Indeed, organizations that do not value creativity will not remain in the market for a long time. We, therefore, put forward the following recommendations.

- ✓ Organizations should encourage creative leadership and creativity by encouraging networks and collaborations with people of diverse backgrounds.

- ✓ Leaders must recognize the importance of all the facets of creativity to foster creative thinking and change.
- ✓ Organizations through leadership development programs must ensure that leaders master the creative process and can facilitate this process in others.
- ✓ They must find ways to build empowering work environments that encourage creative thought.
- ✓ It is important to encourage a creative learning environment that allows collaboration with peers within and outside the organization.

Limitation and suggestion for further study

The focus on the review of the extant literature on creative leadership and creativity somewhat limits the applicability of the study. Scholars should examine more antecedents and consequences of leadership and creativity in varying contexts, especially in emerging markets. Indeed, the current paper contributes to the debate on creative leadership and creativity.

Abstract

The article analyzes the existing certain differences in the interpretation of the concepts of "merger" and "acquisition" in foreign theory and practice and in Russian legislation. The methods of company valuation during mergers and acquisitions are investigated, their advantages and disadvantages are given. An assessment is made of the value of companies in three mergers and acquisitions with the participation of the largest Russian companies in the consumer sector. The result is a structured tabular presentation of the valuation of companies by different methods and an analytical conclusion on relative deviations from actual cost.

Keywords: Profit-Based Valuation Methods, Market, Consumer Market, Value Of Companies, Mergers And Acquisitions.

Introduction

The modern Russian economy is characterized by active processes of mergers and acquisitions of companies. In Russia, mergers and acquisitions were implemented after the adoption of the Federal Law of December 26, 1995 No. 208-FL “On Joint Stock Companies”. It is important to note that such a concept as mergers and acquisitions is absent in Russian legislation. The merger of companies is the emergence of a new entity by transferring to it all the rights and obligations. The term “acquisition’ is not described in Russian law.

According to Russian law, a merger must form a new legal entity. "Acquisition" refers to a purchase of one company by another with the transfer of absolute or partial rights.

According to RBC news agency, despite the fact that in 2018 the number of mergers and acquisitions in Russia was quite small, their volumes reached a record result: $ 13.4 billion. [1]. There is an overview of the most expensive deals in decreasing order:

- Sberbank's sale of its company “Denizbank” to the Dubai banking group Emirates NBD, the transaction amount is $ 3.2 billion;
- VTB’s purchase of 29 % of Magnit shares for $ 2.45 billion;
- Japan Tobacco bought a 100% stake in Donskoy Tabak group for $ 1.7 billion.

Mergers and acquisitions are often carried out on the Russian market, however, indicators in terms of quantity and volume are declining, all of these processes have an explanation - the impact of the global financial and economic crisis.

MIKHAILOVSKAYA “Approaches to Assessing the Value of Companies: A Review of The Russian Consumer Market” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Methods of assessing the value of companies

The following valuation technologies: profit-based valuation methods. There are two methods: capitalization of net profit and the method of discounting cash flows. The main difference is the timing: the method of capitalization of net profit calculates indicators for a year, the method of discounted cash flows calculates indicators for several years, so this method is most often used.

It is based on the opinion that the investor will pay an amount equal to the value of the company's future revenues, and the owner will be ready to sell his business for an amount equal to the current value of the projected future income, respectively, the transaction amount will be market. This method is considered as one of the most common. It is best to use this method for profitable companies than for unprofitable ones.

The discounted cash flow method is one of the most detailed, but there are a number of disadvantages of this method. The difficulty is predicting cash flows and the discount rate in the absence of a large amount of data on which the forecast should be based, and there is also a lot of false information, the results of which will turn out to be an incorrect forecast.

The following valuation methods are the capital market method or analysis of comparable companies, the transaction method or analysis of comparable transactions and the industry coefficient method or analysis of the same or comparable industry.

The basis of this group of methods is to compare companies with similar ones. The object for comparison is selected in such a way that it is similar in economic, material, technical and other characteristics, with which you can determine the value of the object using appropriate adjustments.

Price multiplier is a ratio of the value of invested or equity capital to a financial or non-financial indicator.

This method gives one of the most accurate results when there is relevant information about analogues, reflects the real situation on the market and the cost of the enterprise reflects production and business activities. However, there are disadvantages: this approach takes into account retrospective information without taking into account future development. It is also extremely difficult to find information about analogues, because joint-stock companies do not give their quotes to the stock market, and closed joint-stock companies do not disclose information. Also, certain adjustments are required due to significant differences.

Valuation method based on replacement costs. This approach includes several methods based on determining the costs that are necessary for the reproduction or replacement of the valuation subject, taking into account depreciation and obsolescence. This approach is applicable in assessing the organization as a whole, a controlling stake, new organizations, organizations with no forecasts of future flows, as well as in the absence of market information or if the company was liquidated. The basis of this approach is the determination of the value of the enterprise as the difference between assets and liabilities.

The cost approach allows you to make calculations in cases where the income and comparative approaches are not applicable. However, this approach is not informative if the company has many intangible assets or if the company has high profits. Also, this approach does not take into account the value of the company in the state in which it was at the time of settlement.

Consumer Transaction Market Overview. experimental part

In our opinion, the consumer sector is of interest. Using a review of the Russian M&A market for 2017 [2] and for 2018 [3], 3 transactions with the participation of the largest companies in this sector were highlighted. Transactions are shown in table 1.

To assess the full value of the company, the purchase price of 100% of the company was calculated according to the formula:

$$Company\ value\ = \frac{Transaction\ amount}{Acquired\ share}$$

Originally, financial indicators in US dollars are used for the assessment, and in the reports of Russian companies, the format for the presentation of numerical indicators is the rubles of the Russian Federation, therefore, the amount of transactions and the full value of the company were converted into Russian rubles. For this, the weighted average rate for 2017-2018 was used, presented in table 2.

To determine the most effective approach to valuing companies in the sector, each of them was evaluated using all three methods. According to the results of calculations, this estimate was compared with the actual value of the company upon purchase.

Table 1: The largest transactions in the consumer sector in 2017-2018.

Transaction object	**Buyer - seller**	**Year**	**Acquired amount,** *%*	**Transaction amount,** *million US dollars*	**Full company value** *million rubles*
Magnit	VTB - Bank - Sergey Galitsky	2018	29,1%	2 442	489 683
ГК Detskiy Mir	Private investors - Sistema JSFC, Russian-Chinese Investment Fund, private shareholders	2017	30,5%	325	66 820
M.Video	Safmar Group - Public Investors	2017	24,7%	310	78 702

An analysis of the value of Magnit showed that in 2018 Sergey Galitsky sold about 29% of the shares to VTB Bank for $ 2.4 billion. When recounted, the total cost of the company amounted to 489.7 billion rubles. Recalculation was carried out according to the weighted average exchange rate for 2018.

Table2: Weighted average ruble to dollar exchange rate for 2017-2018 [4]

	2017	**2018**
Exchange rate	58,35	62,71

When conducting the analysis using the discounted cash flow method, we used Magnit IFRS reporting and the conomy.ru portal (to determine the forecast data). First of all, it was necessary to calculate the discount rate. In this case, the WACC formula (weighted average cost of capital) was used for enterprises whose financing is carried out exclusively from borrowed and own funds. Using the financial report of the company for 2018 and the information of the portal conomy.ru, the data [Table 3] necessary for calculating WACC were obtained.

Table 3: Initial data for calculating WACC for «Magnit»[5]

CAMP calculation	
Risk free rate %	5,57
Risk premium, %	8,029
The sensitivity coefficient of the asset to changes in market profitability	0,5885
Tax rate, %	21,38
β_l	0,8221
$CAPM = 0{,}0557 + (0{,}8221 \times (0{,}1359 - 0{,}0557))$	
CAPM, %	12,17
Equity	
Share capital, thousand rubles	392 868 273,5
Cost of capital,% per year	12,17
Share in the capital,%	66,45
Loan capital	
Loans and borrowings, thousand rubles	198 312 958
Cost of loan capital,% per year	8,14
The share of loan capital,%	33,55

Calculation of WACC was made for Magnit for further use as a discount rate:

$$WACC = 0{,}1217 \times \frac{392\ 868\ 273{,}50}{591\ 181\ 231{,}50} + 0{,}0814 \times \frac{198\ 312\ 958}{591\ 181\ 231{,}50}$$

The total value of WACC was 10.81%.

To calculate the discounted cash flows for the company, it was necessary to make calculations of free cash flows. Data for previous periods (Table 4) were used to predict indicators in subsequent periods, which were involved in calculating the value of the company.

Table 4: Cash flow prior to discounting for 2013-2018 for the company "Magnit", in rub. [6]

	2013	2014	2015	2016	2017	2018
Operating profit / loss	49,4	68,8	82,4	77,7	50,9	45,6
Income tax rate	22,1	23,1	17,0	20,9	21,8	21,4
Post-tax operating profit	38,4	52,9	68,3	61,5	39,8	35,9
Depreciation and amortization	13,9	17,3	20,6	25,8	33,7	36,5
Investments	52,5	55,7	54,0	50,4	73,7	53,8
ΔWCR	10,4	8,6	14,0	22,7	12,4	-0,2
FCFF	-11	6	21	14	-13	19

Based on the analysis of data for previous periods, data is predicted for the following periods. As a rule, a period of 5 years is taken to conduct an analysis using the discounted cash flow method. The indicators from the portal conomy.ru [5] were used as forecast data. The calculation results are presented in Table 5. The value of the company was calculated using the formula:

$$Company\ value = \frac{FCFF_1}{(1+WACC)^1} + \frac{FCFF_2}{(1+WACC)^2} + \frac{FCFF_3}{(1+WACC)^3} + \frac{FCFF_4}{(1+WACC)^4} + \frac{FCFF_5}{(1+WACC)^5}$$

Table 5: Calculation of the discounted cash flow for Magnit, RUB bln. [5]

	2019 (forecast)	2020 (forecast)	2021 (forecast)	2022 (forecast)	2023 (forecast)
Operating profit / loss	55,7	58,8	62,8	67,2	71,2
Income tax rate	21,4	21,4	21,4	21,4	21,4
Post-tax operating profit	43,8	46,3	49,4	52,9	56,0
Depreciation and amortization	39,0	43,3	45,8	46,7	47,2
Investments	72,5	58,9	47,4	45,2	43,1
ΔWCR	5,6	4,1	3,3	2,5	1,9
FCFF	5	27	44	52	58
WACC	0,902	0,814	0,735	0,663	0,598
DCF	4,3	21,6	32,6	34,3	34,8
Company value	**127,64**				

When calculating by the discounted cash flow method, the price of Magnit turned out to be 127.6 billion rubles, with the actual purchase value of 489.7 billion rubles. Accordingly, the actual cost and the cost calculated by the discount method diverge almost 4 times.

Next, a cost analysis of the Detskiy Mir Group of Companies was carried out. In 2017, private shareholders bought about 30.5% of the shares from AFK Sistema and the Russian-Chinese Investment Fund for $ 325 million. When recounted, the total value of the company amounted to 66.8 billion rubles. Recalculations were also made at the weighted average rate for 2017.

When conducting the analysis using the discounted cash flow method, I used the reporting of Detskiy Mir GC in accordance with IFRS and the portal conomy.ru (for determining forecast data). First of all, it was necessary to calculate the discount rate. In this case, the WACC formula (weighted average cost of capital) was also used for enterprises whose financing is carried out exclusively from borrowed and own funds. Using the company's financial report for 2018 and the website conomy.ru, the data necessary for calculating WACC were obtained.

Table 6: Initial data for calculating WACC for Detskiy Mir group of companies [7]

CAMP calculation	
Risk free rate %	5,57
Risk premium, %	8,029
The sensitivity coefficient of the asset to changes in market profitability	0,2372
Tax rate, %	19,05
β_l	0,2841
$CAPM = 0{,}0557 + (0{,}2841 \times (0{,}1359 - 0{,}0557))$	
CAPM, %	7,85
Equity	
Share capital, thousand rubles	85 576,2
Cost of capital,% per year	7,85
Share in the capital,%	80,37
Loan capital	
Loans and borrowings, thousand rubles	20 906
Cost of loan capital,% per year	9,09
The share of loan capital,%	19,63

WACC was calculated for Detskiy Mir Group of Companies for further use as a discount rate:

$$WACC = 0{,}0785 \times \frac{85\ 576{,}20}{106\ 482{,}20} + 0{,}0909 \times \frac{20\ 906}{106\ 482{,}20}$$

The total value of WACC was 8.09%.

To calculate the discounted cash flows for the company, it was necessary to make free cash flow calculations. Data for previous periods (Table 7) were used to predict indicators in subsequent periods, which were involved in calculating the value of the company.

Table 7: Cash flow prior to discounting for 2013-2018 for the group of companies "Detskiy Mir", billion rubles. [8]

	2013	2014	2015	2016	2017	2018
Operating profit / loss	2,1	4,2	4,2	6,6	8,0	11,2
Income tax rate	24,4	19,6	16,1	19,2	14,8	12,3
Post-tax operating profit	1,7	3,5	3,6	5,5	7,0	1,3
Depreciation and amortization	0,6	0,7	1,0	1,6	1,8	9,1
Investments	0,8	0,5	5,3	1,7	2,4	3,8
ΔWCR	1,2	0,1	2,1	-0,3	-1,2	6,1
FCFF	0,4	3,6	-2,8	5,7	7,5	0,5

Based on the analysis of data for previous periods, data is predicted for the following periods. As a rule, for the analysis by the method of discounting cash flows, a period of 5 years is taken. The indicators from the portal conomy.ru [https://www.conomy.ru/emitent/detskiy-mir/templates/7029] were used as forecast data. The calculation results are presented in table 8. The cost of the company was calculated by the formula:

$$Company\ value = \frac{FCFF_1}{(1+WACC)^1} + \frac{FCFF_2}{(1+WACC)^2} + \frac{FCFF_3}{(1+WACC)^3} + \frac{FCFF_4}{(1+WACC)^4} + \frac{FCFF_5}{(1+WACC)^5}$$

Table 8: Calculation of the discounted cash flow for Detskiy Mir Group of Companies, billion rubles.[9]

	2019 (forecast)	2020 (forecast)	2021 (forecast)	2022 (forecast)	2023 (fore cast)
Operating profit / loss	12,6	14,0	15,1	16,1	16,4
Income tax rate	14,1	14,5	15,0	15,6	15,8
Post-tax operating profit	1,9	2,5	3,0	3,5	3,5
Depreciation and amortization	9,8	10,6	11,2	11,7	12,0
Investments	3,9	3,4	3,7	3,7	3,6
ΔWCR	-2,6	0,4	0,3	0,3	0,1
FCFF	10,4	9,3	10,1	11,2	11,8
WACC	0,925	0,856	0,792	0,732	0,678
DCF	9,6	8,0	8,0	8,2	8,0
Company value	**41,84**				

When calculating by the discounted cash flow method, the price of Detskiy Mir Group of Companies was 41.8 billion rubles, with the actual purchase value of 66.8 billion rubles. Accordingly, the actual cost and the value calculated by the discount method diverge by almost 1.5 times..

The last analyzed transaction of the consumer sector is the transaction of M.Video. In 2017, public investors sold about 24.7% of the shares to Safmar Group for $ 310 million. When recounted, the total value of the company amounted to 78.7 billion rubles. Recalculation was carried out at the weighted average rate for 2017.

When performing the analysis using the discounted cash flow method, we used the financial statements of M.Video under IFRS and the portal conomy.ru (for determining forecast data). First of all, it was necessary to calculate the discount rate. In this case, the WACC formula (weighted average cost of capital) was also used for enterprises whose financing is carried out exclusively from borrowed and own funds. Using the company's financial report for 2018 and the portal la conomy.ru, the data necessary for calculating WACC was obtained.

Table 9: Initial data for calculating WACC for "M.Video" [10]

CAMP calculation	
Risk free rate %	5,57
Risk premium, %	8,029
The sensitivity coefficient of the asset to changes in market profitability	0,08
Tax rate, %	27,7
β_l	0,119
$CAPM = 0{,}0557 + (0{,}119 \times (0{,}1359 - 0{,}0557))$	
CAPM, %	6,52
Equity	
Share capital, thousand rubles	92 868,3
Cost of capital,% per year	6,52
Share in the capital,%	60,10
Loan capital	
Loans and borrowings, thousand rubles	61 652
Cost of loan capital,% per year	9,06
The share of loan capital,%	39,89

The calculated WACC for M.Video was used as the discount rate:

$$WACC = 0{,}0652 \times \frac{92\ 868{,}3}{154\ 520{,}30} + 0{,}0906 \times \frac{61\ 652}{154\ 520{,}30}$$

The total WACC value was 7.53%.

To calculate the discounted cash flows for the company, it was necessary to make calculations of free cash flows. Data for previous periods (Table 10) were used to predict indicators in subsequent periods, which will participate in calculating the value of the company.

Table 10: Cash flow prior to discounting for 2013-2018 for M.Video, billion rubles [11]

	2013	2014	2015	2016	2017	2018
Operating profit / loss	6,8	10,3	5,6	6,7	8,2	14,7
Income tax rate	24,4	19,6	16,1	19,2	14,8	12,3
Post-tax operating profit	5,6	7,9	4,2	5,2	6,4	10,6
Depreciation and amortization	2,6	2,8	3,2	3,7	3,6	6,1
Investments	4,0	4,4	2,8	4,2	5,3	62,5
ΔWCR	-2,0	-7,3	7,0	-3,9	4,1	-7,0
FCFF	6,3	13,6	-2,4	8,5	0,6	-38,8

Similarly, the discounted cash flow was calculated for M.Video. The indicators from the portal cono-my.ru [10] were used as forecast data. The results are presented in table 11. The cost of the company was calculated by the formula:

$$Company\ value = \frac{FCFF_1}{(1+WACC)^1} + \frac{FCFF_2}{(1+WACC)^2} + \frac{FCFF_3}{(1+WACC)^3} + \frac{FCFF_4}{(1+WACC)^4} + \frac{FCFF_5}{(1+WACC)^5}$$

Table 11: Calculation of discounted cash flow for M.Video, billion rubles

	2019 (forecast)	2020 (forecast)	2021 (forecast)	2022 (forecast)	2023 (forecast)
Operating profit / loss	17,1	18,2	18,9	19,4	19,7
Income tax rate	27,7	27,7	27,7	27,7	27,7
Post-tax operating profit	12,3	13,2	13,6	14,0	14,2
Depreciation and amortization	6,8	7,2	7,5	7,7	7,8
Investments	6,3	5,8	6,0	5,9	5,9
ΔWCR	2,7	-0,5	-0,3	-0,2	-0,2
FCFF	10,2	15,2	15,4	16,0	16,2
WACC	0,930	0,865	0,804	0,748	0,695
DCF	9,5	13,1	12,4	12,0	11,3
Company value	**58,30**				

When calculated using the discounted cash flow method, the price of M.Video was 58.3 billion rubles, with the actual purchase value of 78.7 billion rubles. Accordingly, the actual cost and the value calculated by the discount method diverge by almost 1.5 times.

For the analysis of transactions using the comparative method of Detskiy Mir and M.Video Group of Companies, PJSC PROTEK was selected, and for the analysis of Magnit, X5 Retail Group. As a source of financial indicators, IAS reporting and the conomy.ru portal were used. Key financial indicators are presented in table 12.

A comparative approach involves the use of cost multipliers. In order for the analysis to be the most effective, the most common multipliers were used:

• P / E (market capitalization to net profit)
• EV / Sales (company value to company revenue)
• EV / EBITDA (company value to EBITDA)
• P / B (market capitalization to the book value of equity)

Table 12 The main financial indicators of companies in 2018, billion rubles. [12]

Company	Revenue	Net profit	EBITDA	Carrying amount of equity
Magnit	1 237,0	33,8	94,7	176,9
Detskiy Mir	110,9	5,7	22,5	0,0
M.Video	321,1	8,4	18,0	18,0
PJSC «PROTEK»	251,7	6,4	9,3	32,4
X5 Retail Group	1 295,0	31,4	95,8	176,8

Since both PJSC PROTEK and X5 Retail Group are public companies, it is quite simple to determine their market capitalization and company value. Market capitalization is calculated by multiplying the number of shares by their closing price, and when calculating the value of the company, you need to add the company's net debt to the market capitalization. The calculated coefficients are shown in Table 13.

Table 13 The main cost multiples in 2018

Company	P/E	EV/Sales	EV/EBITDA	P/B
PJSC «PROTEK»	8,11	0,20	5,50	1,60
X5 Retail Group	18,08	0,58	7,83	3,21

Based on these ratios and knowing the main indicators for the analyzed companies (revenue, net profit, EBITDA and book value of equity), their value was calculated. Estimation of the value of the company is derived on the basis of a multiplication of the resulting coefficients of the peers on the financial indicators of the analyzed companies. Final assessment data are shown in table 14.

Table 14 Calculation of the value of companies using various comparative ratios, billion rubles

Company	P/E	EV/Sales	EV/EBITDA	P/B
Magnit	611,2	717,2	741,9	567,8
Detskiy Mir	46,2	22,5	123,6	0,1
M.Video	67,9	65,2	98,8	28,8

Results and Discussion

The results of the studies showed that in assessing the value of companies, the quality of information plays an important role, which affects the value of the company, obtained as a result of the assessment and the reliability of the final result. The assessment of the acquired corporation is usually considered from two perspectives: 1) the cost of the corporation as a single organization (total cost); 2) the cost of the main components of the corporation (objective value). The choice of this or that position does not affect the composition of the methods used, however, it allows you to clearly separate the acquired object from other structural elements of the studied level for a more accurate assessment of its value.

Thus, summarizing the research results, we turn to table 15, which demonstrates the actual value of companies in a consumer transaction, determined by various valuation methods.

Table 15: The cost of companies using various approaches, billion rubles

Company	Actual purchase price	DCF	P/E	EV/Sales	EV/EBITDA	P/B
Magnit	489,7	353,4	611,2	717,2	741,9	567,8
Detskiy Mir	66,8	141,5	46,2	22,5	123,6	0,1
M.Video	78,7	13,4	67,9	65,2	98,8	28,8

In order for the analysis to be of the highest quality, the calculated value of companies by different methods was compared not in absolute deviations, but in percent. A comparative analysis of deviations is shown in table 16, which contains data on the average deviation for each of the methods for assessing the value of companies. Deviations were calculated using the module, due to which, the average indicator by the method was not affected by whether the indicators were underestimated or overestimated.

Table 16 Comparison of deviations in the calculation by various methods from the actual value of companies, %

Company	DCF	P/E	EV/Sales	EV/EBITDA	P/B
Magnit	27,8%	24,8%	46,5%	51,5%	16,0%
Detskiy Mir	111,8%	30,8%	66,3%	85,0%	99,9%
M.Video	82,9%	13,8%	17,1%	25,6%	63,4%
Average deviation	**74,2%**	**23,1%**	**43,3%**	**54,0%**	**59,8%**

As a result, the smallest deviation was achieved when using the comparative approach in assessing the value of the company and precisely when using the comparative multiplier P / E, which shows the ratio of market capitalization to the balance sheet value of equity of companies. The deviation was only 23.1%, which is significantly less than when using other methods and multipliers.

Abstract

The concept of smart city seems to be the best solution for a harmonious future between man and nature, which is not yet very well known, but which can be very easy to implement. This paper presents an in-depth study on the degree of pollution representing a parallel between cities that have the peculiarities of a smart city and non-smart city. The data processing was performed with fuzzy sets and subsequently modeled in MATLAB, thus obtaining dynamic graphs that describe the variation of the degree of pollution starting from the initial concentrations of gases in the atmosphere. It is executed an algorithm that evaluates the pollution on industries in a chosen surface and in response, offers a gradient result that indicates whether its activity is beneficial for the environment or not. The fuzzy relationship is extremely useful in this whole monitoring process, which can be an indispensable tool that, once used, considerably improve the health of the population in that area, representing an important step in health security.

Keywords: Smart City, Pollution, Fuzzy Sets, Fuzzy Logic.

Introduction

A smart city requires the existence of an integrated information system that includes a multitude of cloud computing subsystems, Internet of Things (IoT), Open Data, Big Data, and mobile applications, connected to the Internet through secure networks. They allow the local administration to interact directly with the citizens and the city's infrastructure.

All these strategically mounted sensors allow us to make an accurate and real-time analysis of one of the most harmful factors for the health of the population: pollution

In the following, we will show how fuzzy logic allows us to do this in a way that is as precise and easy to implement as possible.

Fig. 1: General scheme of a Smart City

Particularities of Smart City

Smart City is based on six main verticals, says the Romanian Association for Smart City.

I. Smart Governance

The smart city has a full range of eGovernment services, has a strong IT&C infrastructure, has public-private partnerships that allow it to achieve its goals, practices open governance, transparency, etc.

Smart governance uses available technology and coordinates the activities of other municipalities, achieving synergies through collaborations with other stakeholders and also satisfying the needs of its citizens, in order to improve both public services and trust in public institutions.

II. Smart Economy

In the smart city, economic activities are carried out with eBusiness and eCommerce support. IT&C innovation plays an important role in the development of a smart city.

III. Smart Mobility

Smart Mobility or Intelligent mobility represent logistics and transport activities with IT&C support, existence of online databases, optimization of urban traffic, etc. they are part of the smart mobility feature of a city that can be characterized as smart.

IV. Smart Environment

This feature includes the use of renewable energy, the existence of controlled energy networks IT&C, "green" buildings, pollution control, water quality, air, etc.

V. Smart People

The population of a smart city must have digital user skills, work in a digital work environment, have access to training, be able to consult and provide data online, etc.

VI. Smart Living

In a smart city, the population has a lifestyle influenced by IT&C, advanced health and housing services, cultural services, and social cohesion environment.

Fuzzy Sets

In classical set theory, the membership of elements in a set is evaluated in binary terms according to a bivalent condition - an element either belongs or does not belong to the set. In contrast, the theory of unpleasant sets allows the gradual assessment of the membership of the elements in a set; it is described using the member function evaluated in the actual unit range [0, 1]. Fuzzy sets generalize classical sets because the indicator functions (called characteristic functions) of classical sets are special cases of the membership functions of fuzzy sets if the latter takes only the values 0 or 1. In the theory of content-filled sets, classical bivalent sets are usually called clear sets. Confused set theory can be used in a wide range of areas where information is incomplete or inaccurate, such as bioinformatics.

Fig. 2 : The operating principle of Fuzzy Sets

Fuzzy Estimation of The Degree of Pollution

In the following, we will customize the fuzzy sets so that we can estimate with their help the degree of pollution. We denote X the air which represents a collection of objects and let x (later customized) a generic element of the set X. A set in the classical sense, A, in this case representing the polluted air and respectively B, representing the clean air, both included in X, is defined as a collection of elements x of X such that each element x may or may not belong to the set A, because a fuzzy set expresses the degree to which an element belongs to a certain collection of objects.

$$x = \{x_1, x_2, x_3\}$$

Because we want to use fuzzy to estimate the degree of pollution, we customize x as follows:

$$x_1 = CO2$$

$$x_2 = NH3$$

$$x_3 = NMVOC$$

Let X be a collection of objects x. A fuzzy set "A" over the set X and we define it by a set of pairs ordered by the shape:

$$A = \{(x, \mu A(x)) / x \in X\}$$

- where μA (x) is called the membership function of the fuzzy set A, in the case of the numerically represented quasi-continuous face it will be represented by a mathematical function
- the set X is called the universe of discourse and it can be discrete or continuous

Controller Fuzzy Sets Pollution Case with Carbon Dioxide and Sulphites (Measurement in Ppm)

In Fig.1, Fig.2, Fig.3, are represented the diagrams of the membership functions with which the approximation of the pollution degree in the smart city context is made.

Fig.3: Member function describing carbon dioxide pollution

Fig.4: Function function describing sulfite pollution

Fig.5 Output of the member function.

Fig.6: The graph representing the dependence of polluters-degree of pollution.

Case Study

Fuzzy Sets in Monitoring the Metallurgical Industry in A Smart City Context

Equipping smart cities with pollutant-sensitive sensors has made it possible to monitor the pollution of the metallurgical industry, so we propose a method based on fuzzy sets that provide an assessment of the risk of a pollutant in an industry **i**, on an area **j**, with a quantity **k** of pollutant. Currently, the proposed method would help to identify a high risk caused by the pollutant P, which would help the APCD in the policy of managing polluting activities.

Let the following entities:

$$\boldsymbol{Fuzzy\ minimum\ rule} = \mathbf{min}\,\{\boldsymbol{a}, \boldsymbol{b}, \boldsymbol{c}, \dots\} \quad (1)$$
$$\boldsymbol{Fuzzy\ maximum\ rule} = \boldsymbol{max}\{\boldsymbol{a}, \boldsymbol{b}, \boldsymbol{c}, \dots\} \quad (2)$$

Pollutant monitoring takes place with the help of 3 sets:

$$\boldsymbol{M} = \{\boldsymbol{i} \in \boldsymbol{N}, \boldsymbol{i} \in [\mathbf{1}, \boldsymbol{m}], \boldsymbol{m_i}\} = \{\boldsymbol{m_i}\} \quad (3)$$
$$\boldsymbol{A} = \{\boldsymbol{j} \in \boldsymbol{N}, \boldsymbol{j} \in [\mathbf{1}, \boldsymbol{a}], \boldsymbol{a_{i,j}}\} = \{\boldsymbol{a_{i,j}}\} \quad (4)$$

$$\boldsymbol{P} = \{\boldsymbol{k} \in \boldsymbol{N}, \boldsymbol{k} \in [\mathbf{1}, \boldsymbol{p}], \boldsymbol{P_{i,j,k}}\} = \{\boldsymbol{P_{i,j,k}}\} \quad (5)$$

$$\boldsymbol{P_{i,j,k,Normalized}} = \frac{\boldsymbol{total\ k\ polluting\ in\ a_{i,j}}}{\boldsymbol{total\ production\ mass\ per\ a_{i,j}}} \quad (6)$$

The purpose is to determine the optimal degree of a process **i** for the production of **k** pollutant in the surface **j**. Let be the set C whose element belongs to a certain degree of admissibility.

$$\boldsymbol{C} = \{\boldsymbol{C_{i,j,k}}\}$$

$$\textbf{If } \boldsymbol{C_{i,j,k}} > \mathbf{0} \textbf{ then } \boldsymbol{C_{i,j,k}} = \frac{\boldsymbol{Min}\{\boldsymbol{P_{i,j,k,Normalized}}\}}{\boldsymbol{P_{i,j,k,Normalized}}} \cdot \left(\mathbf{1} - \frac{\boldsymbol{G_{k,j}}}{\boldsymbol{G_{k,critical}}}\right) \textbf{ if not, then } \boldsymbol{C_{i,j,k}} = \mathbf{0} \quad (7)$$

$G_{k,j}$-the amount k of pollutant in the surface j, and $G_{k,critical}$ represents the critical amount reported by APCD (Air Pollution Control District) for each pollutant.

$$\boldsymbol{C_{i,j,k,critical}} = \boldsymbol{Min}\{\boldsymbol{C_{i,j,k}}\} \quad (8)$$

We have on a surface a fixed number of industries that emit the same pollutant, and the norm of the quantity of this pollutant in the environment is established by an agency. We apply this logic to a simple case (2 industries). We will analyze the emission of carbon monoxide (CO) from the crude steel and aluminum production industry in Romania (data 2017). With the help of sensors, the amount of pollutant in the environment can be detected (measured in ppm). Whether the amount of CO pollutant measured is 360 ppm and the norm is 300. The production data are shown in Table 1.

Table 1: Statistical data on production/emission.

Industry name	Average production (kt)	Amount of monoxide emission of carbon on analyzed area (kt)
Production of crude steel	4667	9.45
Aluminum production	1831	24.81

Let the following MATLAB implementation:

```
prod=[4667 1831];
co=[9.45 24.81];
P=co./prod;
C=min(P);
N=360;
norm=300;
rs=' ';
for i=1:2
if C >0
   C=(C/P(i)*(1-N/norm));
else
   C=0;
  end
end
if C==0
   rs= 'High level of pollution produced by industry in the analyzed area'
else
   rs= 'Pollution level is optimal'
end
```

The above program evaluates the tabular data and provides a gradient response per interval [-1,1]. A negative value indicates when stopping the activity of an industry for ecological reasons, and a positive value indicates an optimal emission of pollutants.

Conclusion

This paper comes as a solution to a current highly publicized problem of excessive pollution in urban and peri-urban areas, being very accessible and efficient, estimating the degree of pollution being quite accurate due to the fuzzy logic on which the program is based.

We applied fuzzy sets in creating a controller in MATLAB that can be applied to assess the degree of pollution and that offers a logical data processing. The diagrams of the membership functions are represented in fig.1, fig.2, fig.3. The case study on pollutant emissions from different industries, gave us negative results, which means that the production of crude steel and aluminum throughout Romania emits an excessive amount of CO, harmful. This program can be applied in a smart city very easily because it is equipped with special sensors that allow the evaluation of pollutants in ppm. In this paper, we did not analyze the industrial pollutants in the smart city, because private data on pollutants emitted by each company are required. The conclusion is that such an assessment is possible, which would involve a wide range of applications in the ecology of smart cities.

A Socially Responsible Attitude to An Employee - Selected Aspects

Ewa MAZUR-WIERZBICKA

Institute of Management, University of Szczecin, Szczecin, Poland[1]
E-mail address: ewa.mazur-wierzbicka@usz.edu.pl

Abstract

Corporate social responsibility is an integrated approach to managing an organization that includes responsibility for its overall operation. Currently, focusing on the most important stakeholders and key issues, also in the perspective of a workplace, is particularly important to companies. The aim of this paper is to assess the meaning of a socially responsible approach to an employee - key stakeholder - in companies and to identify its manifestations in practice. The aim of the paper dictates the paper's layout. The outline of the CSR concept is presented, then the issues of a socially responsible approach to employees are addressed and so is the question of the employee area in the CSR concept. The paper is based on a critical literature review and available non-financial reports and existing data.

Keywords: Sustainable Management, Employees, Human Resources, Human Resources Management.

Introduction

Nowadays, the concept that plays a significant role in the global scale is the concept of sustainable development. Its "tool" at the level of an organization involves a concept of corporate social responsibility, the foundation of which is constituted by the stakeholders' concept. At the time when there are more and more voices talking about problems associated with the search for new employees, it becomes crucial to take care of the key internal stakeholder of each company - employee. In the case of socially responsible companies, it is reflected in initiatives undertaken by them and good practices in the employee area. It is often a consequence of the organization's introduction of socially responsible human resources management or orientation towards sustainable management of human resources.

In view of the above, the aim of this paper is to assess the meaning of a socially responsible approach to an employee - key stakeholder - in companies and to identify its manifestations in practice. The aim of the paper dictates the paper's layout. The outline of the CSR concept is presented, then the issues of a socially responsible approach to employees are addressed and so is the question of the employee area in the CSR concept. The paper is based on a critical literature review and available non-financial reports and existing data.

CSR - Introduction

At the moment the concept of sustainable development is becoming increasingly popular thus providing a framework for a long-term vision of stability - despite the fact that it was initiated in the 1960s. Despite the passage of time, it does not lose its significance, quite the opposite, it is present in many strategic documents of international organizations, individual states or regimes. It assumes a lasting, harmonious development that takes place between three basic areas that is economic, environmental (its protection) and social, development which can meet current

[1] The project is financed within the framework of the program of the Minister of Science and Higher Education under the name "Regional Excellence Initiative" in the years 2019 – 2022; project number 001/RID/2018/19; the amount of financing PLN 10,684,000.00

Cite this Article as: Ewa MAZUR-WIERZBICKA "A Socially Responsible Attitude to An Employee - Selected Aspects" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

needs of societies, at the same time not limiting next generations in meeting their needs in the future. What is important, it takes an important place not only in the theory of economics, but also in the theory of management stepping into various areas of activity taken by economic operators.

At the level of a company (micro scale) it seems more appropriate to state that the concept of corporate social responsibility is a tool for implementing the concept of sustainable development (global scale). This concept is based on three main aspects, that is economic, environmental (ecological) and social. A concept that is close to it is the triple bottom line concept (or otherwise noted as TBL or 3BL), which offers a way of thinking on social responsibility that includes not only the company's benefits, but also benefits to the Earth (as in the planet) and people (see more in: Elkington, 1997; Savitz et al., 2006; Willard, 2012). It assumes that the success of a company is influenced by achievements in the following three dimensions:

- economic (financial) - **economic sustainable development –** it improves profitability by more effective use of resources such as staff, raw materials, produced components, energy (in all its forms), water and waste,

- environmental - **sustainable development and environmental protection** - it improves management of natural resources in order to prevent their exhaustion and strives to limit the impact of gas emissions, waste water and waste on the natural environment,

- social - **social sustainable development** - it improves relations between the parties involved in the implementation of the adopted project (employees, suppliers and local community directly affected by a given project); joint actions for the interest of each of the parties increases the likelihood of a successful end to an implemented task,

between which synergy should take place.

According to the triple bottom line concept, one may assume that the companies' task is to implement economically substantiated goals, at the same time remembering to minimize their negative impact on the natural environment and meeting social expectations. Therefore, operation of a company should be looked at in a holistic way, that is not only through a lens of economic profit (seen as the implementation of the basic goal for the company), but one also needs to refer to the goals concerning the natural environment (environmental protection) and social goals (e.g. guaranteeing adequate quality of life). The same assumption guides the CSR concept.

The very concept of CSR is difficult to define clearly due to the complexity of the subject-matter or different perception - by the defining persons - of the centre of gravity, significance or importance of the core matters included in this concept, but also due to its constant development and a differently seen scope of corporate responsibility (see more in: Dahlsrud, 2008; Freeman, Hasnaoui, 2011). Most generally, it is concluded that it is a company's responsibility for its impact on society (EC Communication, 2012).

The article assumes that corporate social responsibility means a long-term approach to operating a business activity which contributes to the achievement of the company's economic goals, at the same time taking care of the natural environment (limiting negative impact on the environment), taking into account social interests and consistently building lasting and positive relations with stakeholders, which involves observance of norms and requirements that are more restrictive than imposed regulations of the law and principles of ethics, and also taking full, conscious responsibility for all its actions.

From the perspective of management, application of CSR principles in practice is a process of learning the changing social expectations and introducing them into the management strategy, that is a process based on permanent cooperation with the company's stakeholders (Rok, 2012; Zieliński, 2014). Implementation of the CSR concept by the organization evidences its perspective thinking, the skill of adaptation to the surrounding reality, creativity, openness to changes and most of all taking into account stakeholders' expectations and needs, both internal and external.

Key internal stakeholders in each organization need to include employees who play a very important role in the company's achievement of success. Creating on the ground of corporate social responsibility conditions of work

which build employees' satisfaction encourages their efficiency, creativity and loyalty. This translates into the company's value as it is the employees that determine the implementation of operational and strategic goals. A well-motivated employee, who is given conditions for development, works in a friendly atmosphere and is engaged in the implementation of the organization's goals is a strategic element of the company's competitive advantage (Mazur-Wierzbicka, 2013). Therefore, employees are a key pillar of the CSR strategy. It is also them who create adequate relations with external stakeholders, they are members of local communities and greatly affect the company's image. Elements which are an absolute basis for the employer's responsibility in relation to employees include: respect for human rights and observance of labour law.

Socially Responsible Approach to Employees

For the last few years a transfer of an interest in the issues of sustainable development and corporate social responsibility onto the area of human resources management (HRM) has been observed. This is why is it crucial to point to and to emphasize the possible activities directed at employees that are undertaken by socially responsible organizations. For example, M. Armstrong in subsequent editions of his book expands the issues of human resources management by i.a. the question of corporate social responsibility and employee well-being (Armstrong, Taylor, 2016).

The strategy of personnel marketing, consistent with the CSR concept, may also be used to implement socially responsible activities directed at an employee. According to it, employees are the company's "internal clients", thus one must strive to meet their needs by creating appropriate conditions for work and development for them. It is because such an approach translates into employees' increased satisfaction, their greater involvement in work and increased performance, which allows i.a. the company to recover the expenditure on personnel activities (it is added value for the company). The most often named factors which affect employees' satisfaction from work include remuneration, relations at work and management style (Zieliński, 2014).

The company's social responsibility in terms of personnel activities may also be looked at through the lens of the goals it should pursue (Fig. 1).

Fig. 1: Goals in the sphere of personnel activities of a socially responsible company

Source: author's own compilation on the basis of (Gableta, 2006; Zieliński, 2014).

The subject-matter of human resources management in the context of socially responsible activities can be treated broader and one can take a closer look at the new trend of development of the personnel function i.e. sustainable

human resources management[2] (Mazur, 2015), which involves activities and practices in the area of human resources management that support the strategy of the organization's sustainable development, which contributes to the achievement of economic, environmental (minimizing the negative impact of the company's operation on the natural environment) and social goals of the organization in the long-term perspective, which are at the same time an expression of care for employees, especially in the question of their fair and equal treatment, their development and well-being. The literature offers may interpretations of this term, in fact just like in the case of the term sustainable development or CSR (see Zaugg el al., 2001; Cohen, et al. 2012; Ehnert, 2009; Pabian, 2015).

Sustainable human resources management may therefore be examined in the following dimensions: economic (see: Guest, 2011; Buller and Mcevoy, 2016), environmental (ecological) (cf. Jabbour, 2011; Jackson et al., 2013; Renwick et al., 2013; Ahmad, 2015; Dumont, 2015; Shen et al., 2016; Tariq et al., 2016; Cheema and Javed, 2017) and social (Pfeffer, 2010; Dubois and Dubois, 2012; Mazur, 2015; Saifulina and Carballo-Penela, 2017).

The social dimension of sustainable human resources management is nothing else but the (already mentioned by M. Armstrong) reference of HRM mainly to the concept of corporate social responsibility which may be expressed in a number of ways, and mainly concerns the creation of a customized workplace where employees can realize their professional goals in compliance with the organization's strategy (Fig. 2). We are then dealing with socially responsible human resources management, which fits within the broadly understood socially responsible company management, being at the moment an under-researched area of operation of socially responsible organizations. This is mainly expressed in personal treatment of employees as key stakeholders of each company (Pocztowski, 2016).

Fig. 2: Examples of practices of socially responsible human resources management

Source: author's own compilation on the basis of (Bombiak, 2018; FOB, 2019).

[2] Terms treated as synonyms of the term sustainable human resources management may be encountered in the literature e.g.: human sustainability (Pfeffer, 2010), sustainable personnel management (Pabian, 2011).

Among many socially responsible activities taken up with regard employees, one should list i.e. examining employees' needs and expectations, guaranteeing safe conditions for conducting work to the employed persons, taking care in shaping harmonious interpersonal relations, employee relationships, their integration, caring for employees' development, developing programmes that facilitate a work-life balance, creating programmes that support employees and counteract abuse in the workplace, avoiding discriminatory practices and guaranteeing equal treatment and equal opportunities regardless of gender, race or religion, or building a healthy organization by teaching employees how to look after their health, recharge their mental and physical potential, how to eat healthy and have an active life style (cf. Pocztowski, 2016).

As pointed out by A. Pabian, people who implement sustainable management and apply principles of sustainable development in their work can be called sustainable personnel (2011; Majewski, 2012; Bombiak, 2018) or sustainable human resources (Cohen, 2011). They may be management staff who outline directions of the organization's operation, managers at all levels, or employees in non-managerial positions. Currently a "sustainable employee" who forms sustainable personnel is the most desirable type of employee for many organizations (Pabian, 2011).

Therefore, a company's orientation towards socially responsible operation may lead in the long run to a transformation of staff into sustainable personnel. This means that first a procedure of a socially responsible approach to the employee must be implemented. With time, the employee, by learning the reality and conditions of the personnel policy based on the assumptions of the CSR concept, will become more aware and informed in this regard, and therefore, by being pro-environmentally and pro-socially moulded, he will be an employee who will join in the circle of sustainable personnel. It is worth for a company which wishes to have sustainable personnel to conduct training sessions and to constantly improve relevant kills of existing employees; whereas when it comes to potential employees, it should develop a relevant and adequate system for staff recruitment and selection in order to gain employees who are already "sustainable", who join in the sustainable personnel built in the company. Recruitment and selection needs are revealed in the phase of a strategic, tactic and operational planning of human resources. External recruitment is an opportunity to obtain "sustainable employees" quickly. The selection of applicants is relatively easy. In order to learn potential employees' pro-environmental and pro-social attitudes the company may use i.s. general and detailed interviews or job interviews. Their important element is adequate preparation of the questionnaire, questions about the applicants' attitudes, beliefs and pro-environmental and pro-social activity.

The activity of "sustainable employees" should contribute both to the achievement of economic goals and to far-reaching levelling out of intergenerational needs, and thus prevention of future serious environmental or social problems (Pabian, 2011).

The employee area in the CSR concept

An important rank to employee issues was given in the ISO 26000 norm. "ISO 26000. Guidance on social responsibility" identifies an area that directly concerns employees i.e. the so-called "Labour practices". This area includes relations that occur in the organization's practice with employees who provide work for the benefit of the organization, both internally and externally. The core subject of "Labour practices" comprises 5 issues: employment and employment relationships, conditions of work and social protection, social dialogue, health and safety at work, human development and training in the workplace (ISO 26000, 2010).

As has been written in the norm „The labour practices of an organization encompass all policies and practices relating to work performed within, by or on behalf of the organization, including subcontracted work. (...) The creation of jobs, as well as wages and other compensation paid for work performed, are among an organization's most important economic and social contributions. Meaningful and productive work is an essential element in human development; standards of living are improved through full and secure employment. Its absence is a primary cause of social problems. Labour practices have a major impact on respect for the rule of law and on the sense of fairness present in society: socially responsible labour practices are essential to social justice, stability and peace." (ISO 26000, 2010).

Companies that operate in accordance with standards of corporate social responsibility and which wish to report and monitor the undertaken socially responsible activities, may use various indicators for this purpose, among which GRI standards are one of the most popular ones, which are somewhat an international model of reporting on responsible business and sustainable development for an organization. The structure of GRI standards is presented in Fig. 3.

Fig. 3: GRI standards

Source: (https://www.globalreporting.org/standards/gri-standards-download-center/).

As presented in Figure 3, indicators falling under Topic-specific standards were grouped into three groups, that is economic, social and environmental disclosures:

- Economic Standards - The 200 series of the GRI Standards include topic-specific Standards used to report information on an organization's material impacts related to economic topics.
- Environmental Standards - The 300 series of the GRI Standards include topic-specific Standards used to report information on an organization's material impacts related to environmental topics.
- Social Standards - The 400 series of the GRI Standards include topic-specific Standards used to report information on an organization's material impacts related to social topics.

In the social standards group, one can identify those which concern (directly or indirectly) the employee area (Table 1).

Table 1: Basic standards addressing the employee area included in Social Standards

Aspect	Disclosure	Description
Employment GRI 401	401-1	New employee hires and employee turnover
	401-2	Benefits provided to full-time employees that are not provided to temporary or part-time employees
	401-3	Parental leave
Labor/Management Relations GRI 402	402-1	Minimum notice periods regarding operational changes
Occupational health and safety GRI 403	**Management approach disclosures**	
	403-1	Occupational health and safety management system
	403-2	Hazard identification, risk assessment, and incident investigation
	403-3	Occupational health services
	403-4	Worker participation, consultation, and communication on occupational health and safety
	403-5	Worker training on occupational health and safety

	403-6	Promotion of worker health
	403-7	Prevention and mitigation of occupational health and safety impacts directly linked by business relationships
	Topic-specific disclosures	
	403-8	Workers covered by an occupational health and safety management system
	403-9	Work-related injuries
	403-10	Work-related ill health
Training and education - GRI 404	404-1	Average hours of training per year per employee
	404-2	Programs for upgrading employee skills and transition assistance programs
	404-3	Percentage of employees receiving regular performance and career development reviews
Diversity and equal opportunity -GRI 405	405-1	Diversity of governance bodies and employees
	405-2	Ratio of basic salary and remuneration of women to men
Non-discrimination - GRI 406	406-1	Incidents of discrimination and corrective actions taken
Freedom of association and collective bargaining - GRI 407	407-1	Operations and suppliers in which the right to freedom of association and collective bargaining may be at risk
Child labor - GRI 408	408-1	Operations and suppliers at significant risk for incidents of child labor
Forced or compulsory labor - GRI 409	409-1	Operations and suppliers at significant risk for incidents of forced or compulsory labor
Security practices - GRI 410	410-1	Security personnel trained in human rights policies or procedures

As has been indicated before, socially responsible companies undertake various activities or initiatives directed i.a. at employees, but not exclusively. Wishing to present socially responsible activities undertaken by organizations, it is worth mentioning here the Responsible Business Forum, which has been shaping, analysing and promoting corporate social responsibility in Poland since 2000. It is the organization which initiated the publishing of reports titled "Responsible business in Poland. Good practices". The first was published in 2003 (FOB, 2003). The reports include examples of socially responsible practices from various areas (since 2011 classification of CSR areas is based on the one adopted in the ISO 26000) submitted by the organization. As seen in Figure 4, the greatest number of initiatives undertaken by companies under CSR was directed at the "Community involvement and development" area while initiatives concerning employee matters came second.

Fig. 4:CSR practices according to the core subjects adopted in ISO 26000 included in reports "Responsible business in Poland. Good practices" in 2011- 2019.

Source: author's own compilation on the basis of (FOB, 2012, 2013, 2014, 2015, 2016, 2017, 2018, 2019).

Most of the activities undertaken as part of "labour practices" concerned activities that fall under employee volunteering, employee health and training and development. In turn, activities concerning counteracting abuse in the workplace and work-life balance were least popular, which is hugely surprising since in the opinion of employees (especially generation Y) it is a very important issue to them (a number of studies also point to it) (Fig. 5).

Fig. 5: Activities of the "labour practices" core subject included in reports "Responsible business in Poland. Good practices" in 2013-2019 (due to combining certain practices in 2011-2012, the presented data starts at 2013).

Source: author's own compilation on the basis of (FOB, 2012, 2013, 2014, 2015, 2016, 2017, 2018, 2019).

The employee market, observed for the last few years in an ever greater number of industries, new generations on the labour market (Y and Z) and a general change in people's awareness result in a situation where companies which want to keep or obtain an employee must attribute greater importance to looking after the employee. Good practices implemented by companies in the employee core subject create a friendly workplace to which one wants to return and in which one wants to get involved in the exercise of tasks given to them. An approach intended to meet the needs and expectations of an employee also builds a competitive advantage of the organization in the face of changes on the labour market. The socially responsible activities directed at the employee benefit both the employee and companies themselves. However, it needs to be emphasized that such initiatives and activities are undertaken by conscious and mature organizations (though it does not mean a company's long presence on the market).

Conclusion

The idea of human resources management in reference to the CSR concept or more broadly sustainable development has been developed for years. The increasing popularity and importance of this subject matter is evidenced by the number of scholarly publications (and not only such) and research. As reserved by professor A. Pocztowski, "(n)ot prejudging to what degree the concept of sustainable human resources management will affect further development of this field of management, one may conclude that it fits within contemporary trends in managing organizations and is a promising direction of theoretical pursuits and empirical research, emphasizing the need to include social and ecological questions in human resources management policy and practices, which gives it a holistic dimension and strengthens its role in contemporary organizations"(2016, p. 312). One must also look in this spirit at socially responsible management of human resources, believed by some to be the a social dimension of sustainable human resources management.

On the basis of a review of various sources of existing data, including reports on good practices published by FOB as well as non-financial reports published by Polish organizations, one may conclude that socially responsible practices are increasingly popular and their number is going up every year. It also needs to be noted that most practices and initiatives undertaken by companies are in the social area, including mostly those relating to an external stakeholder - the community (mostly local) and a key internal stakeholder - employee, where most focus is given to activities associated with employee volunteering, employee health and training and development.

On the basis of these analyses one may suspect that socially responsible activities are more often undertaken by large companies than those that are medium-sized or small. It is a consequence of the fact that it is mostly large companies that implement the CSR concept and it is them that are most visible in presenting their socially responsible practices.

However, it seems that due to the CSR concept's becoming more and more popular among Polish organizations and also due to internal conditions of operation of companies e.g. demographic processes (in place of the people who formed a demographic growth who are approaching retirement age, people born in the time of a demographic decline will enter the labour market), economic determinants (e.g. expected economic recovery) or environmental determinants (pressure to minimize the negative impact on the natural environment, climate change), it can be assumed that in the coming years personnel strategies of Polish companies will be re-oriented towards those which include sustainable human resources management or socially responsible human resources management.

Because the subject-matter discussed in the paper is extensive and multifaceted, the article focused only on a presentation of the most important issues. They may provide a basis for further discussions on various aspects of socially responsible (or more broadly understood – sustainable) human resources management in organizations not only in Poland, but also in other countries or groups of countries. It is a valid and very important subject which requires more in-depth research.

Macro Conditions for The Functioning of a Joinery Production Company in The Situation of An Unpredictable Economic Slowdown

Paweł POSADZY and Joanna KAŁKOWSKA

Poznan University of Technology, Faculty of Engineering Management
Poznan, Poland

Corresponding author: joanna.kalkowska@put.poznan.pl

Abstract

The basis of the functioning of every enterprise is its ability to move efficiently and effectively in the business space. This ability depends on a number of conditions, both intra-sectoral, on which the company can have a direct impact, as well as macro-environmental, political and legal, cultural and social, economic and technological and organizational. The analysis of macro-environmental conditions can be a determinant of wise use of company's resources and lead to success despite the change of its macro-environment. In the article such an analysis was carried out in relation to a particular joinery manufacturing company in a situation of a pandemic economic slowdown. This analysis for the adopted case study allowed to determine the magnitude of the forces of positive and negative impact of individual macro- conditions.

Keywords: Strategic Analysis, Macroenvironment of an Enterprise.

Introduction

The paper presents the author's own analysis of macro-environmental conditions of functioning of an exemplary joinery manufacturing company in a situation of a pandemic economic slowdown. The freezing of the world's largest economies resulted in the creation of a completely new macro-environmental reality for many companies from various industries. The question to be asked in this situation is: what impact will the economic slowdown have in the current and long-term perspective, resulting from the multi-faceted actions taken against the spread of the Covid-19 pandemic, and whether this situation will significantly change the strategy of survival and development of a particular production company.

The assessment of the macro-economic conditions of the company's functioning was made with the use of the PESTEL strategic analysis tool, commonly known to the professional management science community (Włodarkiewicz-Klimek et al., 2010). The six areas of PESTEL analysis, referred to as general segmentation of the environment, with the support of strengths, weaknesses, opportunities and threats (in the form of SWOT analysis) allows to ultimately determine the portfolio strategy of the enterprise, based on in-depth analyses such as: BCG Matrix, ADL Matrix, McKinse's Matrix, GE Matrix. The presented article is limited to determining (for the adopted case study) the size of PESTEL's positive and negative impact of individual macro-indications.

Strategy in The Context of The Company's Capacity to Operate

Each organisation moves in a certain space appropriate to the type of activity it performs. This space is constantly influenced by factors directly linked to the organisation itself and to its immediate sectoral environment, as well as by a wide range of factors that only seem to exist outside the company's daily operations. The latter group of factors, as the practice shows, is extremely important for the survival and development of the organisation, and is referred to as macro-environmental factors. The analysis of macro-environmental conditions is a key determinant of wise use of the company's resources and leads to success despite the variability of its macro-environment.

The success of a company is closely linked to the quality of decisions taken at each level. We distinguish three main levels of management, i.e. the time horizon and material decision-making: operational, tactical and strategic. Each of these levels is characterised by its own time frame and range of decisions. Operational management can be defined as the decisions that are taken by the primary management level, for areas such as departments, branches, lines or

production cells, over a period of time that is no longer than one year in perspective. Tactical management is when decisions are made by middle management for entire plants, divisions or sets of individual business units. The time horizon for tactical management usually ranges from one to three years. The level of strategic management is the domain of company management (chief executive). Strategic decisions affect all organisational units of an enterprise and have a time horizon of over three years (Kałkowska, Pawłowski, Trzcielinska, Trzcielinski, Klimek 2009).
Strategic management is a major component of any development plan for an organisation. Strategic analysis as part of a company's sustainable development plan should be carried out regularly by each company (Ansoff, 1985). Its complexity and high level of uncertainty cause that it is sometimes overlooked by many companies, which may directly affect the fact of survival and development (success) of a given organisation (Maik, Gołoś, Szczerbacz, Walkiewicz 2010, Ohmae 1982).

The company's long-term strategy is also closely linked to the company's ability to operate in a given area or industry. The literature divides the company into operational and dynamic capabilities. A company's operational capabilities are the resources that a given company uses to perform routine activities, i.e. those whose specificity is based on the current stability of the organisation's operations. These activities include most of the processes that allow the company to operate on the market, such as: production, marketing and sales, logistics, etc. Another category of the company's predisposition to operate is dynamic capabilities, referred to as "innovation". Dynamic capabilities have a status higher than operational capabilities, because they are primarily the driving force behind any positive changes taking place in the company. Dynamic capacity is more 'strategic' because it concerns a space that is not fully known or is subject to a high level of uncertainty (Hawrysz, 2020, Mintzberg, 1994)

The strategic analysis of the macro- environment plays a key role in planning the future of the company. In times of great uncertainty and volatility in the environment in which companies operate, a review of the strategy should be carried out on a regular basis and in any situation which significantly affects the company's environment (Zakrzewska-Bielawska, 2015).

The coronavirus Covid-19 pandemic and its direct multifaceted effects, as announced by the World Health Organisation in March 2020, was a situation which had a decisive impact on the environment of most companies in Poland and around the world. We can treat the situation of this pandemic as an element of supply-demand unpredictability which, in the form of a crisis, may occur in every macro-occupational aspect of every company. The main question asked in this publication is: how much influence the crisis caused by the pandemic has or will have on the strategy of an exemplary joinery manufacturing company, which has an established and stable position on the market to date. To answer this question, we took into account, above all, the macro-environmental conditions of this enterprise, because the nature of the pandemic crisis suggests that most changes will be made to the political, legal, economic, cultural and social, ecological and technological and organisational environment of this enterprise. To this end, it is important to develop a model which presents such macro-environmental conditions and to identify those factors which are the result of an unpredictable economic slowdown and multi-faceted changes related to the Covid-19 coronavirus. (Ratten, 2020)

Method of General Segmentation of The Business Environment

Looking through the literature on the subject one can notice that the most frequently and most popular tools of macro-environmental strategic analysis of an enterprise are first of all: PESTEL, Scenario Method and Delphi Method.

Due to the high degree of complexity in carrying out the analysis with the Delphi Method (difficulty in gathering groups of experts) (Trocki, 1997), and the excessive variance of the current economic conditions, which lower the level of confidence in the Scenario Method, the authors of this publication chose the first of the above mentioned analyses as a starting point for determining the magnitude of the positive and negative impact of the title macro-environmental conditions of the strategy for the survival and development of a woodwork manufacturing company. The PESTEL analysis is an extended version of the PEST method used to study macro-environmental conditions of an enterprise. It can be considered that PESTEL is the foundation of the future business strategy (through an in-depth portfolio analysis), as mentioned in the introduction to this article. Properly conducted PESTEL analysis can serve as a kind of environmental compass, indicating potential threats as well as opportunities to be used by companies from different industries (Włodarkiewicz-Klimek et al., 2010, Masłowski, Dendera-Gruszka, Kulińska, 2018, Yuksel, 2012, Risseeuw, Massurel, 1994).

The starting point of the PESTEL analysis is the juxtaposition of the following six basic external factors:

- Political
- Economic

- Social
- Technological
- Environmental
- Legal

Practical conducting of a PESTEL analysis consists of three stages.
As a first step, appropriate questions (problems) should be formulated for each of the six factors mentioned above. Examples of questions in the political area are: the question of the dynamics of change, the political credibility of state authorities or the level of risk of government takeovers and expropriations of investors. In the area of the social factor, the dynamics of changes in the consumer orientation of society and problems concerning demographic issues.

Once the questions for each factor have been formulated, the impact of each factor on the company's or organisation's activities should be determined. Such an influence can be described in relation to the following three dimensions: time, nature and strength of the influence of the factor on the company. Each of these six factors (and within them each analytical problem) may have a present or future time horizon of impact; the nature of the impact may be positive, negative or neutral; and the magnitude of the impact may be determined in degrees of scale of response.

The third stage of the PESTEL analysis is to try to define the correlation between different factors and to find problems (analytical questions) that are insufficiently qualified for one factor only.

The result of the PESTEL analysis may be six tables, one for each factor, in which the most important macro-analytical problems will be described, which may determine the scope and magnitude of positive and negative forces affecting the company's survival and development strategy.

Results of The Analysis of The Macro- Environment of The Company

The analyzed company is a large manufacturing company, with an established position and over 25 years of presence on the Polish market. Earlier analyses showed very clear chances for continuous development and sales growth. The company does not conduct retail sales. It has a network of customers who deal with retail trade. The company's area of operation is primarily Poland, EU countries and individual non-EU countries. As part of the first stage of the PESTEL analysis, six factors of the company's macro- environment and within each of them, the following four questions (problems) were identified (brainstorming method):

Political factors:

1. Decrease in political credibility of state authorities
2. The anti-European political attitude of the current government
3. Possible policy direction for changes in social programmes
4. Risk of government takeovers and expropriations of investors

Economic factors:
1. The spectre of the economic crisis related to the pandemic
2. Decrease in public financial support for innovative activities of enterprises
3. Decrease in Gross Domestic Product and rising unemployment
4. Uncertainty regarding investments by retail clients

Social factors:
1. Decreasing consumer orientation of the population
2. Decreasing stability in society
3. Difficulties in obtaining loans
4. Increased interest in building your own house with a garden

Technological factors:
1. Unfavourable (relative to EU countries) values of innovation indicators
2. Increased cyber-technology and digitisation of production processes
3. Increase in the number and functionality of mobile computer devices
4. Increased importance of digital cloud solutions

Environmental factors:
1. Increase in the severity of adverse climatic events

2. The drought and the stepping stone of the country.
3. Increased environmental awareness of consumers in terms of production and use
4. technological developments
5. Increased demand for energy-saving products

Legal factors:

1. Decrease in public confidence in legal regulations
2. Socially beneficial direction of changes in the Labour Code and building regulations
3. A socially beneficial direction for changes in safety regulations and occupational hygiene.
4. Decrease in the number of building permits

In the second stage of the PESTEL analysis, for each of the factors and for individual questions (problems), the impact of each of them on the company's operations was determined. Such an impact was described in relation to the following three levels: the nature, impact force and time horizon of this factor problem on the company. The results are collected and presented in the six tables below (1-6).

Table 1: Component problems of the political factor of PESTEL analysis

Component problems of the factor	Description	Nature of the problem	Impact force	Time horizon
Decreased political credibility of state authorities	The low quality of state authority's actions, lack of substantive credibility and political particularism pushes Polish companies to the group of countries of the so-called "second speed Europe".	Negative	5	Present
The anti-European political attitude of the current government	The current government's progressive reluctance towards the EU may, in extreme cases, lead to cuts in EU financial subsidies.	Negative	4	Present
Possible policy direction for changes in social programmes	The likelihood of more social programmes as part of recovery programme from the crisis. More surviving social programmes means a larger portfolio of potential investors.	Positive	3	Present
Risk of government acquisitions and expropriation of investors	Since 2017, Poland has joined European outsiders (Greece, Hungary) in this area. This is very bad news for foreign investors in Poland.	Negative	3	Present

Source: own study

Table 2: Component problems of the economic factor of PESTEL analysis

Component problems of the factor	Description	Nature of the problem	Impact force	Time horizon
The possibility of an economic crisis linked to a pandemic	The economic collapse is linked to the global closure of many branches of the economy and restrictions on the pandemic.	Negative	5	Present
Decline in GDP and rising unemployment	The decline in Gross Domestic Product and rising unemployment due to the economic crisis.	Negative	5	Present
Uncertain situation regarding investments by retail clients	The economic crisis may cause many people to hold back on their retail investment decisions (for example, to build or renovate a house)	Negative	3	Present
Decrease in public financial support for innovative activities of enterprises	This public financial support was prompted by the intention to boost the economy hit by the global economic crisis in 2009. When the positive economic results of this support began to emerge, public funding began to be channelled (starting in 2015) to other types of activities.	Negative	4	Future

Source: own study

Table 3: Component problems of the social factor of PESTEL analysis

Component problems of the factor	Description	Nature of the problem	Impact force	Time horizon
Decreasing consumer orientation of the population	The economic crisis, as a consequence of the real reduction in the purchasing power of society, is leading to a reduction in the consumer orientation of society.	Negative	3	Present
Decreasing stability in society	The consequence of many redundancies will be fewer (of any kind and scale) purchases and investments.	Negative	4	Present
Difficulties in obtaining loans	Lower interest rates mean fewer loans and a narrower group of people who can start renovating a flat or building a house.	Negative	4	Present
Increased interest in building your own house with a garden	A few weeks' closure of the society (pandemic lockout) has led to interest in searching for building plots.	Positive	3	Future

Source: own study

Table 4: Component problems of the technologic factor of PESTEL analysis

Component problems of the factor	Description	Nature of the problem	Impact force	Time horizon
Unfavourable (relative to EU countries) values of innovation indicators	The innovativeness of the Polish economy is at a low level and places us in 22nd place among 26 EU countries. The relation to the EU indicator does not give grounds for optimism.	Negative	4	Future
Increased cyber-technology and digitisation of production processes	Progressive automation and robotisation of production processes makes them more stable and independent of e.g. social factors.	Positive	3	Future
Increase in the number and functionality of mobile computer devices	The progressive computerisation of society is an opportunity to move some sales to the Internet.	Positive	3	Future
Increased importance of digital cloud solutions	Cloud solutions mean greater stability of production processes and additional protection against unpredictable effects such as natural disasters.	Positive	3	Future

Source: own study

Table 5: Component problems of the environment factor of PESTEL analysis

Component problems of the factor	Description	Nature of the problem	Impact force	Time horizon
Violence and increasing frequency of adverse climatic events	Increasing public environmental awareness. Increased interest in passive construction.	Negative/Positive	4	Future
Progressive drought and the formation of steppes in the country	Progressive drought and steppe formation of the country	Negative	3	Present
Increasing consumers' environmental awareness of the production and use of technical works	Customers want to buy products from responsible and environmentally sustainable companies.	Positive	3	Present
Increased demand for energy-saving products	Increased consumer awareness of passive construction.	Positive	3	Present

Table 6: Component problems of the legal factor of PESTEL analysis

Component problems of the factor	Description	Nature of the problem	Impact force	Time horizon
Decrease in public confidence in legal regulations	Dramatic, as it is currently only Poland's 21st place in comparison with 26 EU countries, and the deterioration after 2015 of this confidence indicator is not conducive to business activity. The trend is alarming in nature and requires clear reorientation.	Negative	5	Future
Socially beneficial direction of changes in the Labour Code and building regulations	Loosening of the code restrictions on the time and form of work performance and the way of terminating employment contracts. Tightening of construction law regulations - requirement of certificates for construction products and use of passive products.	Positive	3	Future
A socially beneficial direction of changes in legal regulations concerning health and safety at work	Formal introduction of the so-called 'sanitary regime'. Requirement of additional hygienic and personal protection measures.	Positive	3	Future
Decrease in the number of building permits	The number of building permits issued in Poland (including notifications of the construction of these facilities with a construction project) is on a decreasing trend in 2013-2019	Negative	4	Future

Summary and Discussion

In the next table (Table 7), the results of the PESTEL analysis concerning macro-economic conditions of the operation of a joinery manufacturing company in the situation of an unpredictable economic slowdown caused by the outbreak of the Covid-19 pandemic were collected in a condensed form. This table summarises six factors of the PESTEL analysis, average forces of their component problems and the resulting nature of this impact on the business undertakings of the studied company.

Table 7: Table summarising six analysis factors, average forces of their impact and the nature of this impact on business undertakings of the examined company.

Type of factor	Average impact force	Nature
Political	4,0	Negative
Economic	4,0	Negative
Social	3,50	Negative
Technologic	3,25	Positive
Environmental	3,25	Positive
Legal	3,75	Negative

Source: own study

In interpreting this summary, it should be pointed out that the global coronavirus crisis has led to the long-term closure of many sectors of the economy worldwide. Mass redundancies, rising unemployment, a fall in gross domestic product caused panic in the construction investment market, and a temporary slowdown in the flow of new orders to the company in question. From the point of view of the company in question, a dangerous situation is the long-term action of the pandemic affecting the wealth of the potential client's portfolio. Possible loss of job, reduction of earnings, difficulties related to obtaining an external source of financing may cause a decrease in interest of this client in the products of the company manufacturing joinery.

The general conclusion of the above analysis is also the fact that the destructive current and future action of the Covid-19 pandemic is accompanied in Poland by the unprofessional, particularistic management of the government and a high probability of continuation of a trend whose negative image over the past five years was only superficially masked by the results of the previous positive economic situation. The numerical results of the analysis, especially political, economic and legal, of the negative macro-economic conditions of the business activity of the surveyed company are very worrying. The thesis about the probable 'accumulation' of the impact of a pandemic and the style of state management on this type of business can be justified in part by the four figures below (Figures 1-4).

Fig. 1: Political credibility of state power for Poland in 2008-2018 with a projected trend line
source: own study based on www.worldbank.org

The trend presented in Figure 1 (positive in 2008-2015) has deteriorated sharply since 2016 and, for the theoretical model of extrapolation, is heading towards a 'Greek' solution. Compared to the 26 EU countries surveyed, Poland has fallen from a high position in the top seven leaders to a group of outsiders - place 18 with the previous indicator being twice as low. The lack of data from the previous year, especially this one, certainly does not change the trend. The populist and particularist cause of this state of affairs does not require any further comment.

Fig. 2: Indicator of social trust in legal regulations for Poland in 2008-2018 with a projected trend line
source: own study based on www.worldbank.org

The indicator reflecting public confidence in legislation is based on impartiality and public perception of the rule of law - the fairness of the operation of the courts and the police and confidence in the activities of these institutions. It also illustrates the credibility of legal regulations, the quality of their implementation and compliance with legal agreements and property rights. It assesses the effectiveness of the state in preventing violence and crime. The dramatic, because only 21 (in 2018) Poland's position in comparison with 26 EU countries, and the deterioration after 2015 of this indicator, is not conducive to the business activities of enterprises.

Fig. 3: Risk indicator for government acquisitions and expropriations of investors for Poland in 2014-2019 with a projected trend line

source: own study based on www.theglobaleconomy.com

The risk indicator for government takeovers and expropriations of investors, according to The Global Economy, reflects the risk of entrepreneurs being deprived of their property rights by those in power, the change of attitude of the state towards foreign investors and the risk of political manipulation of the functioning of the legal system. European Union countries are classified in seven categories from 1 (low risk) to 7 (high risk). For most EU countries (including Poland), this indicator was, in 2014-2016, correct and consistent with the rules of democratic freedom of management (1). The only exceptions in this period were Greece and Hungary (indicator 2). Unfortunately, from 2017, Poland joined these outsiders. This is a bad signal for Polish companies and for foreign investors in Poland.

Fig. 4: Polish Innovation Index 2010-2019

source: own study based on European Innovation Scoreboard 2008-2019 data

In the period 2010-2019, the innovativeness of the Polish economy was at a low level and placed Poland at the end of the list of European countries with an average level of innovation. The Innovation Index qualifies Poland to the group of so-called moderate innovators. The rate of possible growth and relation to the EU indicator do not give grounds for optimism. According to the statistics of GlobalEconomy.com, Poland was ranked 22nd (out of 26 EU countries), increasing by one position compared to the 2016 ranking. Poland was followed by Bulgaria, Greece, Croatia and Romania.

Positive conclusions can be drawn as follows:

Within the framework of poorly assessed macro-economic policy conditions, the only positive point is the likelihood of the emergence of social programmes as a politically enforced element in the country's recovery from the pandemic crisis. More surviving social programmes may mean a larger portfolio of potential investors for the company in question.

Another opportunity is the possibility of the EU forcing a change in the current form of government as a condition for obtaining anti-crisis and development subsidies. At the political level, there is also the possibility of closer cooperation between the production company and local authorities, as possible direct gestures of these subsidies, under the conditions that the political centre of government will continue the current 'democratisation'. The above solutions will allow the company, indirectly, to mitigate the impact of all the problems mentioned in the analysis, which constitute the economic factor of the PESTEL analysis.

Similar indirect effects may relate to the reduction of the power of 'flare' of the following three negative problems, which make up the social problem: a decline in the consumer orientation of society, a decline in the stabilisation of society's life and difficulties in obtaining life-stabilising loans. The positive character of the production activity of the surveyed company has new signals (lying on the borderline of social and environmental issues) of increased interest in building their own house with a garden. Inhabitants of large housing estates of multi-family buildings make, for the time being, few attempts to search for building plots as an indirect result of the past (and perhaps future) several weeks' pandemic lockout.

Hope for "European interventions" also concerns both the turning back of the Polish state authority from the previous path of devastation of the legal system (which results in a decrease in public confidence in legal regulations) and the withdrawal from the government's negation of participation in the pro-environmental "green order" programme. The socially beneficial direction of changes to the Labour Code and building regulations and legal regulations concerning health and safety at work seems to be forced by the very nature of the threat of the Covid-19 pandemic.

The violence and increasing frequency of adverse climatic events and the progressive drought and steppe formation of the country are equally natural in creating a growing ecological awareness of both energy-efficient and sustainable production and use of technology.

Among the technological factors of the PESTEL analysis, the negative power of influence on production activity has the fact of unfavourable (relative to EU countries) values of innovation indicators. This problem has complex political, legal and socio-economic conditions and requires undertaking at the level of central government.

The progressive automation, robotisation and digitisation of production processes (as well as the tendency to use cloud solutions) makes them more stable and independent even from factors of unpredictable economic slowdown caused by pandemic type phenomena. The increase in the number and functionality of mobile computer devices seems to represent an economic and social opportunity rather than a threat, provided that these devices are used rationally and ethically.

Summing up the results of the PESTEL analysis presented in this publication, it is possible to suggest that the woodwork manufacturing company under investigation is more resilient than developmental functioning in the current situation of an unpredictable economic slowdown. The element of survival is linked to the expectations of European intervention in political, economic, legal and social matters expressed above, and development may be based on the ecological and technological factors cited in this publication.

Possibility to Reduce Food Waste in Poland in the Light of Current Regulations

M MISNIAKIEWICZ

Cracow University of Economics, College of Management and Quality,
Department of Food Product Quality, Krakow, Poland
malgorzata.misniakiewicz@uek.krakow.pl

Abstract

Food waste is a problem of highly developed countries, which mainly affects food consumers and distributors. The FAO estimates show that around 1.3 billion tonnes of food are wasted in the world annually, which is 1/3 of the amount of food produced. In Europe wasted food reaches up to 50% of total food production and amounts to approximately 90 million tonnes. The average European throws away 20-30% of bought food. About 9 million tonnes of food are wasted annually in Poland. Due to the environmental, economic and social consequences of this situation, the problem is growing and is becoming the subject of regulation at international and national levels. One of such regulations is the Act on Counteracting Food Waste adopted in Poland on July 19, 2019.
The aim of this article is to analyse and evaluate the above-mentioned act, to indicate its strengths and potential areas for improvement. Using the elements of the SWOT analysis the compliance of the act with EU regulations, transparency, comprehensibility and completeness of the presented definitions, system - the range of legal and fiscal instruments used in the act, its scope, social utility as well as organizational and financial consequences of its introduction were taken into account. The regulations of the act were compared to the law in selected EU countries - the Czech Republic, Italy and France.
The law in Poland regulates primarily the obligations of sellers in terms of reducing food wastage. Thus, it promotes positive actions in the field of counteracting food waste at the stage of its distribution, while omitting the stage of obtaining and producing food. Its introduction has both positive and negative social, organizational, environmental and economic effects. Monitoring of the effectiveness of the act application is necessary as well as further development of its regulations. That would enable the effective introduction of solutions increasing social awareness, and thus reducing the amount of wasted food.

Keywords: Food Waste, Legal Regulations, Improvement, Reduction of Food Wastage.

Introduction

Food waste *is generally understood as all the foodstuffs discarded from the food supply chain for economic or aesthetic reasons or owing to the nearness of the 'use by' date, but which are still perfectly edible and fit for human consumption and, in the absence of any alternative use, are ultimately eliminated and disposed of, generating negative externalities from an environmental point of view, economic costs and a loss of revenue for businesses* (Avoiding food wastage, 2012, 29).

The FAO defines ***food wastage*** *as all processed, partially processed or unprocessed products intended for or expected to be consumed by humans, and those that, despite their production, have not been consumed.* Often this is because food has spoiled but it can be for other reasons such as oversupply due to markets, or individual consumer shopping/eating habits (FAO, 2014).

The FUSIONS Project (Food Usage for Social Innovation by Optimising Waste Prevention Strategies) has provided a Definitional Framework to harmonise the current definition on Food Waste within the EU 28. ***Food waste is any food, and inedible parts of food, removed from the food supply chain to be recovered or disposed*** *(including composted, crops ploughed in/not harvested, anaerobic digestion, bio-energy production, co-generation, incineration, disposal to sewer, landfill or discarded to sea* (Project FUSIONS).

In the EU most food is wasted at the end of the supply chain, i.e. at the stage of distribution and consumption. As much as 42% of food is wasted in households, two-thirds of which are still healthy for consumption. At the

Cite this Article as: M MISNIAKIEWICZ "Possibility to Reduce Food Waste in Poland in the Light of Current Regulations" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

production stage 39% of the total amount of food is wasted, at the distribution stage, including catering, 14%, and at the stage of sales 5% (European Commission, 2011; Obiedzińska 2017, 131).

In Poland, in contrast to other EU countries, the most food is wasted at the production stage - the food industry generates nearly 6.6 million tonnes of food waste annually. Households waste more than 2 million tonnes of food, and 0.35 million tonnes of food are wasted in Poland at the distribution stage (European Commission, 2011). In total, this gives about 9 million tonnes of wasted food per year, which places the country on 5th position in the European Union. Each Pole throws away approximately 52 kg of food per year. After taking into account the earlier stages of the food product life cycle the amount grows up to 250 kg per Poles per year (Stępień & Dobrowolski, 2017).

The problem of food wastage has a number of environmental, economic and social implications, which require taking systemic and targeted actions to limit its scale. For this purpose, the scientific research and analyses in the field of counteracting food waste should be carried out. Reliable and proven knowledge should be provided and such regulations and laws should be created that will allow for effective implementation of solutions increasing social awareness, enforcing specific solutions and shaping rational market behaviour. One of such solutions is the Act on Counteracting Food Waste passed in Poland on 19 July 2019 (Journal of Laws 2019, item 1680.

Research Method

The presented research includes a critical analysis of the Act on Counteracting Food Waste in Poland in the context of legal regulations in selected EU countries - the Czech Republic, Italy and France. Analyses - identification of the strengths and weaknesses of the regulations adopted in Poland, as well as opportunities and threats of the Act implementation were carried out using the SWOT analysis in February and March 2020.

The aim of the study was to develop recommendations aimed at improving activities in the area of reducing the costs and losses related to food waste. The hypothesis that in selected EU countries, the legal regulations enable a more effective fight against food waste than in Poland was stated. Therefore, there is a chance to develop better solutions on the basis of benchmarking and introduce them in Poland. The analysis and evaluation of the Act on Counteracting Food Waste was carried out in 7 areas:

1. Compliance with EU regulations and strategy.
2. Legal definitions - their clarity, comprehensibility and completeness.
3. System - the resources of legal and fiscal instruments used in the Act.
4. Scope - the extent of food waste in Poland.
5. Social benefit - the potential impacts on society and the environment.
6. Organizational consequences on retailers, charities and consumers.
7. Financial consequences - possible economic and organizational costs and profits of the regulation for all participants in the system.

Research Results

The obtained results of own research were presented according to the analysed areas.

1. **Compliance with the EU regulations and strategy – Confirmed**. The subject of the Act is consistent with the regulations and strategy of the European Union. *The resolution of the European Parliament of 19 January 2012 Avoiding Food Waste: Strategies to Improve the Efficiency of the Food Chain in the EU* indicates the need for action to reduce food waste. The EU Parliament recommends decisive steps to reduce food losses by 50% by 2025. In line with the conclusions of the Council of the European Union on Food Waste and Food Loss (June 2016), the reuse of food that would otherwise be lost is the second priority action, after prevention of food waste, in food use hierarchy. Reducing food waste is also critical if EU Member States are to meet climate change targets and reduce greenhouse gas emissions, as well as fulfil obligations under the European Landfill Directive to reduce the amount of biodegradable waste going to landfills (Council Directive, 1999). Donating food to non-governmental charitable organizations that conduct activities in the field of food redistribution to people in need is one of the most preferred and effective ways of reducing food waste. The solution applied in the Polish act mobilises the participants of the supply chain to limit the amount of food losses by introducing fees, the obligation to educate consumers, and directs unused food towards the most preferred solution in the hierarchy of waste management – redistribution.

2. **Legal definitions – partly confirmed.** Article 2 of the Act introduces legal definitions of food waste, non-governmental organization and food retailer.
   Food waste is understood as the withdrawal of food from the distribution stage and its disposal as waste. Particular attention was paid to foods that are recalled due to impending use-by or best before date, or due to appearance or packaging defects. The legislator defined food waste as a process that takes place only at the distribution stage, bypassing the previous elements of the supply chain or wasting food in the household. Therefore, **the definition is considered incomplete and non-universal, but consistent with the scope of the act**.
   A non-governmental organisation is understood as an organisation which statutory goal is to perform tasks in the sphere of public tasks in the field of social assistance, including helping families and people in difficult life situations and equalizing opportunities for these families and people; supporting the family and foster care system; charity activities, including providing food to people in need or running mass catering facilities for people in need. Thus, the legislator limited the definition in relation to the ones adapted in the Act of 24 April 2003 on Public Benefit and Volunteer Work (Journal of Laws of 2018, item 450) to organizations engaged in activities for specific purposes. In addition, an additional provision was also introduced to the definition, stating that also legal persons and organizational units acting on the basis of the provisions on the State's relationship to the Catholic Church, on the State's relationship to other churches and religious associations, and on the guarantees of freedom of conscience and religion referred to in Art. 3 clause 3 point 1 of the Act of 24 April 2003 on
   Public Benefit and Volunteer Work are considered a non-governmental organization. Thanks to this, church legal entities conducting charitable activities can participate in the food donation system in Poland, e.g. Caritas.
   A food seller is an entity running a food business in the sale of food in a retail or wholesale unit with a sales area of more than 250 sq. m, in which the revenues from the sale of food constitute at least 50% of the revenues from the sale of all goods. The definition of a food vendor contains precise guidelines allowing determining which entrepreneurs are covered by the provisions of the Act. Precise identification of a food seller allows for the precise classification of the enterprise to the group covered or not covered by the regulations.
3. **System –** the Act introduces:
   - An obligation to conclude a contract for the free donation of food between a food seller and an NGO. Therefore, donating food to charity is not a voluntary activity, but a requirement that must be met. The use of this solution leads to the need to conclude many agreements with organizations in a very short time. This is a major organizational challenge for both retailers and charities.
     Organizational chaos may occur in the centres where many entities covered by the provisions of the Act are located. There is no official platform for advertising organizations willing to sign contracts, which could facilitate communication between interested parties. There is also the possibility of a situation where the seller will have difficulty with an organization willing to cooperate. The Act provides for exemption from the penalty for failure to meet the obligation if no organization cooperates with the seller. It is possible that some sellers will intentionally avoid signing a contract with an organization, sluggishly looking for a partner or falsely showing the lack of an organization with which they could cooperate.
   - An obligation to carry out educational and information campaigns in commercial units in the field of rational food management and counteracting food waste. It is assumed that the seller has the ability to influence consumers; to shape more balanced customer attitudes. Moreover, a significant number of sellers have experience in running marketing campaigns.
     When transferring the obligation of carrying out the campaign to food sellers, the dispersion of funds from the food waste fee was taken into account. Organizations may allocate no more than 20% of the funds from the food waste fee to these campaigns.
   - Food waste charge - the basis for calculating the charge is the weight of food wasted in kilograms. The entity itself declares the amount of wasted food, sets the amount of the fee and pays the fee for the non-governmental organization. The imposed charge is a financial "penalty" for food retailers who, despite the planned system and mechanisms for transferring unsold food products free of charge, generate significant amounts of food waste. This is to encourage retailers to take additional steps to prevent food waste. As the complete elimination of food waste is impossible, the basis for calculating the fee is 90% of the weight of wasted food in kilograms. In addition, the seller is entitled to reduce the fee by the costs incurred for educational campaigns in the field of preventing food waste or the costs of performing the contract for the transfer of food for social purposes, respectively.
     To ensure financial transparency sellers are required to provide information on the amount of the fee due and the value of food transferred to organizations in their financial statements.

- Financial penalties for failure to comply with obligations under the Act. The amount of the penalties is:
  - PLN 5,000 - for not concluding a contract with an organization,
  - PLN 500 - 10,000 - for not paying the food waste fee to the organisation's account.

  The local Provincial Inspectorate of Trade Inspection imposes financial penalties. Proceeds from fines constitute the state budget income.

  Considering that the regulations apply to sellers who conduct business on a large scale, the amounts of penalties proposed in the act are small in relation to the organizational effort related to the conclusion of a food donation agreement and the administration of food donation and campaign preparation. There is a risk that for some entities such an inadequate financial penalty will not be sufficiently motivating to undertake actions aimed at reducing food waste.

4. **Scope** - the Act focuses on food retailers, i.e. distribution. The problem of food waste, however, concerns a much wider scale. The Act deals with the general problem in a titular manner, while in practice it covers only a small part of the phenomenon. Due to its specific characteristics, the distribution sector has a high potential to reduce food waste.

   Advanced infrastructure, such as central warehouses, computer systems monitoring the flow of goods, allow for quick and correct identification of food for which the expiry date is approaching, while maintaining optimal storage conditions. Moreover, the centralised decision-making structure allows new procedures to be quickly introduced.

   However, the Act does not apply to large facilities providing catering services, such as hotels, canteens, and restaurants, reception houses, the specificity of which is similar. These types of facilities also experience large losses, and imposing an obligation to donate food on them could significantly contribute to reducing food waste.

   By limiting the entities covered by the provisions of the Act to points where the income from the food sold is at least 50% of revenues, certain large retail outlets, such as gas stations, where groceries and hot meals are sold, even on non-trading Sundays, are not required counteracting food waste. The act does not create any incentives for small retail outlets or smaller grocery stores to apply good practices and minimize food losses.

5. **Social and environmental utility.** Food waste is an environmental, economic and social problem. According to the act, the created system of transferring unsold food for social purposes is to bring positive effects in all three aspects.

   Food distribution through non-governmental organizations to people in need is aimed at improving the standard of living of the poorest people, preventing poverty-related social exclusion and reducing the scale of malnutrition resulting from insufficient financial resources. Moreover, the Act provides for educational and information campaigns to develop rational, balanced consumer attitudes and, as a result, to reduce the amount of food wasted in households.

   From an environmental impact point of view, reducing the amount of food withdrawn from sale to be disposed of can help to reduce greenhouse gas emissions. It should also be noted that food is a finite resource. Suboptimal management of foodstuffs also implies suboptimal consumption of electricity, overexploitation of drinking water and other natural resources. So it is a step in the right direction.

6. **Organizational consequences –** introduction of the Act means:
   - **For the seller:**
     - Finding an organization with which cooperation will be established and concluding a binding contract with it,
     - The need to organize a food donation system and identify safe food donation options,
     - The need to publish information on the amount of food donated and fees,
     - Organization of an educational and information campaign,
     - The need to independently calculate fees,
     - New workplace - people responsible for supervising the reporting of the amount of food donated, calculating the amount of fees and related additional costs,
     - Changes in the financial balance - a change in the scope of financial statements.
   - **For the organisation:**
     - Organization of collection, storage and distribution of large amounts of food,
     - Help in organizing an educational and information campaign,
     - Use of funds from fees for food waste in the field of social assistance,
     - Increasing the demand for employees / volunteers,
     - The need to provide adequate infrastructure - warehouses, distribution center, transport,
     - The need to provide information on the use of funds.

- **For the state administration:**
  - Additional obligations for the Trade Inspection in controlling compliance with the provisions of the Act,
  - The need to present an evaluation of the functioning of the act after 18 months from its entry into force,
  - The need to prepare implementing acts, regulations with a model report on the use of fee funds,
  - The need to handle administrative penalties
  - Carrying out tasks related to the rational use of food.

7. **Financial consequences - the system seems to be coherent in this area**.
   - **For the sellers, the analysed act is related to:**
     - Fees for wasting food, which is an additional cost for companies,
     - Reduction of costs related to waste management,
     - Costs of organizing the collection of groceries, including storage, change of logistics, additional expenses for remuneration of additional people,
     - Costs related to additional activities aimed at reducing food losses,
     - Possible penalties for non-compliance.
   - **For the NGOs there appear:**
     - Costs of handling the collection, transport and storage of food,
     - Investments in infrastructure,
     - Expenses for administrative and operational services, employees,
     - Expending on educational campaigns,
     - Revenue from the fees.
   - **For the public finance sector there appear:**
     - Income from fines,
     - Administrative costs of the system maintenance,
     - Costs related to carrying out inspections - organization, administration, inspectors,
     - Costs of creating new jobs in the office.

The Polish Act on Counteracting of Food Waste is one of the pioneering solutions in reducing food losses in Europe, but is not the only legal document regarding this problem in force in the European Union. To compare the legal regulations in this field at national levels, regulations in the Czech Republic, Italy, France were compiled with the Polish ones. The comparison included: the date of introduction, objects covered by the act, applied solutions, penalties, fees and facilities.

Table 1: Comparison of legal provisions on counteracting food waste in selected EU countries

	Czech Republic	**Italy**	**France**	**Poland**
Year of introduction	2018	2016	2016	2019
Obligation to sign a contract with a food donating organization	Yes	No	Yes	Yes
Objects covered by the act	Retail outlets with an area of more than 400 m2	Sales unites, farmers, producers	Retail outlets with an area of more than 400 m^2	Retail outlets with an area of more than 250m^2
Financial penalties	Yes, CZK 10 million	No	Yes, EUR 3,750-75,000	Yes, PLN 500-10,000
Facilities	Tax credits	Tax credits	Tax credits	Lack
Fee for non-donated food	No data	No	No	Yes
Other duties	No	No	No	Organization of educational campaigns

Source: own study based on the national Acts on the prevention of food waste in the Czech Republic, Italy and France (Pl.ÚS 27/16, 2018; Legge…, 2016; LOI n° 2016-138, 2016).

The law in force in Poland is distinguished by the fee for each kilogram of withdrawn food that could be transferred. In France even a seller donating only a minimal portion, e.g. 1 kg, of such food meets the requirements and will avoid a fine for throwing away valuable products. Ultimately, the Polish act will apply to stores with an area of more than 250 sq m (2 years from the introduction), which will potentially increase the number of food donated. Compared to the scope of regulated facilities in other countries, the Polish Act also covers smaller retailers. In addition, the funds from the fee for each kilogram of food recalled will be allocated to organizing information campaigns on the problem of food waste. The campaigns are also to contribute to reducing food waste and increasing awareness of the problem in the society.

However, the Polish law does not contain provisions referring to good practices, which are contained in the Italian law, concerning all links of the food chain. There is a risk that producers, processors and wholesalers will not take steps to reduce food waste, as the regulations do not apply to them.

The positive effects of the Act on Counteracting Food Waste include:

- Reducing the amount of food wasted, thus reducing the negative environmental impact and financial losses.
- Increasing the availability of resources for the poorest people, thus reducing social exclusion. Support for local communities and social organizations.
- Increasing the security of food supplies.
- Poland was one of the first countries to introduce an obligation to redistribute unsold food. Setting a good example, being a precursor and a model for other countries can positively influence the image of a country abroad.
- The introduction of a charge for wasted food should motivate sellers to introduce measures aimed at reducing the amount of food transferred for disposal, e.g. shelves with products at promotional prices, with impending shelf life. Less food recall means cost savings. Thanks to this, there is a chance to gain the loyalty of environmentally sensitive consumers.
- Reducing the amount of food sent for disposal also means reducing the amount of waste generated. The introduction of the act may contribute to the fulfilment of obligations imposed by the EU on its member states in this respect and to reducing the costs incurred by sellers on waste management.
- Information and educational campaigns are aimed at improving public awareness of rational food management and nutrition. Developing pro-ecological consumer attitudes should bring a number of further changes affecting also other sectors of the economy.

The Act also contains debatable elements that may have negative effects or create the possibility of circumventing the regulation. The weaknesses include:

- The Act does not fully cover the problem of food waste. It focuses on the distribution sector and indirectly on the household sector (social campaigns are targeted at end consumers). Food service establishments that could similarly provide unsold food to organizations operating in the field of social assistance were excluded. Moreover, the legislator did not take into account the production sector with which there are huge losses of food resulting from e.g. overproduction, low-quality raw materials, poor-quality packaging, irregularities in the labelling of goods, etc.
- The definition of a food retailer also excludes a number of large retail outlets, such as gas stations, which actually run regular grocery stores as part of their business, especially on non-trading Sundays, but most of their revenue comes from fuel sales.
- There is the question of whether stores will encourage consumers to make sensible purchases through social campaigns. Currently, marketing strategies that are far from sustainable consumption are popular, i.e. "buy 3 take 1 free". Creative marketing encouraging consumers to improve food management such as "recipe for potato peel crisps" is needed.
- There is a risk that the responsibility for the products will be transferred to the sales representatives of the wholesaler or the manufacturer (in stores where orders are not generated by the system) - the product will be withdrawn and not discarded. It is possible that sellers will start recalling products to the logistics centre so that the documents do not report them as "wasted". Document returns received will appear as "Taken to Fulfilment Centre" and not as food wasted.

- The penalty for not signing a contract or not paying fees for wasting food appears to be inadequately low. The amount of PLN 5,000 seems disproportionately low compared to the formal and organizational effort that must be put on by the seller to organise the food donation.
- Increasing formal and regulatory burdens - obligation to report on the amount of food donated, the amount of the fee, the basis for calculating the fee, and the manner of using the funds from the fees by the organization.
- Each of the participants in the system will face a major organizational and logistical challenge. It is necessary to provide systemic, simple organizational solutions to handle food donation. There will probably be a need to create new jobs or change the scope of duties of employees - in commercial establishments responsible for coordination and reporting, in non-governmental organizations responsible for communication with sellers and redistribution of food obtained, as well as for the preparation of reports, in supervisory institutions of persons responsible for inspections and reporting inspection results.
- It is necessary to prepare implementing acts.
- The state budget will incur expenses related to the control and operation of the system.

Conclusions

Poland as one of the first EU countries introduced regulations on counteracting food waste by redistributing food that is good for consumption. The analysed act may undoubtedly bring positive results. The most important opportunities include the possibility of using unsold food in a manner consistent with the priorities of food waste management in the EU, supporting the poorest, reducing the negative impact on the environment and financial losses related to the disposal of food products. Imposing an obligation on the seller to conduct educational campaigns should additionally have a positive impact on reducing the amount of wasted food.

Unfortunately, the act covers only part of the problem. The obligation to conclude contracts with non-governmental organizations only applies to "big sellers". No additional incentives were created for non-compulsory facilities that could contribute to reducing the amount of food waste. One of the biggest threats is the potential lack of infrastructure allowing for safe storage of the donated food from the moment it is withdrawn from the store until it is handed over to the final consumers. Moreover, it is uncertain whether community organizations will be able to cope with a large flow of food, which is provided on an ongoing basis, with a short shelf-life and therefore a limited shelf life. There is also a risk of reluctance of sellers to cooperate with social benefit organizations, delay in finding a partner for the contract and false demonstration of the inability to cooperate with organizations in the region. Dishonest distributors can also find "creative" ways to report recalled products so that they do not appear as disposed of, thus avoiding the fee. The penalty for failure to comply with the obligation is not high enough to discourage people from circumventing the introduced regulations.

The basis for reducing the scale of food waste will be a change in behavior and practices in every link of the supply chain: at consumers, sellers, processors and producers. Establishing profitable business ties between charities and the food sector may have a positive effect and be a more effective incentive than the system of official penalties.

Summing up, despite the reservations, in particular with regard to the scope of the document, the Act on Counteracting Food Waste may bring about positive effects in all three basic pillars of sustainable development: environmental, social and economic. It is a positive example of the implementation of provisions for the sustainable management of resources in accordance to the EU strategy.

Abstract

Nowadays a loss of biodiversity in Poland may result not only from excessive intensification of agriculture, but in some regions also from the opposite process of abandonment of agricultural use. The study was conducted in 2019-2020, in 30 communes/municipalities, within 3 conservation areas, where traditionally some agricultural activities are still present. In order to show the level of deagrarisation and deanimalisation processes, there was used the zero unitarisation method that indicate an abandonment of agricultural production, mainly for economic reasons. Moreover, there were carried out some botanical research in seminatural plant communities, to show if there is the connection between advancement of deagrarisation, and deanimalisation process and the total number of vascular plant species and distribution of rare species. The results show that there are mutual connections between diversity of plant species, structure of the landscape and its management. In those communes where the deagrarisation process was highly advanced, there was small number of plants in phytosocological releves. The lowest percentage of abandoned farming was noted in the municipalities with relatively good soils, that are located in the Nadnidzianski Landscape Park. That was also the area with the highest number of plants in releves (on average 45-53). Deagrarisation and deanimalisation processes were particularly intensified in the communes located in the northern part of Konecko-Lopusznianski Nature Park, where deagrarisation advancement was > 0.372.

Keywords: Deagriarisation and Deanimalisation, Natural Capital, Mutual Connections.

Introduction

The natural environment in Poland is a subject to transformations related to climate change and civilisation development, which might disturb the natural balance. While species withdrawing from their natural ecosystems are a serious problem, changes in the biodiversity in the agricultural area are less noticeable or their significance is diminished. Therefore, many researchers are more interested in sustaining biodiversity in conservation areas, than in the actual loss of biodiversity in agricultural ecosystems, which occupy a large area of Poland. This phenomenon persists also in the whole Europe, despite considerable attention being paid to the environmental context of contemporary agriculture. Also, concerning economy, biodiversity is often not regarded as part of the natural capital of a specific country or region. However, the recent reforms of the agricultural policy in the EU indicate that the situation may be slowly changing. Still, general perspectives for the protection of biodiversity in agroecosystems and sustainable agriculture are rather grim (Perrings et al. 2006).

Thus, an important area of interest seems to be the analysis of relationship between biodiversity, landscape structure and its management (Billeter et al. 2007). Poland can boast of considerable diversity of agricultural landscape. It may be described by abundance of existing patterns of seminatural landscape elements, especially for areas with extensive agriculture (Edwards, Kollmann and Wood 1999). It is a fact though, that over the past decades some

plant species previously described as frequent are becoming rare. That is generally a result of intense agricultural production and decreased proportion of the seminatural habitats in cultural landscape (Krebs et al. 1999; Robinson and Sutherland 2002). Similar decrease in biodiversity in agroecosystems is observed also in many EU countries (Stoate et al. 2001; Donald et al. 2002). The constant growth of the areas occupied by agricultural land leads to dramatic changes in the structure of the landscape, which is becoming more homogeneous. As a result seminatural habitats, typical for cultural landscape are scarce, mostly small, and often isolated from one another (Duelli and Obrist 2003). Moreover, large-scale, intense farming corresponds to the needs of industrial agriculture, and is featured by higher pesticide and fertilizer inputs, tillage operations, and livestock densities (Matson et al. 1997; Robinson and Sutherland 2002; Benton et al. 2003; Bengtsson et al. 2005; Foley et al. 2005; Tscharntke et al. 2005; Aavik et al. 2010).

But there are also some agricultural areas where situation seems to be quite the opposite. This is visible for areas with advanced or progressive deagriarisation, which is abandoning agriculture for economic and cultural reasons. Nowadays in Poland it is a frequent problem, especially in the southern part of the country traditionally dominated by small farms. That may create some threats for the local plant diversity, especially for seminatural habitats as grasslands, where many rare plant species is still to be found. They are part of various agricultural ecosystems, ranging from wet habitats, to dry xerothermic grasslands. Maintaining the nature of such habitats and their elements depends on proper use of land, and it is also the prerequisite for effective conservation. Apart from deagriarisation, the other negative factor is the decrease in the number of livestock in a specific region, also known as deanimalisation (Musiał and Musiał 2019). It seems these two processes may be adverse for both the economy and nature in the Swietokrzyskie Region, which saw considerable deagriarisation over the past few decades. The aim of the study was to indicate the threats resulting from deagriarisation and deanimalisation for the economy and seminatural habitats in selected conservation areas in the Swietokrzyskie Region.

Characteristics of the studied area

The Swietokrzyskie Region is situated in south-eastern Poland and includes a voivodeship under the same name. It occupies 3.7% of the area of Poland, which makes it one of the smallest voivodeships in this country. The study covered 3 types of conservation areas: buffer zone of the Swietokrzyski National Park (S NP), Konecko-Lopusznianski Nature Park (K-L NP) and Nadnidzianski Landscape Park (N LP) (fig. 1). The largest of these three is the K.-L. NP, situated in the north-western part of the voivodeship, spreading over the area of 98 287 ha and including 13 rural and municipal communes. The second is N LP, situated in the southern part of the Region, with 22 888.6 ha in the area of 10 rural and municipal communes. The smallest, S NP in situated more centrally in the voivodeship and its buffer zone covers 20 786 ha and spread over 7 communes (fig. 1).

For conservation purposes crucial role is played by national park, for which buffer zone is obligatory due to some threats related to human impact (Nature Conservation Act of 16.04.2004, Art. 8 and 9). Still, agricultural activities are allowed there, since they maintain the existing cultural landscape and prevent changes in the agro-forest border. Landscape park has a lower status and less restrictions on development and economic use. Its goal is conservation of unique habitats, but the buffer zone is not mandatory (Nature Conservation Act of 16.04.2004, Art. 16). However, there are specific agricultural and production-related prohibitions, related to slurry disposal of livestock (Gruszecki 2005). Nature park has a similar function, but with more focused on landscape than the nature. Regarding agricultural production, regulations define restrictions for enterprises that may have considerable impact on the environment. However, there are no limitations for the technology of keeping livestock (Nature Conservation Act of 16.04.2004, Art. 23).

Fig. 1: Conservation areas covered by the research in rural and municipal communes of the Swietokrzyskie Voivodeship

Materials and Methods

The study was conducted in 2019-2020, in 30 rural and municipal communes in the conservation areas, where agricultural activities still are or traditionally were present. Part of the research was conducted in the form of a survey, in order to assess the economic and agricultural aspects of such areas. Separate consideration was given to the evaluation of each commune, with regard to the share of agricultural farms classified according to their condition and perspectives. The respondents assessed the proportion of individual categories of farms in a specific commune/municipality, based on the 4 types suggested in the survey:

A - developing farms, with considerable production potential and scale. They invest in land or other fixed assets, use structural funds and/or are leading and growing locally;

B - potentially developing farms, with signs of development. Their production potential is small or medium, but is market-oriented. They do not invest much in technical equipment and are rather inactive on the land market;

C - farms in recession, that maintain agricultural production, but do not invest in development. Their production is only partially market-oriented but they use all or almost all of their land;

D - declining farms, they present various levels of production and economic decline. For the past few years they have not invested in technical equipment and their extensive agricultural production is organized on part of or whole land. Some of them lease and/or fallow the land.

The proportion of individual analytical groups was the basis for a detailed analysis using the zero unitarisation method for the variables describing the municipalities in the whole voivodeship, showing the level of estimated production and spatial deagrarisation (Kukuła 2000). For the calculation, the following five descriptive variables were adopted:

- proportion of non-agricultural (abandoned) land (%);
- proportion of extensified agricultural land and grasslands, maintained only to receive EU subsidies, (%);
- proportion of farms that fallow at least part of agricultural land (%);
- proportion of farms which formally exist, but have completely abandoned agricultural production (%);
- proportion of declining farms on various levels of economic decline (%). It was assumed that all five features are stimulants and their high proportion proves the advanced level of production and deagrarisation. The abovementioned variables-stimulants were normalised according to the algorithm:

$$z_{ij} = \frac{x_{ij} - \min x_{ij}}{\max x_{ij} - \min x_{ij}}$$

The variables had values ranging from 0 to 1, where 0 means no deagrarisation, and 1 - the most advanced deagrarisation. Synthetic factor of production and spatial deagrarianization (PSD) was calculated as the arithmetic mean of normalized values of the diagnostic features. Then the Shapiro-Wilk test was applied to assess the distribution of the dependent variable, which was the basis for discarding the division into analytical groups (PSD) on the basis of standard deviation. A relevant division into analytical classes was applied, based on quartiles. They represent the advancement of spatial deagrarisation, which was described as: highly advanced, advanced, intermediate and poorly advanced.

Analogous calculations were performed while evaluating the deanimalisation of the Swiętokrzyskie Region. The variables describing this process were:

- number of farms in the municipality with more than 30 heads of cattle (cows and fattening bulls), (destimulant);
- proportion of non-productive grasslands (%);
- proportion of livestock-free farms (which no longer breed cattle, swine, sheep or horses), (%);
- proportion of declining farms on various levels of production and economic decline, (%).

The first variable was normalized using the algorithm adequate for destimulants:

$$z_{ij} = \frac{\max x_{ij} - x_{ij}}{\max x_{ij} - \min x_{ij}}$$

The data for the communes described with the dependent variable were divided into four quartiles, which were then placed on the map. Subregional advancement of deanimalisation was pointed out in the communes/municipalities with the conservation areas. There was also an indication of potential and actual consequences of these processes.

The field research covered 60 phytosociological releves according to the Braun-Blanquet method (1964), that are lists of plant species occurring in the plot of 100m². They were carried out is all analyzed communes (2 in each commune), in seminatural plant communities. That served to show the connection between advancement of deagrarisation, and deanimalisation process and the total number of species in phytosociological releves and also the distribution of rare vascular plant species. Latin names of species from the Polish Red Lists were given according to Mirek et al. (2006), and plant associations according to Matuszkiewicz (2014).

Results and Discussion

Analysed conservation areas cover totally 1419.6 km^2 and are diverse a far as nature and soil are concerned. That whole area is dominated by small individual farms with an average area of agricultural land of 3-6 hectares. These are usually bi-professional farms, where statistical owner has another, non-agricultural job, or receives a pension/health pension. In the past they were involved in diverse plant production and kept small herds of cattle or swine, less frequently sheep. The results of the research show that nowadays in the area of Konecko-Lopusznianski Nature Park, farming has been abandoned in ca. 25% of agricultural land, of which 23.3% are grasslands (tab. 1). Also in the communes/municipalities in the buffer zone of the Swietokrzyski National Park, the ratio of abandoned farming is respectively 18.6% and 20%. The lowest percent of abandoned farming was noted in the municipalities with relatively good soils, that are located in the Nadnidzianski Landscape Park. Moreover, agriculture in K.-L.

Nature Park is notable on the account of the highest proportion of extensified agricultural land (48.3%), and farming there is done with minimum expenditure on yield-forming agents. Such extensification may lead to its extreme form, which is abandoning agricultural production, and that is a serious threat to the existing seminatural habitats related to agriculture. As compared to two other analyzed protected areas, this one also includes the most livestock-free farms (62.8%) and those existing only formally, "on paper", but not involved in any agricultural production. This means agricultural land use is abandoned, the land is leased for consideration or for free. In the other two areas the situation is better as regards agricultural activities. The proportion of livestock-free farms is rather high, respectively: 53.4% for the buffer zone and 48.5% for the N LP.

Table 1: Selected characteristics of regression in the agricultural production in three different conservation areas

No.	Specification	Buffer zone of S NP	K-L NP	N LP
1.	Proportion of abandoned agricultural land (%), of which abandoned grassland (%)	18.6 20.0	25.0 23.3	14.3 12.2
2.	Proportion of extensified agricultural land (%)	31.4	48.3	22.8
3.	Proportion of farms that fallow part of the land (%)	21.4	30.6	11.6
4.	Proportion of livestock-free farms (%)	53.4	62.8	48.5
5.	Proportion of farms existing only "on paper" (%)	14.3	17.8	9.6

Threats related to the maintenance of agricultural land use come from the condition and perspectives of the individual farms. The analyses conducted in the communes show considerable differences between the three areas in this respect (tab. 2). The results show that the smallest proportion of developing farms (A) is observed in the buffer zone (11.4%), and in the communes/municipalities of the Konecko-Lopusznianski Nature Park (K.-L NP) (12.8%). The situation is much better in the Nadnidzianski Landscape Park (N LP) (29.8%). Moreover, the proportion of farms with traces of development (B) is similar. The proportion of such farms ranges from 25.8% in K.-L NP to 31% in the buffer zone of Swietokrzyski National Park (S NP). The proportion of farms in recession (C), but maintaining usually extensified field production and, sometimes also livestock, is slightly higher. Their significance is great, because together with farms showing traces of development, they constitute 60-70% of the total number of farms in the studied region. They are therefore decisive in sustaining the agricultural use of fields and using grasslands for fodder. Still, their small size and marginal income from agricultural production as compare to the general income of the whole households are a bad perspective for the future maintenance of the production (Skotarczak and Blaszke 2019).

Table 2: Estimated proportion of four categories of farms regarding condition and development in the conservation areas in the Swietokrzyskie Voivodeship

No.	Specification	Buffer zone of S NP	K-L NP	N LP
1.	(A) developing farms (%)	11.4	12.8	29.8
2.	(B) potentially developing farms (%)	31.0	25.8	26.0
3.	(C) farms in recession (%)	39.7	33.1	32.5
4.	(D) declining farms (%)	17.9	28.3	11.7

More detailed analyses allowed to define the advancement of deagrarisation. Such process of production and spatial abandoning of land use is highly advanced in all three conservation areas. This is particularly intensified in the communes located in the northern part of K-L NP, where deagrarisation advancement is > 0.372. The next four municipalities of that area, situated more to the south, characterize of a slightly lower deagrarisation process (fig.2).

In the buffer zone of the S NP very advanced deagrarisation process refers only to one commune, and andvancement of that process was also confirmed for four other. Only in the commune located in the centre of that buffer zone, deagrarisation was at its lowest > 0,147, although still existent. Agricultural land in the buffer zone is rather varied as regards its use and management. The common denominator is progressing deagrarisation and extensification of production, with regard to both plants and livestock. In the northern part of the buffer zone there are mines, but next to them we will observe typically agricultural land. Generally, in the buffer zone of that national park, human impact on the environment is evident. In the N LP deagrarisation process is from advanced to rather low (poorly advanced). Intermediate level (0,147-0,230) is observed in three communes and low level (> 0,147) in another four communes.

Fig. 2: Synthetic evaluation of deagrarisation process in rural and municipal communes of the selected conservation areas

Just like deagrarisation, deanimalisation is the strongest in Konecko-Lopusznianski Nature Park (fig. 3). It is very advanced in four of its communes, but in the next five it is advanced. In the buffer zone of the national park, two municipalities have advanced deanimalisation, four other intermediate and in one this process is poorly advanced. In the Nadnidzianski Landscape Park deanimalisation process is the least advanced comparing to the two other areas. It is there either intermediate (4 communes) of poorly advanced (6 communes). However, poor advancement of deanimalisation, although definitely good for the maintenance of biodiversity, seems only temporary in this area, as compared to others. Deagrarianization and deanimalization related to agricultural production may be analysed based on the symptoms or consequences with reference to production and management of agricultural space. Production deagrarianization is therefore a sphere whose common denominator includes various conditions or declining farms. It involves a progressive reduction of the productivity of the farms, and a consequent resignation from agricultural production, fallowing, extensification of production and often only formal sustenance in order to receive EU funds. It may also involve a gradual decrease in the size of cultivated land and agricultural production. It also involves an increase in the proportion of livestock-free farms or farms which keep animals only to meet the needs of their own household (Musiał and Musiał 2019).

Fig. 3: Synthetic evaluation of deanimalisation process in rural and municipal communes of the selected conservation areas

After 1989, when Poland shifted from centrally managed to market economy, and especially after the integration with the EU in 2004., there has been noted a gradual change in the macroeconomic conditions for agricultural production. As a result, small-scale animal production became unprofitable, which resulted in people abandoning the breeding of cattle in small herds of 1-5 animals (Musiał and Musiał 2018). Nowadays, in some regions lack of ruminants in the farms or nearby, result in abandoning grasslands. This means part of meadows and pastures is no longer grazed, which leads to the gradual transformation of such seminatural plant associations (Niznikowski et al. 2017). Since the analysis concerns conservation areas, grazing seems especially important, as it is included as one of the protective action plans aimed at preserving the biodiversity of seminatural plant associations (Tscharntke et al. 2005).

The ecological results of deagrarisation and deanimalisation, are gradual changes of the plant associations from seminatural meadows and pastures (*Molinio-Arrhenathretea* class) into various associations of shrubbery and finally into forest (*Querco-Fagetea* class) (Matuszkiewicz 2014). In those communes where deagrarisation is highly advanced, field production is abandoned and no agricultural activities are performed on grasslands. This threatens mainly the most sensitive components of the local flora, which also happen to be rare species, mentioned in Polish Red Lists (Mirek et al. 2006). The poorest advancement of that two processes in the Nadnidzianski Landscape Park, can be lined with existing there the richest biodiversity of seminatural grasslands, comparing to the other two conservation areas. The number of plant species in the releves were on average in N LP 45-53, while in the K.-L NP it was respectively 28-31, and in the buffer zone of S NP 34-37. Moreover, in N LP there were noted also very unique plant species, from the red lists, as e.g.: *Adonis vernalis*, *Arabis recta, Elymus hispidus, Linum hirsutum*, *Stipa capillata, Thymus kosteleckyanus and Scorzonera purpurea.*

The area of Nadnidzianski Landscape Park is nowadays considerably deforested, that promoted the growth of xerothermic plants, which grow on hills, on the calcareous soils. Such xerothermic plant species are phytosociologically classified as *Festuco-Brometea*, that is characterized by plant species that are considered to be relic, and come from the period when steppe was naturally spreading over large areas of the continent (Matuszkiewicz 2014). What is more, they shape the mosaic of local landscape, next to meadows and patches of

schrubs (Solon 2002). Abandoning agricultural production, especially in this region, may entail serious losses for plant diversity, especially with regard to the xerothermic plants. This is related to the actual loss of space and a threat of further loss of the biodiversity of various seminatural habitats, which need grazing by ruminants in order to survive. That is actually the result of how structure of landscaped and type of the management is directly linked with the biodiversity (Groberek et al. 2004; Billeter et al. 2007; Niznikowski et al. 2017). That's why when creating a new, specific form of nature conservation, there is a need to guarantee proper conditions for this protection, but also account for other aspects: economic, social and cultural (Skotarczak and Blaszke 2019).

.

Fig.4: Relationship between landscape management, its structure and biodiversity, in selected conservation areas of the Swiętokrzyskie Region

Areas of conservation have existed in Swiętokrzyskie Region since the 1950s of the XX century. The first established area and at the same time the most significant was the Swietokrzyski National Park in 1950 (Nature Conservation Act of 16.04.2004 - Art. 8 and 9). From among the analysed areas, the Nadnidzianski Landscape Park was established a bit later, in 1986, while Konecko-Lopusznianski Nature Park is definitely the most recent addition (1995). It seems interesting that at the moment, the Swietokrzyskie Voivodeship has the largest proportion of conservation areas in Poland, as they constitute 65% of the total area. Extensive grazing in the communities from the phytosociological classes *Molinio-Arrhentheretea* and *Festuco-Brometea* is necessary there to maintain the appriopriate species composition and the existence of rare vascular plants. This is also why it is constantly necessary to define areas of nature conservation, so as to maintain extensive use of such plant communities, where possible, by mowing and grazing (Duelli and Obrist 2003). Therefore, the role of local landscape structure in the vegetation composition and the advancement of deagrarisation are related to each other and may shape the threats both for the regional economy and nature (Aavik et al. 2008).

Summary

The most evolutive farms and the fewest livestock-free farms are observed in the municipalities in the Nadnidzianski Landscape Park. It is a good tendency from the point of view of nature conservation, in this area with precious seminatural plant communities, whose existence depends on extensive grazing. However, in many places of the analysed area, the fragmentation of agricultural parcels and increasing tendency to abandon breeding livestock in small herds are a serious threat to the advancement of deagrarisation and indirectly also deanimalisation. This process first appears in the areas with poor soils and in urbanised areas or in places with the easy access to cities, where people can easily find a job outside the agricultural sector. However, if these processes are occurring in typically agricultural areas, they may be regarded as particularly negative, both economically and socially. In protected areas the regression of agriculture also entail a serious threat to biodiversity. This refers in particular to various grassland types, because in Polish climate they are seminatural communities. This means when left unattended, such communities will spontaneously turn into forest communities. It seems that abandonment is the most serious threat for communities growing on poor soils, near forests and for those regarded as too weak to be used, but at the same time possessing unique natural values, such as xerothermic grasslands. Farmers from these areas often use means of support analyzed in the first pillar of the CAP, but they are unwilling to engage in agricultural, environmental and climate-related actions, because they believe the bureaucracy and substantive requirements are too high. Farms with advanced level of extensification of agricultural production may stop advancement of deagrarisation by switching to organic farming. Also combining direct payments related to permanent grasslands with the obligation to keep ruminants and maintain grazing there may considerably slow down the deanimalisation and the related loss of biodiversity of the agroecosystems.

Abstract

The trend of inflation in Nigeria has been startling and there was relatively little knowledge of how volatility in stock market prices could influence future inflation in Nigeria. The objective of this study is to determine how inflation trends could be explained by stock market booms and burst. To achieve the stated objective, the study applied the Hodrick-Prescott Filter and Contemporaneous Correlation test on secondary dataset for Nigeria from 1985-2017. The secondary dataset were gathered from the Central Bank of Nigeria statistical bulletin and the Nigerian Bureau of Statistics Annual Statistical Report. Variables relevant to the objective of the study like CPI (consumer price index or inflation) and MCAP/GDP (stock market capitalization to GDP) were analyzed. Findings from the Contemporaneous Correlation test revealed that there is a countercyclical relationship between stock prices and inflation rate. This means that changes in inflation rate happen after changes or fluctuations in stock prices. The Hodrick-Prescott Filter confirmed this finding by showing that this relationship between stock prices and inflation is evident in the past behaviour of inflation and stock prices. This implies that inflation tends to rise when stock prices are falling and inflation falls when stock prices are rising. The study hence, recommends that policies that extend the stock market cycles should be adopted as it has been proven to reduce the inflation rate significantly.

Keywords: Inflation; Stock prices; Hodrick-Prescott; Volatility; Stock Prices Cycles

Introduction

In the early 1960s, household wealth in Nigeria was held majorly in liquid form as stock market at the time was relatively new after launching in 1961 with just 19 publicly listed companies. A typical household wealth portfolio had almost no exposure to the stock market as stock market liquidity was low and the terrain unfamiliar to the then unsophisticated investors. During this period, household spending could be generally tied to a stable labour and investment income with inflation generally under control. Average inflation between 1960 and 1969 was just 3.4 percent (World Bank, 2018).

As investors became savvier, more money poured into the stock market and by 1985, the proportion of stock market capitalization to total money supply in the country had moved from less than 1 percent to almost 12 percent in 1986 and households began to hold some portion of their wealth in the stock market (Central Bank of Nigeria - CBN, 2017). Prior to the mid-1990s, all investments in the stock market were held by Nigerians and it was not until 1995 that foreign investors were permitted to invest in the local stock market. As at year end 2018, Nigerian households still controlled up to 49.13 percent of investments in the stock market, showing that a significant portion of household wealth in Nigeria

remains in the stock market (Onyema, 2018; Okunlola, Babajide, and Isibor (2020). As households began to invest in stock market, their investment income and wealth began to become more volatile and this might have created substantial effects on their spending behaviour and inflationary economic pressure (Nwosa, 2017).

Between 1985 and 2007, proportions of stock market capitalization to total money supply in the economy had risen from 12 percent to 199 percent (CBN, 2017). In 2006, for the first time, there was more money in stock market than was circulating in the economy as stock market capitalization to money supply surpassed 100 percent for the first time, reaching 111 percent (CBN, 2017). As more money left the pockets of households and poured into the stock market, the spending pattern of households was completely altered, and inflation became more volatile.

Since 1985, the inflationary problem in Nigeria has been quite startling. In the 32-year period between 1985 and 2017, Nigeria suffered double digit inflation in 24 out of the 33 observations which led to a severe erosion of the value of Naira in the last 3 decades according to data compiled from CBN Statistical Bulletin (2017). CBN on numerous occasions has tried to use monetary policy to control inflation volatility in the country with little success. The singular inflation objective for CBN during the past 3 decades has always remained to achieve single digit inflation in the country. However, this was only a reality in just 9 of the 33 inflation observations, translating to a low probability chance of 27.2 percent that CBN will achieve single digit inflation in Nigeria in any given year (CBN, 2017). Average inflation during the 32-year period was as high as 19.9 percent, up to 11 percentage point higher than the current single-digit target band of 6-9 percent that Central bank is currently seeking to achieve (CBN, 2018). An obvious challenge CBN has struggled with in the last 32 years is understanding inflation dynamics enough to predict its direction and use monetary policy to steer inflation closer to its monetary goal. In the last 3 decades, disparities between CBN inflation target and actual inflation in Nigeria exceeded 100 basis points in 30 out of 33 observations, translating to 91 percent chance that CBN will fail to achieve its monetary inflation target annually (CBN, 2017).

Stock and Watson (2016) explained that the positive relationship that exists between equity yields and expected inflation arises because current stock prices are valued using forward-looking economic variables which include expected inflation. Therefore, the stock prices themselves could be useful in determining the consensus view on future inflation and economic growth since future inflation and economic growth expectation was modelled into the current stock price by the aggregate market (Apergis, 2017; Achugamonu, Adegbite, Omankhanlen, Okoye, and Isibor, 2019). Farmer (2015) stated that the idea that stock prices can provide useful guidance in forecasting macroeconomic variables has long been established in literature and evidenced in reality. For instance, in 2007, inflation in Nigeria fell below 7 percent, making it the lowest inflation rate on record in over 7 years at the same time the stock market was breaking record highs (CBN, 2018). We can roughly deduce that higher stock prices led households to invest more in the stock market, which eventually reduced inflationary pressure in the economy. However, data compiled from CBN (2018) showed that the following year in 2008 when the stock market collapsed, households became net sellers in the stock market and inflation began to trend upwards again, moving from 6.5 percent in 2007 to 15.1 percent in 2008.

This study contributes significantly to the body of knowledge in monetary economics, asset pricing and market forecasts by showing how one could use stock prices cycles in forecasting inflation in Nigeria. Before now, there was relatively little knowledge of how volatility in stock market prices could influence future inflation in Nigeria or how inflation trends could be explained by stock market booms and burst.

The purpose of the study is therefore to help economists and financial analysts have another better way of forecasting inflation in Nigeria through the use of stock market cycles. By this method, one way of dealing with high inflation in Nigeria would be to examine the stock prices. This would then help in regulating both the stock market prices and also inflation in the nation.

The study's objective is to determine the cyclical relationship that exists between stock prices and inflation in Nigeria. The study introduced the subject matter plus the objectives and significance of the study in the first section which is the introduction. Section two presents a detailed appraisal of pertinent empirical literatures. It also explained the theoretical framework behind the subject matter, and it finally revealed the gaps the study wants to fill. Section three constitutes the methodological outlook to analysing data gathered for the study. Section four contains the data and result presentation while section five presents the conclusion and recommendations proffered.

Literature Review

Most related literary texts begin from defining inflation as persistent rise of prices, which causes four possible challenges, whose austerity relies greatly on anticipations of such inflation (Ball, 2017; Benabou, 1991; Imrohoroglu, 1992). The first and maybe greatest apparent issue is that inflation erodes monetary value, thus constituting tax on sums of money (Antinolfi, Azariadis & Bullard, 2016; Friedman, 2016). So, individuals end up holding lesser real money compared to if inflation was absent, yielding unsatisfactory effects. Numerous works tried to measure corresponding consequential welfare loss by using money demand function and evaluating the portion occupied by inflation beneath the curve. Also, a moderate swift reduction in money's value would exert more consequences for money-spenders, who must complete extra journey to banks to refill their preferred nominal money volume so as to be at par with higher prices (Sieroń, 2019; Omolade & Mukolu, 2018; Isibor, Olokoyo, Arogundade, Osuma, and Ndigwe, 2018).

Farmer (2015) found that the housing bubble burst which led to a stock market decline in 2008 was the primary reason for the great recession that followed between 2008 and 2009. He established a granger causal relationship between stock market and unemployment rate in America, as high unemployment rate was an after-effect of the great recession. After showing that stock prices granger causes unemployment rate in America, the study went on to show via Vector Error Correction Model (VECM), that absence of monetary intervention by Central Bank, a significant crash in stock prices could cause a spike in unemployment rate over the next one to four quarters. Empirically, higher unemployment in a country could lead to an economic recession which is only the occurrence of two consecutive quarterly declined in economic output. This phenomenon may explain the occurrence of the great recession in 2008 when unemployment figure almost doubled, and the country entered its biggest recession following the 1930s great depression. Notwithstanding, this study was restricted to unemployment and stock market with no mention of inflation or other key macroeconomic variables. Moreover, the empirical findings were limited to America, and thereby, not necessarily applicable to Nigeria.

Also, Farmer (2012) had shown that alterations in stock market wealth could likewise emanate in different unemployment rate. Since a change in household wealth could engender variations in quantity of aggregate demand which then makes labour to be hired (or retrenched) in order tomeet increase (or decrease) production levels to match effective demand. Evidence of the link between stock market wealth and unemployment was extensively discussed in Sibande, Gupta, and Wohar (2018). The paper cited numerous examples where empirical literature provided proof that growth in stock market capitalization is typically accompanied by growth in employment rate in America and in Europe.

Formerly termed 'shoe-leather' costs, illustrating further treks to banks, could be more recently called 'banking-transaction' costs. Such journey to banks will be unnecessary when inflation does not exist, hence depicting an expense forced by it (Ashraf, Gershman & Howitt, 2016). Secondly, inflation adversely redistributes wealth from creditors to debtors (Auclert, 2019). If greater prices are unforeseen, borrowers would repay nominal debts in real dollars which are subsequently less valuable. Unpredicted inflation lessens debtors' weight and endangers lenders. It may be argued that this is not necessarily an inflationary cost since it is transferable rather than a net loss. Nonetheless, continual price hike (especially with varying and erratic rates) might make lenders minimise total credit volume supplied, hence depicting real loss compared to monetary balance in a nation (Haberler, 2017).

Thirdly, inflation compels sellers to incur extra inputs to survive rapidly fluctuating prices. These 'menu costs' will alter directly with adaptations in inflation. Quicker increases in prices will force merchants to rapidly modify price levels. Duration used to recount inventories, or re-configurate computers, shows problems imposed by inflation. It is important to recognise that such consequences still prevail even with impeccably foreseen inflation. Rectifying prices immediately from past equilibrium numbers to post-inflation values yet incorporates resource expenditures (Shimer, 2017; Janssen, 2016). All three issues all link to evolution in overall price

The fourth trouble involves mannerism by which alterations in prices may influence dispersal of comparative prices economically. Perhaps inflation just affects nominal prices, and leaves relative prices untouched; all identified costs would still apply. But if it goes beyond to impact relative price levels, then, resources would be misappropriated as some comparative prices will shift from equilibrium point (Nakamura, Steinsson, Sun &Villar, 2018). An avenue of differentiation is that the initial three consequences may merely place a country at a fresh steady state with less general welfare. Whereas, the last challenge could result in total displacement from equilibrium aside aggregate welfare forfeiture.

Theoretical Framework

The observed counter cyclical relationship between stock prices and inflation could be based on Tversky and Kahneman's recency bias theory (1974) which is greatly essential in understanding the household behaviour in financial markets. The recency bias theory postulates that high probabilities are assigned to events that have occurred recently, such that, when stock prices go up, investors tend to believe that it will continually increase for a prolonged time period and vice versa. When investors put more resources in the stock market to reap greater rewards, there are fewer funds available for consumer spending, hence, lower inflation. Likewise, when stock prices are declining, recency bias makes investors to think that such decline would prevail for an extended duration, thereby causing them to typically oversell their shares. This would lead to more funds available at hand, which then increases is spending on discretionary products that in turn trigger demand pull inflation.

The summary of the theory is that more funds in the stock market for investment purposes would lead to low inflation (since it is assumed that there would be less funds flowing in the economy) while less funds would lead to high inflation (since it is assumed that there would be more funds flowing in the economy). This shows the relationship between stock market and inflation based on the theory.

Gaps in Literature

The study observed that although many literatures relied upon quantity theory of money in designing a theoretical framework, many of the studies including the local ones designed empirical models that omitted the arguments of Friedman (1989) that it is not the growth in money supply in itself that is bad for inflation, rather, it is surplus growth in money supply over and beyond growth in real output that causes inflation. This means that money supply, credit or even market capitalization cannot be taken as nominal variables in explaining inflation, rather it is the ratios of the money supply to gross domestic product and similar other variables that may be more useful in predicting future inflation.

Also, the study found that while most of the empirical works in literature showed that money supply can be effectively used to forecast variations in inflation. Very few empirical works have gone beyond developing models to show that stock prices could be useful in forecasting future inflation. Mostly, these literatures speak about a theoretical connection of how asset prices could impact inflation, but many failed to test this theory empirically. This study will build a VAR model to show the predictive strength of stock market capitalization as a useful economic variable in forecasting inflation. The models would be useful in building an improved monetary policy framework that achieves better results in inflation targeting in Nigeria and in other developing world economies.

Methodology

This study adopts the monetary transmission mechanism framework proposed by Olufisayo (2013) wherein inflation could be determined by variations in monetary variables such as money supply, credit, interest rates, exchange rates and asset prices. Theoretically, movement in inflation is stimulated through the monetary transmission channel, as changes in any of the monetary variables holding others constant can lead to variations in inflation. However, economists differ in the weight or importance placed on any of the monetary variable to independently explain changes in inflation as their influence on inflation tends to evolve over time and differ among countries.

According to Olufisayo (2013), the monetary transmission mechanism is the process through which monetary policy decisions are transmitted into changes in inflation and real GDP over time. For the purpose of this empirical analysis, the influence of monetary policy decisions that leads to changes in inflation will be the core focus as we seek to determine the extent to which variation in asset prices (particularly, stock prices) is useful in predicting changes in inflation over time in Nigeria. The study expects that including stock prices into the econometric model will help explain changes in inflation not only from a money market perspective which focusses heavily on changes in money supply but also from a capital market perspective which includes performance of the capital market which impacts on the investment income of households.

Model Specification

The model stated below is specified based on framework for monetary policy transmission mechanism as stated in Taylor (1995). However, the model introduces a modified version of Taylor (1995) which adapts the inclusion of Asab and Al-Tarawneh (2020) in representation of stock prices evolution over time as stock market capitalization to GDP which analyses the excess of the growth in value of equities over and above the expansion in gross domestic product (GDP). Therefore, the restated explicit model is as follows:

$$\text{CPI}t = \beta_0 + \beta_1 \text{ MCAP/GDP}t + \mu t \quad \ldots\ldots (3)$$

Where: CPI represents the consumer price index or inflation; MCAP/GDP represents the stock market capitalization to GDP; β_0 represents constant or intercept term, β_1 represents regression coefficients or slope; μtrepresents the error term or residual.

CPI: The consumer price index (CPI) is considered as the rate of inflation in this study. The adoption of the CPI is necessary since it is the rate of inflation that tracks changes in the general prices of consumer goods and services to which households make their economic and financial decisions. The monetary policy in Nigeria is targeted at controlling the rise in CPI to ensure price stability in the country and encourage rapid economic growth. While there are other measures for inflation, the CPI or headline inflation are the main rates of inflation that is tracked by the monetary authorities, economists, analysts, businesses and households for financial decision making. Changes in CPI will typical draw some form of monetary policy response much more than any other inflation metric in Nigeria.

MCAP/GDP: A significant portion of the wealth of households in the country is invested in the capital market to earn investors some investment income to cover future household spending. However, behavioural economics show that households spending behaviour is altered from the traditional Keynesian theory of income as households typically invest during period of rallying stock prices and sell during periods of declining stock prices such that they are unable to increase consumption due to wealth earned from the rallying market since they continued to invest funds during that period. Typically, when stock prices decline, they sell their securities and will typical increases purchases in consumer goods rather than financial assets during periods of significant stock price declines. In Nigeria, the total market capitalization accounts for more than 50 percent of the total money supply (Omolade & Ngalawa, 2016). If money supply is to be considered critical to predict variations in interest rate, the size of households' wealth in the stock market could also provide inflation guidance since households can easily sell stocks to increase their income during periods when they choose to consume more and invest more of their labour income in the stock market during periods when they chose to save more and consume less. This investment behaviour has implications for consumer price inflation and must therefore be assessed as a possible statistically significant predictor of inflation. However, the study will use proportion of the market capitalization to gross domestic product to measure the influence of the market on inflation like the analysis done for money supply since both serve similar purposes as a store of wealth for households. To which if the size of market capitalization to total output changes in the economy, it could have serious implications for inflation expectation for Central Banks and households.

Technique of Estimation

Hodrick Prescott Filter and Contemporaneous Correlation Test

The HP filter is a univariate detrending technique used to determine the cyclical characteristics of a macroeconomic indicator. According to Laubach and Williams (2016), the HP filter can be used to ascertain the interest rate gap by determining the natural rate of interest based on the cyclical trends of MRI. This process begins by taking the unit root test to ascertain stationarity of monetary variable. This is followed up by utilising HP filter is used to obtain cyclical component from trend component of time series data. Cyclical component is then studied to determine frequency of cycles, the length of cycles and to examine that rarity of unusual deviation of the variable from its trend during periods. If the cyclical component of the interest rate moves above or below its trend, we can assume that the difference is the interest rate gap.

Data and Variable sources

The variables for this study include: consumer price index (CPI) and money supply to real gross domestic product (M2/GDP). The time series data which are secondary in nature covers the period from 1985-2017. The secondary dataset were gathered from the Central Bank of Nigeria statistical bulletin and the Nigerian Bureau of Statistics Annual Statistical Report.

Findings

Pattern of Inflation in Nigeria

We observed from Figure 1 above that inflation has been trending downwards over the years. Average inflation between 1985 and 2018 was 19.7 percent. Inflation peaked at 76.8 percent in 1994 and hit a record low of 0.2 percent in 1999. Based on findings, inflation was below trend between 1985 and 1987, averaging 8.1 percent before rising significantly above trend between 1988 and 1989 during which the average inflation was 52.9 percent. By 1990, the dip in inflation to around 3.6 percent put inflation below trend. In the years between 1992 and 1995, inflation was back once again above trend, averaging 59.6 percent. Between 1996 and 2002, inflation remained below trend, averaging 11.4 percent inflation rate as inflation management improved in the country. The years between 1985 and 2002 were the most volatile inflation periods in Nigerian history as average inflation was 26.4 percent compared to average inflation of just 12.1 percent between 2003 and 2018. Since 2008, inflation movement has closely followed its trend although it stayed slightly above between 2016 and 2018 as a spike in exchange rate in 2016 caused inflation to jump to its highest level in 13 years.

Figure 1: Consumer Price Index (CPI) Pattern in Nigeria

In the years before year 2000, average inflation in Nigeria was 28.8 percent compared to 12.5 percent between year 2000 and 2018. The lowest rate of inflation in before year 2000 was 0.2 percent in 1999, compared to the years after 2000 when the lowest rate of inflation on record is 6.6 percent achieved in 2007. Highest rate of inflation in a single year before the turn of the millennium was 76.8 percent in 1994 compared to 23.8 percent in 2003. Generally, inflation management has improved in the country, inflation continues to trend downwards after its volatile years in the 1990s but with inflation rate still above the single digit target in post 2000 years, it is necessary to understand the factors that led to a downward trend in inflation in order to increase attention to those economic variables to ensure that the achievement of price stability in Nigeria becomes a reality.

When the researcher tracked inflation performance on an annual basis, it was rather easy to establish that inflation in Nigeria has been a persistent problem and price stability in the country which the researcher defined as inflation within

the 0-2 percent band was only achieved in twice throughout the 33-year period, the periods were 1985 and 1999. In 1985, inflation was just 1 percent before the introduction of the failed Structural Adjustment Programme (SAP) in Nigeria, which was a World Bank backed market reform that allowed the Central Bank of Nigeria to move from a system of fixed interest rate and exchange rate to a more market determined interest rate and exchange rate market. Poor implementation of SAP under the military rule caused inflation to spiral out of control as prices rose sharply due to exchange rate induced inflation at the time.

The following year in 1986, inflation rose to 13.7 percent before reducing to 9.7 percent. SAP's target for inflation was an average of 9 percent and it looked like SAP was working at the time. But the initial disinflation didn't last long as series of devaluation and rising interest rate began to have an impact on the inflation rate in the country. By 1987, inflation rate had reached a then record of 61.2 percent before reducing to 44.7 percent the following year. 1990 seemed like the odd year in the decade between 1986 and 1996 as this was the only year inflation fell to single digit. In 1990, a short-lived macroeconomic stability helped suppress inflation to just 3.6 percent, its lowest level since 1985. However, the following year, inflation jumped once again to 23 percent before doubling to 48.8 percent in 1992. For the third consecutive year, inflation rose again, reaching a new record of 61.3 percent. Nigerians had begun to lose confidence in the Naira and there was a wide scavenge to hold foreign currency to preserve household wealth even though holding foreign currency in the country was considered illegal at the time.

By 1994, CBN had decided to temporarily move back to a fixed exchange rate and interest rate system as inflation rate had completely moved out of hand, reaching a new high of 76.8 percent in 1994. Till date, 76.8 percent remains the highest rate of inflation experienced in the country. By 1994, SAP was already considered a failure as it failed to bring inflation under control to its target of 9 percent. Average inflation rate between 1986 and 1994 was 38.1 percent. In the 9-year period between 1985 and 1994, inflation had moved from just 1 percent to 76.8 percent, showing that there was a deep price instability crisis in Nigeria. The move to fixed interest rate brought about instant reward, inflation began to trend downwards almost immediately. In 1995, inflation dropped to 51.6 percent and by 1996, inflation had reduced to 14.3 percent. CBN became more confident that the economy was now much ready to receive a flexible interest rate but held exchange rate fixed until 1998.

In 1997, inflation had dropped further to 10.2 percent, showing that the Central Bank had made the right decision. With oil prices now rising through the 1990s, government finances had become more stable and macroeconomic stability was restored in the economy. In 1998, inflation rose modestly to 11.9 percent. 1999 was a year not just for the move to democratic rule in Nigeria but the year when the country experienced its biggest exchange rate devaluation in history. However, inflation rate fell to its lowest on record, Nigeria experienced 0.2 percent inflation in 1999, and for the first-time prices were perfectly stable over a one-year period. This spelt the end of the worst period of inflationary pressure in the country's history as inflation which average 35.9 percent between 1985 and 1995 was gone for good. Since 1995, inflation in Nigeria has not exceeded 23.8 percent, showing that inflation management in the country has improved since its worst period in the early 1990s but since the turn of the millennium, the Central Bank has still not been able to achieve price stability as inflation has failed to fall under the 2 percent price stability benchmark since 1999.

The lowest rate of inflation in the country since year 2000 was achieved in 2007 when inflation fell to 6.6 percent during the mature stage of Nigeria's first economic bubble which burst the following year. Average inflation in Nigeria between 2000 and 2018 was 12.5 percent, above the Central Bank's single digit target and a long shot away from the price stability benchmark of 2 percent.

Contemporaneous Cross Correlation Test

To achieve study's objective which is to examine the short run relationship between stock prices cycles and inflation, this study employed the contemporaneous correlation test. The Market capitalization (MCAP) is used to represent stock price while Inflation rate is represented by the Consumer Price Index (CPI). To address the objective, the business cycle approach used to separate the time series data into cycles and trends. This is achieved by employing a filtering procedure referred to as the Hodrick-Prescott (HP) (Alege et al., 2017; Agenor et al., 2000; and Kim et al., 2003). The process involved in carrying out this technique is as follows: The series will be transformed into their natural logarithm form; the stationary properties of the series will be tested; detrending the series by obtaining the cyclical element; obtaining the autocorrelation statistics and also the cross correlation of the series (Alege, 2008). A good business cycle filter is one that can eliminate unit roots, remove phase shift and also isolate business cycle frequencies (Baxter and King, 1999).

The HP filter is useful as it helps to account for volatility in the time series variables. Secondly, it can measure whether there is a change in the variable before or after the output changes and finally, the cross-correlation coefficient measures the contemporaneous correlation of a series with respect to another. This will ascertain if a series is pro-cyclical or countercyclical. Table 1 presents the contemporaneous correlation between stock market and Inflation. The results show that the degree of contemporaneous correlation between inflation and stock market is −0.0305 indicating a countercyclical relationship. This implies that inflation tends to rise when stock prices are falling and inflation falls when stock prices are rising. The cyclical patterns of stock market capitalisation ratio and inflation are shown in figure 1 and 2.

The cross correlation test can show which variable leads of lags the cycle. Therefore, it can reveal whether stock price is a leading or lagging indicator to inflation rate. When the maximum value of the cross correlation coefficient between stock price and inflation falls on the left hand side (lag), it means that stock price is the lagging indicator. On the other hand, if the maximum value of the cross correlation coefficient between stock price and inflation falls on the right hand side (lead), it means that stock price is the leading indicator. From table 1, the maximum cross correlation coefficient is 0.3723 suggesting that inflation lags stock prices. This means that changes in inflation rate happen after changes or fluctuations in stock prices.

Table 1: Contemporaneous correlation between Stock Market Capitalization and Inflation

CPI_CY, M2, MCAPCY(-i)	CPI_CY, M2, MCAPCY(+i)	i	lag	lead
. | . |	. | . |	0	-0.0305	-0.0305

.**| . |	. |**. |	4	-0.1845	0.1788

Figure2: Cyclical Pattern of Stock Market Capitalisation

Figure 3: Cyclical Pattern of Consumer Price Index in Nigeria

Empirically, this relationship between stock prices and inflation is evident in the past behavior of inflation and stock prices. For instance, in 2007, inflation had fallen to about 6.6 percent its lowest point in almost a decade which corresponds with when stock prices were most elevated in Nigeria. Rising stock prices had pushed market capitalization to GDP to about 30.9 percent which is the highest value of market capitalization to GDP ever recorded in the history of Nigeria.This shows that higher stock prices led people to invest more in the stock market, which eventually reduced inflation. This result was confirmed by the study of Albulescu, Aubin and Goyeau (2017), Marx and Struweg (2015) and Fama (1981) where a countercyclical relationship was observed between Stock prices and Inflation rate.

Discussion of Result

The cross-correlation coefficient measures the contemporaneous correlation of a series with respect to another. This will ascertain if a series is pro-cyclical or countercyclical. The first objective of the study is to examine the cyclical relationship between stock prices and inflation. From the result shown in Table 1, it was observed that inflation tends to rise when stock prices are falling and inflation falls when stock prices are rising. A major explanation for the result is that investors would want to take advantage of rising stock prices to invest in the stock market and this would reduce inflation because any excess money in circulation will be used to increase investment positions rather than to increase consumption. However, when stock prices decline, most investors would quickly sell-off their securities and hold on to cash rather than invest. This could increase the money in circulation and result in higher inflation. This behaviour is consistent with Keynesian Liquidity preference where Keynes states that “the rate of interest at any time, being the reward for parting with liquidity, is measure of the unwillingness of those who possess money to part with their liquid control over it... It is the “price” which equilibrates the desire to hold wealth in the form of cash with the available quantity of cash (Bibow, 2005). Therefore, if the expected future return on investment is less than households’ desire, they will retreat to cash which could cause a problem of excess cash holdings and increased spending.

Summary

From the result of the contemporaneous correlation, the result provided evidence that there is a countercyclical relationship between stock prices and inflation rate. This implies that inflation tends to rise when stock prices are falling, and inflation falls when stock prices are rising. This therefore shows that stock prices is useful in forecasting inflation and market capitalization should be included in critical variables used in evaluating and forecasting inflation to achieve price stability.

Recommendation

1. The study, hence, recommends that policies that extend the stock market cycles should be adopted as it has been proven to reduce the inflation rate significantly.

2. Investments in stock market should be encouraged by the government to the public as a way of reducing inflation.

3. More investment instruments should be introduced into the stock market so as to generate more investments.

Contributions to Knowledge

1. The study contributes to the theoretical framework by confirming the recency bias theory that explains that when stock prices go up, investors tend to believe that it will continually increase for a prolonged time period and vice versa.

2. The study also adds to existing literature by using the Hodrick Prescott Filter and Contemporaneous Correlation Test to confirm the theoretical framework.

Study Limitations

1. The study used a single model, other researchers can add other macroeconomic variables like exchange rate and interest rate to see if stock prices cycle can be used to predict them.

Abstract

The aim of the article is to discuss the importance of well-being in the lives of women entrepreneurs. The authors attempt to define the concept of well-being and review the results of previous research into the subject in the context of the development of female entrepreneurship in Poland and around the world. The empirical part presents the results of original research carried out at the beginning of 2020. The categories of the quality of life of young female students correspond to the OECD classification, and the authors sought to link them to entrepreneurial intentions. The study should be classified as a case study. In the auditorium survey, the respondents were asked to react to certain statements and reveal their subjective feelings about the quality of life and plans related to running a business in the future. The results of the conducted research prove that students with active entrepreneurial intentions assess the material and psychological aspects of well-being higher than the rest of the students, such aspects including their health, skills and professional competences. According to the authors, knowledge of the factors determining mental well-being is the basis for shaping entrepreneurial attitudes of young people and enables their professional activation. It is therefore useful for laying the foundations of an educational policy conducive to socio-economic development in a modern economy.

Keywords: Well-Being, Quality of Life, Women Entrepreneurs, Female Entrepreneurship

Welfare, Well-Being and Quality of Life

Welfare is a universally recognized goal in the development of societies and individuals. It is directly related to the high level of a country's socio-economic development. In research on the quality of life, this concept refers to living conditions and is considered in relation to the functioning of the economic system (Walaszek, 2017). The term "welfare state" is also used to mean that the most important task of the state authority should be to ensure the economic and social welfare of citizens in accordance with the principles of equitable distribution of wealth and equal opportunities. The "welfare state" assumes responsibility for providing its citizens with a basic, modest standard of living (Esping-Andersen 2010).

The concepts of welfare and mental well-being are not the same, the former denoting the level of affluence and wealth, and the latter the non-material conditions of a good life, such as happiness. However, more and more often, the sense of socio-economic security or lifestyle is included in the scope of individual welfare (Zaremba 2016). Therefore, the concept of mental well-being can be distinguished from the broader concept of welfare.

"Well-being" as a mental state is the effect of cognitive and emotional assessment of one's own life that leads to a strong feeling of fulfillment and satisfaction. It is a feeling resulting from self-realization, a positive appraisal of one's own life and a low level of stress (Niśkiewicz, 2016). Individuals are in a state of mental well-being when positive experiences and pleasant emotions prevail in the environment, outweighing negative experiences and moods (Kasperek-Golimowska 2012, p. 183).

Mental well-being is characterized by variability in the individual's life cycle. People who experience it are more effective in their activities and can use the available environmental resources better (Myers 2000, after: Jach 2013).

Cite this Article as: Paulina SIEMIENIAK and Malgorzata REMBIASZ " Well-Being as A Factor Influencing Women's Decision to Start A Business " Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Mental well-being can be described in six categories: self-acceptance, personal development, having a purpose in life, controlling the environment, autonomy, and positive relations with others (Cieślińska 2013, p. 102).

Welfare is described in OECD countries and other large economies based on the survey of eleven dimensions of people's quality of life. They are: income and wealth; place of work and earnings; living conditions; health; work-life balance; education and skills; social contacts; civic engagement; environmental quality; personal security; and subjective well-being. According to the authors of an OECD report, these dimensions create the so-called "well-being". Since the publication of the first OECD study in 2011, it has become increasingly important to measure well-being around the world, and to publicly debate what matters to citizens (http://www.oecd.org/sdd/OECD-Better-Life-Initiative.pdf).

J. Czapiński equates quality of life with well-being or happiness. Interestingly, the quality of life is measured using both objective criteria (living conditions) and subjective criteria (social, material, environmental, health-related). The subjective dimension has to do with the evaluation of one's own life (Wnuk, 2013).

An important element of the quality of life is the quality of working life. M. Porter points out that the factors that influence the quality of work may refer to (Efrata, Sirgy, 1990):

- characteristics specific to the individual (e.g. attitudes and needs)
- essence of work (internal rewards, level of autonomy, degree of differentiation of activities)
- work environment (e.g. readiness to achieve goals, the ability to transform knowledge, abilities and skills).

The literature on the subject also mentions the concept of employee well-being. In research on this phenomenon, it is assumed that good management may consist in reconciling the imperative of organizational productivity with increasing employee well-being while maintaining the strategic perspective of the organization. Increasing well-being at work brings benefits for both employees and the employer (Kozioł, Wojtowicz, 2016).

It should be stated that the quality or standard of living is an ambiguous concept that can be treated in an objective or subjective way. In the former case, we are dealing with the quality of life itself, and in the latter – with the sense of the quality of life (Kasprzyk, 2012)

Moreover, many studies show that there are differences between women and men in their subjective assessment of well-being when it comes to its types and components. They result from many biological, individual and environmental factors, such as country-specific social norms that determine the accepted characteristics and behaviors assigned to different genders (Batz, & Tay, 2018).

The specificity of female entrepreneurship in the context of the quality of life

According to the research, every third enterprise in the world is run by women (OECD 2017). Such companies are usually distinguished by the following features: they are micro-enterprises, they have a low level of capitalization, and they are slow to expand into foreign markets (Siemieniak, Łuczka, 2016). The development of enterprises run by women is somewhat limited, which may result from the negative attitude towards taking the role of business owners by women.

Social conditions and stereotypes of gender roles make women assimilate a special hierarchy of values, i.e. they spend less time in the company or choose service activities that can be managed from home (Zięba, 2010). Women’s entrepreneurship, understood as the tendency to start their own business, is restricted not only by the belief that they are poorly prepared to set up companies. The growth of an enterprise depends on the ability to balance the requirements of professional and family life, including, in particular, the role of a mother (Siemieniak, Łuczka, 2016).

The importance of entrepreneurship for women’s quality of life is not clear. On the one hand, PARP research shows that it is easier to make the decision to start a business when one does not yet have family responsibilities, due to the difficulty of engaging in both these roles at the same time. On the other hand, some studies show that the necessity to cope with family responsibilities may stimulate the decision to set up one's own business (Siemieniak,

Łuczka, 2016). Such an approach may result from associating self-employment with better earnings and flexible working hours.

Meeting the need for safety as a basis for the well-being of female entrepreneurs

The success of entrepreneurial activity is most often measured by economic indicators and equated with the development of the enterprise, which is evidenced by the expansion of its area of activity, the sales market or the number of customers. However, in the case of entrepreneurial activities undertaken by women, success also depends on significant subjective factors, such as work satisfaction, achievement of aspirations (motivation) and satisfaction with personal life (life satisfaction) (Denkiewicz-Kuczewska, 2012).

It is worth noting that the subjective factors associated with running one's own business also involve a diminished sense of safety compared: to being employed. Entrepreneurs are forced to constantly confront uncertainty due to the changing market situation and competition. The sense of security is of particular importance for self-employed women, who, for a long period of their lives, bear the responsibility resulting from their role as mothers (Siemieniak, Rembiasz, 2017). The sense of safety means a subjective assessment of the level of acceptable risk (Klamut, 2012). When running one's own business, risk factors should be identified and, above all, controlled at each management level (Stańczak, 2014). In order to feel in control, people are forced to constantly assess the level of threats, knowledge gaps and ambiguity (Sadłowska - Wrzesińska, et al., 2016). An individual lives in conditions of constant uncertainty, i.e. a mismatch between the knowledge required and the knowledge available to make a decision (Stańczak 2014).

Despite being exposed to uncertainty, entrepreneurs experience a higher level of job satisfaction and quality of life. It is believed that the factor that determines their well-being is a sense of autonomy and control expressed by the flexibility in assigning tasks as well as the time and methods of their implementation (Siemieniak, Rembiasz, 2018). Flexible working time is defined as: adaptable duration of work, shortened working week, flexible starting and ending hours (Gerlach, 2014). Control over the organization of work may give a sense of work comfort, because it allows for a better adjustment of professional and private activity (Siemieniak, Rembiasz, 2018). Empirical research shows that entrepreneurs can strike a better work-life balance than non-entrepreneurs. Moreover, those entrepreneurs who were motivated by the emergence of an opportunity achieve not only balance but also satisfaction (Zbierowski, 2016).

The research results show that entrepreneurial women differ significantly in their sense of social well-being from women not engaged in entrepreneurial activity, experiencing a sense of acceptance and realization in society, improvement of their relations with the environment and autonomy in decision making. Therefore, running one's own business has a clear impact on increasing the sense of social well-being. In addition, the fact of running a business increases mental well-being and work satisfaction. At the same time, it can be assumed that people who are more satisfied with their lives have greater self-confidence and it is easier for them to take on the challenges of self-employment. It can therefore be concluded that female entrepreneurs differ from other women in terms of their personality characteristics (Denkiewicz-Kuczewska, 2012).

Needs of female entrepreneurs that determine well-being - review of the results of own research

In some concepts, the quality of life in general, including the quality of professional life, is equated with the satisfaction of needs (Pate, 1988). Determining the needs and the degree of their satisfaction in women running their own business is an important factor affecting entrepreneurship development.

Therefore, the aim of the undertaken research was to identify the needs related to running one's own enterprise (actually or potentially). The research carried out in 2013/14 involved a representative group of business owners from the SME sector in the Wielkopolska region and a group of students in economics. In total, 384 women-owners and 181 female students were included in the research, and the groups of respondents were created on the basis of quota selection. The actual state was compared with the imagined state by juxtaposing the needs declared by the current owners of enterprises with the needs of female students, i.e. a group of potential entrepreneurs. It is worth mentioning that more than half (56%) of current female entrepreneurs believe that they have achieved success in

life, which can be considered a significant indicator of well-being. Moreover, students who intend to run their own business are motivated mainly by a desire for decent earnings (40%), while business owners cite a desire to use their knowledge and skills (studied profession) (33.6%), and, in a similar proportion, independence (31.3 % of responses). Most of the obtained results reveal a positive motivation, i.e. women are pulled rather then pushed towards enterpreunership. This leads to conclusions about respondents' welfare, which is in line with the economic development indicators for Wielkopolska, a region considered to be one of the most economically developed in Poland (Siemieniak, Łuczka, 2016).

The table below presents the five most frequently reported factors necessary for the effective running of an enterprise (Table 1). The assessments of female business owners are similar to those of female students who are potential entrepreneurs. Both groups selected the same five top needs out of the thirteen suggested. In the opinion of the owners, the possibility of working flexible and variable hours is ranked second, right after the need for financial support.

Table 1: Factors necessary to run a business - in the opinion of women

The most frequently cited needs:	Current entrepreneurs - women (%) *	Potential entrepreneurs - women (%) *
Financial suport	17.6	20.9
Flexible working hours	13.3	12.8
Comprehensive economic and legal services (relief from bureaucracy)	12.3	13.2
Advice on various problems related to running a business	9.7	12.8
Training	8.9	8.5

** The respondents gave more than one answer. Responses add up to 100% for all 13 factors. Source: own research, based on Siemieniak, Łuczka, 2016, p. 85*

The obtained results can be applied both to the mental well-being of women and the broadly-defined welfare of entrepreneurs. Running one's own business on the one hand provides the basic source of income or additional income that improves the financial situation of the family, and on the other, contributes to women's sense of self-fulfillment and influence whilst confirming their potential.

The conclusions were extended with the results of another study in 2017 (Siemieniak, Rembiasz 2018). These focused on the diagnosis of entrepreneurial attitudes in the context of balancing the requirements of personal and professional life of potential entrepreneurs. The author used her original auditorium survey method to carry out research among 160 students of economic faculties of Wielkopolska universities. Two thirds of the respondents were women. The study revealed the importance of factors necessary for the so-called work-life balance, one of the premises of the mental well-being of working people, including those who are self-employed. The most important factor for the respondents was flexible working time, followed by: home work, being relieved from some of the household / caring responsibilities, the possibility of relaxing at any time of the day and part-time work (Siemieniak, Rembiasz 2018).

Results of research on the quality of life of female students as potential entrepreneurs

The study was conducted in January 2020 and aimed at determining the relationship between the quality of life of students and their entrepreneurial intentions (plans for self-employment). It involved a group of students of management at one of Polish non-public universities, and the research tool was an auditorium survey. The respondents were asked to react to the statements specified in the questionnaire and reveal their subjective feelings about the quality of their lives. The authors of the study are aware of the limitations of survey research. The result could have been influenced by the place (lecture hall) and the respondents' guesses about the results expected by the authors of the research.

This article presents some of the research results, that is those that were obtained for a homogeneous group of 130 young female students aged 21-28. The university where the research was carried out offers the possibility of combining education with work and personal life. The idea is therefore to keep the work-life balance – one of the

factors that determine mental well-being. The table below presents the results concerning the entrepreneurial intentions of the surveyed female students and their involvement in professional work.

Table 2: Responses to the question: "Are you interested in running your own business?"

Answers:	Percentage of responses (%)
Yes	40.8
I run my own business	1.5
No	23.1
I don't know	34.6%

Source: own research

The table above shows that a relatively large group of respondents, as many as 40.8%, is interested in running their own business. Only two students were already self-employed, which is due to the young age of the respondents. A fairly high percentage of active entrepreneurial intentions should be explained by the studied field of business management, which the surveyed young women had chosen consciously. Moreover, 95% of the respondents worked for profit. The authors of the research assumed that students with active entrepreneurial intentions assess their quality of life in more positive terms, achieving a higher level of well-being than people who do not plan to run their own business or do not know yet whether they want to start such an activity.

The results of the study focused on selected areas of well-being according to the previously mentioned OECD classification are presented below. Table 3a presents the results concerning income and wealth, place of work, living conditions and health of students who want to run their own business or already run one. Table 3b contains the answers of female respondents who do not plan to start a company, while Table 3c applies to women who do not know whether they want to start their own business.

Table 3a: Selected material and health aspects of well-being of female respondents with active entrepreneurial intentions

Questions	percentage of responses (%)				
	I strongly disagree	I tend to disagree	Hard to say	I tend to agree	I strongly agree
I am satisfied with what I have	3.6	29.1	20	41.8	5.5
I am satisfied with housing conditions	1.80	3.6	10.9	41.8	43.6
I am satisfied with my health	1.8	9.1	10.9	41.8	36.3

Source: own research

Table 3b: Selected material and health aspects of well-being of respondents not planning to start a business

Questions	percentage of responses (%)				
	I strongly disagree	I tend to disagree	Hard to say	I tend to agree	I strongly agree
I am satisfied with what I have	0.0	16.7	23.3	56.7	3.3
I am satisfied with housing conditions	3.3	10.0	30.0	50.0	6.7
I am satisfied with my health	6.7	26.6	20.0	40.0	6.9

Source: own research.

Table 3c: Selected material and health aspects of well-being of the respondents who do not know whether they want to become entrepreneurs

Questions	percentage of responses (%)				
	I strongly disagree	I tend to disagree	Hard to say	I tend to agree	I strongly agree
I am satisfied with what I have	4.4	17.8	33.3	37.8	6.7
I'm satisfied with housing conditions	4.4	20.0	8.9	35.6	31.1
I am satisfied with my health	11.1	13.3	17.8	40.0	17.8

Source: own research.

Comparing the results from the above three tables, the following conclusions can be drawn: personal wealth achieved highest scores among students who do not intend to run their own business. This may be due to the fact that, if they are in a good financial situation and earn attractive salaries, young people do not want to give up their full-time job in order to run a business which is risky. The table also shows that future potential entrepreneurs are less satisfied with their assets. Therefore, the motives for starting a business in this group include the desire to achieve higher income than in the case of contract work. It is important to bear in mind that the presented empirical research did not reveal the actual wealth status of the respondents, but only their subjective assessment of it. Both groups could therefore be very similar in terms of their wealth and income expressed in money, but students with active entrepreneurial intentions might set themselves higher goals in this respect. On the other hand, for the second group, lower income was considered sufficient.

Moreover, people who are the least satisfied with their housing conditions belong to the group that does not plan to start a business. Here, too, a large proportion of the respondents replied: "It's hard to say." This may be due to the fact that, in Poland, the predominant means of buying one's own apartment is a bank loan and, to obtain a housing loan, entrepreneurs must meet more stringent requirements than in the case of contract work. If a business is the only source of income, banks require the submission of net income statements for the last twelve months or even up to two years. Therefore, banks may refuse to grant a loan due to the uncertain situation of a company that has operated for a short time. In addition, entrepreneurs must prove the amount of income required to be considered credit worthy *(https://www.totalmoney.pl/artykuly/71836,kredyty-dla-firm,kredyt-hipoteczny-a-dzialalnosc-gospodarcza-2020---jaka-mam-zdolnosc-kredytowa-przy-oło-firmy,1)*

When it comes to health, it was rated highest by people planning to establish an enterprise.
The following tables present the assessment of elements related to psychological well-being, such as work-life balance, social contacts and subjective well-being.

Table 4a. Selected psychological aspects of well-being of female respondents with active entrepreneurial intentions

Questions	percentage of responses (%)				
	I strongly disagree	I tend to disagree	Hard to say	I tend to agree	I strongly agree
I have a purpose in life	0.0	0.0	0.0	18.2	81.8
I am satisfied with the level of my personal development	0.0	0.0	3.6	65.5	30.9
I feel independent	0.0	0.0	3.6	45.5	50.9
I am satisfied with my relationships with other people	0.0	1.8	7.3	50.9	40.0

Source: own research.

Table 4b: Selected psychological aspects of well-being of the respondents who do not plan to start a business

Questions`	percentage of responses (%)				
	I strongly disagree	I tend to disagree	Hard to say	I tend to agree	I strongly agree
I have a purpose in life	0.0	6.7	16.7	53.3	23.3
I am satisfied with the level of my personal development	3.3	13.7	33.3	46.7	3.3
I feel independent	0.0	20.0	26.7	26.7	26.7
I am satisfied with my relationships with other people	3.3	16.7	16.7	43.3	20.0

Source: own research.

Table 4c: Selected psychological aspects of well-being of the respondents who do not know whether they want to start their own business

Questions	percentage of responses (%)				
	I strongly disagree	I tend to disagree	Hard to say	I tend to agree	I strongly agree
I have a purpose in life	0.0	0.0	26.7	35.5	37.8
I am satisfied with the level of my personal development	0.0	8.9	35.5	44.4	11.2
I feel independent	0.0	8.9	11.1	40.0	40.0
I am satisfied with my relationships with other people	2.2	13.3	8.9	42.2	33.4

Source: own research.

Self-esteem regarding a clear goal in life, the assessment of one's own personal development and the feeling of being independent and satisfied with relationships with other people scored highest, on average, in students who plan to become or are currently entrepreneurs, and lowest in those who do not want to start their own business. This means that, in the surveyed group of women, the sense of mental well-being increases the likelihood to become an entrepreneur.

The last set of three tables deals with education and skills as important components of well-being.

Table 5a: Selected aspects of well-being related to education and skills of respondents with active entrepreneurial intentions

Questions	**percentage of responses (%)**				
	I strongly disagree	**I tend to disagree**	**Hard to say**	**I tend to agree**	**I strongly agree**
I am satisfied with the field of study I am studying	0.0	2.2	8.9	65.5	23.4
I am satisfied with the level of my abilities	0.0	0.0	5.5	67.3	27.2
I am satisfied with my professional skills	0.0	1.8	0.0	70.9	27.3

Source: own research.

Table 5b: Selected aspects of well-being related to education and skills of respondents who do not plan to start a business

Questions	percentage of responses (%)				
	I strongly disagree	I tend to disagree	Hard to say	I tend to agree	I strongly agree
I am satisfied with the field of study I am studying	0.0	23.3	53.4	23.3	0.0
I am satisfied with the level of my abilities	0.0	6.7	43.3	43.3	6.7
I am satisfied with my professional skills	0.0	13.3	36.7	50.0	0.0

Source: own research.

Table 5c: Selected aspects of well-being related to education and skills of respondents who do not know whether they want to become entrepreneurs

Questions	percentage of responses (%)				
	I strongly disagree	I tend to disagree	Hard to say	I tend to agree	I strongly agree
I am satisfied with the field of study I am studying	0.0	13.3	37.8	28.9	20.0
I am satisfied with the level of my abilities	0.0	22.2	31.1	35.5	11.2
I am satisfied with my professional skills	2.2	17.8	31.1	42.2	6.7

Source: own research.

The results presented in the tables above prove that students with active entrepreneurial intentions assess their skills and professional abilities higher than the rest of the students (cf. Tables 5a, 5b, 5c). They also chose their field of study more consciously as the majority of them decided that they liked their program. Therefore, they are probably more likely to have clear plans for the future and use the knowledge from the studies in their professional lives. The authors of the research are obviously aware of the fact that the presented survey results are not representative due to the non-random selection of the sample and this study should be treated rather as a case study.

Summary

The presented article is an attempt to show the relationship between the concepts of prosperity and well-being and professional activity of entrepreneurs. It particularly refers to the group of women-owners, who are underrepresented among entrepreneurs in Poland and globally. Conducting the research in question is justified from the perspective of the economic development of the entire region. The use of internal resources of each individual contributes to the increase in the welfare of the entire society. Knowledge of the factors determining mental well-being is the basis for shaping entrepreneurial attitudes of young people and enables their professional activation. Although psychological well-being may be subjective, it seems reasonable to look for recurrent themes that characterize groups. It is worth referring to the concept of man formulated on the basis of humanistic psychology, which states that needs guide human action. Their recognition may constitute a point of reference for the creators of social policy.

Abstract

Manufacturing enterprises have to develop uninterruptedly. The enterprise development is often connected with the innovativeness. The innovation problems were entered into the economic publication by J. Schumpeter. The innovativeness, as a characteristic of an innovative enterprise, has not a synthetic indicator. In the references, there are many various approaches to the innovativeness measurement process. The objective of the paper is to present the ordered logit models for assessment of the enterprise innovativeness. The first, theoretical part treats the concept of innovation and the ordered logit model. The second part represents the use of these models.

Keywords: Ordered Logit Model, Level of Innovation, Manufacturing Enterprise, Assessment of The Enterprise Innovativeness

Introduction

At the beginning of 2007, during the Consumer Analyst Group of New York conference, the management of Procter & Gamble was asked how they are able to maintain the business' growth rate amidst increasing spending by the competition. The management of Procter & Gamble replied in three words: innovations, innovations, innovations... [11]. The enterprise development is often connected with the innovativeness. The innovation problems were entered into the economic considerations by J. Schumpeter. He thought that innovations give new possibilities of creation of richness to the resources possessed [10]. With time passing, there occurred new and new innovativeness definitions [1] [2] [7] [8] (Table 1). Contemporary definitions of innovations in the bibliography are described tightly take as a commercial introduction of novelties [8] or broadly as a multi-stage, purposeful process and its effect, which is a beneficial change [9], [12]. Damanpour and Schneider state: "Innovation is studied in many disciplines and has been defined from differentperspectives" [20], [21].

In literature on the subject one may find many classifications differentiating innovations. The categorisation seen most often is based on scope. It identifies product, process (also known as technological), organisational and marketing innovation [8].

When using the definition included in the Oslo Manual textbook, the innovative enterprise is such one that has introduced at least one product and process innovation within the period under the survey [8]. In the article 2 of the Act dated 30 May 2008, concerning some forms of supporting of the innovative activity (Journal of Laws Dz.U. nr 116, poz. (item) 730), by an innovative activity, it is called "the activity consisting in development of a new technology and starting, on its basis, to manufacture new or significantly improved goods, processes or services" [13].

Table 1: A review of definitions - the concept of innovation

Author	Definition
[4]	"Innovation is the process of transforming knowledge into value through the application of new of improved products, processes and systems. Authors use the concept of innovation with reference to the creation of new value for a business, its stakeholders and clients. Contrary to opinions purported by some scholars, an idea or invention only become an invention when their economic potential is effectively realised" [4].
[10]	"Innovation is the introduction into production of new products or the improvement of existing products, improvement or introduction of a new production process (process innovation), development of a new product distribution method, opening of a new market, application of new materials or raw materials for production, introduction of a new production model" [10].
[19]	"An innovative enterprise is an enterprise which, over some time, has introduced at least one innovation to the market - a product or process innovation and as a result of the implementation of the innovation, has improved its competitiveness, achieved total profit, increased employment in the departments of the enterprise requiring specialist knowledge and established cooperation with external partner organizations" [19].
[22]	"Innovations are creative changes in the social system, economic structure, technology and nature" [22].
[23]	"Innovation is the introduction of a new or significantly improved product / process, the use of a new or significantly improved marketing / organizational / technological solution" [23].

(source: own work)

Determining the level of an organization's innovativeness is important to be able to define its strategy and manage it effectively. Innovation management reflects changes in the organization by moving away from traditional processes, procedures, structures and ways of achieving a specific task or objective [24]. Table 2 provides several definitions of management innovation selected by Volberda.

Table 2: A review of definitions – the management of innovation (source: own work)

Authors	Definition
[25]	The introduction of management practices that are new to the firm and intended to enhance firm performance [25].
[26]	The generation and implementation of a management practice, process, structure, or technique that is new to the state of the art and is intended to further organizational goals [26].
[27]	A marked departure from traditional management principles, processes and practices or a departure from customary organizational forms that significantly alters the way the work of management is performed [27].
[28]	… any program, product or technique which represents a significant departure from the state of the art of management at the time it first appears and which affects the nature, location, quality, or quantity of information that is available in the decision-making proces [28].

At the present state of the knowledge, there is no systematised meters for assessment of the innovativeness level of the enterprises acting in the common market. The innovativeness, as a characteristic of an innovative enterprise, has

not, also, a synthetic indicator. In the references, there are many various approaches to the innovativeness measurement process. The objective of the paper is to present the ordered logit models for assessment of the enterprise innovativeness. The use of these models in the described context is new.

The Ordered Logit Model

Ordered variables are applicable in many research areas and are used for measuring the unmeasurable features in survey questionnaires. They have at least three categories among which there is a natural ordering. "Therefore, it is possible not only to state whether the variables for two objects have the same or different values, but also compare these values, that is to say that for one of the objects the variable has higher or lower value than for the other" [5]. For ordered variables modelling most frequently used tool is a multinomial ordered logit model which is an extension of binomial model. The ordered logit model [5], [6]:

- defines/models an ordinal dependent variable with at least two categories which are characterised by natural ordering and which can be compared to one another,
- deals with independent variables of qualitative and quantitative nature,
- allows the analysis of influence of particular variables on dependent variable,
- enables making prognosis of the dependent variable for new values of the independent variables,
- allows making the analyses and prognoses supporting the expert.

Specification, calculation and quality model evaluation methods as well as the ways of the parameter interpreting have been thoroughly presented in e.g. publications [5], [6].

The application of the ordered logit model allows determining the probability of the company affinity to one of the categories assumed by the author: modest innovator, moderate innovator, innovator. The procedure of the innovativeness level evaluation of a production company in the two selected sectors based on the theory of the ordered logit models should, according to the author, be carried out according to 6 steps (Fig. 1):

Fig. 1: The manufacturing enterprise innovativeness assessment procedure based on the ordered logit model theory

(source: own work).

Innovativeness Level Evaluation on The Example of A Manufacturing Enterprise in The Metal and Automotive Sectors

A given manufacturing enterprise carries out its business activity in two sectors alike – metal and automotive sectors. To evaluate the innovativeness level of this company, the procedure specified in Chapter 2 of this paper has been proposed.

In the first step, the level of innovativeness was selected as the modelled variable (dependent variable). The examined enterprise could be qualified as:

- modest innovator,
- moderate innovator,
- innovator.

In the next stage, based on the literature studies, a questionnaire, whose aim was to standardise the questions asked to the companies, was created. The aim of the survey was to obtain the data for developing the innovativeness level evaluation model of companies active in metal and automotive sectors. The questionnaire was delivered via e-mail to the group of respondents having their registered offices throughout the whole territory of Poland and representing micro-, small, medium and large production companies. On the basis of description of the respondents' business activity, out of 239 surveyed companies, the ones that claimed to be active in both metal and automotive sectors, were selected (131 enterprises). The survey contained the set of closed-ended questions divided into 5 thematic groups and demographics where the surveyed persons stated the size of the company they work in and the business sector. In the survey, the person answering the questionnaire had to provide the information on the position at the company. All the respondents represented the companies' management, at least middle management.

In step 3, the following four independent variables (influencing the modelled variable) were selected to model the level of the company innovativeness based on the data obtained from the survey and analysed afterwards together with the analysis of appropriate literature studies:

- number of new products developed in the company in the last 3 years,
- number of new technologies developed in the company in the last 3 years,
- number of employees with engineering or technical higher education degree in the last year,
- percentage of income spent on research and development activity.

Each variable had three possible answers (categories):
- 0-10 range,
- 11-20 range,
- above 20.

The ordered logit model was established in stage 4. For the ordered logit model, a general probability formula, where for i – of this object, the dependent variable will have the value j , is in the form of [4]:

$$p_{ij} = P(y_i = j) = \frac{\exp(\kappa_j - x_i'\beta)}{1+\exp(\kappa_j - x_i'\beta)} - \frac{\exp(\kappa_{j-1} - x_i'\beta)}{1+\exp(\kappa_{j-1} - x_i'\beta)} \qquad (1)$$

where:

$i = 1, 2, \ldots, n \quad (n \in \mathbb{N})$ – object index,
$j = 1, 2, \ldots, J \ (J \in \mathbb{N})$ – value of the dependent variable,
p_{ij} – probability that for i-of this object, the dependent variable will have the value j,
κ_j, κ_{j-1} – cut-off points,
$x_i = [x_{i1}, x_{i2}, \ldots, x_{in}]$ – vector of independent variable value for i-of this object,
$\beta = [\beta_1, \beta_2, \ldots, \beta_n]$ – vector of unknown model parameters of actual values.
For the ordered logit model estimated in research with the use of R statistical software, the probability formula of affinity of i-of this object to one of the categories (1 – modest innovator, 2 – moderate innovator, 3 – innovator) is in the following form:

$p_{i1} = P(y_i = 1) = \frac{\exp(0{,}32 - m_i)}{1+\exp(0{,}32 - m_i)}$	(2)
$p_{i2} = P(y_i = 2) = \frac{\exp(1{,}69 - m_i)}{1+\exp(1{,}69 - m_i)} - \frac{\exp(0{,}32 - m_i)}{1+\exp(0{,}32 - m_i)}$	(3)
$p_{i3} = P(y_i = 3) = 1 - \frac{\exp(1{,}69 - m_i)}{1+\exp(1{,}69 - m_i)}$	(4)

where:

$i = 1, 2, \ldots, 131$ – company number,

$0{,}32$ i $1{,}69$ – cut-off points estimated on the basis of the survey results,

p_{i1} – probability that for -of this company, the dependent variable will have the value 1 – modest innovator,

p_{i2} – probability that for i-of this company, the dependent variable will have the value 2 – moderate innovator,

p_{i3} – probability that for i-of this company, the dependent variable will have the value 3 – innovator,

$$m_i = 0.2x_{i,1.2} + 1.9x_{i,1.3} - 0.3x_{i,2.2} - 2.3x_{i,2.3} + 1.1x_{i,3.2} + 1.4x_{i,3.3} + 1.7x_{i,4.2} + 2.5x_{i,4.3} \quad (5)$$

$[0.2,\ 1.9,\ 0.3,\ -0.3,\ -2.3,\ 1.1,\ 1.4,\ 1.7,\ 2.5]$ – model parameters vector based on the survey results,

x_1 – number of new products developed in the company,

x_2 – number of new technologies developed in the company,

x_3 – number of employees with higher education degree,

x_4 – percentage of income spent on research and development activity.

The designation such as e.g $x_{i1.2}$ is understood as the value of the first independent variable for the second range – [11-20]. The range 0 – 10 was selected as the reference category.

Assignment of the values characterising a given company to particular independent variables took place in the last stage of the procedure. The following results have been obtained:

- number of new products developed in the company in the last 3 years: 11-20,
- number of new technologies developed in the company in the last 3 years: 0-10,
- number of employees with engineering or technical higher education degree in the last year: 11-20,
- percentage of income spent on research and development activity: 0-10.

Based on the formulas (2), (3), (4), (5), probability of a company's affinity to one of the selected categories was estimated. Eventually it has been estimated that the probability that the examined production company active in metal and automotive sectors is innovative, is only 40%. This evaluation was confirmed by an innovation audit of the examined company carried out by experts from one of Polish universities.

Conclusions

With regard to Schumpeter's definition, an unprecedented increase in innovation is generated by the use of robots and sensor technologies in production. The associated processes can be optimized on the basis of disproportionately increasing data [15]. The availability of, for example, quality-related data offers the potential to sustainably improve the susceptibility to errors, process and product quality [16]. Data management allows a new view of innovation. According to the "Cisco Visual Networking Index™ (VNI)", global data traffic will triple by 2021 and then reach a volume of 3.3 Zettabyte per year [17]. Today, one fifth of German companies already use Big Data [18]. The huge amounts of data serve as raw materials, which needs to be processed automatically in order to exploit its full economic potential. By structuring and analyzing mass data and subsequently enriching it with semantic models, for example, profitable knowledge can be generated - Big Data becomes Smart Data. Smart Data in turn becomes the innovation incubator of the 21st century. But many companies still fail to meet the challenge of "Big Data" even though such technologies are available. The problem is often that no concrete goal is set. Without a goal, every innovation project is unnecessary. This makes it all the more important to be able to measure innovation regarding to goals in order to correctly weigh up the investment in knowledge and technology [14].

The study about the innovation level of manufacturing enterprises in the metal and automotive industries becomes important from while the point of view of strategic management and is dependent on, among others, the European Commission guidelines in the aspect of, for example, granting funds for the development of enterprises. There is no one recommended methodology for calculating the company's innovation level. Ordered logit models are used to calculate the probability of a certain phenomenon related to an explanatory variable. In this case, it is the level of innovation. The author of the article indicated the procedure of proceedings, how to assess the level of innovation of the studied production enterprise using the indicated method.

Abstract

In the last period, due to the dramatic increase of IoT and the monitoring possibilities offered by it, in the market appeared the need to count the presence in the meeting rooms of various companies. To meet this need, certain requirements have been established, such as those of a Proof of Concept (POC) project which involves monitoring the presence in two meeting rooms of a customer. From the *Requirements Document* of the POC derives the requirement that is achieved through this work, namely to establish the best people count solution for a meeting room. Three sensor solutions for determining people count are studied in detail and discussed. The results of this paper are useful in rooms reservation, thus being possible to optimize the space management.

Keywords: Requirements diagram, people counting, sensor system, PIR, ultrasonic, Grid-EYE sensors

Introduction

The rapid development in recent years of the sensor systems performance and the increasing speed of networks through which data is transmitted in the cloud, allows enterprise applications to display and use more and more real time data. These can be used to improve the reports, operations, and decisions that the application already had implemented.

The IoT enables physical objects to see, hear, think, and perform jobs by having them “talk” together, to share information and to coordinate decisions (Al-Fuqaha et al. 2015). In the last period, the number of applications that make use of the IoT has increased dramatically and it spans areas from business and manufacturing to home, health care, and knowledge management (Nord et al. 2019).
According to the definition given by the International Facility Management Association (IFMA), Facility Management (FM) is a profession that includes several disciplines helping to ensure the functionality of the built environment by integrating people, space, processes, and technology (EuroFM 2019). In the field of Facility Management (FM), the impact of IoT is growing and IoT is playing an important role in improving FM services.

Among the information obtained using IoT technology, people counting has implications not only in the efficient use of space but also in many other areas of FM. For example, in the study of passenger activity and traffic patterns at airports, the authors found that accurate data on people counting are essential information for people flow analysis and management, space use, service monitoring, security enhancement, productivity assessment, and resource optimization to improve or maintain the operating means at airport facilities (Gerland and McDonald 2016). The Wireless Sensor Networks (WSN) is viewed as an information service provider not only to building management systems but also to wider applications in the enterprise infrastructure (Malatras et al. 2008).

There is a need on the market to see if the meeting rooms are optimally reserved. At the organizational level, this need was transposed through the requirement to monitor the meeting rooms with the help of sensors. In order to demonstrate the reliability of such a solution, a small project, POC type is first needed. From such a project, in fig. 1, is presented a *Requirements Diagram*, where is taken and developed one of the central business requirements that states: "For Proof of Concept (POC) project it is necessary to monitor the presence in two meeting rooms of the client". The synthesis diagram of the entire *Requirements Model* is presented in another article, written by some of the authors of this paper, also sent to this conference (Udrea et al. 2020). *Enterprise Architect* software was used to create the entire *Requirements Model* and other models of the project (EA 2016).

This work realizes the requirement "A study must be done to find the best people count solution in a room" from *Requirements Diagram* presented in fig. 1. It contains a study of choosing the best people count solution for a meeting room.

Regarding the structure of *Requirements Diagram,* when modeling using requirement elements there are numerous Unified Modeling Language (UML) connector types that can be used, however there are two types of relationship that are commonly used with requirement management. One for setting relationships between peer requirements (*Aggregation*), and another for representing how they will be implemented (for example a Realization by a Use Case). Requirements linked by *Aggregation* relationships form a composition hierarchy. High level requirements may be composed of lower level requirements, which in turn are made up of finer and more specialized requirements. This hierarchical structure helps manage the complexity of large systems with thousands of requirements and many elements being employed to implement the requirements (EAReqM 2016). It should be noted that the *Aggregation* relationship is not specified in (BABOK 2015), in the subchapter *Trace Requirements*, where the types of relationships between requirements are defined. As can be seen from fig. 1, the requirements of the presented model are suitable for the *Aggregation* relation.

From the tracking requirements methods available in *Enterprise Architect*, the method of creating and visualizing the requirements using diagrams was chosen. It is simple to use this method and it is best applicable for small models of requirements. The traceability of the requirements in fig. 1 is made using diagrams.

Figure 1: Requirements Diagram, made with Enterprise Architect software

In the context in which there was a need to monitor the presence in meeting rooms in order to improve the room reservation reports of an FM application, there was a requirement to find the best method of people counting. To achieve this, this article aims to find the best method of people counting and human detection by studying various methods and sensor systems.

Method and Procedure

The building, represented by its BIM model, is a main if not central element of FM applications. There are "fixed" features that are determined once and remain valid as long as the building does not change, such as heat transfer and its simulation (Natephra et al. 2018, Pop et al. 2018), building ventilation (Sporr et al. 2019, Chitaru et al. 2018), and features that need to be monitored in real time, such as indoor air quality (Diodiu and Dogeanu 2016) and the counting of the number of people (Ye 2010, Gerland and McDonald 2016).

Regarding the monitoring of people, the identifiable elements can be classified according to several properties. Thus, there can be spatio-temporal properties, classified hierarchically, from fewer to more attributes as follows: presence, count, location, track, identity. There can be behavioral properties, also classified hierarchically: pose, action, activity, behavior, group behavior. And there can be physiological properties: blood pressure, temperature, weight and other properties (Teixeira et al. 2010).

A classification of different people counting technologies is made according to the generation to which the measurement system belongs (Sruthi 2019). Thus, there are first generation technologies (infrared beam counters), second generation (thermal counters) and third generation technologies (video & Wi-Fi counters).

A comparative analysis of localization technologies inside buildings is performed in (Chen et al. 2015). Occupancy detection systems can be categorized as individualized and non-individualized, based on whether an occupant can be identified and tracked in the sensed area. Passive sensors, such as infrared sensors, CO2 sensors, light sensors, and ultrasonic sensors are widely used for non-individualized detection. Most passive sensors use indirect sensing results as an indication of occupancy. Passive infrared (PIR) sensors are commonly used for lighting control in commercial buildings. Another category of detection is the individualized system, which usually uses videos, electromagnetic or radio signals, such as wireless fidelity (Wi-Fi), RFID tags, and Ultra-Wideband (UWB) to track a unique device. The advantages of these methods are validated and compared in the study conducted by (Taneja et al. 2012). Such detection systems are capable of providing higher resolution occupancy information on location, presence, counting, identification, and tracking (Chen et al. 2015).

Another aspect to consider when monitoring people is whether people are on the move or not. In this sense one can talk about techniques that are capable of modeling static or dynamic objects (Teixeira 2010).

In this study it is intended to determine the number of people in a meeting room. This will be done through direct counting or through detection, following that by processing the detection results to obtain people counting. With two motion sensors working together on either side of a door, it is possible to count the number of people entering and leaving a room. Thus, two methods of people counting will be studied, one using a pair of PIR sensors and another using a pair of ultrasonic sensors. The proposed detection method will use infrared technology and a Grid-EYE sensor (Grid-EYE 2020).

The Solution That Uses Two PIR Sensors

The sensor system used in this study is composed of a Raspberry Pi board, a multiplexing connection board and a pair of two identical PIR Motion Sensors (PIR 2020). PIR sensors allow you to sense motion, almost always used to detect whether a human has moved in or out of the sensors range. They are small, inexpensive, low-power, easy to use and do not wear out. For that reason, they are commonly found in appliances and gadgets used in homes or businesses.

The Raspberry Pi used is a Model 4, B (Raspberry Pi4 2019). It is a credit-card-sized single-board computer. The CPU on the board is an ARM v8 processor with 1.5 GHz speed. It has a variety of interfacing peripherals, including 2 USB 3.0 ports, 2 USB 2.0 ports, 2 micro-HDMI ports, 4 GB RAM, Micro-SD Card storage and 40 pin GPIO header. For GPIO port expansion a multiplexing connection board is used.

Two monitors, keyboard, and mouse can be connected to Raspberry Pi through micro-HDMI and USB connectors and it can be used like a desktop computer. It supports a number of operating systems including a Debian-based Linux distro, Raspbian, which is used in our design. Raspberry Pi can be connected to a local area network through Ethernet cable or USB Wi-Fi adapter, and then it can be accessed through SSH remote login.

It is desired to count the persons in a room with two motion sensors working together on either side of a door. The laboratory mounting (on a desk) of the sensors simulates very well the sensors working together in the real situation, on either side of a door. In fig. 2 can be seen the image of the system used in this study and its electrical diagram.

a)

b)

Figure 2: Two PIR sensors and Raspberry PI: a) photo of the assembly; b) assembly scheme

In the schematic representation in fig. 2 b) the following connections are done: the 3-5VDC power pins of the PIR sensors are connected to the 5-volt power supply (2 and 4) of Raspberry PI. The Ground pins of PIR sensors are connected to GND (6 and 14) on Raspberry PI. The digital out (SDA) of one PIR sensor is connected to GPIO7 (11) on Raspberry PI and of the other SDA of the PIR sensor to GPIO17 (11). The calculation algorithm of people count is presented in table 1. A software written in Python was developed to implement these rules.

Table 1: Rules for determining people count using the information received from the two PIR sensors.

Rule 1 When one of the two sensors detects motion, it is checked if the other sensor has also detected motion and if the time interval between the two detections is less than a certain value, what is settable (for example 3 seconds). The three seconds means that a longer time interval is not suitable for a person to walk through the door. **Rule 2** If the condition is met then an entrance or exit to the room is counted, as the last sensor that detected movement was inside or outside. (As positioned, the two sensors are considered one inside and one outside the room in which the counting is done.) **Rule 3** After an entrance or exit to the room has been counted, both sensors are reset (they are considered without detected motion).

In Python code, to check the status of a PIR sensor, an infinite loop can be used (of course with a certain pause set between repetitions) in which it is checked if there has been any input at the sensor pin. But there is also the possibility in which the code is told to wait until an event occurs e.g. when the pin detects a signal. The advantage of the second approach is that processor resources (CPU) are not consumed by repeating a loop. In the case of this study, the variant of waiting to appear, for the event that represents the signal detected by the pin, was used.

Another aspect to be specified is that the PIR sensors used were too sensitive, so their adjustment was made according to the datasheet and the user manual (PIR 2020).

The Solution That Uses Two Ultrasonic Sensors

This solution uses a Raspberry Pi, Model 4, B (Raspberry Pi4 2019), which was presented in the previous subchapter, a multiplexing connection board and a pair of two identical ultrasonic sensors (Ultrasonic 2020). Ultrasonic sensor works on the principle that is similar to RADAR and SONOR i.e. transmits a signal and analyzes the target by capturing the reflected signals. HC-SR05 is an ultrasonic ranging sensor with good accuracy. Ultrasonic sensors overcome many of the weaknesses of IR sensors - they provide distance measurement regardless of color and lighting of obstacles. They also provide lower minimum distances and wider angles of detection to guarantee that obstacles are not missed by a narrow sensor beam. It has 5 pins and can be used in 1-pin trigger/echo or 2-pin.

It is desired to count the persons in a room with two ultrasonic sensors working together on either side of a door. In this study the ability to measure the distance that ultrasonic sensors have will not be used but only the capability that they can detect movement. The laboratory mounting (on a desk) of the sensors simulates very well the sensors working together in the real situation, on either side of a door. In fig. 3 can be seen the image of the system used in this study and its electrical diagram.

In the schematic representation in fig. 3 b) the following connections are done: the VCC power pins of the PIR sensors are connected to the 5-volt power supply (2 and 4) of Raspberry PI. The Ground pins of PIR sensors are connected, using a breadboard to GND (6) on Raspberry PI. The *Trig* pin of one sensor is connected to GPIO4(7) of Raspberry PI and the *Trig* pin of the other sensor to GPIO23(16) of Raspberry PI. It is realized, for each sensor, a voltage divider that is set up for the echo pin (it drops the voltage going to the GPIO pins down to 3.3v from 5v). 1k Ω resistor (R1) and a 2k Ω resistor (R2) are used to achieve this. *Echo* pin of the sensor is connected to R1, R2 is connected to Ground of Raspberry PI, and wire from R1 and R2 are connected to GPIO17(11) of Raspberry PI, respectively GPIO24(18) for the other sensor.

a)

b)

Figure 3: Two ultrasonic sensors and Raspberry PI: a) photo of the assembly; b) assembly scheme

Rules for determining people count using the information received from the two ultrasonic sensors are the same as rules used for PIR sensors. Regarding the Python code, to check the status of an ultrasonic sensor, the solution that checks if the sensor has detected something uses an infinite loop.

The solution that uses a Grid-EYE sensor

This solution uses a Raspberry Pi, Model 4, B (Raspberry Pi4 2019), which was presented in the previous subchapter, a multiplexing connection board and Grid-EYE Infrared sensor (Grid-EYE 2020). Grid-EYE is a high precision infrared array sensor based on advanced MEMS technology. It has the feature of temperature detection of two-dimensional area: 8×8 (64 pixels), digital output (capability of temperature value output), and a compact package. Temperature range of measuring object is from 0 °C to 80 °C.

Figure 4: Grid-EYE sensor and Raspberry PI: a) photo of the assembly; b) photo of the assembly with the Grid-EYE sensor mounted in the ceiling; c) assembly scheme

In fig. 4 can be seen the image of the system used in this study, a photo of the assembly on the desk (a) and a photo with it in working position, mounted on the ceiling (b) and its electrical diagram (c).

In the schematic representation in fig. 4 c) the following connections are done: the VCC (3.3V) power pins of the Grid-EYE sensor are connected to the 3.3-volt power supply(1) of Raspberry PI. The Ground pin of Grid-EYE sensor are connected to GND(9) on Raspberry PI, the SDA pin of the sensor to GPIO2-SDA1(3) on Raspberry PI and the SDA pin of the sensor to GPIO3-SCL1(5) on Raspberry PI.

It is desired to count the persons in a room using this solution. First, Python code was used to display the 8x8 pixels grid given by the Grid-EYE sensor. Then a people count was performed based on the obtained image.

Python has been chosen as the programming language because of its vast data processing toolbox and the existence of an AMG88xx library. The AMG88xx library handles the I2C protocols and returns the temperature values of the 64 individual IR detectors (Hrisko 2018). The *pyplot* interface was also used in Python. *matplotlib.pyplot* is a collection of functions that make *matplotlib* work like MATLAB. Each *pyplot* function makes some change to a figure: e.g., creates a figure, creates a plotting area in a figure, plots some lines in a plotting area, decorates the plot with labels, etc (Matplotlib 2012).

In order to determine the number of people based on an infrared photo, *OpenCV-Python* (OpenCVTut 2013) was used. *OpenCV-Python* is the Python API of *OpenCV*. *OpenCV* was started at Intel in 1999 by Gary Bradsky and the first release came out in 2000. Right now, OpenCV supports a lot of algorithms related to Computer Vision and Machine Learning and it is expanding day-by-day (OpenCV 2013). Using the *scripy.interpolate* module, function *griddata*, that deals with the *OpenCV-Python* interface, and the solution proposed by (Keith 2018), a code that makes blob detection was developed in Python. A Blob is a group of connected pixels in an image that share some common property (E.g. grayscale value). *OpenCV* provides a convenient way to detect blobs and filter them based on different characteristics (Mallick 2015).

Python code for all three solutions can be downloaded from http://www.cladirieficiente.ro.

Results and Discussions

Regarding the first two methods of determining people count, using PIR sensors and ultrasonic sensors the calculation algorithm is relatively simple. Following the tests performed, no errors occurred. However, here is a limitation with this approach: if two people enter a room at the same time, there is no way of detecting the two people apart. Or if people who enter and people who leave meet at the access door or other situations that are easy to imagine.

In this project the display of the code in Python console was sufficient, in later stages, after choosing the optimal solution for determining the number of people, functions will be developed and, depending on the requirements, adequate methods will be found to make the API of the application on the Raspberry Pi PCB.

a) b)

c)

Figure 5: The image obtained with Grid-EYE: a) three people in the room; b) one person in the room; c) two people in the room (8x8 grid given by Grid-EYE, without interpolation)

In fig. 5 is shown the grid given by the Grid-EYE sensor. One can see the presence of three people (a), one person (b) and two people (c). The grid display can be done with or without interpolation, in fig (c) it is missing. Note that the people count algorithm works without the graphical display of the image (but uses it without displaying it). The display of the image is made to better understand what is happening and for didactic purposes.

In the images in fig. 5 the number of people in the room is quite clear, but not all the images are so clear. The result can be influenced by the distance people are from the sensor, if they are sitting or standing, if people are moving, it can also be influenced by various other heat sources.

Regarding the testing, there were some errors in this method, as expected for an information of 8x8 pixels. The calculation method and algorithm are very good and other sensors are recommended, such as FLIR Radiometric Lepton (FLIRCamera 2020) which has a relatively affordable price. It should be noted that *People Counting Software* using Grid-EYE is developed by Panasonic (the sensor manufactures also) (Grid-EYECount 2017), but it is not an open source software.

Conclusions

In the context of the exponential growth of IoT in the last period and of the need of FM to optimize its activity based on the growth of information received from the field, there was a need to count the presence in the meeting rooms of various companies. Thus, the present paper fulfills a requirement that is part of a POC project through which it is desired to monitor the presence and light intensity in two meeting rooms of a customer. The requirement is to establish the optimal method of people counting in the meeting rooms.

Two methods of people counting are studied, one using a pair of PIR sensors and another using a pair of ultrasonic sensors and a detection method, using infrared technology by using a Grid-EYE sensor, then establishing the people count based on the information received by the Grid-EYE sensor.

In the first two methods there are no reading errors due to the sensors, however certain situations that exceed the limit of the possibilities of people counting through this system may occur, such as the simultaneous entry or exit of two people. Furthermore, in case of monitoring the presence in the meeting rooms, attention must be paid to the cumulation of possible errors that would occur for people counting using PIR and ultrasound sensors. That is, the wrong counting of an entrance or exit will be perpetuated at the next meetings, the system has no way to reset (to set the number of people to zero) at the beginning of a session. Although this would not be a problem from a technical point of view, from a business point of view it would be a mistake (it is possible that the meeting started earlier, at another time, for example). A system reset at the end of a working day is not enough.

In the case of determining people count using Grid-EYE, there were sometimes noticed differences in counting compared to the number of people actually present in the room. This may be due to the low resolution of the information sent by the Grid-EYE sensor, or a grid of only 8x8 pixels. In this situation higher resolution sensors are recommended.

In this paper people counting is considered in relation to the entire trace of requirements it satisfies. For example, the level of accuracy that is required in an FM application that deals with *Rooms Reservation*. A very high degree of accuracy would be needed if, depending on the people count, decisions could be made such as canceling a meeting. But if there is interest in the evolution over time of the occupancy rate of the meeting rooms (real number of participants vs. planned number of participants and room capacity), on the basis of which statistical evaluations would be made, then small deviations from the people count could be admitted.

Fiscal Decentralization and Economic Growth in The Czechia

Irena SZAROWSKÁ

Silesian University in Opava, School of Business Administration in Karviná, Czechia
szarowska@opf.slu.cz

Abstract

The Czechia applies a combined model of fiscal federalism with relatively low fiscal decentralisation and belongs to countries with the most territorial fragmentation of municipalities. The aim of the article is to examine relationship between fiscal decentralisation and economic development in the Czechia in the years 2000-2019. There are used following indicators: expenditure decentralisation, revenue decentralisation, intergovernmental transfer decentralisation and tax revenue decentralisation. The empirical tests are based on cross correlation and Granger causality methodology. The results suggest that decentralisation appears to be positively associated with GDP per capita but negatively associated with real GDP growth, except expenditure decentralisation positively correlated in both cases. The relationship is stronger for economic maturity than for economic growth and GDP growth comes first followed by decentralisation.

Keywords: Fiscal Decentralisation, Fiscal Federalism, Subnational Governments, Economic Development.

Introduction

Theory of fiscal federalism has started to highlight fiscal decentralisation since the 1970´s of the 20th century. Fiscal decentralisation (hereinafter FD) is usually characterized by a division of decision - making powers combined with a limited shift of the resources to sub-central governments (SCGs). Aristovnik (2012) notes that many post-communist countries started the public sector reforming process later, with some derogation from the optimal FD implementation. In the Czechia, state decentralisation and local autonomy were understood in a way that gave the right to become a separate local government, to almost each settlement unit, even if that unit was a tiny village. The number of municipalities rose by almost 50%, from 4,120 in 1993 to 6,250 in 2001. Nowadays, the Czechia uses a combined model of fiscal federalism and belongs to countries with the most territorial fragmentation.

In this context, the relationship between economic performance and the size of municipality is often discussed. Economic growth is affected by many factors among other FD (Musgrave 1959; Oates 1972). Studies highlight theoretical prediction that FD enhances the efficiency of government and promotes economic development (Oates, 2005 or Baskaran et al., 2016) but some report present contradictory direction of influence.

The aim of the article is to examine relationship between FD and economic development in the Czechia in the years 2000-2019. The article is organised as follows. Next chapter introduces a theoretical background and literature review. Followed chapter provides a description of methodology and data. Empirical part focuses on FD in the Czechia and the intention is to identify direction of influence as well. Conclusion summaries main findings.

Literature Review

Traditional theory of fiscal federalism is mostly based on Oates's (1972) theorem, which predicts a greater allocative efficiency and production efficiency. An important extension of literature brings 'second-generation' of fiscal federalism which takes into account political and fiscal institutions, imperfect information and political agents. Generally, FD is linked to sharing of fiscal responsibilities and power among central, state and local governments, but the term is not sufficiently clear even in the fields of political science or public administration

(Bird and Wallich, 1993 or Rodríguez-Pose and Krøijer, 2009). Bahl (2008) introduces the pillars and twelve implementation rules for FD.

Thiessen (2003) as well as Martinez-Vazquez and McNab (2003) mention the absence of a formalized theory on the relationship between FD and economic growth. Thiessen (2003) describes a positive relation between decentralisation and growth when decentralisation is increasing from low levels, but that as decentralisation increased, the relation eventually turned negative in a cross section of high-income OECD economies using annual data for a period 1973–1998.

Later Oates (2005) gives a review of the FD characteristics and its economic implications. This and other relevant studies (e.g. OECD and KIPF, 2016) claim to demonstrate the direct of FD on economic growth. However, a causality is not clear and absolute, and decentralisation may affect growth indirectly through its impact on other socio-economic variables, such as macro stability and government quality (Martinez-Vazquez and McNab, 2003), or through its interaction with the institutional framework (Feld and Schnellenbach, 2011). Martinez-Vazquez et al. (2017) offer a complex review of the impact of FD on the economy and society. Most recently, Slavinskaite et al. (2020) introduce a theoretical model for evaluating the FD.

Empirical studies focused on the relationship between FD and economic growth provide mixed ambiguous results, sensitive to the choice of data sample and investigated period. Slavinskaitė (2017) summarizes empirical findings of researches on the impact of FD on economic growth in cross – countries terms. Blöchliger and Égert (2013) present an overview of literature review, which is divided into two groups – cross-country studies and national studies. Many empirical studies are focused on the share of SCG revenue or expenditure in consolidated government revenue or expenditure as the measure of FD. Studies that have reported a positive and statistically significant impact using these measures include, among others, Iimi (2005), who reports significant and positive impact of expenditure decentralisation on per capita GDP growth in a panel of 51 developed and developing countries covering 1997-2001.

Akai et al. (2007) stress the complementarity relationship between FD and economic growth in the USA and promote further revenue decentralisation by computing the optimal degree of FD measured by expenditure decentralisation and revenue decentralisation. Thornton (2007) highlights relationship between FD and long-run economic growth is ambiguous as is apparent from the results of empirical studies.

Contrary to a majority view, it is possible to find many empirical studies with proven a negative impact of FD on economic growth (e. g. Zhang and Zou, 1998, Rodríguez-Pose and Ezcurra, 2011 or Baskaran and Feld, 2013). Some studies even consider decentralisation harmful, especially in the case of developing and transition economies (Rodden, 2002). This scepticism is fuelled by problems often associated with decentralisation, such as increasing deficits, lower quality of government decisions, corruption, increased influence of interest groups, and greater interregional inequalities, which result in lower overall economic growth.

Rodríguez-Pose and Krøijer (2009) examine, using a panel data approach with dynamic effects, the relationship between the level of FD and economic growth rates across 16 Central and Eastern European countries over the 1990-2004 period. While expenditure at and transfers to subnational tiers of government are negatively correlated with economic growth, tax as assigned at the subnational level evolve from having a significantly negative to a significantly positive correlation with the national growth rate.

Gemmell et al. (2013) investigate whether the efficiency gains accompanying FD generate higher growth in 23 OECD countries, 1972–2005. They find that spending decentralisation tends to be associated with lower economic growth while revenue decentralisation are associated with higher growth. Wang (2018) offers diverse results for revenue and expenditure decentralisation as well. He states revenue decentralisation does not affect economic performance. But expenditure decentralisation dividend in terms of an enhanced economic growth rate can be achieved only when the initial share of local government expenditure is smaller than the growth-maximizing degree through along with tax collection and trade openness.

Also Radoniqi (2018) points out that empirical studies about the impact of fiscal decentralisation in economic growth all the time have provided mix results. Her paper reviews, analyses and compares findings of these studies and highlights and explains differences on the dimensions studied from the authors about this phenomenon. Newly,

Carniti et al. (2019) tested effects of fiscal decentralisation on economic growth empirically on a panel of 25 European countries (1995-2015) and focuses on expenditure composition. Their econometric results show that relationship between investment decentralisation and growth is an inverted bell-shaped curve: there is a critical mass of decentralized investments beyond which it is possible to enhance growth.

Jílek (2009) deals with the issue of FD in the Czechia. The analysis shows that though the expenditure decentralisation in the Czechia is quite high, the degree of revenue and tax decentralisation is low. This result is supported also by the comparison with OECD-Europe unitary countries average. Bryson et al. (2004) survey FD in the Czechia too. They conclude the Czechia made more substantial transfers to local governments, but the development of fiscal autonomy was stifled as transfers reduced the need for own-source local revenues. The Czech real estate tax has remained nominal as it was under central planning, and its administration is fraught with moral hazard problems. The property tax never became a tool for generating independent funds. This Sobotovičová and Janoušková (2020) confirm too and present specifics of real estate taxation in the Czechia.

Methods

The aim of the paper is to examine relationship between FD and economic development and also identify direction of influence in the Czechia in the years 2000-2019. The empirical evidence relies on the secondary statistical data of the Czech Statistical Office, Ministry of Finance (monitor.statnipokladna.cz) and the OECD Fiscal Decentralisation Database, data are consistent in time. Since FD has many dimensions (e.g. Harguindéguy et al. (2019) review and compare 25 decentralisation indexes), variables in accordance with OECD definition are specified as follows:

Expenditure decentralisation (EXPD) is the ratio of subcentral to total general government expenditure as defined in (1).

$$EXPD = \frac{EXP_{SCG} - Tr_{SCG(-)}}{EXP - Tr_{(-)}} \times 100 \quad (1)$$

EXP_{SCG} means total expenditures of SCG, Tr_{SCG} transfers provided by SCG, EXP total government expenditures, Tr transfers between levels of government.

Revenue decentralisation (REVD) means the ratio of subcentral own revenue to total general government revenue.

$$REVD = \frac{REV_{SCG} - Tr_{SCG(+)}}{REV - Tr_{(+)}} \times 100 \quad (2)$$

In (2), REV_{SCG} means total revenues of SCG, Tr_{SCG} transfers (grants) received by SCG, REV total government revenues, Tr transfers between levels of government.

Tax revenue decentralisation (TAXD) expressing the ratio of subcentral tax revenue (TAX_{SCG}) to total general government tax revenue (TAX):

$$TAXD = \frac{TAX_{SCG}}{TAX} \times 100 \quad (3)$$

Intergovernmental transfer decentralisation (TRFS) means transfers between the central government level and social security which are considered to be internal and have not been taken into account when calculating either the inter-governmental transfer revenue or the total revenue.

It is necessary to point out that the Czechia is a unitary state, SCG is formed by municipalities and regions and values of SCG (expenditure, revenues, tax, transfer) is equal to a sum of financial flows for these basic and higher self-governing units.

Economic development is assessed using the real GDP growth rate (RGDP) and nominal GDP per capita (GDP) expressed in Purchasing Power Parity (PPP). GDP per capita values were transformed into natural logarithms. It is necessary to test the stationary time series before starting analysis. Unit root tests identified that all time series are stationary at the first differences (RGDP and EXP also at level data). The empirical tests relating decentralisation and economic performance are based on cross correlation methodology.

Cross correlation assesses how one reference time series correlates with another time series, or several other series, as a function of time shift (lag). Cross correlation does not yield a single correlation coefficient but rather a whole series of correlation values. Like all correlations, cross correlation only shows statistical associations not causation. Consider two financial series and, then the cross-correlation at lag (lead) k is defined as follows:

$$\rho(y_{t+k}, x_t) = \frac{T\sum_{t=k-1}^{T}(y_{t+k} - m_y)(x_t - m_x)}{(T+k)\sqrt{\sum_{t=k}^{T}(y_{t+k} - m_y)^2}\sqrt{\sum_{t=k}^{T}(x_t - m_x)^2}} \qquad (4)$$

where ρ is the correlation coefficient and m_x and m_y are the means of corresponding series. The series can be related in three possible ways: (i) y_t can lead x_t ($\rho(y_{t-k}, x_t) \neq 0$), (ii) y_t can lag x_t ($\rho(y_{t+k}, x_t) \neq 0$), (iii) series can be contemporaneously related ($\rho(y_t, x_t) \neq 0$).

Granger causality methodology is also applied. The Granger causality refers to a specific notion of causality in time-series analysis. A time series X is said to Granger-cause Y if it can be shown, usually through a series of t-tests and F-tests on lagged values of X (and with lagged values of Y also included), that those X values provide statistically significant information about future values of Y.

Results and Discussion

FD in Czechia and development of analysed variables

The 1993 Constitution established the Czechia as a sovereign unitary state and guaranteed two levels of SCG system, with no hierarchical link: the higher self-governing units (the regions), and the basic self-governing units (the municipalities which are regulated through the Municipal Act 128/2000). Regions were established in 2000 (Regions Act 129/2000). There were instead 77 district offices, which were deconcentrated units of the state territorial administration and which, to a certain extent, worked as surrogate regional governments. The system of intergovernmental fiscal relations in the Czechia remains quite centralized. A fair assessment of the current system is that the Czechia may be considered as having a significantly deconcentrated state administration structure. This is because all of the activities of district offices and the bulk of the activities of municipalities have been aimed at implementing the central government's policies at the local level. Most of the fiscal decision - making power emanates from the center and local level governments have only a marginal influence on local fiscal matters.

The contemporary government in the Czechia is organised in a three-tier structure: the central government, 14 regions and 6258 municipalities (Czech Statistical Office, 2018). The capital Prague has a special statute and is considered both a region and a municipality. The most of the municipality's revenues come from shared taxes, where the largest part consists of the collection of VAT. However, municipalities also have the possibility to set their own fees and have in their delegated powers, the collection of property tax. Municipality also may freely dispose of its properties and can also have rental income, sales, or conduct business. The distribution of revenue from shared taxes between the various levels of government, and consequently between the municipalities is precisely defined in the Act 243/2000 Act on budgetary allocation of taxes. Municipalities also receive state subsidies for the performance of state administration under delegated powers as Figure 1 shows.

Fig. 1: Combined model of fiscal federalism in the Czechia

A degree of decentralisation has evolved during the transition. Regions and municipalities are entitled by state law to both autonomous responsibilities, over which they have considerable freedom with regards to financial and legal aspects, and delegated responsibilities, which need to be executed according to central government guidelines. Municipalities are autonomously responsible mainly for pre-elementary and primary education, local social welfare, environment, public housing, public transports and local roads. Regions are autonomously responsible for secondary education, regional road networks, regional economic development and healthcare. SCGs get their revenues from taxation (own-source), grants and other sources, mainly fees resulting from the provision of services. Sub-national expenditure represents 11.8% of GDP and 27.0% of total public expenditure. The revenue of municipalities can be broken down as follows: 9.5% from autonomous taxation, 46.9% from shared taxation, 27.7% from grants and 15.9% from other sources. The revenue of regions can be broken down as follows: 0.2% from autonomous taxation, 34.7% from shared taxation, 62.3% from grants and 2.8% from other sources (Czech Statistical Office, 2018).

Fig. 2: Development of variables in percentage (2000-2019)

As Figure 2 reports, expenditures are more decentralised than revenues. While both revenue and expenditure became more decentralised over the past 20 years, expenditure decentralisation outpaced revenue decentralisation, resulting in a higher vertical fiscal imbalance and growing intergovernmental grants (for details look at Halásková and Halásková, 2017 and 2018; Szarowská, 2014 and 2015). Martinez-Vazquez et al. (2017) draw attention to shared taxes usually appear in official statistics as sub-national revenue, although the SCG has no autonomy in determining the revenue base or rate. When the degree of taxing power of SCGs is considered, the decline of revenue decentralisation and stagnation of tax autonomy is seen. New increase of decentralisation is visible from 2013 and is connected with a positive economic development. Overall, expenditure decentralisation (EXPD) has increased from 24% (2000) to 29% in 2018. SCGs have a very low share in total tax government revenues and increase of revenue decentralisation (REVD) is only 3 percentage points (from 16% to 19%) in the analysed period. A degree of revenue FD is similar the EU average (18%) as is reported by Czech Statistical Office (2018) as well as OECD and KIPF (2016). Very low value (about 1%) of tax revenue decentralisation (TAXD) results from the fact the Czechia is the country without tax legislative powers at the sub-national level. SCGs are highly dependent on financial redistribution by the government. The system of shared taxation, according to which approximately 9%

of state taxes are transferred to regional authorities and about 22% of state taxes are transferred to local and regional authorities, leaves the latter considerable freedom in deciding how these resources should be used within the field of their proper responsibilities. Municipalities have a limited discretion by adjusting (local and size) coefficients over the property tax (representing about 3% of municipal revenues) and full discretion over local fees (representing 2.3% of municipal revenues in 2018). Intergovernmental transfer decentralisation (TRFS) stagnates and is nearly zero. Economic growth reports cyclical development. Maximum value is reported in 2006 (+7.25%), minimum in 2009 (-4.35%), mean value is 2.97%.

Results of Granger causality

Pairwise Granger causality tests are applied for examining relations between GDP growth and EXPD ratio as well as other selected variables in a short-term. It is important to mention that the statement for example "Expenditure Granger causes GDP" does not imply that GDP is the effect or the result of EXPD. Granger causality measures precedence and information content but does not by itself indicate causality in the more common use of the term. The null hypothesis should be rejecting if probability is less than 0.05. Table 1 summarizes results for lags one and two years. Bold values indicate hypothesis, which should be rejected.

Table 1: Granger causality tests

Null Hypothesis:	Lags: 1 year			Lags: 2 years		
	Obs.	**F-Statistic**	**Prob.**	**Obs.**	**F-Statistic**	**Prob.**
EXP does not GC GDP GROWTH	19	0.503	0.488	18	0.436	0.623

GDP PER CAPITA does not GC TRfS		0.198	0.662		0.017	0.982

Note: GC means Granger cause

One can find only two examples of one-way Granger causality from GDP growth to tax revenue ratio TAXD and intergovernmental transfer revenue TRFS for the 1 year lag. The causality from economic maturity expressed by GDP per capita to decentralisation variables is not revealed in any case. With the lag of 2 years, there is not reported any Granger causality between analysed variables. From this point of view can be concluded that there is just one-way causality, which was reported from GDP growth to TAXD and TRD. That means GDP growth comes first followed by decentralisation. Deeper analysis focused on direct impact of variables will follow in a next paper.

Results of Correlation Analysis

Correlation is a statistical technique that can show whether and how strongly pairs of variables are related. The correlation coefficient can vary from –1 to +1. The correlation coefficient –1 indicates perfect negative correlation,

and +1 indicates perfect positive correlation. Its value smaller 0.1 means zero correlation, from 0.1 to 0.35 weak correlation, from 0.35 to 0.7 moderate correlation and higher than 0.7 express strong correlation. The results in Table 1 report cross-correlations for all possible combinations of growth and decentralisation variables.

Table 2: Correlation coefficients

	Real GDP growth	Correlation	GDP per capita	Correlation
Expenditure ratio	0.151	weak positive	0.496	moderate positive
Revenue ratio	-0.224	weak negative	0.872	strong positive
Tax revenue ratio	-0.404	moderate negative	0.756	strong positive
Transfers	-0.215	weak negative	0.477	moderate positive

Findings suggest that decentralisation appears to be positively associated with GDP per capita but negatively associated with GDP growth, except expenditure decentralisation, which is positively correlated in both cases. Coefficients also express correlation is stronger for economic maturity expressed by GDP per capita than for economic growth. The information about GDP growth provided by Table 2 can be interpreted as economic growth does not relate exclusively on the degree of FD of a country (coefficients of correlation are very low).

The results are similar to the conclusion about the relationship between GDP per capita growth and decentralisation observed in the research of Martinez -Vazquez (2016). Aristovnik (2012) also finds a weak positive correlation between FD and economic growth in Eastern European countries, so the case of the Czechia confirms this trend. Coefficients suggest that FD might accelerate economic growth. The similar conclusion is possible to find in Iimi (2005), Akai et al. (2007) or Thornton (2007).

Found positive correlation coefficients and positive influence of the degree of FD on economic performance may be affected by country differences in political and administrative decentralisation as Rodríguez-Pose and Ezcurra (2011) also assumed. In terms of subnational expenditure and revenues, the results of empirical evidence are in line with the findings of other empirical studies on FD and economic growth, such as Thiessen (2003), Iimi (2005), Akai et al. (2007), or Rodríguez-Pose and Krøijer (2009), but opposite as Zhang and Zou (1998), Rodden (2002) or Rodríguez-Pose and Ezcurra (2011). The variety is generated due to differences in used econometric models, country samples, observation periods and considered variables.

Conclusion

The aim of paper was to examine relationship between FD and economic development and identify direction of influence in the Czechia in the years 2000-2019. The empirical tests relating decentralisation and economic performance are based on cross correlation and Granger causality methodology.

Decentralisation process in the Czechia is driven by both economic and political forces. Currently the Czechia uses a combined model of fiscal federalism with a three-tier structure: the central government, 14 regions and 6258 municipalities (Czech Statistical Office, 2018). Municipalities and regions form the SCG level and they are entitled by state law to both autonomous and delegated responsibilities, which need to be executed according to central government guidelines. SCGs are highly dependent on financial redistribution by the central government. Shared taxes usually appear in official statistics as sub-national revenue, although the SCG has no autonomy in determining the revenue base or rate. Municipalities have a limited discretion by adjusting (local and size) coefficients over the property tax and full discretion over local fees. Very low value of tax revenue decentralisation results from the fact the Czechia is the country without tax legislative powers at the sub-national level. Expenditures are more decentralised than revenues. Over the past 20 years, expenditure decentralisation has increased from 24% (2000) to nearly 29% in 2019.

The Granger causality identified just one-way causality, which was reported from GDP growth to tax revenue ratio and intergovernmental transfer revenue for 1 year lag. That indicates that GDP growth comes first followed by decentralisation. But this result is very limited to draw general conclusions. Deeper analysis focused on a direct impact of variables will follow in next paper. Correlation analysis implies decentralisation appears to be positively

associated with GDP per capita but negatively associated with GDP growth, except expenditure decentralisation positively correlated in both cases. Coefficients express that correlation is stronger for economic maturity than for economic growth.

As economic maturity has significantly increased during the analysed period, it allows formulating implications for the government/economic policy. FD simplifies system of public sector and local SCGs, because responsibility for managing public resources is assigned to the lower level of governments. As mentions above, the Czechia belongs to countries with the most territorial fragmentation of municipalities. Hence, specific decision-making actions and changes should include institutional intergovernmental cooperation. The high territorial fragmentation at the lowest tier of government is the most remarkable attribute of the administrative structure and can be seen as a reason for a low level of revenue decentralisation, although expenditure decentralisation is a relatively high.

Revenue autonomy should be enhanced by increasing predictability of local budgets and e.g. resuming tax-effort incentives. The Act on budgetary allocation of taxes should be modified to decrease differences between local governments. A system of transfers should concentrate on reducing the number of specific subsidies, and boost transfers and programs stabilizing SCG budgets in a medium-term framework.

Although the research adds new empirical evidence to the literature, it should be remembered that country specifics are crucial in modelling fiscal decentralisation-growth effects and strongly depend especially on their size, territory specification and fragmentation as well as socio-economic maturity. That´s why future research will be focused on Visegrad countries with similar historical background and other European Union member states.

Abstract

There are numerous health-related issues that can occur during flight, for both passengers and crew members. The incidence of these issues rises for those who fly frequently. Among these risks are noise-related stress and frequent exposure to radiation, both ionizing, in the form of cosmic radiation and non-ionizing, in the form of UV rays. Numerous studies have correlated exposure to radiation with increased risk of developing several illnesses, especially cancer. Noise has also been documented to produce physical, physiological and mental effects on individuals. This paper aims to provide an overview of literature regarding this problem in order to highlight its importance and to propose several solutions that could alleviate the issue. Regarding cosmic radiation, we propose shielding the inner fuselage of aircraft in order to reduce the amount of radiation that enters the plane. We analyze the viability of this solution regarding added mass and shielding capability. We also touch briefly upon Z-grade materials, that are used in shielding satellites and that could be used in shielding aircraft as well. Regarding UV rays, we have found a simple and cost-effective solution, which can block UV rays without reducing windshield visibility.

Keywords: Radiation, Aviation, Health, Ergonomics.

Introduction

Flight safety and health are two major concerns for aviation. While flight safety has direct economic consequences for aeronautical companies, health has the downside of not being so easy to translate into money, which means that it is not a primary subject of interest for investing and for researching solutions for problems in this area. Therefore, we aim to bring to light three of the main issues regarding health of aircraft crew and frequent flyers: cosmic radiation, UV rays and noise-related stress. We illustrate the main causes of health issues among aircraft crew in an Ishikawa Diagram in Fig. 1.

Fig. 1: Ishikawa diagram on health-related issues of pilots and frequent flyers (Source: Authors)

Radiation is one of the most important factors to consider when talking about health issues during flight. There are two types of radiation that increase in intensity at higher altitudes, namely cosmic radiation and UV rays.

Cosmic rays are a type of radiation that comes from space. This radiation is caused by charged particles generated by the sun and by primary photons and α particles from outside the solar system, which interact with the Earth's atmosphere (Bagshaw and Illig, 2019). Cosmic radiation is a type of ionizing radiation, which means that its high amount of energy enables it to detach electrons from other atoms of molecules, effectively modifying their structure, or ionizing them. Other well-known examples of ionizing radiation are Gamma rays and X-rays. Exposure to ionizing radiation can kill cells or cause them to mutate and function improperly. This has numerous health effects, such as burns, organ failure or even death.

We are exposed to a small amount of cosmic radiation every day. This has been calculated at a global average of 0.27 mSv per capita (Bouville and Lowder, 1988) and poses no significant health risks. The International Atomic Energy Agency sets a safety limit of 1 mSv / year for the general population (International Atomic Energy Agency, 2018), representing the total amount of radiation that a person can be exposed to during one year without any risk to their health. However, the small amount of cosmic radiation mentioned above is the one measured at ground level. Cosmic radiation increases with altitude, estimated to double for every 4500 feet (~1.37km) (Aw, 2003). Radiation doses experienced by most cabin crew fall in the range of 1 mSv – 6 mSv per year (Zeeb et al, 2003). This means that some aircraft personnel are exposed yearly to radiation doses 6 times over the safety limit. Studies validate the increased risk of cancer in aircraft crew, caused by this excess radiation: double the risk of leukemia, malignant melanoma and non-Hodgkin's lymphoma and a 9.67 times higher risk of other skin cancers, compared to the general population (Zeeb et al, 2003). Another study identifies a 1.9 times higher risk of breast and prostate cancer and a 4.72 times higher risk of leukemia in aircraft crew, compared to the rest of the population (Lim, 2002).

Fig. 1:Annual effective dose of radiation for various professions (Source: Authors)

A study published by the US National Council on Radiation Protection and Measurements (Schauer and Linton, 2009), which estimates annual radiation exposure for workers in various fields of work, collected data which shows that aircraft crew are exposed annually to almost twice as much radiation as workers in nuclear plants. We have presented this data in the chart in Fig. 2 above.

Apart from radiation, another important issue comes in the form of noise. Even though this problem has been the focus of several research and development attempts, it is not yet fully solved. There is evidence that working in noisy environments can lead to serious damage to both physical and mental capacities. Cockpit noise can lead to permanent damage to pilots' hearing abilities (Nwabeke, 2001). A German study (Grebig, 1971) classifies noise in three categories, based on their effects on health: Stage I noises are between 30 and 65 dB and lead to mental effects; Stage II noises are between 65 and 90 dB and lead to mental and material effects; Stage III noises are between 90 and 120 dB and lead to mental, material and otological effects. These effects also depend, on a certain degree, on the psychological reaction to noise. A negative reaction worsens the effects and increases the sensitivity of the individual to the stress factor. Conversely, a positive attitude can alleviate part of the stress, but it is still not enough to prevent damage from prolonged or heightened exposure to noise. Noise is of even greater importance when it comes to pilot performance. This can have serious repercussions to flight safety, given that noise can influence a pilot's ability to correctly perform the necessary maneuvers and tasks involved in flying the airplane.

State of the Art

At the moment, nothing is done in order to insulate the interior of aircraft against cosmic radiation, probably because this problem does not have a noticeable economic impact to motivate investment into finding and implementing a solution. The aluminum used to construct aircraft is not a good insulator, due to its relatively small atomic number of 13. Materials that successfully block radiation have a high number of electrons per unit volume, high electronic mean excitation energy, high density and tight binding corrections for the inner shell electrons (Wilson et al, 1995). One such material is lead. The high atomic number and high density of lead allows it to successfully block ionizing radiation. It is the industry standard for terrestrial radiation shielding, such as shielding against X-rays in nuclear power plants, labs and medical facilities. It is also used to create lead aprons to reduce patient and doctor exposure to X-rays during medical imaging, such as CT scans or radiography. We will analyze the viability of using this material for shielding aircraft in the next chapter.

UV radiation represents an electromagnetic radiation in the wavelength range of 100 nm to 400 nm. It is commonly divided into three types: UVA, in the range of 315-400 nm, UVB, in the range of 280-315 nm and UVC, in the range of 100-280 nm. UV rays that come from the sun pass through the atmosphere, which absorbs 100% of UVC radiation and approximately 90% of UVB. Several studies highlight UV as the cause for 65% of melanoma and for 90% of non-melanoma skin cancers (Linos et al, 2009) (Armstrong and Kricker, 1993) (Pleasance, Cheetham et al, 2010). Additionally, a study of more than a quarter million participants has identified that pilots and air crew, which are exposed to radiation on a regular basis, have twice the incidence of melanoma compared to the rest of the population (Sanlorenzo, Wehner et al, 2015) . This highlights the fact that UV radiation is, indeed, a significant health risk. Another insight that this research provides is that, even though airplane windows provide some filtering of UV radiation, it is not enough to keep this type of radiation within acceptable limits.

Airplane windshields are commonly made from either composite glass or from polycarbonate plastic. While only 1% of UVB rays pass through plastic and glass windows, up to 53.5% of UVA rays can pass through airplane windshields (Nakagawara, Montgomery and Marshall, 2007). This is likely one of the main causes for the increased incidence of skin cancers among pilots and it confirms the fact that current airplane windshields do not provide adequate filtering against UV rays.

Regarding noise, there have been several developments that have alleviated part of the issue since the debut of jet airplanes. According to Michael J. T. Smith, these were generally prompted by government legislation and numerous lawsuits that forced companies to adhere to certain noise limits regarding noise, both inside and outside aircraft (Smith, 1989). A recent article that presents a review of sources of aircraft noise and the developments that have been made in order to reduce it (Sadeghian and Bandpy, 2020) groups noise into categories, based on the element that generates it. Thus, we have airframe noise, which is created by the non-propulsive components, fan noise created by engine fans, flap noise created by airplane flaps during takeoff and landing and jet noise created by the engine. The article also presents a summary of solutions that have been adopted in order to reduce noise, such as optimizing the shape of the aircraft, or improving various parts of the engines in order to produce less noise during functioning.

Proposed Solutions

Thanks to its very high density, lead is a very good choice in blocking ionizing radiation (Khan et al, 1981). However, its high density quickly adds up to a high total mass for most applications. In aviation, weight is a very sensitive issue, with economic, as well as environmental implications. Higher aircraft mass means burning more fuel, which translates to higher cost per flight and greater environmental pollution. However, if a thin enough layer of lead is used, the extra added mass is small enough to allow installation on aircraft without major drawbacks.

Our solution involves underlaying the entire fuselage of the airplane with a thin layer of lead, in order to shield against cosmic radiation, effectively blocking most of it from entering the fuselage. In order to determine an adequate thickness for the lead layer, we can consider the following aspects:

- For adequate protection during a CT scan, the patient wears a lead apron with lead thickness of 0.25mm (Cheon et al, 2018) (Hyun, Kim, Jahng and Kim, 2016)
- During a CT scan, where lead aprons are used, the patient is subjected to about 20 mSv of ionizing radiation (Schneider, 2010)
- Radiation doses experienced by most cabin crew fall in the range of 1 mSv – 6 mSv per year (Zeeb et al, 2003), that being more than 3 times less radiation than a CT scan

We have concluded that a lead thickness of $t = 0.1\ mm$, meaning three times smaller than that of a lead apron, should be enough to protect aircraft passengers and crew against cosmic radiation during flight. This should be good enough as a theoretical basis and needs further testing in order to certify that it works as intended.

We will continue by calculating the impact it would have on a Boeing B737 Max 8 airliner, in order to evaluate whether this thickness is viable for an airplane of this size. Specifications for the B737 aircraft are publicly available on the Boeing official website and the ones of interest in our calculations are as follows:

- H_f – Fuselage height: 4.01 m
- W_f – Fuselage width: 3.76 m
- l_f – Estimated fuselage diameter, assuming the fuselage as a cylinder with diameter: $D_f = (H_f + W_f)/2 = 3.885\ m$, then $l_f = \pi \cdot D_f = 3.14 \cdot 3.885 = 12.1989\ m$
- L_f – Fuselage length: 39.52 m
- M_{TOW} – Aircraft maximum takeoff weight: 82,190 kg

Considering the density of lead as $\rho_{lead} = 11.34\ g/cm^3 = 11340\ kg/m^3$ and our chosen lead thickness of $t = 0.1\ mm = 10^{-4}\ m$, we determine the total added mass to be:

$$M_{added} = D_f \cdot L_f \cdot \rho_{lead} \cdot t = 12.1989\ m \cdot 39.52\ m \cdot 11340 \frac{kg}{m^3} \cdot 10^{-4}\ m \approx 546.7\ kg \quad (1)$$

Taking into consideration the Maximum Takeoff Weight of the aircraft as 82,190 kg, the added mass of the shield represents only 0.67% of the aircraft maximum takeoff weight. This should have minimal impact on costs and

emissions and, because it is uniformly distributed across the entire fuselage, it should also have minimal impact on the balance of the plane.

A simple analysis also reveals the reduced added cost pertaining to this method. For this analysis, we will consider the price per kilogram of lead at the time of writing this thesis (August 2020), which is 1.8 USD per kilogram. It is neither an all-time high, nor an all-time low and it can serve as a fitting model for estimating costs. If we multiply this by M_{added} , which is the estimated weight of the necessary lead used for shielding an airplane, we determine that the cost of raw materials is only 984 USD, which is insignificant, even when factoring in extra manufacturing costs, compared to the cost of an airplane (approximately 121 million USD in 2020 for a B737 Max 8).

A promising alternative solution to lead shielding is shielding using Z-grade materials (Fan, Roeske and Scrivner, 1996). These are currently used for shielding sensitive electronic components of satellites in space and are very effective at blocking radiation. They are composed of alternating sheets of low-Z and high-Z materials, which roughly translates to materials with low atomic numbers alternating with materials with high atomic numbers. Promising candidates for such materials are various aluminum alloys as low-Z and tantalum as high-Z. We have illustrated an example of a Z-grade shield in Fig. 3.

Fig. 2: Schematic of a Z-grade shield (Source: Authors)

These materials are a viable solution only if they turn out to be lighter than the equivalent lead shield that we have presented above. For now, not enough data is publicly available in order to calculate the impact of such materials on the total mass of the airplane, or how thick the required shield could be. However, they show a lot of promise and should be investigated more when further research will be done.

Regarding UV rays, we have found a simple and cost-effective solution to improve filtering for the windshield. This comes in the form of a transparent window film, which can block up to 99% (depending on the manufacturer) of both UVA and UVB rays, without impacting the clarity of the windshield. They also reject up to 78% of incoming solar heat, which helps to remove extra stress during pilot working hours. They are commonly made of laminated polyester film layers, modified in such a way as to block UV rays from passing through. Common modifications can be impregnation with dyes or carbon particles, or coating with a layer of deposited magnetic metal vapors. UV rays are either reflected, absorbed or scattered, depending on the manufacturing process used to create the film (Springer, 2008). Certain manufacturers also produce fireproof varieties of film, which is very important regarding aircraft regulations and flight safety. Non-fireproof varieties are very flammable and produce toxic vapors, which cannot be evacuated during flight.

Because they are made of polyester, they have negligible mass compared to the airplane, which means they do not affect the balance or fuel consumption of the plane. The installation process is very easy. They can be cut to shape and size and applied to the interior window surface. They are generally easy to peel from the glass if they need to be replaced. The material is durable, most manufacturers offering warranty of 10 – 15 years, some even offering lifetime warranty. Given that the average lifespan of an airplane is 30 years, they require few replacements. An added benefit of this solution is that it can be easily used for existing planes, without requiring major modifications.

Regarding noise, we have come up with a solution that is complementary to the technologies that have been developed so far. Even though it is simple, this approach received surprisingly little attention in previous literature, as far as we have been able to see. It consists of insulating the airplane with a layer of sound-absorbing panels, made of bonded acoustical cotton (Baccouch et al, 2020) (Asdrubali, 2006). This material can be easily applied to the interior panels of the fuselage, given the fact that these panels can be cut to custom shapes and sizes, to fit appropriately. This material is flexible and lightweight, but durable and it is made from processed recycled cotton. One of its most important traits is that it is fireproof. It can be used in any type of environment and it is currently used for soundproofing concert halls, theaters, firing ranges and other locations where fireproof material is recommended. A simple analysis analogous to the one presented for lead shielding reveals that it would mean adding approximately 500 kg to the total mass of the airplane, depending on the thickness and density of the specific model of panels chosen.

Conclusions

In this paper, we have studied the impact of radiation on the health of aircraft crew and frequent fliers. After a thorough analysis of literature, we have confirmed that radiation and noise represent major issues in aviation and are sadly overlooked by companies because of their low economic impact. Taking this into account, we have provided cost-effective and easy to implement solutions for reducing or blocking cosmic and UV radiation and for reducing noise inside aircraft. These can reduce health risk for passengers and personnel and improve ergonomic conditions aboard the airplane. Implementing the proposed solutions offers the following advantages:

1. They eliminate or highly reduce the environmental factors that lead to a higher risk of various types of cancer for air crew and frequent fliers
2. They are cheap solutions, which do not require developing new technologies
3. They are easy to implement
4. They have little or no impact on plane balance and key characteristics, such as windshield visibility
5. They are readily available on the market, using tried and tested materials
6. They are independent of aircraft model and can be incorporated into any type of airplane
7. They are durable and safe and do not require special maintenance

Abstract

Until recently, each department in a company had its own specialized application that it used to carry out its activity, which raised many problems and was an inefficient way of working. ERP programs aim to solve this problem so that a modern ERP allows all departments in the company, whether it is sales-orders, marketing, distribution, service, supply, procurement, production, accounting, management, invoicing, human resources / salary etc. to work in a single application, which brings many benefits. Through this research, the authors aim to present the evolution of ERP systems. A study is conducted in order to establish the main functionalities and components of modern ERP systems. There is proposed a set of instructions in order to identify the suitable ERP system for each organization that is considering implementing one.

Keywords: ERP systems, information system, process automatization.

Introduction

The term "ERP" was established in 1990 by the technology consulting company Gartner, while the precursors of this type of software came to life in the 1960s. Business software programs at that time were dedicated exclusively to companies that made production. The software helped manufacturers better manage the management of raw material stocks. During the 1970s these systems evolved into programs called Materials Requirements Planning (MRP). At that time, only very large companies could afford such systems. It is estimated that around 700 companies around the world were using an MRP system at the time. In 1972, the company SAP was founded, which proposed a business software that would work in real time, this being an absolute novelty. In the 1980s it went from Materials Requirements Planning (MRP) to MRP II Manufacturing Resource Planning which brought in addition many circuits optimized for the production area. In 1990 MRP II evolved into ERP which in addition to the production part, came with other integration modules such as accounting, finance, sales, payroll, inventory management and so on. Since the 2000s, it has moved to ERP II, which is what is actually used on the market today. ERP II systems are much more extensive than the normal ERPs of the 1990s. ERP II comes with other integrated modules in addition to the basic ones. Thus, currently, a quality ERP should also have modules such as Business Intelligence for analysis and real-time graphical reports, WMS for warehouse activity management and rapid inventory, CRM for customer relationship management, B2B / B2C online store, etc. With the help of an ERP application, data entry, collection, validation, processing, aggregation, transfer and export can be performed in a systematic and efficient way. The data in the ERP is then distributed to each person who has access rights and the need to work basis with that information in order to

Cite this Article as: Olivia Doina NEGOIȚĂ, Mirona Ana Maria POPESCU, Anca Alexandra PURCĂREA, Mihai Valeriu POPESCU and Georgiana MOICEANU "An Overview Over Adopting ERP Systems in Companies" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

best perform their activity and / or to any computer system that integrated with the ERP, such as a e-commerce platform / online sales site. The common database for all departments in the organization is the fundamental element of an ERP. Thus, an ERP software makes the entire process from supply from supplier to sale to the end customer to be accurate, efficient, fast and transparent, which ensures complete traceability of any operation. Basically, an ERP solution allows the different departments in the company to communicate, share and access information with the rest of the company much more easily, thus increasing data transfer speed and data accuracy. Due to the fact that the departments in the company use a common database, which contains uniform, accurate and updated data in real time, integrated with the workflows of the organization, an ERP significantly improves the ability to report, analyze and make decisions. The authors conducted a research in order to establish the principal stages of ERP Systems evolution. There are presented the main functionalities of these systems to highlight the advantages that are brought by their usage in a company. Since there are a variety of solution on the market, the authors propose a set of steps that are to be considered when is chosen an ERP System and there are listed the key elements that define a successful implementation. Nevertheless, the paper treats the disadvantages brought by the systems.

State of the Art

In modern SMEs, the innovation element is given by the adoption of ERP. Antoniadis (2015) examines the critical factors that may affect the implementation of an ERP system during a crisis period. The findings indicate that managers do not use the system at its entire capability.

The risk of implementing an ERP system in a small company is also approached by Johansson (2020). Until now, most of the studies were taken on large companies. Therefore, the research is focused on a small company and the results indicate that are recommended integrated solutions.

The information flow has become an important aspect in every business. Therefore, Ociepa-Kubicka (2017) presents the benefits of ERP systems in companies, where the management processes can be improved.

The data security when transferring the ERP data to the cloud is analyzed by Saa (2017). The concerns regarding the confidentiality and integrity of data becomes a problem especially at large organization. The author proposes a hybrid solution where sensitive applications are on-premise.

Bjelland (2018) studied two perspectives regarding ERP systems: the vendor and the users, which vary when it comes to updates. According to the research users encounter obstacles given by the size of the update, insufficient information.

The aim of Chang (2020) is to investigate the process of moving to cloud ERP systems in organizations. Therefore, data collected from 212 top managers was analyzed through equation modeling.

The implementation of Cloud ERP systems brings organizations a better control of the business processes. Egbon (2020) debates the challenges of using ERP systems over cloud.

Trending functionalities and components of an ERP System

Each ERP system comes with its functionalities and components. In Figure 1 there are presented the most important functionalities that a modern ERP system encompasses nowadays.

1. **Integration**

Integrating departmental data and various IT systems with ERP is the most important functionality a company needs.

2. **Automatization**

An ERP manages and automates a multitude of business operations in the company and ensures direct and continuous inter-departmental communication. This increases employee productivity and resources are allocated more efficiently.

3. **Accounting / Taxation**

The general accounting part, sometimes also called the financial-accounting component, ensures a correct accounting and the financial management of the company. The functionalities of an ERP in this area vary from case to case: automation of recording accounting information taken from primary documents, making accounting records at analytical and synthetic level, creating statements for NAFA (D394, D390, etc.), creating reports and accounting documents required by Fiscal Code (balance sheet, VAT reporting, taxes paid to the state budget), but also accounting

notes, journal, account statements, cash register, sales and purchase journal, balance sheets, profit and loss account and so on and so forth.

4. Sales management

An ERP system deals with optimizing the sales flow within the company. Orders, proforma invoices, final sales invoice, receipts - all these operations become fast and transparent through the automation that an ERP solution brings. But the best part is that sales are closely linked to the inventory management and supply side, so people can access reports that contain real-time updated data to see what the inventory situation is at any given time. This avoids out-of-stock situations that lead to loss of sales and optimizes orders to suppliers based on the current needs of the company.

5. Human resources

In the area of employment contracts and wages, an ERP helps companies to comply with the legislation on Labor Law / Wages Law. The part of Payroll / salary calculation, centralized management of full-time and part-time contracts, creation of standardized employment contracts for different positions, record of holidays and many other operations are managed in a centralized way, so that different reports can be easily obtained.

6. Inventory management

It is extremely important for a modern business to accurately manage its stocks to know at any time what is the state of the inventory. For example, with the help of ERP software, a company can easily see which products are the most sold / sought after by customers so as to ensure that they are always in stock. Also, you can see which the products are whose stock is not running at all, so you can liquidate the stock to recover the money stuck there.

7. Delivery of orders

An ERP is the best tool a company can use to increase productivity, efficiency, speed, accuracy, and transparency when it comes to delivering orders to customers.

8. Production

Perhaps the most important aspect that an ERP solution for production solves is that it aligns and integrates the production process with the quantity of raw material in stock which allows increased control over production capacity, detailed reports, optimizations of the production process, the use of production recipes and many other things.

9. Reporting and data analysis

The fact that an ERP collects, standardizes and centralizes in a common database all the data coming from the departments is a great advantage in terms of updating and accuracy of the data used for business analysis. Through integration with a BI (Business Intelligence) system, the ability to quickly analyze huge volumes of data increases exponentially.

10. Customer relationship management - CRM

In a good ERP system, there are many reports that can be obtained about customers such as those that contain data about sales, reversals, receipts and so on, which allow a better understanding and segmentation of customers. By integrating the ERP solution with a CRM system, users and management can gain a much clearer perspective on customers.

11. Transparency and traceability

Whether it's common operations such as sales or more complex processes such as production, ERP software is there to transparently record what's happening in the company and ensure traceability across all streams. of business.

Fig. 1: Functionalities of a modern ERP system

Key elements for choosing an ERP

One question that most companies face when they start looking for a new integrated IT system is which option to choose. There are a lot of solutions on the market that can be called more or less real ERP applications. Thus, the authors recommend a certain set of steps to find and choose the right ERP system, found in Figure 2.

Fig. 2: Steps to choose an ERP system

To choose an ERP system, we start with the first step in this process, namely establishing the reasons why it is necessary for the company. There are many reasons, the most important being found below:

- modernizing the information system;
- increasing productivity through automation;
- integrating departmental activity to obtain global data and reports at company level;
- reducing operating losses and expenses;
- minimizing the risks to which the organization is exposed;
- obtaining accuracy in inventory management;
- opening online sales channels;
- organizing the accounting department, regarding the legislative updates, etc.;

The second step is to establish the most important functionalities of the ERP system related to business. Setting the budget in the third step should be seen as an investment and not a cost. The price of the solution increases with the

benefits it brings. There are several types of architectures and types of ERP on the market. You can opt for an on-premise ERP system that assumes that the application will be installed on your own server, at the company's headquarters. If you opt for Cloud, then the ERP solution will be installed on the server of a hosting service provider. Also related to the costs involved in implementing such a system in the company, in step 5, a SaaS subscription (Software as a service) seems at first sight the least expensive solution because you pay a certain amount of money per month, depending on the number of users of the ERP system, on medium term (2-3 years of use). However, such an option could eventually become more expensive compared to purchasing the ERP solution from the beginning. The research on the chosen ERP system consists in requesting references from ERP providers and discussions with them in order to obtain feedback related to the degree of satisfaction brought by ERP and the support services offered by their provider.

When deciding on an ERP solution, it is important that it is scalable so as to solve most of the current problems, and if the business grows the possibility of integrating other modules in the future should exist. The following are elements that must be considered for the successful implementation of an ERP system (Table 1). As a general manager or project manager, it is important to pay close attention to things related to change management, that is, to make people understand why it is important for the company, for them and for customers to adopt a new ERP system.

Table 1: Elements for a successful ERP system implementation

Nb.	**Element**
1	Choosing a team of employees to assist you and tell you what their needs are in their departments. Tip: listen carefully to their needs, but you decide what is best for business and focus on the things that really bring added value in general, not just make a person's job easier.
2	Assessing the needs, problems and business objectives in general
3	Selecting a project manager
4	Evaluating and selecting the best ERP system for you and your business
5	Hardware / IT infrastructure audit
6	Functional analysis of work circuits together with the ERP provider
7	Establishing an implementation plan with the supplier
8	Implementation and change management (people need to understand why a new ERP is needed and what it helps them to do, otherwise resistance to change will intervene, which will create big problems in the future)
9	Data cleaning and migration in the new ERP
10	Providing optimal conditions for training related to the use of ERP
11	The actual implementation of the ERP
12	Establishing an internal ERP consultant who is very well prepared by the ERP provider

There are countless reasons why an ERP implementation fails, but the situations that occur more frequently are:

- Poorly defined objectives for ERP implementation

  Most companies see the implementation of an ERP as a key solution to all the problems in the organization, but do not allocate the necessary time to specifically define what they want to achieve from the new ERP and what would be the goals to achieve after the implementation, which clearly leads to a failed implementation.

- Lack of management involvement in ERP implementation

  The project team needs a leader with whom to discuss certain directions of action, to allocate and prioritize resources of time, people, money for ERP, to encourage people to make increased efforts, etc.

The project manager cannot always do these things, especially if he does not have a very high authority within the company.

- Wrong choice of ERP provider

  An ERP is a long-term investment, and the appearance of very high discounts and / or bonuses are used for contract signing purposes. An important step is represented by requirement of customer referrals from the ERP software provider.

- Treating ERP implementation as a simple IT project

  Implementing an ERP is a matter of business strategy. That is why it is necessary to give it maximum importance and resources.

- Lack of a good project manager

  Every ERP implementation must be approached methodically. First, the people who will be part of the implementation team (project manager, key users and IT) are chosen. That team must have a global perspective on the business and the skills needed to implement the project from start to finish.

- Communication problems

  Many ERP application implementations suffer from inadequate communication between management, employees, the deployment team, and the ERP software provider.

- Underestimating the transfer of data from the old application to the new ERP

  The removal of unnecessary information, mistakes and duplicates in order to use a qualitative database first.

- Resistance to change

  It is important to communicate to each department the concrete benefits that the new ERP will bring in their daily tasks. Employees need time to familiarize themselves with the new system through training and user manuals.

- Underestimation of budget and allocated resources

  One of the most common problems is the underestimation of the effort required for implementation.

- ERP customizations / customizations

  An optimum ERP has circuits validated and tested over time by many companies. One of the most common reasons why ERP implementations fail is that some organizations insist on modifying different ERP circuits. In addition to the fact that sometimes those circuits are not so well optimized, customizing the ERP application costs a lot both in terms of developing new circuits and in terms of maintenance costs. The more customizations, the harder it is to maintain and update the application.

- Lack of patience and the ability to solve problems

  The positive results of implementing a good ERP appear at the earliest after a period of time.

- Poor post-implementation support

  Post-implementation support is vital because that is when users of the new ERP need the most help from their software provider.

- Lack of ability to integrate ERP with other solutions

  When choosing an ERP system for implementation, it is recommended to know in the long term what are the next steps taken in business development.

Conclusions

Over time, management techniques and practices have evolved into a set of generally accepted rules (best practices) specific to each business vertical. Although resulting from a long sedimentation process, these “best practices” are also subject to the continuing need for resynchronization with structural changes in the business environment. The

role of an ERP application is to facilitate their incorporation and updating in the company's business processes. An ERP system is composed of a series of modules that are intended for various departments, such as: production, financial-accounting, procurement, sales. Although it has an extremely varied nature, the information is operated only once and is accessible to any module it needs. This saves time, resources, reduces the likelihood of committing operating errors, facilitates access to last minute information, etc. One of the usual features of an ERP application is to store all the information in a single database. Being a single system, there is only one vision of results. This eliminates the problem of "multiple truths", in which each department has its own set of results, analyzes and conclusions, often contradictory. Current ERP systems achieve the integration of all management functions of a company, starting from planning, ensuring the stock of raw materials and materials, defining technologies, coordinating production processes and, last but not least, achieving financial accounting management, human resources, of stocks of finished products and ending with the development and maintenance of relationships with customers and business partners. Such an ERP application allows decision makers to perform complete analyzes on the implementation of the business plan. Through the options for simulating the activities and through the flexible and dynamic nature of the applications, forecasting plans, evaluations and predefining the evolution trends of the industry of which the company is part, qualitative analyzes, integration with new e-business technologies and online communication can be realized.

Abstract

A wide range of scientific articles, as well as studies and research in the field of IT for business, highlight the significant opportunities that arise with the global spread of advanced information technologies and the cloud computing model, both in terms of the possibilities of small and medium enterprises. compete with large ones, as well as to increase the competitiveness of developing countries. Considering these records, business opportunities in Romania where most businesses are small and medium, and the economy is developing, can be significant. Thus, the authors conduct a quantitative research through an online questionnaire distributed to SMEs in Bucharest to identify digitalization trends and the adoption of new technologies. The study highlights the concepts of IT mobility, Social media, Big Data and the Cloud Computing. As a result of digitalization, it is increased process automation and operational efficiency. The majority of companies are facing a challenge when it comes to Cloud Computing solutions due to their cost, but a website to present their products and services represents a must have.

Keywords: Information Technology, SMES, Process Digitalization.

Introduction

Technology is one of the so-called pillars of competitiveness. A country's technological availability barrier is measured by the capacity of the country's economy to adopt existing technologies to boost the productivity of its industries, with specific emphasis on the ability to capitalize on information and communication technologies in day-to-day activities and production processes to increase efficiency and improving competitiveness. Access to and use of information technology are key factors in assessing the level of technological availability of the country. Regarding the availability of the latest technologies, the report states that Romania ranks 48th out of 67 countries (https://www.gfmag.com/global-data/non-economic-data/best-tech-countries), which indicates poor availability of advanced information technologies in the country.

Nowadays all areas of activity are based on use, to a greater or smaller extent, of information technology and computers. The use of ICT is present in the most diverse activities and for making decisions based on the information that is obtained from the processing of data collected.

Cite this Article as: Olivia Doina NEGOIȚĂ, Mirona Ana Maria POPESCU, Anca Alexandra PURCĂREA, Mihai Valeriu POPESCU and Bogdan Dumitru ȚIGĂNOAIA "Advanced Information Technology in Romanian Companies" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Through this paper, the authors aim to bring current notions regarding the advanced information technologies used by companies. Based on them, a market research was conducted to determine the advantages that companies pursue by adopting information technologies, the difficulties they encounter in their implementation at the organizational level, the importance they give to the presence in the online environment where the activities take place. more and more, especially in the current situation, as well as the degree of inclination towards the use of Cloud Computing.

State of the Art

Because of the Internet and digitalization there was a considerable change in marketing strategies and business communication. The geographical and time limits are no longer an obstacle. Patrutiu-Baltes (2016) presents the new world which is the online environment and deliberates the digitalization is a key when it comes to competitive advantage. Ilcus (2018) also talks about the digitalization in each field of humans lives with a focus in business world by presenting the advantages brought to the companies.

The adoption of internet connected digital technologies by companies is analyzed by Pagani (2017). The findings identify three types of digitalization considering the link most impacted. IT and innovation have a huge impact on small and medium sized enterprises, therefore Lecerf (2020) made a study to demonstrate that these two concepts can improve SMEs internalization. His research was based on a survey which had around 600 respondents.

By gathering data from a considerable number of European SMEs which are using IT artefacts at a common base in order to innovate their business models, Bouwman (2017) outlines that there is a correlation between these two concepts which impacts positively the performance.

Startups have an urgent need to internationalize as soon as possible. Neubert (2018) conducts 73 interviews with senior managers and the findings indicate that digitalization increases the efficiency of decision processes and the strategies are more easily optimized.

SMEs are considered to be the backbone of the economy in a developing country. Adopting ICT in these countries comes with challenges. Afolayan (2015) illustrates during the study the need for both managers and employees to participate at continual trainings to be up to date with ICT and offer suitable solutions for organizations.

Bouwman (2018) developed an empirical study on SMEs which use social media and big data in order to innovate their business models. Both have a positive role on business performance according to the results and also business models are driven by big data mainly.

The services provided by organizations are improved by using information and communication technologies. A literature review regarding critical factors which have an impact on the relation between business and IT is made by Sanchez (2020).

The performance of a business is given by the capability of enhancing IT. Also, the human resource cannot be neglected. Turulja (2016) uses survey data and structural equation modeling to research the connexion between IT, HR and business performance. The results indicate that its capabilities have a role on human research management rather than in business performance and human research management can impact business performance.

Methodology

The study carried out by the authors consists in undertaking a bibliographic research through which are presented the new work technologies introduced by informatics. In relation to these concepts, a questionnaire was built between April and June 2020, the period in which personal work was supported due to the pandemic, and the research method used was the survey. The applied tool is the questionnaire administered online through a link distributed by email using Google Forms. The research targets respondents from all companies in Romania. The conduct of this field research aimed at evaluating the following dimensions:

- Organizational needs of respondents related to digitization trends;
- Level of enrollment in current trends in technology use, such as the adoption of the Cloud Computing model, Social Media, IT mobility and Big Data solutions;

- Ways of reporting employees to the new job opportunities introduced by mobile computing, Cloud Computing and Social Media.

As the study is aimed at the adoption and use of advanced information technology, before proceeding to the presentation of research findings, a brief presentation of what is advanced information technology is depicted. In the context of this study, advanced refers to major trends in information technology with applicability and business use: IT mobility, Social Media, Big Data and the Cloud Computing IT model.

1) *IT mobility.* The processes power that was exclusively found on personal computers only a few years ago, is increasingly being transferred to portable devices such as tablets, smartphones, which brings multiple advantages, but also organizational challenges. The mobile computing landscape has evolved rapidly over the past two decades. Unlike traditional cell phones, modern mobile devices incorporate advanced operating systems and can connect to the Internet, and advances in mobile communications enable the rapid transfer of data across mobile networks. Companies are increasingly advancing in the adoption of mobile applications that go beyond the simple activity of checking correspondence, moving towards the implementation of mobile software that supports collaboration between employees, encourages interaction with customers and improves customer loyalty.

The BYOD concept - an acronym for Bring Your Own Device - is relatively new in business literature and refers to the use, by employees, of their own mobile communication and computing devices to perform service tasks. Because portable computing technology has performance and capabilities comparable to workstations, the transition to BYOD is both feasible and natural in terms of employee trends. From the perspective of IT management, however, there are debates about the degree to which this phenomenon would be desirable or easy to manage. At first glance, BYOD seems to be advantageous for companies, by eliminating investments in equipment specifically designed for mobile business applications, their management and maintenance. However, the IT functions of companies are reluctant to embrace the BYOD way of working, as they are not yet sufficiently prepared for this transition. The challenges that arise in this context are mainly related to: - The need to maintain the confidentiality of information and to continue to ensure a high degree of security of organizational data; - The need to develop business applications that are compatible with different types of mobile devices and different operating platforms. Many organizations face the unplanned and unintentional installation of the BYOD trend, as many employees use personal devices to download work emails or to channel organizational data into more or less secure applications installed on personal devices. BYOD initiatives require new organizational security policies and tools to minimize business risk. While the "office of the future" requires more flexibility, mobility and convenience in carrying out work tasks, it becomes clear that the BYOD phenomenon cannot be ignored by business management but must be evaluated and adopted in the most appropriate way to ensure organizational security. and the success of the initiative.

2) *Social Media.* Web 2.0 designates new ways to consider and exploit the organizational possibilities of the web. According to them, the content and information on the web is no longer offered to visitors only by the media, governments and private companies, but also by private individuals, connected to each other through informal Internet-based networks, and who contribute and actively participate in the provision and spreading information around the globe through the web. With the spread of social networks such as Twitter, Facebook, LinkedIn, etc., it is expected that companies will be more present in virtual social media due to a series of considerations, starting from the simple fact that these networks are populated by customers and consumers. The term "Enterprise 2.0" or "Social Enterprise" / "Social Business" is increasingly used in reference to Web 2.0 computer applications and tools used for business or organizational purposes. The value of using these technologies comes from the fact that they facilitate the creation of a work environment with fewer constraints, allowing employees the freedom to work at their own pace and in their own ways, while contributing to increasing employee involvement for work tasks and the projects it carries out. Although social networks are in the spotlight in the context of social media and are very popular, the concept itself is broader and includes, in addition to public social networks, Web 2.0 tools and applications such as blogs, wikis, websites dissemination and exchange of information, widgets, mashups and others, with applicability both in the external environment of the organization and in the internal organizational environment, using the company's Intranet.

Some studies show that most of the business value in the field of Social Media is related to the internal use of Web 2.0 tools. This leads to increased employee productivity by facilitating communication and collaboration between them. Executives are increasingly recognizing the usefulness of social platforms in the organizational environment. And while awareness of the importance of the concept of "Social Business" is growing, the perception of its most important aspects diverges depending on the managerial level and the function conducted. Thus, CEOs and marketers may be inclined to consider that the most important capitalization of the potential of "Social Media" technologies is an outward-looking one, in the direction of developing affinity for the brand, while production managers or project leaders can choose for the intensification of the internal valorization, in the direction of the

project management. Regardless of the field they lead, most executives perceive social technologies as having the potential to transform the way organizational activities are carried out.

Executives are increasingly recognizing the usefulness of social platforms in the organizational environment. And while awareness of the importance of the concept of "Social Business" is growing, the perception of its most important aspects diverges depending on the managerial level and the function conducted. Thus, CEOs and marketers may be inclined to consider that the most important capitalization of the potential of "Social Media" technologies is an outward-looking one, in the direction of developing affinity for the brand, while production managers or project leaders can choose for the intensification of the internal valorization, in the direction of the project management. Regardless of the field they lead, most executives perceive social technologies as having the potential to transform the way organizational activities are carried out.

3) *Tools in the field of analytics.* Organizations have begun to place more importance on data and invest more in its collection and management. The Big Data concept is a combination of three components: volume (organizations collect data from various sources, including banking, social media or sensors and data transmitted between machines. New technologies allow the storage of this mass of data), speed (the sharing of information is done with an unprecedented speed and in an increasingly shorter time), variety (data comes in all formats - from structured, to digital and unstructured documents, e-mails, video, audio or financial transactions). The importance of big data does not start from the quantity, but from its use. Information from any source can be used and analyzed in such a way as to provide answers in terms of reducing costs, reducing processing time, developing new products or making smart decisions. Traditional information management and analytics processes are mainly aimed at supporting internal decision-making processes. They operate with structured data, existing mainly within the organization. Compared to traditional analytical tools, the Big Data concept introduces changes in three dimensions: (1) data types, (2) their accumulation speed, and (3) their volume. With the launch of the Web 2.0 environment, around 2005, much of the valuable data for businesses is generated outside the organization, by consumers and Web users in general.

Beyond the information collected within organizations and the increasing volume of data generated by computers in their operation, those obtained from outside the organization, whether structured or unstructured, have multiple sources that can include information posted on social networks and products viewed in virtual stores, information read by sensors, GPS signals from mobile devices, computer IP addresses, cookies, barcodes, etc. But many of the most important data sources are relatively new. It is argued that the explosion of data volume characteristic of the present phenomenon, Big Data, comes from unstructured data. Within them, unlike the data generated by users, which originate from information provided voluntarily in different Web dissemination environments, there is also intercepted data. The latter refers to information passively collected from the online behavior of individuals, such as, for example, online search terms or locating individuals through applications present on mobile devices. In this context, some researchers express that each person becomes "a mobile data generator".

4) *The Cloud Computing model.* All three trends presented above are effectively supported by the Cloud computing model. It is based on the convergence of Internet technologies and the virtualization of software and networks. Adopting the Cloud Computing model allows companies to buy the exact type and amount of computing resources they need (business applications, memory space, computing power, security services, and more), when they need it, from organizations specialized in operating data centers. Within this IT model, servers, networks, applications and other elements of business computing are made available to IT departments and users via the Internet. The Cloud IT model involves a major transformation in the way businesses consume IT services and manage IT resources. In the case of the traditional model, companies make massive investments in IT resources dedicated to precise and predetermined operational goals and in infrastructure, including hardware, software, computer networks and IT staff. Cloud Computing is increasingly becoming a way for organizations to increase IT capacity and add IT capabilities "on the go", without the need to invest in new infrastructure, staff training, new software licenses, and so on. Although the idea of the Cloud Computing model is simple at its core, the impact and mechanisms of its applicability in business are rather complex. Among the considerations to be considered in the analysis of the decision to migrate to Cloud Computing are data portability, information confidentiality, service level agreements, interoperability and more. There are different types of Cloud Computing services, the main ones being related to computer applications (SaaS - Software as a Service), application development platform (PaaS - Platform as a Service) and infrastructure services (IaaS - Infrastructure as a Service), the latter consisting of virtual server networks or clusters, network software and data storage, in a system designed to enhance or replace the functions of a data center. At the same time, there are different forms of implementation for the Cloud Computing model: private (internal or external), public, hybrid, community.

Results Interpretation

Respondents from the category of companies providing components, solutions and IT services participating in the first part of the study consider that the most important types of advantages pursued by Romanian companies in relation to IT use are automation (81%) and operational efficiency (70%) according to Figure 1.

Fig. 1: Advantages pursued by Romanian companies regarding digitalization

This result indicates the opinion of the respondents on the way information technology is perceived in Romanian companies and the basic level of its use. There is also a focus on serving customers in new ways. 40% of participants rank this advantage among the top three most important. While the number of mobile Internet users is increasing, and in Romania it is relatively high, it is expected that Romanian companies will direct initiatives and marketing messages towards the mobile communication environment. It is also expected that more and more companies will act to meet the desires of employees to use mobile technology. We consider that this new orientation is noticeable in the responses of IT providers, when highlighting departments / areas of organizations in Romania that are mainly targeted by solutions and services in the field of mobility (Figure 2). After the sales function (90%), the marketing and production (60%) are starting to gain attention in terms of the application of mobile technology.

Fig. 2: Organizational areas targeted by IT solutions for mobility

Cloud Computing services and solutions are currently located in an area of low interest for Romanian companies. Most participants indicate a weak or rather weak interest in this regard (62%), while 38% appreciate the interest of Romanian companies for the Cloud Computing model as average. As factors that slow down the adoption of advanced information technologies among Romanian companies, most respondents among suppliers (56%) consider that financial problems are critical, and 33% of participants note them as important. The financial

difficulties are considered the most significant in the process of adopting advanced information technologies in Romanian companies. Considerations related to the difficulty of organizational change are also noted. These are considered as critical factors in slowing down the process of technological renewal by 31% of IT providers and noted as important by 56% of them.

It is found that the most common problems raised by organizations regarding computing technology are related to the investment in advanced information technology. This result confirms the opinion expressed by the IT systems and solution providers who participated in the research, but the financial difficulty is noted only by 38% of the respondents (Figure 3).

Fig. 3: Difficulties encountered with information solutions

In second place in terms of reported difficulties is the need for information and training on new technologies (32%). It is noteworthy that one third of respondents do not face problems in terms of computing technology. Regarding the presence in the online environment, it is observed (Figure 4) that most of it is based on the existence of a dedicated website (90%), while the next tool, social networks are indicated in a much lower percentage. (40%). Only 7% of companies use Web 2.0 tools such as wikis, blogs or forums.

Fig. 4: Presence in online environment

The degree of availability of the participating companies to invest in services / applications in the Cloud computing model is rather low (Figure 5).

Confirming the findings of the research, the answers highlight the low availability that exists in the companies participating in the study for the adoption of the Cloud Computing model. Only 20% of respondents indicate high interest regarding it inside the company they represent. The answers obtained from the set of questions aimed at line management and non-leadership staff reveal the increased importance for respondents of the following elements:

faster access to the data they work with, easier access to them, activities in a mobile environment, workplace flexibility, better computing technology and the presence of an internal social platform.

Fig. 5: Availability of companies to invest in Cloud Computing

Conclusion

It is noteworthy that the last place as an average value of the importance indices selected by the participants is occupied by the presence of internal social media, and this is explained by the fact that their usefulness and potential are understood and valued only after their use. Also, where they are present, capitalizing on their business potential requires involvement from participants and management support through promotion, cordial guidance and an encouraging attitude and lacks tension. Finally, we emphasize that the advanced information technologies that are the subject of this study are disruptive to the business environment. This implies the emergence of important opportunities for organizations as well as major organizations change. As in the case of the previous disruptive innovation (e.g. the introduction of the Internet in the business environment), and in the case of the adoption of the Cloud Computing model there is a period of time when this transition is optional and some entrepreneurs and business decision makers prefer to postpone it. However, the adoption of the new model will gradually turn from desideratum to imperative. Both IT solutions and services will continue to develop in accordance with the Cloud IT model, in order to operate in such a paradigm. For this reason, those companies that maintain or even develop the traditional IT model risk having increasingly limited access to state-of-the-art IT technologies and solutions. According to the study the Romanian companies do not tend to invest in Cloud Computing solutions especially due to their high costs. Nevertheless, the majority of the respondents work for companies that have a website which now is considered to be a key element in the online environment. When it comes to the implementation of information technologies there are a serios of challenges at organizational level.

Abstract

Developing socially responsible university's good practices requires HEIs stakeholders' identification and conscious relationships. Students constitute numerous, important stakeholders. The HEI's basic activity is connected with them – education supported by science development and relationships with the surroundings, where students will find employment and HEI - opportunities to conduct research. Social responsibility principles realization requires HEI to identify students' needs and expectations and include them in its activity; from students – active attitude and engagement. The study's aim is identifying the gap between students' expectations towards socially responsible university and perception of these activities. Knowing differences between expectations and perception enables modification and improvement of activities resulting from the university's social responsibility strategy. On the other hand, as in one Polish HEI – Gdynia Maritime University (UMG) which lacks such a strategy, knowing the gap can come useful when designing activities in the social responsibility strategy. To this end, expectations and students' perception towards Socially Responsible University were compared on the UMG example. The study is based on the analysis of the literature and questionnaire research results obtained in the Authors' two research projects.

Keywords: Socially Responsible University, Dimensions of The University's Social Responsibility, SRU Strategy, Gap Between Expectations and Perception.

Introduction

In the contemporary knowledge-based economy, in times of globalization, technology development, climate change, and economic and values crises not only enterprises must enjoy economic growth and a high position on the market simultaneously taking care of natural environment and social expectations and needs.

Nowadays, all organisations, including higher education institutions (HEIs), must practice social responsibility in their daily activities and development strategy. Establishing socially responsible universities' good practices requires knowledge about stakeholders, their problems, needs and expectations towards HEIs and their conscious modification. Among the university stakeholders the most important are students (Berman, 1990). The HEIs basic activity is their education (Ławicka, 2016) supported by science development and relationships with the surroundings, where graduates find employment and the university - opportunities to conduct research (Leja 2013). Developing mutual relationship: university-student based on social responsibility principles requires the university to know students' needs and expectations and taking them into account in its activity (and development strategy) as well as students' active attitude and engagement. The study's aim is identifying the gap between students' expectations towards Socially Responsible University (SRU) and perception of its activities. Knowing this gap allows, on the one hand, modification and enhancement of activities of university's social responsibility. On the other hand, as in Gdynia Maritime University (GMU) that lacks this strategy, it can be useful in its development. To this end, students' expectations and their SRU perception were compared on the example of the Faculty of

Expectations and the Reality in Students' Opinion as Guidelines to Refine the Social Responsibility Strategy" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Entrepreneurship and Quality Science (FEQS) in GMU (Poland). The study's first part presents SRU essence and characterizes its dimensions found in the literature and its dimensions identified and ranked by students during the Authors' first research project. Then, the second research project' results concerning students' evaluation of definite activities in the investigated university (within specified areas) with regard to their compliance with the SRU concept were briefly characterized. Identification of the gap is useful in designing activities when preparing the social responsibility strategy meeting stakeholders' (here: students) needs and requirements.

Organisation's Social Responsibility essence (Corporate Social Responsibility; CRS)

The CSR concept coined and disseminated in the second half of 20th century is mainly associated with enterprises, which it obligates to develop the policy, make decisions and choose economic activity respecting the society's aims and values (Raport, 2011).

CSR can be defined as the management concept oriented towards long-lasting, positive relationships with various stakeholders integrating economic, legal, social, ethical and environmental aspects of enterprises' operation. It comes from the assumption that generating profits can and should incorporate a widely understood care for social and natural environment (Teneta-Skwiercz, 2013).

Globalization and social-economic, technical and technological development as well as changes in the world, financial crisis of the first decade of 21st century and its impact on the world economy spurred CSR development and showed there is no escape from social responsibility (Smith, Lenssen, 2009). They made it clear that not only enterprises should be socially responsible, but all organisations around (Spodarczyk, 2015; Wolska, Kizielewicz, 2015).

ISO 26000 states that each organisation should "assume responsibility for its decisions and activities' impact on the society and environment through transparent and ethical behaviour" (ISO 26000, 2015).

ISO 26000 is popular and recognized guidance - the universal approach adaptable to specificity of each organisation willing to behave in a responsible way (Raport, 2011).

Implementing socially responsible activities by any organisation requires planning the social responsibility strategy (Cybal-Michalska, 2015). The first step for its effective preparation and implementation is identifying the organisation's main stakeholders, their needs and expectations, which the organisation should satisfy (Teneta-Skwiercz, 2013). The organisation's main external stakeholders are enterprises, purchasers (including consumers); local, regional and central authorities, nongovernmental organisations, banks, HEIs and natural environment (as nonperson stakeholder that we all should care for). The organisation's internal stakeholders are its employees.

Due to HEIs' specific tasks in the country's social-economic system and their civilization-cultural role (Białoń, Werner, 2012; Dima et al., 2013; Cichowicz, Nowak, 2019), they should also be proponents of social responsibility principles (Benedek, Takács-György, 2014). They should teach them and set good examples so as to have socially responsible graduates (citizens) (Społeczna odpowiedzialność, 2019). In HEIs, external stakeholders (except these already mentioned) are also candidates, their parents, graduates, advisory organs (supervision) working with the university's Senate, the region (country) community (Ławicka, 2016), and as internal stakeholders - also students, administration workers and academic staff.

University Social Responsibility and its dimensions

A socially responsible university is a HEI serving the surroundings. Its responsibility towards the society involves preparing graduates to become knowledge employees and building close relationships with economic practice and local governments (Leja, 2013). University Social Responsibility means a strategic and systems approach to managing HEIs and developing cooperation and dialogue with stakeholders, which contributes to sustainable development, building values and attitudes in the citizen society, supporting academic values and creating new ideas, keeping and developing scientific-didactic competences that influence effectiveness and innovativeness (Społeczna odpowiedzialność, 2019). So SRU, apart from classical dimensions: ecological, social and economic, takes into account also the scientific-didactic dimension. It requires development of the social responsibility strategy, whose aims are oriented towards satisfying the main stakeholders' needs and expectations and incorporating them in CSR education programs (Ławicka, 2016).

University Social Responsibility issues are becoming increasingly significant. More and more HEIs worldwide are implementing the social responsibility strategy and its good practices, which is reflected in various international organizations' reports (Cichowicz, Nowak, 2019). For instance, business universities introduce practices based on the Principles for Responsible Management Education (PRME) (within the program: Global Compact ONZ, 2007). They are based on six principles of responsible management education: purpose, values, method, research, partnership and dialogue (Koksal Arac, Madran, 2013) and enable students to understand the sustainable development subject so that in the future – as economic life members – they can balance its aims with enterprises' economic aims (PRME, 2019). Among 767 signatories worldwide Poland is represented only by a few HEIs[1] (Roszkowska-Śliż, 2010; Popowska, 2016; Społeczna odpowiedzialność, 2019). Five best European universities[2] have undertaken socially responsible activities focusing on the areas: education for sustainable development, responsible campus, social responsibility culture, ethical leadership, dialogue with the society, social responsibility of science. The world best universities[3] (Społeczna odpowiedzialność, 2019) and Polish signatories[4] (Lista sygnatariuszy Deklaracji SOU, 2019) of University Social Responsibility Declaration (Deklaracja SRU) refer to the UN's Sustainable Development Goals (SDGs) stated in the 2030 Agenda. The SRU declaration was formulated in 2017 as a result of academic community cooperation with the then Ministry of Development (Społeczna odpowiedzialność, 2019). Twelve principles of SR in it refer to ethics, graduates' social and citizen attitudes, promoting social responsibility principles and sustainable development in study programs, scientific research and implementation projects within partnerships with various entities, dialogues with the surroundings, and engagement in the form of voluntary work, care for the university organisational order or its responsibility for natural environment (Deklaracja Społecznej Odpowiedzialności Uczelni, 2017).

Although Polish HEIs are nowadays more frequently implementing the socially responsible activities strategy, it is not yet common practice (Karwowska, Leja, 2019). For many universities it is still one-time action (Leoński, 2019). Few HEIs refer to University Social Responsibility Declaration or PRME. Most often examples of socially responsible universities' good practices are based on ISO 26000 and its main areas (Leoński, 2019; Mackiewicz et al., 2018), or they concern the main SRU dimensions resulting directly from its definition due to its universality, i.e.: economic, environmental, social and educational dimension (Karwowska, Leja, 2018). Universities also independently undertake initiatives to formulate cooperation principles with selected stakeholders not following indicated examples or modifying them for their own needs. The key to formulate effectively social responsibility good practices (and the strategy) is identifying the university's main stakeholders and their needs/expectations in mutual relationships (Szelągowska-Rudzka, Spodarczyk, 2018).

Socially Responsible University activities oriented towards students

The most important HEIs stakeholders are students; you must start from them when developing relationships and university's activities based on social responsibility principles (including the strategy development), because the university's socially responsible activities correspond to its main activity: education, science development and relationships with stakeholders (Leja, 2013). Their aim is ensuring the appropriate education quality, knowledge transfer to the economy, boosting growth and satisfying the contemporary society's needs, future elites education, active social policy towards students and employees and social barriers elimination (Piasecka, 2015; Cybal-Michalska, 2015). With regard to students – future graduates – these activities must ensure education that will enable them to actively participate in the civilization development, practice their profession and become a desirable professional on the local and global job market. To this end, the university must have a wide didactic offer, competent staff, university culture (the way students are treated, their attitudes formed), adequate material resources (classrooms equipment, laboratories, library, reading room, social base), and contacts with the scientific and business community, the region and abroad (internships, foreign exchange, etc.) (Ławicka 2016; Kowalska 2009; Białoń, Werner, 2012). It is also indispensable to refer to students' (stakeholders) needs and expectations and take them into account in daily activities. The Authors think the actual realization of socially responsible activities requires a conscious approach and engagement of all parties, the university and students (or other stakeholders groups).

Stakeholders will engage more in the university's activities if they feel they are right. The Authors identified the most important for students SRU dimensions in their relationships with the university: values, relationships, graduate, education and effective organisation (Szelągowska-Rudzka, Spodarczyk 2018). The Authors agree with the literature view that the basis for socially responsible activities are values (Kowalska, 2009; Cybal-Michalska, 2015) and relationships between the parties (Piasecka, 2015), here: university-students, whose effect thanks to the education process and effective organisation is the graduate desirable in the present job market. This graduate will acquire competences and values, whose basis is respect for work, tolerance, readiness to help, honesty in relationships, respect for others and for natural environment, and the university's worthy representation (Szelągowska-Rudzka, Spodarczyk 2018).

The most important identified dimension of University Social Responsibility for surveyed students is education, whose final outcome is the graduate with competences desired by the market, but without excessive engagement (rather a beneficiary of the university's activities).

It must be emphasized that FEQS neither has the social responsibility strategy nor realizes formalized socially responsible practices – only II-cycle students have the subject: Corporate Social Responsibility.

Lack of the social responsibility formal strategy does not prevent students from evaluating selected areas, especially that their proposals of areas: values, relationships, education, graduate and effective organisation are integral elements of each university and as essential from the social responsibility perspective they can and should be identified when refining the strategy and taken into account before its development and modification of its activities.

Research Characteristics

This study's main aim is identifying the gap between students' expectations towards socially responsible university (SRU) and their perception of its activities to modify the pursued strategy or to plan activities of the social responsibility future strategy. The research was realized on the example of FEQS, UMG. The following detailed objectives were adopted:

- identifying students' expectations towards socially responsible university
- indicating students' perception of identified SRU activities on the example of FEQS
- identifying the gap between students' expectations towards SRU and perception of the university's activities in selected social responsibility areas (values, graduate, education, effective organisation).

The aim was achieved using the results of the Authors' two independent research projects realized in FEQS.

Within the first project the Authors conducted the qualitative research using brainstorming, 2017) as there was a need to identify social responsibility areas essential for students taking into account HEI's operation specificity. As a result, the following university's social responsibility areas proposed by students were identified: values, relationships, graduate, education, effective organisation). In the successive qualitative research (sample of 242 FEQS students; the auditory questionnaire, 2019) importance of the areas for students and detailed features describing them were determined.

The other research project consisted in a questionnaire (2018). Respondents were asked to evaluate selected activities undertaken by the university and then these activities were assigned to social responsibility areas of ISO 26000 and adapted to the university's specificity (c.f. Mackiewicz et al, 2018). The study comprised 111 students and the auditory questionnaire was the method to collect data.

Some activities proposed by students within the first project overlapped with activities of ISO 26000 - the subject of the other research project. Therefore, the Authors decided to identify the gap between students' expectations and perception of these activities using both projects results as they could be later used to develop activities of the planned (future) social responsibility strategy.

Results

Basing on the first research project results, the Authors identified the university's five social responsibility areas (values, relationships, graduate, education, effective organisation) and their importance from the students' perspective (Szelągowska-Rudzka, Spodarczyk, 2018; Spodarczyk, Szelągowska-Rudzka, 2019). Respondents when asked how important are features characterizing particular areas, mostly stated that they all should characterize the university socially responsible towards students. Therefore, the Authors focused on answers "definitely yes" (and not on averages) as they reflect the students' determined attitude (absolute conviction) towards investigated features and simultaneously demonstrate their certain hierarchy. In the comparative analysis of selected research results presented below the Authors also focused on answers "definitely yes" and only their percentage values are presented in Table 1. From all the analyzed features of the proposed SRU areas only these corresponding to ISO 26000 dimensions were chosen.

It results from the comparative analysis that education, as expected from HEI's activity essence, was identified as the most important area for socially responsible university. It is proved by the highest number of "definitely yes"

responses to features characterizing this area (provides scientific-didactic staff on the appropriate level (…) and education for the job market needs) (Detailed data is collected in Table 1). The effect of the highly valued by respondents education quality is the graduate meeting the job market expectations (38%). The next important SRU area is effective organisation (ensures material support for students, 37%; has the modern didactic base (…), 32%). The lowest respondents' expectations level (11% to 27%) concerns features representing the values area (educates; cares for natural environment; instils universal values in students (…)) (Table 1).

Table 1: Socially responsible HEI. Expectations and students' perception

Features of socially responsible HEI:	Area of SRU	Answers "definitely yes" (%)		Gap (O-P)
		Expectations (O)	Perception (P)	
ensures scientific-didactic staff on the appropriate level (knowledge, skills to transfer it)	K	42		
my university has high quality human resources (administration workers, lecturers, university authorities)			31	11
educates for the job market needs	K	42		
my university is characterized by high quality educa-tion, development of skills desired by the job market			12	30
prepares graduates who meet the job market needs	A	38		
I am satisfied with services offered by the university			10	28
my decision to choose this university was right			17	21
I will recommend my university to others			18	20
I am proud I am a student at this university			21	17
provides material support to students	O	37		
supports physical development, ensures medical care			8	29
offers help to minorities and students with special needs (social benefits)			15	22
is characterized by lecturers' engagement in classes	K	34		
quality of classes conducted by scientific-didactic staff is high			14	20
has the modern didactic base (equipment of classes and laboratories)	O	32		
creates material conditions to study: library, reading-room			21	11
ensures access to didactic materials			16	5

Then, to the anticipated SRU features, respondents' evaluation of the level of their realization by the investigated university (perception) were assigned (the other research project). The feature most valued among respondents (31%) was ensuring high quality human resources by the investigated university. This feature is connected with education dimension. Evaluation of the other features relating to all investigated SRU areas (including education) varies and therefore when interpreting results the focus was to identify the gap (Table 1). It was achieved by indicating the difference between the number of answers concerning expectations towards SRU features and the number of answers concerning realization of selected WPiT activities concerning the Authors' proposed areas.

With all the investigated features (for identified SRU areas) respondents' expectations are higher than perception of their realization level. Differences are from 3 to 30 points. The biggest gaps (about 20-30 points) concern features characterizing the areas: education (my university is characterized by high quality education (30 points), quality of classes conducted by scientific-didactic staff is high (20 points); graduate (e.g. I am satisfied with services offered by the university (28 points); my decision to choose this university was right (21 points), I will recommend my university to others (20 points) and effective organisation (supports physical development, ensures medical care (28 points), offers help to minorities and students with special needs (22 points). The smallest differences (3 to 12 points) occur with features representing the area: values (educates within human and social values, disseminates citizens' solidarity (3 points), develops individual responsibility (12 points)) (Table 1).

Conclusions and Discussion

The conducted research results indicate that for students the most important social responsibility dimension is education, which is not surprising. Choosing to study they want to acquire solid knowledge and simultaneously increase their chances on the job market. Undoubtedly, the university's good organisation, among others: ensuring the appropriate study conditions by creating the material base (classrooms equipment, libraries, etc.) and nonmaterial benefits (respecting student's time, ensuring various development forms, medical care) facilitates effective knowledge acquisition (developing future graduates' competences, who will find employment in various organisations).

To a lesser extent, respondents recognize importance of values as the SRU area. It does not mean, however, that this area should be treated as marginal by the university authorities. Students' education and scientific research are the main HEIs' aims. Yet the university, due to its specificity, also plays the significant educating, opinion-forming and quite often expert role (thanks to professional staff). Therefore, it is predisposed, as no other organisations, to be socially responsible. It is responsible not only for equipping students (and later graduates) with hard competences (knowledge), but also making them sensitive to ethical, environmental and social issues (soft competences). Even if students do not yet recognize importance of these competences, HEI is obliged to raise their awareness by introducing CSR classes and, above all, by its own example of such activities and the academic community' engagement in them. Also, the system of values and relationships based on them constitutes the indispensable base.

In the presented comparative analysis, the relationships dimension was not included. Lack of reference to this area is a result of not taking it into considerations in the research on students' perception of the university's socially reliable practices. It is so, because in ISO 26000 such area does not exist. Therefore, the Authors think this is one of premises to conduct research on specificity of HEI social responsibility. Identification of areas essential for stakeholders will enable developing the social responsibility strategy and activities resulting from it, which will not be only "image" practices, but will reflect care for really important things. The widely understood academic community's engagement in developing socially responsible university can lead to stakeholders' real participation in implementation of activities they proposed. Such an approach can also raise awareness of social responsibilities issues and simultaneously make them not only executives of this strategy, but "guardians" of the principles they established. When developing (and investigating) University Social Responsibility it is indispensable to refer to relationships as the dimension which proved essential for students (the most important internal stakeholders; Berman, 1990). This also confirms importance of reference to stakeholders' expectations in effective development of mutual cooperation based on social responsibility principles.

The comparative analysis results showed that in all University Social Responsibility areas (values, graduate, education, effective organisation) and activities characterizing them the real situation does not meet respondents' expectations (Table 1). It is worrying that the greatest gaps occur in the most important activities according to respondents, which is the area: education. Basically, only in one case (my university has high quality human resources) there was a smaller gap. The question arises why high quality staff does not guarantee high quality education and students' satisfaction? This is an important problem in the investigated university. Perhaps the answer should be: teaching methods, the way of transferring knowledge, study programs or their organisation (insufficient contacts with enterprises, other HEIs). In order to eliminate this gap, it is worth identifying its cause

and undertaking correction activities. Here this could mean e.g. increasing academic staff's didactic and communication competences, involving entrepreneurs (employers) in programs creation, more intensive cooperation and experience exchange with HEIs, which have greater didactic competences or better-established relationships with economic practice. Also improving organisation of the university's work and didactic classes' realization can contribute to students' better perception and streamline the educational process. Perhaps students and workers should be also encouraged to share their opinions, suggestions, and reservations in order to develop good practices and the university's social responsibility strategy. It will also affect university evaluation from the graduate's perspective (ambassador of the university's socially responsible activities in the social-economic surroundings).

In the values area (similarly to some features related to education) the gap between expectations towards University Social Responsibility and the actual situation evaluated by students is also relatively small. The Authors doubt whether this is because the university's activities in this area are on such a high level or because this area is rather underestimated by students. As it results from considerations so far, developing the university's social responsibility without emphasizing values and relationships with stakeholders is not recommended. The HEI strategy should aim at showing students the appropriate ethical examples based on human rights, respect, tolerance and openness to new ideas and another person. These assumptions will constitute the basis for students' education, whose value on the job market will not only mean hard, specialist competences, but also their responsible use. Therefore, the university should refer to internal stakeholders' opinions, their needs and expectations, their definite proposals of activities which will develop the university's social responsibility practices and will be included in its strategy. This does not stand in contradiction to dimensions of University Social Responsibility - ISO 26000, SRU Declaration or practices and examples promoted by the best European or world HEIs (Społeczna odpowiedzialność, 2019). On the contrary, it can significantly complement them and enrich, because developing relationships with the university's stakeholders requires their engagement in the process of developing good practices and the social responsibility strategy.

Summing up, developing the university's social responsibility strategy depends on the right identification of stakeholders, among who the most important are: students, future students, employees (academic staff, administration and technical workers), graduates, employers, local community, local government (regional, central) and natural environment. Each stakeholders group can have slightly different expectations towards Socially Responsible University. The Authors started from research on students' expectations towards the university social responsibility areas. They intend to continue research on other stakeholders groups. The identified areas will constitute the basis for universal guidelines/proposals for the university. It is interesting for the Authors to see if the areas identified in this way will correspond to the areas proposed by other researchers, SRU Declaration (2017) or practices based on PRME. The next step in developing the strategy is to determine importance of particular areas and activities in these areas. The results of cyclical research, whose aim will be to identify the gap between expectations and stakeholders' perception, will enable improvement of university's social responsibility. It will be possible thanks to monitoring the university's impact on particular group and fast response when the stakeholders' good is threatened.

The Role of the Sense of Security in Times of Covid-19 Pandemic - The Research of the Young Polish Employees

Ewa MATUSKA

Wojciech PIESTRZYNSKI

Pomeranian University, Slupsk, Poland
wojciech.piestrzynski@apsl.edu.pl

Abstract

The paper presents the analysis of quantitative research conducted during first two months of the lockdown caused by Covid-19 pandemic among the sample of (N=189) Polish employees representing youngest work generations (Millennials). Two variables: the sense of security and depression symptoms were statistically controlled via two-way analysis followed. The study assumed that young employees, depending on belonging to a particular gender, differ in their psychological reception of the psycho- social threats induced by coronavirus crisis: women are more keen to react with depression although the level of the personal sense of security of men and women stays on moderately high level. Moreover, the level of personal security determines the severity of depression symptoms in a such way that the higher the intensity of the sense of security, the lower the intensity of the characteristics of depression. The found results can be used as recommendations for introducing more holistic well-being and health and safety system measures in organizations.

Keywords: Sense of Security, Depressiveness of Employees, COVID-19 Crisis, Organizational Health and Safety System

Introduction

The global COVID-19 health crisis has caused collateral damage by amplifying totally unexpected economic and psychosocial threats, dangerous for mental well-being of individuals and employees. Main socio-economical threats are bankruptcy and minimized activity of many companies (Tucker 2020) what implies significant rise of unemployment. Recent McKinsey's analysis estimates (Chinn et al, 2020) that up to COVID-19 crisis nearly 59 million jobs will be closed (cc 26 percent of total employment across Europe). The key challenges imposed by the crisis are also rapid demands for changes in routine business models and connected with this challenges put in front of the workforce and managers (Ritter and Pedersen 2020b). Employees can feel not only real danger of possible job loss or minimized salary, but also threat of social isolation, feeling overloading with new mode of work (i.e. remote or hybrid) or of the pression to overtake gaps in their professional skills, especially connected with ICT (Information Communication Technology). Managers have to find fast adequate supportive solutions to help their workforce in crisis situation as there is an urgent need to develop adaptative organizational measures protecting not only physical but also a mental health of employees and guaranteeing their sufficient work efficiency (Ritter and Pedersen, 2020a). There are suggestions that nowadays HR systems should be more relationship-oriented in order to combat the risk of prolonged isolation among employees working remotely and to better prepare them for situations like the current crisis (Carnevale and Hatak 2020).

The main theory underlying this approach is the wide concept of human and social well-being and a bride concept of life satisfaction, where economics and sense of personal and social security are interconnected (Wills-Herrera et al 2011). In a such way, the physical and psychosocial security context disrupted by current coronavirus crisis determines not only economic survival but also basic conditions for development of individuals and organizations. Employees representing particular work generations probably differ in their reception of the current crisis situation.

It is probably the source of the high psychological stress especially for the youngest employees (Millennials) as they till now didn't experience economic crisis in their professional life.

In a line with above assumptions this paper has been conceptualized. Authors has based on the literature review and on the basis of the own quantitative research done via two questionnaires disseminated on-line: A. Beck's Inventory (IDB - Beck Depression Inventory) and non-standardized questionnaire regarding the subjective sense of security.

Research Design

A sample of 189 working women and men, aged 20-35, from region of Pomerania in Poland, randomly selected, was tested for their sense of security and susceptibility to being infected with depression symptoms in connection with the ongoing epidemiological COVID-19 threat. The study was conducted at the turn of April and May 2020, when pandemic restrictions were strict as the speed and range of the disease spread was high. The research was done by indirect testing method, using two on-line versions questionnaires: A. Beck's Inventory (IDB - Beck Depression Inventory) and non-standardized questionnaire regarding the sense of security. Subgroups of respondents, female and male, did not differ significantly regarding to the age (see Table 1) and were 26 years old per average.

Table 1: Descriptive statistics of the age of respondents

Gender	N	Min.	Max.	Median	Average	SD	Bias	Kurtosis
F	91	20	35	26	26.45	4.49	.5539	- .80518
M	98	21	35	26	27.13	3.75	.4813	- .5815
(U = 3881.5, z =1.53552, p =.12356)								

Source: own elaboration

Results and Discussion

The following research problems were formulated: 1. *Does gender differ intensity of the sense of security and depression symptoms of young employees experiencing the first phase of coronavirus crisis?* 2. *To what extent does the sense of security correlate with depression symptoms that are represented by the study groups?*

Table 2 summarizes descriptive statistics of the sense of security for examined employed young women and men. The average sense of security for women was slightly higher than for men. The study groups differ slightly in terms of standard deviation. Nevertheless, statistically analyzing both groups, it cannot definitely be said that they differ statistically significantly in perceiving personal security (U = 4227.5, z = -. 6147, p = .5418). Therefore, it should be noted that all examined respondents had a moderate and moderately high sense of security. This indicates that the real threat caused by the COVID-19 pandemic did not significantly disturb the sense of security of the surveyed young employees.

Table 2: Descriptive statistics of the sense of security of respondents

Gender	N	Min.	Max.	Median	Average	SD	Bias	Kurtosis
F	91	1	5	5	4.37	.8117	.917	- .4447
M	98	1	5	5	4.26	.9366	1.40	1.918
(U = 4227.5, z = -.6147, p = .5418)								

Source: own elaboration

Considering the phenomenon of examined depression symptoms among young employees, it should be emphasized that there are statistical differences in their intensity in the studied groups (U = 3504.5,

z = -2.5388, p = .01108). Greater saturation of depressive features can be seen in young women. The final picture of this phenomenon is justified by the average (F35 = 9.03, M35 = 7.85), (see Table 3).

Table 3: Descriptive statistics of depression symptoms of respondents

Gender	N	Min.	Max.	Median	Average	SD	Bias	Kurtosis
F	91	0	34	7	9.03	7,99	1.168	.9229
M	98	0	58	3.5	7.85	10.76	2. 312	..6.4814
(U = 3504.5, z = -2.5388, p =.01108)								

Source: own elaboration

Searching for the answer for the second problem *('Is there a relationship between depression and sense of security?'*) the Pearson's correlation indexation was used (see Table 4). With its help it was established that the examined women make their sense of security dependent on the intensity of depression-specific characteristics (r = .3078; p = .002997). The research did not show such a relationship for the examined men (r = - .1632; p = .10835).

Table 4: Correlates between depressive symptoms and the sense of security of the F/M respondents

Gender (N)	Variable 1	Variable 2	Pearson's r	p < 0,05
F 91	Depression	Sense of security	.3078	.002997
M 98	Depression	Sense of security	- .1632	.10835

Source: own elaboration

Summarizing obtained results, Polish young employees occurred to be mostly free from depressive symptoms and have experienced the subjective sense of security on the moderate level despite of the stressful pandemic situation examined at the turn of April and May 2020. However, the tendence to react in a depressive way in connection to experienced level of the sense of security was discovered in a case of surveyed women, but not in case of the male subgroup.

Conclusions

Coronavirus pandemic crisis demands for deep adjustments from side of employees regardless of their age, although especially youngest work generations can be especially vulnerable for the reception of different threats imposed by this situation. In times of coronavirus crisis not only physical health of employees' but also their psycho-social health is highly insecure. Thus it seems to be useful to introduce a holistic view on the health and safety system in organizations. The first step in this direction should be adequate recognizing the "weak points" of the psychological health of the employees' and the fields of possible intervention on organizational level, especially in a company health and safety systems. According to presented research health risky subgroup of Polish employees seem to be young women who tend to react in a more depressive way in compare to male in high stressful situation like the current pandemic crisis. They need a special attention and support which should be proposed by the respective HR units in theirs organizations

Abstract

The article describes topical issues of freedom of religion and prevention of religious discrimination in the US education system. It examines constitutional provisions, judicial decisions, legal materials and the president's position on the interaction of religion, the state and the education system. The practice of the US Supreme Court on the financing of religious higher education institutions, the conduct of religious ceremonies and the use of religious symbols is analyzed. The article seeks to comment on academic freedom in the context of free expression of religious beliefs, as well as the activities of religious associations in the system of education.

Keywords: Religion, Education, US Constitutional Law, US Supreme Court, Principle of Equality, Discrimination

Funding : The study was funded by the Russian Foundation for Basic Research № 19-011-00559

Introduction

The issues of interaction between religion, the education system and the state have been very significant for Russian society over the past decades. In the post-industrial and information society, education acquires key importance for the development of various aspects of public life such as economic prosperity of the country, development of social infrastructure, active political and, in particular, electoral culture (Nikolaev B.V., Emelin M.Yu., Pavlova N.A., 2020), spiritual and moral foundations of society. After many years of communist ideology Russia has been restoring religion as one of the most important spiritual foundations of society. That is why the study of the long experience of the United States in the field of legal interaction between religion and education is of particular scientific importance and relevance.

The constitutional principle of equality and non-discrimination has traditionally been foundational to the US legal system (Nikolaev B.V., Pavlova N.A., 2018). In recent decades, education has gained particular importance in terms of combating discrimination on the basis of race, gender, disability (Nikolaev, 2010), age (Nikolaev B.V., Pavlova N.A., 2016) and other grounds. The prohibition of racial and national discrimination "is a fundamental imperative for the entire American legal system". (Nikolaev, 2018)

One of the most pressing issues of legal regulation of education in the United States is the issue of interaction between church, state and school. Originally education in the United States had strong religious roots, if not exclusively religious origins. Even in the colonial period educational institutions were established under the

Cite this Article as: Boris V. NIKOLAEV, Nataliia A. PAVLOVA and Mikhail Yu. EMELIN" Religion and Education: Law and Practice in the USA" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

patronage or strong influence of the Christian Church, and, despite the secular trends of the War of Independence era the 1820s became a turning point in the spread of a new type of the so-called denominational colleges established by religious minorities precisely to preserve religious education. (Geiger, 2005) At the same time, the following decades witnessed the growing secularization of both American society in general and the education system in particular.

Other factors of American reality give even greater social and legal significance to religious themes in the US education sector. Here belong extraordinary diversity of religious movements, the decentralized structure of the federation and various legal regulation of issues of religion and church in the US states; stable national traditions that inevitably bring religious motives into education; rather flexible court practice in those matters, and finally, the fact that it was cases in education that became, perhaps, the basis for the development of the general theory and practice of the American judicial system on the issues of interaction between the church and the state.

On the one hand, the modern United States demonstrate religious tolerance, freedom, and diversity; on the other hand, the church continues to have a significant influence on public policy, the social environment, and the education system. Thus, out of 32,500 private schools, 22 percent were Catholic, 45 percent were from other denominations, and only 33 percent had no religious affiliation. Religious affiliation affects the number of students in schools. For example, there were fewer Catholic schools (3 percent) than non-denominational schools (39 percent), and there were very few other religious schools (40 percent) (that is, they had 50 or fewer students). In addition, there was a higher percentage of Catholic schools (5 percent) than non-sectarian schools, and other religious schools (2 percent each) were very large (with 750 or more students).(Hussar, 2020)

In 2017, the United States had 878 religious institutions of higher education, and the number of students reached 1,885,965 people. Unconditional leadership belongs to the Catholic Church (229 institutions), followed by the United Methodists (94 institutions), Baptists (64 institutions), the Presbyterian Church (56 institutions), Jewish institutions (34), the Evangelical Lutheran Church in America (27 institutions). Of particular note is the growth (from 1980 to 2017) in the number of religious institutions of higher education (Interdenominational – from four to 34, as well as Undenominational – from zero to 20) (Snyder, 2019). There is a tendency towards an increase in the number of doubters, as well as adherents of "spiritual, but not religious" beliefs (Miller, 2016)

The influence of the church has been significant in recent decades, and even increased during the presidency of conservative Republicans. All this happened despite the tendency to secularize public life and the higher education system. Thus, President R. Reagan repeatedly pointed out that, in his opinion, morning prayer was necessary in public schools, and he would support a constitutional amendment that overturned the decisions of the Supreme Court in the 1960s. (Grant, 2004)

At the beginning of the 21st century, the George W. Bush administration maintained a close and developing relationship between the state and religion, which caused conflicting assessments on the part of researchers. This continued until the recognition of the "new theocracy" in the modern USA (Buchanan, 2005).

Some changes in state policy took place during the period of Barack Obama's Democratic administration (the initiatives to withdraw the constitutional amendment banning homosexual marriages and expanding guarantees for the protection of the rights of sexual minorities, and removing barriers to research on stem cells). At the same time, the powers of the White House Office for religious organizations and local communities, created by the previous president, were confirmed and even expanded (Executive Order 13498 Amendments to Executive Order 13199 and Establishment of the President's Advisory Council for Faith-Based and Neighborhood Partnerships, February 5, 2009 , 74 FR 6533, February 9, 2009).

The Trump administration actively supported the idea of freedom of religion in difficult times when traditional religious values and the new mainstream ideas of American public and political life clashed in defense of the rights of sexual minorities and transgender people. Thus, in his proclamation of January 16, 2018, he recalled that "Faith is embedded in the history, spirit, and soul of our Nation", stating that "No American – whether a nun, nurse, baker, or business owner – should be forced to choose between the tenets of faith or adherence to the law." That was a direct reference to the court decisions against persons who due to their religious beliefs refused to provide services to homosexual couples. On the contrary, the official statement of the spokesman dated June 30, 2020 expressed support for the decision of the US Supreme Court in the case of *Espinoza v. Montana Department of Revenue*, 591 U.S. ___ (2020), which declared unconstitutional restrictions on state funding for private schools solely on the basis of the religious affiliation of such schools. The support of religion and religious values is also evidenced by a number of Executive Orders issued by D. Trump: EO 13926 Advancing International Religious Freedom (06/02/2020 85 FR 34951), EO 13831 Establishment of a White House Faith and Opportunity Initiative (05/03/2018. 83 FR 20715).

The US Constitution does not contain regulations on religion, and it was just the adoption of the Bill of Rights in 1798 that filled the gap in constitutional regulation. The First Amendment prohibits the establishment of religion by any constitutional or legislative act but somewhat prohibits the adoption of laws that violate or restrict free exercise of religion. In practice, the court was not always able to reconcile these decisions with complete certainty, and that, first of all, was complicated by the tough and sometimes aggressive state legislation in relation to religious communities and rituals, in particular in the field of education.

Religious issues received broader resolution in state constitutions and legislation. Only four states had basic laws establishing a particular religion after the First Amendment to the U.S. Constitution was passed. In 1833, the last of the states, Massachusetts, dropped the corresponding constitutional provisions. Modern state constitutions contain general provisions on state laws on the rights to freedom of conscience, in many cases supplemented by specific provisions on religious issues in education.

There is a significant variety of constitutional regulation of the interaction between religion and higher education at the state level, however, the most typical elements of such regulation can be distinguished (along with the general provision on freedom of conscience in bills of rights). Almost all state constitutions (with the exception of the Vermont state constitution) prohibit public funding of religious institutions and programs. Such a prohibition may be absolute, but it may also contain a number of reservations and restrictions. In addition, the state constitutions prohibit religious instruction in public education institutions; they also prohibit any discrimination on a religious basis in education, especially in admission to an education institution or employment (including the use of a religious test or qualification); prohibit compulsory religious services or ritual activities. At the same time, a number of constitutions contain a special provision on respect for religious, moral and educational values, taking into account the religious basis of public morality in many states, as well as the role of the church in the formation of the education system in general and higher education in particular.

The Civil Rights Act of 1964 became the basis for the prohibition of religious discrimination in the education system, and was supplemented by the corresponding anti-discrimination provisions of the Higher Education Act and the Primary and Secondary Education Act.

The practice of the US Supreme Court is of particular importance due to the decentralized and unsystematic legislation in this area. It was education that turned out to be a "testing ground" for the development of the Supreme Court's case law on religion. Of the eight cases published in the collection of the most important religious court cases for the 300 year period of the American history, seven are directly related to education (Johnson, 1992).

One of the basic principles in the practice of the Supreme Court is the principle of "neutrality" of the state in relation to religion and the church. The favorable "neutrality" often cited in Supreme Court cases has its roots in the history when powerful sects or groups joined efforts of the government and religious organizations to seek official support from the state or federal authorities. This is now prohibited by law.

The next reason for recognizing neutrality is that religious education and religious beliefs are the right of every person, and these are not determined by the state. The legislation guarantees this right. Thus, a violation of the freedom of religion clause implies certain coercive measures, while a violation of the establishment of religion clause does not imply such measures (School District of Abington Township v. Schempp, 374 U.S. 203 (1963).

At the same time, this kind of neutrality cannot be absolute, even if the intention of the court was to erect, in the words of T. Jefferson, "the wall of separation between the church and the state." The court in many decisions demonstrated the ability to constitutionally and legally regulate religious issues and even established direct prohibitions, especially if issues of public safety and the fight against crime were considered (in particular, in the so-called "Mormon case" or in the case of the use of drugs as an element of religious rituals). In many cases, the court recognized the possibility of state funding for religious institutions and in some cases protected the rights to worship and even propaganda of religious views presented in "open forums" in education institutions.

The judgment in *Lemon v. Kurtzman, 403 U.S. 602 (1971*) established a rule for determining religious neutrality, which includes three criteria: 1) legislative act or state action must have a secular purpose; 2) they should neither give the advantages of religion, nor hinder its implementation; 3) it is inadmissible to encourage "excessive involvement of the state" in religious issues. The court traditionally adheres to the "strict analysis" rule, which requires the public respondent to prove that the relevant actions were motivated by "irrefutable public interest" and received the most "narrowly tailored" in terms of securing such interest (Kaplin, 2007).

All education and religious cases considered by the US Supreme Court can be divided into a number of groups. The first group includes the cases of the so-called "school prayers", the second – the issues of state funding of religious institutions, the third – the issues of academic freedom and, in general, freedom of expression in a religious context in the educational environment, the fourth - other issues of ensuring freedom of conscience.

The US Supreme Court confirmed the existence of the so-called "pastor's exception". State demands on religious institutions to recruit or fire their members constitute excessive government interference in church affairs. Such actions interfere with the internal governance of the church, depriving the church of control over the choice of those who will personify its beliefs. It is important to balance "the public interest" in complying with employment discrimination laws and the interest of religious groups in choosing those who will preach their beliefs and fulfill their mission. The First Amendment establishes requirements for the dismissal of clergy in order to ensure the freedom of the church in determining the employment of its ministers. Thus, the US Supreme Court favored First Amendment guarantees over anti-discrimination provisions of the law, thus confirming one of the important exemptions in anti-discrimination policy. The doctrine of "pastor's exception" was formally interpreted by the Supreme Court. Considering the unanimity of the judges in this decision, it can be concluded that further judicial practice is directed towards the inadmissibility of interference in the organizational issues of religious groups.

The practice of the Supreme Court was quite favorable for religion in matters of protecting the right of students to participate in student forums. In 1981 (Widmar v. Vincent 454 U.S. 263 (1981)), the Court ruled unconstitutional the University of Missouri's ban on the provision of university premises to a religious student group while other student organizations were provided with premises. The court found the university's behavior unjustifiably discriminatory with regard to freedom of religious expression by students.

Of considerable interest are the cases related to the defense of academic freedom in higher education in a religious context. In *McCollum v. Board of Education* 333 U.S. 203 (1948) and *Zorach v. Clauson* 343 U.S. 306 (1952) the court considered the issue of the possibility of religious instruction in schools. The court found the practice unconstitutional in the first case, in the second, on the contrary, upheld the actions of New York state legislators. The main differences between the two programs before the Court were as follows: (1) in the first case, students who did not want to participate in the activity had to move to another room, while in the second case it was done by those wishing to attend classes; (2) in the first case, religious instruction took place in a regular classroom in a public school, while in the second, it took place outside school; (3) in the first case, the teacher and school staff worked closely with the religious instruction program, while in the second case, staff were not encouraged to persuade or coerce students into religious instruction. (Kern, 1972)

One of the most unusual ("Indeterminate" in the words of M. Chamber) (Chambers 1973) from the point of view of the general practice of the Court and its extreme indulgence in the interests and beliefs of religious groups was the case of *Wisconsin v. Yoder 406 U.S. 205* (1972), in which the Supreme Court upheld Old Order Amish followers who refused to follow school laws establishing compulsory schooling. They stated that "the introduction of compulsory schooling after the eighth grade might threaten or even destroy free expression of religious traditions within the group".

Once again, the court ruled against the head of the Christian Law Society of the University of California (*Hastings College of Law v Martinez in 561 US (June 28, 2010*) with a minimum majority. The college management rejected the application of the Christian Law Society for registration of a student organization, which would later receive the right to use the funds, equipment, and communication channels of the college. The reason for the rejection was that the provisions of the society's Statement of Faith act (requiring sexual activity only in marriage between a man and a woman) contradicted the college's open door policy, which prohibited the expulsion of students on the basis of their religious beliefs or sexual orientation. The Christian Law Society declared that the college management had violated the provisions of the Ist and XIVth amendments to the US Constitution. In the district court's view, the college did not require the Society to admit any specific groups, but only set reasonable conditions for the provision of its funds and aids, and thus pursued a neutral policy towards religion. This position was confirmed by the Court of Appeal, and then by the majority of the judges of the US Supreme Court (Judges Ginsburg, Breuer, Kennedy, Sotomayor, Stevens). The opinion of the opponents of the decision was prepared by Judge Alito (supported by Scalia, Thomas and also Chief Justice Roberts), who stated that "today's decision of the Court has violated free expression in favor of the prevailing standards of political correctness in higher education institutions of our country."

The financing of religious institutions is one of the most significant parts of the case law of the Supreme Court on the interaction of religion and education. In *Everson v. Board of Education 330 U.S. I* (1947), the court recognized constitutional the practice of state funding for travel to private schools. The Court also upheld the possibility of issuing textbooks on secular subjects (Board of Education of Central School District No. 1 v. Allen 392 U.S. 236

(1968)), and the federal college building grant program in Tilton v. Richardson 403 U.S. 672 (1971). The court also approved the South Carolina program to fund construction projects in private nonprofit colleges and did not find the college's activities "convincingly sectarian," and also found that the funds were not used solely for religious purposes (Hunt v. McNair 413 US 734 (1973)). Using the argument that the college was not "convincingly sectarian" allowed the support of annual grants to Catholic colleges under the Maryland Private Higher Education Program in *Roemer v. Board of Public Works of Maryland 426 U.S. 736* (1976).

The court found it constitutional to provide government funding for conducting compulsory educational tests, as well as awarding a grant to a Christian college student given the general nature of such a program and that the grant was given directly to the student but not to the institution concerned (*Witters v. Washington Department of Services for Blinds 474 US 481 (1986*)). Government funding for sexual counseling services for students in religious institutions, along with other educational institutions, were also found constitutional (Bowen v. Kendrick 487 U.S. 589 (1988)). U.S. 589 (1988)).

In *School District of Grand Rapids v. Ball 473 U.S. 373* (1985), the court ruled that New York City and Grand Rapids (Michigan) were unconstitutional on the basis that they paid salaries to teachers working in the "lagging groups" and teaching electives classes. The court ruled that such a relationship might demonstrate a certain bond between the church and the state. In their opinion, this could lead to the unintentional involvement of teachers in the promotion of certain religious ideas and an indirect excessive rapprochement between the state and religion.

But the court changed its decision (from 1985) in the case of *Agostini v. Felton 521 U.S. 203* (1997) and allowed teachers who taught "lagging classes" in religious schools to receive remuneration from public funds. In accordance with a 1993 ruling, the court recognized the constitutionality of payments to a sign language interpreter performing this activity in a religious school from public funds (Grant, 2004). In 2000, the judgment in *Mitchel v. Helms* 503 U.S. 793 (2000) pointed to the possibility of religious schools "to receive material resources (books, computers) from the state, if such assistance extends to all educational institutions and is intended for secular, neutral programs, programs of a non-ideological nature."

It should be noted that in many cases the decisions of the court were adopted by a minimum majority (5-4), and in the latter case the votes were completely divided according to the 3-2-3 model, and as a result, only the so-called plural opinion was achieved, which is not a binding precedent for further court decisions in this area.

In 2002, in *Zelman v. Simmons-Harris* 536 U.S. 639 (2002) the Court upheld the provision of vouchers to children from low-income families to attend a private religious school. The case involved 4.5 thousand children from Ohio, who attended 41 religious schools. Doubts were expressed about the legitimacy of these decisions, since the education of children in religious schools is not compulsory and each parent has a choice. This turned out to be a positive moment for the justification of the educational policy of George W. Bush, for whom the provision of school vouchers became a "trump card". (Grant, 2004)

In *Meuller v. Allen 463 U.S. 388 (1983)*, the court unequivocally upheld the possibility of providing financial benefits to students and their parents even if they chose private, including religious institutions. However, in the case of *Committee for Public Education v. Nyquist 413 U.S. 756* (1973 the court declared unconstitutional a provision on special financial benefits for students in parish and other private schools. The researchers note the vague and, in some cases, "ad hoc" nature of the court's judgment, which prohibits the provision of therapeutic and diagnostic services in a religious school, but at the same time allows these services in a mobile room and allows other very borderline cases (Choper, 1995)**.**

Judges themselves acknowledge some degree of uncertainty, assuming that "there is no 'exact scientific method' for determining the degree of interconnection between the church and the state," and all relevant factors must be considered together to determine the degree of such interconnection (*Roemer v. Board of Public Works of Maryland*, 426 US 736 (1976)). There is a significant number of judgments in favor of providing government funding (at both the federal and state levels), provided there is no discrimination and there is proof that the funding is intended for secular purposes.

The Supreme Court appears to be even more "liberal" with regard to higher education. This is due primarily to the extremely decentralized nature of US higher education and indirect control by the state. There are practically no public higher education institutions in the country and there is a significant share of private universities and colleges, including those of religious affiliation. The court explains this peculiarity of its position by the fact that students of higher education institutions are more independent and in this case less susceptible to propaganda (including religious propaganda) (Tilton v. Richardson 403 U.S. 672 (1971)).

In *Locke v. Davey* 540 U.S. 712 (2004) the Court considered the constitutionality of the Washington State financial aid program, which was not extended to degree programs in theology. Confirming some contradiction between the two provisions of the federal Constitution, the court pointed to additional prerogatives in this case on the part of the state authorities, which could, under the circumstances, give preference to the values of separation of church and state embodied in the state constitution over the federal interest in ensuring the freedom of conscience of the individual. Thus, the Court emphasized that the state could have extended its program to theology, but the freedom of religion clause does not mandatorily require it to do so. As you can see, in this case, the "less strict" analysis rule was applied, in contrast to the "strict analysis" rule which was applied in a significant group number of other court decisions, as well as the "minimal analysis" (Kaplin, 2007) used, for example, in the case of *Employment Division v. Smith*, 494 U.S. 872 (1990).

This position significantly expands the prerogatives of the states in determining financial policy in relation to religious institutions and programs. *Hein, Director, White house office of faith-based and community initiatives, et al. v. Freedom from religion foundation, inc., Et al. 551 U.S 587 (2007)* relates to a taxpayer lawsuit against the executive branch (in particular the White House Religious Groups Initiative) regarding the holding of religious conferences sponsored by them, which violates the provisions of Amendment I to the US Constitution.

The District Court rejected the claimant's application on the ground that Clause I of the Religion Amendment is addressed to the United States Congress and cannot be applied directly to executive acts. However, the Court of Appeal reconsidered the decision because the activity was funded in accordance with the decisions of Congress and, therefore, the claim was well founded. The Supreme Court, by a majority vote, upheld the district court and, accordingly, the executive branch.

Arizona Christian School Tuition Organization v. Winn et al. 563 USA (2011) considered the possibility of taxpayers to put government agencies in issue for funding activities that may have a religious purpose. A district court ruled that Arizona's tax-exempt practice was unconstitutional for donations given to schools, which in turn used such donations privately, including religious schools. The Court of Appeal upheld the taxpayers' position. The US Supreme Court by five votes (Judges Kennedy, Roberts, Alito, Scalia, Thomas) to four (Judges Kagan, Breuer, Ginsburg, Sotomayor) reviewed the decision of the Court of Appeal, finding its interpretation overly broad in the Flast case involving direct government spending, and no tax credit. In the case of *Espinoza v. Montana Department of Revenue*, 591 U.S. (2020) the conservative majority of the court ruled unconstitutional funding restrictions on religious schools, which was discriminatory not only against such schools, but also families who had chosen such schools to teach their children.

In recent decades, the activities of the court have been characterized by certain contradictions. These refer to changes in practice (recognition or non-recognition of actions as constitutional; the provisions of the doctrine and rules underlying such decisions). It is worth pointing to the tense procedure for making decisions with a minimum majority of votes (5-4) and even (in the absence of an absolute majority) by achieving multiple consent.

Substantial polarization is characteristic of the party's assessment of the Court's activities. About three-quarters of Republicans and their independent supporters have a positive opinion of the Supreme Court, compared with 49% of Democrats and their supporters, and the 26 percentage point difference between the two parties is one of the largest in two decades. (Brockway, 2019) However, it is the Supreme Court of the United States that remains the last judicial and constitutional instance ensuring public and private interests between religion and higher education, creating both federal and state laws in accordance with the provisions of the US Constitution.

Abstract

Simulation is becoming more and more powerful in management, especially strategic one. In the paper, we introduce a novel framework for combining two modelling techniques: agent-based models (ABM) and Multi-resolution modelling (MRM). Both of these methods are well known and wide practical usage. Simulation is a commonly known and recognized business decision making support method. However, their use in a single environment, and in addition reinforcement learning, provides additional opportunities for a variety of (in terms of conditions) test scenarios, shortening decision verification time, obtaining synthetic simulation data for further research and optimization for uncharacteristic conditions. The implementation of such methods allows companies to adaptively track changing in market conditions as well as to anticipate environmental changes. Moreover, machine learning algorithms (clustering and classification) for software agents will improve the scope and dynamics of the simulation models and technology. By using the approach, it is possible to analyze many business strategies (e.g. what would happen if shipments were delivered twice a day).

Keywords: Agent-Based Modelling, Transportation Simulation, Multi-Resolution Simulation.

Introduction

The problems of optimizing the structure of the parcel distribution system as well as the optimal scheduling of deliveries are characteristic for courier companies and still require better solutions (Barreto et al (2007)). The methods of operational research and artificial intelligence and machine learning are used to solve these problems. Nowadays, due to the size of the problems and numerous and detailed limitations, fast simulation methods are used to verify proposed solutions. High-resolution software simulators use the notion of a software agent to represent, among others, couriers with vehicles, warehouses with staff, senders and recipients of parcels. The inclusion of many details in the simulated objects and, on the other hand, the generalization of descriptions when no high resolution is required, leads to a multi-resolution simulation of a logistics company. Such a simulation enables verification of task solutions: optimization of network structure, scheduling of deliveries of goods to zones and points by means of allocated vehicles, promptness of deliveries of designated routes, unit costs of package delivery, identification of bottlenecks, forecasting of times and costs in various conditions, verification of decision-making scenarios (what if). Such a wide range of requirements and the specificity of the tested implementations of optimization algorithms make it necessary to build a dedicated simulation environment for algorithm testing and decision support in a delivery/courier company.

The current solutions (e.g. route optimization in eMapi) are mostly based on deterministic networks, assuming that if, for example, the journey between locations takes some time, it is a fixed one. The innovation and novelty of the proposed solution is to use a solution based on stochastic models, agent simulation as well as multi-resolution modelling (MRM). A concept “resolution” is defined as level at which an object is simulated. Obviously, it is strictly related to modelling constraints and criteria for the dimensions and the degree of detail. A simple object (like a vehicle) is a high-resolution entity (HRE) while a group of objects will be called aggregate low-resolution entity (LRE). Multi-resolution modelling (MRM) is very useful in the analysis of complex adaptive systems, as it is very computationally complex to track all relevant objects, their characteristics and cause-effect relationships at a very detailed level. It was verified in a research study by Rabelo et al (2015), Su-Youn and Tag Gon (2012). At all the levels the agent simulation techniques, both simple and with the reinforcement learning, were used. Agent simulations seems to be an important element at a starting phase of the development of new business. Further, implementation of such methods allows companies to follow changing in market conditions. Urban simulation (traffic, delivery, parking) is generally a particularly productive area for new agent-based simulation approaches, especially when there are many interdependent factors and there is a need to train or adapt models. In a research study by Beheshti and Sukthankar (2014) there is presented a case study describing benefits from a hybrid simulation method for forecasting transportation patterns. The paper by Klugl and Bazzan (2012) presents the advantages of agent techniques over other types of simulation in the traffic domain - including capacity for imbuing objects with learning and adaptive behavior and simplicity of generating populations with heterogeneous behavior algorithms. Deep Reinforcement Learning is a very general paradigm (e.g. a toolkit OpenAI Gym). – in the presented study e.g. the deliveryman agent learns from examples of optimal behavior in the so-called "last mile" (e.g. parking in the right place).

Optimization methods and algorithms

The subject of research in the simulation framework are algorithms for optimal (or suboptimal) scheduling of goods deliveries to zones and points by allocated means of transport along assigned routes. The algorithms are limited by restriction to the indicated areas, the given allocation of goods to zones, requirements regarding means of transport, costs (time and financial), as well as taking into account traffic disruptions. The simulation environment will allow to run and test the algorithms as well as collect and share the results to compare the algorithms for different sets of input data.

For the purpose of algorithm learning it will be necessary to generate training data. Comprehensive tests of algorithms conducted in the environment will require historical data, but also data generated on the basis of empirical distributions identified in historical populations.

With appropriate configuration such framework can also be used as a parameter calibrator - to verify the calibration parameters of a selected algorithm with a fixed type of input data.

Finally, with a generator of data about goods for distribution, scheduling algorithms, random disruption generator (e.g. natural – weather conditions or artificial - traffic events) and a process and event simulator, it will be possible to use the framework as a scenario analyzer (what-if).

Fig. 1: The concept of simulation environment for testing the implementation of algorithms

The user's cooperation with the algorithm testing environment (the simulator framerwork) and the implementation of delivery scheduling algorithms, will be multi-stage and may include:

- preparation of the test scenario, including: entering data for the algorithms, configuration of a series of experiments, parameterization of random number generators, random data generation according to picked distributions;
- configuration of the tested algorithm;
- parameterization of conditions, e.g. vehicle movement in order to test their influence on the result of scheduling;
- specification of conditions for the execution of the experiments:
    - experimentation mode (graphical/text);
    - the pace of simulation time.

Finally, the environment for simulation testing of algorithms will allow to evaluate the quality, sensitivity and effectiveness of implemented algorithms. In order to carry out diverse and complex research, it is suggested to provide scenarios and data sets covering as many possible cases occurring in the environment.

Fig. 2: Testing in the algorithm testing environment

Quality and Sensitivity Testing

The expected results of the environment for simulation testing of algorithms are a set of characteristics and parameters to be configured before each experiment. Performing single or a series of experiments will allow to gather a set of values for selected parameters of simulated objects and processes. They will build sets of numerical data for quantitative evaluation of distribution costs for following resource variants:

- partial and aggregated results for routes:
    - lengths,
    - leave and return times for the vehicle (e.g. from/to the warehouse);
    - travel time periods;
    - service and waiting time periods.

It is important to indicate the influence of the scope and quality of historical data made available to the environment on that the possibility and appropriateness of the results collected in the simulation. The collected results will be qualified by route and vehicle. Through different scenarios and configurations of the collected data, scenario analyses (what if) will be possible for:

- required types and number of vehicles for effective on time completion of tasks;
- distribution possibilities with the available resources and time and area conditions;
- distribution costs for resource variants.

Efficiency and Effectiveness Testing

Independent characteristics will describe reliability, efficiency and effectiveness of algorithm implementation. They will provide answers to questions:

- Are the algorithms able to perform the task at the right time?
- In what time do the algorithms perform the task?

The delivered software components for testing will be treated as "black boxes", contact with them will be made through available software interfaces, without the possibility to modify their internal codes. Observations of the work of

algorithms will be possible only through the output data, and it is assumed that among them there will be information about the state (progress) of the algorithm's work.

Architecture and software components of the simulation framework

The three-layer architecture of the desktop IT system includes layers:

- presentation (graphic and text interfaces),
- logic (algorithms under investigation, environment logic),
- resources (database, files),
- integration to access the algorithms and their input data.

The basic software components of the simulation environment for testing algorithms are: simulator, implementation of scheduling algorithms (procedures), network data providers, map and historical data resources (e.g. about rides, service at the destination).

Fig. 3: Diagram of the components of the simulation environment for algorithm testing

The Control Package contains object components responsible for controlling the data flow and functions in the environment. This involves the MenuGuiMgr interface manager, which acts as an intermediary between the user and the environment functions performed by the components in other packages. Access to the functions of other packages is done with the help of intermediary workstations (registered in the main manager): DisplayMgr, EditMgr, AlgorithmsMgr, SimulationMgr, ApproximationMgr and ResourcesMgr.

Algorithms package includes code libraries of tested algorithms, to which configurable access will be realized through a defined interface. The software codes of the algorithms (software components) delivered for testing will be treated as "black boxes", without the possibility to modify their internal codes. They are available for the simulator through a unified software interface. Supervision and monitoring of the algorithm work (readiness, current status and task completion) will be possible through callback functions recorded in the algorithm components and the test environment.

Access to the components of the Edit package will take place through the Facade, whose task is to control a simplified bidirectional message and data flow from/to the components responsible for editing a number of data sets and parameters:

- EditParamCfgAlg - edition of parameters and algorithm configuration;
- Network Edit - editing of connection network data (data downloaded from outside the environment through a fixed interface or created from scratch in the environment);
- EditTasks Delivery - editing of data concerning the delivery task: warehouses, points, vehicle fleet (data downloaded from outside the environment through a fixed interface or created from scratch in the environment);
- EditRandom - edition of parameters for configuring number generators and random processes.

In the Simulation package there is a component that represents the characteristics (structure) and dynamics (behaviour) of the real system using mathematical models written in the program algorithms. By experimenting with the simulator, the real delivery system will be studied, recognized and tested in various scenarios (including those that would be difficult to obtain under real conditions). The variable scale of simulation time (including event time) will allow to perform experiments up to several hundred times faster than in real time.

In the Approximation package, the components are responsible for implementation:

- Statistics - point and interval estimation for a series of experiments - will enable statistical processing of accumulated values for selected parameters of simulated objects and processes. They will be the basis for quantitative evaluation;
- Evaluation - quantitative and qualitative, absolute and comparative, evaluation of algorithms for different tasks and conditions.

The Display Package has components that realize configurable in the environment text (Textual Image), graphic (Graphic Image) and network connection graph (Graphic Image). It provides access to edit all parameters.

The other two component packages are Random and Resources. The Random component will be responsible for generating pseudo-random numbers, monitoring parameters and variables and statistical estimates. Random number generators are based on computational formulas. Subsequent values generated by the generator are determined from the previous ones. The first value is called the grain of the program generator. It can be initialized by the user (seed number) or by the system (according to the current astronomical date and time). Initialization by the grain number ensures repeatability of the designated numbers in case of unchanged initial data. This is called pseudo-random number generators. The evenly distributed number generators are of particular importance, as the numbers they determine are the basis for methods of generating pseudo-random numbers of any distribution. The most common are regular number generators based on linear algorithms. The values of random variables with other distributions are generated by the methods: reversal of the distribution, elimination and superposition of distributions. There will be implemented methods of generating random numbers: uniform, exponential, hyperExponential, laplace, erlang, gamma, normal, beta, student, lognormal, Poisson, geometric, binomial, triangular.

Method of Simulating Events and Random Processes

Computer simulation over 60 years of its use has been understood and defined in many ways. We will assume the definition that it is a quantitative and qualitative method of modelling in formal language and mapping structural and behavioral features of systems (real or designed) in a computer program, allowing to experiment with the model (instead of the system) and observe in it the processes taking place in the simulation time. It is a recognized alternative to experimenting with a real system or its physical prototype, to methods of mathematical analysis, and replaces informal inferences based on experience and intuition. In the construction of a simulation model, the static and dynamic components of the system to be simulated should usually be mapped. The static structure describes the objects included in the modelled system together with their features and relations connecting them into relationships. It is sufficient only

in the case of a static simulation, omitting the phenomenon of time lapse. In dynamic simulation it is necessary to define formal models and software algorithms for determining successive states of objects in the modelled system. It is assumed that in the process of simulation the values of features describing the system in specific moments or intervals of the simulation will be determined, which will be given deterministically (deterministic simulation) or randomly/pseudo-randomly (stochastic simulation).

The original discrete agent-based simulation software package is dedicated to facilitate creating constructive simulation software – both discrete and quasi-continuous as well as hybrid. The basic entity is an object '*o*' with its attributes:

- $O = \{o = <id, c>\}$, $c \in C^O$, $id \in N$ - a set of simulated objects of '*c*' class that are identified by an '*id*' with a unique value;
- C^O - a non-empty set of classes of modelled objects;
- A_c - a non-empty set of attributes specified for the $c \in C^O$ object class;
- V_a^c - a set of acceptable values of the $a \in A_c$ attribute of the $c \in C^O$ objects class.

The C^O and A_c sets contain the numbers of modelled object classes and their attributes. At any time *t* of the simulation time each measurable feature of the system is represented by an ordered quadruple: $<o, a, v, t>$. The state of the modelled system *ST(t)* will be the vector created by all attributes of all objects at the simulation time *t*. In the simulation $v \in V_a^c$ values of $a \in A_c$ attributes are determined as a result of the user-defined state change function. Consequently, along with the assumptions for each object there are defined: the state vector with attributes and either the events or periodically executed equations that change the values of attributes (and finally a state of the system). The term event '*e*' from a finite set of events is understood as the algorithmic change in object's state which is scheduled for a specific simulation moment *t*.

In practice, many methods of dynamics mapping are used in models and simulation programs, which is the basis for their classification due to the way of simulation time lapse mapping and state change modelling:

- continuous in time - continuous or quasi-continuous functions are used to describe the phenomenon of time lapse (this does not apply to the description of state changes), e.g.: Euler, Runge-Kutty, Adams Bashforth, Adams Moulton or Gear methods. A specific subclass are system dynamics analysis methods, which bring multi-level and multi-element systems closer in a holistic (rather than fragmentary) way through specially introduced concepts of stock, flow and feedback loop;

- discrete - discrete functions are used in the description of time lapse, the domain of time is a finite set of discrete moments:

- time-driven - the value of time increases with a fixed value t: ti+1=ti+t, then the calculations for the new state are performed;
- event-driven - the time value results from the moment of the next event, i.e. a change in the value of selected state attributes or a change in the structure of system objects.

In the presented simulation environment, a discrete time-driven method with a variable rate of time (according to the astronomical time, accelerated or delayed) was used.

Case Study

The application offers single algorithm execution as well as multiply executions defined by scenarios. When executing the algorithm the user must choose one of the VRP algorithms, its calibration parameters, the start time and the criteria which will be taken into account finding the schedule. Currently implemented criteria includes distance, time and cost. **Fig. 4:View of the algorithm execution section, presenting the result of the Annealing algorithm**Fig. **4**4 presents a view of the execution of the Annealing Algorithm with provided parameters. On the right we have the execution time and the summary of the schedule. It is also possible to view the schedule as a network where all of the routes, for each vehicle are presented.

Fig. 4:View of the algorithm execution section, presenting the result of the Annealing algorithm

The created schedule for delivery can be later verified with simulation. The user can select a set of predefined weather conditions and time which influence the distributions of specific times in the schedule and the probabilities of accepting the package not within the opening hours. The distribution for a specific vehicle or distance can be overridden from the network view of the schedule. The failure of the vehicle can be simulated as well given the time and duration of failure, that can be provided by an exact value or a distribution. The application currently support the following distributions: Beta, Binomial, Erlang, exponential, F-distribution, Gamma, Geometric, Log-normal, Normal, Poisson, Student, Uniform and Weibull. To verify the schedule the random seed and the number of simulations must be provided.

Once the simulation is complete it is possible to view the modified schedule (considering the simulation). The network view uses two colors to indicate nodes the have been reached outside the opening hours of the node. The green color indicates that the vehicle reached the node too early. In this situation the vehicle waits or leaves the package if the customer is able to accept it earlier. Red nodes were reached too late by the vehicle, after the end of opening hours, if the vehicle is unable to leave the package it continues to following nodes. The bar on the bottom allows to view the situation at different times of the simulation to indicate the exact time where the simulation started to drift away from the schedule. It is also possible to play the simulation at provided acceleration.

Fig. 5 presents a result of a one of the simulations in very bad weather conditions for a schedule created with Tabu algorithm. Only the customers closest to the warehouse received their packages in expected time, the rest was not delivered the same day. The Annealing algorithm was more successful in bad weather conditions. Due to the fact that the routes were shorter only 5 packages were not delivered. None of the packages were delivered before time. Under other circumstances the Tabu algorithm receives better results. The third network represents the simulation of the same schedule in bad conditions combined with Christmas time. Based on the results it can be noticed, that more people were able to accept their packages outside expected hours.

Fig. 5: Network representing the simulation result of the schedule received as a result of the Tabu algorithm (very bad weather)

Fig. 6: Network representing the simulation result of the schedule received as a result of the Annealing algorithm (bad weather and holiday season)

The last section of the application provides analysis and statistical data. For every time characteristics of the schedule, routes and customer a set of statistics is calculated including the mean, variation, standard deviation , range and confidence interval. It provides insights about implied schedule modifications. The analysis section also provides a set of charts for each of the simulations. The charts include histograms for service, drive times and differences from the schedule, Gantt charts for every route and a chart showing the differences from the schedule through the whole route.

Fig. 7: Chart representing the time differences from the schedule for every simulated vehicle

Fig. 8: Chart representing the delays for specific routes (Y Axis) at specific nodes (X axis)

Summary

Simulation is becoming more and more powerful in management, especially strategic one. Some businesses have even made the rule that no strategic decisions should be taken without simulation analysis. By using simulation it is possible to analyze many business strategies (e.g. what would happen if shipments were delivered twice a day). This will allow you to gain an advantage over your competitors, including: prior verification of business strategies, as well as adapting services to market needs. The profits from the use of simulations can be measured by various indicators: operating costs, order processing times, warehouse filling levels, idle times or the performance of individual resources. The implementation of such methods allows companies to adaptively track changing in market conditions as well as to anticipate environmental changes.

Today, agent simulations are increasingly used to create strategic models. On the basis of an experiment carried out on the historical data of a certain company, it was found that the results of the simulation deviated from the actual ones by no more than 25%. We intend to use supply chain process prediction and optimization algorithms in the environment, including: multiple regression prediction method and ARMA time series method. Moreover, machine learning algorithms (clustering and classification) for software agents will be applied more widely. Biologically inspired algorithms (evolutionary algorithms, swarm intelligence algorithms) may also be taken into account in order to map the cooperation of agents in motion.

Coopetition between Data Center Service Providers as an Economical Solution for Multicloud Infrastructure Deployment in Polish Public Sector

Andrzej PESTKOWSKI

Wroclaw University of Economics and Business, Poland
andrzej@pestkowski.pl

Abstract

This paper concerns the phenomenon of business strategy of coopetition between two major cloud computing providers, Google and Microsoft, who jointly prepared an unprecedented solution of multicloud infrastructure for Polish public sector organisations. It is assumed that such project might be more effective from the perspective of cost, time management and human resources engagement than the traditional approach of building own data center or implementing other cloud models presented in the paper. During the research various aspects and approaches of the abovementioned phenomena have been considered in the context of economic analysis of specific IT infrastructure deployment models such as IaaS, SaaS or PaaS. The author also investigates the events, motives and benefits that lead companies to deploy the coopetition strategy. The study is divided into the theoretical, conceptual and empirical parts that gradually reveal the answers to the research questions made by an author. Conclusions drawn from this paper can be useful for entrepreneurs and their decision-making process. Also, they may constitute a solid basis for further research in this field.

Keywords: Data Center, Cloud Computing, Coopetition, Business Strategy, Multicloud, Polish National Cloud.

Introduction

In modern economy digital presence of European enterprises and public sector organisations is one of the most important strategic factors as it allows to reach their customers quickly at almost any time. This statement is especially important considering the fact that in 2018 in the European Union 89% of all households had access to the Internet at home and 83% of them were regular Internet users. Moreover, the number of worldwide Internet users is rising year by year reaching in the same year 3.92 billion people who represent 51,4% of World population (Telecommunication Development Bureau, 2020). As a consequence of the aforementioned trends more and more companies are starting to mark their appearance online. Indeed, in 2018 on average 77% of all EU-28 enterprises had at least an Internet website (Statistics Poland, 2019, p. 94). This implicates forced demand for data center services as every website and most of other interactions in the Internet must be hosted and operated with the use of special servers mainly located in data center buildings. However, while basic hosting infrastructure is used by the majority of enterprises and public administration companies, it is not the case with more advanced cloud computing services such as e-mail systems, storing files, backups or database hosting which are used only by 26% of enterprises (Eurostat, 2019a, 2019b). Furthermore, in 2017, over one third (35 %) of people in the EU who had used the Internet within the 3 months prior to the Eurostat survey (2019a) used this kind of cloud services. It is worth pointing out that the lowest share was noted in Poland with the result of just 20% comparing to the highest of 59% in Denmark. In the light of the foregoing facts the author has decided to raise that topic with an aim of finding and analysing possible economical solution for implementing cloud infrastructure within the most vulnerable public sector in Poland that distinguishes itself from other countries by the lowest rate of cloud computing usage in the European Union. It is assumed that digital transformation to hyperscale multicloud infrastructure is currently one of the most innovative and recommended solutions (Datamation, 2020). Thus, during the course of the research the author focuses specifically on the recent ground-breaking project called "Polish National Cloud – PNC" operated by one of the major companies from Polish Public Sector: Poland's largest bank - PKO Bank Polski and Poland's government unit – Polish Development Fund that are named together as "National Cloud Operator – NCO". Since one of its main objectives is to increase the usage of cloud computing technology by Polish public administration, enterprises and implicitly by Polish citizens, this project might be considered as a valuable source for effectiveness analysis from the perspective of economic and management sciences. What is worth mentioning, NCO launched PNC in 2018 by implementing an unprecedented

strategy of coopetition between two global Data Center competitors – Microsoft and Google. It is at least unusual in such an immense project to choose third party solutions especially for government units where security issues are among the most important ones. Nevertheless, NCO not only decided to go for commercial solutions but also at the same time convinced providers Google and Microsoft to invest 3 billion USD in their data centers in Poland to secure locally the highest quality of service (The Economic Times, 2020; Wilczek, 2020). Hence, the project is not only innovative from the technological perspective but also as an economical phenomenon. That is why the author has decided to analyse this case from a wider perspective and conducted research on other possible economical solutions for implementing multicloud infrastructure by comparing them with titular coopetition through effectiveness variables such as: cost, time consumption and human resources allocation.

Theoretical Background

This section will broaden the deliberations about the economics of data center as well as the business strategy of coopetition that was mentioned in the introduction. The focus shall be put on the theoretical issues that might bring better understanding of the multicloud infrastructure concept and its challenges from an economic perspective. It is also necessary to properly characterise the concept of coopetition, which is why various approaches and definitions will be presented. The author also concentrates on the coopetition strategy as an unusual approach in cloud computing industry especially when government infrastructure is launched.

Cost Effectiveness and It Security in Data Center Deployment

Data center is a specifically designed building in terms of high security standards with the capability to store and share commercial (enterprise class) computers called servers. Typically, servers stored in these buildings operate as a nonstop service twenty four hours a day, seven days a week often with financially insured guarantees of remote availability. Servers are designed to be mounted in special cabinets called racks where usually one server is considered as 1 rack unit (U) where the industry standard is to fill 1 rack with 42U. Finally, those servers and racks are connected to high performance Internet connection with fast and guaranteed bandwidth via Ethernet ports, switches and routers which allows remote access to the infrastructure (Tian and Zhao, 2015; Wu and Buyya, 2015, pp. 152–156). Thanks to the abovementioned technology customers may benefit from almost unlimited access to their IT systems from any place in the world where Internet connection is available. It is noteworthy that enterprises which own or rent servers in data centers do not have to be connected to the servers or might be even completely offline and still their IT systems are online and available from Internet due to the direct usage of data center resources instead of its own. This is one of the most important advantages of IT systems to be remotely located in data center, as in effect enterprises purposely secure infrastructure in case of failure or any other security issues.

A server installed in data center enables to launch any type of IT system, tool or software known in the digital economy for enterprises at every level of market development. Thus, starting from a small business through medium size enterprises and ending with the large ones, the following typical use cases of servers can be specified: websites, e-mail systems, office software, specialised enterprise management software (ERP / CRM), accounting systems, 3D rendering, artificial intelligence, machine learning, big data and many others.

Although data centers are able to handle almost all needs of an organisation in the field of IT and certainly there are numerous advantages of such a technology, they have one feature that brings out the problem of data security. It is the psychological issue that comes from this revolutionary approach to provide services remotely, which means that when placing IT systems in the data center, one usually does not obtain physical access to the server or full control over its configuration. Admitting this should not be a problem in the era of the developed Internet network, it is a significant blockage for potential customers, especially in the case of the public sector organisations analysed in this article. Therefore, as a part of the decision process, organisations might deploy IT infrastructure in an alternative model to the one mentioned before - building own server room or even data center directly at the enterprise's premise. However, this kind of decision has another significant drawback that raises the problem of economics, which is the need for high capital investments, hence the return (cost effectiveness) might be achieved only under the conditions of economies of scale. This type of project entails extensive costs, both fixed and variable, which means that in the vast majority of organisations such an approach is unprofitable from the financial point of view and might be justified only by a large quantity of used servers that results in a reasonable level of unit cost. As a consequence, every

organisation designing its IT systems faces two types of risk: security and financial with a substantial ability to decrease at least one of them to the minimum. Thus, in the article the author has decided to analyse these risks by searching for possible economical solutions for its reduction in the context of coopetition strategy implied in the example project.

Both foregoing phenomena, the need for high capital investment and psychological blockage to outsource IT infrastructure, might be explained on theoretical level, by citing a number of conditions and standards that should be fulfilled by all professional data centers, regardless of whether they are owned or outsourced. These conditions are necessary if the organisation wants to ensure the so-called High Availability (HA) environment, i.e. maintain almost 100% availability of services, even in the event of unpredictable failures of single components. One can distinguish such standards as (Wu and Buyya, 2015, pp. 151–367; Tian and Zhao, 2015; Xu and Liang, 2015; Geng, 2015, pp. 2–14; Harms and Yamartino, 2010):

- Full system redundancy, meaning the replication of independent hardware necessary to run servers: power supply, network cables, network devices that allow access to the Internet such as routers, switches and others
- Professional fire protection systems, most often in the form of automatic gas extinguishers
- Providing additional solutions for the protection against sudden power loss: connection to at least two separate and self-contained electricity transformer stations combined with backup power supply inside of Unit Power Supply (UPS) batteries that could be charged by disaster recovery power generators run by diesel engines
- Redundant precision cooling solutions with industrial air conditioning or liquid cooling
- Multiple building and hardware physical protection tools, such as: multi-layer fire resistant doors, special technical floor with fire resistant overlay and ability to take heavy loads, reinforced walls and burglar-proof fencing
- Access control systems only by authorised employees (for example authorisation with codes, cards, face detection, fingerprints detection)
- CCTV systems with the ability to record and store video recordings
- Warning systems, sound and visual danger signalling
- Round-the-clock technical support and incident response staff
- Financial guarantees called SLA (Service Level Agreement), which often oblige data centers to ensure 99.95% availability of the service during the year. In the event of SLA breach compensation is paid at minimum in the amount of the monthly infrastructure cost

Taking into account all these aspects, it should be stated that for the vast majority of enterprises operating in the digital economy, it would an ineffective decision from the cost perspective to build their own data center. This is applicable not only for running individual services such as websites, software or industrial systems where it is impossible to reach reasonable level of cost, but also for more complex projects that requires, inter alia, an additional level of backup or redundancy. However, taking large-scale multicloud solutions into consideration that the author analyses in this article, theoretically, one might choose between building own data center and outsourcing IT solutions, as both projects involve high investment expenditure and are real substitutes for each other.

cloud Computing Technology Among Data Center Services Models

In order to fully explain the specifics of the titular multicloud solutions, one should also briefly scrutinise the models of data center services, because each of them provides a different balance between security and financial costs, which is a crucial factor for the aim of this paper.

The first segmentation of data center services might be described as Cloud Computing Service Models that are differentiated based on the type of service provided by cloud providers. Usually, three different service models could be distinguished:

- Infrastructure as a Service (IaaS). In this model cloud providers offer fully secured IT infrastructure of computing power in a form of dedicated servers, virtual private servers, virtual machines or data storage as a service. However, in IaaS, cloud providers usually do not support customers on the configuration level so it is necessary to acquire knowledge on managing the operating system (OS) and software layers, also from

the security perspective. Customers are usually allowed to install arbitrary operating systems or software of their choice, but do not get access to the underlying hardware.

- Platform as a Service (PaaS). In this type of service model cloud providers offer platforms with user-friendly interfaces where customers could develop and deploy their own cloud applications in a form of their own virtual machines. Here, the cloud provider manages virtualisation systems as well as arranges ready-to-use solutions for network security. Often operating system is managed by data center too. Nonetheless, this kind of solution requires much more control of resources by the cloud provider and implies less possibilities for nonstandard configuration by customers.
- Software as a Service (SaaS). In this case complete software solutions such as e-mail systems, CRM, ERP, collaboration services, storage space, are offered by the cloud service provider as a service available from web interface or a mobile device application. Customers benefit from easy remote access to the service without the need of local installations on their devices. Hence, this model might be used even for enterprises that do not have appropriate human resource teams responsible for IT systems. Still, SaaS model cannot be implemented on a large scale as an only solution for every digital need of an enterprise, as it is characterised by the lowest possibility for adaptation and configuration. Moreover, most of data centers offer SaaS on the basis of public cloud clusters that are shared with other customers, which might be potentially insecure or at least not efficient in terms of peak performance.

For the purpose of the paper it is of key importance to juxtapose the abovementioned cloud computing service models with a traditional IT approach of building own data center. One might find such a comparison in Figure 1 that depicts blocks of infrastructure under control of customer or cloud provider.

Fig. 1:Comparison of cloud computing service models with a traditional IT approach from the perspective of management. Source: (Harms and Yamartino, 2010, p. 12)

It could be observed that in traditional IT framework enterprises gain the highest level of control as well as configuration. However, as it was stated before, this requires not only high capital investments but also the involvement of qualified human resources such as IT department (administrators, system operators, development operators, security experts, technical support). Additionally, this deployment strategy is usually the most time-consuming, which is also crucial in order to effectively distribute enterprise resources. Therefore, alternative models of infrastructure deployment by cloud providers' solutions are becoming a more and more attractive choice.
Yet another segmentation of data center services is related with distinctive deployment approach in the level of ownership, privacy and security. In the division named as Cloud Computing Deployment Models one might usually find four types of models:

- Private Cloud. An infrastructure environment run by a cloud provider only for one enterprise with no possibility for outside access as well as any resources sharing with other clients. Usually this type of

deployment is offered in a form of PaaS model where the customer receives preconfigured servers with prepared virtualisation and security rules. Thus, it combines all benefits of cloud infrastructure such as high availability and scalability with some aspects of traditional IT environment especially in a field of data security.

- Public Cloud. One of the most popular and innovative model of infrastructure deployment based on computing power distribution between many clusters that are filled with dozens of servers configured and managed by a cloud provider. In this model the customer must not be able to affect hardware as its elements are shared with other customers and cannot be interfered at any level. Hence, the enterprises can benefit from high computing power due to sharing economy model established by data center. Nonetheless, there are some disadvantages comparing to other models and just to name a few: lack of personal adaptations of servers, forced virtual machine configurations, possible lowered performance during peak hours. Thus, such model is very cost effective considering the fact that the same server configuration might be much cheaper comparing to other models, but at the same time security rules and configuration flexibility are not equally high.
- Hybrid Cloud. By this term one should understand a combination or interconnection of different cloud models and traditional IT infrastructures (e.g. between public cloud, private cloud and dedicated servers). Hybrid cloud is widely considered for large scale scattered projects where enterprises must reach their end customers globally or when the demand for IT resources is volatile.
- Multi Cloud. In principle it is much similar to Hybrid Cloud model, although in Multi Cloud a single point of failures must not be present. That means, single dedicated servers or more widely traditional IT approach should not be considered as well as single a location for cloud provider. Only high availability infrastructure found in Private Cloud or Public Cloud models separated in at least two redundant locations might be considered as Multi Cloud. Thus, it is treated as the highest level of security while building IT infrastructure along with the most assured high availability standard.

Thereby, Multi Cloud model analysed in this paper is undeniably very desirable for most of the organisations especially for the entities presented in the research that is public sector administration. What is also relevant, Multi Cloud infrastructure can simultaneously meet the features of various models, for example it might be deployed as Private Cloud in the PaaS model, but also could be configured as Public Cloud in SaaS model. Moreover, due to the application of site redundancy it definitely involves high capital investments. Therefore, it is the author's objective to verify the most effective solution for Multi Cloud deployment in terms of cost, time management and human resources engagement in the context of the aforementioned business strategy of coopetition.

Business Strategy of Coopetiton As A Solution for Cost Effectiveness

Constantly changing business environment with high intensity of industry rivalry has led the strategy and management scholars to establish over the years a completely new business strategy of coopetition. Various views (Fernandez *et al.*, 2014; Gnyawali and Park, 2011; Ho and Ganesan, 2013; Raza-Ullah *et al.*, 2014) emphasize coopetition as a strategy that indicates simultaneous cooperation and competition between two or more firms with an aim to provide a more valuable product from the customer's perspective. This strategy, in turn, causes higher revenue for each cooperating rival comparing to the strategy based only on competition (Ritala, 2012). It is assumed that through the established coopetition either a product's final unit cost will be lower or the quality or effectiveness of value chain activities will rise (Bouncken *et al.*, 2015; Brandenburger and Nalebuff, 1996). These effects might occur by exchanging one or more of the following resources: human, financial or physical capital, rare materials or components, knowledge, innovations (patents, know-how) or unique, effective processes (Kotler and Keller, 2012, pp. 221–244; Grimm *et al.*, 2006, pp. 44–48). However, to make it happen, the basic rule of coopetition strategy, that is the rivalry suspension, must be established (Bengtsson and Kock, 2014). The lack of competition in gathering of some of the indicated resources may result in a better performance of each partner considered as higher margin. Increasing the level of margin is possible by virtue of greater effectiveness in resource processing.

In the case of IT projects analysed in the paper, one might observe that coopetition can primarily be an effective business strategy by integration of the value chain of two competitors on its early stages such as manufacturing, logistics or technological development. Competitors benefit most if they leave their systems, software, brand, sales and marketing in the scope of rivalry, but simultaneously decide to coordinate and cooperate in some areas regarding hardware, technology standards, and innovations. Considering cloud providers it is recently a widely used strategy visible especially in loosening the effect of technology lock-in. In such a situation, data center service competitors,

wanting to offer maximum security, in line with the standards of site redundancy, began to enter into agreements that integrate their solutions to such an extent as to be able to offer two different products to one customer. Before coopetition occurrence it used to be very unlikely for cloud providers to allow its customers to easily migrate, change or integrate cloud infrastructure with other solution providers. Nonetheless, it seems to be an informed decision dictated by economic indicators. Cloud providers purposely cooperate with each other in order to help its customers to lower the total cost of ownership (TCO) of Multi Cloud infrastructure which, as it was stated before, is usually very expensive (Buyya *et al.*, 2011; Madhavaiah *et al.*, 2012). Instead of providing only one part of the infrastructure, e.g. Private Cloud, leaving the second site to be built by the customers on their own, competitors decided to integrate virtualisation, backup and migration tools in order to enhance the overall cloud providers' market share. For this kind of activities one might identify such tools: implementation of the same type of hypervisor such as KVM, VMWare ESXi; providing free and compatible disaster recovery software; providing complementary and compatible backup software; popularising virtual machines migration tools. As a part of coopetition agreements vendors are also involved in an increasing number of OpenSource projects that allow them to maintain their own competitive advantages. In the meantime such projects support creating new advantages, but together with competitors. OpenSource projects usually equip customers with migration tools, which gives them free and easy choice of cloud provider, but at the same time it keeps them in one homogenous technology (Openstack.org, 2020). One might notice that somehow it is yet another strategy for technology lock-in, but more liberal for customer's choice. This paper sheds a new light on the aforementioned aspects concerning the unprecedented coopetition between one of the biggest cloud providers Google and Microsoft that decided to cooperate and arrange one joint solution for Polish National Cloud. Both companies provided two independent data center sites with an ability to migrate between them without interruption. As a result, National Cloud Operator received a multicloud infrastructure with the abilities of disaster recovery, that did not have to be built at all and in effect use its financial and human resources.

Materials and Methods

The main aim of the study is to analyse the effectiveness of multicloud solution provided by Google and Microsoft for Polish National Cloud and assess whether coopetition is actually more resource effective than the traditional approach of building own data center. The study also attempts to compare the abovementioned multicloud deployment strategies with two other possible scenarios that the author of this paper discovered during the research as feasible and widely used in similar projects: a) building own data center as the main site one and rent servers from cloud provider for a backup site two; b) rent servers from data center A for main site one and rent servers from a different data center services provider B for a backup site two. Thus, during the research the author analyses four substitutes for the same concept of multicloud solution prepared for public sector organisations in Poland. It is also of key importance to identify and discuss the causes and effects of such decisions especially from the perspective of economics and management sciences. The general research methodology depicted in Figure 2 is based mainly on the pragmatist approach with a focus on the operationalisation of many concepts introduced in the paper. The methodology of non-participant observation as well as strictly defined cause and effect relationship analysis have been used as well. The empirical qualitative study with the support of numerical data has been conducted with the use of comparative method with numerical analysis of variance especially between the Total Cost of Ownership (TCO), systematic reviews and systematic data collection.

Fig. 2: Study workflow and assumptions. Source: Author's work

In order to broaden the deliberations on economic effectiveness of coopetition occurrence between Microsoft and Google for Polish National Cloud project the author has carried out research basing on four possible scenarios the concept of which is presented in Figure 3:

Fig. 3: Visual presentation of conducted research. Source: Author's work

For the purpose of the research the following *ceteris paribus* assumptions have been made:

- Basing on the typical data center configuration for large enterprises project size of one multicloud site is set to capacity of 120 racks that could contain 5000 dedicated servers plus 10 additional racks for network and storage equipment
- There must be two sites implemented with automatic migration or disaster recovery tools configured, and each site must be the same size

- Essential dedicated server configuration (1U) should contain at least 8 core / 16 threads CPU and 64 GB of RAM
- Each solution is calculated for the virtualised environment where provisioning rules are applied with overbooking set to 2x. Thus, one virtual machine should represent computing power of 16 cores / 32 threads vCPU and 128 GB vRAM.
- Storage capacity is set for adaptive mode, which means that 5000 TB of storage should be divided for all virtual machines according to demand
- Investment lifetime cycle is estimated to last 60 months (5 years), hence during that time infrastructure should be up-to-date and work round-the-clock with manufacturer warranty to do so
- All data represents actual costs, prices, salary or timeframes applicable for Poland markets in 2020

As a result, all necessary data are presented in the form of a table in Table 1 that might be useful for an easy comparison of each solution:

Table 1: Resource comparison needed to run multicloud infrastructure for analysed project

Variables	Selected solution (A, B, C or D)
Data Center Facilities	Costs of building a structure and general systems (if applicable)
Redundant power systems	Installation costs of power systems without monthly usage of electricity (if applicable)
Power Distribution Unit and Cabling	Costs of additional power distribution systems without monthly usage of electricity (if applicable)
Cooling systems and air distribution	Installation costs including devices for cooling system and air distribution (if applicable)
Fire Suppression and Physical Security	Installations costs of firefighting systems and physical security including devices (if applicable)
Network devices and cables	Installation costs of network devices needed for remote connection (if applicable)
Redundant Internet connection	Monthly cost of Internet connection needed for remote connection multiplied by planned investment lifecycle time horizon
IT human resources cost in deployment phase	Monthly cost of human resources engaged in installation phase multiplied by months needed to finish the step
IT human resources cost for maintenance	Monthly cost of human resources engaged in maintenance of infrastructure multiplied by planned investment lifecycle time
Software and other licenses	Monthly cost of all software licenses needed for multicloud replication multiplied by planned investment lifecycle time

Average cost of electricity	Average monthly cost of electricity needed to run each solution multiplied by planned investment lifecycle time (if applicable)
Dedicated servers cost	Total cost of all dedicated servers needed to run both multicloud sites (if applicable)
Monthly cost per 1 virtual machine	Calculated or given monthly cost (price) per 1 virtual machine
Monthly cost of all virtual machines (two sites 5000 VMs each)	Monthly cost per 1 virtual machine multiplied by total established amount of virtual machines
Monthly total cost of ownership (two sites 5000 VMs each)	Calculated monthly total cost of ownership that includes installation phase costs in each solution divided by planned investment lifecycle time
Monthly total cost of ownership (TCO) per 1 virtual machine	Calculated monthly cost per 1 virtual machine including installation phase costs in each solution divided by planned investment lifecycle time
Percentage of coopetition variant of TCO per 1 virtual machine	Percentage comparison of TCO per 1 virtual machine with reference to titular coopetition scenario D
Time spent from project start to production use of VM's (in months)	Estimated time needed for deployment phase (from installation phase to production phase)

Results

Following the objectives outlined in the materials and methods section the results of the analysis shall be provided in this section. To explain the most important cause and effect relationships author provided results in a form of the table presented below:

Table 2: Results of conducted research on possible multicloud deployment solutions for Polish National Cloud

Variables	Solution A	Solution B	Solution C	Solution D
Data Center Facilities	$ 657 895	$ -	$ 328 947	$ -
Redundant power systems	$ 39 474	$ -	$ 19 737	$ -
Power Distribution Unit and Cabling	$ 52 632	$ -	$ 26 316	$ -
Cooling systems and air distribution	$ 210 526	$ -	$ 105 263	$ -
Fire Suppression and Physical Security	$ 65 789	$ -	$ 32 895	$ -

Network devices and cables	$ 39 474	$ -	$ 19 737	$ -
Redundant Internet connection	$ 631 579	$ 315 789	$ 315 789	$ 78 947
IT human resources cost in deployment phase	$ 473 684	$ 78 947	$ 236 842	$ -
IT human resources cost for maintenance	$ 1 657 895	$ 1 263 158	$ 828 947	$ 631 579
Software and other licenses	$ 236 842	$ 157 895	$ 118 421	$ -
Average cost of electricity	$ 568 421	$ -	$ 284 211	$ -
Dedicated servers cost	$ 15 789 474	$ -	$ 7 894 737	$ -
Monthly cost per 1 virtual machine	$ 68,08	$ 40,99	$ 75,03	$ 40,99
Monthly cost of all virtual machines (two sites 5000 VMs each)	$ 680 789	$ 409 895	$ 750 289	$ 409 895
Monthly total cost of ownership (two sites 5000 VMs each)	$ 680 789	$ 440 158	$ 750 289	$ 421 737
Monthly total cost of ownership (TCO) per 1 virtual machine	$ 68,08	$ 44,02	$ 75,03	$ 42,17
Percentage of coopetition variant of TCO per 1 virtual machine	161,43%	104,37%	177,90%	100,00%
Time spent from project start to production use of VM's (in months)	8	2	6	6

Source: Author's work based on (Antal, 2020; DataCenterKnowledge, 2007; Dell, 2020; Geng, 2015, pp. 121–135; Google Cloud, 2020; Harms and Yamartino, 2010; Microsoft, 2020; Neil Rasmussen, 2019; Ongoing Operations, 2020; Ponemon Institute LLC, 2016; Wu and Buyya, 2015; Xu and Liang, 2015)

Discussion and Conclusion

The main purpose of this paper was to examine the effectiveness of multicloud solution provided by Google and Microsoft for Polish National Cloud and assess if their coopetition agreement is actually more resource effective than the traditional approach of building own data center. The comparison to other mixed strategies for multicloud deployment has been conducted too. It has been established that indeed, from the cost perspective, coopetition between the abovementioned partners might be *ceteris paribus* more effective comparing to other solutions of: a) building own data centers; b) building own data center and rent backup site from cloud provider; c) rent main and backup site from two different cloud providers. However, the difference between Total Cost of Ownership in a monthly calculation is not significant for all presented solutions since one might observe that in "Solution B" it is only 4,37% more expensive than the titular coopetition strategy. What is also worth mentioning, in qualitative variable described as time spent for infrastructure to be ready to use, the analysed coopetition agreement seems to be *ceteris paribus* less effective due to longer period needed for configuration comparing to "Solution B". Nonetheless, it should be noted that coopetition agreement in this particular project certainly positively affected its members' chain value and has led to provide more complex solution with lower operational costs as well as possible easier usage due to the

abandonment of vendor lock-in effect. Moreover, it is an undeniable fact that because of the development of cloud computing technology, the traditional IT approach presented in this paper as an alternative solution for large enterprises infrastructure model is *ceteris paribus* no longer cost, time and human resources effective comparing to modern IaaS, PaaS and SaaS models. Probably, for much bigger projects that involves very long-term investment lifecycle time, it might be considered as a better solution, which in author's opinion is something to be considered for analysis in the future research. Taking into consideration all of the theoretical, conceptual and empirical aspects raised throughout the course of the research one should definitely consider business strategy of coopetition as an economical solution for mutlicloud infrastructure deployment for most of the enterprises and public sector organisations.

Abstract

Development of digital technology has led to emergence of new business models including the multisided platforms, which have become the basis for active development of e-commerce companies. Today, competition among e-commerce companies is intensifying and there is a need in a more detailed study of their competitive strategies and sources of competitive advantage. This article is based on the results of qualitative research of Russian and French marketplace consumers, which allowed identifying their competitive advantages and comparing competitive strategies.

Keywords: Multisided Platforms, E-Commerce, Competition Strategies, Competitive Advantages.

Introduction

Nowadays economic activity, which is based on advanced digital technologies related to electronic commerce and electronic business, is being formed and expanded quite actively in all economically developed countries. This trend also applies to Russia and France. Today it is a fact that the Internet information network is rapidly growing and developing. The level of computer literacy is rising and developing very fast. Communication facilities also do not stand still and over a half of the world's population actively exchange information by means of various technologies.

Multisided platforms have taken an important place in the global economy as a result of the information technology revolution. Multisided platforms are diverse, do not have a clear concept, their classification requires further refinement, and certain methods are needed to be developed for their analysis and evaluation. The research issues related to multisided platforms are wide in such sense that without dividing them into types it is impossible to conduct the research, therefore it is necessary to narrow the topic and focus on a specific example. In the era of the Internet, it will be relevant to use e-commerce as the example for this research.

The goal of this research is to study the essence of competitive relations in the market of multisided platforms on the example of e-commerce Russian and French companies.

Theoretical Background

The concept of a "multisided platform" is quite extensive. It is necessary to highlight several basic and popular definitions in order to concretize the study. Each expert describes a multisided platform as a complex of various components that create a platform for exchange between market participants [3, 4, 5, 8]. In addition, scientists show

Cite this Article as: Valentin GALENKO, Iana SALIKHOVA, Olga TABELOVA and Lyazzat BUDIROVA“ Competitive Strategies of Multisided Platforms on The Example of Russian And French E-Commerce Companies” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

that almost every multisided platform is related to IT technology [8]. Some define the platform as an economic activity that is carried out between intermediaries on the same site [5].

However, such broad concepts don't fit the study, which is associated with the platform competition in the market, since a full analysis of the multisided platform and a highlight of the concept of competition in the market will be more difficult without a more narrow definition. The European Commission has accurately and clearly described the essence of the multisided platforms [4]. A functional study of the platforms will help to identify the general trend and form a concept of competition in this market.

Competition Concepts

The market position of the company is considered from the position of competitive advantages on the basis of the model of imperfect competition markets, approaches of the industrial organization theory and the strategic planning theory, therefore the choice of the effective strategy should be carried out depending on the market type and available resources.

M. Porter created a model that is expressed in the unity of relationship between important aspects of competition: competitive forces of the industry, competitive strategies, competitive advantages. Porter believed [9]: in any industry, the intensity of competition and the expected size of profit are determined by the interaction of factors that form the structure of the industry.

Success in competition is the choice of the competition strategy (leadership in costs, leadership in differentiation and focus on costs or differentiation) depending on the situation in the industry. The competitive strategy is based on competitive advantages, their deepening and improvement, which allows us to gain a strong market position and achieve high financial results. He examined the issues of companies' effective performance and success in competition by considering the characteristics of the current competitive (external) environment and internal capabilities (resources) of the company.

Resource – if it is necessary to adapt companies to the conditions of variability and uncertainty of the market environment, it is important to determine the sources of competitive advantages; in the competition, the company needs to transform its own unique value into a long-term strategy.

M. Tresi and F. Wiersema developed a theory of unique values, where any unique value of the company in the eyes of consumers is considered as a competitive advantage. They believed: the following areas of search for unique values can be distinguished [9]:

1) improvement of production processes and operational activities;
2) product improvement;
3) improvement of customer service processes.

Institutional – due to the emergence and development of new organizational forms that are highly flexible, it became necessary to reorient the companies' strategies towards combining competition and cooperation between market participants, considering long-term relationships with consumers, partnerships and strategic alliances as the main sources of competitive advantages.

J. Moore's theory focuses on the driving force of the economy that is not only traditional competition, but also cooperation. Drawing analogies between the ecological system and the business environment, Moore sees the company as an element of an ecosystem where processes of competition and evolution, which Moore called "co-evolution," are developing together. Since new conditions for companies' functioning (eco-environment) make the strategy aimed at creating a competitive advantage for a company much less effective, the companies need to develop the strategy that is consistent with the external environment and combines elements of competition and cooperation towards the joint evolution of all ecosystem companies [9].

While developing the competitive strategies, it is necessary to take into account the Antitrust laws (documents that allow regulating competition within the legal framework) of different countries; it is also important to remember that imperfect competition prevails in a modern market economy: pure monopoly, oligopoly and monopolistic competition. The main feature of the market for such competition is the ability of individual sellers and buyers to influence the price to a certain degree. But the Antitrust legislation just limits the competition and identification of market boundaries, does not allow it to be precisely assessed by any methods, and, moreover, not all laws are applicable to the current market trends, especially in the digital field.

The classical models are more applicable to the traditional market, not to the market of multisided platforms, that is, they are not fully suitable for digital markets. Nevertheless, some competition concepts can be applied to such platforms due to their functional characteristics. By analyzing the Porter model and conducting PEST analysis it is possible to understand how to compete with the platforms in a better way. Porter's current research is the foundation for digital economics and multisided platforms. By exploring threats and weaknesses, as well as competitive advantages, developing a successful concept of competition in the platform market dramatically simplifies the tasks of strategic management. The rest concepts need to be either developed or corrected, taking into consideration that multisided platforms are often technology related.

The main concept of competition in the Internet is the "long tail" concept developed by C. Anderson [6]. This concept examines not very popular goods that are in low demand. These goods could increase their profitability because consumers are leaving the main markets. This theory is supported by the growing number of online marketplaces that make the competition for shelf space less tough and allow a countless number of products to be sold, especially through the Internet. The overall demand for these less popular goods as a comprehensive whole could rival the demand for the mainstream goods. While main products achieve a greater number of hits through leading distribution channels and shelf space, their initial costs are high, which negatively influence their profitability. In comparison, long tail goods have remained in the market over long periods of time and are still sold through off-market channels. These goods have low distribution and production costs yet are readily available for sale. For example, different types of retailers: physical, hybrid, pure digital with no physical goods.

The analysis of E-Commerce Markets

The E-Commerce Market in Russia

According to DataInsight 2018 [10] Russian e-commerce market is diverse and ambiguous. For example, statistics include online stores that have regular outlets, which are familiar to customers. These are mainly the products representing such categories as electronics and technology (ex, M.video) and goods for home (ex, Petrovich). The rating also includes representative offices of foreign companies in Russia – IKEA и Leroy Merlin (goods for home). DNS technopoint was mentioned in the rating as a separate online store, but in reality it belongs to the DNS network, so that is why it was deleted from rating.

The leading companies are mainly associated with electronics and technology, as demand for these types of products is constantly growing. Consumers in Russia have a variety of gadgets with technological innovations, constantly try to update them, that is, they buy the latest released products. Most consumers are young people who keep up with the times. They strive to develop in various directions, therefore they often engage in freelance work, and this requires more time, so purchases in online stores are gradually gaining momentum. Clothing stores are less in demand, as it is easier for people to pick up wardrobe items in traditional stores.

Table 1: E-commerce Russian companies from Top-100 (compiled by the authors based on data [10])

№	Store name	Goods category	Online sales (mln. rub.)	
			2018	Changes, % (2017-2018)
1	WildBerries	Universal	111 200	74%
2	CitiLink	Electronics and Technology	73 200	33%
3	M.video	Electronics and Technology	52 800	46%
4	Ozon	Universal	41 770	73%
5	DNS	Electronics and Technology	38 810	83%
…	…	…	…	…
96	Kuvalda	Goods for home	1 860	31

The last positions of the rating are mainly highly specialized stores that do not have a wide range of products and do not inspire confidence among buyers, since there are not too many stores and purchases are made only through websites.

At the moment, the Russian e-commerce market is at the stage of development and has every chance to reach the world level, but it is necessary to develop certain strategies and follow common standards in order to satisfy consumer demand. Constant monitoring of how the market is changing at the online sites is also required.

The E-Commerce Market in France

According to e-commerce top-100 rating 2018 [2], the e-commerce market of France is mainly inhabited by foreign companies like Amazon and Booking.com. Basically, these stores are universal, that is, they sell a variety of goods. Their profits are noticeably higher as the market has gained popularity among consumers and marketing of products takes place throughout Europe, not only in France. It is profitable for them to sell universal products.

The leading positions are held by a number of foreign representative offices and several domestic companies. Each company has high sales ratings as well as marginally changing profits compared to previous periods. French consumers value the balance of life, because it's easier for them to buy in some large stores where everything is in common and quick access, and therefore online sales are high.

Table 2: E-commerce French companies from Top-100 (compiled by the authors based on data [2])

№	Store name	Goods category	Online sales (mln. eu.)	
			2018	Changes, % (2017-2018)
1	Amazon	Universal	184 303	4
2	Leboncoin	Universal	162 501	-2
3	CDiscount	Universal	60 92	-8
4	ebay	Universal	41 042	-4
5	Booking.com	Travelling	31 355	7
…	…	…	…	…
96	Digitick	Events	2 137	-23
97	UGC	Events	2 176	-10
98	NaturaBuy	Hobbies	2 160	10
99	Just eat	Food	2 146	10
100	Voages	Travelling	2 145	9

As for the last positions of the rating, they are mainly highly specialized stores that sell tickets for cultural events, as well as a number of online stores that sell items for personal use, such as travel, hobbies, food. These stores do not have ordinary stores, therefore only a certain part of the population is also aware of them.

The design of empirical research

The goal of the empirical study is to identify the competitive strategies and competitive advantages of Russian and French e-commerce companies.

Tasks:
1. To analyze the competitive strategies of e-commerce.
2. To conduct semi-structured interview with e-commerce consumers in order to analyse how consumers choose companies for purchases.

The main method of an empirical study is a qualitative method in the form of semi-structured and in-depth interviews.

The purpose of the semi-structured interview of consumers is to identify the impact of competition on consumer behavior when they choose what e-commerce company to buy from.

Research questions:
1. How buyers choose e-commerce companies to buy from?
2. What criteria of online purchasing are important for buyers?
3. What companies of e-commerce buyers choose to buy from?
4. What competitive advantages do the leading companies have from the buyers' point of view?
5. Which e-commerce companies are competitors in the French and Russian markets?

A group of interview questions related to e-commerce: general information about consumers (activity, gender, age, city of residence), about consumers' purchases (how often they buy products online, where/when/why do they buy products, etc.), about the leading companies and their competitors.

The Results of Empirical Research

The respondents for consumer interviews were selected solely among the clients of the leading e-commerce companies, according to DataInsight statistics and e-commerce book. Nevertheless, it was already evident at the stage of consumer surveys that Wildberries are often compared to the Ozon store. Each respondent answered truthfully, they were not confused in their answers, that is, they did not contradict their own words. Unfortunately, some of the answers came out short because the respondents were also chosen among strangers, that is, they did not reveal themselves too willingly and there were some deviations from the guide interview with the addition of extra new questions and the removal of the fixed ones. The interview involved 6 people, 3 from Russia and 3 from France.

The analysis of e-commerce competition

Wildberries

The international online store with a universal assortment of goods (clothing, electronics, household goods, etc.). It works in the markets of the Russian Federation, Belarus, Kazakhstan, Kyrgyzstan and Armenia, as well as in Poland.

The goods are various, each consumer can find something that will satisfy him/her with both the price and quality. There is also a discount system.

The company works directly with clothing manufacturers and official distributors. They independently form the assortment line of their goods in the online store and retail prices. Wildberries makes money on commissions based on the results of sales. Delivery across Russia takes place from its own logistics center in the Moscow region as well as warehouses located in large cities. Payment can be made in cash or by card. The store's website is understandable enough, logically divided into sections, where all the necessary information is provided to consumers and suppliers. Moreover, at the website consumers can find an online fashion magazine, advices from fashion experts and other buyers, etc.

The main competitive strategy is B2C business model and cooperation with suppliers.

Ozon

Ozon is the online store with a universal assortment of goods (clothing, electronics, household goods, etc). It operates in the market of the Russian Federation, only a certain number of goods' types are delivered to countries such as Azerbaijan, Japan, the USA, the EU countries and other locations.
Each consumer is offered multiple discounts and promotions, but the prices for delivery vary, especially when speaking about delivery abroad, depending on customs duties. Also, Ozon offers referral programs. The quality of goods fully corresponds to the prices. Delivery is amazingly fast and is done through various channels and methods: courier service, postal delivery, etc. A successful logistics system for covering as many territories as possible is established.

The store's website is accessible to everyone, divided into product catalogs, including special catalogue with healthy goods (today some people try to pay special attention to their health). In addition to this, there is also a mobile application, which allows being in touch with store 24/7.
The main competitive strategy is B2C business model and cooperation with suppliers.

The Table 3 below evaluates and compares these two online stores. The ranking takes place on points on a scale of 1 to 5, the rating makes 1 for bad, 2 – less good, 3 – average, 4 – good, 5 – excellent respectively.

Table 3: Assessment of competitors – Wildberries and Ozon (complied by the authors based on the data [7])

Competitive characteristics	Wildberries	Assess-ment	Ozon	Assess-ment
Access to website	Accessible and understandable website. Extra features: • A store guides. • Fashion encyclopedia. • Exchange of customer experience (galleria of fashion). • Mobile application.	5	Accessible and understandable website. Extra features: • Mobile application. • Extra catalogue with healthy goods. • Referral program.	4
Logistic system	Cooperation with clothing manufacturers and official distributors. Delivery across Russia from its own logistics center in the Moscow region and warehouses located in large cities. Delivery by post and courier service.	5	Warehouses located in large cities. Delivery by post and courier service.	4
Price and payment system	Low to high with discounts. Cash, credit card.	5	Low to high with discounts (price on delivery depends on taxes). Cash, credit card.	5
Variety and quality of goods	Universal Good quality	5	Universal Good quality	5

In general, Wildberries and Ozon show wonderful results in the main characteristics, such as diverse assortment of goods. But Wildberries has greater advantages that define it as a stronger competitor. It has a great logistics system, an interesting and easily accessible website, and payment is carried out in two main ways - online or in cash. Its main advantage is the logistics system, which includes its own logistics center, large warehouses, and cooperation with large suppliers. Ozon is represented only in the Russian market with delivery to some other countries, the price of which depends on customs duties. However, the website has an advantage over the Wildberries website with extra catalogues and referral programs. Ozon is recommended to have logistics centers not only in Russia, but also in other countries so that to minimize transport costs and duties. Wildberries shouldn't lose its grip in the ranking of online retailers and continue developing technologically.

Respondents' answers and this analysis show that companies are strategically developing in the right directions. Their competitive advantages are similar. But Ozon is inferior to Wildberries in the size and functional characteristics of logistics channels. The Ozon website is stronger with interesting new catalogs that are relevant to the modern world. Wildberries should pay attention to accessibility to other regions of Russia. The range of products from companies is wide and often satisfies customers with the quality of not only the product itself, but also the service. Price, delivery, goods and services in common are important to consumers. It is necessary to stay in the market of marketplaces in Russia for such large players, since some consumers buy goods on foreign websites such as Aliexpress.

Leboncoin

It is a French website of free classified ads that covers all regions of France, where new and used goods are sold, information about the services provided by individuals and professionals is published. Collaboration with partners allows saving on many storage facilities. There is a sorting base where goods are stored and sent to the recipient through a courier service or postal delivery. Payment occurs only online by credit card. Everyone has access to the website for general familiarization, but for certain functions the user needs to register an account, then, for example, the user will be able to publish his advertisement on finding or hiring new employees. On the website everything is

divided into catalogues of goods and services, and consumers can also sort by geography of France to find what they need within walking distance. Also, the website has a mobile application. Leboncoin is widely represented in social medias (ex., Facebook).

The main competitive strategy is partly B2C – partly C2C business models and cooperation with suppliers.

CDiscount

The online store that sells a variety of goods, which is focused on offering goods to its customers at a reduced price, thanks to discount programs like Black Friday sales or some kind of holiday sale. Each CDiscount partner is licensed and has a quality guarantee. Logistics is provided efficiently, since large warehouses are used in cities in France, it is possible to order goods at home or pick up a parcel at the pick-up point, which saves money on delivery. The store has a mobile application that is constantly updated. The site is partially accessible (the main points after registering the account), all categories and sections are understandible, in addition there is an extra section, where the guide and tips for buyers are provided so that they can be sure of the right choice they made when buying. CDiscount posts news on Youtube, Facebook, Twitter. Payment on CDiscount is possible in various ways.

The main competitive strategy is B2C business model and cooperation with suppliers.

The Table 4 below evaluates and compares these two online stores. The ranking takes place on points on a scale of 1 to 5, the rating makes 1 for bad, 2 – less good, 3 – average, 4 – good, 5 – excellent respectively.

Table 4: Assessment of competitors – Leboncoin and CDiscount (complied by the authors based on the data [7])

Competitive characteristics	Leboncoin	Assessment	CDiscount	Assessment
Access to website	Incomplete access to website functions, but understandable website. Possible to sort by catalogue of goods and services, sort by geography. Mobile application. News posting in different social media.	4	Incomplete access to website functions, but understandable website. Possible to sort by catalogue of goods and services. Mobile application. News posting in different social media.	4
Logistic system	Partnership collaboration and sorted base. Delivery by post.	5	Large warehouses and pick-up-points are used in cities. Delivery by courier service.	5
Price and payment system	Low to high, depends on consumers. Only credit cards – online payment.	3	Low to high with discounts. Payment in various ways.	5
Variety and quality of goods	Universal	5	Universal	5

Respondents called these companies competitive with their certain advantages and disadvantages. Basically, customers are satisfied with both companies, as they satisfy their demand for goods and services. But they like Leboncoin more because they can sell or buy used goods. CDiscount only sells goods and some small services. Prices for goods vary, accessible to everyone. CDiscount is less competitive because it does not specialize in buying or selling used goods compared to Leboncoin. However, Leboncoin loses in competition because the payment options are limited. Compared to CDiscount, Leboncoin does not have a section of product tips and guides, but the logistics system is wider.

Wildberries and Leboncoin

Following the data of the Similar Web analytical portal for the last period (December 2019 - February 2020), Wildberries and Leboncoin show good results in terms of indicators.

In Wildberries, most users access the site using mobile devices (56%). This can be explained by the fact that the company developed mobile applications specifically for its store. In Leboncoin, users use more computers (56%). This company does not have its own mobile application, and the website is adapted more for desktops. Wildberries mainly works in Russia, so most users are citizens of this country. Same is true for Leboncoin and France respectively. Wildberries advertises more on Google and Leboncoin on Yahoo. If we compare the use of Google by both companies, Leboncoin uses Google less compared to Wildberries (14%).

Compared to Leboncoin, Wildberries is less visited, since it is mainly a store that sells goods, not services, that is, Leboncoin is not only an online retailer, but also a message board where a user can obtain services and buy new or used goods.

Engagement
Dec 2019 - Feb 2020 Worldwide

Domain	Monthly visits	Monthly unique visitors	Visits / Unique visitors	Visit duration	Pages per visit	Bounce rate
leboncoin.fr	**152.7M**	**21.78M**	**7.01**	00:11:28	13.28	**22.87%**
wildberries.ru	93.59M	18.56M	5.04	**00:11:51**	**15.82**	25.59%

Fig. 1: Engagement of Wildberries and Leboncoin [1]

When speaking about percentage of incoming traffic from each marketing channel, Wildberries and Leboncoin use more direct channels and less display ads channels. It is more effective for such companies.

Fig. 2: Channels overview of Wildberries and Leboncoin [1]

Wildberries spends less on advertising per click ($ 1.01 per click) than Leboncoin ($ 1.27 per click). This is because Wildberries, in comparison with Leboncoin, is a more highly specialized company.

Top Search Terms: Organic

Dec 2019 - Feb 2020 Worldwide Desktop Only

leboncoin.fr wildberries.ru

Search Term	Traffic Share	Group Share Split	Volume	CPC

leboncoin	13.79%	100%	14,850,000	$0.38
wildberries	3.68%	100%	1,646,670	$0.08
bon coin	3.22%	100%	5,673,330	$0.49
вайлдберриз	2.17%	100%	2,081,670	$0.21

Fig. 3: Top-search terms of Wildberries and Leboncoin [1]

These companies use social networks that are popular in their own countries, for example, Facebook is popular in the European Union, and VKontakte is popular in Russia and CIS countries. The diagram shows that Wildberries pays more attention to advertising on social networks than Leboncoin. Wildberries uses Youtube more, as it is easier to show goods and look at customer reviews, as well as hold fashion webinars.

	leboncoin.fr	wildberries.ru
Facebook	81.29%	2.01%
Youtube	15.22%	35.66%
VKontakte	0.04%	47.15%
Odnoklassniki.ru	< 0.01%	8.86%
WhatsApp Webapp	0.34%	2.12%
Instagram	0.23%	2.02%
Others	2.88%	2.18%

Fig. 4: Social networks of Wildberries and Leboncoin [1]

Wildberries and Leboncoin are different, it is difficult to compare them. Each company has a clear website, but access to Leboncoin is limited. The range of products from companies is diverse, but in addition to products, Leboncoin also provides services. The payment system is wider with Wildberries, while at Leboncoin only online payment is available. Logistics at the stores is also different, although both companies have a delivery system and partnerships with suppliers, Leboncoin uses only postal delivery. The Wildberries' advertising campaign is stronger than the one of Leboncoin, although there are more advertising costs. Wildberries website is less visited than the website of Leboncoin, as this company provides a wider range of services. It is recommended for Leboncoin to use more advertising on social networks and reduce advertising costs. In general, both companies are strong competitors in the e-commerce market.

Conclusion

The results of empirical research show that the majority of consumers choose e-commerce companies according to standard criteria: price and quality of goods, logistics (mainly delivery time and points of delivery). They also identified some of the competitors of the leading e-commerce companies and expressed their opinion on the competitive advantages of companies, which shows what strategy the companies should better use in order to satisfy consumer demand.

The e-commerce market of France is quite developed, but the majority of respondents say that most companies are foreign, that is, there are very few domestic stores. Every respondent named Leboncoin and CDiscount as the companies that they choose for purchases based on price, quality, assortment of goods and services. The standard criteria are important for them, but one respondent mentioned an unusual reason for choosing Leboncoin – to reduce pollution of the planet. In Europe, especially in France, they care about health and the environment very much, so it is important for companies to show that they are Ecofriendly and oriented to sustainable development.

The Russian market of e-commerce is quite developed, but among the main large companies, the selected consumers have the opinion that the competitors of Wildberries are only Ozon, as well as foreign representatives in the market, like Aliexpress and Amazon. Consumers often buy goods in these stores because the price and quality are higher, as well as the site and logistics are more convenient compared to other companies. In addition, the system of accumulating discounts and a convenient return are important to consumers. In general, customer service should be really high these days so that to be able to satisfy customers' demand for goods and services.

Modelamiento De Ecuaciones Estructurales Aplicado Al Ámbito Del Teletrabajo. La Autonomía, Factores Estresantes Y Agotamiento De Teletrabajo

Resumen

Este estudio explora la relación entre la autonomía, factores estresantes y el agotamiento, asociados al teletrabajo, utilizando modelamiento de ecuaciones estructurales. A partir de encuestas aplicadas a teletrabajadores, se evalúa un modelo de comportamiento. Los resultados muestran que el aislamiento incide negativamente en los factores estresantes asociados al teletrabajo, sobrecarga de trabajo, conflicto trabajo-hogar y ambigüedad de rol, mientras que sólo la sobrecarga de trabajo incide en el agotamiento de teletrabajo.

Palabras Clave: Modelamiento, Teletrabajo, Comportamiento.

Las organizaciones han presentado un crecimiento importante en la cantidad de teletrabajadores, quienes utilizan la tecnología para trabajar fuera del lugar de trabajo (Villafrade y Palacios,2013), lo que presenta sus propias características y aspectos negativos en los trabajadores, relacionados con el estrés a que se encuentran expuestos en distintos ambientes fuera del lugar del trabajo común (Weinert, Maier y Laumer,2015).

Este estudio busca establecer si la autonomía (características del teletrabajo), afecta a factores estresantes asociados al teletrabajo, como la sobrecarga de trabajo, el conflicto trabajo-hogar y la ambigüedad de rol, incidiendo en el agotamiento de teletrabajo.

Antecedentes e Hipótesis

El teletrabajo es trabajar a distancia, fuera de la organización, utilizando tecnologías de información y comunicaciones (Camacho y Higuita,2013), posee tres características (Weinert, Maier y Laumer, 2015): autonomía, falta de información y aislamiento. La autonomía es la medida en que los individuos pueden estructurar cómo y cuándo realizan sus tareas laborales, mientras trabajan desde casa (Spector,1986).

Tres aspectos son factores estresantes asociados al teletrabajo:

-Sobrecarga de trabajo, la cantidad de trabajo excede la capacidad de un individuo mientras trabaja desde la casa (Baruch,2000).
-Conflicto trabajo-hogar, las demandas de la vida laboral y familiar son incompatibles en algún aspecto, de modo que la participación en un rol se hace más difícil debido al teletrabajo (Golden,2012).
-Ambigüedad de rol, el grado en que el trabajador carece de información clara sobre su rol mientras trabaja desde casa, y se observa en los trabajadores ya que presentan la necesidad de responder a las demandas constantes estimuladas por el presentismo que eventualmente resta tiempo al trabajo (Ayyagari, Grover y Purvis,2011).

Cite this Article as: Karla ADAMS-CORTEZ, Sergio ARAYA-GUZMÁN and Cristian SALAZAR-CONCHA "Modelamiento De Ecuaciones Estructurales Aplicado Al Ámbito Del Teletrabajo. La Autonomía, Factores Estresantes Y Agotamiento De Teletrabajo" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Uno de los factores estresantes asociados al teletrabajo es el agotamiento (Weiner, Maier y Laumer,2015), el tedio físico, emocional y mental por la participación a largo plazo en situaciones exigentes, siendo los profesionales de las tecnologías particularmente vulnerables a él (Moore,2000).

Sobre la base de los planteamientos anteriores, surgen las hipótesis, para teletrabajadores:

H1:La autonomía incide en la sobrecarga de trabajo.
H2:La autonomía incide en el conflicto trabajo-hogar.
H3:La autonomía incide en la ambigüedad de rol.
H4:La ambigüedad de rol incide en el conflicto trabajo-hogar.
H5:El conflicto trabajo-hogar incide en la sobrecarga de trabajo.
H6:La sobrecarga de trabajo incide en el agotamiento.
H7:El conflicto trabajo-hogar incide en el agotamiento.
H8:La ambigüedad de rol incide en el agotamiento.

Metodología

Se aplicaron encuestas a teletrabajadores de empresas nacionales y multinacionales presentes en Chile.

Siendo el teletrabajo un aspecto que presenta cierta complejidad social dadas las variables involucradas, resulta conveniente utilizar modelos de ecuaciones estructurales (SEM), ya que permite incorporar variables no observables medidas indirectamente por variables observables, siendo principalmente utilizado en el desarrollo de teorías en investigaciones exploratorias, enfocándose en explicar la varianza de las variables dependientes que examina el modelo de investigación, de manera de probar las relaciones entre variables latentes en el nivel teórico, constituyendo una herramienta de utilidad en investigaciones en el campo de las ciencias sociales (Hair et al., 2014), ajustándose a las características de este estudio. El análisis estadístico de los datos utilizó SEM basado en PLS-SEM y el software SmartPLS.

Resultados

Los resultados presentados corresponden a 50 encuestas válidas. Los datos obtenidos validan satisfactoriamente la evaluación de ajuste del modelo y el modelo de medida, cumpliéndose las condiciones exigidas según la literatura. La evaluación del modelo estructural se presenta en la figura 1, soportándose hipótesis H1, H2, H3, H4, H5 y H6. Los resultados señalan que: la variación de la sobrecarga de trabajo es explicada en un 65,9% por la variación de la autonomía y del conflicto trabajo-hogar, la variación del conflicto trabajo-hogar es explicada en un 56,9% por la variación de la autonomía y de la ambigüedad de rol, la variación de la ambigüedad de rol es explicada en un 14,3% por la variación de la autonomía, la variación del agotamiento de teletrabajo es explicada en un 67,8% por la variación de la sobrecarga de trabajo.

Figura 1: Modelo Estructural

(Fuente:Elaboración propia)

Conclusiones

Los resultados muestran que autonomía afecta (negativamente) a sobrecarga de trabajo, a conflicto trabajo-hogar y a ambigüedad de rol, de los teletrabajadores; mientras que sólo sobrecarga de trabajo incide en agotamiento de teletrabajo, la incidencia de conflicto trabajo-hogar y de ambigüedad de rol sobre agotamiento de teletrabajo no son significativas.

La utilización de PLS-SEM ratifica lo señalado por autores como Cepeda, Nitzl y Roldán (2017), siendo útil para efectuar análisis de variables en un contexto complejo, facilitando el desarrollo de estudios en distintas áreas de las ciencias sociales.

Resumen

Este estudio explora la relación entre gestión del conocimiento y rendimiento organizativo en instituciones educativas de Fuerzas Armadas, utilizando modelamiento de ecuaciones estructurales. A partir de encuestas aplicadas a personal de estas organizaciones, se evalúa un modelo de comportamiento. Los resultados muestran que existen relaciones significativas entre las variables del modelo propuesto, y que la utilización del conocimiento incide en el rendimiento de la institución, especialmente en aspectos asociados la rapidez en la toma de decisiones y la capacidad de adaptarse rápidamente a los cambios del entorno.

Palabras Clave: modelamiento, gestión del conocimiento, comportamiento.

Introducción

El conocimiento constituye una mezcla de experiencias, valores, información y saber hacer (Hernández,2016), su gestión puede colaborar en el desarrollo y mejora de los niveles de competitividad, rendimiento de la organización (Nonaka y Takeuchi,1995).

Este trabajo busca explorar si la gestión del conocimiento incide en el rendimiento de instituciones de educación superior de Fuerzas Armadas, entendiendo que en dicha gestión intervienen la creación, almacenamiento, transmisión y utilización del conocimiento.

Antecedentes e Hipótesis

Pallarès (2014) plantea la gestión del conocimiento como un conjunto de etapas a través de un proceso continuo, contemplándose la creación, adquisición, captura, transmisión y utilización del conocimiento, para incrementar el aprendizaje y los resultados de las organizaciones.

Este estudio se enfoca en instituciones educativas de Fuerzas Armadas, con un sistema propio de educación, habilitadas para entregar títulos técnicos y profesionales.

El conocimiento generado puede ser útil para generar nuevo conocimiento, permitiendo que la organización aprenda, motivando que sea almacenado para facilitar su retención y posterior recuperación (Fainholc,2006). El conocimiento almacenado en una memoria organizativa, puede utilizarse en el futuro, para perfeccionar los productos y/o servicios y facilitar la toma de decisiones (Hernández,2016).

Cite this Article as: Eduardo PALACIOS-FUENTEALBA, Sergio ARAYA-GUZMÁN and Cristian SALAZAR-CONCHA "Modelamiento De Ecuaciones Estructurales Aplicado Al Ámbito De La Gestión Del Conocimiento Y El Rendimiento Organizativo En Instituciones De Educación De Fuerzas Armadas" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

La memoria organizativa está compuesta por tres depósitos de conocimiento, donde se almacenan las ideas pasadas, que influyen en la forma de conducir las acciones presentes: las personas, los sistemas de información y la cultura organizativa (Joglar,2010).

El conocimiento creado y almacenado no es útil si no es transmitido a otros miembros de la organización para ser utilizado (Nonaka y Takeuchi,1995), en los procesos de toma de decisiones o en la generación de nuevo conocimiento (Pereira,2014).

El desarrollo de nuevas ideas o proyectos requiere de una transmisión eficaz del conocimiento, permitiendo una mejor efectividad al momento de tomar decisiones (Fontalvo, Quezada y Puello,2011).

El conocimiento puede ser utilizado para mejorar la efectividad de las organizaciones, mejorar la calidad del trabajo, reducir errores, mejorando la forma de hacer las cosas (Wiig,1997), su uso eficiente permite alcanzar mejores rendimientos Valhondo (2003).

Estos planteamientos sustentan las hipótesis, para instituciones de educación superior de Fuerzas Armadas:

H1: La creación del conocimiento incide en la memoria organizativa.
H2: La memoria organizativa incide en la transmisión interna del conocimiento.
H3: La transmisión interna del conocimiento incide en la efectividad organizativa.
H4: La efectividad organizativa incide en el rendimiento organizativo.

Metodología

Se aplicaron encuestas a personal directivo y administrativo de la Escuela de Suboficiales de Carabineros de Chile (Sede Concepción).

Siendo la gestión del conocimiento un aspecto que presenta cierta complejidad social dadas las variables involucradas, resulta conveniente utilizar modelos de ecuaciones estructurales (SEM), ya que permite incorporar variables no observables medidas indirectamente por variables observables, siendo principalmente utilizado en el desarrollo de teorías en investigaciones exploratorias, enfocándose en explicar la varianza de las variables dependientes que examina el modelo de investigación, de manera de probar las relaciones entre variables latentes en el nivel teórico, constituyendo una herramienta de utilidad en investigaciones en el campo de las ciencias sociales (Hair et al.,2014), ajustándose a las características de este estudio. El análisis estadístico de los datos utilizó SEM basado en PLS-SEM y el software SmartPLS.

Resultados

Los resultados presentados corresponden a 50 encuestas válidas. La evaluación de ajuste del modelo global, indicó que, para la memoria organizativa sólo se visualiza la variable sistemas de información, lo que se consideró para continuar con el proceso, cuyos resultados se presentan.

Los datos obtenidos validan satisfactoriamente la evaluación de ajuste del modelo global y el modelo de medida, cumpliéndose las condiciones exigidas según la literatura. La evaluación del modelo estructural se presenta en la figura 1, soportándose hipótesis H1, H2, H3 y H4, apreciándose la relación y explicación existente entre las variables.

Figura 1: Modelo Estructural

(Fuente:Elaboración propia)

Conclusiones

Los resultados muestran que en instituciones educativas de Fuerzas Armadas existe un desarrollo de la gestión del conocimiento involucrado en su funcionamiento, presentando relevancia aspectos como la creación de conocimiento a partir del conocimiento existente, lecciones aprendidas y mejores prácticas, la disponibilidad de medios que permitan acceder fácilmente al conocimiento existente y actualizado, incidiendo positivamente en el rendimiento organizativo, principalmente en la rapidez en la toma de decisiones y la capacidad de adaptarse rápidamente a los cambios del entorno. La utilización de PLS-SEM ratifica lo señalado por autores como Cepeda, Nitzl y Roldán (2017), siendo útil para analizar variables en un contexto complejo, facilitando el desarrollo de estudios en distintas áreas de las ciencias sociales.

Abstract

The increasing frequency of landslides in the most urban and densely populated Penang Island in Malaysia has become a continuous cause for concern of hillside development governance. This study uses directed content analysis of secondary data to examine good governance for sustainable hillside development, urban landslides and their socioeconomic impacts. Findings show that Penang has a comprehensive and interconnected governance framework for sustainable hillside development. However, differences in the level of compliance and commitment to the framework by governance stakeholders have resulted in different types of policy failure. The exact socioeconomic costs of landslides borne by affected stakeholders also cannot be determined. Recommendations include addressing causes of policy failure and strengthening stakeholders' commitment to the principles of good governance for sustainable hillside development.

Keywords: Landslides, Good Governance, Policy Failure, Sustainable Development.

Introduction

Penang Island is situated at the mouth of the strategic Malacca Straits in Malaysia. It is the most urban and densely populated island in the country; whereby its size of 293 km^2 is home to almost half of Penang state's 1,766,800 population (Department of Statistics Malaysia 2020). Safety Guideline for Hillsite Development 2012 (SGHD) states about 40% of the island comprises Class 3 lands (slope gradient of 25% to 35%) and Class 4 lands (slope gradient of more than 35%); whereby intense residential, infrastructure, commercial construction, and agricultural activities have led to ever increasing hill clearing and slopes development. Data from 2010 onwards show an upward trend of annual and maximum rainfall in Penang; which experts partly attribute to climate change (Abdul Halim, Mohd Daud & Liew 2014). These factors, along with poor design and construction, inadequate/absence of regular maintenance, and lack of communication amongst stakeholders, have resulted in the increasing incidence of slope failures and landslides (SGHD 2012, p.8). Thus it is not surprising that Penang Island is classified as a landslide prone area by the National Slope Master Plan 2009 – 2023. Yet despite having the clearest guidelines and strictest laws on hillside development in the country, incidences of fatal landslides continue to occur in Penang especially from 2017 to 2019.

This article adopts a good governance perspective to provide new interpretations of the phenomenon researched by asking several pertinent questions in the context of sustainable Penang state's hillside development, namely: (i) what are the characteristics, interactions and processes of governance?; (ii) what are the socioeconomic impacts?; (iii) what are the types of policy failure that can be observed? The article ends by putting forward recommendations that can contribute to sustainable hillside development through good governance strategies and prevention of policy failure.

Literature Review

Numerous types of landslides occur the world over. Landslide mapping can be conducted to produce hazard and risk maps used to formulate guidelines, policies and procedures on land use planning that are appropriate for landslide management (Pradhan & Lee 2010). The tasks of formulating, implementing and evaluating guidelines, policies and procedures that promote sustainable hillside development fall under the ambit of hillside development governance.

The concept of "governance" can be confusing because “neat and precise definitions” are elusive as the interpretations and scopes of “governance” vary according to the actor/institution, approach, composition, level, objective and type of governance discussed, and the context within which the discussion takes place (Jreisat 2002; Kaufmann, Kraay & Mastruzzi 2010). Governance comprises government (the state, nature of political regime and formal institutions of public administration/management, but is also inclusive of other stakeholders outside of formal government, e.g., those in civil society, customers/citizens, and community groups that exercise influence over policies, actions and decisions regarding the betterment of public life and society (Srivastava 2009).

The pursuance of sustainable development requires policy frameworks for “institutional mechanisms, processes and practice” that are conducive to policy coherence (OECD 2016, p.16). Effective policy frameworks in the forms of laws, acts, official guidelines and procedures, should provide governance actors with the ability to: (i) better analyse interactions between goals and the effects of policy actions on their attainment; (ii) realign institutional mechanisms to attain sustainable development goals; (iii) identify and monitor the rate of progress on attaining those goals (OECD 2016). Hence sustainable hillside development requires coherent policy frameworks that are complementary and reinforcing in nature to enlighten governance actors on: (i) the principles and objectives of hillside development; (ii) their accountability, roles and functions; (iii) processes and procedures that must be observed, structures and arrangements of interactions, and punishments that can be meted out for transgressions committed. However, given the increasing occurrences of urban landslides in Penang island, it is pertinent to ask whether public policies pertaining to their prevention have failed. Policy failure assumes three forms, namely policy making process failure, programme failure, and politics failure (McConnell 2015). In terms of urban landslides, policy failure is more contentious and enjoys high public visibility because of the urban nature of the society affected.

Urban landslides are landslides that occur in environments that have been modified by human beings through extensive land-use change. Urbanization leads to the expansion of human settlements, land clearing, infrastructure development, growth of business premises/ industrial zones, and recreational/tourism activities. This leads to ecologically fragile hillsides being developed; resulting in direct or indirect socioeconomic impacts (Schuster & Highland 2001). Direct economic costs include repairing, rebuilding, replacing and maintenance activities of properties and/or equipment/machinery damaged, while indirect economic costs encompass costs incurred because of mitigation/prevention strategies, reduction in productivity and tax revenues due to destruction/damage to industrial, residential and recreational properties, injuries and deaths to people and livestock. The costs of losses incurred are borne by private and/or public organizations (Schuster & Highland 2001). Social impacts of landslides include loosening of communal bonds and decreasing social capital because of relocation of affected communities/residents, psychological trauma because of compromised societal safety, health and wellbeing, and feelings of distrust towards government and its machineries.

Methods

This desktop research uses a directed qualitative content analysis method to validate or extend the analytical framework used below (Hsieh & Shannon 2005). Secondary data (comprising previous research, official national data sets, and relevant textual materials) are analysed as follows. First, the dimensions of good governance for sustainable development and policy failure are used to construct a coding scheme and determine relationships between codes; whereby the dimensions in Table 1 are used as coding categories (Potter & Levine-Donnerstein 1999). Second, each dimension is given an operational definition.

Table 1: Dimensions of Good Governance for Sustainable Development and Policy Failure

Good governance	Dimension	Definition
	(i) Articulation	Capacity of individuals to seek freedom, make decisions on the use of shared resources issues, being confident and being responsible for actions taken.
	(ii) Mobilization	Capability to mobilize social capital through networking, local dialogues and empowerment at the grassroots level.
	(iii) Distribution	Realigning society's power relations by delegating "power and responsibilities" and institutionalizing political pluralism.
	(iv) Confirmation	The institutionalization of realigned power relations to prevent marginalization of weak members of society from being discriminated/disadvantaged.
	(v) Voice and Accountability	Encompassing citizens' participation ability to choose their government, freedoms of expression, association and media.
	(vi) Absence of violence and political stability	Probability of government destabilization through violent unconstitutional means.
	(vii) Government effectiveness	Civil service impartiality, effectiveness of public service delivery, policy formulation and implementation quality.
	(viii) Regulatory standard	Policy and regulations frameworks on policy formulation and implementation for development.
	(ix) Rule of law	Clean, fair, just and effective judiciary and law enforcement agencies.
	(x) Corruption	The extent and forms of corruption, including the ability of private entities usage of state's apparatus for their benefits.
Policy failure	(xi) Policy making process failure	The type of policy made has not been constructed to reflect policymakers' original vision, processes used are deemed illegitimate, inadequate support for the policy, as well as widespread criticism of the process used.
	(xii) Programme failure	Policy has not been implemented according to plan, predetermined outcomes have not been achieved, target groups have not benefitted from the programme, fundamental public policy criteria (e.g., economy, efficiency, effectiveness) have not been met, and prevalent opposition to the strategies and/or goals of the policy implemented.
	(xiii) Politics failure	Governments as society's vision setter and mediator of conflicts performed through the construction and construct of public policies, can fail to attain desired political outcomes; thus resulting in, among others, the loss of political credibility, tarnished reputation, uncontrollable agendas, as well as the ruin of core governance values

Source: Adapted from Hayden (2002, pp. 13 - 31), Kaufmann et al. (2010) and McConnell (2015, pp.230-236)

Third, the predetermined codes are used to categorize relevant texts, and new codes are constructed for uncategorized texts. Fourth, findings are then discussed in light of the aforementioned dimensions of good

governance for sustainable development and policy failure. Finally, new findings/categories that offer contradictory and/or a more enlightened view of the phenomenon are used to provide recommendations and to make appropriate refinements to the analytical framework to be used in future research.

Findings and Discussion

Composition of stakeholders

Penang's hillside governance comprises government actors, NGOs, private interests, community members/local residents as well as political parties that are directly and indirectly involved with/affected by landslides and landslide related issues. Government actors comprise federal, state and local governments entities including the Federal Government, Public Works Department, Department of Irrigation and Drainage, Meteorological Department, Town and Country Planning Department, Ministry of Natural Resources and Environment, Department of Environment, Department of Survey and Mapping, Construction Industry Development Board, Mineral and Geoscience Department, Department of Occupational Health and Safety (DOSH), Penang Chief Minister, the Mayor, Penang State Executive Council, Penang State Forestry Department, Penang Local Government and Housing Development Committee, Penang Hill Land Working Committee, District and Land Office, and Penang Island City Council (MBPP). Special task forces can be formed when needed.

NGOs include Penang Forum, Friends of the Earth Malaysia, Citizens Awareness Chant Group, Consumer Association of Penang (CAP), Water Watch Penang, Malaysian Nature Society, and the Environmental Protection Society Malaysia (EPSM). NGOs can form specific arms as platforms for the public to share information and air their concerns, e.g., Penang Hills Watch (PHW) is an information platform of Penang Forum on hill clearing activities, issues and impacts. Private interests include property developers, infrastructure construction firms and private property owners while political parties that have interests in and/or voiced concerns over the occurrences and impacts of landslides in Penang include the component parties of Barisan Nasional (BN) and Pakatan Harapan (PH). Finally, hillside development governance also include community members/local residents, acting individually or through residents association.

Figure 1: Terrain map of Penang Island according to gradient.

Source: The Penang Safety Guideline for Hill Site Development (2012, p.2)

Processes and Interactions

SGHD 2012 streamlines and takes into consideration existing federal and state development plans and guidelines (e.g., National Slope Master Plan 2009-2023, Penang Structure Plan 2020, Guidelines on Slope Maintenance in Malaysia 2006, Guidelines of Siting and Zoning of Industries and Residential Areas 2017, Guidelines for Erosion and Sedimentation Control 2010), to promote slope safety while minimizing adverse environmental impacts. It provides detailed explanations and instructions to all stakeholders, and also specifies their responsibilities before, during and after undertaking hillside development projects. Before an application for a planning permit is submitted, a pre-submission consultation must be performed by the Submitting Person or SP (e.g., Architect, Engineer, Geotechnical Engineer, Planner or Surveyor) with relevant government authorities by ensuring documents including land classification and suitability, terrain mapping, layout plan and land survey plan are made available. The Final Layout Plan must be submitted with the Final Geotechnical Report for approval to MBPP One Stop Centre (OSC). The OSC submits the Geotechnical Report to the Risky Land Development Committee Secretariat of Penang Public Works Department (PWD) for distribution to the Technical Departments of MBPP, Minerals and Geoscience Department, Department of Environment, Department of Irrigation and Drainage, Town and Country Planning Department, and the Hill Site Engineering Division of PWD. The Final Layout Plan is also checked and commented upon by the Technical Departments; that must also determine whether there are any objections to the proposed development, the grounds for the objections and whether the objections merit rejecting the proposed project (Aliran Admin 2017).

The OSC compiles and communicates comments/requirements made by the Technical Departments to the applicant, who is then required to demonstrate compliance of requirements as stated by the Geotechnical Engineer and the Risky Land Development Committee. Once the Layout Plan has been synchronized with the Geotechnical requirements, the Risky Land Development Committee Secretariat can approve the Geotechnical Report, and the Planning Department of Penang Local Authority can confirm and recommend the plans for approval. The OSC can then issue Final Approval for the project. The whole process takes 108 days to complete.

Once approval is given, competent engineers must be appointed to ensure and monitor developer's compliance with the guidelines during the construction process. Slopes and earth retaining walls constructed must abide by Guidelines on Slope Maintenance in Malaysia, 2006. Routine and non-routine maintenance inspection must be undertaken by maintenance/inspection team, competent personnel and geotechnical engineers.

Dimensions of Good Governance

Findings show that the governance structures of Penang state's hillside development do provide means for individual articulation and group mobilization whereby his/her voice and concerns can be heard either individually, or as a group via printed and social media, politicians and political parties, NGOs, issue networks and resident associations. Regular federal and state elections mean concerns on landslides and hillside developments can influence voters' voting decisions, while ensuring the accountability of political office holders to election promises made on issues of development, landslide prevention, public safety and welfare. Penang state enjoys political stability, without violent incidences that can lead to government destabilization through violent unconstitutional means. However small scale public protests do occur as exemplified by protest staged by the residents of Taman Seri Rambai and Taman Lau Geok Swee to the proposed construction of 3 blocks of high rise buildings on the hill slopes behind their residential areas (Opalyn Mok 2017), a protest held outside of City Hall on October 26, 2018 in remembrance of those who have lost their lives in the 2017 and 2018 landslides (Predeep Nambiar 2018), and a protest by Sungai Ara residents against a hilltop residential development project comprising 14 blocks of 602 apartments, 92 bungalows and two clubhouses (S Arulidas 2020).

Regulatory standards comprise policy, guideline and regulation frameworks on policy formulation and implementation of hillside development are comprehensive and numerous. The Guidelines on Slope Maintenance in Malaysia 2006 aims to increase public awareness on hillside risks, provides explanations on slope monitoring and maintenance, and identifying signs of impending landslides. The National Slope Master Plan 2009-2023 is an overarching national policy containing slope and landslide mitigation strategies and action plans at national, state, and local levels. Guidelines for Slope Design 2010 contains standard engineering practices, existing technical requirements and design materials to be used to design and assess the stability and safety of slopes, and risks mitigation. Guideline for Erosion and Sedimentation Control 2010 provides guidance on construction and

development sites' management and control of erosion and sedimentation. Guidelines of Siting and Zoning of Industries and Residential Areas 2012 provide guidance to project owners, Local, State and Federal authorities on site selection and the need for adequate buffer zones. The Penang Structure Plan 2020 is formulated in line with Part III of the 1976 Town and Country Act. Policies and strategic plans on land use are prepared by the Director, Town and Country Department and approved by State Planning Committee and MBPP. The Penang Safety Guideline for Hill Site Development 2012 is also part of the overall strategy to make Penang "Safe and Green" by specifying explicit and coherent design requirements, application procedures, transparent processes for approval, clear construction communication and controls strategies, and specific mechanisms for post construction slope maintenance. These regulatory standards do influence government effectiveness as they promote civil service impartiality, effectiveness of public service delivery, policy formulation and implementation quality.

The people of Penang island have access to judiciary, tribunals and law enforcement agencies whose tasks are to protect the rights of affected stakeholders and ensure that they comply with regulatory frameworks on safe hillside development in a clean, fair, just and effective manner. Two procedures can be used to challenge local planning authorities' decisions on proposed development projects. First, applicants must write formal letters to the local planning authorities concerned appealing for reconsideration of decisions made to decline planning permission or enforce planning conditions. Second, section 23 of the Town and Country Planning Act 1976 enables stakeholders to lodge an appeal to the Appeal Board if local planning authorities reject their appeals. The Appeal Board can choose to overturn, impose conditions, or sustain the decision of the local planning authorities. Only after all the administrative procedures have been exhausted, can the applicants turn to the courts for assistance to determine if the planning authorities have not exercise their discretionary powers judiciously (Ainul Jaria Maidin 2016). Indeed there have been instances when disputes between property developers, concerned citizens, residents associations and NGOs, have reached the High Court and the Court of Appeal (Intan Amalina Mohd Ali 2017).

Findings show that problems regarding the distribution and confirmation dimensions of good governance are still prevalent. Despite realigning society's power relations by delegating "power and responsibilities" and institutionalizing political pluralism in hillside development governance, these do not adequately protect "weaker" stakeholders from being disadvantaged because of power relations, funding and expertise constraints. Although corruption does happen, there is inadequate data to form valid assumptions on the extent and forms (including the ability of private entities usage of state's apparatus for their benefits) in hillside development governance.

Socioeconomic impacts of landslides

From 1973 to 2013, estimated losses amounting to more than USD 1 billion have been incurred because of landslides in Malaysia (Abdullah 2013). However it is impossible to determine the exact socioeconomic costs incurred because of landslides in Penang island because not all direct or indirect costs have been accounted for in a systematic and comprehensive manner as the costs are borne by private entities/individuals and/or public bodies. Findings indicate that the direct and indirect costs incurred are substantial. For instance damages attributed to landslides because of a freak storm at Penang Hill in 2017 meant more than RM 10 million is spent on slope strengthening and stabilisation, road repairs and controlling soil erosion (The Star 2018). As a preventive strategy, the State government has stated in its 2018 Penang Budget that an allocation of RM 10 million has been made for protecting of hill slopes, conducting a study on climate change, and illegal farming. (Lim Guan Eng 2017).

Findings show that from 1989 to 2009, 56 landslide incidences have occurred in Malaysia whereby 541 lives have been lost in 33 of the incidences (Center for Excellence in Disaster Management & Humanitarian Assistance 2016). No corresponding figure can be found for Penang island during the same period. However from October 2017 to June 2019, 24 deaths and 7 injuries can be attributed to Lengkok Lembah Permai landslide in Tanjung Bungah, Bukit Kukus Paya Terubong landslide and Lost Paradise Resort landslide in Tanjung Bungah. The incidences of fatal and non-fatal landslides do leave psychological trauma, social and lifestyle stress, feelings of hopelessness, anger and guilt, on individuals, residents of nearby housing estates, as well as disaster response workers (Ministry of Health Malaysia 2013). The costs associated with treating these adverse effects have yet to be accurately determined.

Policy Failure

Findings indicate the prevalence of policy failure occurring in the context of urban landslides in Penang island. Despite the existence of numerous and interconnected regulatory standards, programme failure happens because predetermined outcomes of slope maintenance, and preventing hillside landslides and soil erosion, have not been adequately achieved. Indeed the fatal landslides of 2017, 2018 and 2019 occurred after the adoption of SGHD 2012. Moreover from 2008 to 2015, the MBPP had approved 56 mixed development and residential schemes projects on hillsides above 25 degrees gradient or above 250 feet high in Balik Pulau, Batu Ferringhi, Bayan Lepas, Paya Terubong and Tanjung Bungah, by Ivory Villas, Farlim Group, JKP Sdn Bhd, Setia Promenade and Sunway City (Penang) Sdn Bhd (Opalyn Mok 2015). In the case of a residential development project in Lorong Lembah Permai, Tanjung Bungah, the planning approval application had been rejected by the Department of Environment because of the absence of a buffer zone between the proposed site and the permanent granite quarry; whereby construction would be in contravention of the 2012 Guidelines of Siting and Zoning of Industries and Residential Areas (Bernama 2017).

Developers not complying with, and circumventing regulatory standards, also led to programme failure; whereby slopes were cut back to a steeper gradient than specified, slope treatment and maintenance were not properly conducted, and the required Erosion and Sedimentation Control Plans (ESCP) were not observed (Rexy Prakash Chacko 2019). From 2008 to 2015, 68 illegal hill clearings were detected with the MBPP issuing stop work orders and instructing private landowners to undertake slope strengthening measures and implement land mitigation strategies. They could also be charged under Section 70A of the Road, Drainage and Building Act 1974 (Act 133) (Opalyn Mok 2015). Conflicting policy and action of the State government and the MBPP on hill slopes development also contributed to programme failure. Two instructive examples include: (i) the status of "hill lands" as classified under the Land Conservation Act 1960 can be revoked if the proposed projects are re-categorised under "special projects" and; (ii) despite the Penang Structural Plan's specifying clearly that housing development in Tanjung Bungah must not exceed 15 units per acre, the State government and MBPP had chosen to disregard this policy (Malay Mail 2017). It is important to note that MBPP's Geotechnical Unit, NGOs and concerned individuals do not have the capacity to effectively monitor and detect all legal and illegal hillside development activities; hence self-regulation and compliance by other stakeholders (e.g., developers and private landowners) are needed if programme failure is to be prevented.

Politics failure occurs when the State government, in its capacity as society's vision setter and mediator of conflicts, and in its quest to be an "entrepreneurial state" that is "clean, green, safe and healthy" that is able to provide "housing for all" in all of Penang's five districts, is conflicted in the prioritization and balancing of these goals in the context of its professed values of competency, accountability and transparency (Lim Guan Eng 2017). The findings show that the pursuance of public policies on sustainable hillside development is not the top most priority of the State government. Even if the DAP led Pakatan Harapan State government loses political credibility, suffers a tarnished reputation and compromises its core governance values in this area, it is evident that it feels these setbacks are well compensated by its performance in other policy areas.

Policy making process failure happens when it fails to ensure that policies made really address the underlying problems. For instance, the incongruence between policies made on hillside development and actions of the State government and the MBPP, raises doubts on whether the policy making process make policies that really reflect the policymakers' original vision, or are they simply window dressing the issues? This is exemplified by the ongoing RM 545 million project Paya Terubong Paired Road that links Paya Terubong to Lebuh Bukit Jambul and a new elevated road/link bridge to Jalan Tun Sardon (refer to Photo 1). Funded by private developers and the MBPP, extensive slope cutting, land clearing, blasting and excavation activities can lead to landslides because of steep barren slopes, as well as the exposure of core stones and bedrock (Rexy Prakash Chacko 2019)

Fig. 1: The Tun Sardon Link Bridge

Recommendations

It is evident that Penang's hillside development governance comprises core, peripheral and occasional actors whose actions, interactions and obligations are clearly specified by the relevant regulatory frameworks. Indeed seven out of ten good governance dimensions have been met. However distribution and confirmation dimensions have yet to be successfully realized and the corruption dimension needs further research before conclusive comments can be made. Thus it is recommended that attention be paid to strategies that can bring about meaningful realignment of society's power relations and institutionalizing political pluralism so that some core (but weak), peripheral and occasional governance actors are not marginalized.

The composition, characteristics, interactions and processes of hillside governance do provide for the attainment of sustainable hillside development if all stakeholders commit themselves to, and make this goal, their top priority. This will address some of the fundamental causes of programme failure, politics failure and policymaking process failure arising from conflicting policy and action, confrontational stakeholders' interactions, and weaknesses in monitoring and regulating hillside development. Hence funding, capacity and expertise building, especially on the part of government authorities, NGOs, resident associations and private individuals, are needed to counterbalance, monitor and hold politicians, property developers and private landowners to account. These measures, on top of stiffer penalties, can ensure that regulation capacity is not overstretched. It is recommended that a thorough research to determine the exact socioeconomic costs of urban landslides be conducted ASAP. Only then can the State government appreciates the political, economic and social price of not putting sustainable hillside development as a top priority in Penang island.

Conclusion

Good governance for sustainable hillside development is possible and policy failure can be addressed if all stakeholders, especially core governance actors, realize the socioeconomic impacts, as well the associated costs, of urban landslides in Penang island. However a consultative and participatory approach, as well as the practice of competency, accountability and transparency, must be internalised by all stakeholders to prevent conflicting objectives and foster positive cooperation and interactions between them. Indeed the pursuance of individual objectives by stakeholders without a firm commitment to attaining sustainable hillside development, can only result in lose-lose situations for all.

Resumen

Este estudio explora la relación entre creadores e inhibidores del tecnoestrés y la satisfacción y compromiso laboral de usuarios finales de Tecnologías de Información y Comunicación (TIC), considerándose uno de los creadores, la inseguridad tecnológica. A partir de encuestas aplicadas a usuarios finales, se evalúa un modelo de comportamiento. Los resultados muestran que la inseguridad tecnológica disminuye la satisfacción laboral, mientras que los inhibidores la aumentan, y que la satisfacción laboral incide positivamente en el compromiso laboral de los usuarios finales de TIC.

Palabras Clave: Modelamiento, Tecnoestrés, Comportamiento.

Introducción

Es habitual que las personas utilicen Tecnologías de Información y Comunicación (TIC) en tareas laborales, lo que les puede ocasionar efectos negativos, afectándoles psicosocialmente, surgiendo el tecnoestrés, referido al estrés causado por el uso de TIC (Tarafdar, Tu y Ragu-Nathan, 2010).

Este trabajo busca explorar si determinados creadores e inhibidores del tecnoestrés inciden en la satisfacción y compromiso laboral de usuarios finales de TIC, centrando la atención en uno de los creadores, la inseguridad tecnológica.

Antecedentes e Hipótesis

El Tecnoestrés es un estado fisio-psicológico no saludable, relacionado con el uso de las TIC, que se produce cuando surge un desajuste entre las demandas que plantea el uso de la tecnología y los recursos disponibles para gestionarlas (Ragu-Nathan et al., 2008), constituyendo un efecto psicosocial negativo del uso de las TIC (Cárdenas-Velásquez y Bracho-Paz, 2020).

Los creadores de tecnoestrés son (Tarafdar, Tu y Ragu-Nathan, 2010): sobrecarga tecnológica, invasión tecnológica, complejidad tecnológica, inseguridad tecnológica, e incertidumbre tecnológica. No obstante, este estudio se centra en la inseguridad tecnológica, debido a que en los momentos actuales muchas personas han debido afrontar la necesidad u obligación de utilizar la TIC en forma permanente en su trabajo, debiendo conocer, comprender y utilizar adecuadamente dichas tecnologías, en lo posible al mismo nivel de aquellos que más saben utilizarlas, ya que, de no ser así, podría motivar inconvenientes a la organización, corriendo el riesgo de ser apartados de sus labores.

Cite this Article as: Álvaro QUIROZ-BUSTOS, Sergio ARAYA-GUZMÁN and Cristian SALAZAR-CONCHA "Modelamiento De Ecuaciones Estructurales Aplicado Al Ámbito Del Tecnoestrés Y Su Incidencia En La Satisfacción Laboral Y Compromiso Laboral En Usuarios Finales De Tecnologías De Información Y Comunicación" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

La inseguridad tecnológica se refiere a situaciones en las que los usuarios se sienten amenazados por perder sus trabajos, ya sea por la automatización resultante de las nuevas tecnologías o porque otras personas tienen una mejor comprensión y manejo de ellas (Tarafdar,Tu y Ragu-Nathan,2010).

Existen factores organizativos que inhiben el tecnoestrés en el uso de TIC, asociados al apoyo, acompañamiento y soporte técnico de los usuarios finales y la participación de éstos en las etapas de implementación de TIC, permitiendo familiarizarse con ellas, facilitando su aprendizaje y comprensión, originando una buena opinión de los usuarios, lo que podría afectar positivamente a su satisfacción laboral (Ragu-Nathan, et al., 2008).

La percepción que los usuarios presenten de las TIC podría afectar la percepción que tienen sobre aspectos relacionados con su trabajo (Araya et al.,2018), afectando su actitud y comportamiento, los que se relacionan directamente con la satisfacción y compromiso laboral (Sánchez et al., 2013). En este sentido, la satisfacción laboral aporta a que las personas se sientan más involucradas con su organización, más a gusto de pertenecer a ellas, lo que repercute positivamente en su compromiso laboral (Marquina-Vergara, 2018).

Los planteamientos anteriores sustentan las hipótesis, para usuarios finales de TIC:

H1: La inseguridad tecnológica incide negativamente en la satisfacción laboral.
H2: Los inhibidores del tecnoestrés inciden positivamente sobre la satisfacción laboral.
H3: La satisfacción laboral incide positivamente en el compromiso laboral.

Metodología

Se aplicaron encuestas a personas que utilizan TIC en el desarrollo de sus tareas habituales.

Siendo el tecnoestrés un aspecto que presenta cierta complejidad social dadas las variables involucradas, resulta conveniente utilizar modelos de ecuaciones estructurales (SEM), ya que permite incorporar variables no observables medidas indirectamente por variables observables, siendo principalmente utilizado en el desarrollo de teorías en investigaciones exploratorias, enfocándose en explicar la varianza de las variables dependientes que examina el modelo de investigación, de manera de probar las relaciones entre variables latentes en el nivel teórico, constituyendo una herramienta de utilidad en investigaciones en el campo de las ciencias sociales (Hair et al.,2014), ajustándose a las características de este estudio. El análisis estadístico de los datos utilizó SEM basado en PLS-SEM y el software SmartPLS.

Resultados

Los resultados presentados corresponden a 50 encuestas válidas. Los datos obtenidos validan satisfactoriamente la evaluación de ajuste del modelo global y el modelo de medida, cumpliéndose las condiciones exigidas según la literatura. La evaluación del modelo estructural se presenta en la figura 1, soportándose hipótesis H1, H2 y H3, apreciándose la relación y explicación existente entre las variables.

Figura 1: Modelo Estructural

(Fuente:Elaboración propia)

Conclusiones

Los resultados muestran que la inseguridad tecnológica (creador de tecnoestrés), reduce la satisfacción laboral del usuario final de TIC, mientras que los inhibidores del tecnoestrés (asistencia al usuario y facilitación de aprendizaje) la aumentan.

La utilización de PLS-SEM ratifica lo señalado por autores como Cepeda, Nitzl y Roldán (2017), siendo útil para efectuar análisis de variables en un contexto complejo, facilitando el desarrollo de estudios en distintas áreas de las ciencias sociales.

UML Based Ontology for the Extraction of Historical Geographic Information

Piotr KOSIUCZENKO

Institute of Information Systems, Warsaw, Poland
piotr.kosiuczenko@wat.edu.pl

Abstract

Processing textual information in large files is time consuming and error prone. Investigating past and historical data concerning geography and economics can be facilitated a lot when the data is stored in a data base or has a proper form. There was a lot of research concerning the transformation of textual data to an ontology in a methodical way. In this paper, a method is presented for the extraction of geographic and economic information from a historic Lexicon. The method is based on software engineering techniques and follows an iterative cycle. It results in a well-defined ontology specified using UML class diagrams which can be queried using Object Constraint Language. An evaluation of the model is discussed. This research may help in assessing regional development, qualitative and structural changes in the regional economy, assessing ownership, infrastructure and living standard transformation.

Keywords: Software Engineering, Geographic Information Systems, Ontology, UML.

Introduction

Querying heterogenous properties in historical data is a complex problem. In case of geographical and economical information, queries can concern regional development, quantitative, qualitative and structural changes in the economy of a given region, ownership, transformation of economic units, change of living standards, economic structure, economic potential, infrastructural development, standard of living for residents. The problems are exhorted if the data is in a textual form.

In order to facilitate such queries, one needs a well-developed data structure with an appropriate querying language and mechanisms. This requires first a well-developed ontology and then a transformation of into an appropriate data structure based on the ontology. Ontologies represent the intentional aspect of a domain for governing the way the corresponding knowledge bases are populated (see Wong et al. (2012)).

Ontologies are a very well-studied research topic. Ontology learning from text can be defined as "the process of identifying terms, concepts, relations, and optionally, axioms from textual information and using them to construct and maintain an ontology, as pointed out by Wong et al. (2012). It is also a well-studied topic. Various methods have been developed including statistical analysis (cf., e.g. Khurshid et al. (2005)), classification techniques (cf., e.g. Larin et al (2011)). There exist also methods for ontology construction (cf. e.g. Fawei et al. (2019) and Fawei et al. (2019)). In case of GIS systems various methods can be applied ranging from the statistical ones, to data mining-based ones (vide, e.g. Arabameria et al. (2019) for a comparison).

A closely related topics are the Geographical Information Systems. GIS concern of geographic data such as objective events, entities occurring on, above and below the Earth surface. They are aimed at storing, processing, representing, analysis, visualisation and retrieval of geographic data (cf., e.g. Larin (2011)). The typical problems in GIS construction

Cite this Article as: Piotr KOSIUCZENKO "UML Based Ontology for the Extraction of Historical Geographic Information" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

are the conceptual modelling of the geographic objects and their relation, identification of objects, definition of attributes (e.g. object tree and object forest), spatial relationships. There exist also approaches to modelling and extraction of GIS (cf., e.g. Zhu et al. 2018)).
The topic of this paper is a method of extraction of ontology from historical geographic data contained in a relatively well structured and complete Lexicon called "Lexicon of the Kingdom of Poland" by Sulimierski et al. (1880-1902), as it is called, containing geographic and economic information about the Kingdom of Poland in XIX century. The overall goal is to propose a general method for extracting ontology from a Lexicon resources using the example of the "Lexicon of the Kingdom of Poland". The Lexicon is used for various historical studies including ownership structure, economic development, industrialization, infrastructure, local development etc.

We decided to base the ontology on an object-oriented model described using UML class diagrams (cf. OMG (2017). The reason is that the model must accommodate various kinds of information and meta-information and must allow for sophisticated querying concerning different aspects of the historical development. In our opinion, the best suited query language is the Object Constraint Language (OCL, OMG (2014)) because it is well integrated with UML class diagrams, possesses very expressive querying capabilities and supports various datatypes. We did not use the statistical methods to extract the ontology (cf., e.g. Khurshid et al. (2005)) since the data we process is relatively precise and well-structured and the corresponding class diagram is small and relatively easy to elicit.

Model Construction

We decided to use methods of software engineering due to the choice of UML and OCL, and also to the fact software engineering provides well-developed and mature methods of system specification extraction and development. In particular, we used Design Patterns proposed first by Gamma et al. (1994) (see also Bafandeh et al. (2017)) to obtain well-structured model and the Refactoring method aimed at redesign of models and code developed by Fowler (1999) (see also Baqais (2020)). Both have proved very useful in model construction and modification.
We define the ontology in terms of:

- collection of classes that form denotations of terms
- attributes that characterize the terms
- a class inheritance hierarchy which relate terms in respect to their generality
- relations between classes and their structural presentation

One of most fundamental features of SE methods is their iterativeness, as well as agility in terms of adaptability to existing needs. Thus, the method used is highly iterative and takes into account the need to continuously modify the ontology as new categories of geographical units and new types of dependencies between them emerge in the processing of successive parts of the Lexicon and subsequent information.

In our aroach, the starting point was an a'priorical class diagram corresponding to the terms, concepts and relationships among geographical units and administrative structures. This initial structure forms the initial framework in the construction of the required ontology. The diagram than is modified iteratively: new classes, dependences and associations are added, and the inaropriate model elements removed and modified.

Fig. 1: The Ontology Creation Cycle

The aroach to ontology extraction is shown on Fig. 1: starting with the before mentioned initial model, we sulement and modify it step by step. The consecutive step in the modification corresponds to the next Lexicon entry. Each step has the following elements:

- Selection of the next Lexicon entry
- Categorization of the items corresponding terms: e.g. city, administrative unit, hamlet, post office, parish, ...
- Identification of the terms in the description of the selected entry, categorization of the corresponding terms and entries if not already performed, establishment of the structural relationships between them
- Verification that the relationship between the term and the terms that aear in the description of the selected entry is aropriate. If not, then the class diagram is refactored: its elements are modified and replaced aropriately
- Addition of new model elements such as classes, inheritance relations, associations and attributes
- In the case of role change by an item corresponding to a term replace inheritance with delegation

It has turned out that after few iterations of the cycle, ca 40, on randomly selected entries the resulting class structure remained stable and the refactoring was not needed anymore, but we needed only to add new elements into the object diagram. Thus, the structure is adequate for the purpose, the subject of change being only the addition of new element.

The Model

Below we present a simplified form of the ontological hierarchy by the alication of the above-mentioned procedure. The model is generic, uses multiple inheritance and delegation. In the model we have essentially geographical objects and reified associations such as relative location, i.e. a so-called classifier that is both an association and a class at the same time. As a consequence, associations in this model are objects (it is a reification of relationships).

In this class diagram (see Fig. 2), the basic units are geographical objects which correspond to the Geographical Object class. There are essentially two subcategories here: Administrative Unit and Geographical Unit. This results in a dichotomous division of geographical objects. All other categories of geographical objects are details of these two classes, e.g. Governorate, County, Community etc. on the one hand and School, River, etc. on the other.

Administrative units are modelled by the class Administrative Unit and its respective subclasses which describe the administrative role of the geographical features. The generic Location class models the location of spatial objects, such as geographic coordinates. This information can be specified in greater detail in aropriate subclasses.

The above model is based on multiple inheritances but also has to take into account changes in roles over time, e.g. the fact that a hamlet can become a town, a private home can become a post office etc. Various roles played by the same object at the same time can be modelled by multiple inheritance. However, this kind of modelling restricts the expressiveness and flexibility of the ontology. A geographical object can play many roles at once. When roles are used, each of them is characterized by a separate object of the aropriate category, e.g. a farm, a hamlet, a post office (reification of roles). Roles can be treated as subclasses, this requires the use of multiple inheritance, or reified by a dedicated class as in the "State Pattern" (cf. Gamma et al. (1994)). We chose the second option due to its flexibility. Since there can be many such roles at the same time, in the diagram we specify the aropriate multiplicity at the end of the association (in the diagram we use also *). The time in which such roles are played is characterized by attributes startDate and endDate, whose values are objects modelling moments in time (with day, month and year attributes). This allows static modelling of the fact that a given geographical object starts and ends to play a given role at certain moments in time.

The use of roles allows more sophisticated patterns of search for information about the condition of individuals at a given time and its evolution over time but makes the queries more sophisticated than in the case of multiple inheritance. It should be noticed that we aly here the "Replace inheritance by delegation" refactoring pattern (cf. Fowler (1999) and Baqais (2020)).

The diagram on Fig. 2 shows the most fundamental part of the obtained ontology. There are five fundamental classes: Spatial Object, Location, Geographic Unit, Role, Administrative Unit and Functional Unit. The root class Spatial Object is characterized by its name, some other attributes as well as a set of locations. The class Location is characterized by geographic coordinated (not shown on the diagram) and can be farther specialized. The class Geographic Unit is a special case of the Spatial Object, the geographic units can play different roles. The roles are objects of the class Role, the class Role is subclassed by Administrative Unit and Functional Unit dividing it in two separate categories.

Fig. 2: The Class Diagram of the Ontology

The classes are related by associations. Spatial objects have their locations. There can be multiple location objects for one spatial object if the object is stretched over certain area. We use here association of type composition to express existential dependences since the locations exist only to specify locations of the corresponding spatial objects. Similarly, one geographic unit can play several roles, one after another or in parallel what is specified by the corresponding association; in this case we use also composition to indicate the fact that roles are existentially dependent on the object playing them.

The class diagram requires some additional constraints, which can be specified in OCL (not shown on the diagram). For example, there is a constraint saying that a point, i.e. an object of class Point, has one, and only one, location not several ones. Similarly, a river location can be specified by a sequence of location objects with certain consistency criteria imposed. The use of OCL to specify additional constraints makes this ontology very general and flexible. However, for a person who is not familiar with object-oriented modeling, it is more difficult to understand.

In order to further make the role reification model more flexible, we divide roles into two groups: administrative and functional. This allows for uniform treatment of all roles, such as “governorate” and 'county' on the one hand, and 'school' and 'factory' on the other. We introduce also dates for spatial objects and roles, since both can have their start

and end date. For example, a building can play a role of school in certain time-period. It should be noted that this does not prohibit playing other roles in other time-periods, the other time-periods can be disjoint, overlaing and the same as the first one.

The queries concerning properties of the constructed model can be expressed in OCL. The major OCL-construct aimed for this purpose is select, which selects all objects with a given property. It has the form X->select(x : C | condition(x)), where X is a collection of objects of class C and condition(x) is a Boolean-valued condition concerning objects of this class. The selection results in the set of objects x belonging to X and satisfying the condition. There exist some other operators such as quantifiers, iterators, collectors etc. which make the language very expressive. This allows one to write very detailed queries concerning the investigated model.

Evaluation

We analyzed the adequacy of the proposed ontology in terms of structure, consistency, adequacy and usability. In general, there are several aroaches to systematic to ontology evaluation (cf., e.g. Gangemi et al. (2005) and Gangemi et al. (2006) for a more systematic aroach and references to further reading).

The structure of the ontology proved to be relatively simple with rather few model element kinds. The paths in the graph corresponding to the class diagram on Fig. 2 are relatively short, and the average path length is relatively small. The so-called fan-outness, i.e. the number of outgoing edges, equals one apart of roles and locations. In general, the number of roles is also relatively small due to the fact that most spatial objects play one or few roles over time. In the case of locations, the number can be higher if the object has a complex shape.

One of the key issues is the modelling of time aspects. Objects of interest can aear in time, assume different roles and cease to exist. This can be adequately modelled using the proposed ontology and we did not encounter any counterexample when processing the lexicon.

The ontology proved to be consistent with the Lexicon. As mentioned above, after relatively few cycles of the Lexicon processing, the ontology proved to be stable, in the sense of not requiring changes, but only addition of new model elements, such as classes. We did not have also many problems with equivocal terms, as they are easy to resolve and relatively small in number.

The constructed ontology proved to be adequate in the sense of covering the dictionary terms. It is also adequate in the sense of allowing complex and detailed queries. In respect to usability, the most complicated thing proved to be the querying. OCL requires a certain degree of skills in reading of class diagrams and understanding the query language, in particular, the selection of objects. Nonetheless, we think that the problems are due mostly to the fact that it is not easy to ask a precise question concerning complex models like this. The questions we ask in a natural language are usually imprecise. Making them precise requires considering a lot of details which the asking person may be unaware of or do not care about. Thus, the problem is not caused by the ontology as such.

Conclusion

In this paper, we discussed a construction of an ontology corresponding to a historical Lexicon of the Kingship of Poland. To construct it, we alied standard methods developed in the area of software engineering. In particular, we used an iterative aroach to class diagram design when processing the dictionary. We alied also well-known design patterns and the refactoring aroach. In effect, we obtained a stable and adequate class diagram which allows for complex querying. The processing procedure concerning Lexicon entries proved to be simple and natural, so that even a person untrained in software engineering can follow it. Thus, the use of software engineering methods proved to be successful in terms of the use and the quality of the results.

Proposed method of historical ontology extraction can be integrated with other methods for GIS-information extraction such as bivariate and multivariate statistical and with data mining methods.

Abstract

European This pilot study explores the impact of several factors on passenger satisfaction with public transport services. This article's main purpose is to analyze the quality of the subway transportation services and the impact it has on the satisfaction of the travelers. For this reason, data obtained from primary sources was used, represented by 147 respondents, through a simple and random sampling method. After framing and testing six hypotheses, it could be emphasized that the subway transportation services are the most appreciated among all ways of public transportation in Bucharest because of the high speed and comfort. The only inconvenience is the bigger price, compared to the surface transportation.

Keywords: Public Transport, Transportation Quality Services, Metro Transportation, Passenger Satisfaction.

Introduction

The Quantifying the satisfaction of passengers using public transport services is important for both research and practical development of services. According to Ranaweera and Prabhu (2003), in order to increase the degree of customer satisfaction and improve the transport infrastructure and the services that will be offered, it is necessary to know what their needs are and to what extent they are or have been met. Surveys provide essential information for authorities aiming to improve infrastructure and services and highlight passenger satisfaction (Le-Klähn et al., 2014; Lai and Chen, 2011; Mouwen, 2015).

Machado-Leon et al., (2017) stressed that the profitability of the public transport system is conditioned by its distribution, but also by the number of passengers. The passenger satisfaction is given by the quality of transport services provided.

Passengers who have a positive experience in using the transport system will continue to use this system and will contribute to the sustainable development of the city (Eboli and Mazzulla, 2009 a,b). The quantification of passenger satisfaction is followed by transport operators through periodic surveys.

Friman and Fellesson, (2009), state that a positive experience related to transit services leads to the use of these services again. This impact is being generated by the positive experience that passengers had. The passenger's perception of this services is associated with their provider.

The quality of public transport services is measured with the help of indicators based on data related to the quality of transport services perceived by passengers, the confidence in transport infrastructure and passenger loyalty (Eboli and Mazzulla, 2012).

Three significant factors that contribute to passenger satisfaction have been identified: "Safety, security and comfort", "Infrastructure quality" and "Ticketing facilities".

Consistent with studies by Cavana et al., 2007, the attributes associated with each factor should be at the level of passenger expectations. The most significant attributes that influenced passenger satisfaction were the cleanliness, safety and security offered by the means of transport.

Transport policies that seek to encourage public transport ridership while reducing car dependency have long been identified as an important aspect in the development of socially, environmentally, and economically sustainable cities (European Commission, 2017).

Public transport providers are constantly looking for ways to increase their ridership, either by gaining new or maintaining current passengers. In recent years, societies' increasing concern about climate change and pre-serving the environment has led public transport providers in many countries to become more oriented towards environmental sustainability (Vicente et al., 2020; Saw et al., 2020)

Service quality is more difficult to describe than product quality as most services cannot be counted, measured, inventoried, tested, or verified in advance of sales to assure. Quality evaluations are not made solely on the outcome of a service; they also involve evaluations of the process of service delivery.

We can't talk about the quality of the services and the satisfaction of the clients without defining these concepts. Therefore, the quality is the aptitude of an offer-maker for producing/ensuring good characteristics and services, at a certain and settled level, according to the requirements of the clients (Bruhn, 2001).

The client satisfaction is strongly related to the service post-purchase behavior and the influence of the personal characteristics of the consumer. The satisfaction has as baseline the service's evaluation of the consumption's experience and some attributes that are linked to the quality of the services, like: the credibility, the maximum responsibility from the providers, the staff politeness, the speed, the comfort and short waiting time in the metro stops.

Scope, Targets and Hypotheses

The scope of the research is to identify the quality of the subway transportation services in Bucharest and the impact on the passengers' satisfaction.

To achieve this goal many aspects related to the passenger's metro experience were taken into account and they are as follows:

Q1: Determining the main reasons behind the decision to ride by metro
Q2: Determining the frequency of metro ridding
Q3: Identifying the opinion of the respondents concerning the quality of the subway transportation services
Q4: Determining the level of satisfaction concerning the subway transportation;
Q5: Identifying the reasons of dissatisfaction;
Q6: Setting the profile for the passengers

The hypotheses of the research are named under way of anticipation of the answers that are referring to the concerned issue:

H1: The majority of the respondents choose to ride the metro because of the short travel time, no matter the weather conditions.

H2: Over 60% of the respondents are traveling by metro at least once per day
H3: The majority of the respondents, over 80%, consider that the subway transportation services are of high quality
H4: The majority of the respondents are satisfied with the metro
H5: The reasons of dissatisfaction are: the traffic from the metro stops at high peak hours and the waiting time between the metro trains in days like Saturday and Sunday
H6: Over 50% of respondents are employees, female, aged between 18 and 50 years old with incomes between 2080 and 3000 RON.

The Methodology of The Research

This research is structured on phases of a normal research, which are: the preliminary phase, the projecting phase and the accomplishment phase. After choosing the sources of information, it is necessary to further proceed to the new phases that have into consideration defining the variables, classifying them, choosing the scales bars to measure the variables, choosing the research instruments that are used. Defining the variables takes into account formulate them, so that they reflect the problems within the research and to be according to the updated trends of the domain.

The research follows many variables categories: baseline variables (the main considerations that count when choosing the metro public transportation), descriptive variables (the age, the gender and the occupation), the circumstance variables (the financial situation of the respondents), the independent variables (the metro travel frequency), the dependent variables (the quality of the subway transportation services).

Ghosh et al., 2017, recommended the convenient sampling technique for data collection, because the random sampling technique was not feasible for such an analysis. Considering the fact that by conventional sampling each person would not have the chances to be a respondent, in order to overcome this difficulty, the survey was conducted for a period of three months at different times of the day so that different categories of passengers (commuters, pupils and students, business people, etc.) could be included.

Ways of collecting data

The data was collected during December 2019 – February 2020, in the main metro stops from Bucharest city. Because the data collection methods were done by meeting respondents in the metro stops, a simple and random statistical sampling method was used, so that every member of Bucharest's population had the same chance to be selected.

The data collection instrument was the questionnaire. This contained a filter question through which the target population that had certain characteristic, was identified. The questionnaire consisted of 16 closed questions, open, double choices answers, multiple choices answers and has covered all existing possibilities.

The Target Population

The target collectivity was represented by the citizens of Bucharest city and those citizens that use the public transportation. There were analyzed 147 valid questionnaires out from the 170 that were completed.

The analysis and interpretation of the obtained data

In other research, a scale with an odd number of categories was approached to allow respondents to report and have neutrality. This is because some people do not want to express themselves on the subject. Thus, the respondents had the opportunity to opt for an answer that could express their opinion at that time without being influenced by the final results of the research. (Stieger et al., 2007).

To accomplish the first tarted, we analyzed the question: `Which are the most important factors that contribute to choosing riding the metro?` With the help of the semantic differential, we analyzed the answers of the questioned people. Therefore, we noticed that the respondents choose to travel by metro because of the short time travel with a medium score of 4,31 while the weather conditions had a medium score of 3,72. After this analysis, there is a confirmed hypothesis that *The majority of the respondents choose to travel by metro mainly because of the short time travel independently of the weather conditions.*

Table 1: The most important factors contributing to the choice of traveling by subway

Name of the variable	Conceptual variable	Operational variable	Score
The reasons that stand as stoneground for the decision to travel by metro	The reasoning behind the determination of the respondents to travel by metro	The proximity of the metro stop	3,87
		The transportation safety	3,85
		The Comfort	
		The lack of other means of transportations in the area	3,87 3,91
		The waiting time in the metro stop	
		The weather conditions	4,31
		The price of the travel	3,72
			3,82

To determine the use frequency of the subway transportation, the question from the questionnaire was the following: *How often do you travel by metro*? I have noticed that the respondents are traveling daily by metro with a percentage of 45%, but another percentage of 37% prefer to travel every 2-3 days. A percentage of 17% of the respondents are weekly traveling by metro and only 1% is traveling monthly, as they prefer other means of public transportation. From all these, the hypothesis that *over 60% of the respondents are daily traveling by metro*, comes in disapproval.

Fig. 1: The metro travel frequency

The opinion of the respondents regarding the quality of the subway transportation services was very favorable with a percentage of 64%, concerning the travel directions, 50% had a favorable opinion about the waiting time between the metro trains and were indifferent towards the cost of the travel with a percentage of 30%. This aspect suggests that for the respondents, the travel price does not matter or that the price of the metro travel is much more expensive that the surface public transportation. In addition to that, there is one hypothesis that does not qualify anymore, which is that the majority of the respondents, over 80%, consider that the subway transportation services are of high quality.

Table 2: The opinion of the respondents regarding the quality

Name of the variable	Conceptual variable	Operational variable	Percent (%)
The opinion of the respondents regarding the quality of the subway transportation	The point of view of the travelers concerning: the price of the travel, the directions of the travel, the circulation timeframe	Very favourable Favourable Indifferent Unfavourable Very unfavourable	64 50 30 4 2

To the question Which is the level of satisfaction in regards to riding the metro?, the questioned people answered in the following way, as can be seen in figure 2.

Fig. 2: Level of satisfaction regarding the metro travel

It can be seen that 41% out of the respondents are very satisfied about riding the metro, while 29% are satisfied by it. After this analysis, it can acknowledge that the hypothesis that the majority of the respondents are satisfied with riding the metro, comes in disapproval.

To reach our goal about the reasons of dissatisfaction with riding the metro, the respondents answered the question: Which are the main reasons of dissatisfaction that you have met during metro riding. The answers of the respondents can be visualized in figure 3.

Fig. 3: The dissatisfaction reasons of the metro travel, displayed in percentages

It can be noticed that the main dissatisfaction reason is represented by the price of the metro travel, with a percentage of 31%, followed by the traffic in the metro stops at the high peak hours with a percentage of 29%, followed by the waiting time in the metro stops with a percentage of 23%. Therefore, the hypothesis that the reasons of dissatisfaction are the traffic in the metro stops at the high peak hours and the waiting time in the metro stops on days like Saturday and Sunday, is partially confirmed.

The profile of the respondents was created by analyzing the four variables that can be seen in the below tabel:

Table 3: Profile of respondents

Profile of the respondents	Age	< 18 years 18 -34 years 35 - 50 years 51 – 64 years > 65 years	5 63 45 26 8
	Sex	Male Female	65 82
	Income	< 2080 RON 2080 - 3000 RON 3001 - 4000 RON > 3000 RON	20 65 58 4

	Status	Employee Student Retired Others	83 44 16 4

In Table 3 can be seen that 63 of the respondents have an age between 18 and 34 years, followed by the persons aged between 35 and 50 years. About the gender of the people, 82 persons were females and 65 males. Out of these, 83 people are employees with an income between 2020 and 3000 RON. As per this analysis, we can confirm the hypothesis that Over 50% of the respondents are employed people, females, with an age between 18 and 50 years old, with incomes between 2080 and 3000 RON.

The limits of Research

The limitations of this research consist in the fact that the sample is not statistically representative, and the research cannot be generalized at the level of the entire city. This is a pilot study that lays the groundwork for future research.

Conclusions

After this analysis, the authors considered that all the goals of the research were accomplished. After testing the six hypotheses, it was seen than the most important factor that influences the decision to ride the metro, in the disadvantage of other means of transportation, the short time travel by metro, independently of the weather conditions. Other important factors are the lack of means of transportation in the area, as well as the metro stop proximity.

Moreover, a significant percentage of the respondents are riding the metro every two-three days, followed by the ones that travel daily. It can be easily noticed that there exist even respondents less interested in riding the metro because the travel frequency is lower, as they are traveling on a weekly or even monthly basis.

The majority of the respondents are very satisfied by metro riding, this happening because of the fast speed, comfort and safety. In another way of expression, there are also dissatisfied people, the reasoning being the price of the metro travel which is higher than the surface public transportation, the high traffic in the metro stops at high peak hours and the waiting time between in the metro stops on days like Saturday and Sunday.

Quality of service is closely related to passenger satisfaction and therefore is possible through quality affect demand for services. The role of carriers is to offer the highest quality services and thus to retain existing customers, but also attract new ones.

Therefore, local authorities as well as transport providers should make a significant effort to improve passenger satisfaction by improving the quality of service.

At the national level, the government supports investments in metro transport infrastructure in order to increase safety and comfort, as well as the degree of traffic transfer and decongestion. It is considered the modernization of the subway lines, the completion of the started projects and the provision of quality and safe services. Given the fact that in recent years industrial areas have been reconfigured, it is necessary to develop other lines of connection with the newly created industrial areas.

The present research can extend to another one that concerns the study of the quality of the subway transportation services, in the European Union and the comparison to Romania.

Abstract

Nowadays the issues of understanding the technogenic elements of environmental structure of human life and activities in the framework of socio-humanitarian knowledge are beyond the focus of scientific research. The article presents author's understanding of the phenomenon, which we define as Technogenic Man-Measurable Systems (TMMS) in its most futurological aspect, reflecting, however, the existing trends in the development of scientific and technological progress.

Keywords: Technogenic Man-Measurable Systems (TMMS), Technosphere, Anthropic principle, Hybridization, Synergetics.

Introduction

The issues of understanding the status and importance of the technology in the socio-cultural contexts of human life and activities have a certain history in scientific and philosophical thinking. However, the problems of studying human environment are traditionally concentrated in the framework of natural sciences and other specialized areas of knowledge, taking into account its environmental (in the broadest sense) and biological parameters. For example, environmental sociology can be understood as a relatively new field of scientific inquiry in addressing the problem of balancing the social factor as an element of the environment and the necessity of considering its impact on an individual and the society.

In this type of scientific and social space the limitations of the approach to the problem of integrating technogenic phenomena into natural and socio-cultural contexts of spaces of human life and activities is obvious. The fragmentation of scientific research results makes it difficult to form a holistic viewing of these processes, provoking turning to interdisciplinary methodological and explanatory constructs, the formation of which is currently being carried out, but it is still not sufficiently acknowledged and approved, although it is certainly promising.

1. It is sufficient to analyse the difficult path of the Theory of Complexity in Russia. This theory is better known here as Synergetics. Methodologically important issues of Synergetics foundations and its possible approaches in different areas of science can be found in the works of V.G. Budanov [14]; S.P. Kapitsa, S.P. Kurdyumov, G.G. Malinetsky [24]; K. Mainzer [28]; I. Prigogine, I. Stengers [33]; V.S. Stepin [35]; H. Haken [20]; D.S. Chernavsky [17].

2. The works that reflect the adaptation of the topological theory to socio-humanitarian and interdisciplinary knowledge are essential for the study (see, e.g. [10-13]).

Cite this Article as: Evgeny KAMENSKY, Irina ASEEVA and Vicktoria BELKINA" Modern Horizons of Evolution: from Nature, a Human Being and Technology to Technogenic Man-Measurable System " Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

3. Certain aspects of complex forecasting and modelling in relation to the state and the development of technogenic and other transformations of human environment and human being future are being developed (see, e.g., Benjamin et al. [4]; Bostrom [9]; Kirk [25]; Kurzweil [26]; Waldeman [39]; Kamensky [23]; Boev E. & Kamensky [8]).

4. Special attention should be paid to the works in which the concept of the technosphere as a part of the noosphere is distinguished (V.I. Vernadsky [38]; K. Popper [32]; M. Heidegger [21]). However, none of the approaches suggested in the works of these authors has been accepted as a universal one by the scientific community. Although the importance of universalism is obvious, it still remains a marginal area of scientific methodology and practice.

In this paper the most general, but, nevertheless, as it seems to us, rather significant philosophical and methodological outlines of understanding the dynamics of the development of technical and technological complex connected with human life and involved in the contextual processes of human environment transformation are presented.

Research Methodology

Socio-humanitarian paradigm of today's world, tending to interdisciplinary, problem-oriented, not subject-oriented fields of knowledge in its ultra-modern trends of development, continues to use orthodox, traditional doctrines of explaining and interpreting new anthropotechnical phenomena illustrating the trends of hybridization of different systems, however. TMMS as a product of new types of relationships of 'living-nonliving', forming atypical for each system characteristics and effects can be referred to such phenomena nowadays. Nevertheless, there is almost no comprehension of technogenic elements of environmental structure of human life and activities, in particular in the framework of socio-humanitarian knowledge. These issues are addressed in the field of philosophy of science and technology on a larger scale, but they still remain marginal in the scientific community. We believe that, first of all, this is due to the interdisciplinary nature of these explanatory models, immaturity of their methodological and conceptual apparatus that makes them open and vulnerable for 'criticism' of the orthodox representatives of different branches of science.

Results

We also believe that in view of the above mentioned theories and concepts the problem of technogenic development and transformation of human environment in the most generalized form can be illustrated by the following provisions:

1. Technology, being a product of human activities, is an indicator of cultural evolution of a human being throughout the whole historical and socio-cultural development. Technosphere products are associated with the development of a human being as a species, being a cause, a tool, and a result of human intellectual evolution.
'Anthropological turn' as a relevant characteristic of the current time lies in the increasing trends of anthropotechnical hybridization reflected in the ideas of transhumanism. Despite the fact that the representation of this 'turn' can be traced in other contemporary social phenomena (such as transgender and homosexuality, the popularization of which is becoming an important feature of modern society), it is easy to notice that it is typical for the developed countries with powerful technological potential capable of modelling non-biological scenarios of human reproduction in a homogeneous world. Consequently, the focal point in this case is also a technogenic factor of human evolution and non-obvious vectors of human future development, initially perceived as independent, will exist due to the technical and technological progress on closer examination.
2. The processes of the unification of technological, socio-cultural, and personal spaces imply that all of them adapt to the models of technology 'ontology'. For example, now the vital developments in the field of the management of people and the objects of non-anthropic and non-social sphere are actually based on the principles of algorithmic presentation of the activities of social groups and individuals in similar way to technical systems in which the main characteristic is their functionality. Hence, a mechanistic approach to a human being as a set of utilitarian qualities and his utilitarian and functional potential without taking into account a complex creative characteristic of a personality and his individual characteristics. Similar processes can be observed in relation to the culture of management, organizational culture, and social culture.
3. The very culture of modern consumer society is based on the fetish of innovations in engineering and technology

as the main consumption product. As a result, because of the particular complexity of the technology, it is attributed with true social and anthropic qualities, which is possible only as a simulation of these characteristics at the present level of progress, however. Conversely, there is a counter trend: a person himself becomes mechanized by the analogy with technogenic subjects, which facilitates a kind of dialogue between technology and a human being. In other words, it is difficult to make a human being from a robot, but it is much easier to make quite the opposite. Hence, there is a simplification of the essence of the anthropic subject; this comes into conflict with his self and other latent existential contents of a personality which have not been reliably studied. As a result, in today's society an uncontrolled increase in the cases of frustration, deprivation, and other psychosocial disorders occurs on a massive scale.

So, the anthropological turn of modern civilization probably lies in the crisis of the consumer society, the crisis of postmodernity based on the enormous achievements of the technical and technological development of the current stage, which gave a person more free time reducing the degree of self-preservation efforts. The whole history of human development is the history of the technological development when, becoming more complex in the direct proportionality, it facilitated the struggle of humanity for survival in the natural environment, transforming both this very environment and the methods of interaction of the society with it. In fact, we are talking about the formation of material culture as it is, expressed in its peak achievements reached by the phenomenon of civilization of a particular type.

4. It is obvious that currently 'over-optimization' (N. Taleb) of social system is taking place, which leads to its destruction. Social immunity is disappearing, unpredictable existential risks (N. Bostrom) are growing, and searching for a new paradigm of existence is becoming urgent. In this case it seems that a throwback to the past orthodox grounds is impossible since progress achievements have become an integral part of our lives and they are our environment. To destroy the environment means to destroy a modern human being and this intention is 'decadence' (F. Nietzsche).

5. We can assume that human achievements have formed 'a super-environment' and now, in view of its complexity, this environment is objective, and a human being as a subject should be simplified. Two macro-scenarios of further development are obvious: either a human being will progress intellectually, becoming more complex according to the mentioned trends, that is simply impossible on a mass scale in the conditions of pragmatic consumer ideology of the time or a human being will become a 'One-Dimensional Man' (after H. Marcuse), with a distinct functional in a particular area of social and professional practices, by means of which he will adapt to the environment in which he lives and carries out his activities.

Therein lies the main paradox of the situation: initiated and implemented by a human being technical and technological progress as a product of the intellectual evolution triggers the regress of the very humanity destroying human adaptive potential. In this aspect, the ideas for new foundations of social stratification are becoming relevant. They are reflected in the ideas of a 'Creative Class' and the similar ones but, in fact, they go back to Plato's ideas about the ideal social structure based on the power of intellectuals-philosophers.

Apparently, the only way of correcting the situation is to create artificial conditions for restoring and improving 'social immunity' of a human being, his adaptive structures as the guarantor of the preservation of subjective autonomy. However, nature, probably, activates the natural mechanisms of correcting the destructive tendencies through the descriptively recorded phenomena of the transformation of pathologies, normal distribution and the like. These phenomena are related to the processes of self-organization of the systems which are the subject of trans-scientific areas of modern knowledge, but which are not understood to this day. New diseases, wars and other disasters may act as unpredictable convergent effects, risks of our time, but perhaps they stimulate the process of restoring natural harmony despite their catastrophic values in the world people conscience. There are proponents of these viewpoints both in scientific and in futurological journalistic literature.

6. The consumer society as the product of the postmodernity of technogenic civilization can achieve balance and order only bringing together 'the principles of life' of a human being and technology, harmonizing these principles. It is possible to destroy this type of society as a stage of human evolution only from the outside through the external links of the system. However, if the society is developing in a similar global environment of the global world system (with respect to its characteristics), then there is probably no objective factor leading to a crisis of this type of social organization. Circular determination starts to work. Under these conditions, the only thing we can rely on

is the existence of a human being as his fundamental potential, his creative and dynamic essence which is self-determined 'from inside'. He is a kind of important cause capable to stimulate self-development regardless of any circumstances.

Then it is possible that these trends will be broken from inside, if singularity which is not connected with technical and technological progress but defined by unlocking a fundamental human potential, the boundaries and the content of which are absolutely not studied to this day occurs. But the logic of life tells us that this can most likely happen only by means of its stimulation by technical (technological) methods. Moreover, this can occur in different scenarios.

7. In our opinion, being widely advocated today the ecological approach as opposed to the technogenic one is doomed to remain a utopia if it does not take into account the problems of technological development as it implies devastation of intellectual evolution of humanity which is intimately connected with technological development.

The main conclusion that can be made by assessing the current situation of the development of society, a human being and technology is as follows: the technosphere occupies more and more space between 'the world of society and a human being' and nature at least through its technogenic products that mediate this relationship.

For example, we can travel in the mountains but in a car, or we can enjoy the sounds of nature but in audio recording, etc. The characteristic feature of this time is that the current achievements in technical and technological progress interfere in the very essence of the biology of life, changing the true natural processes but still in accordance with its natural mechanisms. This is the main principle of anthropotechnical hybridization consisting of technical replication of natural biological processes. However, for example, in accordance with the ideology of transhumanism, it is probable that through achieving singularity, when uploading consciousness to virtual networks radically different from the existing principles of 'life' of post-human will be observed; according to N. Bostrom at this stage of the development of human reasoning a prediction of these principles is impossible.

Discussion

So, we will try to outline our vision of the phenomenon which we call the technogenic man-measurable system in its most futurological aspect which, however, reflects the existing trends of the development of scientific and technical progress. First of all, let us operationalize this phenomenon.

We believe that man-measurability originates from the very ideology of anthropocentrism and humanism, enclosing a human being in the subject matter of comprehension by a human being himself, and most importantly, in the terminology of Protagoras considering a man as "the measure of all things". In this case, if we look at the issue at least from the origins of the fundamental ideas of Renaissance Humanism, it is possible to speak about radical man-measurability, putting anthropic subject in opposition with nature. Modern paradigm of humanism, based on the integration of scientism and subjectivity in the sense of postnonclassical models, as we have already said, is represented, for example, by Synergetics. V.I. Arshinov and V.G. Budanov [1, 61] suggest that man-measurability relates to the problem of understanding the ontology of synergetic systems on the basis of postnonclassical methodology, for example, by the analogy with quantum processes understanding.

V.I. Arshinov and V.G. Budanov argue that a new unified worldview can and should be built in the context of the paradigm of the complexity of the world and a human being, nature and human existence enrooted in nature, involved in it, and therefore in balanced relationship with it; human existence constructs in its collective becoming another 'manmade' nature of technology and social institutions [1]. We suppose that this viewpoint reflects a truly synergetic aspect of the problem, which lies in mentioning nature-measurability and man-measurability of modern reality. However, the theory of the balanced relationships of human existence and nature (not in its cosmological sense), at least the nature of the Earth in the conditions of its current state and the trends of scientific and technological progress and the evolution of human intelligence raises a number of questions [16]. Here there is rather a tendency of man-measurable restructuring of nature.

A human being rather changes nature through technology, than destroys it provided that this is not about pathological scenarios of the sterilization of the planet due to technological catastrophes, industrial and other man-made disasters or similar anthropotechnical causes. This assertion is based on a rather trite idea that all living

organisms, and even noncellular protoforms of life, to which viruses can be referred today, transform nature. In this case, these processes are considered natural. For example, virologists say that viruses control open-ocean streams, they are responsible for the formation of some rocks consisting of the remains of plankton which died from a viral infection, which significantly affects physical and other parameters of the planet. However, we still believe that a technogenic scenario is the most likely one. And this is the reason of our interest in the analyzed issue of modern trends of the development of technogenic sphere and its integration with the contexts of the existence of the anthropic subject, in which it was previously represented but in a different, instrumental form.

We believe that man-measurability is a category denoting, apparently, an assessment of the object from person's perspective of involvement, participation, and complicity. That is 'human assessment', but only considering a person as a subject of this assessment. In this case it is necessary to remember about the so-called anthropic principle in all its interpretations, the analysis of which is given in the scientific literature (see, e.g., Polozova [31]; Barrow and Tipler [3]; Carter [18]; Boev [7]; Arshinov [2]; Budanov and Aseeva [15]).

V.I. Arshinov and V.G. Budanov [1] note that the cybernetic understanding of the 'human-computer' system reduced it to the information processing system, i.e. a system of symbol manipulation based on a set of rules. But then, the same cybernetic perspective of the evolution of this system resolving into a progressive linear displacement of a person and his full replacement by a computer appears.

Even N. Berdyaev [5, 6] wrote that the means of life often substitute for the goals of life; they can occupy so much human life space that the goals of life eventually and completely disappear from human consciousness. And it occurs on a grand scale in our technical epoch. Of course, technology for a scientist making scientific discoveries or for an engineer inventing something can become the main content and the goal of life. In this case, technology as cognition and an invention receives a spiritual meaning and refers to the life of spirit. But the substitution of the goals of life by technical means can imply depreciation and extinction of the spirit. And so it happens. A technical instrument is heterogeneous in its nature both for those who use it and for the purpose it is used for. It is heterogeneous for a human being, human spirit and meaning. Currently, the representatives of the newest forms of romanticism, ecological approach, environmentalism and similar branches of science use these arguments in their reasoning of anti-technocratic positions, and it is difficult not to agree with them.

However, the current state of the problem analysis illustrates new approaches and models of understanding, based on the search for universal system qualities of anthropic and technical systems. In particular, V.I. Igonin [22, 38] suggests that 'a technical system' and 'a human system' are the forms of energy existence. After this follows the recognition of 'a technical system' as a subject of 'man-measurability' as a result of understanding the energy unity of 'a subject' moving in its progressive development and a technical system which he creates. The self-organization of the subjective energy-technical system goes in the direction of the energy-technical enhancement of the space of its energy state.

At the same time, it seems that this viewpoint, though developing the ideas of perpetual motion in the constructs of development through self-organization can be regarded as one of the modern images of the stated by G. Leibniz assertions of the basic levels of classical science, which made specifically stable pendulum an object of scientific interest (see, e.g., Prigogine [34]).

In the modern truly synergetic understanding a TMMS can be represented as a dynamic non-equilibrium system. We mean that in the case of integrating in the process human activity and complex analytical (or another, but usually computer) equipment the status of controlling subsystem transfers from an anthropo-biological subsystem to a technical one or vice versa; it occurs swiftly, according to the current objective or even task, which reflects this the process as a process of operational status change of the control parameter (or even of the order parameter). In this case this process can accompany TMMS work both within a predetermined tunnel of the objective (the attractor) and in the space of bifurcation with the highly ramified objective tree (the operational choice situation), for example, in multiaspect predictive planning of particularly complex systems evolution without defining the desired (specified) scenarios of such development.

Thus, such activity presupposes the potential presence and reaching an indefinite number of bifurcation points which require operational decision-making not only on the basis of predicting the determined scenarios based on machine extrapolation, but also on the basis of intuitive or other latent non-formalizable mechanisms for defining

objectives and decision-making by the subsystem 'man'. In such a complex interaction a transition of the subsystems between two base statuses (controlling and instrumental) without the possibility of statically-stable definition of any of them for the subsystems will be observed. It is likely that a nonlinear pendulum or other oscillatory kind of the parametric dynamics of hierarchical structure of TMMS without destroying its hybrid ontological content will be observed.

The outlined process can be described with the introduced by us category of 'the horizontal hierarchy' which represents a dynamic response of a static hierarchical system in a specific space-historical period. The opposite is also possible, in some cases for a number of specific classes (kinds) of systems a static vertical hierarchy is no more than a characteristic feature of horizontal hierarchy within a specific period if we rely on at least the proposition of 'perpetual motion in nature'.

In our opinion, at this stage of the development of interdisciplinary knowledge it is quite difficult to determine whether the proposed constructs are nonlocal methodological or they are ontological characteristics of the systems. But it seems to us that they are topical in both senses for TMMS in particular. TMMS will always be ontologically non-equilibrium but at different points of time it may have different internal factor structure (configuration of subsystems) represented only by two macro-types of vertical hierarchy as its static characteristic at a particular point of time: 'anthropo-biological subsystem- technical subsystem' and vice versa. It is possible that there may be moments of transition without clearly identifiable status indicators of subsystems in the bifurcation points of objective defining and decision making (choice) concerning the directions of the development (activity). The change of the operational status allows keeping the necessary level of the subjective order of the system optimally organizing specific linear processes within the system during its dissipations with the environment within the current attractor.

Therefore, we can assume that the phenomenon of horizontal hierarchy is an indicator of the dynamics of vertical hierarchical structures or systems in general, or, at least, of biocoenosis or certain populations of species in them. In complex systems a struggle for the controlling status of one of the parameters can occur. It is possible that a dynamic state that allows existing operational status change of two or more parameters not only as controlling parameters, but also as order parameters will be a new homeostasis of the system. This is due primarily to the expansion of the range of the goals of human society which has to integrate the priorities of the development of previously separate spheres of social practices into a single stream of goal-setting. In this case, social systems will be inclined to organize a network, rather than centralized deterministic form, and the mechanism of horizontal hierarchy will be determinant in their homeostasis; vertical hierarchy will be a private response to the local objectives of the existence. Such grounds, for example, are the foundation of the ideas of civil society as a set of associations of free individuals, and any other network structures. A successful example of the use of the concept of the order parameter in the sociological aspect can be found in the work of H. Haken [19]. And speaking of the TMMS subjectivity, we can conclude that the parametric design of the internal structure of such a system is the most successful for describing the fundamental bases of its hybrid nature.

As an example, it is also possible to imagine that under condition of implementing the integration of 'computer-brain' (N. Bostrom) as a result of the irreversible system failure which threatens with the loss of valuable arrays of information, through the regulation of the system by means of the mechanisms of negative feedback the biological subsystem may be disabled (destroyed) as the most vulnerable and unreliable when its most valuable core (consciousness, personality, memories, knowledge) will be stored on a reliable technical (artificial) data storage device. Such algorithms can well be 'firmwared' in the programs of the TMMS operation in the nearest future or be formulated as a principle of 'objective necessity'. It is probable that these results will be achieved in addressing the fundamental issues concerning the relationship between psyche and somatics, and, in fact, as a result of the victory of materialist or idealistic paradigms of the human worldview or understanding their integral unity on the basis of new scientific discoveries in the field of cognitive science, transpersonal psychology and related areas of knowledge.

It is not excluded that the specified scenario of horizontal hierarchy in the context of the forced system socio-anthropo-technical integration will be possible in the conditions of the development of antagonistic trends of the social, technical and technological development of a human being. In the process of this integration the subsystems will struggle for the autonomy (in borderline cases even by means of destructing the second subsystem which acts as a subsystem-opponent, not a subsystem-partner).

Therefore, two basic scenarios of socio-anthropo-technical hybridization and TMMS development are obvious. In this case the very TMMSs are represented in two types:

1) simple systems which do not make decisions by means of an anthropogenic subsystem. For example, 'man-manipulator" or any other technical device.
2) complex systems making decisions by means of an anthropogenic subsystem.
Undoubtedly, this classification is the most general and not final, and it needs further clarification. Here it is important to understand its main criterion which is the ability of technical and technological subsystems to make autonomous decisions not just as an optimal algorithm with regard to a number of factors according to the programmed scenarios and their combinations, but, particularly, 'the simulation of will'. But more importantly, according to K. Mainzer's position, is:
"<...> nonlinear dynamics can generate complex patterns and system states, which cannot be forecast in the long run without increasing loss of computability and information. Thus, artificial minds could have their own intentionality, cognitive and emotional states, which cannot be forecast and computed similar as is the case with natural minds" [30, 282].

However, in this case it is appropriate to refer to the TMMS non-equilibrium state once again. It currently cannot be understood as an absolute characteristic, since both of its basic subsystems (a man and technology) are quite autonomous at the present stage of technological development. For example, if the system 'man-computer' will be decomposed, then both of its subsystems will be autonomous in relation to each other as ontological objects. However, from the viewpoint of the functionality of the system the two basic scenarios can also be viewed:

1. A human being as a subject in relation to the overall functioning of the system is the subsystem determining the life of the system almost at any time due to having will and freedom to make decisions about the relevance of the existence of the system. In this case, having performed a set of appropriate functions the system temporarily stops operating, at least by switching off the computer. In this case, a technogenic subsystem of TMMS is functionally referential.
2. In the case of 'man – life-supporting appliance' TMMS the functionality of the technogenic subsystem of the system is much more referential in relation to anthropic subsystem. In this case, a technogenic subsystem provides the functionality of the whole TMMS and is ontologically referential. Nevertheless, a person still has the possibility of switching it off, in spite of the destruction of the whole system itself.

Thus, two main forms of communication and topology criterion of TMMS can be identified: according to the basic type of communication (or ontology) and according to functionality.

It is also essential to remember that the extent and the quality of communication of the subsystems are much higher in the ontological types of systems than in the other types. These can serve as a criterion for their classification. It is the development of TMMS with these types of communication that characterizes the current stage of these systems development as a fundamentally new one. This is the protoform of organic unity of TMMS of the future as inseparable integrity of anthropotechnical subject or anthropotechnical form of ontology. V.I. Arshinov writes that the problem is to stimulate strongly the process of the convergent extension of the practices of technocultural anthropologically oriented mediations which generate recursively hybrid cognitive interfaces between the converging levels of reality; at this, complexity, as irreducible integrity, is this very potential context in which this 'double' technocultural convergence can only be fully implemented [2, 84].

At present the predominant type of non-equilibrium lies in the ontological referential relations of anthropic subsystem in the TMMS structure. The vector of the future consists of the displacement of the reference to the technogenic component or to their ontological equilibrium at different variants of functional non-equilibrium.

Thus, the formation of the phenomenon of 'horizontal hierarchy' in TMMS is the criterion for assessing its integrity as the indicator of integrative subjectivity. The displacement and the dynamics of the operational statuses in the cycle of life-support will characterize its complicacy as dynamic integrity with further strengthening 'horizontal hierarchy' localized now as the principle of the functioning of more complex and integrated structure of TMMS in its subsystem relationships and structural loci. A network type of structure (rather than a center-deterministic type)

is the most adequate principle for organizing such system existence.

The issue of building futurological models of the formation of subjectivity of technogenic phenomena has arguments both objectively supporting and refuting these trends. For example, the fact that technology has no ability of self-positing (goal-setting of its development) indicates a significant difference when describing the trends of its subjectivity formation. Upon reaching the status of a subject in terms of its autonomy from a human being, we cannot already talk about TMMS and will focus on new forms of subjectivity; though this subjectivity will be anthropomorphic, its self-development may lead to a new hybrid form of ontology. In this perspective TMMS is a transitional form between the instrumental and subjective status of technology in which man-measurability may not be included any more. Modern technologies allow only creating TMMS which are the main objective of the current stage of scientific and technological progress, whereas gaining autonomous status by technology is mainly an accompanying scenario usually of apocalyptic nature. On the other hand, according to V.S. Stepin (2011), in the case of TMMS in a so-called activity triad each of its subsystems can change the status alternately in the range of 'subject-means-object' controlling, supporting, and saving each other. In this case it becomes obvious that a connective of 'artificial intelligence - natural intelligence' works more using poorly formalized languages peculiar to ordinary consciousness and intuition rather than using strict logic. One of the indicators of the processes of the formation of the anthropotechnical subjectivity is that currently there is a contradiction between the self-service of equipment and its functional area [6, 28].

In addition to this, the most important aspect in understanding the problem of anthropotechnical hybridization is the observability of universal synergetic laws in the activity of the very technical systems. For example, overloaded buffers behave remarkably similarly to infected people. If the buffer is overloaded, it tries to send packets to neighbouring routers. As a result, overload is spread in the space. On the other hand, routers can restore. This is not only an exemplary metaphor, but a hint *concerning nonlinear mathematical models* describing genuine *epidemic processes*. According to K. Mainzer, computer networks are computer ecological communities [29].

In fact, we are talking about the formation of the protoforms of technology autonomy as an aspect of its subjectivity. This can be observed not only in the simulation of such anthropomorphic characteristics as reflexivity, dialog-based character, variability of choice, the form of a response to the impact, etc. More accurate and in-depth studies of complex systems discover the universality of these characteristics which may probably converge into new forms of ontology provided that we take into account not just biomechanical, physiological and psychological characteristics of anthropic principle but the necessity of creating appropriate interfaces. All these trends continue showing human moving away from anthropobiomorphizm and even socio-cultural determination to some new horizons of existential representation.

Conclusions

Perhaps the given processes are a certain stage in human evolution according to the general principles of human existence organization, of the existence of human 'ego', of consciousness as a psychical-spiritual essence of a biological individual, which are currently largely described but have not been learned ontologically. In particular, between the world and a human being there is always perception and interpretation which is prior to conscious awareness and understanding, as the necessary processes of rational knowledge unlike the knowledge of acquaintance which is deep and fundamental in relation to the focus of all psychical processes, but which is based not only on biochemical, but also, probably on other already non-physical stimuli. Consequently, the status of an observer in human life always involves the use of 'a tool' which may define the highest autonomy of a human being among animal species of the planet in relation to the natural environment.

Theories of immortality and other areas of transhumanism are based on the postulation of changing the natural processes of biological and ecological functioning of human body. This postulation can result in the technologies of artificial programming of the processes of life, the creation of the models and principles of controlling these processes with the provision for coordination and change of certain physiological algorithms and the conditions of the environment. Currently, the devices for life-sustaining treatment are already the protoforms of such processes, but they are still used for organizing and supporting natural physiological processes. Over time, it is likely that these very processes will be modified on condition that the decision concerning the necessity of their optimization to the external goals of human existence in relation to the natural laws of life is made.

In such conditions the anthropotechnical subject does not seem science fiction. It serves as an advanced oriented model of the development of technical and technological evolution. In this respect one ought to bear in mind that these processes develop in parallel in the area of the development of technogenic high-tech anthropomorphic forms implementing their functions only simulating anthpropic qualities not only in the aspect of the imitation of physical species characteristics, but also reproducing the models of physiological functioning, thinking, and social behavior. As a result, we consider these trends as 'converging' ones. They will produce a convergent effect after mutual integration and form that very 'anthropotechnical subject'.

Abstract

The current stage of economic development is characterized by profound transformations in the social and economic order, which have led to the emergence of a post-industrial society with an economy in which information and knowledge are the main factors of production. Rapid and effective innovation is a prerequisite for economic development. In view of the need for the sustainable development of the national economy and the inclusion of the leading technology supplier countries, the organization of a technology transfer system, that ensures that innovation results move from research and experimentation to application becomes one of the most important tool for the scientific and technological development of the Russian Federation.

Keywords: Innovation, Efficiency, Competition, R&D, Investment, Business Processes.

Introduction

One of the main objectives of the Strategy for Scientific and Technological Development of the Russian Federation is to establish an effective system of communication in the field of science, technology and innovation, providing for the increased responsiveness of the economy and society to innovation and the creation of conditions for the development of knowledge-based business. Lapidus L.V. notes that this task is predefined, set in the program «Digital economy of the Russian Federation» (approved on July 28, 2017. Government of the Russian Federation). The goals and objectives of increasing competitiveness in the global market, both in individual sectors of our economy and in the economy as a whole. The programme is aimed at creating conditions for the development of the knowledge society in the Russian Federation, improving the well-being and quality of life of the citizens of our country by improving the availability and quality of goods and services; digital economy using modern digital technology, awareness-raising and digital literacy, improving the accessibility and quality of public services for citizens as well as security both within and outside the country».

According to M.Logachev, the key element of such a system is a subsystem of technology transfer, primarily from the scientific and educational sphere to business. In this context, the assessment of the efficiency of technology transfer in Russia and the identification of possibilities for its improvement are particularly relevant. The main

component of the technology transfer system is the Technology Transfer Centers (CTT), which are designed to solve the key problem of Russian universities and scientific organizations - the problem of bringing scientific developments to industry, or commercializing the results of intellectual property (RIP).

A comparison of the changes in the number and structure of the technology transfer centers and the research and development community led to the following conclusions:

- the increase in the number of Tpts (37 percent) was more than twice the increase in the number of research and development organizations (15 per cent);
- the increase in the proportion of universities in the structure of research and development organizations (p. 14), was accompanied by a reduction in the proportion of university CTT in the distribution of the CTT to basic organizations (p. 18);
- the significant decline in the proportion of scientific organizations in the structure of research and development organizations (para. 16), has had little impact on the share of technology transfer centers in the distribution of the CTT among the basic organizations;
- while there has been no significant increase in the number of other research and development organizations, the share of these organizations' technology transfer centers in the distribution of the CTT to the parent organizations has more than doubled.

In addition to the technology transfer centers, small innovation enterprises are an important instrument for technology transfer from science and education.

The role of technology transfer in innovative development

The innovation component of entrepreneurship has been of great interest and interest to economists. In particular, Mr. Schumpeter, the innovator of innovation theory, who saw innovation and corporate research as major drivers of economic dynamism, noted the competition that they generated: The task of entrepreneurs is to reform and revolutionize the way of production by introducing inventions and, more generally, by using new technologies to produce new goods or old goods, but by a new method, thanks to the discovery of a new source of raw materials or a new market of finished products - up to the reorganization of the former industry and the creation of a new industry».

The economic literature highlights an innovative type of entrepreneurship oriented towards the constant search for new opportunities, new products and services, «Public technical economic process leading to creation of the best in its properties of goods (products, services) and technologies by practical use of novelties». As Schumpeter wrote: To produce means to combine the things and forces available in our sphere... To produce something different or another means to create other combinations of these things and forces», and accordingly singled out five cases of «implementation of new combinations».

In the opinion of Schumpeter, the main force initiating the upward pulsations of the economic situation is the spread of «beams» of interrelated innovations - clusters with high potential of market diffusion: «The rise is over, and the depression comes after the expiry of the time that must take place before the products of new enterprises enter the market... a new rise follows the depression when the process of absorption of new goods is finished». The introduction of radical innovations creates additional profits for entrepreneurs, stimulating the massive transfer of capital into new technologies and thus the massive spread of new high-efficiency industries. In anticipation of high profit the new technology is imitated by groups of entrepreneurs: «early recipients», «early majority» and «backward». Increasing the number of simulators initiates a wave-like process similar to the long waves of Kondratiev.

Among Russian scientists, the problem of techno-economic development is being addressed in particular by S. Y. Glazhev. In his fundamental work «The Theory of Long-term Techno-economic Development» describes the view of innovative cycles as «technological patterns», emerging of a set of technologically related activities - technological complexes connected into a reproducible integrity by stable production and technological relationships. The emergence of new chains of conjugate processes means the displacement of old ones, so that any major innovation within the technological community takes the character of its reconstruction on a new technical basis, which may also mean the emergence of a substantially new technological community. Britvina V.V. notes

that, in turn, each technological community, through its pervasive technological chains, is linked to other technological communities of the same technological order. Therefore, changes in any technological community are limited by the ability of the neighboring populations to absorb these changes, and if they occur, induce corresponding changes in the rest of the technological order».

Technology Transfer at A Time of Innovative Economic Development

Having analyzed the conditions of efficiency of technology transfer within the national economy, we have concluded that it is fully determined by the efficiency and quality of the national innovation system as a subset of knowledge and technology generation and transfer, infrastructure, market, production, education, legislative subsystems, as well as the quality of macroeconomic policies. Pyataeva O. and Nurgazina G. note that the issues of technology transfer at the level of the national innovation system and from the perspective of the foreign economic activities of a given country need to be considered in relation to overall socio-economic development.

Moreover, in the modern phase of the innovation cycle of the Russian economy, transfer takes two forms: direct and indirect transfer. Direct transfer assumes that the university and the potential buyer are informed of mutual interests and offers, know each other and interact directly. It takes the form, for example, of the development of technologies through direct contracts with enterprises and organizations; the trade of licenses for inventions, know-how, useful models, industrial designs, trademarks; and the organization of scientific and innovative enterprises at university. One of the peculiarities of the Russian direct transfer of innovative technologies is the singular nature of transactions for the transfer of intellectual property under license agreements.

The second peculiarity: the presentation of products at exhibitions remains an effective mechanism of technology transfer, and in particular the high-tech products of small higher education enterprises.

The indirect mechanism of technology transfer implies the inclusion in the chain of «higher education - enterprise» of innovative structures promoting the expansion of information exchanges and contacts, promotion of scientific and technical products of higher education institutions. These include technology transfer centers, innovation centers, technology parks and business incubators.

At present, the following innovative structures of the indirect transfer mechanism exist: the Office of Innovation Activities, which includes a business incubator, patent services center, innovation and presentation center, and the innovative center «Technopark».

The Patent Services Centre is the most innovative of all existing structures and plays an important role not only in the legal protection of the results of intellectual activity, but also in the promotion of intellectual property. In addition to the legal protection of intellectual property, the center carries out some work on the commercialization of technologies: preparation of licensing agreements, preparation of exhibits for Russian and international exhibitions, and carrying out patent and market research.

Research Results

1. Due to the weak economic component, there is a lack of development of the mechanism of entry of the innovative product into the market (lack of an innovative infrastructure supporting commercialization of innovative products).
2. The low level of development activity in patenting their inventions, which reduces the benefits of REED production, as proprietary Reeds do not become a commercial product and can only be used in the development of technological processes.
3. Lack of initiative and necessary training of the research team in decision-making on commercialization of Reeds and their transfer to the real economy.

Foreign experience demonstrates that in place of the ZTT - «scientific shops», which serve as the official contact point for applications of potential partners and customers of scientific research, as well as rendering various kinds of consulting and reference services to employees of universities and scientific organizations, come TST-«entrepreneurs». These centers act as a coordinator and active participant in all stages of technology transfer, from

the initial assessment of the potential value of inventions to the organization of interaction with industry during the introduction and operation of technologies.

The functions of TTC-«entrepreneurs» in our country could be performed by centers of experimental production, having not only modern specialized industrial equipment, but also highly qualified personnel. Such centers could build on existing technology parks and industrial (industrial) parks and provide the following services to the intellectual product developers and enterprises, especially small and medium-sized innovative ones:

- technology audit (feasibility study);
- engineering design;
- development of regulations for technological production;
- project and exploration works and the formation of technical conditions for the integration of the technological solution into the production process;
- development of a pilot model.

Funding for the establishment of such centers should be based on budgetary and extrabudgetary co-financing based on a project approach, That is, if there is a demand from an industrial enterprise for innovative development, its financing should be carried out both by the industrial enterprise and by the scientific or educational organization. Such a measure would significantly reduce risks and increase the likelihood of the product being commercialized.

Another important step in the development of technology transfer in Russia could be the adoption of a PCF aimed at supporting technology transfer centers based on institutions of higher education, research organizations and industrial enterprises, as well as small innovative enterprises; established with the participation of TTC. Given the time lag between support for the establishment and development of the DOT and the output that should compensate for the costs incurred, the VTF should be implemented for at least five years.

Such a comprehensive approach will promote the self-development of technology transfer mechanisms in Russia, which in turn will be a factor in increasing the level of innovation of our economy.

Emotions and Digital Media: At the Origin of a New Paradigm

Giusi Antonia TOTO

University of Foggia, Foggia, Italy, giusy.toto@unifg.it

Pierpaolo LIMONE

University of Foggia, Foggia, Italy, pierpaolo.limone@unifg.it

Abstract

In recent years, the fusion between the theories of emotions and digital technologies has emerged strongly in the psychological studies panorama. The purpose of this article is to trace the theoretical precedents to the study of the construct of emotions in relation to digital media. Contemporary experiments and investigations (2010-2020) have led to the emergence of a new theoretical paradigm: the digital emotion experience. Starting from emotional regulation and the mediation produced by digital technologies, the digital emotion theory represents a collective that contains different theoretical experiences. We try to take stock of what has been scientifically produced up to now and what prospects for future research can be advanced.

Keywords: Emotion, Media, Digital Technology, Self-Regulation, Learning.

Birth of The Relationship Between Emotions and Digital Technology

The theories of emotions have a long tradition in psychological studies, but the approach of this construct to media education is contemporary. For an overall analysis of the theories of emotions that represent the epistemological antecedents to this article, see the volume Game and Learning by De Serio and Toto (2020). The theories of James/Lange (1884) and Cannon/Bard (1928/1931), despite being conceptually in opposition, both proved to be true in subsequent experiments and scientific studies (Anolli & Legrenzi, 2006). However, contemporary research has analysed specific aspects of the emotional process by focusing on cognitive evaluation, tendency to action, mediation between sensation and cognition, coping strategy, function of medium between man and environment, and tools for communication (tab 1).

Table 1: Emotions translated into action through technology

Emotion	Technological action
Prosocial messages	Sharing information
Competition	Perception and skills related to perceived stress
Positive emotions	Tendency to networking
Negative emotions	Networking inhibition
Decision making	Collaboration and information retrieval

In contemporary teaching, a now widespread tool is the ‘serious game’, which is part of the broader debate on gamification and learning (Sailer et al., 2017). Serious games, which are games designed for teaching, have a complete history, aims, and paths, unlike gamification, which represents the use of playful elements in a learning context (Lister, 2015). The use of games in teaching has made the debate of experimentalists and pedagogues fluid to the point that the focus of study and research has shifted to the flourishing 'side effects' of playful teaching practice. In fact, educational

Cite this Article as: Giusi Antonia TOTO and Pierpaolo LIMONE “Emotions and Digital Media: At the Origin of a New Paradigm” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

games are used in teaching practice through the fusion of fun and learning objectives; the logic behind them can be exemplified through the model of the competition of knowledge learned through quizzes or adventure games (Limone, 2012). In fact, edutainment is that set of didactic strategies that intersect fun and education, with the aim of testing skills such as decision-making or problem solving. The most recent experiments in the context of edutainment can be reviewed in the contexts of e-learning and corporate training (Toto, 2019). The first studies that trace a link between emotions and technology focus on the main repercussions of videogames in learning the diffusion of latent prosocial messages to the processes of sharing experiences by players. The processes of sharing and competition in gaming contexts mediated by digital technology seem to be influenced by the emotions and cognitive assessments of users (Toto & Limone, 2020). Experimental studies on adults (Boyle et al., 2016) have shown that the sharing of experiences takes place during the game if the user is acted on by positive and gratifying emotions; if, on the contrary, the player experienced by negative emotions he would be more resistant to the information-sharing process. Another component that acts in moments of playful sociality is competition: the perception of skills influences the stress perceived by the player and the competition processes in video games. The dimension of competitiveness also presents gender differences that are reflected in the relationships and self-perceptions of players (Vermeulen et al., 2014). In digital games, users must quickly find information and make decisions, even managing to share information and collaborate on the network (Gee, 2003). Collateral to this type of activity is the theme of the flow experience inside the motivation of Csikszentmihalyi (1997), which represents deep immersion in an activity that is particularly interesting for the subject and that the subject focuses on without other distractions. The involvement and motivation narrated by the players within the digital media experience take on the same characteristics as the flow experience (tab.2).

Table 2: Characteristics of the flow experience and motivation in videogames

videogame	
Flow experience	Motivation
Sense of control	Environment manipulation
objectives, feedback, required skills (antecedents)	goals, feedback, required skills
loss of contact with the temporal dimension and loss of self-awareness	Immersion in the activity
increase in learning and consequent modification of behavior	Procedural learning

In literature, the flow experience has been structured in three moments: antecedents, flow experience proper, and consequent. Flow antecedents are elements that trigger the flow experience process described in terms of clarity of objectives, feedback, and required skills, but also with a high degree of playability (Kailii, 2005). The flow experience itself is defined as moments characterised by loss of contact with the temporal dimension and loss of self-awareness, but at the same time the subject perceives a high degree of control and sense of manipulation of the surrounding environment. Finally, the consequences of the flow experience are described in terms of increased learning, modification of behaviours, and perception of control over one's own behavior.

Review and State of The Art of Digital Regulation in Relation to Digital Media

The web, in addition to access to and exchange of information and daily use that is by now undeniable, has become a daily space for social interaction. Psycho-pedagogical studies examine the application of the construct of emotions and the paradigm of emotional intelligence to all dimensions of human existence. Studies in relation to this broad field of application range from interdisciplinary contributions from sectors such as computer science, psychology and communication studies, to more varied methodological insights from qualitative to quantitative techniques for measuring digital emotions. The research in the field of video interviews and ethnographic studies that investigate the possibilities of social networks for emotional expression are innovative. Emotions play a fundamental role in the act of sharing news and content and in the importance of emotional activation for digital users who organise and participate in social movements (Serrano-Puche, 2020).

A study conducted by Blumberg et al. (2016) among adolescents in the United States looked at the importance of social media in the lives of American adolescents. Through some sites, adolescents have had the opportunity to share and express their emotions. Research has shown that among adult participants, the use of social networks increases positive emotions or dampens negative emotions. Little is known about how teens can use social media to regulate their emotions, and researches are in greatest development stage.

Extensive gamification literature has documented a broad debate about digital games in training contexts and learning practices (Toto, 2019) for cognitive development, particularly during primary school. Contemporary research shows how active children aged 6 to 12 are digital media users (Rimé et al., 2020). In the reviews of the gamification literature it emerges that this age group is little studied in relation to the use of interactive media compared to early childhood and adolescents. This absence of studies leads to a lack of data and reflections in relation to the effects of early media use in early childhood and the consequences it will have in the subsequent phase of adolescent development. The research input was born about twenty years ago through Greenfield's (2009) studies of the effects of digital games on the development phases of child. These studies emphasised the importance of the development of cognitive socialisation in relation to the use of digital technology in late childhood and pre-adolescence. In this first study, in addition to establishing the gender gap in the use of games, some cognitive dimensions influenced by this use emerge, including spatial representation, iconic skills, visual attention, and future academic performances.

Music learning studies have also shown extraordinary evolutionary power in early childhood. In fact, it has been shown that learning music has an influence on psycho-physical development from a psycho-dynamic perspective, on the development of intelligence, and finally on the design of new technologies. The relationship between intelligence and music in contemporary studies has reached a high degree of parameterisation with the investigation of all the dimensions involved, and recently music learning studies have been producing specific research in the field of acoustic and audio technology (Toto, 2017). The Spotify streaming service, one of the largest online music providers in the world, has a profound ability to shape everyday realities through digital technology by controlling delivery of recommended playlists to users. An analysis of 500 predefined playlists (Eriksson & Johansson, 2017) shows that the recommended tracks evoke individual freedom and flexibility, while at the same time prescribing normative temporalities, neoliberal subjectivities, functional approaches to music, and monetisation of intimacy. This confirms how the development of new technologies has created a new socio-cultural context in which students are immersed, and new languages and media with which the educational sciences must dialogue.

Especially within the experiments reported in the conferences and in the grey literature, there are demonstrations of the bidirectional relationship between emotions and digital media. Recently, Sarsenbayeva et al. (2020) conducted a study on facial expressions and emotions elicited through the use of smartphone applications. The results reveal that in most cases the use of the application drives users' emotions, but effects can also be produced in the opposite direction, i.e. the emotional states influence the choice of some applications. This demonstrates how studies on technology and emotional states can influence the psycho-physical well-being of the subject, and having this relationship in the second instance can be used in educational planning (Toto, 2018).

Emotional Regulation Measurement Tools

Emotional regulation (RE) is a psychological process in which strategies have been used to deal with emotions and achieve personal, social, organisational or work goals, facilitating the most appropriate response to the demands of the environment. Among the tools most used to measure emotional regulation within media contexts are, as we have already mentioned, the use of apps via smartphones, video interviews, and ethnographic research. An interesting study that rereads an important questionnaire that measures emotional regulation is that of Hirschle and Gondim (2019). Scholars analyse the regulation of emotions in the workplace (RE-Trab). The quastionnaire is an adaptation of the ERP-Br, a reduced version of the Emotion Regulation Profile (ERP), which evaluates two ways of regulating emotions: up-regulation (positive emotions), which predicts a greater use of adaptive strategies than maladaptive ones, and down-regulation (negative emotions), which predicts a greater use of functional strategies compared to dysfunctional ones. From this study four adaptation strategies emerge as a function of emotional regulation at work: adaptive and

maladaptive (positive scenarios), functional and dysfunctional (negative scenarios). The Emotion Regulation Profile-Revised (ERP-R) developed by Neils et al. (2011) is based on two theoretically significant factors: the under-regulation of negative emotions and the up-regulation of positive emotions. An interesting result also emerges from the validation study of the questionnaire, namely that the ERP-R scores are positively related to emotional intelligence and the relevant personality dimensions.

A fruitful field of study is related to coping styles and the ability to regulate emotions. According to this line of study (Haines et al., 2016), an optimal regulation of emotions may not simply concern the use of coping strategies; according to the strategy-situation adaptation hypothesis, emotion regulation strategies lead to well-being only if used in appropriate contexts, i.e. in this type of process it produces positive effects if it also includes the dimension of cognitive evaluation. The use of re-evaluation in relation to all the life and situational contexts of the subject does not create well-being in itself – it leads to positive results if it is used in uncontrollable and unexpected situations. In fact, in these situations, emotional activation has a more stress-oriented patina. The same type of speech was conducted in relation to the lived experiences in immersive digital environments and social networks, in which the subject is called to respond in situations, with the addition of feeling personally involved in virtual contexts. Continuing on the studies (Troy et al., 2019) in relation to the regulation of emotions and their re-evaluation (changing interpretations to change emotions), the research also looked at distraction, i.e. linked to the ability of human beings to direct attention to changing emotions (tab. 3). Both of these strategies are effective for regulating the experience of both negative and positive affects; moreover it has been shown that suppression, that is, forcibly changing the external expression of emotions, is ineffective.

Tab. 3: Actions integrated in the process of regulating emotions

Actions	meaning
the revaluation	change interpretations to change emotions
The distraction	the ability of human beings to direct attention to changing emotions
suppression	that is to change the outward expression of emotions

It is unclear whether this pattern of effects generalises to the context of everyday stressors, a common part of daily life where effective emotion regulation should be particularly beneficial. For this reason, Hirschle and Gondim have oriented their research to work contexts. To date (Nozaki & Mikolajczak, 2020), the field of emotion regulation (ER) has largely focused on intrinsic RE, i.e. the regulation of one's emotions, and only recently has there been a focus on extrinsic ER, i.e. regulation of emotions in relation to an external subject. Emotional experiences trigger the social sharing of emotions through digital media. The social participation of emotions is a complex process linked to the communication of episodes and feelings that pass through the subjects and that translate into intrapersonal and interpersonal and social effects. Within social media, the sharing of positive or negative emotional episodes affects relations with the public, to the point of producing wider social effects in relation to norms and social relationships, beliefs and collective resilience. In relation to the world of adolescents, Vignoli et al., (2019) have shown that the intensity of negative emotions and perceived intimacy are positively related to the frequency and depth of sharing on social media. Active use of social networking sites (SNS) is positively associated with well-being, improving social support, and feelings of connection. Conversely, passive use of SNS is negatively associated with well-being by fostering social confrontation and envy (Masciantonio et al., 2020). Most of these studies focused on Facebook, and a survey conducted during the COVID-19 pandemic showed that passive use of Facebook is negatively correlated with well-being through social confrontation, while the active use of Instagram is positively related to life satisfaction and negative effects through social support. However, TikTok use was not associated with well-being, and the only significant relationship for Twitter was between active use and lower life satisfaction. The conclusions reached in the analysis of social media as well as digital media must differentiate between the approaches and models of investigation to truly understand how human interactions take shape (Cohen, 2014).

Contemporary perspectives of digital emotion experience

A contemporary evolution of the theories of emotions is the application of the model of emotion regulation to digital technologies, for which it would seem to establish itself in the panorama of studies as a new research paradigm. In trying to juxtapose the salient elements of the theories of emotions, it becomes clear that affective states are evolutionary adaptations to the environment and evaluations of opportunities in relation to behaviour in the situation (Nesse & Ellsworth, 2009). According to Gross's (2015) model of emotion regulation, subjects evaluate their affectivity in relation to the set goals and decide whether to modify them through specific regulation strategies. The complex process of regulating emotions is summarised by Gross in five steps (tab. 4):

Table 4: Gross model of emotion regulation

STEP 1 *Situation selection* Approaching or avoiding situations.	**STEP 2** *Change of situation* Selection of the elements to be modified in relation to the emotional response elicited.	**STEP 3** *Selective attention* Focus attention on the relevant emotional elements.
STEP 4 *Cognitive change* Re-evaluation of the situation that had an emotional impact on the subject.	**STEP 5** *Response modulation* Even if the individual has already provided an emotional response to a given situation, he can remodel this response also from a physiological point of view.	

The need to modulate emotions is linked to hedonic and well-being reasons that subjects implement to avoid painful situations (Tamir, 2016). For example, subjects can up-regulate their emotions, that is, increase well-being to amplify creativity or, on the contrary, develop anger and therefore increase competition. Even the instrumental motivations linked to the achievement of performance objectives require socially acceptable behaviours and can trigger the process of emotion regulation (ER). The general functioning of this regulation mechanism has been translated by Wadley and colleagues (2020) in relation to the universe of digital virtual technologies (table 4), as can be seen in the grid below:

Table 5: Examples of digital ER, organized using Gross's emotion regulation process model. Source: Wadley et al., 2020.

ER steps (Gross model)	Examples of ER
Identification phase	Using a smartphone app to help identify their emotions, declare and guide the choice of the opportunity to initiate regulation.
Selection phase	Review of online resources that suggest and develop strategies, such as distraction or cognitive change.
Implementation phase	* no example shown in the original article.

Situation selection	Choose to watch videos online, rather than doing a job or task or attending an organizational meeting.
Change of situation	1) Using digital communications to affect your work or family situations. 2) Use of music playlists in the workplace or in shops.
Development of attention	1) Browsing images on a smartphone during a stressful job. 2) Comfort an angry child with a game on a tablet. 3) Ruminate on Facebook posts or events.
Cognitive change	Search online for information or alternative perspectives on a situation.
Modulation of the emotional response	Express a constructed but desired emotional state via social media posts.
Monitoring phase	Use a digital watch to monitor your state and physiological responses and evaluate if your digital ER efforts are effective

Among the contemporary research reporting the representation of a model of regulation of emotions in relation to digital technologies, we recall the study by Myrick (2015). In this regard, the study reports the use of video clips or musical platforms as the tools most used to cope with stressful situations (Wadley et al., 2019). There are even playlists that categorise a list of music tracks associated with specific emotional evocations (Eriksson & Johansson, 2017). Furthermore, video games can be used by adults as distractions from stressful situations and, hybridised with social networking systems, they also allow self-reflection and social sharing. Further reflections must be reported in relation to online shopping or other recreational moments (video or audio) involved in the process of regulating emotions carried out during smart-working activities. A sector in full development for the application of digital emotion regulation is hybrid technology, which integrates real and virtual notes to influence the user's mood. Examples in this sense are hybrid technologies oriented to the use of perfumes in learning processes or in the selection of olfactory abilities, which activate learning processes on specific brain patterns (Miglino et al., 2014). The repercussions in terms of learning and identity, therefore, are no longer just specific issues of media education, but also lead to the purest psycho-pedagogical research and computer applications.

Abstract

This article examines the role of transformational leadership in establishing trust through empowering remote subordinates. It inspects the challenges faced by managers and employees during the pandemic lockdown and suggests that transformational leaders increase their subordinates' organizational trust through empowering them. At the end, this article provides employers with some techniques useful in engaging and empowering remote employees by creating an atmosphere of trust, which will simplify the adaptability to the unanticipated change in the business environment. This article, therefore, relies on several interrelated concepts: Leadership, Employee Engagement, Employee Empowerment, Trust, and Safety. Trust, a crucial factor in the business environment, defines the basis of the leader-subordinate relationship. The more trustful this relationship is, the more effective the organizational targets are met. Thus, an effective leader should seek ways to institute a confident work environment. One of these ways is to keep subordinates engaged through empowering them. This study was needed to clarify the leader's role in establishing engagement among remote employees. The selected approach to this study was qualitative based on structured interview questions to ten employees in a pharmaceutical company during May 2020, the third month of the lockdown. This company was specifically selected due to the importance of this sector as a continuous provider of major necessities during a hectic period. They were asked about the challenges they had faced during the lockdown referring to technological issues, work hours, relationship with leaders and with colleagues, motivation, organizational trust, team collaboration, and social distancing.

Keywords: Employee Empowerment, Employee Engagement, Transformational Leadership, Trust

Introduction

The occurrence and rapid spread of covid-19 and the resulting non-ending lockdown, had obliged managers to shift from a daily face to face interaction with their employees to a rather daily remote one. The unexpected pandemic lockdown obliged the majority of organizations to convert to a remote, safer, and unanticipated workplace. Unfortunately, no one had time to be trained to the new situation. The best solution to carry on with business activities was to rely on the human capital and, of course, on technological means. Technology is not a major issue, especially that it was an important mean in conducting business before the pandemic. What was crucial was how to help subordinates to adapt themselves to the sudden changes and to keep them engaged, especially in this period of high family, safety, and business stress. Covid-19 had imposed itself as the number one worldwide threatening virus to which nobody was physiologically and psychologically immune. No industry was able to call for help from another one: all of a sudden, everything was totally new for everyone around the globe. Many challenges came across and winners were definitely organizations which were flexible enough to adapt to this change. Therefore, leaders found themselves facing a new situation: how to keep going, far apart from people, far apart from the workplace, far apart from daily routine? How to motivate isolated employees to work in the light of the stressful conditions we were all getting through? It seems clearer than ever now that what was needed were situational leaders to keep subordinates' engagement levels as high as possible: the more subordinates are engaged, the more likely they will be motivated to achieve business goals. Based on literature review, trust unveil its

efficiency through the process of engaging and empowering subordinates. It goes with no saying that the maestro in all of this is definitely efficient organizations' leaders.

Literature Review

To begin with, it should be noticed that none of the concepts discussed in this article is new to literature. What was new, however, was the lack of thorough articles concerning the current pandemic. And that is of no surprise, since, as said earlier, everything was new to everyone.

Since Covid-19 is all about attacking people's health, it is important to mention the importance of safety in the workplace. Yearly, firms spend a lot of money to eliminate workplace accidents because, evidently, unsafe environments negatively affect the human performance (Battaglia et al., 2015). Therefore, firms need to create an employee safety behavior atmosphere characterized by "employee safety compliance" and "employee safety participation" (Griffin & Neal, 2000). As its name suggests, safety compliance oblige employees to comply with the company's safety procedures and policies. Safety participation, on the other hand, shows how employees are getting involved to make the work environment a better one (Griffin & Neal, 2000). Both attitudes indicate how organizations commit themselves to stimulate a long lasting approach to handle the safety issue (DeJoy, 2005). It is in the light of this information that the decision of the 2020 lockdown was taken. As a result, working from home had instantly became the new ordinary "job style" actualized through technological means. Currently, there is no face to face contact between people at the workplace. Therefore, managers are neither being able to get a direct look on employees working behavior, nor to actually detect their worries. As an alternative, we are dealing now with "remote leaders", a situation that induces challenges for both employers and employees.

As a matter of fact, not all employers were able to take off with this new working style. Many testified that they do not know how to efficiently manage remote employees, demanding a kind of support to simplify their task. It was also stated that employers did not have confidence in the employees' skills. They noticed that the performance of the remote subordinates is less than that of physically closed workers (Parker et al., 2020). They had higher hopes from their distant subordinates (Fallon, 2014).

Employees, on the other hand, complained that their managers were micro managing them, closely monitoring their work, not taking into consideration their home privacy, interfering with their family demands and children home schooling: They relate that to the possibility that their managers lack trust in their capacity to have things done (Parker et al., 2020). This was proven through the managers' expectations that they should be responsive all day long by answering work phone calls, by instantly replying to emails, and by being available for sudden video meeting. The lack of trust added more stress to the already stressful pandemic situation (Parker et al., 2020). In addition, remote employees nostalgically compared their work style before and after. The absence of the daily interaction with colleagues made them feel as if they were no longer a part of a team (Elvekrog, 2015). The usual office meetings, lunch gatherings, and talking about essential and non-essential matters were suddenly replaced by formalized communication and necessary discussions (Elvekrog, 2015). Back when they were in the office, they used to detect the climate and energy throughout the day. This had helped them in carrying on their daily tasks accordingly (Bates, 2013). Most of them had to work for longer hours at inadequate time such as early mornings, late evenings, and weekends to demonstrate engagement (Alert Media, 2016). In brief, remote employees felt isolated, victimized due to additional work, and micromanaged (Michaels, 2016).

Employee Engagement

The question of trust was raised several times upon reading the lockdown challenges. When the manager does not trust subordinates, the natural reaction would be to adopt a weak, micro management approach. Micro management, especially during this period of uncertainty and stress, demotivate employees, which will certainly damage productivity. A weakening productivity is certainly not an option in an almost economic breakdown. Now that it is nearly certain that there is no covid-19 remedy in the horizon, a pressing must would be to improve managers' skills allowing them to effectively manage their employees by building trust from a distance (Parker et al., 2020).

Specialists in the organizational culture refer to remote working technique as a culture of engagement (Piaget, 2013) (Pierce, 2013) (Roark, 2013) where the managers' role is to establish a working climate composed of profound employees' engagement and resilient leadership (West, 2013). Nowadays, employee engagement had become a crucial factor in firms' survival, thus, virtual leaders are paying more attention to this specific approach (Adkins, 2016). Engagement is defined as the employees' attachment to their work to the point that they involve themselves completely and enthusiastically in performing their roles (Kahn,1990) (Gallup, 2017). Engaged employees who identified themselves with their related firms become strongly committed to that firm and consequently strive to achieve its targets (Mowday et al., 1982). The uprising reliance on remote working had led employers to question their capacity in establishing, sustaining, and controlling a workplace culture of engagement with their distant subordinates (Adkins, 2015) (Roark, 2013) (Tugend, 2014). This is especially important throughout important meetings where disengaged employees tend to skip crucial discussions (Pullan, 2016). Therefore, employers should strive to implant employees' engagement to increase productivity and profitability. As a matter of fact, effective leaders are those who are capable of rising their subordinates' engagement (Hackbarth, 2017) through adopting a flexible oriented business culture (Azanza et al., 2013). During the pandemic, employees' engagement had experienced many obstacles that somehow weakened it. Some of these challenges are listed below:

Virtual workplace: By definition, a virtual workplace is a firm that partially or completely operates via electronic means (emails, phone calls, video calls, video conferences). It does not necessitate daily physical interaction with stakeholders (Cole et al., 2014). Distance between leaders and followers can be interpreted in three ways (Antonakis & Atwater, 2002): physical distance, perceived social distance (status, rank, and power), and perceived interface occurrence (the frequency of interaction). Physical distance was imposed worldwide and raises the importance of physical proximity between employers and employees. Dispersed distance between the two parties would hinder the employees' capacity to capture leaders' role model behavior (Howell et al., 2005).

Lack of face-to-face interaction: Traditionally, managers used to measure the degree of subordinates' engagement by moving around them in the office and directly observing their work performance (Peters & Waterman, 1982). This technique is impossible when we talk about remote work environment (Gaskell, 2014), leading to a potential disconnection (Fallon, 2014), which leads in its turn to a communication issue. Communication plays a major role in the leader/follower relationship and its absence has certainly serious consequences such as distrust and isolation (Fried, 2013) (Wiesenfeld, 2001).

Resistance to change: The pandemic had proven that only firms that are adaptable and open to change can survive (Miller et al., 1994) (Piderit, 2000) (De Dreu & Van de Vliert, 1997). In order to cope with changes, especially sudden ones, firms need their employees' collaboration (Porras & Robertson, 1992). Research showed that when employees resist to change, their company will be seriously damaged because of lack of satisfaction, productivity, and psychological well-being (Bordia et al., 2004) (Miller et al., 1994). Resistance to change could be detected on three levels (Piderit, 2000):

- Cognitive level where subordinates do not quite understand the nature of the change and negatively interpret it (Armenakis et al., 1993) (Stanley et al., 2005)
- Affective level where subordinates display feelings of anxiety and depression vis-à-vis change (Bordia et al., 2004)
- Behavioral level where subordinates express worry, strikes, or sabotage (Armenakis et al., 1993)

Altered organizational culture: Organizational culture is an intricate body of values, beliefs, practices, and behavioral norms which unite personnel in workplace (Alvesson, 2013) (Cao et al., 2015) (Schein, 2010). Organizational culture is clearly articulated in the physical workplace because its features are noticeable (Alvesson, 2013). A physical interaction enables managers to observe the behavior of their employees. Thus, they are able to interfere whenever a deviation occurs (Pinho et al., 2014). On the other hand, organizational culture in a distant atmosphere that lacks physical interface, is not clearly communicated, and there are no clear approaches of detecting remote work cultures (Anitha, 2014). The pandemic lockdown and the presence of technological communication means had obliged managers to consider new ways in raising their employees' engagement (Ross, 2016). Thus, there is growing need to enable leaders understand remote work context and embrace the changes since it is the only way to increase engagement and productivity (Anitha, 2014). A suggestion would be the adoption of "results-oriented work

environment policy" which allows remote employees to choose their work time and place as long as the results expected from them are achieved (Petrone, 2015) (Valcour, 2013).

Trust

In brief, a remote workplace prohibits managers to tangibly and frequently detect workers' performances. Thus, managers do not have enough information about subordinates' engagement. This naturally leads to a trust issue between both parties (Atwood, 2015) (Turmel, 2014). Trust, a major determinant of effectiveness (Nasomboon, 2014), is often absent in remote working relationships (Pangil & Moi, 2014).

Trust is defined as 'a psychological state comprising of the intention to accept vulnerability based upon positive expectations of the intentions or behavior of another' (Rousseau et al., 1998). The higher the level of organizational trust, the higher the level of teamwork (Coulter & Coulter, 2002) and the more successful and companies would be (Shockley et al., 2000). Trust in leaders is connected to constructive job attitudes, administrative fairness, and efficiency in terms of communication and organizational relationships (Dirks & Skarlicki, 2004). Distrust may occur when individual or business goals had not been met (Norris, 2009). Interpersonal trusting relationships push all involved parties to display positive energy and to express honest care (Lewis & Weigert, 1984), which improves organizational performance (Reilly, 2014), increases creativity and critical thinking (O'Brien, 2001), and push employees to work beyond expectations (Reina, & Reina, 1999).

Organizational trust, sustained on a daily basis (Petrovs, 2005), is composed of two elements: cognitive and affective (Dirks & Ferrin, 2002)

- Cognitive trust: Rational and calculative, it focuses on anticipated benefits from a business exchange relationship (Tyler, & Kramer, 1996)
- Affective trust: It is composed of personal bonds, respect for others, and care for their wellbeing (Lewis & Weigart,1985)

Companies are becoming more and more aware of the importance of establishing and sustaining trust between employers and employees, especially now that most of them are working from a distance. And who is in charge of establishing and sustaining this trustful climate? Naturally, effective leaders (Bennis, 2002) (DePree, 2002).

Effective Leadership

Leaders' effectiveness depends on their ability to influence others, referred to as "situational favorability" (Fiedler, 1967). In case leaders were unable to exert influence, remedy actions must be considered, from imposing leadership training sessions, to firing the leader, or changing the situation. Every situation requires a different effective leadership style. Consequently, leaders are labeled as effective when they have the ability to identify the style that should be used in every situation encountered.

To better understand leaders' effectiveness, it is important to observe how they behave on a daily basis. Since Consideration and Initiating Structure are the strongest leadership components (Blake & Mouton, 1985) (Stogdill, 1950) it is worth to mention them here.

Consideration, employee centered or a relations-oriented approach: It describes how leaders create effective job relationships through trusting subordinates, respecting them, and taking into consideration their emotions (Fleishman, 1953). Managers strive to create a good communication environment (Dutu, C. et al, 2015) (Popescu, A.L. et al, 2019). This style is further explained through five behaviors (Hemphill & Coons, 1957)

- Acting as a member: Manager establish informal relationships with employees
- Integrating: Managers create an agreeable climate and limit conflicts
- Communicating: Managers provide and take information from employees
- Recognizing: Managers approve or disapprove employees' behaviors
- Representing: Managers defend the group and work for its wellbeing

Initiating structure, a production centered or task oriented approach: It describes how leaders assign employees' roles (Fleishman & Peters, 1962). Managers provide instructions, coach, explain policies, set priorities and deadlines (Yukl et al., 1988). Their style is referred to as the "Tell and Sell" style, or the clarifying style. It is proved that it increases subordinates' performance more than the "do-your-best" instructions (Locke et al., 1982). This style is further explained through three behaviors (Hemphill & Coons, 1957)

- Initiating: Managers create and facilitate business practices
- Organizing: Managers describe each task and clarify the hierarchy
- Producing: Managers set goals and induce employees to increase their productivity

Transformational leadership augments employees' organizational commitment (Bono et al., 2003). Thus, it is unanimously regarded as effective (Judge & Piccolo, 2004).

Transformational Leadership

It is a process where both leaders and followers engage together to raise motivation toward goal achievement (Bass, 1985) (Burns, 1978). The social exchange theory clarifies the connection between transformational leadership and organizational commitment (Masterson et al., 2000). This theory suggests that the leader/follower relationship is based on a mutual exchange relationship, and that the psychological and emotional contentment received from the conduct of transformational leaders increases employee engagement (Castro et al., 2008). Transformational leaders create a strategic vision, and consistently communicate it by "walking the talk" (Avolio & Bass, 2002). This style comprises *four* types of behavior (Bass, 1990):

- *"Idealized Influence" – "Charisma"*: Generally speaking, subordinates usually trust charismatic leaders whom they take as role models. Those leaders influence them to work for the overall company's good, support them, and increase their self-confidence (Howel & Avolio, 1993)
- *"Inspirational Motivation"*: By optimistically picturing the future, leaders appeal others emotionally. They deliver attractive objectives, set high standards, and provide clear understanding about tasks. Subordinates will be more motivated to reach objectives, both on an individual and a team basis (Bass, 1985). Transformational leaders create a dynamic organization of vision that helps the company in coping with changes.
- *"Intellectual Stimulation"*: Leaders propose new and challenging tasks to subordinates, and ask them to be creative in their performance (Bass, 1985). Transformational leaders clearly explaining the situation to followers and encourage them to critically and creatively approach it. This stimulates subordinates' intelligence. They become more attentive to the importance of their tasks, thus more motivated toward accomplishing goals (Katz & Kahn, 1978). Leaders' style here could be referred to as supportive and participative (Porter et al. n.d.). As they support, empower subordinates, leaders produce a trusting environment (Gillespie & Mann, 2004)
- *"Individual Consideration"*: Leaders are careful about subordinates' differences. They treat them with respect and dignity raising by such their level of maturity. They develop subordinates through coaching and mentoring attitudes (Bass, 1985). This style emphasizes on subordinates' need and skills. It helps them to reach their own goals through achieving the organization goals, and inspires them to communicate and adapt to changes (Bass & Avolio, 1994). Subordinates would become more satisfied which will increase their commitment and their task performance (Yukl, 1998)

Furthermore, transformational leadership had been associated to empowering leadership (Spreitzer, 2008), which affects job satisfaction, commitment, and performance (Amundsen & Martinsen, 2015).

Empowerment

Empowerment is regarded as an employee psychological state and as a management practice (Conger & Kanungo, 1988). It is a power sharing approach (Hollander & Offermann, 1990) which increases one's perception of self-efficacy (Conger & Kanungo, 1988). From subordinates' viewpoint, empowerment is composed of (Thomas & Velthouse, 1990):

- Individuals' perceived value of their work
- Individuals' competence in performing the tasks
- Individuals' self-determination in initiating and regulating actions
- Individuals' impact on organizational outcomes

Due to lockdown, some businesses moved from a command and control leadership model to employee empowerment and accountability model. Empowerment had been connected with the following organizational practices (Blanchard et al., 1995) (Popescu, D. I., 2018):

- information sharing, which enables employees to fulfill their job requirements
- autonomy through boundaries, which requires organizational structures and practices that boost self-directed activities
- team accountability which suggests that teams possess decision-making authority and performance accountability

According to Jensen (2006), empowered employees feel that their work is meaningful, that they are competent, that they can influence their environment through their work, and that they have control in accomplishing their tasks.

The literature review detected some studies that relate transformational leadership as an effective form of leadership to organizational trust.

Research

This study was needed to clarify the leader's role in establishing engagement among remote employees. The selected approach to this study was a qualitative based on structured interview questions to ten employees in a pharmaceutical company. Survey participants were interviewed via zoom application using a questionnaire which contains questions about what they had endured during the lockdown with their respective managers. They were asked about the challenges they had faced during the lockdown referring to technological issues, work hours, relationship with leaders and with colleagues, motivation, organizational trust, team collaboration, and social distancing.

When asked whether they had the appropriate tools needed to carry out work from home, all of them answered that they laptops but the problem was with the weak internet connection which imposed serious challenges during video call meeting. Participants affirmed that, regardless of the internet connection, what was missing in the whole new situation was the assistance of the IT department. Several technological troubles occurred which necessitated experts know how. They had to deal with that by phone and this had put extra pressure on the whole matter.

They were also asked whether they had continued to work at the regular office time. Since they work with pharmacies, and this specific industry was subject to severe work pressure during the pandemic, the majority of the participants answered that they felt that the workload had augmented a lot, and they had to accomplish work within and after the regular working hours. This fact left them with anxiety especially that working from home proved to be a nonstop one that could last the whole day and night. What adds complexity to the matter was the presence of the whole family around: other members had to fulfill their own jobs also occupying special places at home, children who required home schooling, babies crying, not mention other factors that caused distraction and stress.

Participants were also questioned about the relationship between them and their direct managers and between them and colleagues. They affirmed that nothing replaces face to face collaboration, either with upper management or with colleagues. They clarified that the situation was also new for their managers who lack the knowhow of directing work from afar. Since this was new, several conflicts aroused, which took time to be resolved due to the absence of the body language cues, critical in conflict resolution. Managers, lost in this brand new situation, had put more effort than normal to manage the least details. This is particularly understandable: they have a goal in front of them and they want to achieve it and report to the higher management as well. In order to do that, they moved to traditional management techniques, by closely detecting every details, not taking into consideration the appropriate time or manner to do so. This had left employees with feeling of anxiety vis a vis this new micromanagement way. They started to feel as if they are constantly inspected, they started to show regret if they take a break to catch their breath or simply to occupy themselves at home with their families. The sight of the cellular phones and laptops had become by itself a source of stress. Especially that no one is allowed to go outside, and managers assume that all employees are at home, which meant to him/her that they are ready to work or to start a video call at any time.

Some participants had even reported that their respective managers used to call them just to make sure they are working. Unfortunately, trust was lost, and so did engagement and motivation. The uncertain nature of the new disease, the tough economic conditions, the shortage of money, most of companies 'inability to pay salaries, all of these are factors that contributed further in lessening the degree of trust between employees and their institutions. Furthermore, as they had been required to constantly be present remotely, employees had even showed negative feelings toward their own families at home materialized by keeping them away. This maximized the feeling of isolation in this tough period where what was needed the most was comfort and relax.

As for the employee-employee relationship, participants showed understanding toward their colleagues because they were all in the same situation together. Surprisingly, some participants raised a matter of confidence toward their colleagues. As they were all living a period of stress, their behavior changed negatively, becoming more and more aggressive, rude, and leaned to decrease their task by charging it to another one. All of this contributed in loosing trust in one another.

As the lockdown period was postponed, managers and colleagues started to normalize the situation. Most participants agreed that the behavior of their respective managers started to change to the better after one month of the lockdown. They affirm that this is certainly due to two factors: fist, they had understood that the lockdown may last a long time and thus, their micro managing ways were causing stress upon them and upon their subordinates. Consequently, they shifted their managing techniques to a friendlier one, providing them with frequent and accurate feedback, respecting their family time and house occupation. It is at this period of time, that both parties felt relieved and started to get used to work remotely with a higher degree of satisfaction. According to one participant, it was his manager's shift to an acceptable positive behavior that had led him to feel more engaged toward his company. As managers' techniques took a delegation way, colleagues felt much better vis a vis their management and their colleagues. It is only then that they had noticed the privileges from working from home: they do not have to commute each day to start working, they do not have to wear their finest clothes to attend meetings, they started to plan their daily tasks and arranged them in a way that does not put much contradiction with their family.

Results

The interviews resulted in identifying three employees' worries:

To begin with, they showed concerns related to trusting the firm. Naturally, trust was highly questionable during this period because of the nature of the global uncertainty imposed by the spread of covid-19. What mattered in this research was how trust in leaders was perceived among remote employees. It was found out that they were worried about many things:

- The ability to efficiently perform tasks on time from home with no direct assistance: according to the interviewed samples
- The possibility that their efforts and sacrifices, doubled and tripled during this lockdown, will not be recognized fairly in terms of salary and promotion
- The possibility that, due to downsizing and the overall bad economic situation, they will be released from work

The second apprehension was related to the efficiency of the department collaboration, whether it continues to be successful or not especially where all features of body language techniques had suddenly disappeared.

Finally, it was observed that employees were concerned that the rush they had been living through will keep them socially isolated for a longer period of time. They suddenly moved from an environment full of people walking around to an aloof, isolated one.

Those tensions, very high at the start of the lockdown, were gradually decreased as time passed by, especially that respective managers did all what it takes to instill a trustful and collaborative climate. Isolation was the least concern to be reduced, since it was not practical in the meantime to socialize.

Conclusion

Virtual work environment had suddenly become the new normal working environment made possible because of technological means and made urgent because of the lockdown. One might think that leaders are no longer in need since everyone knows his/her task, what is expected from him/her, and does not have to waste time in socializing. However, it is a rather silly thought: leaders are needed now more than ever. Their efficient presence is the element that leads organizations to survive. Of course when we talk about efficient leaders, we automatically think of transformational ones who know how to engage employees to organizational goals taking into consideration the situation imposed. Some leaders may have the intention to do so, but may lack the know-how. Consequently, training sessions are a must to acquire new techniques such as reengineering management which enables them to efficiently reorganize their teams. This highlights independence and empowerment which fights two types of apprehension raised above, namely trust and collaboration concerns. Although employee empowerment is stimulated, it is being criticized due to the extra work employees will be doing. As a result, companies should always make sure that empowering their employees is for the sake of both organizations and staff and should not be taken as an excuse for workload (Ongori & Shunda, 2008).

Recommendations

As Covid-19 continues its flight around the globe, organizations are becoming more aware of the importance of leaders' role in engaging employees to the overall goals through building a climate of trust. Leaders are not born with special techniques triggered whenever one calls for them. This is why, it is important to raise the question of continuously training managers and providing them with adequate techniques that enable them to efficiently handle the situation on hand.

Actions should start at the highest level possible: leaders cannot instill a climate of trust if they are not being trusted from their upper management. Change must be created at the top and streamed to the bottom. In addition, top management should make sure that remote workers have the necessary equipment and tools that allow them to operate remotely. Leaders should be well aware that the new remote culture, despite its benefits from overhead cost cutting, is an invasion to employees' home privacy. Ideally, homes are related to relax, however nowadays, everyone, including children, are home which does not present the best work environment.

Furthermore, managers must understand that their important presence should be distinguished from micromanagement. Micro management helps in eliminating trust, which, once gone, is very hard to build again. Empowering personnel proves to be the best option to keep them engaged: providing employees with autonomy increases their motivation. However, autonomy should not be confounded with the complete absence of the leader. On the contrary, regular communication to provide information, guidance, and support are very important and should remain. One important technique is to train managers in how to manage by results, which highlights the concept of job autonomy. Granting employees the freedom to select when and how to work is important. Equally important is how to assess them. Instead of checking up on them, managers should emphasize on the work outputs rather than work inputs. This is specifically translated in the Results Only Work Environment technique which gives trusts employees to exercise judgment in solving problems; boosts their creativity, and allows them to work freely as long as the end results are met.

Limitations

This article relied heavily on literature taking into consideration a small qualitative case study. This naturally carries many limitations.

First, the sample of the study was small, composed of employees working at the same business firm. Despite the overall observation that the majority of remote employees were all living the same struggle during the lockdown, one cannot over generalize the conclusions. This is why, it is better to increase the sample population in a future research so that results would be more comprehensive and more accurate.

Second, in the same talking, the interviewed remote employees were all selected from one single company that belongs to one single industry sector. This imposes again a generalization concern. For

better results, future research may scrutinize the concepts dealt with here by comparing several industry sectors.

Third, the organizational behavior concepts raised in this research were, like all the other concepts, subjective. One cannot forget the awful stress period everyone had been living through, and perhaps some of the answers were not grasped as accurate. A future study that links employees' feelings toward remote working to quantifiable organizational performance variables would be very useful.

Abstract

The food system should align to the principles of sustainable development by making the food more available, qualitative and locally made, with the least possible negative effects on the environment and the health of both humans and biodiversity. The main purpose of this investigation is to overview the trends of the Romanian cheese market between 2015 and 2019, while discussing it in terms of sustainability and by comparing the indicators internationally. A secondary data analysis was conducted based on several market indicator, like production, price, consumption, expenses and trade, collected from the Romanian Institute of Statistics, Eurostat and International Trade Centre. Some of the results indicate the need of developing the cheese market towards sustainability by promoting local consumption and production.

Keywords: cheese, consumption, production, sustainable development.

Introduction

The model of sustainable development aims to consider all aspects of society and environment in developing all economic activities, including the food sector. It is not enough to ensure food security and safety, but also the sustainability of the food system, of which cheese market is a part. Some of the most recent research focus on technological and biological improvements of cheese production (Mindru et al., 2018; Rusu et al., 2016), better waste management from cheese-related activities (Pal & Nayak, 2016), reducing the environmental impact of cheese production (Tarighaleslami et al., 2020), and different analyses on local cheese (Marcoz et al., 2016; Wilkinson et al., 2017).

The aim of this research is to explore the trends of the Romanian cheese market by investigating secondary data from the Romanian Institute of Statistics, International Trade Centre and Eurostat. The indicators were also discussed in relation with the principles of sustainable development.

The paper is structured as follows. The next section presents the evolution of the scientific literature on the cheese topic from Scopus, Web of Science and Google Scholar, by conducting a systematic analysis with the help of the bibliometric technique. Then, the section on results and discussion illustrates the trends of the main statistical indicators of Romanian cheese market between 2015 and 2019. The paper ends with concluding remarks, acknowledgement and references.

Literature Review

The first search about cheese on two scientific databases, namely Web of Science and Scopus, generated 31485, and 33155 publications in September 23, 2020. When the search criterion was narrowed down to indicate the literature from 2015 and forward, 8498 publications were found published by Scopus (Elsevier, 2020) and 9127 documents were identified on Web of Science (Clarivate, 2020).

Cite this Article as: Gabriel POPESCU, Nicolae ISTUDOR and Alina ZAHARIA "Trends of the Romanian Cheese Market" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The Scopus (Elsevier, 2020) publications on cheese have increased by 14.89% in 2019 compared to 2015. Out of the 8498 Scopus papers on cheese, 34.44% are open access and more than 95% were written in English. Also, 90% were published in a journal and 82% were research articles. With more than 95% of the Scopus studies on cheese, their most frequent areas of interest are: agriculture and biological sciences (57.64% of papers) biochemistry, genetics and molecular biology (20.88% of papers), and medicine (17.02% of papers). The first three authors with the most numerous publications on cheese are Brittante, G., Cipolat-Gotet, C. and Cruz, A.G., with more than 38 papers each, while the highest citations were registered by Mozaffarian, D., Marco M.L. et al. and Galus, S. & Kadzińska, J., with more than 187 citations in September 2020. Only 4% of the Scopus papers are in the field of economics and business, the most cited ones focusing mostly on topics connected to the environmental impact and the effects of environmental taxes on cheese-related activities (Palmieri et al., 2017; Säll & Gren, 2015), the added value and the consumer's willingness to pay for the protected designation of origin and the protected geographical indication (Marcoz et al., 2016; de-Magistris & Gracia, 2016), the waste management and waste reduction from cheese-related activities (Pal & Nayak, 2016; Eriksson et al., 2016), the technological improvements of cheese production (Gharibzahedi et al., 2018), the tourism development around cheese products (Fusté Forné, 2015), and others. The most recent results from the Scopus database indicate the possibility of reducing the environmental impact of cheese production by using renewable energy (Tarighaleslami et al., 2020), and a new system model for cheese factories based on automation technologies (Matsumoto et al., 2020). Further, three papers about cheese and Romania were found on Scopus since 2015, which investigated the technological process and the composition of ecological cheese (Mindru et al., 2018), the environmental pollution level by dairy wastewater from cheese and butter production (Tița et al., 2017), and the presence of E.coli in the unpasteurized cheeses marketed in Romania (Tabaran et al., 2017).

The Web of Science (Clarivate, 2020) publications on cheese have increased by 23.02% in 2019 compared to 2015. Out of the 9127 Web of Science papers on cheese, 40.78% are open access, 88.48% were research articles and, similar to Scopus studies, more than 95% were written in English. With more than 76.47% of the Web of Science studies on cheese, their most frequent areas of interest are: food science technology (49.14% of papers) agriculture (16.59% of papers), and chemistry (10.74% of papers). The first three authors with the most numerous publications on cheese are Brittante, G., Cruz, A.G., and Esmerino E.A. and Freitas M.Q. with more than 47 papers each, while the highest paper citations were registered by Thirumdas, R. et al., Clune, S. et al., and Gijsbers, L. et al., with more than 149 citations in September 2020. Only 1.37% of the Web of Science papers are in the field of economics and business, the most cited ones focusing on topics connected to the effects of environmental taxes on cheese-related activities (Säll & Gren, 2015), consumer behavior of children of cheese balls placement in movies (Matthes & Naderer, 2015), the drivers for the development of geographical indication of artisan cheese (Wilkinson et al., 2017), the influence of local products and their origin, like cheese, on the attractiveness of tourism destinations (Alderighi et al., 2016), the differences between food policies requirements of artisan cheese and the consumer preferences (Waldman et al., 2015). The most recent results from the Web of Science publications indicate negative influence of several firm-level factors, like cash conversion cycle, on the profitability of cheese companies (Fernández-López et al., 2020), the shift of the increase in public taxes from producers to consumers (Lyssiotou & Savva, 2020), the significant negative impact of fraud on fragile food like cheese (Rocchi et al., 2020), no impact of cheese market liberalization on prices if high-quality is the focus (Hillen & von Cramon-Taubadel, 2019). In addition, seven papers about cheese and Romania were found on Web of Science since 2015. For example, Rusu et al. (2016) found pesticide residues in milk and dairy products, inclusively cheese, in all samples analyzed, emphasizing thus the human health risks generated by their consumption. Also, Tabaran et al. (2017) revealed high prevalence of E.coli in the unpasteurized cheeses marketed in Romania.

Methodological Framework

This study paper investigates the Romanian cheese market during time, in terms of cheese production, price, consumption, expenses and trade. The secondary data analysis is focused on the 2015-2019-time frame because of comparability reasons, as the investigated statistical organizations made changes in the methodology of primary data collection and processing of some indicators before 2015 determining an impossibility of comparison with previous yearly information. More, the average annual consumer price indices were determined by making an average of the monthly consumer price index from the Romanian Institute of Statistics.

Results and Discussion

The Romanian cheese production increased steadily each year in the analyzed time frame, with a total growth of 17.13% from 2015 to 2018, at 95082 tons of cheese in 2018, according to NIS (2020). Since 2007, when Romania entered in the European Union as a member country, the cheese production increase has been of 20.46% in 2018, while, from 2001 to 2018, it has registered a spike of 164.95%. Also, Romania was placed on 16th position of the 28 EU member states in terms of cheese production in 2019, while being placed on 17th place in 2015 (Eurostat, 2020a). However, Romania registered the fifth highest increase of cheese production at EU28 level between 2015 and 2018. Thus, it could be observed that Romania recorded significantly higher cheese productions in the years before entering in EU compared with the ones after 2007. A cause of this situation could have been generated by the necessity of compliance of Romanian producers to the EU regulations and the increased market competition due to the free trade rules.

Surprisingly, the number of active enterprises in the field of manufacturing cheese and other milk products registered a 4.57% decreasing trend between 2015 and 2018, from 416 to 397, although the total number of Romanian enterprises increased by 12.20% in the analyzed time frame. If 2018 data was compared to 2002, the first year with statistical availability for this indicator, the decreasing trend was of 45%, although the total number of Romanian enterprises rose by 51% during the same period of time. However, by reporting the 2018 data to 2015, it was observed that the number of employees has barely grown by 0.13%, while the annual industrial production prices and the turnover of manufacturing cheese and other milk products have significantly increased by 16% and 48%. When comparing the number of enterprises at EU level, Romania was placed on fifth in terms of the highest number of producers, after Italy, Spain, Greece and France, indicating a high interest of Romanian producers in producing cheese (Eurostat, 2020b).

In terms of Romanian cheese consumption, the Romanian Institute of Statistics reports data on the following categories of cheese: cheese and cream, cow cheese (cottage cheese), sheep cheese, fresh acid curd (cow) cheese, pressed (yellow) cheese and other milk products. Figure 1 illustrates the structure and evolution of annual cheese consumption, by type, based on the average monthly consumption from NSI (2020) data during 2015-2019.

Fig. 1: The annual average cheese consumption per person in Romania between 2015 and 2019
Data source: NSI (2020)

The Romanian average consumption of cheese and cream per capita registered increases by 19.61% in 2018 and by 20% in 2019 when compared to 2015. However, in real terms, this indicator increased by 3 kg/person from 2015 to both 2018 and 2019. Specifically, the Romanian average consumption of cow cheese (cottage cheese) per capita registered small increases by 3.40% in 2018 and by 1.36% in 2019 when compared to 2015. In real terms, this indicator increased only by 0.18 kg/person, respectively 0.07 kg/person, from 2015 to 2018, respectively 2019. Also, the Romanian average consumption of sheep cheese per capita registered increases by 14.85% in 2018 and by 13.97% in 2019 when compared to 2015. However, in real terms, this indicator increased only by 0.18 kg/person, respectively 0.40 kg/person, respectively 0.38 kg/person, from 2015 to 2018, respectively 2019. Next, the Romanian average consumption of fresh acid curd cheese (cow) per capita registered increases by 13.28% in 2018 and by 15.50% in

2019 when compared to 2015. In real terms, this indicator increased very little, by 0.43 kg/person, respectively 0.5 kg/person, from 2015 to 2018, respectively 2019. Further, the Romanian average consumption of yellow cheese per capita registered significant increases by 26.32% in 2018 and by 33.33% in 2019 when compared to 2015. However, in real terms, this indicator increased by 0.36 kg/person, respectively 0.45 kg/person from 2015 to 2018, respectively 2019.

So, the cheese products consumption registered an increase trend in the period between 2015 and 2019, which could be determined by changes in consumption preferences and increases of incomes, as suggested by Dobra & Sandru (2016). The analysis also revealed that the cheese consumption per person has not necessarily changed due to the quality of being part of the EU membership. However, it seems like Romanians have increased preferences of yellow cheese, which registered the highest yearly rises compared to cow and sheep cheese. Moreover, when comparing the trends of cheese production and consumption, it can be observed that they are similar in evolution, the total cheese and cream consumption representing around 3.7% of cheese production in the analyzed time frame.

Further, the average annual consumer price indices of cheese products, which indicate the overall evolution of prices, have increased by 8.01% in 2019 compared to 2015 (NSI, 2020). However, it diminished by 0.28% in 2018 compared to 2015. These trends were registered by both cow cheese and sheep cheese. Also, this indicator registered a lower growth compared to the consumer price index for food goods, but a higher increase compared to all Romanian goods. Also, when considering the harmonized index of consumer prices for cheese and curd from Eurostat (2020c), Romania positioned on ninth place of the 28 EU member states in 2019 in terms of the price increase, namely of 2.2, the first two being for Portugal and Lithuania.

The average price of cow cheese was 14.8 lei/kg in 2015, i.e. around 3.3 euro/kg, and 17.1 lei/kg in 2019, i.e. around 3.6 euro/kg (NSI, 2020). Also, the average price of sheep cheese was 19.4 lei/kg in 2015, i.e. around 4.3 euro/kg, and 22.4 lei/kg in 2019, i.e. around 4.7 euro/kg (NSI, 2020).

Additionally, figure 2 illustrate the comparison between the average monthly income and the cheese expenses, showing that the trends have increased since 2015 based on, among others, price increases.

Fig. 2: The cheese expenses and the population's income in Romania between 2015 and 2019
Data source: NSI (2020)

Moreover, the share of agri-food expenses in the monthly average income of Romanian population has decreased from 22.5% in 2015 to 16.1% in 2019, meaning that the income has increased more than the agri-food expenses during time. As the food is a basic need, these previous analyzed indicators show that the Romanian have increased their accessibility to basic goods, going towards achieving economic and social sustainability. In terms of the share

of cheese and cream expenses in the total monthly average income of Romanian population, table 1 shows that it has decreased by 0.26% between 2015 and 2019, from 1.45% in 2015 to 1.19% in 2019. Considering the study of Guga et al. (2018) and the average consumption determined between an adult male and female, 0.77 kg of sheep cheese, 0.58 kg of cow cheese, 0.41 kg of yellow cheese, and 0.25 kg of cream should be a minimum monthly consumption by an adult for a decent living, meaning a minimum total of 2.01 kg cheese and cream. Based on these, the monthly cheese and cream consumption is under this minimum with approximately 0.5 kg in 2018.

Table 1: The share of cheese expenses in the monthly average income of Romanian population, by type

Type of product	Share of cheese expenses in the income	2015	2016	2017	2018	2019
Cheese and cream	total income	1.45%	1.39%	1.39%	1.26%	1.19%
	monetary income	1.65%	1.55%	1.54%	1.37%	1.28%
Cow cheese (cottage cheese)	total income	0.48%	0.43%	0.41%	0.36%	NA
	monetary income	0.54%	0.48%	0.45%	0.39%	NA
Sheep cheese	total income	0.30%	0.28%	0.27%	0.26%	NA
	monetary income	0.34%	0.31%	0.30%	0.28%	NA
Fresh acid curd cheese	total income	0.21%	0.20%	0.20%	0.18%	NA
	monetary income	0.24%	0.23%	0.22%	0.20%	NA
Other milk products	total income	0.14%	0.15%	0.20%	0.18%	NA
	monetary income	0.16%	0.17%	0.22%	0.19%	NA
Yellow cheese	total income	0.28%	0.27%	0.27%	0.24%	NA
	monetary income	0.32%	0.30%	0.30%	0.26%	NA

Note: NA means that the data is not available.

The Romanian cheese trade indicates a significant negative balance in 2019, being ranked on 23rd position in cheese imports and on 39th in exports worldwide (ITC, 2020). The first three country importers of cheese products from Romania are Greece, Italy and United Kingdom, while the first three country exporters are Germany, Poland and Italy (ITC, 2020). Both total value of cheese exports and imports have increased in 2019 compared to 2015, but the imports grew more than the exports, by 21.9% instead of 14.5% (Eurostat, 2020d). In terms of quantity, the growth of cheese imports and exports was higher, by 76.3% and 78.09% for the cheese imports in 2018 and 2019 reported to 2015, as well as by 45.9% and 41.2% for the cheese exports in 2018 and 2019 reported to 2015. It seems like the exported quantity has slightly decreased since 2018. However, imported cheese quantity rose significantly more than the Romanian production with approximately 20% yearly average increase compared to 5% of yearly average rise. When considering the sustainability principles, which considers also ensuring food security from local production, it seems like the cheese market is not quite sustainable, as the share of imported cheese in total Romanian production has reached 91% in 2018 compared to 60% in 2015.

Conclusion

The main focus of this paper was to present the trends of the Romanian cheese market between mainly 2015 and 2019. The findings suggest that the cheese market in Romania is growing, as the trends of production, consumption, and exports registered increases between 2015 and 2019. However, it could be observed that the number of active enterprises in the field of manufacturing cheese and other milk products has decreased in the analyzed time frame, indicating a higher performance of these companies on the market. Also, the cheese imports increased significantly more than the local production, which indicate the need of taking measures for improving the sustainability of the cheese sector. One measure could focus on promoting the local production and consumption of cheese products.

Future endeavors could focus on determining the current Romanian's behavior in terms of purchasing and consuming cheese and, also, new market opportunities for sustainable development. Also, future studies should focus on investigating the effect of the COVID-19 pandemic on cheese market.

Abstract

With the advent of AI, businesses get deeper real-time insights into what customers want and based on these insights, businesses can create a personalised experience for every individual customer. The online marketing media adopting AI applications has influenced the customers buying behavior and is essential in understanding AI acceptance by online customers. The currents research is developed to fill this gap. The paper endeavours to specialize the influence of Artificial Intelligence in extended TAM on digital marketing and online customer experience. The paper further attempts to identify the essential effect of factors of artificial intelligence in future purchase intention of the online shoppers. Data for the research were collected through both interview and survey from 175 online shoppers; an online questionnaire is used to collect data from the millennial. The research findings posited that Indian millennial depend more on online media for their purchases. The Technology Acceptance Model enhances to analyse Artificial Intelligence (AI) and its impact on consumer behavior in online marketing. Interviews focus on the consumers who depend more on online media platforms in their day to day life for the review of the products they purchase. The study is helpful for online retailers and web designers by recommending them to know the pulse of consumers, these create a potential to encourage consumers to buy more online. A comprehensive literature review highlights a close understanding of Artificial Intelligence and therefore portrays the importance of Artificial Intelligence in online marketing. The findings indicated the variables have significantly influenced consumer behavioral intent unlike the existing studies which remained unsuccessful in clubbing all the factors into one study, this has initiated the consumer behavior with effect from artificial intelligence.

Keywords: Artificial Intelligence, Consumer Buying Behavior, Perceived Ease of Use, Perceived Usefulness, Online Marketing, TAM, Trust.

Introduction

The e-commerce sector has seen a boom within the Asian region in recent years. India, the southern state, had the fastest growing online retailer market in 2019. According to Statista Research Department, today's business world is ruled by consumers, it's necessary for any marketers to interact between business and consumers. It's estimated that there'll be 1.92 billion global digital buyers in 2019, e-commerce retail sales are expected to account for 13.7% of world retail sales in 2019(Stalidis, Karapistolis and Vafeiadis, 2015). Advertising comes as an aid in influencing and communicating the business idea prevalent within the market to the consumers(Chukwu, Kanu and Ezeabogu, 2019).Within the era of Digital Marketing, the standard way of advertising is replaced by another popular tool. Within the next few years, we are getting ready to witness the planet we sleep in entirely disrupted by improvements in artificial intelligence. Artificial Intelligence will likewise keep it up changing how organizations promote. Truth be told, these Digital Advertising methodologies would be incomprehensible without a straightforward variety of Artificial Intelligence(Sajjad, 2016). These frameworks work autonomous, setting the right types of advertisements before the right types of individuals at the right time keen about complex calculations and large data. This is often what's called "programmatic advertising." Not excessively sometime within the past, promotion advancement was, for the foremost part, an innovative undertaking. Today, it's everything about that specialize in and conveying the right message. Consumers and business to business (B2B) purchasers are overpowered day by day with

Cite this Article as: Jisha VIJAY and Indu MANISH KUMAR "Using an Extended Technology Acceptance Model to Explore Digital Marketing and Consumer Buying Behavior" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

promotions(Bilal Ahmad *et al.*, 2019). The overwhelming majority of them are superfluous so that they just close the advertisement or proceed onward to their next assignment(Qaisar, Sial and Rathour, 2018). At the purpose when this happens, publicists lose cash. With Artificial Intelligence, social media can streamline their arrival on speculation by just putting advertisements before pertinent watchers(Purcărea, 2017). Promotions are often purchased consequently(Mihić and Kursan, 2010), at that time customized at scale. Numerous promoters are as of now utilizing this innovation(Karbasivar and Yarahmadi, 2011; Dumitriu and Popescu, 2020). Artificial Intelligence makes it possible for e-commerce retailers and web designers to analyse scores of interactions a day and ultimately target offers all the way down to one customer – an experience every marketer dream of providing(Purcărea, 2017). Sales teams are now empowered with information we've never seen before(Qaisar, Sial and Rathour, 2018). The marketers personalise the sales cycle through Artificial Intelligence-driven applications that are helping sellers to interact with the proper prospects with the proper message at the proper time.

The study aims (1) to study the role of Artificial Intelligence in advertising on consumer's intention to online purchases, (2) to validate the factors of Artificial intelligence in buying decision, (3) to develop a model depicting the acceptance of Artificial Intelligence and Consumer buying behavior. Given the wide-running subject of artificial intelligence and its numerous applications, the researcher constrained the extent of this paper to just its effect on the customer's buy choice. The subject of artificial intelligence in promoting itself could likewise be sufficiently immense to legitimize narrowing the extent of exploration down further into explicit applications and use cases. Notwithstanding, the expectations for this paper were to deal with the issue in a way that has a characteristic passage point for buyers to begin understanding about artificial intelligence while giving enough detail to each application and use case to gracefully novel bits of knowledge. The geographical scope of the study limits to the state of Kerala, India. The information collected from online shoppers during the period of January 2020 – August 2020.This paper has importance because for an advertiser, organizing the utilization of different media stages for publicizing is ending up being a problem. Today, the promoting cost of each medium is unfathomably high, and any unseemly media techniques are frequently an exorbitant choice. Promotions are visiting despite everything become more brilliant and increasingly inserted in our day by day lives. Publicizing heads need to understand media sees and their impact on the consumer buying decision. Inside the current examination, the researcher attempts to explore distinctive publicizing media impacting consumer behavior and providing a better shopping environment to the target group. This assessment is of most extraordinary significance to the current situation of the advertisement publicizing, as this may give basic encounters concerning changing among modernized media.

Research Problem

The Technology Acceptance Model regarding Artificial Intelligence on consumer behavior raises questions which the study describes below:

1) How does Artificial Intelligence in online marketing perform to influence consumer's intention to buy online? The model analyses the behavior of consumer for purchase intention, when the new method is implemented assessment is made whether it had a positive impact on consumer future buying behavior.
2) How well do the factors of Artificial Intelligence influence the buying decision? The model will analyse the significant factors which influence the behavioral intention of users, explaining which factor is of great value in their purchase decision.
3) Is there any model that can better depict the relationship of Artificial Intelligence on online consumer behavior? The focus of the study is less that to prove or disprove the Technology Acceptance Model, than in using to identify Artificial Intelligence on consumer behavior. Also, the relatable factors that best accounts the model should be brought together.

Literature Review

Technology Acceptance Model

Technology Acceptance Model, introduced by Fred Davis (1986), is an adaptation of Theory of Reasoned Action unequivocally custom fitted for showing client affirmation of data framework. The goal of Technology Acceptance Model (TAM) is to give an explanation of the determinants of general PC acceptance, prepared for explaining user conduct over a sweeping extent of end-client PC innovation. In an ideal world, one may need a model that is valuable for desire just as for explanation, with the objective that pros and specialists can recognize. The purpose of this study to analyse the factors of technology acceptance model and trust on future purchase intention of online shoppers with effect from the application of artificial intelligence investigated perceived ease of use, and perceived usefulness

creating trust in the minds of shoppers and thereby having an effect on the attitudes, actual behavior and future intention of shoppers. The study supports the effect of artificial intelligence among consumers' in buying online because statistics recommend the model fits the data absolutely. H1: The study found the relationship between perceived ease of use and perceived usefulness in online shopping; this is similar to that of the existing study. The consumer easiness in accessing the online platforms while shopping is likely to let him or her in the usefulness of the online platform. H2: As stated, Perceived ease of use will have a significant impact on customer trust to online shopping(Bertea, 2016), the consumer's easiness inaccessibility creates a trust in the minds of the consumers, they are intended to shop more due to the sense of trust developed in their minds, the study shows the association between ease of use and trust in the minds of consumers. H3: the results shows, perceived usefulness will have a significant positive impact on customer trust to shop online, the study demonstrated the impact of usefulness in generating trust among shoppers, perhaps similar studies on trust and consumer buying decision have studied so far, the findings of the present study analyse the role of TAM factors, perceived ease of use and perceived usefulness in building trust among consumers. H4: Trust will have a significant impact on customer attitudes concerning shopping online(Wu, Chen and Chiu, 2016), studies have associated the importance of consumer trust in shopping, however, the present study relates to the two factors of TAM in developing trust among online shoppers. H5: mentioned in the review of literature perceived usefulness have an impact on attitudes concerning shopping. H6: Perceived usefulness has an impact on attitudes in using artificial intelligence among online shopping. H7: Attitude will have a significant impact on customer actual behavior concerning shopping online(Sinha and Kim, 2012; Zuroni and Goh, 2012; Akbarm *et al.*, 2015). H8: Actual behavior will have a positive impact on customer future intention to shop online(Sharma, Sivakumaran and Marshall, 2010). The present study depicts the fact that artificial intelligence in the current context has leveraged online consumers in shopping more, with their technological aspects. Marketers are starting at now prepared to envision what sorts of ads really influence your purchasing conduct. Promotions are going to continue ending up being more astute and logically introduced in our regular day to day existences in view of Artificial Intelligence. Gradually, these Artificial Intelligence calculations can get acquainted with your conduct, and before you know it, they understand you better than you know yourself. For sure, even today, the impact Artificial Intelligence is having on our overall population can't be ignored. Be that if the customers know about AI or not, computerized reasoning has changed the way how both the purchasers and advertisers think, act and settle on choices in the market. In the future, AI can make the showcasing life simpler, for both the customers and advertisers that gives motivation and invigorates the dynamic quicker than others, its why a particular structure may be inadmissible and look for after reasonable therapeutic advances. A key purpose behind the Technology Acceptance Model is to give a reason to follow the impact of outer components on inner convictions, perspectives, and desires. TAM plans to attempt to achieve these goals by perceiving not many key elements suggested by past exploration dealing with the mental and practical determinants of PC acceptance, and using Theory of Reasoned Action for exhibiting the theoretical associations among these variables. A couple of changes in accordance with the principal TRA approach, maintained by open speculation and verification, while considering these destinations for TAM. TAM sets that two explicit feelings, perceived usefulness and perceived ease of use, Perceived usefulness (U) portrays as the anticipated client's enthusiastic probability that using a specific application framework will extend their movement execution inside a legitimate setting(Scherer, Siddiq and Tondeur, 2019).Perceived ease of use (EOU) suggests how much the inevitable client desire that the target structure ought to free from the exertion. All things considered; history shows that individuals who have purchased from your association before are well on the way to buy more than once on the off chance that they are content with the general excursion.

Artificial Intelligence Applications

Alan Turing was the one who coined about artificial Intelligence in an exceeding proposal and over the years it faced many changes in every field and this study explores Artificial Intelligence within the web marketing platform. Artificial Intelligence retains the flexibility to analyse vast tracts of information, which incorporates human behavior(Campbell *et al.*, 2020).Unless you want to look at it from the point of view of the consumer, the advent of the digital age, and now Artificial Intelligence, has changed the environment for the consumer vis-a-vis offering prices and products. All that a customer should do to press for the highest effective price or the highest efficient product in excess of the price range is to use his mobile IP system and the search the full marketplace for what they require(Akram *et al.*, 2018).The introduction of Artificial Intelligence now affects almost every stage of a customer journey(Hoanca, Marinchak and Forrest, 2019; Campbell *et al.*, 2020). The good customer service never ends at a sale; it continues way beyond that. The use of Artificial Intelligence in the buyer's journey, for now, could even be in an early stage, with some brands testing the water by introducing chat-bots(Koch, 2018).But experts believe the day isn't far away when Artificial Intelligence will affect every stage of the customer journey from marketing messages, ads, product design and shipping. Virtual shopping assistants or recommendation engines that help

consumers find a product from catalogues is another area where engineering helps(Chin, Water and Swatman, 2005; Chastel *et al.*, 2019; Hoanca, Marinchak and Forrest, 2019).

1. Programmatic Advertising

Each advertiser knows that it is a reality –consumers are drawn to meetings, which slowly makes them faithful to a brand. Due to the mechanical framework strategy for assembling goods for the general population within the disconnected environment, very little personalization could be anticipated as reasonably expected. However, this changed with the advent of digitization(Dannenberg *et al.*, 2020).Data that included individual customers analyse to create a propelling experience to step back to the e-store in them. Now, with the help of AI inside the picture, and its ability to analyse enormous lumps of data at high speeds, personalization of things has taken on a whole new sense(Schipmann, 2019). With the assistance of Artificial Intelligence now an advertiser can break down client assessments across different social media platforms, and coordinate client profiles to their social encounters in regard to a specific item. It can see what a customer's style is and adjust item proposals progressively, while the client shops(Scherer, Siddiq and Tondeur, 2019). Such software engineering created yield is then being utilized by certain retailers to deliver items which may interest a private client's taste. Artificial intelligence, at each phase of a client venture, will offer increases to a retailer moreover as its clients.

2. Visual Search Optimization

All things considered, quite a bit of shopping can be a visual encounter. Visual search anticipates to need the user experience to the accompanying level. Brands will transfer pictures of items in their stock, each with their one of a kind code(Verhagen and Van Dolen, 2011) .When customer transfers a picture of an item they like, in their online inquiry, Artificial Intelligence-based programming will assess it and consider viewpoints like brand, and shading, etc. This should be possible by dissecting the pixels inside the picture. It'll at that point surface proposals on elective brands or items, tired ongoing(Xu and Huang, 2014).On the other hand, Artificial Intelligence-based programming prepares to give proposals of items upheld a customer's history, different preferences. Experts anticipate that after the visual search completely swung, instances of deserting of shopping baskets will diminish essentially. Utilizing AI, brands can look over petabytes of data to foresee consumer conduct, and gives visual suggestions to singular customers(Schipmann, 2019).Going ahead, organizations are visiting be prepared to consolidate designing and visual abilities to create systematic models to spot even smaller-scale patterns and buyer personal conduct standards, so make shrewd suggestions.

3. Virtual Personal Shopper

Artificial Intelligence-driven remote helpers can influence be exceptionally compelling proposal frameworks. Virtual private shopping assistants (VPSAs) made possible by recent advances in artificial intelligence (AI) are expected to help users find the best deals online, possibly also acting on behalf of the user after gaining the user's trust(Chin, Water and Swatman, 2005; Hoanca, Marinchak and Forrest, 2019). To achieve such functionality in enhancing the user experience, VPSAs will have to collect and manage highly personal data about the users. There's little uncertainty that they keep up the possibility to rebuild the retail business, and in the end, help drive deals. Where time is cash, purchasers will discover utilizing an individual shopping aide, so to talk, powerful. Virtual shopping models offer an altogether new point of view for e-commerce on the Internet as they give a solid feeling of reality by significant collaboration which permits the model of an item that tries. This is because every single digital model looks like their physical partners as intently as conceivable with visual three-dimensional pictures, behavioral, haptic and sound-related qualities.

4. Product Recommendation

Product recommender systems are typically deployed by e-commerce websites to enhance user expertise and increase sales. Product recommendation systems can help e-commerce websites to provide personalized decision support and information service for customers. It frequently interacts with the customer and analyzes customer feedback to update the recommendation results to best match the customer interest with higher accuracy(Tronvoll, 2008). However, the recommendation is proscribed by the merchandise info hosted in those e-commerce sites and is barely triggered once users are playing e-commerce activities. AI detect users' purchase intents in near-real-time(Dai, Ye and Gong, 2009; Schipmann, 2019).The product recommendation feature is meant to provide an alternative source of new ideas for customers who now visit the store less frequently. Recommendations are generated by matching products to customers based on the expected appeal of the product and the previous spending of the customer. Product recommendation provides us with no rigorous basis for introducing shoppers to new kinds of products beyond those

classes and sub-classes that they already buy. This demonstrates both the flexibility and weakness of content-based filtering systems(Lawrence *et al.*, 2001).As new info concerning relationships between products becomes accessible it will be incorporated by shaping new options.

5. Chatbot

Chabot's designed for e-commerce sites helps as the end to end cat platform to automate customer engagement, customer supports and acquisitions, Chabot's have the capacity to handle thousands of requests at the same time and respond in a meaningful manner. Moreover, customers are not necessarily required to visit the e-commerce site; they can interact with the brand using their preferred channel like WhatsApp, Facebook etc. and make their purchase. It is now turned for other players to grab the opportunity and deploy their own Chabot's to engage with customers. The user, rather than interacting with a non-interactive multi-panel interface, will directly raise the chatbot for a product of his need. The user will kindle a specific feature of the product and compare varied product on the fundamental options that are to his feeling(Campbell *et al.*, 2020). From the point of booking till the point of delivery, the user has a lot to ask; including the status of delivery, mode of payments, request a custom date, enquire delivery time and various other FAQs. E-commerce Chabot help with shopping and post-sales support. Beyond customer engagement, they are helping in vendor management as well. All first-level client support queries may be handled by the chatbot and for classy queries, the matter may be noted and a price tag may be generated. The user can add personal info, update addresses, view purchase history, add cards and even track order and refund status. Using Chabot's, the entire experience of shopping online can be improved and made more fun for the customers.

Hypothesis Development

Review of related literature on artificial Intelligence and its influence on online shopping indicates that the trust belief in online shopping can be further related to perceive ease of use and perceived usefulness and these both will be directed to the attitude of online consumer behavior and their future intention. The safety and reliability in the online store increase the dependency of consumers browsing. Displaying product suggestion of customer desires, online has resulted in easiness of consumer shopping behavior(Alauddin *et al.*, 2015). Studies have shown that proper navigation helps shoppers in the usefulness and saves time thereby increasing the level of attitude and resulting into the actual behavior leading to the future buying intention of the shoppers. Thus, the researcher proposes the following:

H1: There is a significant statistical relationship between perceived ease of use and perceived usefulness in online shopping.

H2: Perceived ease of use will have a significant impact on customer trust to online shopping.

H3: Perceived usefulness will have a significant positive impact on customer trust to shop online.

H4: Trust will have a significant impact on customer attitudes concerning shopping online.

H5: Perceived usefulness have an impact on attitudes concerning shopping.

H6: Perceived usefulness have an impact on attitudes in using AI among online shopping.

H7: Attitude will have a significant impact on customer actual behavior concerning shopping online.

H8: Actual behavior will have a positive impact on customer future intention to shop online.

Research Methodology

The Questionnaire was developed from the Technology Acceptance Model; the survey questionnaire consisted of two parts. The first recorded the subject's demographic information. The second identified the subject's perception of each variable in the model. The demographic variables assessed were gender, age, level of education, income level, frequency of online shopping and the degree of familiarity with Artificial Intelligence services. The sample consisted of people who have used E-Commerce sites for their purchase. To determine the model salient beliefs for the usage of the Online platform, online interviews were conducted with millennials, we chose to elicit beliefs from millennials since they are the one who has more access to the online media, it was found that 52 per cent of online shoppers aged 26 to 35 per cent were regular online shoppers. The geographical coverage of this study is limited to the millennial age groups residing in Kerala. The size of the convenient sample for this study is 137 respondents which has been determined based on the online shoppers. The current research is a quantitative study with the help of a questionnaire survey. A 5-point Likert scale was used to show the agreement/disagreement towards each question. The Regression analysis was carried out to understand the relationship between the different variables towards consumer buying behavior.

Results

When planning a brand new system, the researcher's and practitioners would really like to predict the acceptance of the newly established system by the users, to analyse whether it's been able to fully influence the users, to require actions to create them fully acceptable to the system, to boost the business impact resulting from the massive investments in time and money related to introducing new information technologies into organizations. The current research has relevancy to all or any of those concerns. The study proposed the extended Technology Acceptance Model that integrated the variables like perceived ease of use, perceived usefulness and trust on the consumer buying behavior and attitude with the implications of AI needs.

Fig 1: Research Model of Extended TAM including Artificial Intelligence impact in Online Marketing.

The conceptual model was analysed by using the correlation and regression on Artificial Intelligence in the online marketing media has changed the face and dimension of marketing in its various aspects, the personalised marketing means have conquered the consumer buying behavior, unlike the earlier mean advertising on products of customers choice. Artificial Intelligence helps to identify the customers repeated purchases, desires and choice's, making the available information online to customers screen had made it easier for buying decision (Fei Gao, 2016), thus for a customer who expects the right product at right time with right characteristics Artificial Intelligence helps to provide it on customers screen (Schipmann, 2019).

Table 1: Simple linear regressions between Perceived Ease of Use and Perceived Usefulness

Model Summary			ANOVA	
Model	R Square	Std. Error of Estimate	F	Sig.
1	0.974	0.15056	5172.281	0.000

Coefficients

Model		B	Std. Error	t	Sig.
1	Constant	0.192	0.052	3.732	0.000
	Perceived Ease of Use	0.988	0.014	71.919	0.000

Table 1 analyzes simple linear regressions and predict the the dependent variable (perceived usefulness) using the independent variable (perceived ease of use).The P value for the statistics is less than 0.05 estimating that the coefficients falls somewhere in tat 95% confidence interval.The model confirms to significantly predict the dependent

variable (Perceived Usefulness).Thus, the model confirms: Perceived Usefulness = 0.192 + 0.988 Perceived Ease of Use + Ɛ.

Table 2: Multiple linear regression between Perceived Usefulness, Perceived Ease of Use and Trust

Model Summary			ANOVA	
Model	R Square	Std. Error of Estimate	F	Sig.
1	0.943	0.21379	1127.368	0.000

Coefficients

Model		B	Std. Error	t	Sig.
1	Constant	0.126	0.077	1.642	0.103
	Perceived Usefulness	0.991	0.122	8.098	0.000
	Perceived Ease of Use	-0.065	0.122	-0.532	0.596

Table 2 analyses multiple linear regressions and predict the dependent variable (trust) using the independent variable (perceived usefulness).The P value for the statistics is less than 0.05 estimating that the coefficients falls somewhere in tat 95% confidence interval. The model confirms to significantly predict the dependent variable (trust).Thus, the model confirms: Trust = 0.126 + 0.991 Perceived Usefulness + Ɛ

Table 3: Multiple linear regression between Perceived Usefulness, Perceived Ease of Use, Trust and Attitude

Model Summary			ANOVA	
Model	R Square	Std. Error of Estimate	F	Sig.
1	0.969	0.16205	1433.747	0.000

Coefficients

Model		B	Std. Error	t	Sig.
1	Constant	0.148	0.059	2.521	0.000
	Perceived Usefulness	0.317	0.093	3.421	0.001
	Perceived Ease of Use	0.443	0.113	3.912	0.000
	Trust	0.228	0.065	3.481	0.001

Table 3 analyzes multiple linear regressions and predict the dependent variable (attitude) using the independent variable (perceived usefulness, perceived ease of use, trust).The P value for the statistics is less than 0.05 estimating that the coefficients falls somewhere in tat 95% confidence interval.The model confirms to significantly predict the dependent variable (attitude).Thus, the model confirms. Attitude = 0.148 + 0.317 Perceived Usefulness + 0.443 Perceived Ease of Use+0.228 Trust + Ɛ

Table 4: Simple linear regression between Attitude on AI in online shoping and Actual Behavior

Model Summary			ANOVA	
Model	R Square	Std. Error of Estimate	F	Sig.
1	0.958	0.17650	3132.896	0.000

Coefficients

Model		B	Std. Error	t	Sig.
1	Constant	0.364	0.063	5.768	0.000
	Attitude	0.916	0.016	55.972	0.000

Table 4 analyses simple linear regressions and predict the dependent variable (actual behavior) using the independent variable (attitude).The P value for the statistics is less than 0.05 estimating that the coefficients falls somewhere in tat 95% confidence interval. The model confirms to significantly predict the dependent variable (actual behavior). Thus, the model confirms: Actual Behavior= 0.364 + 0.916 Attitude + Ɛ

Table 5: Simple linear regression between Actual Behavior and Future Intention

Model Summary			ANOVA	
Model	R Square	Std. Error of Estimate	F	Sig.
1	0.954	0.20391	2794.581	0.000

Coefficients

Model		B	Std. Error	t	Sig.
1	Constant	-0.394	0.079	-5.006	0.000
	Actual Behavior	1.068	0.020	52.864	0.000

Table 5 analyses simple linear regressions and predict the dependent variable (future intention) using the independent variable (actual behavior).The P value for the statistics is less than 0.05 estimating that the coefficients falls somewhere in tat 95% confidence interval. The model confirms to significantly predict the dependent variable (future intention). Thus, the model confirms: Future Intention = -0.394 + 1.068 Actual Behavior + Ɛ

The data after collection is processed and analysed following the requirement and purpose at the time of the development of the scale. It is essential for such a scientific study that only the relevant data should be used from the collection of such a voluminous data and processed through the proper statistical tools. Data were thoroughly evaluated before analysis. To check whether characteristics of Artificial Intelligence influenced the online shopping pattern of consumers, Regression analysis was applied to check whether these two dimensions were dependent or not. The data has been investigated according to the objectives of the research.

Discussions and Conclusions

The purpose of this study to analyse the factors of technology acceptance model and trust on future purchase intention of online shoppers with effect from the application of artificial intelligence investigated perceived ease of use, and perceived usefulness creating trust in the minds of shoppers and thereby having an effect on the attitudes, actual behavior and future intention of shoppers. The study supports the effect of artificial intelligence among consumers' in buying online because statistics recommend the model fits the data absolutely.H1: The study found the relationship

between perceived ease of use and perceived usefulness in online shopping; this is similar to that of the existing study(Verhagen and Van Dolen, 2011; Bertea, 2016; Dönmez-Turan and Kir, 2019).The consumer easiness in accessing the online platforms while shopping is likely to let him or her in the usefulness of the online platform.H2: As stated, Perceived ease of use will have a significant impact on customer trust to online shopping(Barnett, Hone and Kaczmarski, 2013; Bertea, 2016; Wu, Chen and Chiu, 2016; Schipmann, 2019) ,the consumer's easiness inaccessibility creates a trust in the minds of the consumers, they are intended to shop more due to the sense of trust developed in their minds, the study shows the association between ease of use and trust in the minds of consumers.H3: the results shows, perceived usefulness will have a significant positive impact on customer trust to shop online, the study demonstrated the impact of usefulness in generating trust among shoppers, perhaps similar studies on trust and consumer buying decision have studied so far, the findings of the present study analyse the role of TAM factors, perceived ease of use and perceived usefulness in building trust among consumers.H4: Trust will have a significant impact on customer attitudes concerning shopping online(Babin, Darden and Griffin, 1994; Tingchi Liu *et al.*, 2013; Wu, Chen and Chiu, 2016),studies have associated the importance of consumer trust in shopping, however, the present study relates to the two factors of TAM in developing trust among online shoppers.H5: mentioned in the review of literature perceived usefulness have an impact on attitudes concerning shopping.H6: Perceived usefulness has an impact on attitudes in using artificial intelligence among online shopping.H7: Attitude will have a significant impact on customer actual behavior concerning shopping online(Sinha and Kim, 2012; Chandra and Sinha, 2013; Koslow and Lee, 2020).H8: Actual behavior will have a positive impact on customer future intention to shop online. The present study depicts the fact that artificial intelligence in the current context has leveraged online consumers in shopping more, with their technological aspects. Marketers are starting at now prepared to envision what sorts of ads really influence your purchasing conduct. Promotions are going to continue ending up being more astute and logically introduced in our regular day to day existences in view of Artificial Intelligence.AI aids in building character profiles on every individual(Lawrence *et al.*, 2001; Liao, Shen and Chu, 2009; Koch, 2018; Hoanca, Marinchak and Forrest, 2019; Schipmann, 2019) .Gradually, these Artificial Intelligence calculations can get acquainted with your conduct, and before you know it, they understand you better than you know yourself. For sure, even today, the impact Artificial Intelligence is having on our overall population can't be ignored. Be that if the customers know about AI or not, computerized reasoning has changed the way how both the purchasers and advertisers think, act and settle on choices in the market. In the future, AI can make the showcasing life simpler, for both the customers and advertisers that gives motivation and invigorates the dynamic quicker than others.

Implications

The investigation looks at to the possibility of Artificial Intelligence related to online consumer lead in buying decision after Fred's Technology Acceptance Model. Resulting in affirming posted messages, the assessment found that purchasers search for information from various sources before buying things and organizations, and they evaluate and reflect their satisfaction in the wake of buying things and organizations. Artificial intelligence is promoting on the web media practice progressively noticeable effect so as that customers can search for every single concerned datum, collect data from existing customers anyway much as could sensibly relies upon before deciding to buy. They don't need to meet the others and solicitation their inclination towards thing and organizations, artificial intelligence comes as a guide by giving the information and substance of individual needs. Computerized reasoning used for customer centering by flinging as careful as a possible response for solitary customers, and help them with choosing the right buying decisions. Moreover, they can leave their feeling, impression and offer information with others too. This shows absolutely online customer lead in the dynamic method to buy. The findings have suggestions for executing procedures to impact buyer over the current stage, the outcomes show that the Artificial Intelligence inside the showcasing field has vanquished buyers mind in their purchasing conduct, yet to help the acknowledgment demonstrative measures must actualize to build the trust factors. The advancement includes confronted difficulties inside the sort of trust issues on account of an out sized number of fake sites and items, which was the clarification that purchasers would not look for merchandise or administrations online (Shapiro et al., 1980).Reliable sites and quality confirmation from makers are handling the issues heedlessly, as they seem to recognize the item that is of consumer decision at the correct time through Artificial Intelligence produce better items and administrations to clients and look for development and advantages for the business inside the long haul.

Restriction

Artificial intelligence in promoting is intricate and quickly creating. Taking everything into account; the researcher’s exploration faces obstructions of the potential for quickly getting obsolete. Further, the immense methods for likely usage of artificial intelligence in the advertising field have limited to simply have the choice to focus on the focuses the investigation have found commonly critical to the step by step practice of advertisers. Artificial intelligence

applied to look is one point that purposefully forgotten about because of time imperatives in having the option to inquire about, orchestrate, and give a valuable viewpoint of the subject. These restrictions mean this paper is in no way, shape or form a thorough examination of the role of artificial intelligence in digital marketing.

Abstract

5 years after the Sustainable Development Goals (UN, 2020) have been stated, the society still has other major problems to face, rather than turning their general consumption pattern into a more sustainable one. Even more, the majority of the population is not aware of the possible individual contribution to a sustainable development, not even in what regards sustainable food. Hence, the purpose of this paper is to evaluate the use of social media networks for engaging people in taking action for changing their food consumption patterns into more sustainable ones, considering that this type of communication with individuals has become an important marketing tool for companies, so it may be as well used as means of communication for other important topics, such as sustainability. A secondary purpose is to evaluate the researchers' interest in studying this type of communication for developing the field of study. The conclusions of this study show that there is an increasing interest from both researchers and regular people towards learning more about sustainable food.

Keywords: Sustainable Development, Social Media, Communication, Consumption Pattern.

Introduction

Since the introduction in official world level discussions of the sustainable development issue, in 1987 (Bruntland Report, 1987), with specific attention to the sectors of food, energy, industry, urbanization and economic development, the actors who were called out to take action were rather large entities, state institutions (Meadowcroft, 2007; Moran et al., 2008) or private companies (Escobar & Vredenburg, 2011; Rowledge et al., 2017;) and less, the regular consumers.

Recent studies (Belz & Peattie, 2009; Bamossy & Solomon, 2016) show that the individual consumption pattern needs to be changed, since the entire global population has almost reached 8 billion people (Worldometer, 2020) and it is growing. Hence, common individual actions for sustainable development might count more than the state regulations or company strategies.

So, if individuals may act for developing sustainably, then: why don't we do it? Consumer behavior theory shows that there are drivers and barriers in the decision-making process of every consumer, yet there are no recipes for controlling them. Authors find that, among others, pro-environmental education (Meyer, 2015), opinion leading (Jansson, Nordlund & Westin, 2017), opinion seeking (Jansson, Nordlund & Westin, 2017), social norms (Jansson, Nordlund & Westin, 2017), existence of regulations (Driver, Saunders & Guenther, 2011; Sáez-Martínez et al., 2016) are general drivers of a sustainable consumption pattern, while low income (Czeczotko, Górska-Warsewicz & Laskowski, 2020), the high availability of unsustainable products (Fróna, Szenderák & Harangi-Rákos, 2019), the general lack of education and awareness on sustainability and sustainable choices (Fróna, Szenderák & Harangi-Rákos, 2019) are general barriers. Developing on this idea, the general statistical trends show that the world consumption pattern is not getting any more sustainable, but it consumes the resources at an unprecedented pace

Cite this Article as: Maria C. DIACONEASA, Florentina CONSTANTIN and Gabriel POPESCU "Approaches on Sustainable Food on Popular Social Media Networks" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

(Fróna, Szenderák & Harangi-Rákos, 2019). Hence, the need to find proper tools for guiding large masses of consumers towards sustainable consumption is obvious.

While international institutions like the United Nations or the European Union have taken upon themselves to offer both knowhow and financing for various projects that might contribute to reaching common Sustainable Development Goals (UN, 2015), some studies show that after the first five years with a general state commitment to these goals, the results are not going in the right direction (del Río Castro, Fernández & Colsa, 2020; Huan et al., 2020; Moallemi et al., 2020).

In this case, a tool that has proven its power of influence on consumers through time will be considered further for evaluating the possibility to contribute to shaping a sustainable consumer. This tool is the mass media (Isernia & Marcolin, 2019), with an accent on the recently developed segment of social media (Simeone & Scarpato, 2020).

Some studies have considered the influence of social media in developing sustainable fashion (Rausch & Kopplin, 2020), sustainable tourism (Palazzo et al., 2020) sustainable energy use (Abdelkader, 2020) or sustainable consumption (Anthony et al., 2020) in general, all of them considering the convincing power of popular people on those who want to be like them. The current study aims at evaluating the use of popular social media networks for influencing people to choose sustainable food.

The objectives of the study are: 1) Determining the interest of researchers in evaluating social media influence on sustainable food consumption; 2) Determining the use of social media networks in communicating about sustainable food and 3) Determining the engagement of users with the sustainable food related posts on social media.

The research is conducted through the use of a mixed method approach, using a bibliometric analysis, a word frequency analysis and further a social media analytics software for quantitative analysis.

Theoretical Background

The consumer behavior regarding food consumption and the various factors that influence it have been of interest to researchers for a long time due to the central role that it occupied in the survival and culture building of people (Vermeir et al., 2020; Flaherty et al., 2018), some of them stating the fact that there is significant difference between attitude towards consumption and real consumption behavior (Vermeir et al., 2020).

Studies regarding the factors that influence the real consumption behavior have been conducted world-wide on larger or smaller groups. For example, some studies on consumer behavior show that knowledge of organic foods (Singh & Verma, 2017), health consciousness (Singh & Verma, 2017), subjective norms (Singh & Verma, 2017), perceived price (Singh & Verma, 2017), food availability (Singh & Verma, 2017), and purchasing convenience (Zhu et al., 2013) have a positive influence on choosing organic food, as well as age, income level and education level (Singh & Verma, 2017; Zhu et al., 2013). Information availability, awareness and education (Kikuchi-Uehara, Nakatani & Hirao, 2016), presenting sustainable, but less desirable food (insect-based food) in a foreign language (Geipel, Hadjichristidis & Klesse, 2018), the possibility of easily recognizing a sustainable product in stores (Czeczotko, Górska-Warsewicz & Laskowski, 2020) are other drivers towards sustainable food consumption.

There are also less expected factors that influence sustainable food consumption behavior, such as religion (Singh et al., 2020) or moral competences such as: self-regulation power, love of learning, beauty appreciation, kindness, humility and modesty, leadership and perspective (Valor, Antonetti & Merino, 2020), as part of the educational process, and even the culture of people (He et al., 2020).

Another important factor that contributes to the behavior and decision-making process of humans is the mass media (Ma, Seenivasan & Yan, 2020) through its role of communicating relevant events to the mass public, such as environmental science results (Junsheng et al., 2019), social events (Imtihani, 2014, Chen, & Stoecker, 2020) or political representation (Khalida et al., 2013).

While the mass media has its role in influencing the development of sustainable food consumption (Isernia & Marcolin, 2019), a specific segment of the media steals the attention regarding influencing sustainable food consumption, and that is social media (Simeone & Scarpato, 2020). The power of social media may act both

positively, through raising awareness on local food or purchasing concerns (Simeone & Scarpato, 2020), as well as household waste management (Jiang, Van Fan & Klemeš, 2020), but it may also produce negative effects due to the lack of trust in social media posts for a considerable number of consumers (Stephen, 2016).

The social media is a new marketing tool for small scale or large-scale producers due to the real time possibility of engaging consumers (Cao et al., 2020; Abeza et.al, 2020) by giving them the opportunity to interact and express their liking or disliking of a product or service through the "like", "share" and even "comment" or "review" options (Proserpio & Zervas, 2017; Pentina, Guilloux & Micu, 2018). Also, social media networks are used for improving communication related to health awareness (Young et al., 2020), social engagement (Alkashri et al., 2020) and even tourist destination choice (Palazzo et al., 2020). New learning opportunities have been developed based on the use of social media networks that are closer to the youth's liking (Ansari & Khan, 2020). Yet, the free access to almost any discussion on social media networks may have its downsides, generating conflicts (Dineva et al., 2020), aggressivity (Sadiq et al., 2020), cyberbullying (Abaido, 2020; Craig et al., 2020) and even favor the activity of sex offenders (Caputi et al., 2019), wildlife traffickers (Xu, Cai & Mackey, 2020), drug traffickers (Jones et al, 2020) and other types of criminals (Resende de Mendonça et al., 2020).

Materials and Methods

For determining the attention researchers pay to the influence of social media networks in regard to sustainable food, a bibliometric analysis based on the results found on the Scopus data base will be used. The key words used for retrieving this batch of articles is "sustainable" and "food" and "in" and "social" and "media".

To complete the bibliometric analysis a visual summary of the most important sub-topics used in the Scopus retrieved article abstracts will be generated using the Vosviewer software, based on word frequency.

The analysis will be completed by using social media analytics (Camacho, Luzón & Cambrie, 2020) on the topic of sustainable food for determining the interest and engagement of users. Two popular networks will be analysed (Antonakaki, Fragopoulou & Ioannidis, 2020): Twitter and Facebook. Twitter is more text-based sharing platform (Antonakaki, Fragopoulou & Ioannidis, 2020). Facebook is a mixed platform, based both on visual and text content (Dogruer, Menevi & Eyyam, 2011).

For determining the appearance of the sustainable food topic on social media, the BuzzSumo platform was used, as a quantitative analysis provider based on internet posts regarding topics searched by a user (Moscadelli et al., 2020; John, 2019).

Results and Discussion

The results of the Scopus database search phrase returned 488 articles, the first one being published in 1999. In the following figure the evolution of indexed articles in Scopus data base on the considered topic may be seen.

Fig. 1: Time evolution of articles indexed in Scopus on the topic of "sustainable food in social media"
Source: Scopus, analyze results based on TITLE-ABS-KEY, 2020

The maximum number of articles on this topic indexed in Scopus was 50 in 2014. The overall interest of researchers on this topic is increasing, even if it has a fluctuating trend.

There is only one author with four articles on this topic, but there are other eight authors with three papers on the topic. Yet, most of the authors who appear on the list of this topic have only one article that responds to this search phrase.

Considering the countries that generated most of the retrieved articles, they may be seen in the following figure.

Fig. 2: Origin country of articles indexed in Scopus on the topic of "sustainable food in social media"
Source: Scopus, analyze results based on TITLE-ABS-KEY, 2020

The countries that serve as origins for most of the indexed articles in the Scopus data base are United States of America (115), United Kingdom (56), Australia (44), India (33) and the top 5 publishing countries is completed by Germany (32).

Considering the type of document, the allocation by types may be seen in the following figure:

Fig. 3: Document type of articles indexed in Scopus on the topic of "sustainable food in social media"
Source: Scopus, Analyze results based on TITLE-ABS-KEY, 2020

More than 60% of the documents are scientific articles, published in respected journals, 18.2% are book chapters and 8.8% are conference papers, while less than 8% are other types of documents. This may be seen as a considerable commitment from the authors to developing this topic.

As a summary of the sub-topics that can be found in the articles retrieved from the Scopus database on the topic of "sustainable food in social media" the Vosviewer software was used. The obtained map may be seen in the following figure.

The total number of words in the 488 abstracts is 15558, 472 terms appear with a frequency of at least 10 times in the corpus. On the map appear the words with the highest frequency (283). The shades between light and bright yellow represent the intensity of use for these sub-topics.

There are two main categories that raise the interest of researchers. First, the actors' category, meaning the groups that appear in the articles as those implicated or summoned on social media to act in the area of sustainable food: the industry and the consumers. Second, the motivations category, formed from the most discussed reasons/motives on social media for considering sustainable food: health and climate change. Another category that has started to form may be named solutions and is composed by crop, aquaculture, insect, biomass. The other sub-topics are still underdiscussed and cannot be clustered into categories.

Fig. 4: Density map for the sub-topics used in the 488 Scopus articles on "sustainable food in social media"
Source: authors own abstracting using the Vosviewer software

The secondary purpose of the paper is accomplished, the interest of researchers is on an increasing scale. The study of social media use in communicating specific messages for consumers has shed a new light on marketing tools, as well as, bringing new specific tools and methods of study.

Through the use of the BuzzSumo platform, the total content of posts related to sustainable food was retrieved and analyzed. In this case, the first search on this analytics platform was the obvious one "sustainable food". In the following figure, the word cloud generated by this search may be seen.

Fig. 5: Word cloud generated by BuzzSumo using "sustainable food" search phrase
Source: authors' own abstracting using BuzzSumo

The total number of concepts used in relation to sustainable food is small, only 15, showing a concentration of these specific ideas. Based on their frequency of use, we may conclude that the influencers or those who post on this topics debate more around the issues of food security, food production and food system, but topics such as health and healthy eating, sustainable agriculture and technology and climate change receive an increasing amount of attention.

Fig. 6: Word cloud generated by BuzzSumo using "local food" search phrase
Source: authors' own abstracting using BuzzSumo

Compared to the word concentrated word cloud generated by the "sustainable food" search, the "local food" phrase generates a considerably larger number of topics related to or included in it. It is important to notice that "locally sourced food" is the center of discussion, along with "buy local", "food bank" and "food option", all of them being areas of interest in sustainable food and food security. The relation between food and tourism is also an exploited topic as it is revealed in the figure above. Food alternatives such as "organic food" or "vegetarian food" are included in the "local food" discussion.

Related to the total number of posts and engagement on the topic of sustainable food, BuzzSumo generated the following figure for the September 2019 – September 2020 period.

Fig. 7: Total posts and engagement generated by BuzzSumo using "sustainable food" search phrase
Source: authors' own abstracting using BuzzSumo

A total number of 8,448 posts were found by this searching phrase in the analyzed time frame and they summed up a total of 510,445 engagements from users, including likes, shares, or retweets. The highest engagement was registered in June 2020, while the lowest was registered in September 2019.

When using the "local food" search term, as an alternative for the first one, BuzzSumo provides significantly more results, as it can be seen in the following figure.

Fig. 8: Total posts and engagement generated by BuzzSumo using "local food" search phrase
Source: authors' own abstracting using BuzzSumo

In September 2019 – September 2020 period, a total number of 24602 articles were posted online and had a content related to local food. The total engagement was of 5,153,887 considered any user interaction with the posts. April 2020 was the month with both the highest number of posts and engagement from users, while September 2019 was the month with the lowest number of posts and engagements in the analyzed time frame.

Considering which social network received the highest attention from users, the following figure provides a clear image.

Fig. 9: Most engaging platform as generated by BuzzSumo
Source: authors' own abstracting using BuzzSumo

Facebook is the leading social network in what regards user engagement, followed from a considerable distance by Twitter. The highest engagement was received by local food posts, with 200 engagements, while sustainable food engaged little over 50 users on Facebook. Twitter engaged less than 10 users in both cases. Other networks such as Reddit or Pinterest receive even little interest on this topic.

Considering the type of reactions among Facebook users, as the most engaging social network platform on these topics, based on emoticons expressing user emotions, the following figure presents the most common reaction generated for the two considered topics.

Fig 10: Most used reaction in relation to the searched phrases as generated by BuzzSumo
Source: authors' own abstracting using BuzzSumo

The most encountered reaction among users engaged in the topics is "love" for both alternatives, followed by the amusement reaction and the amazement reaction. The negative reactions of sadness and angry are the least used, per total. Yet, the local food related posts generate a sad reaction to almost ten users.

Conclusion

Considering the increasing interest that both sustainable food and social media influence had on various areas, the present research aimed at shedding some light on the possibility of using social media as a locomotive for changing the current food consumption pattern into a more sustainable one.

Drawing on other studies, the influence of social media is hard to control, generating both positive and negative effects for and from the users of social media networks. Yet, the benefit of international open access for every user is undeniable when thinking about the possibility of offering information and educating large groups of consumers.

Based on the bibliometric analysis of the articles indexed in Scopus database, the results show that researchers have an increasing interest in studying this particular topic, both qualitatively and quantitatively. Considering the large number of approaches, it is still difficult to see well defined clusters of sub-topics, but the actors implicated in sustainable food and the main motivation to choose this type of food are starting to take contour.

Through the use of BuzzSumo platform a quantitative analysis was performed in order to determine if there is any interest for using social media platforms to communicate about sustainable food and to see what kind of engagement these posts generate. Two popular social media platforms were considered: Facebook and Twitter.

Looking at the quantitative results, we may notice that there is also an increasing interest for this topic on both social media platforms considered, but Facebook secures its role as leader in relation to the considered topic. Both the number of posts on the topic and the number of engagements is higher on Facebook than on Twitter.

The alternative search for "local food" generated considerably more results than the "sustainable food" one. One possible explanation might be the difference of word difficulty between the two words, local may seem more accessible for a larger number of people, giving them the confidence to express their engagement through the "like", "share" or "comment" options. Yet this is a hypothesis that needs to be further developed.

Some limitations for this study may be generated by the fact that a trial version of the BuzzSumo platform was used and the search phrases were selected by the authors to be comprehensive, yet a number of synonyms might generate different results.

The study should be of interest to researchers, as it contributed to developing a niche type of analysis on a tool that still needs a lot of attention, to users of social media platforms, in order to better understand and use their activity on these platforms, and not least, to administrators of social media networks who should be more aware of the importance of their tools in the larger context of sustainable development.

Acknowledgment

This article is part of the research project "Towards Sustainable Food and Drink Choices among European Young Adults: Drivers, Barriers and Strategical Implications" (SUSCHOICE) (ID 66). SUSCHOICE is a transnational project and part of the ERA-Net SUSFOOD2 with funding provided by national sources (MIUR-Italy, RCN-Norway, PM-BLE-Germany and UEFISCDI-Romania) and co-funding by the European Union's Horizon 2020 research and innovation programme.

Head of the Department of Public Management and Administration, Poltava State Agrarian Academy, 36003, Poltava, Ukraine, e-mail: tnloz@rambler.ru,

Abstract

The article is devoted to the study of the problem of sustainable development in post-communist countries using the analysis of the practice of the European Union on the observance of the optimal ratio between the satisfaction of modern needs of society and the preservation of opportunities for this in the future. It is noted that in post-communist countries, the task of promoting sustainable development is complicated by the need to transform the entire system of public relations. It is concluded that there is a relationship between the level of corruption and economic development of countries. The difference between the indices of competitiveness and the perception of corruption indicates the presence of specific national factors that determine the scale of corruption.
A sociological survey of public officials revealed the presence of both political and mental determinants. The key problems of overcoming corruption are highlighted and the range of main tasks for combating corruption is outlined.

Keywords: Sustainable Development, Prevention of Corruption, Post-Communist Transformation, Civil Society, Experience of Post-Communist Countries.

Formulation of the Problem

The concept of sustainable development (CSD) is one of the most attractive because it aims to reconcile the economic, social and environmental components of society. The formation of the CSD was carried out under the influence of the ideas of V.I. Vernadsky on the Noosphere (early twentieth century), the Declaration of the First United Nations Conference on Environment and Development (Stockholm, 1972), the Second United Nations Conference on Environment and Development (Rio de Janeiro, 1992), the Kyoto Protocol (Kyoto, 1992, 2005), the UN World Summit (Johannesburg, 2002), the Third UN Conference on Sustainable Development (Rio de Janeiro, 2012), the UN Summit on Sustainable Development (New York, 2015)) (Stages of emergence and formation of the concept of sustainable development, 2020; Sustainable Development Goals: Ukraine (national report, 2017). Acquaintance with the listed documents testifies that since 1992 until 2012, for 20 years, the world community emphasized the need to strive for balanced rather than sustainable development. The efforts of scientists were aimed at solving a complex problem - finding a compromise between the consumption of resources and the volume of their reproduction within economic systems, different in level of development. Reducing the level of corruption in all its forms is extremely important for sustainable development, as corruption undermines the economic stability of states through the shadow economy, and the restriction of competition leads to inefficient allocation of resources and newly created value in society and negatively affects the quality of goods and services.

The Sustainable Development Strategy "Ukraine - 2020", approved by the Decree of the President of Ukraine (Decree of the President of Ukraine, 2015), identifies 5 areas of activity: employment, climate change and energy, research and innovation, education, poverty alleviation. Agreeing with the allocation of economic, social and environmental components of the Sustainable Development Strategy as the main ones, it is necessary to understand that the presence of mental changes and political will becomes a necessary condition for the implementation of its tasks. Accordingly, increasing attention is paid to identifying and taking into account both the factors of positive impact on sustainable

Cite this Article as: Mykola LAKHYZHA and Tamara LOZINSKA“ Sustainable Development And The Problem of Corruption in Post-Communist Countries” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

development and obstacles, the most notable of which is corruption. Thus, the study of the impact of corruption on sustainable development is an urgent task for Ukrainian scientific thought.

A review of the Special Literature

A review shows a significant attention of the public, politicians and scientists both to the issue of sustainable development and to the prevention of corruption. Thus, in Ukraine in 2005 the results of thorough marketing research of the global perspective and sustainable development of the country were published Belarus O.G., Matseyko Y.M. (2005), there were data of scientific research on sustainable development in the EU Perga. T. (2017), which were based on studies of European scientists in the late 90's - early 2000's Carew-Reid J., Prescott-Allen R., Bass S., Dalal-Clayton B. (1994); Meadowcroft J. (2007)**.** It should be noted that the rapid growth of attention to the problems of sustainable development was caused by the studies of D. Forrester (1971) and D. Meadows (1974), which they conducted on behalf of the Club of Rome and which concerned the definition of economic growth. As the authors' conclusions about the growth of environmental problems were disappointing, the search for causes of disruption of economic systems and ways to reduce the risks of environmental degradation. In Ukraine, in particular, intensified research on anti-corruption issues, which was recognized as one of the serious threats to sustainable development Novak A. (2018), and encouraged the study of international experience and taking into account the recommendations of the European Union. "… The need to respond to threats and problems, the source of which is corruption ..", according to T.V. Ilyenok, contributed to the development of international regulations to prevent corruption Ilyenok T.V. (2013). Ukraine's aspirations for integration with the European Union have had a positive impact on the development of anti-corruption mechanisms Moldavan E.S. (2012); Prokhorenko O. Ya. (2011). Also noteworthy are the results of sociological research on the state and causes of corruption in Ukraine, posted on the website of the National Agency for the Prevention of Corruption (Official Website of the National Agency for the Prevention of Corruption, 2020).

Thus, the purpose of the study is a continuation of the identification of the potential and real impact of corruption in post-communist countries on the implementation of the concept of sustainable development in order to develop proposals for minimizing corruption risks.

Research Methodology

The study takes into account the methodological foundations of sustainable development, in particular its components and principles, as well as determinism. The scientific research was based on the results of research and conclusions of scientists, whose work served as a source base for the theory of sustainable development and the theory of corruption. Along with a brief review of the specialized literature, the method of comparative analysis was also used to identify the main factors influencing sustainable development and to establish the degree of influence of the scale of corruption. The method of retrospection was used to compare the stages of formation of the concept of sustainable development in European countries and Ukraine.

The results of the application of the index organization method of determining the perception of corruption by the international organization Transparency International were used to compile a rating of countries on this indicator and the competitiveness index. The analysis of identifying the main factors of corruption was carried out using the methodology of sociological research, namely - a survey of government officials on the causes of corruption.
To obtain secondary and primary information used:

- scientific publications and national reports;
- legal documents of national and international levels;
- research results published on the official websites of the National Agency for the Prevention of Corruption and Transparency International;
- data from empirical studies obtained by the authors during trips to Armenia, Georgia, Bulgaria and Poland.

Identification of Sustainable Development

Based on numerous attempts to define the essence of the concept of "sustainable development", the latter can be identified *as a process of balancing productive forces, meeting the needs of all members of society while maintaining and constantly reproducing the integrity of the environment and maintaining a balance between its potential and society.* Based on this interpretation of this concept, the main features of sustainable development are attention to man, taking into account not only the positive but also negative consequences of economic development and the desire to preserve natural diversity for future generations. This broad concept has a national specificity, especially noticeable in post-communist countries that are at different stages of development and are part of various international entities: the European Union, the Commonwealth of Independent States, the Eastern Partnership. Among the post-communist countries, the most acute problems of balancing economic, social and environmental development are manifested in the former Soviet republics (except for the Baltic countries and the former Yugoslavia). If EU member states have committed themselves to implementing the principles of sustainable development, enshrining them in the provisions of the Amsterdam Treaty (1997) as a comprehensive goal of EU policy and developing an appropriate Strategy Review of the EU Sustainable Development Strategy (2006), Ukraine, despite acknowledging the problem, announcing its intentions and acceding to international documents, has failed to take real action to ensure sustainable development.

Perception of the idea of sustainable development in post-communist countries

An analysis of regulations and other materials governing measures to ensure sustainable development in post-communist countries shows both the importance of this issue and its breadth and a number of complex tasks that need to be addressed, which is hampered in many cases by incomplete post-communist transformation. Our retrospective analysis leads to the conclusion that discussions on sustainable development began in the post-communist countries in the mid-1990s, which, in our opinion, was largely due to the desire to integrate with the European Union and the European Union's support for those preparing for EU membership. Common in the policy of sustainable development of post-communist countries was their accession to EU programs, coordination of sustainable development tasks at the national and regional levels with the tasks of the EU, the creation of mechanisms to support sustainable development. However, already in setting priorities for sustainable development in these countries, national characteristics emerged, such as economic corruption, which prompted governments to identify additional tasks. In most countries, the prevention of corruption was limited to a declaration of intent for good public governance with respect to the principles of openness and transparency in government, but in practice no significant progress was made in minimizing corruption risks.

Ranking of post-communist countries by indices of competitiveness and perception of corruption

Compilation of annual rankings of countries according to the Corruption Perceptions Index allows tracking the achievements and failures of post-communist countries in the field of combating and preventing corruption (Table 1).

The difference between the competitiveness and corruption scores given for each country suggests that corruption in many countries is closely linked to the level of economic development. Observing the relationship between the level of economic development and the fight against corruption, it should be noted that political factors and the mentality of the population are also important. In our opinion, relying on the political will of the leadership and the mentality of the population, it was possible to significantly reduce the level of corruption in countries such as Georgia, Estonia and Montenegro and precisely because of lack of political will and corruption of the population failed to achieve this in Russia, Azerbaijan, Kazakhstan. Ukraine and Moldova. It is characteristic that all these countries are former republics of the USSR and are not part of the EU.

Table 1 : Ratings of post-communist countries according to the Competitiveness (IC) and Perceptions of Corruption (PC) indices, 2019

Country	Place for IC	Place for PC	The difference in points	Country	Place for IC	Place for PC	The difference in points
Estonia	31	18	13	Serbia	72	91	-19
Czech Republic	32	45	-13	Montenegro	73	68	5

The threatening impact of corruption on the country's economic capacity has prompted the Ukrainian authorities to reform the system of public administration, one of the tasks of which has been to institutionalize anti-corruption activities. In recent years, the country has developed an anti-corruption legal framework and created special institutions. In 20914, the Verkhovna Rada of Ukraine passed a number of anti-corruption laws and decided to establish a specialized anti-corruption body - the National Anti-Corruption Bureau of Ukraine (NABU). In connection with the strengthening of the anti-corruption component in the activities of the Ukrainian authorities, the positive experience of neighboring countries, which managed to achieve significant success in the fight against corruption, as well as the analysis of anti-corruption methods in countries with high levels.

Poland's experience in combating corruption

In the early 1990s, there was a penetration of corruption in all spheres of life in Poland. The level of corruption increased significantly during the post-communist transformation due to the change of value orientation and weakness of state structures, taking the form of clientelism, nepotism and nepotism. During this period, shock therapy, administrative and other reforms related to the decentralization of public administration have gradually changed the economic, political and social situation, as well as the mentality of the population. As a result of a series of high-profile political scandals, corruption became perceived by the authorities and society as a threat to the security of the state, which forced the government to develop anti-corruption measures. Prior to joining the EU, according to Polish scholars Bak M., Kulawczuk P., Szczesniak A. (2001), corruption was a significant barrier to Poland's economic development, as it not only distorted competitive processes in the economy, but also hampered the integration process. Polish economy with the European Union. Positive developments in the fight against corruption began to take place after the adoption of the Law of the Republic of Poland of 16 November 2000, “which established a new state financial intelligence body, which provides for the implementation of the following tasks: cessation of criminal activity in the

financial sector. institutions that oppose the use of illegal sources of income ”Szamrej-Baran I., Baran P., 2014; Suprun T.M. (2017).

Awareness of the importance of the fight against corruption for building a democratic society in Poland has grown through EU action, which has been particularly evident in the run-up to accession and in the first years of membership. The economic and social achievements of the country within the framework of the implementation of the sustainable development strategy were of significant and perhaps crucial importance. There is a noticeable shift in Poland from anti-corruption to prevention, which is especially evident in the growing attention to the ethical principles of public servants and the creation of a system of anti-corruption training. The main factors for reducing the level of corruption were: the formation of anti-corruption public opinion, which was facilitated by the high level of religiosity of the population; purposeful activity of authorities; high-quality institutional support for anti-corruption activities.

Fight against corruption in Bulgaria

Bulgaria is an example of a country that is a member of the EU, but has not made significant progress, either in ensuring sustainable development or in preventing corruption. As noted in the Report "Strategic Directions for Preventing and Combating Corruption. 2015-2020 » "Corruption is one of the most serious problems of democracy in Bulgaria" Strategic Guidelines for Prevention and Counteraction to Corruption (2020). Bulgarian authors draw attention to political corruption, corruption in the public administration, the judiciary and the economic and financial spheres, emphasizing that it is political corruption that determines the nature and trends of corruption in other areas, as evidenced by anti-corruption protests in Bulgaria in recent years. arose constantly and increased in August-September 2020. A number of strategic anti-corruption documents proved ineffective, and studies conducted by Bulgarian scientists indicate "про stagnation in the fight against corruption" Shopova P. (2019).

The situation is even more difficult in states that have not yet become EU members, in particular, in Ukraine and a number of other republics of the former Soviet Union, where the processes of post-communist transformation are still incomplete, and economic and social tasks, burdened by the problem of external debt, enter contrary to the objectives of sustainable development.

Specifics of anti-corruption in the Republic of Kazakhstan

The Republic of Kazakhstan is under constant anti-corruption monitoring by international organizations. The 2011 monitoring report provides an optimistic assessment of the state of the fight against corruption, highlights the authorities' attention and a number of important reforms. The high level of corruption in Kazakhstan is recognized by the authorities, which periodically announce anti-corruption campaigns. For example, former President of the Republic of Kazakhstan N. Nazarbayev declared a "holy war" on corruption, "10 anti-corruption measures" were adopted, but not only many high-ranking officials, but also the president's family were involved in corruption scams (Kazakhgate).

As in Russia, in Kazakhstan, in addition to domestic corruption, corruption plays a significant role in the development of useful deposits. For example, Nazarbayev's grandson pointed to corrupt interaction between the governments of the two countries (Nazarbayev's grandson asked for political asylum in Britain, 2020), and British journalist N. Kochan, as a result of an expert visit to Kazakhstan, notes that corruption in Kazakhstan is glaring because of power and business Kochan N., (2014). After the change of government, the anti-corruption situation has not changed significantly.

Imitation of the fight against corruption in the Russian Federation

In Russia, the fight against corruption is widely declared by the authorities. For example, the fight against corruption was included in the Concept of Russia's presidency in Group 20 in 2013. The Russian government regularly reports its fight against corruption to a special group of the Council of Europe, but in the vast majority of cases it is a formal or incomplete fulfillment of obligations. Thus, the report of the Group of States against Corruption for 2019 noted that Russia has implemented satisfactorily only 9 of the 22 recommendations. At the same time, according to public activists, GRECO monitoring often receives information from the Russian authorities without verification and public

consultation Logvinova M., (2020). Independent researchers from the Coalition for Sustainable Development of the country noted the need to change course in ensuring access to justice and control of corruption. Independent researchers from the Coalition for Sustainable Development of the country noted the need to change course in ensuring access to justice and control of corruption. To reduce corruption and create effective, accountable and transparent institutions, it is proposed to improve the anti-money laundering system, review public procurement practices, criminalize bribery, and facilitate access to information.

Features of anti-corruption in the Republic of Moldova

In Moldova, corruption is systemic. According to expert surveys, on average, one citizen gave bribes 5 times a year, and an entrepreneur - at least 3. The specificity of the Moldovan economy is a high level of oligarchization, which can not but affect the government and increase corruption. A clear example of impunity was the embezzlement of $ 1 billion from three state-owned banks in 2014-2015 “Can Moldova emerge victorious from the grueling fight against corruption?”(2020).

Successes and problems of corruption prevention in Ukraine

In Ukraine, since 1997, work has begun on the implementation of the provisions of sustainable development. In 1998, the National Commission for Sustainable Development of Ukraine under the Cabinet of Ministers of Ukraine was established and a government draft of the concept of sustainable development of Ukraine was prepared. In December 1999, the Resolution of the Verkhovna Rada of Ukraine “On the Concept of Sustainable Development of Settlements” was adopted, according to which the state undertook to create conditions for a full-fledged living environment. In April 2003, the Resolution of the Cabinet of Ministers of Ukraine "On Approval of the Comprehensive Program for the Implementation at the National Level of Decisions Adopted at the World Summit on Sustainable Development for 2003-2015" was adopted. The Ukraine 2020 Sustainable Development Strategy states that a key basis for security should also be the provision of fair and impartial justice, the immediate cleansing of government at all levels and the implementation of effective anti-corruption mechanisms. Issues of preventing corruption are constantly on the agenda of the Ukrainian authorities, examples of which are frequent changes and clarifications of legislation, the announcement of anti-corruption campaigns, the creation of special anti-corruption bodies and more. Experience shows that the main problem remains political corruption, which is facilitated by the mentality of the population.

Conducted by the authors during seminars on anti-corruption held in 2019 in Kyiv, Kyiv and Poltava regions of Ukraine for civil servants, the survey of students allows to identify and rank the factors of corruption (Table 2).

Table 2: Results of the survey of civil servants of Kyiv and Poltava regions. on identifying the causes of corruption in Ukraine, 2019 (a total of 250 respondents)

№	Corruption factor	Number of respondents who named the relevant reason	Share of the total number of respondents, %
1	Imperfect legislation	110	44,0
2	Socio-economic problems	95	38,
3	Uncontrollability and impunity	77	30,8
4	Low level of remuneration of civil servants	64	25,6
5	The mentality of the population	58	23,2
6	Ignorance of laws by the population / low level of legal culture	45/5	20,0
7	Imperfect judicial system	30	12,0

8	Nepotism / Intertwining of power and business	24/16	16,0
9	Political and economic instability	23	9,2
10	Inflated, unprofessional bureaucracy	23	9,2
11	War / Use of its power	8/6	5,6
12	Weakness (absence) of civil society	14	5,6
13	Lack of political will and anti-corruption system	11	4.4

Source: compiled by the authors based on the results of the analysis of questionnaires.

As we can see, drawing on the experience of foreign countries in developing anti-corruption legislation and establishing specialized anti-corruption bodies has not yet made significant progress in preventing corruption. Experts of the Organization for Economic Cooperation and Development (OECD), monitoring specialized anti-corruption bodies, concluded that the functioning of such bodies in some countries shows more negative practices than successful ones. Having made an attempt to systematize the causes of failures of specialized anti-corruption organizations in Ukraine, we come to the conclusion that the main ones are:

– imperfection of the legislation, which is manifested in the vague wording of the rights and responsibilities of anti-corruption bodies;

- bureaucratization of the management staff, focus on formal features of activities, non-transparency of decision-making procedures;

- redundancy of administrative regulation of economic life, which has not been reduced;

- lack of political will;

- weakness and low professional level of the government opposition, underdevelopment of civil society;

- the custom of petty bribery in all spheres of public life, which does not cause significant public condemnation.

We consider it necessary to make a number of proposals aimed at reducing corruption risks in the public administration system, in particular those related to sustainable development.

1. Since one of the common corruption risks is vaguely written rights and responsibilities of public officials, which allows them to make their own decisions (in legal practice it is about expanding discretionary powers), it is advisable to insist on reducing the proportion of evaluative judgments in regulations. , such as: "if necessary", "under adverse conditions", "in special cases", etc. This will reduce the impact of discretionary powers on business regulation and business support.

2. It is necessary to continue the practice of using information technologies in public administration and expand their capabilities (creation of administrative service centers on the principle of "single window", synchronization of databases of government agencies, electronic queues, etc.), which significantly reduces business time and prevents direct contacts between officials and clients.

3. Digitalization of public services in Ukraine has the peculiarity of using paper analogues in parallel with electronic documents, and therefore it is necessary to gradually abandon the paperwork, which will have economic, social and environmental effects.

4. It is necessary to reduce the number of instances from which it is necessary to obtain approval or confirmation. Sometimes the usual awareness is not enough, and therefore there is a need to place explanations on the websites of organizations, premises and advisory support of entrepreneurs not only through advisory bodies, but also through other executive bodies..

The study shows that in post-communist countries, addressing sustainable development and combating corruption depends to a large extent on the state of civil society, the political will of the leadership and the quality of public administration..

Concluisons

Retrospective analysis allows us to conclude that the combination of transformational and sustainable development goals in post-communist countries. The incentive role of the European Union is noticeable, and the implementation

of its recommendations and the use of financial assistance have significantly facilitated and accelerated the transition period, having a positive impact on addressing socio-economic, environmental issues and preventing of corruption. In post-communist countries, there is a shift in emphasis from anti-corruption to prevention, which is especially evident in the growing attention to the ethical principles of public servants and the creation of an anti-corruption training system.

There are significant differences between post-communist countries, both in terms of sustainable development and in terms of preventing of corruption. The countries that became members of the EU, first of all Poland and the Baltic States, achieved the best results. Economic and social achievements in the framework of the sustainable development strategy were essential. However, the main factors for this were: the formation of anti-corruption public opinion, which was facilitated by the high level of religiosity of the population; purposeful activity of authorities; high-quality institutional support for anti-corruption activities.

The low efficiency of the anti-corruption bodies established in Ukraine prompted the identification of the reasons for the weak impact on corruption and the outlining of proposals to reduce corruption risks in the public administration system.

The Expectations and Challenges of a New Generation Leader

Dorota BALCERZYK

Dr., Assistant Professor at the Faculty of Management of the General Tadeusz Kościuszko Military University of Land Forces in Wrocław
Email: dbalcerzyk@interia.pl, ORCID iD: 0000-0003-3948-7146.

Abstract

The publication deals with an intergenerational team's conditions and specificity that pose a challenge for a manager with leadership ambitions. The article aims to provide a research report. It presents the perspective of the millennial generation (Gen Y) and its expectations towards the leader. The research results are part of the search for new directions of leadership. In the digital age, expectations towards a leader are surprisingly traditional. Authenticity, social competencies, shared values, and trust turn out to be priorities for the young generation.

Keywords: Leadership, Leader, Generational Cohorts, Generation Y, Trust.

Introduction

Information technology undoubtedly influences the way the millennial generation lives and works; it determines their needs and preferences. The Millennials constitute the youngest of the generational cohort. The work identifies some of the differences between generations and their impact on functioning as an employee. There are recognized preferred advantages in the workplace and the generations' strengths and weaknesses. The young generation is seen as a challenge to contemporary leadership. The stereotype functioning among employers describes them as lacking authority and demanding. The leader's role is to reach out to every group, every member of the team, and make them follow him/her. One cannot speak of a leader without followers. Referring to Kupperschmidt (2000), it can be emphasized that when managers and co-workers do not understand the generational differences, conflicts arise, and job satisfaction and productivity decrease.

Despite the pressure of success and constant changes in the environment, today's leaders should understand that getting to know people's opinions, needs, and expectations are crucial to lead them. Hence, the author's goal was to learn about the young generation's views on leadership and their expectations towards a manager with leadership ambitions.

The Employees' Specificity and Generational Peculiarities

The study by Erst & Young (2013) confirms that managing a multigenerational team is a challenge. In the literature (Espinoza 2018, Lyons et al. 2015, Ruth et al. 2013), there is a division into generational cohorts: silent generation, baby boomers, generation X, generation Y, and generation Z.

The smallest generation is the "silent generation," which includes people born between 1925 and 1942. They make up a small percentage of the workforce. They grew up in the Great Depression; hence, they were loyal to the employer, and their ethos was based on cooperation with the system. The next distinguished generation is "baby boomers." Their representatives were born in the years 1946-1964 and are the so-called post-war baby boom generation. Baby boomers grew up in times of high demand for employees when employers took care of them. They were taught that the work ethic is essential. They were socialized to socialization. There are increasingly fewer representatives of those two generations, i.e., people aged 55+, on the labor market.

Cite this Article as: Dorota BALCERZYK " The Expectations and Challenges of a New Generation Leader" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The generation X are the "baby boomers'" daughters and sons born in 1965-1979. They entered the labor market in difficult times. In Poland, it was the time of changes and re-privatization and the first period of unemployment. They witnessed their loyal parents lose their jobs. When looking for employment, they focused on development. There are more people with higher education (almost twice as many as in their parents' generation). They value personal development, independence, diversity, and diligence. Unlike baby boomers, they are result-oriented, not process-driven. The generation X is the first to objectify work and treat it as a transaction. The generation X is often skeptical and pessimistic. They are sometimes distrustful of their superiors. They do not allow themselves to make mistakes, which they treat as a personal failure. It is harder to find multitaskers among them. The generation X uses computers and smartphones; they are familiar with the technology. However, they can be called guests, not natives in the world of technology (Prensky, 2001). They still trust face to face contacts and paper documentation more than files and disks.

The subsequent generation is referred to in the subject literature as the Millennials. Unfortunately, there is no agreement on the entry and exit framework for this generation. Some authors (Espinoza 2018) are inclined to the position that the generation Y, also known as the millennial generation, are people born in the years 1980-1989. Ruth et al. (2013), similarly to A.J. Nicholas (2009), recognizes the framework of the generation Y as people born in 1981-1999. The generation Y belongs to the baby boom of the 1980s. In Poland, they are the first generation to grow up and brought up in conditions of freedom, without socio-political restrictions, no borders, economic emigration opportunities, and the availability of modern technologies. They are characterized by greater flexibility, openness to change, and readiness to learn than the generation X (Stosik, Leśniewska, 2015, p. 187). More noticeable is the reluctance to commitments, less loyalty to the employer, focus on oneself, one's needs, and benefits.

The millennium generation also includes the generation C, also known as the generation Z or XD. It includes people born since 1990. The term "generation C" is derived from the English words "*connect, communicate, change*", which in a way describes the characteristic pillars of this generation: Internet, communication, and readiness to change. It is the youngest employee group that can be described as natives in new technologies. Representatives of this generation have explored the world with a smartphone in their hands. Their "childhood neighborhood" is a global world; they represent global values; they had global idols (Harry Potter, The Hobbit, etc.). Unfortunately, they entered the labor market in difficult times of crisis. On the other hand, employers expected their employees to be available at any time, accept unprotected positions, and maintain employment. The effect of specific conditions is distancing oneself from temporary jobs, constant search, and reluctance to build relationships. The GUS research (2020) shows that representatives of this generation constitute the largest share among Poland's generations. They are considered the best-educated generation. Among them, almost every second person has a university diploma, knows foreign languages, and eagerly uses technology.

Research Methodology

Studies of literature and desk research preceded the preparation of the research material. The presented analysis is part of broader research on leadership issues. A questionnaire was used to obtain the respondents' opinions on the research questions. The research issues included obtaining answers to the questions posed: How is leadership understood? What terms is a leader identified with? What are the determinants of a leader? What leadership competencies do the respondents consider the most important?

The research sample included 340 people, working students studying management at higher education institutions located in Lower Silesia. Women constituted 51%, and men 49% of the studied group.

The research sample was represented by very young people, aged 19 to 35, constituting 75.2% of the respondents. People aged 36 to 45 accounted for 15.3%, and those aged 46 to 55 - 3.5% of the sample. The remaining respondents (5.9%) were the oldest age group, i.e., over 55 years old.

Nearly half of the respondents (49.4%) work in a company with over 100 employees. The remaining respondents work in smaller companies employing from 51 to 100 people - 12.4%, 21 - 50 employees - 10.6%, 11 - 20 employees - 7.0%, 6 - 10 employees - 10,0%, and up to 5 employees - 10.6% of the respondents.

The characteristics of the research sample also took the position held in the company into account. Only 5.3% of the respondents held a senior manager position, 21.8% - a middle-level manager (manager), and 11.7% - a lower-level

manager. The largest group of respondents, 61.2%, were people occupying a different position than those listed in the cafeteria.
Therefore, the research sample was mainly young people, representatives of the millennium generation. A small percentage was representatives of the X and BB generations. Very few of them were senior managers. One-third of the respondents performed the functions of a middle and lower-level manager. It can be assumed that they represented people at the stage of creating a professional career (Super 1992) and aware of the need to develop managerial skills.

Leadership in the opinion of the millennial generation

One of the key issues raised in the research was to learn the respondents' views on how leadership is understood. The respondents were offered three statements, from which they could choose the one that best describes leadership.

The largest percentage of respondents, 54.1%, chose the answer that described leadership as "the ability to effectively influence people by releasing their strength and potential in order to enable them to pursue the greater good." A much smaller percentage, 25.9% of the respondents chose to define leadership as "the relationship between those who want to lead, and those who respond to their call and want to follow them. This relationship is based on mutual respect and trust." A slightly smaller percentage (20%) indicated that leadership is "a relationship of influencing others, the ability to lead more or less numerous groups of followers." The answers' cafeteria was very similar; it differed only in the second element of the definition defining the goal and the process conditions. The respondents' answers imply the statement that the definition of leadership including the goal in the definiens gained the most indications. On the other hand, the smallest percentage of respondents agreed with the most general definition of leadership.

It was interesting for the researcher to seek the respondents' associations with leadership. Among the proposed cafeteria, they were to choose one most appropriate term. The results are presented in Figure 1. More than 55.3% believed that leadership was related to management. Many fewer, 19.4%, indicated that they associated leadership with strategy. Creativity was chosen by 9.4% of the respondents. Other leadership factors considered necessary by the researcher in the aspect of contemporary challenges gained little respondents' favor. The partnership was chosen by 4.7%, trust by 4.2%, and openness to change by 4.1% of the respondents. The lowest percentage (2.9%) indicated intuition.

Fig. 1: Leadership factors in the respondents' opinion (5)

Source: Own research

Another issue raised in the research was the question of the conditions that should be met to become a good leader. 42.4% of the respondents expressed the view that a good leader *needs to have the authority and respect of co-workers*. According to 18.2%, the *trust should be established in co-workers*. A slightly smaller percentage of the respondents - 17.1% -considered *experience as required*. According to 14.1% of respondents, *inborn qualities are necessary*.

Fewer respondents (4.7%) believe that it is enough to *develop leadership competencies*. The fewest respondents indicated that an *appropriate position in the organization is necessary*.

Fig. 2: Determinants of the leader

Source: Own research

The key issue addressed in the research was to find out about the respondents' expectations regarding the leader's competencies. The questionnaire included competencies in five areas, which the author considered the pool necessary for the 21st-century leader. The data obtained from the respondents' answers made it possible to rank the most fundamental areas of the leader's competencies and identify them, which are presented in Table 1.

Table 1: List of the most important leader's competencies

	Areas of leader's competencies	**Identification of areas**
1.	**Interpersonal and social skills:**	communicativeness, inspiring and motivating, building trust, working with people
2.	**Personal predispositions and development:**	specialist and expert skills, ability to solve problems, taking initiatives, personal development
3.	**Character and values:**	being honest and righteous
4.	**Focus on results / results and achievements:**	setting high goals, taking initiative,

		but also taking responsibility for team performance.
5.	**Master of change / strategy and flexibility:**	developing a strategic perspective, connecting the group with the external world, including the cultural one, anticipation, updating activities taking into account the organization's needs.

Source: Own research

The respondents considered the following competencies as the most fundamental ones: interpersonal and social skills, personal predispositions and development, character / values, focus on results / achievements, and the master of change, i.e. strategy and flexibility.

Interestingly, in the digital era, online operation, short messages, contacts via social media (Balcerzyk 2019, Groysberg and Slind 2012), the respondents considered that the most imperative thing for a leader is to have personal and social skills. In this area, the author included skills such as communication, inspiring and motivating, building trust, and cooperation with people. Undoubtedly, social competencies are a *sine qua non* condition for the leader's competency model (Balcerzyk, Zapala 2020). The ability to build trust deserves special attention in the field of social, interpersonal competencies. Actions taken in this direction favor positive relationships with others, identify common areas and goals and engage employees to act. Having social competencies allows the leader to create a team and make the team grow, and its members want to share their knowledge.

Personal predispositions and development are the competencies that gained the second position in the respondents' expectations. As the identification of this area, the author proposed specialist and expert skills and the ability to solve problems, take initiatives, and personal development. These predispositions and skills are called functional competencies in the subject literature (Balcerzyk and Zapała, 2020; Delamare Le Deist and in, 2005). Some aspects of the predisposition and development area related to finding oneself in a difficult situation and the ability to reflect and solve problems are part of the modern organization's leader's competencies.

Research shows that character and values are the third most crucial leader's competencies. The importance of the leader's character has been emphasized over the centuries. References to the leaders' values and qualities can be found in Greek and Roman mythology through Plato's "State". To this day, one can find supporters of the charismatic leader concept. The data obtained from the research show that the character traits and values represented by a leader are still significant for subordinates. In the literature on management sciences, particular importance is attached to the values shared by the organization (Koźmiński 2004, Bjerke 2004). According to Korzyński (2018), the subordinates' behavior is regulated by the norms and values functioning in a given organization. The representation of the professed values is, among others, organizational culture, which is sometimes more durable than organizational changes. Hence, the leader's values must be consistent with the employees' values and the organization.

Outcomes, results are a common measure of an organization's success in the market. Focus on results and achievements is an area that, according to respondents, was ranked fourth among all other areas of competencies. From the point of view of the organization, shaping this area determines its effectiveness. Effective organizations have high morale and high performance (Maxwel 2013). A leader who can build dynamics of action and has an impetus that is difficult to overcome is extremely valuable for the organization.

It would seem that in a modern organization operating in an environment marked by change, the area of competencies called by the author "master of change" would gain the greatest importance among the respondents.

It turns out that the result of the study puts it in the last position. The "master of change" was identified in the research by strategy and flexibility, which are represented by developing a strategic perspective, connecting the team with the outside world, including the cultural one, and anticipating and updating the activities undertaken to take the organization's needs into account. From the respondents' perspective, competencies in the area of such activities are not the most important for them.

Conclusion

A highly effective leader is the best ally of a real vision and mission. However, it should be noted that the leader cannot lose shared values and character while pursuing the goal. Through his/her strength and dynamics, he/she makes people follow him/her. In pursuit of their goals, people develop, trust each other, learn from each other, and support each other. The changes taking place in the organization's environment and the willingness to face new challenges make organizations look for new leaders. Consequently, leaders are continually looking for new challenges. They must remember that listening to their followers' needs should be of crucial importance to them. All this will get any venture into action. According to Generation Y, the main associations with a lead are directing and strategy. The priority leader's competencies in Millennials' expectations are determined by interpersonal – social and specialist - expert skills and their development. The determinant of a good leader is to have authority and respect among co-workers and build their trust. Therefore, the challenge is not easy for the leader since young employees expect the synergy of personality, predispositions, and team management skills from the leader in achieving the goal presented to them.

Abstract

Purpose: The objective of this paper is to generate a better understanding about studies related to general logistic trend and customer behavior due to supply chain and logistic trend, and detailing about its impact in a specific geographical area (UAE). **Design / Methodology:** Substantial study on the relevant subject and its data base with an aim of covering as much area as possible by collecting inputs from various types of industries as well as various types of people in different age groups. **Findings:** This paper highlight the details about the organic and operational impacts underwent in UAE trading sector due to the changes happened in Supply Chain and Logistics arena. According to this paper, impacts underwent in UAE trading sector can be segmented into: 1) changes undergone in trading sector in UAE due to global trend and new approaches on Supply Chain Management and Logistics, 2) benefits obtained by importers / exporters in UAE due to global changes on SCM and Logistics , 3) analyze and identify the customer / consumer benefits locally and internationally in UAE due to new trend in SCM and Logistics and 4) analyze the process changes and its differences between conventional SCM and Logistics with new trend. **Research Limitations and Implications:** The main challenge and limitation faced during the survey was related to the geographical area of coverage and the availability of sample size. Based on this point, this study could be magnified or extended by collecting a large size/ data of samples from another geographical area / country which is more easy to access. In another words, there is a unique opportunity to conduct this study to another country with a for a larger sample size. **Originality Value:** There is a vast scope on this study considering the fact that Supply Chain and Logistics industry have underwent a day night difference by the last couple of decades. This paper does a deep dive on trends and its subsequent impacts which are visible in the trading industry . Considering UAE is a main hub for trading into Middle East and Africa, implementation of trends were fast considering to other regions. Technological evaluation and its impact we very well seen in this specific area which are detailed in the paper.

Keywords: SCM, Supply Chain strategy, Logistics Trends, Impact on SCM in UAE.

Introduction

Logistics in general is termed as movement of a product or service from one point to other to cater some needs / requirements. The products, services and resources controlled and managed in logistics can consists of mostly physical products such as FMCG products, finished machinery / equipment products, live animals, fluids and liquids. Apart from this, abstract or virtual items, such as energy, time, elements of information can also become part of the products in movement. The logistics related to physical products generally includes the integration of flow of information from point to point, handling of products / material, production of the products, packaging the product prior shipping, inventory handling, transportation of the item, warehousing the product, and often security part of the whole process.

Cite this Article as: Lalu PILLAI, Harsh PUROHIT and Santhosh KUMAR "Literature Review & Research Gap: How Global Changes in Supply Chain Management and Logistics made impact on Trading Sector in United Arab Emirates (UAE)" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Though logistics business consists of many activities, a conventional study of Logistic and operations management mostly affects the fields of infrastructure in Logistics, facilities of transportation, and planning of inventory. "Supply chain management can be broadly state as the systemic and strategic coordination of functions involved in a business, and the strategies and policies affecting the functions of business in a particular organization and across the whole businesses within the umbrella of supply chain, for the objective of productivity enhancement and long range (extended) performance of a certain company and the supply chain as a whole." The terms "Logistics" and "supply chain" are academically and industrially correlative, the reason of this common similarity nature is, both these factors are extremely related and pertinent to the circulating this product in its whole product life cycle, and both of these are highly considered as the core aspect of competitive review or evaluation of "model management science"

The United Arab Emirates is commonly and generally known as UAE which is a union of seven emirates, and its own monarch rule is applicable on each Emirate. "The seven Emirates - Abu Dhabi, , Dubai, Ajman, Ras al-Khaimah, Fujairah, Umm al-Quwain and Sharjah," - form jointly the Federal Supreme Council, which chooses a president every five years. After the independence in 1971 from Britain, President of UAE is always nominated as the ruler of Abu Dhabi and Vice President and Prime Minster is the rule of Dubai. Abu Dhabi is the capital of UAE and it holds the high degree of autonomy. UAE is strategically located in this Arab region and Middle East, and having border with Arabian Sea, Persian Gulf, Saudi Arabia and Oman.

Changes Undergone Due to New Approaches on Logistics and Supply Chain Management

Logistics industry in Gulf Region has enjoyed a huge growth and high reputation in recent years, and though there was a recession and hard economic climate, it has reasonably performed well. Being a core element for several GCC countries' future development plans, Logistics industry has always considered as a pivotal factor and it played as a fundamental pillar of regional economies. The rate of growth of logistics market in this region is high compared to other market segments. As per Saudi Gazette dated 13th July 2019, Its recent growth recorded is 7.3 per cent which is expected to touch a dollar value of $66.3bn by 2020 . In 2015, logistics accounted for 10 per cent of the UAE's figures mainly due to UAE's aggressive diversification and development plans. And the Middle East region's mounting competencies have supplemented international acclaims and due recognition. Based on "World Bank's recent Logistics Performance Index", UAE ranked 11th out of 160 countries, outdoing the countries such as Canada, Denmark, France, Australia and Finland "(https://lpi.worldbank.org/international/ scorecard/radar/254/C/ ARE/2018)" Compared to other Middle East emerging countries UAE ranks first in the list. Agility, a Kuwait based logistics firms report shows in January 2018 that among 50 emerging markets, UAE is the third best logistics centre in which China ranks first, followed by India on second position. Bahrain is on fifth position, followed by Oman in sixth and Saudi Arabia in seventh slot. (https://www.agility.com/interactive/2018index/) Though the external view proposes plain sailing, there are so many replicated challenges, tests, changes and developments that regional logistics firms must withstand with and familiarize to in order to keep themselves at the front of the leading list.

UAE became the third highest logistics centre out of 50 emerging markets just because of its investments in infrastructure and ease of doing business across the country. UAE's rank slipped one place since economic boom in India helped them to sped past with reforms to take the No 2 position just behind the emerging markets leader China. Size and growth appeal establishes 50 per cent of the overall assessment. Compatibility and connectedness each added up for 25 per cent of the overall score. UAE was ranked first in terms of market compatibility which evaluate ease of doing business, business ambiance, market risks, opportunities and other key values. It was also ranked No 1 in terms of market connectedness, just because of the highly developed infrastructure. Market compatibility for the top 10 includes all six Gulf countries. UAE has invested a huge amount in IT systems to enhance the total supply chain operations productivity as well as to reduce the supply chain visibility and to educate the managerial persons. The following trends can be noted:

- To have an improved productivity from better planning and Decision making, IT system with an added transactional processing element has been applied in UAE and various efforts are made to apply more technically proven IT systems. Most of the respondents given high priority for analyzing logistics productivity and using IT system tactically and systematically.

- Long implementation time and Insufficient IT resources were the key hurdles for IT utilization to support operational logistics activities. These were the problems and issues pertaining to low quality project management skills. Companies in UAE recruited additional head counts who are skilled, qualified and experienced in process planning and implementing projects which supported them to sensibly implement outsourcing activities both in the preliminary setting up phase as well as during its ongoing day to day operations.
- UAE was able to deliver IT solutions that can provide results rapidly to the requirements of the business and that provides value now without giving an additional burden to IT costs later, which helped to maximize and increase the presently existing investments while budgeting a major portion of infrastructure and resources to developing / widely increasing IT resolutions that can highly influence technological and process innovation vs. maintaining and managing the existing / current solutions.

The Literature Review Based on The Proposed Objectives

Changes in UAE Trading Sector due to global trends and new approaches on Supply Chain Management and Logistics : According to "Bowersox, D.J. and Closs, D.J. (1996)" "Supply Chain industry has been highly influenced by the exponential growth of big data. Data can be helpful as well as disruptive in a business. According to Sundarakani, B,et.al.(2012) Supply Chain Management (SCM) productivity and success of few specific companies in the United Arab Emirates (UAE) is purely based on systematic application and implementation of Information Technology (IT). This was possible mainly based on a qualitative analysis which they performed within the organization. This paper focus on the main pillars of IT which enhanced the SCM performance from a user / beneficiary's perspective. The data analysis and survey results have highlighted that the key respondents are well aware that implementing new IT system does not necessarily fetch or produce immediate results / benefits, but in a long run it would be highly beneficial financially and from a process perspective. The study detailed a study the IT impact Supply Chain Management in UAE. This details about the Modern concepts in IT and its beneficial usage in Supply Chain Management. According to Cooper, M.C., et.al. (1997) "The outsourcing has always started from in its most basic of forms. Example are outsourcing of management of canteen, management of building and security, computing service etc.

Revenue benefits due to global changes on SCM and Logistics : According to Dittmann, P.J. (2013) "A purchase decision is always made based on cost of goods and services by any business than just competing on price. According to Ballou,R.H, et.al.(2000) "in their work on SCM said that Changing market condition demand to streamline the critical barriers such as Supply Chain Planning and Optimization. The inability to dynamically adjust to the demanding environment and executing plans in response to changing market conditions are the most important challenges now a days

Analyze and identify the customer / consumer benefits due to new trends: Hines, T. (2004) details about "Supply Chain Strategies, Customer Driven and Customer Focused strategies", and it highlights the main challenges facing organizations while designing, implementing a successful Supply Chain strategy in global environment. This specifically indicate that three main factors such as Customer Focused Strategies, Customer Driven Strategies and Supply Chain Strategies, are in a closed process circuit of any organization. According to Foster, T.A. (2006) "Business today is very competitive and going through a highly professional and global environment. Irrespective of location or market base, this scenario forces companies to consider the whole world in their marketing and competitive strategy analysis.

Visible process changes with new trends: According to Ballou,R.H, et.al.(2000) "in their work on SCM said that Changing market condition demand to streamline the critical barriers such as Supply Chain Planning and Optimization. According to Beamon, B. M. (1999) "Performance management and its review is running through a process of starting with supply, to manufacturing to arranging / planning distribution and finally to the consumer / end user. As part of conventional performance measure, this study highlight the point that, selection of elements related to performance measurement is an important step in the design, planning and evaluation of any system. Measuring of a performance becomes difficult once the system becomes larger and complex.

Methodology

The overall methodology adopted and considered in this study would be descriptive research type. The core goal or objective of descriptive research is to describe a phenomenon and its attributes and characteristics. This research is more focused and developed on what rather than how or why a case is evolved or aroused. Based on this point, observation and survey tools are often used to gather data (Gall, Gall, & Borg, 2007). As widely know, in these kind of studies, the data may be collected qualitatively, but it is often analyzed quantitatively, using frequencies, percentages, averages, or other statistical analyses to determine relationships.

Analysis projected or stimulated by descriptive questions is primarily focused to discover facts, not to test theory. "The hypo is not causal but simply that common perceptions of the facts are or are not at odds with reality" (Pinsonneault and Kraemer, 1993, p. 80)

Even though a variety of methods are available in the descriptive research, survey method is chosen with the objective of eliciting detailed information from a large number of respondents. Researchers understand survey method as the way of providing right answer questions that have been aroused, to resolve hypothetical and general issues / problems that have been came up, to assess need of the study and set the goals which are to be achieved, to evaluate and confirm whether has met the pre-determined objects or not, and most importantly, to set a milestone and baseline for future comparisons and studies to measure trends across a certain period of time, and in general to describe and determine what exists, in what amount, and in what context." (Isaac & Michael, 1997, p. 136). Because the research was considered descriptive, the best option was to go for a questionnaire survey which fits as an appropriate approach (Bailey et al., 1995). A questionnaire administered by the interviewer is utilized as this method is helpful in collecting data based on appropriate classification of questions wherever needed. Apart from this, the method guarantees higher rate of response from the respondents since the questionnaire are objective based.

Descriptive statistical analysis is resorted by using statistical tools such Frequency "Analysis, Fisher's Exact Test" and "Kruskal Wallis Test" for analyzing and assessing the demographic variables. The research findings are tabulated to give a clear and concise information about the findings. The findings are shown with the help of graphical representation tools, diagramsand tabulation tables. For precise and accurate analysis of the data under study, advanced statistical software such as SPSS is used so that the human error can be reduced to the minimum.

Literature Review

Supply Chain and Digital technology : According to "Bowersox, D.J. and Closs, D.J. (1996)" Supply Chain industry has been highly influenced and affected by the exponential growth of big data. Data can be helpful as well as disruptive in a business. Cost optimization, responsiveness and greater integration are most visible while a historical data based process is set. According to Cooper, M.C., et.al. (1997) The outsourcing has always started from in its most basic of forms. Now a days even core competencies of a company is also delegated out or used for outsourcing. It is said that 'Anything which distracts a company from their focus will be considered for outsourcing'. Even with all these minimum 75% of companies outsource at least one element of Supply Chain Management. Creating the greatest value , productivity and achieving the organizational goals does not require them to own, manage, and directly control all of their assets, processes and resources. As per "Supply Chain 4.0 – the next – generation digital supply chain published by Mckinsey and Company in Oct, 2016", Digital supply chain is mostly applicable to the trade of books, music and film. However, now a days this is also conceptualized to include business to business services and the best example is fashion design and R & D - product development.

Demand Planning Begins at the end of the Cycle and Measuring Supply Chain Performance : Demand Planning process begins with a statistical forecast. Data sources for the forecast will contain Sales Orders Plan, Contracts received from customers, Orders received from intercompany and finally from the key stakeholders such as from suppliers. According to Ballou,R.H, et.al.(2000) in their work on SCM said that Changing market condition demand to streamline the critical barriers such as Supply Chain Planning and Optimization. According to Beamon, B. M. (1999) "Performance management and its review is running through a process of starting with supply, to manufacturing to distribution and finally to the end user/ consumer". This specific study details the analysis of supply chain performance indicators and measuring tools which are extensively used in various supply chain processes /models and further it gives a an idea to create a framework for right selection of PMS (Performance Measurement System) which can cater as a solution for supply chain related issues.

Supply Chain Strategies: Out Sourcing, Customer-driven and Customer-focused: Non-core competencies associated in an organization will consume time, energy and workspace and help management to defocus from their core objective. This is a huge change compared to conventional supply chain approach. According to Chopra, S. et al. (2004), Companies are constantly focusing on what they regard as their core activities or competencies. Hines, T. (2004) details about Supply Chain Strategies, Customer Driven and Customer focused strategies. It highlights the main challenges facing organizations while designing, implementing a successful Supply Chain strategy in global environment. Further this paper details that the texture of supply chains in commonly found industries which includes global and local organizations. More over this paper focus on various geographical locations and its advantages in the globe in order to manufacture a product by taking the advantage of geographical location which can be marketed to consumers / customers globally and locally.

Globalization impacts, increased competition and Pricing in Supply Chain Management: According to Foster, T.A. (2006) Business today is very competitive and going through a highly professional and global environment. It is prominent to consider that most of the global firms have changed the operational way in which they handle / manage their Logistics Activities. Value added service to a business sector can be only provided by Supply Chain process. According to Dittmann, P.J. (2013) A purchase decision is always made based on cost of goods and services by any business than just competing on price. A value added service on other areas are very important as well. This is why supply chain impacting in a huge way in pricing structure and competitive edge.

Additional Values are added to the Business Process through new trends in Supply Chain Management: When an increased market share or revenue is discussed, most of the business leaders will think and discuss various ways of lowering the prices on their products or services. Since price is a vital and influential component to any purchasing decisions, buyers will also opt to develop value from aspects other than the price-to-value ratio of a product which they wish to procure. A review of these value added components will lift the business more efficiently, produce more proficiency, efficiency and optimize the complete supply chain and that would allow the business to increase the over all added value services / offerings to the customers.

Logistics performance : On "Global Smart Logistics Conference in China" (2017) Bert Hofman states that efficient logistics bridge organizations to local and international markets, and further it influence the productivity and efficiency of global value chains pertaining to manufacturing and competitive edge of a country's economy within the pre-set value chains. According to Chow, G.,et. al.(1994) logistics changes are considered to be the main driving force for the competitiveness of an organization and a specific country which is basic factor to job creation and economic enhancement / growth. The journal highlights how GDP per capita and Logistics performance measure are inter-related which is the back borne of an economic development. This study detailed about economics built around trade which details mode of payments, mode of shipments involved in a trade etc. In the technology side, this details the need and use of modern technology in to Logistics side. Further this details about the role played by WTO.

Structural changes in logistics: how will port authorities face the challenge or a fundamental change According to Notteboom, T. E., & Winkelmans, W. (2001) market environment related to port and port operation around the word at a specific time period. As per their study, the market environment pertaining to port operation has considerably and dramatically changed recently. The paper states that this is a continuous process which poses lots of challenge to the port authorities. Import / export process is discussed in details right through the paper. This also discusses the impact associated with structural changes in international arena of trade, international business transactions, transportation and shipping industry in view of strategic and operational issues related to port management. This paper is one of the most vital study in terms of conventional / operational changes within the last 10 years.

Strategic alliances in the container shipping industry : a global perspective: As per Slack, B ,et.al.(2002) recent alliances strategically made in the shipping industry is the prime logistic trend which is highly positive from operational perspective. The paper has a deep dive on recent developments in container shipping industry in view of the formation of strategic alliances by leading logistics movers. This study detailed about strategic alliance and its benefits around the world. Container sharing all aspect been detailed here. This paper is detailing global aspect of strategic alliance and cooperation between shipping lines and not limited with to a specific region According to Tavasszy, L. A.,et. al.(2003) "Logistics process and chains which are constantly changing to promote increasingly global movements". In another words, tailor made products for a certain region or product customization and shortest delivery cycle are the most demanding / challenging trend in logistics service. The study on this paper further shed

light and highlights the inter-relationship in global and local arena between logistics, trade, and transport. Tavassy's study is very prominent since this does not go on wide angles or various logistics trends rather it focus on few trends in depth and details.

The Importance of Logistics Information Technologies and Knowledge Management Capabilities on Intermediaries' Performance : According to Yavuz, M (2017) in a cut throat competitive market, profit making by an organization is totally based on strategic steps. This paper emphasis that since technology is evolving on daily basis, to create an effective and competitive logistics strategy, any company needs a centralized or core logistics Management. Further, this chapter runs through LIT – Logistics Information Technologies and KMC – Knowledge Management Capabilities and indicate that LIT and KMC are vital for a supreme performance on any organization.

Digital export towards U.A.E. : According to SARTOR, G. (2017). the mode of trade in UAE, specifically in fashion industry. It details that in recent years, B2C and B2B2C E-commerce has become a vital element and gained a strategic importance in all parts of supply chain including, distribution of raw material / finished products, local / global trading, collaboration of partnership business and most importantly in export trade. This study goes into the details and express that "Physical distance is greatly reduced". As per this study, many global players and corporations prefers E-commerce which predominantly nullified many obstacles posed by traditional, channel based distribution. This study specifically details the way fashion trade is spread over UAE. Further it details how logistics and supply chain helps fashion trend and its traders to satisfy their customers in UAE.

Blockchains for supply chain management: Architectural elements and challenges towards a global scale deployment : According to Litke, A(2019) Blockchains are attracting the attention of stakeholders in many industrial domains, including the logistics and supply chain industries. This study provides, a detailed explanation on methodological side, the way how blockchain plays a role in supply chain and the way it is fit for the supply chain industry. Study details, the pivotal role blockchain plays in scalability, performance measurements, consensus of mechanism, privacy considerations, importance of location and cost. All these factors are directly or indirectly influenced by blockchains and the study gives a detailed outlook on the same.

Conclusion

Study related to general logistic trend and customer behavior due to supply chain and logistic trend, and detailing about its impact in UAE was made which helped in understanding the following. 1) changes undergone in trading sector in UAE due to global trend and new approaches on Supply Chain Management and Logistics, 2) benefits obtained by importers / exporters in UAE due to global changes on SCM and Logistics, 3) analyze and identify the customer / consumer benefits locally and internationally in UAE due to new trend in SCM and Logistics and 4) analyze the process changes and its differences between conventional SCM and Logistics with new trend.

There are multiple factors which makes this study very significant. The researcher compiled globally effected changes and trends of two different but inter – linked processes, and measuring its impact depth in a selected geographical arena where trade is one of the most important financial activity. The researcher found various factors that made it valuable to any organization, any business sector, marketers and consultants, government as well as research individuals.

UAE market is highly competitive in the sense that various traders are competing each other with cut throat competition mode. The researcher highlighted the fact that a company who sustain in this market will have to have a superior customer support platform. The global changes identified in Supply Chain Management as well as Logistics are proven elements for improving customer satisfaction if it properly applied in an entity. This makes this study prominent in this region.

The research work is conducted systematically by applying statistical tools as employed by researchers in similar studies. The approach to study based on research methodology has given ample opportunity to deploy the collected data based on a step by step approach so that the data could be used effectively by sharply focusing on the core objective of the study. This approach has enabled to perform the data analysis in a more systematic way so that relevant information could be drawn by deploying the apt statistical tools.

Abstract

Now a day's child security is an essential area of concern. Recently, a crime against children is increasing at higher rates, and it is time to offer a safety system for the kids and objects. Tracking kids and individual objects remotely are the main goal for every for safety protection. There are various systems used for tracking the position of objects such as a car, but there is no such system made for tracking a human being. The paper provides a smart, inexpensive solution for preventing losing kids while going out alone or with their parents based on the Internet of Things (IoT). Our proposed system ensures maximum security and ensures live tracking for their kids. This paper proposed a model for child safety through smartphones that can track their children's location and give the exact coordinates of the child's location in real-time anywhere. In case of emergency, children can send a quick message and its current location via Short Message services. This proposed system is validated by testing on the Android platform. The correct operation of the system verifies the proposed system.

Keywords: IoT, Smart Kids Tracking, Arduino, Smart Object Tracking, GSM.

Introduction

Many cases of missing children are reported. Parents always worry about the possibility of the kidnapping of their children. Children's Tracking system becomes more critical worldwide to assure parents that their wards are safe from suspicious actions. Today, smartphones are the basic need of the user. These smartphones provide lots of features that make our life so simple and more straightforward. This paper is focused on the safety of children. Today child safety is an important issue globally as child crime is rapidly growing across the world. In this paper, we build an IoT system connected with a smartphone to provides tracking the children. When the child is crying, the mobile app is sent to parents through text message to their Android mobile device. Android terminals have internet and GPS, GSM, SIM card.

Nowadays, the Internet of Things (IoT) has a central role in most of our regular lives. IoT contributes to connecting several fields such as industrial applications, homes, healthcare, automobiles, entertainment, sports, and many different areas. (Chaudhari et al., 2015), (Rajaram et al., 2016) studied the importance of applying IoT-connected appliances in our life. Many other researchers, known in the literature on IoT applications, such as (Abdul.Elminaam & Alenezi,, 2017), (Abdul.Elminaam et al., 2019), (Abdul.Elminaam & Awad, 2018), (Abdul.Elminaam, Abd-ELfattah & Ali, 2018), (Abdul.Elminaam, Alenezi & Ali, 2018), (Stankovic, 2014) explored IoT applications' importance in our lives. When the Internet of Things cooperates with the Internet of Services, it will provide users with services that are aware of their surrounding environment and enlarge our social communications with other people and objects. The most recent IoT fields are smart systems, such as smart homes where various multimedia services are attached and embedded into electronic appliances and supported with high-quality full-duplex communication channels. Recently, researchers have made extensive efforts on smart home technology (Sudhir, 2007) to enable humans to fully control their home appliances from a remote location in full swing. By ingathering humans, home, service, and community domains all together are becoming possible by the wide use of the clue of smart home with IoT technology. In the Internet of Things systems, where many objects are connecting through the internet, big data is produced. Researchers have suggested new different IoT applications, such as smart wearable devices, smart home appliances, e-health systems, etc. (Jiong et al., 2014), (Castillejo et al., 2013), (Mitton et al., 2012).

Cite this Article as: Diaa SALAMA ABD-ELMINAAM, Rasha ORBAN and Fatma SAKR"IOT Based Smart Life Saver System for Kids and Objected Tracking" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In (Alduais et al., 2018). focuses on kids and children's safety by sending warnings to their parents about the danger around them. Similar research was developed in the same area to monitor the school buses until they arrived at their school, which made many parents satisfied with the safety level. More developments are performing on sending the child's place or the body they are installed

IoT systems are the primary source of the evolution of usage and penetrated the user's life. The main idea of IoT refers to when everything is being connected; you can do many things you were not able to do before, while information transfer between sensors and actuators devices are allowed. Recently, advances in technology support many features such as adaptability, real-time monitoring, and traceability (Atzori et al., 2010). IoT applications can be observed in several areas such as home, human life safety, agriculture, health, and so on. Generally, these are prefixed by the word "Smart," Ex. Smart Kids Life Saver.

The IoT connects everyday objects to the internet and facilitates machine-to-human and machine-to-machine communication with the physical world . The IoT aims to bridge the gap between humans and technologies via simple or complex objects. These objects make the interaction between humans and their surrounded environment is applicable. In other words, delivering any sort of information or command is transmitted through sensors and actuators that may be integrated in vehicles, buildings, and common environments (NasneenFathima, 2016).

The purpose of the proposed paper is to develop an embedded system for a kids and objects tracker system; this system allows the parents to locate and track their child in real-time with great peace of mind to parents who will save many kid's objects loss. The system is interfaced with a mega 8266 microcontroller programmed in embedded C language.

This paper focused on the security domain in which the IoT applications are used to protect people, cars, and things from kidnapping through tracking. As a result, these cases require a unique system that helps parents locate their children and reassure themselves that they are in a secure place. Consequently, it must be an application to solve this thorny problem.

The proposed system provides a solution to this problem, using sensing technology and a smartphone application, and providing a better service at affordable costs. More specifically, it 3

Adapts a popular technology that combines a smartphone application with a microcontroller. The application will use Global Positioning System (GPS), Global System for Mobile Communication (GSM), and General Packet Radio Service (GPRS) technology that is one of the most common ways for tracking. A device is also embedded inside the child's bag, whose position is determined and tracked in real-time.

The remainder of the paper is structured as follows. We provide related work and background on IoT technology, including discussing the Role of IoT in Smart Life Saver Systems. Moreover, discuss system architecture design in the second section. System development is addressed in the third section, and In the fourth section, we discuss the system implementation, is given. The paper concludes with a summary of this research's main findings and possible future research lines to be explored in the fifth section.

Literature Survey

In this section, we discuss previous studies which were interested in explaining and developing smart kids and objects tracking with various approaches and methods as follow:

Rajput et al. (2019) implemented a children tracking system device for children attending school. The significant advantage of this wearable device is that it can be used in any cell phone type. This device helps parents know their child's location using WiFi and Bluetooth services embedded on the device. However, WiFi and Bluetooth cause some leakage in response between the parent and child, so it is considered an unreliable medium of communication.

Thakur et al. (2019) aimed to develop a Smart IoT system for child tracking to help the parents locate and monitor their children. If the sensor reads any abnormal values, then an SMS message is sent to both parents' mobiles, And MMS indicating an image captured by the serial camera is also addressed. They used the LinkIt ONE board programmed in embedded C, but the disadvantage of using this board is its high cost.

Chaudhari et al. (2020) aimed to design and construct IoT systems by using the LPWAN technologies rollout network, which is used worldwide. This Low Power technology for vast area networks is a recent solution for Kids Tracking GPS devices problems. This type of technology uses and transmits low data rates, which will reduce the required processing power.

Gupta and Harit (2016) By smartphone availability, they proposed a highly increased security system and kept live tracking for children to determine their children's location, especially in emergencies. Children can send a quick message and their current location via Short Message services. The system is validated and tested on the Android platform.

Baruah1 and Dhal1 (2019) proposed an IoT secured object tracking system where a cloud server manages the tracking media. The proposed research's main feature is to enable the customer to go offline without estopping the travel status update task. The outsourcing of the travel status update task has been handled without compromising the security and privacy level. The difficulty is the use of homomorphic encryption, which in turn increases the computational cost.

Luo et al. (2019) suggested a novel predictor module called active tracking. The system directly predicts the next actions in the camera behavior rather than the objects tracking outputs. The reinforcement learning techniques are used to control and deploy systems, but this requires high computation complexity and long latency time.

Zhang et al. (2019) Developed and designed an object tracking system. The system requires lightweight computing time, limited computing capacity, and memory space to realize tracking. They have proposed a new algorithm for region correlation filter fitting for edge devices been used. The mentioned used technique can fit most IoT devices to keep relatively high accuracy but for objects only.

Banduch (2018) have been built a product for parents and kids safety keeper with a security AWS partnership. They also have offered a network-based solution rather than a SIM- card based security solution. They have produced an IoT enabled tracking child tracking wearables or smartphone devices, but the devices have failed to live up to user expectations because of being bulky or too large for little wrists size. They used security issues with tracking devices for system hardware: Encryption keys and Unsecured Bluetooth. Bluetooth Low Energy (BLE) devices create connections with smartphones with quick authentication but not reliable for use.

Kolaskar et al. (2016) has discussed the design and the implementation of real-time and offline GPS trackers using the Global System for Mobile Communication (GSM comm.), Arduino, Storage Card (SD), and SIMShield. The system applied for vehicle security applications. The system behaves as a coordinator for the user who received a registered user's location who made a call on a number provided with a GSP application attached to an Arduino microcontroller. The collected data have automatically stored on SD at the same time to be used next in the case of an existing geographical location is offline.

Saxena et al. (2015) has developed an anti-theft vehicle system that stops the stolen vehicle and tracks its location through the embedded GPS and GMS devices as well as a web application. When the owner or any authorized person drives the vehicle or operates it remotely, the system is converted to the sleeping mode. However, The control signals which cause the vehicle engine to stop or cease are issued when the theft is discovered, so the responsible people send SMS to the microcontroller. The system will be reset in order to restart the vehicle. This application protects the vehicles from theft, so it is more security parks.

In (Nandini et al., 2019) focuses on implementing a child tracking system for every kid or child wandering home or staying home alone. If the child is pressed on the panic button on his watch in the proposed system, the message will be sent on the parent's mobile and the child's location in terms of Latitude, longitude, and location. Parents can be creating a profile in the android application. In this application, the parent can be adding contacts and locations. After that, parents can be seeing the list of previous add contacts and locations. After messages arrive in the receiving message box on the parent's android application, parents directly read the message and see the child's current location on Google MAP. These proposed tracking devices can be worn as wristwatches (Saranya & Selvakumar (2013).

Many other researchers who are recognized in the literature on different IoT applications , Optimization and Metaheuristics algorithms such as [Abd Elminaam, D.S.(2020)], [Elminaam, D.S.A.(2018)], [Elminaam, D.S.A . (2018)], [El-Ashmawi, W.H.(2019)] ,[Abd Elminaam, D.S.(2019)], and [El-Ashmawi, W.H.(2020)] studied the optimized solution for complex problems. As a result of the collected information, we decided to combine all the features that the previous attempts worked on to enhance the expected results' efficiency.

Taking into consideration all of the mentioned work, other works considered Tracking Kids and constraints in their models for tracking. In this paper, a model that handles different constraints in the tracking will be formulated. This model made tracking in real-time and decision dynamically at runtime. We also provided this framework with new tracking protocols. The proposed framework is tested using mobile applications that were developed using Android.

The Proposed kids and objects tracking system

This section demonstrates our proposed kids and objects tracking system for using IoT. Designing a child tracking system to assure parents that their child is safe from suspicious actions. The information of the child being missed is sent to the respective parent's mobile if they move beyond the coverage area. Also, when children want to convey that they are in danger, they will press a panic button on their school i-card. Mobile terminals have internet. It adopts message from the child and delivers to respect parent android mobile using internet

Kids and object tracking system by GSM uses Arduino powered by battery, as Arduino is the mastermind and organizes all the system processes(see Fig.1). It is connected to sensors (X, Y types). The sensor knows the state of the body for its Pitch or Roll; also it exists in the system connection between Arduino and Smartphone are made by a device called See Shield Interface which transfer and translate information from the smartphone to Arduino and vice versa.

It also helps the child ask for help by sending SMS with the location in the message. The energy needed by the device ranges from 9-12 volts to a small battery that gives Arduino energy to work, and Arduino feeds its sensors.

Fig. 1: The architecture of the overall system.

Fig. 2: The System Response With SMS

There are many components of this architecture(see Fig.1), which are the following:

- **Power supply**
- **Arduino Mega board (ESP8266)**
- **Shields**
- **GPRS**

Before we continue, we should know some idioms or definitions that make it easy to understand our work, such as Arduino, shield, and GPRS.

- **Power supply**

Power supply is a single supply voltage 5V. In some cases, the ripple in a transmitting burst may causes voltage drops when current consumption rises to typical peaks of 2A. To the power supply must be able to provide sufficient current up to 2A.

- **Arduino** is an open-source platform used in building electronics systems. Arduino consists of both a microcontroller (a physical programmable circuit board) and a piece of the software component, or IDE (Integrated Development Environment). IDE is the platform that runs on our computers and is used to "write" and "upload" computer code to the physical board. Arduino Mega is a release from the Arduino family and is compatible with most of the shields designed for other Arduino boards. We must make sure that the shield's operating voltage is compatible with the board voltage before we intend to use a shield. Most of the shields operate at 3.3V or 5V, which is compatible with our used board. If we intended to use shields with higher operating voltage, the board could be damaged.

- **Arduino Mega board is an A**rduino MEGA 2560 With a Built-in WiFi "ESP8266" component and has a Pigtail connector for an antenna. It is an excellent board because we would have a massive benefit if we connected the antenna on this device. We increase a far distance reach, measures from 90 meters to 240 meters away, contributing to our kid's tracking system. This board has an important feature, which is *selector switches*. The first selector switch allows the ESP to interleave the connection between the two terminals TX0 and TX3. The second selector switch is the "DIP" Switch. The board has a crucial recording mode of the ESP8266. All the pinning is entirely and is compatible with the ATmega pinout.

Fig. 3: Arduino Mega With WiFi Built-in

- **Shields** are pre-built circuit boards and are used to fit on the top of the Arduino microcontroller. The shields provide additional capabilities like connecting to the internet, controlling motors, controlling LCDs or LEDs screens, providing cellular or other wireless communication, and much more.

Fig. 4: Shield Application On Mobile

- **GPRS** is an abbreviation for "General Packet Radio Service". GSM was firstly designed for a circuit-switched network type. Nextly, GPRS has added packet switching functionality to the GSM networks. GPRS was added to GSM specifications in 3GPP Release 97 and used in Releases 98 and 99. This has enabled us to deliver the internet on mobile devices connected to the GSM network. Customers have to check whether the GPRS feature is available on the mobile they need to purchase. GPRS offers faster data transmission rates.

Fig. 5 : Switch on / off and XY Sensor

The Proposed System Implementation and Configuration

When the pitch & Roll sensor sends emails to Arduino, which do some logarithmic calculations and compared to what is already programmed, in the case of an increase in reading above the natural level, it is a non-nature of the body on which the device is installed.

The Arduino gives an order to send a message with the body's status and its location as the GPRS_GSM network continuously receives the site. This message passes through the shield interface, which translates Arduino's commands to the intelligent device, sending an SMS to the future and contains longitude & altitude.

You can also use the command key to start the process by sending a request for help message through Arduino, and then the Interface to a GSM device that sends SMS include the site identification.

For the proposed system configuration; We were using Arduino mega microcontroller use to store and process data quickly and accurately. It contains a 52 pin (input) used for both the data or the data's output. It is numbered from 1 to 52. we can improve it by adding other sensors. This type of Arduino also has a total of 15 exclusive access points to analog. Arduino can be connected to the computer through a USB connection and allow us to load programming codes that we have programmed on C code.

Arduino has designed a unique key to allow new code to load or modify, making sure that no other code is charged with the unintended error, which made it more secure. a LED light is added to show if Arduino works or not.

The sensor on the device is XSO match sensor, which calculates three variables X, Y, and Z. it contains five exits, one plugin, another for Earth, and the rest.

X is plugged into the A8 pin.
Y is plugged into the A9 pin.
Z is plugged into the A10 pin.

Results and Discussions

The propsed system results are shown in Fig.6, Fig.7, Fig.8, and Fig.9 . the selected operating system is Android to over all the features. SMS is used for communicating between the child side and the parent side. The application developed to make a user-friendly approach on both sides. The architecture of the proposed system depends on two Android phones one is on the child side, and another is on the parent side .

In fig.6, In this message, Latitude and longitude number, date and time, SIM card number through that message has come.

All results come positive; when we try it roll position, we find that the X-Y sensor accurately work. We find that by the moment of the rolling, which includes help request as it programmatically designs. We got the same result when it rolled to the left.

When it tried to above position pitch, we find that the X-Y sensor accurately work. We find that by the moment of the body coup, which includes help request as it programmatically designs when we know that on the child, it is easier to send SMS to request help from parents once we press the button.

Fig.6: Object Motion Tracking By GPS

Fig.7: The pitch & Roll status

Fig.8: The System Sends An SMS Automatically

Fig. 9 : Receptor Response When Seeing the SMS With the Object Location

We found that the performance of the proposed system varies from place to place. The results show us that the proposed system's functionality depends upon the cellular networks, and sometimes the working is poor due to low cellular connectivity.

Conclusion

In this paper, we developed a real-time tracking for locating missing children based on IoT. The study aims to child tracking and monitoring system based on GPS, GSM, GPRS modules and Arduino. The proposed system allows tracking children using the application of the IOT and identifying the coordinates of their locations in real time and at any place to protect them from losing or kidnapping by exploiting the IOT's technologies. This paper's proposed

solution takes advantage of smartphones, which offers rich features like Google maps, GPS, SMS, etc. The microcontroller used in the proposed method (Arduino MEGA 2560 With WiFi Built-in - ESP8266) .its official price is not high, available for more customers. In the future, we aim to resize it and increase the number of sensors and determine a specific zone for children. It sends a random SMS when the child or the object moves far from its zone. The results show the superiority of the propsed solution over other solutions.

Abstract

Fruits are foods with many human health benefits and since ancient times they have been a major source of energy with low-calorie content. For agriculture, fruit plantations represent a very important category due to the high incomes generated per hectare. The present paper aims to analyse the Romanian fruit market, both in terms of demand and in terms of supply, identifying the consumption trends of the population and those of supply. The research results reflect the current situation, as well as the evolution of the Romanian fruit market in terms of quantity consumed, market value, quantities produced, import and export.

Keywords: Sustainable Development, Organic Fruits, Fruits Processing, Fruits Supply Chain.

Introduction

Fruit growing is one of the main sectors of agriculture, offering assorted diversity on the domestic market. The fruits are eaten mainly fresh, being a healthy snack full of vitamins, but can also be eaten processed as dehydrated, dried, canned, jams, syrups, juices, frozen. Capitalizing on the production of Romanian fruits is important, especially in the fresh state being a quick and tasty snack. Also, the fruit sector contributes to the local economy through trade, both internally and foreign, the fruits market being a complex one that has continuous activity, and which is still developing in Romania.

The purpose of this study is the analysis of the Romanian fruit market, both fresh and processed fruits, to determine the level of its development in the period 2010-2019. The paper is structured in the analysis of the main components of a market, namely the demand for fruits and the preferences of Romanian consumers and the offer from Romania, which is based on both domestic production and imports. The main statistical indicators and their evolution were analyzed to identify the current situation of the fruit market and to present some directions, both for consumption and production, which will lead to the sustainable development of the fruit market in Romania.

Literature Review

Fruit production is an important part of Romanian agriculture, and the adaptation of varieties to current conditions as well as investments in appropriate storage and refrigerated storage and proper packaging for protection are important given that the author Pet (2014) states that due to the high degree of perishability of fruits that rapidly affect the

Cite this Article as: Gabriel POPESCU, Marian Catalin CUCU and Ioana PANAIT "Considerations on Sustainability on the Romanian Fruit Market – Production and Consumption Trends" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

commercial appearance. Due to the seasonal nature and the very high dependence of agricultural crops on meteorological conditions, in the absence of investments in crop protection or production insurance, the instability of fruit production affects the economic viability of companies especially through price fluctuations. (Turek and Ion, 2008)

Ion et al. (2008) emphasize that fruit imports are important for the Romanian market because the climate does not allow the production of fresh fruit throughout the year thus Romania became a net importer of fruits in order to cover the needs of the population. Marin et al. (2018) states that Romania has fertile and good soils for fruit crops, but the efficiency is low due to the lack of technologies at farm level and the low degree of associativity.

In the current context of globalization, of the desire to achieve the most sustainable activities, agriculture and the agri-food market are gaining significant importance. The rising trend of the consumption of organic products as well as the importance given to the traceability of the products from the producer to the final consumer are actions that define the desire to reach the notion of sustainability.

Granatstein and Kupferman (2008) they consider that sustainability is a direction of development of agriculture that includes horticulture and must consider the three pillars of sustainability through concrete actions to improve the agricultural sector. From the economic point of view, it is important the economic efficiency in the agricultural exploitation to ensure an improvement of the competitiveness on the market to obtain the economic viability. Horticulture and fruit production must ensure the food security of the population for the social pillar, and regarding the natural environment, the farmer must rely on an integrated management that ensures the rational use of pesticides. The adoption of a sustainable development of agriculture aims at a fruit production that has a minimal negative impact on the environment, while ensuring the safety and food security of the population and a fair trade. (Jemrić et al., 2017) Slavin and Lloyd's (2012) in their study assert that fruits and vegetables have a high content of nutrients and fibre while providing food with a high intake of vitamins and minerals. Also, Pem and Jeewon (2015) state that fruits are rich in antioxidants, and the consumer must consume a mix of fruits to benefit from their maximum potential. The positive effects of fruit consumption are also recognized in 2004 by the Food Agriculture Organization (FAO) and the World Health Organization (WHO), which recommends a daily consumption of at least 400 grams of fruits and vegetables.

EUFRIN (2011) states that the fruit sector is a strategic one in the European Union (EU), this being also valid for Romania, especially in terms of the added value that this market has in socio-economic development, mainly at local level. For long-term development, the organization of producers under different associative forms is important in this essential sector of agriculture, having the role of stabilizing the market through its important role especially in terms of prices (Aquila and Petriccione, 2012) which is the most important link between supply and demand.

Methodology

The methodology of the paper consists in performing quantitative statistical analysis to identify the situation of the fruit market in Romania and to identify consumption trends. The database contains statistical data processed and taken over from the National Institute of Statistics Romania (NIS), International Trade Centre (ITC) and the Ministry of Agriculture and Rural Development (MARD). In the analysis of the international trade with fruits, the statistical data provided by ITC for the category Edible fruit and nuts, peel of citrus fruit or melons were taken into account.

Analysis of the Romanian Fruit Market

The Romanian fruit market in high season when the Romanian production appears on the shelves also appears the pressure of the competition. The main characteristics of the fruit and vegetable market according Popescu (1999) are the variety of products that differ depending on the seasonality, the variability of production that depends on the geographical area but also on years and the perishability of fresh fruits and vegetables, these being ultra-fresh. Knowing the particularities of the fruit market in Romania provides important information for analysing production and consumption trends that lead to the formation of an important market in the economy.

The fruit and vegetable market has been regulated at European level by Common Market Organisation since 1962 in order to contribute to the objectives of the CAP and starting 2008 a new reform has taken place (Cacic et al., 2009)

having applicability for Romania as well. The 1996 reform of the fruit and vegetable sector emphasizes the importance of producer groups in agriculture to increase market competitiveness. (Cacic et al., 2009)

In table 1 is the Romania's food balance for the fruit category which includes details about all the fruits equivalent to tonnes of fresh fruit.

Table 1: Romania's food balance for fresh fruit and fruit products

Unit: tonnes

Indicators	2014	2015	2016	2017	2018
Usable production	2,085,118	1,994,433	1,978,478	2,125,614	2,957,785
Import	877,063	1,049,491	1,236,462	1,251,362	1,266,777
Export	112,738	115,073	100,320	88,912	98,324
Internal availability for consumption	2,849,443	2,928,851	3,114,620	3,288,064	4,126,238
Industrial processing	1,148,824	1,140,366	1,111,837	1,362,322	1,746,940
Total losses	86,071	88,191	97,503	88,369	120,734
Stock change	17,236	-40,442	12,329	-44,084	100,729
Available for human consumption	1,597,312	1,740,736	1,892,951	1,881,457	2,157,835
Average annual net food consumption - kg/inhab.	80.2	87.8	96	96.1	110.8

Source: NIS, 2020

Carrying out an analysis on the fruit food balance (2014-2018), in 2018 compared to 2014, there is an increase of 41.85% of domestic production. The imported quantity increased by 44.43%, and the exported quantity of fruits registered a decrease of 12.79% (although reporting the year 2018 to 2017 there is an increase of 10.59%), during all this time the domestic consumption availabilities increasing by 44.81%. The amount of processed fruit increased by 52.06%, while the total amount of losses increased by 40.27%. In 2018 compared to 2014, the average annual net consumption / inhabitant increased from 80.2 kg to 110.8 kg, an increase of 38.15 percentage points. Carrying out an analysis on the food balance of fruits from 2018, compared to 2017, there is a 39% increase in domestic production. The imported quantity increased by 1.23%, the exported quantity of fruits registered an increase of 10.59%, during all this time the domestic consumption availabilities increased by 25.49%. The amount of processed fruits increased by 28.23%, while the total amount of losses increased by 36.62%. In 2018 compared to 2017, the average annual net consumption/inhabitant increased from 96.10 kg to 110.8 kg, an increase of 15.3 percentage points.

The share of imports in domestic availability is high, registering over 30% in the period analyzed, Romania being dependent on food imports to ensure the entire needs of the population. Two causes that lead to large quantities of fruits and fruit products imported by Romania are the high consumption of citrus whose imported quantity increased in 2018 versus 2017 by 8.69%, and exotic fruits, especially bananas for which 7.90% more quantities were imported in 2018 compared to 2017, but also the import of processed fruit products because the degree of industrialization of the Romanian agricultural sector is low due to the lack of the necessary infrastructure, but also to the investments in this activity.

The demand of fruits in Romania

The demand for fruits has a permanent character, but the supply of Romanian fruits is seasonal, considering the specifics of the climate and the way of cultivation. Most of the farms from Romania are semi subsistence farms and it represents a significant part from their daily alimentation, so the expenses for the purchase of fresh fruits in the rural area are lower because the rural inhabitants are based on their own production which is largely dedicated to self-consumption, making various processed preparations in the form of jams or compotes for later consumption.

Graph 1: The evolution in Romania of the average monthly consumption of fresh fruits per inhabitant and by areas of residence

Source: NIS, 2020

In Romania, the average amount of fruit consumed by a person from a rural area is clearly lower than the average amount of fruit consumed by a person from an urban area. During the analyzed period, the gap between the two residence averages registered values between 1.42 kg and 0.96 kg, the biggest difference being registered in 2014, at the opposite pole being the year 2018.

Although in rural areas the amount of fruit consumed by a person is less than the value recorded in urban areas, its growth rate in 2019, considering the base year 2010, was much faster. While in urban areas the average amount of fruit consumed by a person increased by only 7 percentage points, in rural areas there was an increase of 23 percentage points.

Graph 2: The evolution in Romania of annual consumption and production per inhabitant

Source: NIS, 2020

Following an analysis of the average annual fruit consumption of a inhabitant compared to the average annual fruit production per capita, a much higher production is found compared to the amount of fresh fruit consumed, but insufficient to ensure the necessary fruits and products, from fruit to fresh fruit equivalent. While in terms of consumption of fresh fruit there is a slightly upward trend in quantity (reaching that in 2019 to consume on average / inhabitant with 5.4 kg more fruit than in 2010), production has fluctuated from year by year, a feature of agriculture resulting from the strong influence of weather conditions. The highest fruit production / inhabitant, in the period 2010-2019, was registered in 2018 (93.1 kg / inhabitant), at the opposite pole being 2017 with only 54 kg / inhabitant. The

consumption of fruits and fruit products in fresh fruit equivalent is also on a slightly upward trend, registering in 2018 an increase of 10 percentage points compared to 2010. For 2019, the statistical data on the indicator consumption of fruits and fruit products in fresh fruit equivalent are missing.

Graph 3 shows an analysis of per capita consumption at the level of each fruit category for the period 2010-2019.

Graph 3: The evolution in Romania of annual consumption on fruits category

Source: NIS, 2002

The most consumed fruits by Romanians are apples and pears, being produced with tradition for Romanian fruit growing and with various varieties. Compared to the base year, 2010, the consumption of apples and pears decreased by 12.31%. Among the local fruits, the apple is among the only ones that are suitable for long-term storage and we can find it on store shelves even in spring. Lately, apple producers have also turned to processing, appearing on the domestic market apple juices with different fruits mixes under different brands and packaging.

Bananas are in second place in the preferences of Romanian consumers, being an exclusive imported product for which demand has been growing in the last 6 years and which has a higher consumption in the cold period when domestic production is absent from the market. Citrus fruits, especially oranges, mandarins and lemons are often consumed by Romanians, especially in the cold season when there is a higher supply on the market and the price is more attractive, and in the warm season citrus fruits are consumed more in the form of fresh juices.

Table 2: Dynamics of spending on the purchase of fresh fruit in Romania by area of residence

Indicators	Residences	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Fruits expenditures (RON/inhabitat/months)	Rural	5.81	6.14	6.58	6.21	7.29	8.12	8.43	9.76	11.01	12.33
	Urban	12.98	13.37	13.74	14.42	15.4	15.63	16.47	18.4	19.99	20.74
Share of fruits from total agrifood products expenditures	Rural	4.70%	4.65%	4.75%	4.35%	5.04%	5.27%	5.24%	5.53%	5.50%	5.49%
	Urban	6.32%	6.30%	6.16%	6.14%	6.45%	6.50%	6.65%	6.70%	6.60%	6.40%

Source: NIS, 2020

Carrying out an analysis on the expenses with fruits generated by a person on average per month, by areas of residence presented in table 2, we find that in 2010 a person from rural areas spent on average 55% less than a person from urban areas while until in 2019 this difference was on a downward trend, reaching to spend 41% less in 2019. During

all this time the amount allocated by one person on average per month for the purchase of fruit registered an upward trend, reaching 2019 compared to 2010 by 112% among people in rural areas and by 60% in terms of people in urban areas.

The share of fruit expenditures in the total food expenditures made by a person with a rural residence environment increased approximately constantly, reaching from 4.70% (2010) to 5.59% (2019). In the urban area, the share of fruit expenditures in total agri-food expenditures ranged in the period 2010-2019 between 6.16% (2012) and 6.70% (2017). This difference in fruit expenditure registered between urban and rural areas is mainly due to subsistence agriculture found in rural areas, an action that reduces the need to buy among them.

Fruit supply on the Romanian market

In summer-autumn, local fruit production continues to be marketed largely in traditional markets, even though various more modern distribution channels have been developed, but the traditional one is gaining the trust of consumers through authenticity. In table 3 are presented the fruit production by tree species in Romania where there are oscillations of the production volume, in 2019 the production obtained being at the level of 2011.

Most agriculture is greatly influenced by the climatic characteristics of each year, this also happens among fruit productions in Romania, the quantities obtained varying from one year to another. In the period 2010-2019 the highest production is found among plums, representing between 38% and 47% of the total fruit production in Romania, followed by the production of apples with a share of 33-42% of the total fruit production, at the opposite pole being the production of peaches and nectarines.

The contribution of the productions obtained from fruits coming from the familiar gardens represents, from year to year, between 1.8% and 2.8% of the total fruit production registered in Romania. In the period 2010-2019, the highest fruit production, at national level, was registered in 2018, reaching the value of 1,813,420 tons, year in which the share of fruits obtained in family gardens registered the lowest contribution (1.8% of total fruit production). 2018 was a year rich in fruits for Romania, being a record year for the obtained production, with 71.32% more compared to the previous year. There were increases in production for all categories analyzed, except for strawberries and nectarines. Thus, cultivation in protected areas such as glass greenhouses, solariums or more modern, hydroponic greenhouses, is important because it can better stagger production, and the season can be shifted to cover the needs at the beginning of the season or can extend the domestic season. The vulnerability of fruit crops to increasingly unstable weather events, but also when diseases and pests occur, causes producers to innovate to provide support to reduce the risks they are exposed to throughout the year and help them achieve economic viability for further development of the activity.

The lack of associative forms persists in Romania, currently according to MARD there are 23 producer organizations operating in the fruit and vegetable sector, subsistence farms predominate, the production destined for self-consumption is high and intermediaries are not absent from the distribution of fruits. The fresh fruit marketing

channels in Romania are divided between classic channels (traditional markets, fairs, directly from the farm gate) or modern channels (retail, online). Also, an important consumer is the HORECA market which needs fresh products daily, and currently a community of Slow Food is developing which is based on food preparations based on raw materials from the vicinity. In the fresh fruit trade, the emphasis falls on short supply chains to ensure the freshness of the fruit to the final consumer.

The table above reflects the top of the most important fruit import and export partners in Romania. Regarding the import of fruits in Romania, the most important partner in 2019 was Greece with 19% of the total value of fruit imports, followed by Germany with 17%, the Netherlands with 11%, Turkey with 9% and Poland with 7%. Germany is the country that registered the highest value increase, if in 2010 Romania imported fruits worth 3,702 thousand euro, in 2019 the value of fruit imports from Germany reached 108,173 thousand euro.

Regarding the value of fruit exports from Romania, Italy is the country to which the highest value is exported, representing 20% of total Romanian fruit exports, followed by Germany (13%), the Netherlands (11%), the United Kingdom (9%) and France (7%). In the period 2010-2019 the highest percentage increase in the value of exports was to the United Kingdom (an increase of 7928 percentage points).

Source: ITC, 2020

Regarding the main fruits imported by Romania for value reasons in the first place in 2019 is the category citrus fruit, fresh or dried representing 26% of the total value of imported fruits, followed by the category bananas, incl. Plantains, fresh or dried with 24%. The highest percentage increase identified in 2019 compared to 2010 is found among the category apricots, cherries, peaches including nectarines, plums, it increased from 8,191 thousand euro in 2010 to 49,657 thousand euro in 2019 (an increase of approximately 506 percentage points). As a result of the increase in grape consumption in recent years, according to Chart 3, grape imports have increased mainly to cover demand from the Romanian off-season.

Regarding the export of fruits, the category other nuts, fresh or dried represents in 2019 40% of the total value of fruit exports, although the value of this category decreased by 13% in 2019 compared to 2010. The highest growth rate, in 2019 compared to 2010, is found among the category fresh strawberries, raspberries, blackberries, black or white or red currants, gooseberries, this category recorded an increase of 9.721 thousand euro (an increase of 433 percentage points).

Graph 4 represents the trade balance of Romania for the product category Product: 08 Edible fruit and nuts according to the classification and statistical data of ITC Trade, being registered a value deficit regarding the international fruit trade throughout the period 2010-2019.

Graph 4: The evolution of Romanian trade balance regarding fruit trade

Source: ITC Trade, 2020

The Influence of Price on The Fruit Market

Gilbert and Morgan (2010) states in their study that the high perishability of fruits determines a large volume of goods on the market in a short time that influences the selling price, but adequate storage and staggering production on the market over a longer period can limit price volatility.

The following graph shows the dynamics of the consumer price index for the fruit category which includes fruits and canned fruits, being an index that shows the monthly evolution of the price compared to the same month of the previous year.

Graph 5: Monthly dynamics of the consumer price indices in Romania for fruits and canned fruits

Source: NIS, 2020

Overall, in 54% of the entire analyzed period there were increases in the price index targeting fruits and canned fruits, July, August and November showed increases in 7 of the 10 years analyzed compared to the same month of the year previous. A main factor of influence on the two summer months of the evolution of the price index is represented by the production/ha obtained, on the Romanian market being mostly domestic production. Regarding November, this

represents the beginning of imports, which extend until at least May, and which demonstrates the volatility of prices and their evolution externally when demand increases a solution being the imports.

The most important decreases of the analyzed indicator were in March and April 2019, when they decreased by 12.14%, respectively 11.47% compared to the same period in 2018, this taking place after two successive price increases in previous years.

The consumer price index is an indicator that measures the evolution of the price, and according to chart no. 5 there is an annual oscillation, noting the year 2017 which is the only year in the analyzed period 2010-2017 in which there were significant increases for all month, this happening after 2014 and 2016 were the years with the most constant months in decreasing the value of the index, 2018 will be the beginning of a year in which the first 4 months will continue the accelerated growth rate and will be maintained until September inclusive, following that the index will decrease by up to 10% in November 2018 compared to November 2017. following that in January-July 2019 the index will decrease after the similar period of the last two years has experienced a significant acceleration.

Trends in Romanian Fruit Market

The added value of fruit production is improved if the culture and the obtained production are certified organic. In recent years, organic agriculture has developed in Romania, being an agricultural system that supports the sustainable development of the Romanian agricultural sector. Organic farming is a booming branch of agriculture, gaining a growing share from year to year compared to conventional agriculture. Fruits and vegetables are the most popular and sought after organic agricultural products among consumers.

Table 6: The evolution of organic certified areas in Romania and the share of areas cultivated with fruits

Surface type	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Total organic farming area (ha)	182,706	229,946	288,261	301,148	289,251	245,923	226,309	258,470	326,259	395,228
Orchards, vines, cultivated fruit bushes (ha)	3,093	4,166	7,781	9,400	9,438	11,117	12,019	13,165	18,569	22,143
Share of fruits organic area (%)	1.69%	1.81%	2.70%	3.12%	3.26%	4.52%	5.31%	5.09%	5.69%	5.60%

Source: MARD, 2002

Regarding the total cultivated area in organic farming system, in Romania, it registered an increase of 116% in 2019 compared to 2010, during which time the cultivated area with perennial crops of orchards, vines and shrubs in organic farming increased from 3,093 ha in 2010 to 22,143 ha in 2019 (an increase of 616%). If in 2010 the area cultivated with perennial crops of orchards, vines and shrubs in organic system represents 1.69% of the total surface cultivated in organic farming, until 2019 its share increased significantly, representing 5.6%. The diversification of production gives the farmer an advantage and increases the competitiveness on the domestic market.

In 2018 there was the largest share of certified organic areas that are grown with fruit, due to the faster growth rate compared to the evolution of the total area, being 41.04% higher compared to the previous year, while the total organic agricultural area increased by 26.22%.

The observance of the standards regarding the commercialization of the fruits is elementary for the development of the horticultural sector, and the application for obtaining the voluntary quality certificates that guarantee a production obtained in conditions of alimentary security based on good agricultural practices. The fruit sector must follow to build a stronger supply chain to improve performance of all stages through activities that lead to the sustainable development of the sector.

Conclusions

Extensive fruit plantations in an extensive system, with low productive potential that leads to low yields characterizes Romanian horticulture. The low degree of reconversion of the fruit plantations and endowment of the fruit plantations with modern technical equipment for washing, sorting, packaging to offer a safety production, but also the lack of adequate storage spaces stagnates the development and competitiveness of the sector.

The reconversion of local orchards and the adaptation of crops to the new requirements by appealing to innovation and technology to increase yields and obtain a quality production, and investments in fruit growing show long-term results, ensuring optimal conditions adapted to the requirements of the production area.

The analysis of fruit consumption according to the environment of residence indicates a higher consumption among urban inhabitants, compared to those in rural areas, a main factor being the fact that rural people consume significant amounts of fruit only during harvest periods, when they have disposition of own production while urban consumers have a constant consumption behaviour throughout the year, this fact being due to the much easier accessibility to a wide range of fruits.

The largest fruit productions in Romania are represented by plums and apples, and regarding the imports besides the exotic and citrus products that cannot be satisfied from the domestic production, Romania registers high imports of apples, pears and quinces as a result of covering the needs due to the lack of high-performance storage spaces that allow long-term storage.

Although the share of fruit expenditures in total food expenditures represents in 2019 only 5.49% (rural) and 6.40% (urban), fruits have a significant importance on human nutrition. In conclusion, Romania is a country with a huge potential in terms of fruit production capacity, while the amount of fruit consumed by Romanians is on an upward trend. Regarding the organic surface cultivated with perennial crops of orchards, vines and shrubs in organic system, there is a rising trend in the analyzed period, registering in 2019, compared to 2010 an increase of 616%, which indicates the high attention paid to this segment both in terms of producers and consumers.

For a harmonious development of the Romanian fruit market, both actors involved must support the improvement of the current situation through concrete actions, respectively the demand represented by the final consumer must adopt a lifestyle with a high consumption of fruits considering the benefits to human health and at the same time to choose to consume more sustainable fruits as organic fruits, while the offer must be developed based on research and innovations that will contribute to higher yields and a safe production, the product respecting all standards.

The Dilemmas Regarding Imbalances in Globalization Processes

Jolanta ZIEZIULA

University of Szczecin, Institute of Spatial Management and Socio-Economic Geography,
Szczecin, Poland, jolanta.zieziula@usz.edu.pl

Abstract

Globalization is probably one of the most commonly used words to describe the modern world in the last thirty years. However, the protests of the opponents of globalization are becoming increasingly frequent. What is this happening? The aim of this paper is to depict the negative phenomena associated with the development of globalization processes which contribute to the general imbalance of global growth processes and prevent sustainable world development. An attempt has been made to identify the conditions which need to be met to achieve optimum or at least sufficient balance. The analysis investigates the four principal spheres of globalization processes: economic, institutional, social and natural. The dialectical method was adopted to analyze the phenomena. The research was carried out using cause and effect, induction and deduction methods. The paper was based on the generally available, extensive source literature. The study carried out demonstrates that each of the spheres mentioned above remains in a great imbalance which prevents the achievement of an overall equilibrium. It is, therefore, necessary to take action to restore partial equilibria and then (or at the same time) coordinate the different components in order to create an overall equilibrium – integrated governance.

Keywords: Globalization, Equilibrium, Development.

Introduction

Globalization has probably been one of the most commonly used words to describe the modern world in the last thirty years. The concept of globalization has many different definitions, especially that the theory of globalization, which generalizes the current state of knowledge on the subject, has not yet been developed (Misiak, 2009). In the theory of international economic relations, globalization is often defined very generally as the process of destroying state border barriers for exert market forces (Szymański, 2001). In another approach, globalization is considered as the internationalization of economic activity (Stonehouse et al., 2001), i.e. grassroots, business-to-business measures to transfer economic activity beyond national borders. At the level of businesses, globalization involves the integration of dispersed international functions and activities and the entities which implement such functions and activities (Suszyński, 2003). In the source literature, aspects related to the natural environment – its degradation, the need for reconstruction and protection in general – are becoming more and more significant. Relatively less attention is paid to the institutional aspects of globalization processes.

W. Szymański, in the analysis of contemporary globalization processes, emphasizes their incompleteness and one-sidedness, manifesting itself in the preference for vested interests and microeconomic rationality (Polak, 2009). Is that why there is a growing outcry against globalization from its opponents? What is this happening?

The global balance may be defined differently, as an integrated governance. Borys (2011) describes "integrated governance" as a positive final result of global developmental changes. Integrated governance creates many governances, including: economic, social and environmental governance, but also spatial governance and institutional and political governance which does not restrict the proposed "collection" of governances. According to Borys, this approach is the most suitable to highlight the interdisciplinary of the process of balancing and sustainable development

of the world and the need to approach it in different scientific fields and disciplines (i.e. legal, technical, sociological and psychological and economic sciences) and in practice.

Sustainable development may be defined as a lasting improvement of the quality of life of contemporary and future generations by creating appropriate proportions, mainly between three types of resources, also referred to as human/social, natural and economic capital, listed in different order, however treated equally, as elements of a larger system in which we live and which affect our proper functioning (Żylicz, 2010, Piontek, 2010). In such an approach to sustainable development institutional factors (including political and legal factors) do not occur.

The aim of this paper is to depict phenomena associated with the development of globalization processes which contribute to the general imbalance of global growth processes and prevent sustainable world development. An attempt has been made to identify the conditions which need to be met to achieve optimum or at least sufficient global equilibrium.

The presentation and evaluation of the phenomena was carried out in three main spheres of globalization processes: economic, institutional, social and natural. The dialectical method was adopted to analyze the phenomena. The research was carried out using cause and effect, induction and deduction methods. The paper was based on the generally available, extensive source literature.

The Economic Sphere of Globalization Processes

The prevailing economic trend of globalization processes involves the marketization of all areas of life – providing an opportunity to operate a business freely all over the world.

Zacher (2008) correctly defined the framework of globalization processes and those which are economic in nature are specified below:

- global capitalist system (technological, turbo, digital);
- market, as a systemic element, which involves total marketization (everything for sale) – societies become marketable (not civic);
- short decision horizon (quick profit) and
- hegemony of large transnational corporations/concerns (TNCs).

Among numerous economists, Kołodko (2010) as well stressed the importance of a liberal ideological basis for globalization processes, especially those that value freedom, democracy, private ownership and entrepreneurship, competition and economic freedom. Man was considered homo economicus and this entails the respect for their individualism (pursuing only micro-economic efficiency), treating profit as the sole criterion of success, encouraging maximization of consumption to increase production, disregarding the social and natural aspects of management, and at the same time applying state economic interventionism.

Supporters of classical economics believe that the free market is effective. The classical theory of an efficient market assumes the existence of a large number of entities which, before deciding to buy or produce and sell, collect and analyze all relevant information about both the probability of past events and the probability of future events. It is assumed that in an efficient market, important information regarding both past and future is easily accessible to decision-makers. With this information, optimal decisions may be taken (Davidson, 2012).

It should be borne in mind that decisions taken now will have an impact in the future. The production of most goods and services takes time, thus companies must now make decisions to produce products that may only be sold in the future. Moreover, when planning an investment, companies must assess the potential profits from the investment over its lifetime. This period often extends into years or even decades into the future. And yet even the purchase of goods and services to be delivered today requires the buyer to estimate the usefulness of this purchase, also in the future.

For markets to be efficient, both buyers and sellers would need to know the effects of all possible future situations. The assumption that the future may be known in advance is preposterous. Accordingly, if the future is unknown, current market participants are generally unable to make decisions that will be assessed as effective in the future. We should, therefore, agree with Davidson who maintains that it is necessary to reject the predominant theory of market efficiency (Davidson, 2012).

When it comes to decisions about significant expenses (or possible significant profits), people "know" that they know nothing about the future and any mistake may be very costly. Therefore, in many cases the most reasonable solution may be to avoid involvement (Davidson, 2012). This results, among other things, in the reduction of effective demand – a condition necessary for development – where this demand would exist.

And yet, insufficient effective demand is one of the key crisis-generating factors in the capitalist economy, hindering the economic development of individual companies, countries and, eventually, the world.

Undoubtedly, micro-economic rationality is often in conflict with macro-economic rationality. The principle of cost containment and profit maximization, as well as the increased profit-generation capacity of transnational concerns (TNCs), which are growing in strength, entail and increase the inequality in economic development of individual countries and regions of the world as a result of vested and conflicting interests of individual companies. However, there is a cognitive gap due to the lack of research on the impact of global expansion on the macro and micro-economic equilibrium in individual countries and regions. It has not been properly researched whether achieving global rationality by transnational concerns is in any case in line with the national interest of the host countries, especially the poor ones. Moreover, there are no studies on the impact of the global expansion of transnational concerns on the macro and micro-economic balance in individual countries and regions. Doubts are growing.

The main benefits (especially for TNCs) in the process of globalization lie in the unlimited possibilities to increase the scale of production (and other activities to use their accumulated capital), and thus reduce unit costs and increase not only the mass of profit, but in many cases also the rate of profit, provided that they may take advantage of the effective global demand that exists. The reduction of production costs may be achieved, inter alia, through the use of cheaper production factors outside the home country, especially raw materials and labor (including intellectual capital). In addition, lower prices in the country receiving foreign capital and the lack of strict environmental protection requirements may generally be conducive to cost reduction.

The processes of globalization are a prerequisite for changes in the functioning of businesses and above all for the creation and development of increasingly powerful transnational corporations. At the level of TNCs, the changes involve integrating activities scattered across several countries in order to provide the greatest possible benefits to the corporation treated as a whole. The involvement of companies in activities abroad may, at least in part, counteract the adverse effects of business cycles (prevent or mitigate the effects of the economic downturn in the home country and even mitigate the effects of local crises). The expansion abroad often entails the demand for products from the home country and for complementary activities in that country. In addition, there is a profit transfer (at least in part), which increases purchasing power in the home country and stimulates declining domestic demand, which is particularly important, especially in times of economic downturn. As a result, the state administration, particularly in highly developed countries, often supports foreign businesses. Adequate support may have a positive impact on the economies of countries from which transnational corporations originate. Therefore, state institutions are also involved in the implementation of programmes aimed at increasing the international competitiveness of domestic enterprises, at

mitigating the process and costs of adjustment to global competition, or at promoting the development of an information and knowledge-based economy.

Globalization processes have both positive and negative effects on national economies. This impact is multifaceted. In addition to the positive impact of globalization processes on the economies of the countries from which multinational corporations originate, negative effects were also observed. Corporations, while continuing the process of externalization, relocate part or all of their business activities abroad, thus reducing domestic demand. This is due to the reduction in employment and purchasing power of all employees in the home country (Zimniewicz, 2016)

Countries with the inflow of foreign capital of TNCs experience rising employment and the increased purchasing power of the local population. Unfortunately, there is also a negative impact on the economies of poor countries, partly due to unequal distribution of benefits from international trade (Krugman, Obsfeld, 2007). The processes of globalization are asymmetric in nature – they do not affect everyone and everything equally. Asymmetry results from the enormous economic dominance of the West, with the USA at the forefront. The strongest companies (companies often supported by states) set the standards of globalization which bring them advantage and from which they may benefit most (Polak, 2009). Weaker countries are being exploited.

The nature of exploitation of poor countries is defined in the source literature by three forms of imperialism (Deszczyński, 2014):

- "trade imperialism" means export of raw materials and food from underdeveloped countries at unfairly low prices and import of surplus finished goods of TNCs from highly developed countries at relatively high prices (increasing incomes of "imperialists");

- "capital imperialism", i.e. export of capital by transnational corporations to underdeveloped countries and using it to make higher profits than those that would be generated in the countries of the capital origin, at the expense of the economies of the host countries;

- "imperialism of economic aid" – state bodies in highly developed countries buy and transfer part of their domestic production to poor countries, compensating domestic producers for insufficient domestic demand.

This activity ties recipients of economic aid to donor countries, inter alia, by allowing additional exports from those countries to recipient countries.

In economic terms, globalization means the expansion of the capitalist system into an ever larger area of the globe. The world economy, according to Kołodko, is to a lesser extent divided into national economies and to a higher extent composed of those economies as interdependent elements. The correlations within the global market are particularly evident in the financial markets. The instability of global risk financial capital flows is one of the main causes of growing financial crisis (Kołodko, 2008).

Economic imbalance in the macro and micro-scale is an immanent feature of the capitalist economy. However, the internal contradictions relating to the operation of the market economy are multiplied and exacerbated in the wider process of globalization.

The Institutional Sphere of Globalisation Processes

Business activity depends both on the activity of the companies themselves and on the operating conditions created by other entities, at home and abroad. In addition to businesses, the process of globalization involves various groups of institutional entities, such as states, international institutions and organizations and non-governmental organizations.

Due to their specific features and functions, institutional and political elements are sometimes identified within the structure of the integrated governance as a separate governance (Borys, 2011).

The development of contemporary globalization has been significantly influenced (and continues to be influenced) by nation states (Zorska, 2007). In addition to traditional activities concerning legislation, stabilization, security, etc., state institutions are involved in the implementation of programmes aimed at increasing the international competitiveness of national economies, mitigating the process and costs of adjustment to global competition, introducing new solutions (institutional and legal), as well as promoting the development of an information and knowledge-based economy.

Whether foreign enterprises may operate in a given country depends, among other things, on the degree of economic freedom permitted in that country, i.e. the lack of government coercion or restrictions in terms of production, distribution and consumption of goods and services, apart from the absolute necessity arising from the protection of citizens (Misiak, 2009). In this respect, individual countries are divided into the following economies: liberal, rather liberal, medium-liberal, rather non-liberal and non-liberal. For example, liberal economies include Hong Kong, Singapore and Ireland. Poland is considered a rather liberal economy. The greater the freedom (economic and political liberalism), the lesser systemic influence of state institutions.

As was mentioned above, the strongest companies set the standards of globalization from which they benefit most (Polak, 2009). America (mainly the USA) is striving for synergy of key factors determining the trends of globalization. The rivalry between America and Europe (the European Union) – mega players on the global scene – is growing in the main areas of globalization changes. However, Asia, in particular China and India, is rising in importance (Misiak, 2009).

International organizations, including those supporting international trade and economic growth, participate in the globalization process as well. They are conducive to the processes of globalization. According to Stiglitz (2007), the World Trade Organization (WTO), the International Monetary Fund (IMF) and the World Bank (WB) play a major role. International organizations are of particular importance in expert (including conciliation) and coordination activity. The greater the role played by these organizations, in accordance with the intent and economic and political power of the Member States, the greater the opportunities for action. For example, the WTO is exerting pressure to remove all obstacles to trade and the IMF is enabling the increase of the supply of capital for development (investment) purposes.

Institutional support for globalization processes has contributed significantly to the development of many enterprises and the transformation of some of them into transnational concerns (TNCs). It would seem that in the process of globalization the world is becoming a “global village” with excellent tools for instant communication and that institutional equilibrium is relatively easy to achieve. However, that is not the case.

The phenomenon of so-called “structural violence”, also referred to as system lobbying, may be observed more and more frequently (Laska, 2006). It is based on the fact that entities strong in the economic structure use considerable financial resources to convince other countries to introduce solutions and regulations favoring the strongest entities (Zimniewicz, 2016). The International Monetary Fund, the World Bank and the World Trade Organization, in which representatives of the most developed countries have the deciding vote, are used for the above purpose. And yet, these organizations were established to work together on a global level and to ensure economic stability in the public interest. They grew out of Keynesian understanding of the need for state stimulation of the economy when the market fails (Stiglitz, 2007).

Among international organizations, integration groupings such as the European Union play a very important role. They have an increased capacity to influence global processes by delegating part of their competences, which have traditionally been national competences, and by holding substantial financial resources from the Member States.

It is generally accepted that the activity of the TNCs is a factor that enhances global economic rationality. This is due to the fact that it allows a given company to benefit from locating individual stages of production where it is the cheapest. Is achieving global rationality, however, always in the national interest of the host countries, especially the poorer ones? And do the countries of origin of transnational corporations actually benefit in the long run, when institutional entities (especially state entities) are less able to interfere in the activities of companies?

A concentration of supranational power of large companies and their groups – transnational corporations, is observed in the world. However, they are becoming less and less dependent on the operating conditions in one country, as they may easily find other beneficial locations for their activity which they use to avoid paying levies (taxes). There is no doubt that in the process of globalization the role of countries in the economy is eroded by effective attempts to limit their sovereignty (Domaradzka, 2016).

It should be borne in mind that the principle of cost containment and profit maximization, as well as the increased profit-generation capacity of supranational companies, which is beneficial for companies, may undermine the interests of each state, its stability and security, as well as limit the state's ability to influence demand and the budgetary impact on the socio-economic sphere. This is due to the fact that TNCs, through effective lobbying in the legislative sphere, may disregard states. They often receive financial support from public funds, basically without paying taxes, if they conduct business activity and make even a small profit. Transnational corporations are operating on an increasing scale, however, are still guided by micro-economic rationality. They selfishly take over power (and, consequently, wealth – earned or appropriated) for the benefit of owners and board members, passing on the costs to global society.

As already mentioned, both states and international organizations are not free from the influence of strong lobbying on the part of the TNCs, which are able to cause changes in the legislation granting corporations even more power. However, the risks associated with their wrong decisions are effectively passed on to society (Zimniewicz, 2016).

Liberalism, i.e. the institutional dominance of the stronger entity over the weaker entity in economic and military terms, still prevails as the economic and political doctrine of the world. The economically strong entities do not have a considerable need to take account of weaker communities, through their institutions. The attempts and ability to coordinate the cooperation of the strong with the weak are insufficient. The need to increase the capacity of people of the “Western periphery”, often treated as “talking tools” or even “redundant elements”, has not been recognized as well (Michnowski, 2006).

Imbalance leads to chaos. The chaos is exacerbated by the inefficiency of the mechanisms of controlling the process of socio-economic and natural life of the earth applied by politicians at the national and international level (Michnowski, 2006). Contemporary control is mainly based on the intuition of politicians who have no access to knowledge about the properties of communities transformed by their policies, which are often covert. Moreover, politicians do not have access to knowledge about the complex political consequences of their own and foreign policies. Hence, the policies are often counter productive. There are no institutional mechanisms for recognizing the conditions and consequences of political decisions taken, which prevents conducting politics properly (Michnowski, 2006).

According to Sadowski (2006), one of the most important and so far most militarily effective form of counteracting asymmetrical globalization processes is terrorism, which becomes more and more prevalent. The author draws attention to global military threats.

To a greater extent, they seem to come from other participants in international relations rather than individual countries. An example of a global organization of cultural and religious extremism, referring to Islamic civilization, is Al-Qaeda. Its aim is to establish a pan-Islamic caliphate in the world through cooperation with Islamic extremist groups. Its activity includes for example the establishment of ISIS and the acts of terror experienced by some countries in recent years, playing a significant role in globalization processes.

The Social Sphere of Globalization Processes

It is believed that unemployment and the growing unfair distribution of globally produced wealth are among the most serious socio-economic problems in the world today. Attempts are being made to change this situation at the international and regional level (also within particular groupings e.g. in the European Union (Bielecka, 2008; Kołodko, 2013 et al.)). They have been rather unsuccessful.

The processes of globalization and the introduction of a market economy have not brought the desired results in Russia and most other countries undergoing political transformation. The transformation in Russia, in the form recommended by international economic institutions, has led to unprecedented poverty. Tittenbrun (2007) writes extensively about the transformation in Poland and its negative effects.

Critics of globalization accuse Western countries, especially the USA, of hypocrisy. They have encouraged developing and transforming countries to remove trade barriers, leaving barriers in their own countries. They have thus prevented export earnings, mainly for underdeveloped countries, which are essential for their development and for improving the living conditions of their populations. In general, developed countries have managed globalization processes in such a manner as to seize a disproportionate share of the benefits at the expense of underdeveloped countries. An example includes the extension of intellectual rights under the Uruguay Round of GATT (the predecessor of the WTO) in 1995. The established governance reflected mainly the interests of manufacturers rather than users, which, inter alia, allowed Western pharmaceutical companies to increase profits and more effectively thwart the production of “their” drugs by countries that could not afford to buy licenses (Stiglitz, 2007). As a result, some of the world's poorest countries have become even poorer. In addition, easing the control over capital markets, e.g. in Latin America and Asia, has benefited Western banks, while the less developed countries were adversely affected. The inflow and sudden outflow of speculative capital to and from these countries entailed a currency crash and weakened banking systems.

Finally, even if programmes carried out in accordance with developed countries' recommendations were counter-productive in underdeveloped countries, those countries still had to pay the debts incurred to implement the failed programmes.

Uneven economic development accompanied by income polarization is an inherent feature of modern globalization processes. One of the growing trends is increasing socio economic diversification due to the uneven distribution of the benefits of economic growth. The area of relative poverty of the unemployed as well as of part of the employed is growing, even in conditions of favorable macro-economic indicators and the economic standing of enterprises.

As is known, economic diversification has always existed, however, its current degree raises concerns, especially due to the fact that, to an increasing extent, it is distributive effect of globalization processes (Polak, 2009).

Unlimited enrichment of some at the expense of others results from disregarding social aspects of management (Kołodko, 2010). As there is no dominant axiology of the common good – common interest, social relations are regressing (Michnowski, 2006).

Stiglitz (2007) believes that globalization processes contribute to the breakdown of social ties. This leads to the well-known phenomenon of exclusion of large groups of society, also in countries that are not excluded from globalization processes (Zacher, 2008). Undoubtedly, however, as a result of exclusion, but also exploitation, a significant number of people in underdeveloped countries live in extreme poverty.

Globalization has not reduced the scale of poverty and has even increased it. Nor has it enhanced stability in the world. Unemployment is rising. Crises plague almost all countries of the world.

People's protests against the policies and actions of institutions responsible for globalization are nothing new. Less developed countries, for example, have rebelled for years against overly restrictive cost reduction programmes imposed on them. More and more people decide to emigrate to highly developed countries, largely for economic reasons. This is the case, even though in these countries as well, the population is experiencing the negative effects of globalization, such as unemployment and the pauperization of larger social groups. There is a strong disintegration of society (Stiglitz, 2007 et al.).

Protests against globalization, also in developed countries, are mounting. Generally speaking, at the heart of the protests is the conviction that globalization does not improve the lives of those who need it most and that it does not bring the benefits promised to people. The gap between those who possess and those who do not is widening.

The mounting protests of the population under anti-globalist and alter-globalist slogans, although justifiable, are generally not very well organized and as such cannot change the processes of globalization. However, they indicate that many people feel wronged and that resistance to the processes of globalization may increase.

Asymmetry of globalization processes has become one of the factors of the global social crisis. It reflects the self-destruction of the existing developmental trajectories.

The Natural Sphere of Globalization Processes

The negative impact of globalization processes on the environment is regularly raised in the literature (Płachciak, 2011). Zimniewicz (2016) draws attention to examples of over exploitation of natural resources, e.g. in Congo which provides valuable and rare raw materials. In the process of obtaining raw materials, apart from the TNCs, even UN soldiers are involved. It is difficult to believe that they are not aware of the fact that they participate in the over-exploitation of the environment (and people).

According to Stiglitz (2007), globalization processes contribute to the destruction of the environment, especially in less developed countries. One of the most serious problems is the side effect of globalization, which is the degradation of the environment: air, water and soil and the adverse climate changes observed.

Globalization processes are characterized by a massive relocation of production processes. It is necessary due to, inter alia, restrictive CO2 emission standards in certain countries. Companies that cannot afford to install expensive carbon reduction equipment or only want to reduce costs may relocate the production to countries where such restrictions do not apply. If the relocation of production is accepted, the host countries are exposed to an increased CO2 emission, while the countries that outsource production reduce it. This results in a global air pollution.

According to UN reports, approximately 50 million tonnes of electronic waste is produced annually worldwide, only 10% of which is recycled. The rest is deposited in the landfills. The very “green” European Union introduced strict regulations concerning this type of waste. However, most of it is mixed with still usable electronic equipment and sent outside the Union; the situation is similar in the United States and Japan. The main recipients of e waste include China, India and Africa – in particular Kenya and Nigeria. The reason for relocating electrical waste is cost. In the European Union, the United States and Japan, the costs of e-waste disposal are high, which renders such activity unprofitable, even though the disposal methods used allow the recovery of up to 90% of rare materials. It is more profitable to send e-waste to Africa. In Africa, approximately 25% of raw materials is recovered. The rest is wasted irretrievably. This enormous waste is accompanied by air, soil and water contamination. The morbidity of the population is dramatically increasing (Ziemniewicz, 2016).

There is no doubt that the negative impact of globalization processes on the environment is escalating. There is excessive consumption and devastation of environmental resources, despite remedial efforts.

Those products which are relatively more environmentally friendly than their predecessors may also have a negative aggregated effect on the natural environment (in all countries combined) (Żylicz, 2010). Moreover, it was found that (despite actions taken to protect natural resources), dematerialization of production in developed countries is accompanied by an aggregate increase in consumption of natural resources, including non-renewable ones. A particularly important conclusion of the Meadows and Forrester study (Płachciak, 2011) is that a global disaster (as a result of unsustainable development) does not have to result mostly from the depletion of natural resources. The disaster may be caused by the degradation of the natural environment – air, water and land (Michnowski, 2006).

The degradation of the natural environment is exacerbating. It in particular affects farmland, tropical forests, biodiversity. Greenhouse gas emission is rising. There is a growing threat of melting glaciers, rising sea levels, increasing hurricane frequency and strength. The ozone depletion is accelerating (Michnowski, 2006). Air, water and soil pollution is reaching unprecedented levels, despite the development of increasingly eco-efficient techniques and technologies!

Nature is in a state of chaos. It is exacerbated by the random protection and restoration of natural resources, which at the same time often causes degradation of other resources. An example includes the restrictive protection of grey seals or cormorants in Poland at the mouth of the Vistula which results in the complete destruction of salmon (Dunin-Kwinta, 2016), and such examples may be found in other countries.

Until recently, economic growth at the expense of the natural environment did not threaten the existence of its destroyers. The environment had developmental surpluses (Michnowski, 2006). However, in the course of the globalization processes it was not taken into account that the processes of life are irreversible. Pollution already emitted to the environment cannot simply be withdrawn from it. Homoeostatic properties sustaining human life cannot be restored in the destroyed biosphere. If a key link in the biological chain mutually supporting life on earth is broken, it will not be restored by genetic engineering applied (Michnowski, 2006), or at least not immediately.

The progressive destruction of the natural sphere is a consequence of the moral degradation of the hitherto naturally primitive, short-sighted and egoistic form of social and economic development of the world community, especially its highly developed part. This development is based on the principle of strong growth at the expense of the environment.

Excessive consumption of resources and the devastation of the environment are largely due to a lack of economic, institutional and social responsibility, fostered by globalization. Undoubtedly, the global natural imbalances are constantly growing.

Conditions and Methods of Restoring Global Equilibrium

The analysis of the components of globalization processes, considered to be the most important ones: economic, institutional, social and natural components, proves that each of them is in a state of deep imbalance. The domination of economic capital in globalization processes entails numerous adverse institutional, social and natural consequences. They cause permanent, growing imbalance in the overall system we live in. A global disaster is becoming a reality.

Regardless of the depletion of natural resources, if the socio-economic infrastructure, including the dominant selfish axiology, is left unchanged, such a disaster will occur. This disaster will be caused by the degradation of the natural environment (Michnowski 2006), but also by the further disintegration of the world community, which has clearly escalated in recent years.

Restoring balance naturally is out of the question. Sustainable development is contingent upon such an establishment of relations which will not affect the ability of the natural environment to provide its services in the future. The development of the human eco artificial environment in the world, including the infrastructure created, may not be

reversed (in a peaceful manner), however it is possible to modify the existing urbanization, industrialization, automotive and consumption trends and related waste (Zacher, 2008).

Many representatives of the world's elites, decision-makers and scientists (and, under their influence, the general public) still lack a proper understanding of the chief causes of the global crisis, which results in a conservative continuation of the Darwinian, selfish, informationally malfunctioning social relations (Michnowski, 2006). The anti-liberal conclusions of the Meadows' team regarding the urgent need to take action for a radical transformation of civilization, based on the axiology of the common good, are not taken into account. Moreover, there is still no political willingness to implement UN programmes for sustainable development and no requests from moral authorities (e.g. John Paul II) to cooperate in the implementation of specific developmental restructuring proposals. What are the reasons for such omissions?

The global crisis is a fact and a real threat to the existence of societies. It stems from the maladjustment of the world community to live in the present state of rapid change and risk. This maladjustment is a result of insufficient flexibility of the community and its economy, as well as insufficient active intellectual potential, including in particular the failure to convince the world political bodies about the necessity of initiating the civilizational transformation, which is a requirement for the permanent development of the world community, including in particular building informational and educational foundations for sustainable development (Michnowski, 2006).

It is necessary to radically improve the mechanisms of controlling the process of socio-economic and natural life by creating opportunities for supporting politics, its objectives and profound consequences with computer simulation methods as well as knowledge about the properties of social systems, which condition such simulation.

Without knowledge of the essential properties of eco-social systems and modern policy making methods supported by high information technology, it is not possible, among other things, to combine the increase in prosperity (and quality of life) “here and now” with the increase in prosperity of future generations. It is also not possible, as has been the case so far, to conduct an economic policy in such a manner as to render economic growth sustainable and permanently foster the quality of life of all people and ensure the proper condition of the natural environment (Michnowski, 2006).

All actions require, in the first place, a broad and theoretical basis convincing the decision makers. The theory of international economic relations has raised such, mostly partial, issues as: international conditions of economic processes, models of economic interdependence or conditions of macro-economic policy coordination, as well as the causes and models of contemporary currency crises and the related threats and consequences of financial market globalization.

The noteworthy, contemporary economists who recognize the need for a fundamental, comprehensive change in the approach to the development processes of the capitalist economy, and thus to the processes of globalization, include, apart from the Nobel Prize winner Joseph Stiglitz (2007), Polish economist Grzegorz Kołodko (2013), but also American economist Paul Davidson (2012). The above authors recommend rejecting the doctrine of liberalism and restoring a more active and, most importantly, effective state policy, not only in terms of economy.

Regardless of the pace of change, it is unlikely that a coherent global system of the world economy, and in particular a global and widely accepted regulator, will emerge in the near future. Due to the existence of nation states, diverse management conditions, accumulated wealth and regulatory and control capacities, solutions for restoring partial equilibria should be, in the first place, introduced in individual countries.

Subsequently, using inter-state and international agreements, institutional (and legal) arrangements should be coordinated in such a manner as to contribute to global integrated governance.

The need of departure from treating earth only in narrow ecological terms (global ecosystem) is strongly emphasized in the Global Programme of Change developed under the leadership of Gro H. Brundtland by order of the UN. The

programme was presented in the Report of the World Commission on Environment and Development published in 1987 (Michnowski, 2006; Płachciak, 2011). The programme recommends a gradual change in production and consumption models correlated with sustainable development requirements. As a result of the change in production models, adequately modified products and technologies should have positive impact on the (social and natural) environment. A change in consumption models should radically reduce irrational, and in fact needless consumption, for example only prestigious consumption (Michnowski, 2006).

The Global Programme for Change promotes social justice, solidarity, harmony and equality within and between countries, in full respect of national sovereignty and territorial integrity. The priority tasks include the elimination of poverty, unemployment and social exclusion in all countries of the world. It was also considered necessary to socialize the benefits of globalization. It is necessary to increase properly remunerated employment (enabling decent living) and to improve multi-level governance. It was confirmed that achieving sustainable development requires a forward-looking approach and broad participation of institutional entities in the implementation of such a policy. It was stressed that counteracting threats requires solidarity, dialogue and cooperation, as well as support of modern technology (Michnowski, 2006).

First of all, risks of an economic and social nature should be recognized. They contribute to military threats whose occurrence depend on the effectiveness of reducing such risks.

It should be emphasized that unemployment and the growing unfair distribution of globally produced wealth are among the most serious socio-economic problems in the world today. However, in the face of growing public opposition and escalating terrorism, attempts to distribute world wealth more fairly should still be made. Taking in refugees from poor countries does not solve these problems. Kołodko rightly points out that international enforcement and control mechanism, in addition to national ones, have to be enhanced, even though this is extremely difficult.

The most developed systems of counteracting unemployment and fair distribution of the generated national income and wealth in general exist in Denmark and Sweden. They are also in place in other countries. However, it turns out that these systems are not fully efficient and budgets do not withstand excessive social burdens. They tend to be reduced e.g. in the UK, Germany or France. However, insufficient demand significantly inhibits economic development. Thus, states make further attempts to increase it, inter alia, through transfers of a social nature. The introduction of so-called “civic income” in Switzerland and Finland in 2015 may be deemed such an attempt.

Coordinated action is needed to ensure that all those who want to work are employed and to eliminate injustice in the distribution of income and wealth. It is essential to ensure, at least in part, an even distribution that will contribute to the maintenance of social peace. It is important that the positive distributional effect does not discourage people from working and developing entrepreneurship – does not lead to stagnation or even collapse of the economy. Therefore, such measures for increasing employment and salaries must be taken as a result of which the salary growth rates would be slightly below the growth rate of the economy, and an inheritance policy should discourage a life of idleness.

It is crucial (and possible) to provide people with stability and a sense of social security, so that they are willing to spend more and save less. As a result, the necessary general demand, which is permanently insufficient in a developed capitalist economy, may grow.

The most important thing, however, is to convince the decision-makers of the validity of such changes even if, in the short run, they would incur minor financial losses. In the long run, however, they would benefit from a new, global and fairer economic and social order.

Michnowski (2006) rightly points out that to avoid a global disaster it is necessary to:

- urgently assist politicians with computer methods for the simulation of their political actions and decisions, by creating an informative basis for policy, including an information system enabling access to knowledge about the profound consequences of political actions and decisions and other changes in the conditions of human and natural life;

- continue research into the characteristics and proper development of eco social systems, facilitating the correct simulation of the behavior of such systems under different environmental conditions;

- develop a far-reaching strategy of civilization transformation and define the basic strategic undertakings necessary to shorten its duration;

- develop the ability to effectively eliminate the negative consequences of moral degradation, which is spreading at a faster rate with the development of science and technology;

- develop skills of intercultural dialogue and cooperation as an essential condition for the development of synergies necessary to overcome the global crisis.

Undoubtedly, it is necessary to accelerate actions aimed at overcoming environmental degradation and negative economic and social phenomena, especially in individual countries. This requires special control over the activities of transnational concerns in each country and, as far as possible, coordination of activities between the countries in which the concerns operate so as to eliminate the negative effects of their actions in the social and natural sphere, but also in the economic sphere (tax evasion or obtaining undue public aid). In other words, it is necessary for the institutions to implement and monitor the implementation of the remedial measures (e.g. a general tax on capital movements).

As regards countering the escalating global military threats, Sadowski (2006) rightly indicates that international peacekeeping pressure must be created. Without taking all possible measures to solve the main problems of the modern world peacefully, we are in danger of a world war.

Both the concept of integrated governance and the concept of sustainable development do not emphasize that it is necessary to achieve and maintain internal balance in the individual components of each capital, i.e. partial equilibria. I am convinced that the global equilibrium will not be achieved other than by “working out” methods to achieve global partial governances, and only the coordination of these governances will allow the achievement of an integrated global governance, a global equilibrium.

Summary

The research shows that each of the analyzed spheres – economic, institutional, social and environmental – remains in a deep imbalance which is aggravated in the process of globalization. This prevents the achievement of an overall equilibrium. It is therefore necessary to take action to restore partial equilibria and then (or at the same time) ensure the coordination of equilibria in each sphere in order to create an overall equilibrium – integrated governance. This requires considerable institutional efforts aided by the up-to-date IT knowledge.

Abstract

The mechatronic system is the result of the integration of mechanical and electrical / electronic parts. Mechatronics has developed and continues to develop more and more with the development of mechanics, electricity and especially electronics. The production process can be complicated, depending on the complexity of the mechatronic system. Therefore, the organization of production activities is very important in obtaining a finished product, as desired. Depending on the mechatronic system, there is a certain way of punctual testing of the product parts within the production process. For a mechatronic system, step-by-step testing was performed. For this testing in the production process, models inspired from software testing are considered.

Keywords: mechatronic system, software testing, testing methodology, production process, integrated design.

Introduction

Mechatronics, also called mechatronic engineering, is a multidisciplinary branch of engineering that focuses on the engineering of electrical and mechanical systems. It is a combination of robotics, electronics, computer, telecommunications, systems, control and product engineering. The term "mechatronics" is defined to provide a framework for technical and practical considerations.

The concept of mechatronics has evolved from the original definition given by the Yakasawa Electric Company. The term "mechatronics" was introduced by an engineer (Tetsuro Mori) from the Japanese company in 1969.
As a word, it was registered as a trademark by the Japanese company, with registration number "46-32714" in 1971 and used since 1972. The company subsequently issued the right to use the word in public, after which this term began to be used throughout the world.

In dictionaries, the term officially appeared in 2005, in Larousse (France). Nowadays, the word is translated into many languages and is considered an essential term for the industry.

The French standard NF E 01-010 (2008) defines mechatronics as an "approach to the synergistic integration of mechanics, electronics, automation and informatics in the design and manufacture of a product to increase and / or optimize its functionality". Many people treat mechatronics as a modern word, synonymous with robotics or electromechanical engineering.

On the beginning, the field of mechatronics was a combination of mechanics and electronics.

Fig. 1: Origins of the word mechatronics

As the complexity of technical systems continued to evolve, the definition was extended to include more technical areas.

The interest of this area of interdisciplinary engineering is to design powerful automated systems and to allow the control of complex systems.

Testing of a Mechatronic System

The mechatronic system can be designed and / or developed in several test models. The methodologies implemented were inspired from the software testing.

Testing is necessary to check the mistakes which could appear. Without testing, some permanent failures could come, and the whole mechatronic system could be useless. All steps from the production needs to be checked, because some mistakes could appear in any step of the production.

Software development models are different processes or methodologies that are selected for project development. These depends on the project objectives. In software testing are some development life cycle models. Those were created in order to achieve a specific goal of the product. Not all the time the same testing model is used, this depends on the complexity of the product.

The selection of a testing model has an impact on the type of test performed. In the testing methodology is defined the plan of testing and which techniques should be used.
Nowadays are used various software development models or methodologies. Some examples are: Waterfall model, Agile model, incremental model, RAD model, iterative model, spiral model, prototype model and the V-shaped model and its variations.

The mechatronic system can be tested during the production process from several points of view. Depending the manufacturing process, it can follow a certain type of model in testing. The focus is on the Waterfall and V-models, which are being usually the most models used in testing.

The Waterfall-Model

This model is a breakdown of project activities into linear sequential phases. Here, each phase depends on previous results and corresponds to a specialization of tasks. This approach is used for certain areas of engineering design. In software development are less iterative and flexible approaches. The progress flows largely in one direction ("down" like a cascade) throughout the phases.

The Waterfall-model begins with the manufacturing and construction industries. When this model was first adopted for software development, there was no recognized alternatives to knowledge-based creative work. This model refers to the fact that it should move to another phase only when the previous phase is reviewed and verified.

Fig. 2: Product testing of the "Waterfall" model

In the case of the Waterfall model, very little customer interaction is involved during product development. This could create serious disadvantages. Once the product is ready, it can be shown to end users. When a malfunction occurs, the cost of solving the issues is very high. This situation appears because everything is updated from the document to the logic of the design. In practice, the Waterfall model has been replaced by other models.

The V-model

This model is a simple variant of the traditional Waterfall model of system or software development. As in Figure 3, the V-model is based on the cascading model by emphasizing verification and validation.

The V-model takes the bottom of the Waterfall model and bends it upwards in a “V” shape so that the activities on the right check or validate the work products of the activity on the left.

The left side of the V-model represents the analysis activities that break down users' needs into small, easy-to-manage pieces. The right side of the V shows the corresponding synthesis activities that agree (and test) these parts into a system that meets the needs of users.

In V-model each phase needs to be completed before the start of the next phase. Product testing is planned in parallel with a corresponding development phase from this model.
Requirements such as BRS and SRS start the life cycle`s model just like the Waterfall model. In the V-model a system test plan is created before starting the development. The test plan focuses on fulfilling the functionality specified in the requirements collection. The HLD phase focuses on the architecture and design of the system. This phase provides an overview of the solution, platform, system, product and service or process. In this phase an integration plan is created. This is needed to test the capacity of collaboration from the software systems. The LLD phase occurs when the actual software components are designed. This phase defines the real logic for each component of the system. The class diagram with all methods and the relationship between classes falls under the LLD. Component tests are also created at

this stage. The implementation of the code takes place in the implementation phase. Once the coding is completed, the execution path continues on the right side of the “V”. The previously developed test plans are now used.

The V-model demonstrates the relationships between each phase of the development life cycle and the associated test phase. The horizontal and vertical axes represent the time or complexity of time (from left to right) and the level of abstraction.

Fig. 3: Product testing of the "V" model

The verification can be done partially on the left side of the V-model. It is an incorrect approach to say that the validation only takes place on the right side of the V-model. The simplest way is to say that the verification is always in accordance with the requirements (technical terms) and validation versus specifications or user needs. Validation can be expressed by the thing that the system is being build and verification if the system is being built correctly.

Production process of a Mechatronic System

In order to allow a systematic process of designing mechatronic systems with a high level of integration, is needed a so-called multidisciplinary integrated design. Until now, nobody provided an effective solution that can fully support the entire design process to achieve such an integrated multidisciplinary design.

In order to organize design activities from different disciplines and to help designers achieve multidisciplinary integrated design, can be followed a design methodology based on a multidisciplinary interface model.

In accordance with systems engineering practices, is used an extended V-model as a macro-level process in the proposed design methodology. This starts with identifying the system-wide requirements and ends with a user-validated system. The hierarchical design model is adopted as a micro-level process. It supports specific design phases in which individual designers can structure design subtasks and can proceed and react in unforeseen situations.

In order to ensure coherence and traceability between the two levels, the multidisciplinary interface model is proposed. This design methodology is demonstrated by studying the process of designing the mechatronic system.

To test the state of a mechatronic system, any of the models listed above can be used. Of course, depending on the test model chosen, there are certain advantages or disadvantages.

The presented design methodology adopts the extended V-model as a macro-level process and hierarchically the design model as a micro-level process. Multidisciplinary, the interface model helps designers ensure coherence between the two levels.

The macro-level design process adopted an extended V-model process to present the overall flow for the mechatronic system. The left branch of the V-model extension represents the system design sub-process and is described in qualitative models. After analyzing all the requirements for the whole system, subfunctions and subsystems are defined. During the system design sub-process, the design phases are identified as: specification, functional model and architectural phases. As is represented in figure 4.

Fig. 4: Testing methodology for a mechatronic system

The right side of the V-model represents the sub-process integration system. In the extended V-model, this sub-process can be divided into two phases.

The objective of the compatibility testing phase is to guarantee and ensure correctly multidisciplinary integrated subsystems between different design teams. If the subsystems prove to be incompatible with each other, then the iterative process needs to be continued. The compatibility of the test in the early stages of system integration significantly reduce the number of iterations in the later phase. As a result, the overall development costs and time to market can decrease accordingly. Verification and validation at this stage is used to test the integrated performance of the system and verify that the system works and meets all the requirements previously proposed according to the designed plan. If the system needs to be improved, the previous design and phases will be repeated.

The hierarchical structure will be applied in the three phases of the system design sub-process. The design parameter hierarchy is proposed to help designers define key parameters in specific sub-process disciplines.

Regarding requirements, the specification is derived from all mechatronic system and it can provide initial information about what customers are requesting. The requirements may apply to the general system, or to each subsystem (or

component) or the interconnection between two subsystems. Therefore, the requirements can be detailed by breaking them down into additional ones, thus creating a hierarchy of them.

If all interfaces from the mechatronic system have been shown to be compatible, which means that all components have been properly integrated with each other, the design process should be checked and validated. The verification and validation phase are used to test the performance of the integrated system and it is verified whether the system performs the proposed function and meets all the previously proposed requirements. If the system needs to be improved, the initial operating phase will be repeated.

Previously, the data of V-model and the hierarchical design model used as design processes at macro and micro-level were discussed.

The multidisciplinary interface model is understood to use and support the ease of implementation of the system architecture during design at the model phase and to test the compatibility between them which are presented in subsystems at the compatibility testing stage. Achieving coherence between the two process models is obtained from any direction, from the macro or micro-level.

The proposed extended V-model shows a general flow for the design process of mechatronic systems. It can generally be divided into three processes: system design, discipline specific design and system integration.

Fig. 5: Connections between level processes in production methodology

During the two design processes (system-specific design and discipline), each stage can be detailed by a hierarchical structure as a micro-level process. In the system design, hierarchical structure can be used to establish the requirements specifications, the functional model and the architectural model.

Moreover, it was proposed to prioritize the design parameters with the help of designers to define key parameters from the design specific to the discipline. In general, the coherence between the macro-level process and the micro-level process is ensured by the hierarchical structure during the two design sub-processes.

This model provides a common representation for interfaces, which can be used both in the architectural phase-model of the system design as well as in the compatibility testing system process compatibility stage. In the architectural model phase, the three attributes of the multidisciplinary interface model can define an interface from different levels of decomposition or different disciplines with the same terminology.

The coherence between the architectural design model of the discipline-specific design sub-process system can be determined by this common representation of the interface.

In the compatibility test phase are tested the proposed-based interface of the multidisciplinary model. It is also tested the compatibility between subsystems (or components). This is helping designers to decide whether the design process can move to the next stage (verification and validation phase). Otherwise, it should return to the initial design phase, which refers to the discipline-specific process or the architectural model phase of the process system design.
With the support of the multidisciplinary interface model, designers can return to the general flow of macro-level process development from specific micro-process design activities. The connection between micro and macro-level processes is strengthened by the multidisciplinary interface model.

Figure 5 shows the consistency between the two levels of processes. This consistency is ensured by the hierarchical structure during the design of the system sub-processes and the design of the discipline-specific design process. During this time, the interface model will be designed during the system integration process.

The aim is to demonstrate the use of the proposed design methodology in a mechatronic design process. This type of approach can have applications for many mechatronic systems, thus facilitating the production process.

Conclusions

The models from the software testing could be used in production methodology of the mechatronic system. This situation occurs with the complexity of the software part(s) from the mechatronic system.

The V-model could be used for small to medium-sized projects, where the requirements are clearly established. And it needs to be chosen when ample technical resources are available, with the necessary technical expertise. With this model, a high level of customer trust is required. As no prototype is produced, there is a very high risk to meet customer expectations. So, the software testing techniques wrong used are not a good idea, without a clear plan previously realized for the production. On the top of this, the mechanical parts of the mechatronic system could create some extra issues. As a result, the final product could not functionate because of the software, mechanical or electric / electronical parts. Designers from various disciplines perform concurrent design activities in each sub-process of the entire design process to achieve better design.

In the proposed model, it was presented a model-test adapted to the mechatronic system. This it was created based on its interfaces. And the execution it was done step by step, as the integration of the product was done. This approach is based on the current models, as the V-model could be adapted inside in such a system.

Abstract

In modern society the features of thinking, individual and collective consciousness and unconscious of people are largely determined by digital reality, including social networks, messengers, etc. In the situation of the coronavirus pandemic and forced self-isolation, the use of various gadgets, and consequently appeal to digital reality, has increased significantly. The article considers the results of the research on the reflection of the problem of COVID-19 pandemic in quantitative and content characteristics of graphic Internet memes in social networks. Based on the content analysis, 11 main semantic types of memes about coronavirus have been identified, reflecting current psychological and emotional problems of Russians: attitudes to restrictions, a new way of life; attitude to oneself and self-image acceptance in a new situation; relations with authorities; economic, material problems, health, well-being, hopes for the future, problems of alcoholism, changes in the geopolitical situation, problems in interpersonal relationships, methods of treating a new disease.

The research concluded that during the period of a sharp increase in the number of infected people, the number of memes about coronavirus in users feeds was not dominant, but the number of likes suggests that they attract the most attention of users in comparison with memes on other topics. The topic of the coronavirus is of primary importance for Russians and memes that appear will have a significant impact on the perception of coronavirus, attitude to the current situation and behavior. Memes, when read directly, can evoke both positive and negative emotions, some groups of memes may have a prolonged effect on users, which can lead to depressive states. Certain groups of memes have a psychotherapeutic function. Memes, therefore, can serve as an indicator reflecting the content of public conscience and unconscious of people, as well as a way to influence it.

Keywords: COVID-19 pandemic, graphic Internet memes, quantitative and content characteristics of Internet memes, psychological perception and impact, psychotherapeutic function of Internet memes.

Introduction

In the era of widespread digital technologies in modern society, the features of thinking, consciousness and collective conscious and unconscious of people are largely determined by digital reality, including social networks, messengers, etc. In the situation of the coronavirus pandemic and forced self-isolation, the use of various gadgets, and consequently appeal to digital reality, is increasing significantly. First of all, digital reality reflects what is most disturbing to the

ZAKHAROVA "Reflection of The Problem of Covid-19 Pandemic in Quantitative and Content Characteristics of Internet Memes in Social Networks" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

population in the current situation – coronavirus. At the same time, the content of messages significantly affects awareness, understanding and attitude to coronavirus. According to the methodological principle of the unity of consciousness and activity, the content of the psyche, namely consciousness and the unconscious, can be explored by products of activity. The content of social networks and messengers also acts as such products for those who create them. One of the most popular objects of social networks is the so-called "meme". A meme is a unit of information significant for culture. A meme is any idea, symbol, manner, or mode of action that is consciously or unconsciously transmitted from person to person through speech, writing, video, rituals, gestures, etc. and has a certain effect on their cognitive, emotional sphere, or (more indirectly) – behavior.

Due to the increased availability of mass media, individual texts and their components become popular and are repeatedly reproduced, which allows us to talk about the emergence of text memes, as well as Internet memes, if communication takes place in the virtual space. Moreover, one of the characteristic features of such communication in the postmodern era is irony (Gutorenko L. S., 2016).

Internet meme is information in one form or another (a media object, that is, an object created by electronic means of communication, a phrase, concept, or activity) that spontaneously becomes popular, spreading on the Internet in various ways (through social networks, forums, blogs, messengers, etc.) (Internet Meme [Electronic resource] URL: https://ru.wikipedia.org/wiki/ Internet Meme (accessed 00.00.2020).

Internet memes are a unit of information transmitted through Internet communication (Shchurina Yu. V. , 2012).

The Internet has made the spread of memes a highly visible practice, and the term has become an integral part of the spoken language of netizens (Shifman L. , 2013).

Researchers of mass communications claim that the use of memes, along with hype content and various fakes, has become a modern trend in the transformation of the media environment (Kiuru K. V., Krivonosov A.D. , 2018).

The Internet meme is currently understood not only as a manifestation of network creativity, but also as an artifact of the modern culture of participation, a way of public discussion, and an instrument of electoral and protest communications (Shomova S. A. , 2019). In modern digital culture, the political Internet meme is one of the most widespread and little-studied phenomena. Understood as a unit of transmission of cultural information on the Web, such a meme is considered by scientists, on the one hand, as a spontaneous product of mass creativity, a mechanism of political participation, and on the other hand, as an instrument of political PR technologies, a way of "overestimating" or "underestimating" the image of a political leader (Shomova S. A. , 2019). The trend of using Internet memes in the electoral struggle for votes has become a new trend in modern politics (Elissev S. M., Gluchich V. A., Samarina E. A. , 2018). Internet memes represent a potentially powerful form of socio-political participation in the online community (Ross A.S., Rivers D.J. , 2019).

Most often, memes have the character of images accompanied by a certain text, sometimes animated. It is this category of memes that we will explore. Visual images captured in a meme have a significant impact on the human psyche. According to scientists, the connection between visual and verbal parts of Internet memes is implicit and the function of the visual component is to form a special emotional tone of information, to provide a holistic and at the same time flexible understanding of a specific message by placing semantic accents that allow the recipient to clarify perception and interpretation of the verbal component. The information presented in the visual component is based on various associative relationships (Khraban T. , 2019).

A graphic meme can be an effective object for studying the psyche based on the principle of projection. More than 100 years ago, projective techniques were developed and effectively used. Projective techniques are based on the psychological mechanism of projection, and many of them use images as the object of projection, as well as a certain activity of the subjects in relation to these images (write a story, choose the one you like best, etc.) (Burlachuk L. F., 1997). The same is true for memes in social networks – users view them and show activity – "like", i.e. vote for the meme they like. The impact of memes on the psyche can be of two types. The first impact has a direct, momentary character – usually conscious – and in this case it causes the same emotion that it is directed at (funny – joy, etc.). The second impact has a delayed, cumulative character – usually unconscious – when long-term observation of memes on a certain topic causes a certain stable mood, which does not always correspond to the nature of the meme (funny memes lead to depression).

These methodological grounds allow us to use visual graphic information posted on the Internet as a means of studying the content of consciousness and the unconscious of people at large and attitudes to certain phenomena and events (in our case, COVID-19 pandemic) that may not always be sufficiently understood, reflected, and in some cases simply pushed out of consciousness due to their high trauma to the psyche.

In this article we will look at the content of graphic memes posted on Odnoklassniki social network. We will limit ourselves to graphic images due to: first, their number and dominance, second, their stronger impact on the psyche (compared to text messages), and third, their greater accessibility to viewing (compared to video messages).

Odnoklassniki social network was chosen because, according to analytical data, it is in the top 10 social networks and resources in Russia, its monthly user audience in 2019 was 23.4 million people. At the same time, Odnoklassniki ranks second in terms of audience activity (45.2%) after the social network VKontakte. At the same time, women predominate in the social network: 61%, the adult audience is more active, especially the segment 35-64 years old (Audience of Social Networks in Russia 2019. 18 June 2019 / Popsters [Electronic resource] URL: https://popsters.ru/blog/post/auditoriya-socsetey-v-rossii] (accessed 18.06.2020). Odnoklassniki remains a "regional" social network in Russia, and the main purpose of visiting this social network is interpersonal communication (Social Networks in Russia, winter 2015-2016. Figures, Trends, Forecasts , Shopolog. [Electronic resource] URL: https://www.shopolog.ru/metodichka/analytics/social-nye-seti-v-rossii-zima-2015-2016-cifry-trendy-prognozy/] (accessed 18.06.2020). Accordingly, news spreads within the network to a greater extent on the principle of rumors, in the social network feed there are either news from groups that a person subscribed to, or those that were voted for ("liked") by his friends. Accordingly, the credibility of these messages and their emotional impact on the user of the social network is higher than just when viewing a news feed. As for age characteristics of the target audience, these are people who currently make up the most stable layer of our society, those who regularly pay taxes, go to elections, are loyal to the state and authorities, that is, those who form stable "rear" under any circumstances. On the one hand, it may seem that it is difficult to expect any protest activity from this social group, however, this category will be stable only up to a certain limit, but if this limit is passed, it will affect very wide strata of the population and it will be very difficult to stop this protest activity. That is why it is very important to study social attitudes that are formed in this social group and in this social network.

The purpose of this article is to investigate quantitative and content characteristics of memes in Odnoklassniki social network in connection with how they reflect the problems of COVID-19 pandemic.

The research objectives are:

1. To determine what percentage of memes are dedicated to coronavirus and how important they are.

2. To establish a typology for the content of memes about coronavirus – i.e. their subject content.

3. To find out dominant emotions in relation to coronavirus (by the content of memes)

2. Materials and Methods

During the week, memes that appeared in the feed of three users of Odnoklassniki social network were recorded, counted, and analyzed daily. The count was carried out after 23.55 each day, and all graphic memes that typified first were recorded:

1. Related or not related according to their content to coronavirus.

2. Based on the content analysis of memes content, their classification was carried out, which eventually allowed us to identify the main semantic types of the coronavirus meme – i.e. those current topics related to COVID-19 pandemic that concern residents of the Russian Federation.

3. Determination of the emotional load of the meme (positive or negative) – is defined by the mood that the meme should cause.

4. The number of "likes" for each image was fixed, regardless of its content.

5. The average results were calculated for three users.

Sample. The study examined the feeds of three users of Odnoklassniki social network – women with an average age of 43.2 years, who in total have 123 virtual "friends" and visit the social network daily. The total number of memes viewed by three users within the week was 4230. Memes were recorded from April 20 to April 26, 2020. At the beginning of this period, the number of people infected with coronavirus in Russia was 42,900, and at the end of the period – 80,900 people (Shchurina Yu. V. , 2012). This was a period of a sharp increase in cases, which, accordingly, caused some concern and attention to this issue.

Results and Discussion

Analysis of Odnoklassniki users feeds showed that the number of messages about coronavirus is only 19% of the total number of graphic messages. However, the average number of likes that users give to memes about coronavirus is 152.7, while the average number of likes for graphic images on other topics is 35.14. Accordingly, memes about coronavirus find an emotional response in the minds of Russians, attract attention and encourage activity (at the first level – voting for this meme), i.e. they have a significant impact potential.

According to the research results, all memes can be divided into 11 thematic categories. It should be noted that all of them had a pronounced humorous character, but in some cases they reflected good humor, carrying an emotionally positive color, and in some cases – evil satire, carrying an emotionally negative color. In accordance with this, memes in each category were designed to evoke either positive emotions (laughter, joy, optimism) or negative emotions (annoyance, anger, irritation, impotence) in viewers. Quantitative indicators of memes are shown in table 1.

Table 1: Quantitative characteristics of "memes" in Odnoklassniki social network

Groups of memes (by content)	**% of the total number of coronavirus memes (frequency of occurrence)**	**Average number of "likes" in the group (affiliativeness)**	**Rating based on frequency and affiliativeness**	**Ratio of positive and negative emotionally colored memes within the group (%)**	
				Positive	**Negative**
Restrictions	17.22	192.03	1	82.98	17.02
Humor over oneself	32.97	133.57	2	83.33	16.67
Power	9.52	199.00	3	0	100
Economy	5.13	312.67	4	42.86	57.14
Health /well-being	7.69	144.98	5	61.90	38.10
Blackhumor	4.40	109.33	6	33.33	66.67
Hopes for the future	6.23	74.10	7	52.94	47.06
Alcohol	4.40	88.40	8	100	0
International politics	3.66	93.30	9	80	20
Sex	6.23	54.71	10	88.24	11.76
Methods of treatment	2.56	60.58	11	57.14	42.86

The most numerous group of memes was designated by us as “humor over oneself”, which, however, has only the second rating in importance. It included mostly positive images (83.33%), the main purpose of which is to cheer up and raise smb.’s spirits. The subject matter of such memes does not have any pronounced social orientation and mainly reflects those aspects of self-isolation or pandemic that either cause laughter in themselves, or that provoke people to certain actions that eventually lead to comic situations. Quite often, to increase the emotional impact on the user, heroes of well-known and favorite films (“Gentlemen of Fortune”, “Ivan Vasilievich Changes Profession”, etc.), or pets that begin to acquire anthropomorphic traits and abilities become heroes of memes. Such inversions are not accidental. In this situation, animals are often given more rights than their owners, but animals in the network, as a rule, evoke positive emotions and this attitude continues to persist in coronavirus memes. Such memes primarily have a psychotherapeutic function of psychoemotional discharge, search for positive moments in the current situation, which in some cases can somewhat ease the psychological discomfort of self-isolation.

The second type can be defined as memes that reflect various aspects of restrictions associated with coronavirus. This group ranks first in terms of frequency and likes. Most of them are emotionally positive (82.98%). At the same time, memes of this category reflect a negative attitude to the restrictions imposed, their meaninglessness. The most frequent heroes of these situations are police officers who are called upon to monitor compliance with restrictions. Emotionally positive memes in this category also have a psychotherapeutic function, designed to alleviate discomfort due to restrictions on freedom. Emotionally negative memes of this category in significant quantities can provoke dissatisfaction with the current situation, strengthen protest moods. Typically, such memes reflect a situation where restrictive measures make it difficult to meet any basic human needs.

The third category of memes reflects attitudes to the actions of authorities in the context of coronavirus. All memes of this group are of an emotionally negative nature and reflect people’s dissatisfaction with the position of the government, its powerlessness in the face of the pandemic, and ineffectiveness or senselessness of the measures taken. These memes, when directly perceived, can cause positive emotions and laughter. It also produces a certain therapeutic effect – the opportunity to express your opinion (in particular, dissatisfaction) with respect to those institutions with which a person in a normal situation can not interact directly. At the same time, in the long term, the impact of these memes can have a cumulative effect and, after a certain time, form a negative emotional state, a sense of insecurity.

Other categories of memes are noticeably smaller, but they are quite relevant, as evidenced by a great number of likes.
The fourth important group comprises memes on economic consequences of COVID-19 pandemic, in this group the division of emotionally positive and negative memes is approximately the same (43% and 57%). Here, as a rule, negative economic consequences of forced self-isolation in the long term, as well as current economic difficulties associated with lack of financial resources at present are discussed. Despite their humorous nature, these memes, in the long run, have a negative emotional impact, despite the fact that directly upon reading they evoke positive emotions.

The fifth group in importance reflects various aspects of health and well-being – as a rule, these are fears that in conditions of self-isolation a person will begin to feel worse – his weight will increase or alcohol consumption will appear, which will lead to alcoholism. These memes are more likely to have an outwardly positive emotional color (61.9%) and can evoke positive emotions directly in the process of reading, however, their cumulative effect with an increase in the number of memes of this group can lead to depressive states, dysmorphophobia, provoke bulimia or anorexia. A separate group of memes is devoted directly to the health status of patients, symptoms, and course of the disease, and they cause more negative emotions.

Memes with black humor are not numerous, but they occupy the sixth place in importance and reflect both, in general, rather optimistic moods of the population in the pandemic situation, and rather pessimistic forecasts (66.67%), as well as depressive states caused by the current situation. Perhaps a significant part of fears is simply repressed and not reflected in the memes. However, the mere appearance of memes with black humor in general can aggravate the state of users in the course of their viewing. So far, however, due to their small number, they do not have a significant destructive effect on the psyche, but a significant number of “likes” can greatly increase the influence of this group on the psyche.

Some memes reflect Russians' hopes for the end of the pandemic. In terms of memes, this is a fairly rapid and favorable process (52.09%), and in terms of forecasts, the forecasts are disappointing (47.06%). A small number of such memes, apparently, are due to general uncertainty of the situation in which the Russians found themselves and absence of objective and reasonable official information, forecasts for the end of the pandemic. The presence of a significant number of memes with a positive and optimistic outlook could have a positive impact on the psychoemotional state of users. At the same time, memes with pessimistic forecasts can provoke depressive moods.

Alcohol topic does not appear often (perhaps due to the orientation of the social network "Odnoklassniki"), but the memes of this group are 100% positive. As a rule, these are memes where alcohol is positioned as a means of treatment or as a possible danger of getting drunk in quarantine, but this option is not considered as something tragic or even negative. Alcohol is positioned as a kind of material embodiment of the national character, national "spirit" and strength of the nation. Alcohol often acts as a Russian national feature that can act as a panacea and explain the low mortality rate for COVID-19 in Russia.

The "international politics" category reflects understanding of the global impact of coronavirus on life in the world and changes in international politics caused by these impacts. As a rule, the semantic context of these memes emphasizes a more advantageous position of Russia in comparison with other countries (80%), as well as irony over other countries in a situation where early ambitions of these countries turned out to be unfounded in the situation of COVID-19 pandemic. In part, these memes also have a psychotherapeutic function, but its effectiveness in comparison with other categories will be lower due to the fact that the problems of international politics at the moment were much less relevant to the population of the Russian Federation than internal problems.

Some of the memes reflect sexual relations during the coronavirus period and how it affected them. For the most part, memes are also positive (88.24%), and have a psychotherapeutic function. In doing so, they also discover sexual problems that self-isolation during the pandemic can cause. At the moment, there are no reliable scientific researches on how self-isolation influenced the sexual life of Russians. It can be unambiguously noted that this influence exists and its main vector is the

limitation of possibilities for realizing one's sexual needs. This will eventually lead to a decrease in the quality of life, psychosomatic well-being and provoke stressful situations, psychoemotional tension, i.e. destabilize the mental state and aggravate the course of self-isolation. In this situation, the appearance of such memes, even of a mild humorous nature, can only increase negative states.

A separate group of memes is dedicated to methods of treatment for coronavirus. The appearance of this group is caused by a certain weakness of modern medicine in the fight against this disease, lack of vaccines and drugs with a directed spectrum of action. Offering their "home" and "folk" remedies for coronavirus, these memes indirectly blame modern medicine for its weakness. In general, memes are emotionally positive (57.14%), but the appearance of such memes and the growth of their number can provoke depressive and panic moods in the long term.

Conclusion

Despite the fact that in absolute terms the number of memes on the topic of coronavirus does not take the leading position, they have a high emotional importance, which indicates that the topic of the coronavirus at the time of the study was of primary importance for Russians and all the memes that appeared had a significant impact on the perception of coronavirus, attitude to the current situation and behavior.

The subjects of memes reflect the current psychological and emotional problems of Russians, first of all: attitudes to restrictions, a new way of life; attitude to oneself and self-image acceptance in a new situation; relations with authorities; economic, material problems, health, well-being, hopes for the future, problems of alcoholism, changes in the geopolitical situation, problems in interpersonal relations, methods of treating a new disease.

Memes when read directly can cause both positive and negative emotions, which is why certain groups of memes have a psychotherapeutic function and their presence in the network is highly desirable, but some groups of memes, despite the direct emotionally positive impact, can have a delayed emotionally negative effect.

Thus, the study of actual Internet memes in a number of situations (including global impact) allows us to determine the current emotional state of people and issues relevant to them, which can be used in psychological forecasting in the short term, as well as, to a certain extent, manage the states of large masses, by including memes of the appropriate substantive and emotional nature in the Internet content.

The study of Internet memes and other information products of this kind provides modern psychology with a powerful tool for monitoring the psychological state of society not only during the coronavirus period, but also in situations of other global social, natural, and political changes. Despite the fact that long-term forecasts are currently one of the priority directions in Russian and world psychological science [15], it is important that psychology is ready to respond to completely unexpected, global big challenges.

Impact of Video Visualization in Improving the Read Rate of Privacy Policy of Automated Vehicles Among Users: A Comparative Study

Glorin SEBASTIAN

gsebastian6@gatech.edu

Abstract

Privacy is becoming extremely crucial for companies to operate especially those that utilize customer information for their operations. With the emergence of new technologies such as Internet of Things (IoT), Automated vehicles, mobile payments, privacy is no longer a compliance issue, but also a user responsibility to ensure he is aware of the risks of sharing his personal data with third parties. There is a big effort to understand how the Privacy policies can be made easier to read and understand. In this paper, we share the results of a comparative study on users who read a Privacy statement from an autonomous vehicle provider and compared its effectiveness to that of a video visualization that explained the policy. The study focused on the users' understanding and recall. Our research shows that video visualization greatly increases click and read through rates as well as helps the user understand the risk associated with privacy notices better.

Index Terms- Privacy Policy, Autonomous vehicles, Notice and Choice, Internet of Things.

Introduction

Data Privacy concern is a growing issue for every entity that handles user personal information. With more US States proposing privacy laws, also a possible federal Privacy statute on the horizon, the number of Data privacy issues are bound to increase. As the autonomous vehicle market grows, the IoT market is expected to grow at a similar pace, if not faster. The report published by Allied Market Research, Global Autonomous Vehicle Market by Level of Automation, Component, and Application: Global Opportunity Analysis and Industry Forecast, 2019-2026, notes that the global autonomous vehicle market is valued at $54.23 billion in 2019, and is projected to reach $556.67 billion by 2026, registering a CAGR of 39.47% from 2019 to 2026.

Self-driving cars combine a variety of sensors to perceive their surroundings, such as radar, lidar, sonar, GPS, odometry and inertial measurement units. In the research study by Taeihagh, Araz, and Lim, Hazel Si Min. (2018), a self-driving car, also known as an autonomous vehicle (AV), connected and autonomous vehicle (CAV), driverless car is a vehicle that is capable of discerning the environmental inputs and drive with no human instructions. Advanced control systems interpret sensory information to identify appropriate navigation paths, as well as obstacles and relevant signage.

Even though most Privacy laws require mandatory Privacy notices be displayed on websites and interfaces where customer private information is collected, as discussed in this study, most end users do not read these notices, and even if they do, given the esoteric nature of the Policy statement, they do not fully comprehend the content.

Security concerns surround autonomous vehicles, given that the vehicle is constantly sharing telematics data. This telematics data includes VIN number, software information, present speed and distance information, which is very sensitive as it clearly lets someone know of the driver's exact location, and car information details which could be used by a malicious hacker to perform cyber hacks and attacks on connected cars.

Another privacy issue associated with Autonomous vehicles is unsolicited marketing. If the user doesn't read the privacy statement fully, he might miss that the vehicle vendor could have contracts with third parties to enable third party cookies which gather information about the user which in turn can be used by the third parties for unsolicited marketing including spam emails.

Cite this Article as: Glorin SEBASTIAN "Impact of Video Visualization in Improving the Read Rate of Privacy Policy of Automated Vehicles Among Users: A Comparative Study" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Privacy policies are used by companies to notify users about data practices and to validate their agreement with privacy requirements. Privacy policies provide information such as what data is collected from the users, with whom it is shared, what steps are taken to protect the collected user data.

The research study by F. Schaub, R. Balebako and L. F. Cranor, May-June 2017 notes that the privacy notices are lengthy in general that describe the company's data practices and they typically not only fail to influence privacy decisions but are largely ignored by the users. However, privacy policies in general are ineffective due to the following reasons:

1. *The complexity of language and legal jargons used:*
   The jargon related to regulations used in the policies is difficult to understand. Based on McDonald Et al., (2008) reading a privacy policy takes on an average 10 Minutes. However, understanding most privacy policies requires higher educational level. A study by Schaub et al. (2017) discusses about the reasons behind the ineffectiveness of privacy policies and they show that most of these privacy policies are not read by the users or if they are read, the users cannot understand the privacy risks due to the complexity of the privacy policies.

2. *Readers do not understand what is relevant and important:*
   One very important reason for the esoteric nature of the Privacy policies is that the policy is laid out without any indication of which part is relevant or important to the end user and which is not. There has been studies by Shayegh, Parvaneh, and Ghanavati, Sepideh (2017) that illustrate how this can be solved, with methods such as: Dividing the privacy policy into Definition, Facts, Action, Non-Relevant, and Cross References section and then removing the Definition, non-Relevant sections and creating cross-referenced section, graph from annotated action section, generate Notice and Choice.

3. *Channel for showing Notices:*
   Selecting the correct channel to display the Privacy notice is yet another challenge. Most websites display the privacy notice on the computer screens, however some IoT devices face challenge here due to the limited screen space. Using the video approach to the Privacy Policy, also helps the users to hear the privacy Policy if there are limitations to the IoT display interface.

The approach suggested by Shayegh, Parvaneh, and Ghanavati, Sepideh (2017) includes two phases, one is analysis of Privacy Policies via annotation and second phase is annotating action with its sub-annotations into five categories including:

#D (Definition): defines the key terms including what is data, privacy, and security

#F (Facts): this section includes important information about the business of the company that force them to collect, use or share user data

#A (Action): Most important part of the Privacy policy for the end user as it describes the actions that can be done by the user including the options to opt-out from data collection

#NR (Non-Relevant): Mainly consists of the part that is added to make the privacy terms more readable, examples for each statement, titles etc.

#CR (Cross References): Includes the links to other pages as cross references

Finally the suggestion is to remove #D and #NR, create cross-referenced section #CR including a graph from annotated action section.

Our proposed approach builds on the research performed by Shayegh, Parvaneh, and Ghanavati, Sepideh (2017). The approach proposed in this paper is to use the emerging technologies of Analytics and Data visualization as well as animation to ensure Policy statements are better read and that the users are fully aware of the risks and their options before accepting the Privacy policies.

Materials and Methods

The present observational study was conducted among 172 users during August and September, 2020. In this study, we assessed the understanding of an autonomous vehicle Privacy statement in pdf format, against understanding from a video created from this Policy statement. Out of the electric car privacy policies of Nikola motors, Rivian, Nissan, Tesla, BMW and Chevrolet, the privacy policy of Tesla was randomly selected using lottery method. The 172 study participants were randomly split into two groups of 86 each. Each of the respondents were emailed an online survey consisting of five questions. .The control group had to read the sample Privacy Policy pdf and answer the survey, while the intervention group had to watch the video shared and answer the same survey.

The main considerations while designing the video format from the pdf document of the Policy were as follows:

1. The user needs to be made aware of which of his personal information is collected in the form of Telematics data as well as the steps taken to ensure that the stored information is safeguarded
2. The user should be aware of which of his data would be shared with third parties
3. Compliance with State, Federal and international Privacy laws
4. How can the user opt-out from sharing and from which of this Data

Fig. 1: Screenshot from the Youtube video on Privacy Policy (Tesla), Sebastian G (2020)

Data Analysis: The data collected was analyzed and expressed as percentages and proportions.

Results

The socio demographic data of the study population is shown in Table 1. Although Majority of the study participants of both intervention and control groups were well educated, they were not in the habit of reading privacy policies fully.

Table 1: Socio-demographic data of the study population

Sl.no	Demographics	Control group	Intervention group
1.	*Highest educational attainment*		
	Bachelor's degree	5.8%	37.2%
	Master's degree	94.2%	61.6%
	PhD degree	Nil	1.2%
	Did not complete Bachelor's degree	Nil	Nil
2.	*Place of residence*		
	USA	11.6%	64%
	India	68.6%	19.8%
	Others	19.8%	16.3%
3.	*Habit of reading privacy policies fully*		
	Yes	12.8%	11.6%
	No	86%	73.3%
	Maybe	1.2%	15.1%

With an average reading speed of 300 wpm, the time taken for an average user to read the sample Privacy statement (Tesla) was 12 minutes. The average time taken for watching the video is 5.50 minutes. The text statistics and readability test scores of the sample privacy Policy are given in table 2 and table 3 respectively (Tesla Privacy Policy).

Table 2: The text statistics for the sample Tesla Policy statement

Text Statistics	Details
No. of sentences	176
No. of words	3977
No. of complex words	909
Percent of complex words	22.86%
Average words per sentence	22.60
Average syllables per word	1.80

Table 3: The readability test scores for the sample Tesla Policy statement explained

Readability test	Score	Required Education Level
Flesch Kincaid Reading Ease	31.6	College (Difficult to read)
Flesch Kincaid Grade Level	14.5	Difficult to read
Gunning Fog Score	16.4	College Senior (Difficult)
SMOG Index	13.1	College (Difficult to read)
Coleman Liau Index	14.7	College (Difficult to read)
Automated Readability Index	14.2	College (Difficult to read)

Assessment of the control group and intervention group using the same assessment questions revealed that the intervention group had a better recall and had a better understanding of the privacy policy compared to the control group. (Fig 2.)

Fig. 2: Comparison of assessment scores between intervention and control groups

Discussion

The present study assessed the level of understanding of an autonomous vehicle Privacy statement in pdf format, against understanding from a video created from this Policy statement. Our proposed approach builds on the research performed by Shayegh, Parvaneh, and Ghanavati, Sepideh (2017). Our approach is to read through the Policy statement and divide it into 5 sections.

1. *Data Collected and Security:* The details of what data is collected from the end user, how is it processed and what security is enabled for this Data while transit and storage.
2. *Sharing information Policy:* This details with whom including which third parties does the entity share customer information
3. *Purpose used for:* Includes the details on the purpose for which the Data collected is used
4. *Permit:* Opt-out options: This lists the opt-out options for the end user, including the rights and responsibilities of the user
5. *Compliance to state, federal and international privacy Laws:* The policy should also mention how it complies to state federal and international privacy laws.

An earlier research (Sepideh et al. (2017)) has suggested the use of AI and NLP (Natural Language processing) to parse the policies to determine which sections need to be part of the Privacy statement and which does not. Since every company is different based on the industry it is associated with, based on our research we suggest that the parsing and determining the best sections to be visualized must be based on the review of the Company Policy experts, with legal background. Once the sections required for the privacy Policy is finalized the company needs to ensure all the decided five components needs to be included in the Animation or the visual presentation for the end user.

From the results of the study, the video form of the privacy statement is much more effective for the end users. It takes ~12 minutes for the users to read the privacy policy, however the video cuts that time almost by half to less than 6 minutes.

The animated video helps the end users with better recall as well as helps them connect with the content of the presentation at a personal level. The animated version of Policy would greatly help change the user perception about the privacy policy from dry and boring to interesting and relevant. If the company can create an animated avatar, that avatar can be used to represent the company in several other ads as well, thereby increasing the relatability of the company with the end users.

The results show that based on the survey questions, the users in intervention group, who answered the questions same as that of control group ,but after watching the video had a better recall than the users in the control group who read the Policy document. The survey results show that using more Video and visualization cannot just reduce the time for the end users but also increases the effectiveness of information recall, thus helping the end users better understand the Privacy Policy. Also from the comments section of the survey, when asked if the video was better than the usual pdf format, the end users responded overwhelmingly positively saying that it greatly helped them concentrate and that the normal data format could be boring thus causing the users to not concentrate enough while reading through.

Video visualizations increase the curiosity of the user and keeps him engaged, while also effectively educating the user about the Policy details. This study applies to Policy documents in general as well as noted in the review article by Sebastian, G (2020), Risk and Controls including adequate policy documentation is becoming very crucial in most areas including system implementation. It is not only important for law to mandate that privacy notices be displayed, or that the end users are notified of any changes to the Privacy notices, but it is also required to make sure that the Privacy notices are readable.

Rather than including a long poorly constructed multi-page Privacy Policy as a 'check the box' item, use of an animated video increases the brand image and also convinces the end users that the company cares about their Data and personal well-being. We believe that increased customer trust in the company brand would lead to better and longer relationships with the end users. It also reduces the compliance cost of companies, since the users would be better aware of the data privacy risks and follow the procedures which leads to lesser privacy data issues.

Conclusion

Data Privacy concern is a growing issue for every entity that handles user personal information. Even though most Privacy laws require mandatory Privacy notices be displayed on websites and interfaces to inform users about the details on the customer private information collected and options to opt-out (if any), as discussed in this study, most end users do not read these notices, and even if they do, given the esoteric nature of the Policy statement, they do not fully comprehend the content.

Through our study, we were able to demonstrate that the use of visualization can greatly impact the readability in a positive manner. Based on our research and analysis, we found that using video visualizations greatly improves the readability of Privacy Policies, thus would recommend companies to use this approach compared to the regular pdf format. Future studies can include details on how the video visualizations can further be improved, for example, by making use of Chatbots, Artificial intelligence, Augmented reality, and other cutting-edge computer technologies.

Resumen

Las universidades chilenas buscan la mejora continua ante un mercado educacional cada vez más exigente. Para apoyar el progreso de las universidades, el Estado de Chile otorga distintos fondos de financiamiento, entre ellos el fondo basal de desempeño. Estudios previos consideran que el capital intelectual es un factor influyente en el desempeño de las universidades, hipótesis a validar en este artículo. Se busca analizar los factores determinantes del desempeño y proponer indicadores que apoyen su gestión. La metodología utilizada contempla el diseño de un modelo estadístico lineal que relaciona el desempeño con el capital intelectual. Para acotar la muestra se obtienen datos de la Universidad Católica del Norte, institución educacional chilena. Los resultados permiten concluir que existe una relación entre el capital intelectual y la gestión del desempeño, proponiendo seis indicadores de capital intelectual para facilitar esta gestión.

Palabras claves: Capital Intelectual; Desempeño; Indicadores; Universidades Chilenas; Fondos De Financiamiento.

Introducción

Las universidades pertenecientes al Consejo de Rectores de las Universidades Chilenas (CRUCh) son evaluadas y reciben financiamiento del gobierno a través de diversos fondos, tales como, Aporte Fiscal Directo (AFD), Fondos para la Investigación (CONICYT), Fondo de Desarrollo Institucional (FDI), Aporte Fiscal Indirecto (AFI), entre otros. En el año 2012 surgió un nuevo fondo de financiamiento denominado Fondo Basal por Desempeño, el que es distribuido entre las instituciones con base en el cumplimiento de indicadores de resultado de desempeño (Ministerio de Educación, 2012).

Edvinsson y Malone (2000), plantean que los modelos tradicionales de gestión financiera contable se muestran cada vez más estáticos respecto de la organización moderna, la cual posee una estructura fluida, relaciones estratégicas, empleados capacitados, programas de trabajo en grupo, recursos intelectuales humanos, que ciertamente se traducen en un valor pocas veces medido por la organización. Diversas investigaciones y estudios previos, muestran que uno de los factores influyentes en el desempeño organizacional de empresas y también de instituciones de educación superior, es el capital intelectual (CI) (Bueno, 2003; Funes, 2010) y sus principales componentes, capital humano (CH), capital estructural (CE) y capital relacional (CR) (Bueno, et al., 2008), definidos en la siguiente sección.

Este artículo busca verificar que el CI afecta en el desempeño de las universidades, considerando los criterios asociados al fondo basal de desempeño. Sumado a esto, se selecciona como muestra una institución educacional

ROMERO "Indicadores de Capital Intelectual para Gestionar el Desempeño en Universidades Chilenas" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

chilena, Universidad Católica del Norte (UCN), sede Coquimbo, perteneciente al Grupo II del CRUCh (Consejo de Rectores de las Universidades Chilenas), recopilando sus datos, a través de un cuestionario para un posterior análisis estadístico de regresión entre el desempeño y el CI.

Finalmente, se desarrolla una propuesta de indicadores de CI orientados al logro de los resultados de desempeño calculados por el Ministerio de Educación, como así también, se contará con un instrumento adecuado para medir el capital intelectual, sirviendo de base para las universidades que deseen crear mayor valor organizacional.

Marco Teórico

Para comprender la base de este artículo, se presentan los principales conceptos utilizados y las variables dependientes e independientes consideradas en el análisis (Tabla I y Tabla II).

Capital intelectual (CI)

Entre las variadas definiciones de capital intelectual, Edvinsson y Malone (2000), lo definen como el conjunto de activos, que, a pesar de no estar reflejados en los estados contables tradicionales, pueden llegar a generar valor para la empresa en el futuro.

Componentes del CI

Existen diversas opiniones respecto de las componentes del CI, pero la más utilizada es aquella que considera tres componentes básicos y fuertemente interrelacionados: capital humano (CH), capital estructural (CE) y capital relacional (CR) (Stewart, 1997; Edvinsson y Malone, 2000).

El capital intelectual es más que la simple suma de estos tres elementos, su riqueza reside en las interconexiones entre ellos (Roberts, 1999). El capital intelectual es capaz de generar un incremento en el valor de la universidad y su propósito es permitir a una universidad tomar ventaja de oportunidades frente a sus competidores.

CH en las universidades

"Conjunto de conocimiento explícito y tácito del personal de la universidad (profesores, investigadores y personal de administración y servicios) adquirido a través de una educación formal e informal y de procesos de actualización incluidos en sus actividades. Por lo tanto, el capital humano constituye la fuente de innovación y renovación de las universidades y se encuentra en: las ideas geniales que aparecen en el laboratorio, el conocimiento generado a través del proceso de investigación, las experiencias obtenidas en el desempeño laboral, o en las habilidades adquiridas por el personal mediante un proceso de desarrollo organizacional" (Tamayo, 2014).

CE en las universidades

"Conocimiento explícito relativo al proceso interno de difusión, comunicación y gestión del conocimiento científico y técnico en la universidad. Es la capacidad organizacional, la infraestructura tecnológica, física o comunicacional que mantiene, desarrolla y sostiene el capital humano. Se puede dividir en Capital organizacional (el entorno operativo derivado de la interacción entre investigación, gestión y procesos de organización, tecnología y cultura) y Capital tecnológico (patentes, licencias, software, bases de datos, etc.). Indicadores representativos para el capital estructural son las inversiones en tecnología de información y literatura (en unidades monetarias)" (Tamayo, 2014).

CR en las universidades

"Recoge el amplio conjunto de relaciones económicas, políticas e institucionales desarrolladas y mantenidas por las universidades, y también recoge cómo la universidad es percibida: su imagen, atractivo, fiabilidad, etc. Esta categoría incluye todas las actividades y relaciones entre la universidad y los socios no académicos: firmas, organizaciones no lucrativas, autoridades públicas, gobierno local y sociedad en general. Indicadores típicos son el número de miembros en asociaciones científicas, vínculos con otras universidades y contactos con alumnos" (Tamayo, 2014).

Medición del CI

La recopilación bibliográfica permitió identificar diversos modelos de medición y gestión del CI desarrollados y utilizados principalmente en Europa y Norteamérica, tales como: Modelo Navegador Skandia (Edvinsson y Malone, 1997), Modelo Balanced Scorecard (Kaplan y Norton, 1997), Modelo Índice de Capital Intelectual (Roos, Roos, Dragonetti, y Edvinsson, 1997), Modelo Diamante de Bontis (1998), quién desarrolló trabajos pioneros en mediciones subjetivas del desempeño, mediante percepciones de los empleados. En el caso específico de la medición del capital intelectual en universidades se han identificado casos en Italia (Manes Rossi, Nicolò, y Tartaglia Polcini, 2018), España (Ramírez, Merino, y Manzaneque, 2019), Australia (Bongiovanni, Renaud, y Cairns, 2020), Colombia (Arias-Pérez, Lozada, y Henao-García, 2019) y México (Machorro, 2013).

Dentro de todo lo revisado, no se encontró un modelo de medición específico de CI para las universidades chilenas, por lo que se procede a elaborar un cuestionario pertinente, basado en el estudio de naturaleza similar realizado por Machorro (2013) para los institutos tecnológicos del estado de Veracruz, México.

Variables Del Estudio

Con la finalidad de diseñar modelos lineales entre desempeño y CI, se establece como variables dependientes (Y_i) a los indicadores de desempeño del fondo basal (Tabla 1) y como variables independientes agregadas (x_i) a las variables de CI, las que, a su vez, agrupan a sub variables (z_i) para cada una de las categorías del capital intelectual (Tabla 2).

Tabla 1: Variables Dependientes

Variables Dependientes		
Descripción	**Código**	**Unidad**
Publicaciones Scopus 2014	Y_1	Cantidad
Académicos jornada completa por cada 100 alumnos matriculados	Y_2	Cantidad
Académicos que son doctores	Y_3	Cantidad
Tasa de titulación en carreras de pregrado con duración de 8 semestres	Y_4	[%]

			Grado de confianza transmitido por UCN a un estudiante	z_{30}	

Metodología

El presente artículo tiene un carácter cuantitativo, en el que se pretende evidenciar la relación que existe entre el CI y el desempeño organizacional, establecida como la hipótesis base a verificar. El método utilizado considera el diseño de modelos estadísticos lineales analizados con técnicas de regresión. A continuación, se detallan las hipótesis, objetivo, muestreo y cuestionario para la validación de las hipótesis planteadas.

Hipótesis

Las hipótesis definidas para el artículo son las siguientes:

H_1: Existe relación entre los indicadores de desempeño del grupo II de universidades del CRUCh y el capital intelectual. Caso UCN, sede Coquimbo.
H_2: Existe relación causal directa entre las componentes de capital intelectual CE y CR con los indicadores de desempeño de las universidades del grupo II del CRUCh. Caso UCN, sede Coquimbo.
H_3: Existe relación causal indirecta entre la componente de capital intelectual CH y los indicadores de desempeño de las universidades del grupo II del CRUCh. Caso UCN, sede Coquimbo.
H_4: Existe diferencia significativa en las percepciones de capital intelectual entre las distintas unidades académicas de UCN, sede Coquimbo.

Objetivo

El objetivo general es proponer un conjunto de indicadores de capital intelectual, orientado al logro de los resultados de desempeño para las universidades del grupo II del Consejo de Rectores de las Universidades Chilenas (CRUCh). Caso UCN, sede Coquimbo, según la medición del año 2015. Para lograr su cumplimiento se procede a las siguientes etapas.

Diseñar un instrumento de medición de las variables de CI para UCN

Una vez identificadas las variables para la medición del CI determinantes del desempeño (Tabla II), se diseña y ajusta un instrumento de medición del CI mediante un cuestionario adaptado al escenario chileno. La validación del diseño del instrumento la realiza un panel de expertos en la fase de prueba.

Evaluar y validar el instrumento de medición

Para verificar la relación entre desempeño y CI, se recopilan datos por medio de un cuestionario, en donde los informantes clave (directores, jefaturas y académicos de las distintas unidades académicas), responden acerca de su percepción sobre el CI presente en UCN (escala de 1 a 7). En paralelo, se obtienen medidas a partir de datos secundarios proporcionados por fuentes oficiales de la universidad.

Posteriormente, se realiza el análisis de datos en donde la hipótesis a probar es coincidente con H_1, definida como hipótesis base de este artículo. Finalmente, se concluye acerca de los indicadores de las variables determinantes en el desempeño.

Proponer indicadores de CI

Para lograrlo se elabora una propuesta de los indicadores de CI apropiados para el logro del objetivo.

Un esquema general de la metodología aplicada se presenta en la Figura 1.

Figura 1: Metodología utilizada

Muestreo

La población finita considerada se compone por los académicos de planta de UCN, sede Coquimbo. La intención fue abarcar la totalidad de académicos, tratándose de un censo con porcentaje de participación (Tabla 3).

Tabla 3: Tasa de participación

Tasa de Participación			
Unidad Académica	**Cantidad Académicos Jornada Completa de Planta**	**Cantidad de Respuestas**	**Tasa de Participación**
Fac. de Cs. del Mar	38	15	39%
Fac. de Medicina	37	21	57%
Esc. de Cs. Empresariales	17	14	82%
Esc. de Ingeniería	12	9	75%
Esc. de Derecho Coqbo.	12	7	58%
Depto. de Teología Coqbo.	11	7	64%
Depto. Cs. Básicas	11	10	91%
	138	**83**	**60,14%**

Cuestionario

El cuestionario de CI, ha sido diseñado en base al instrumento utilizado anteriormente en la evaluación de la influencia del CI en el desempeño organizacional de los institutos tecnológicos descentralizados del Estado de Veracruz (Machorro, 2013). El cuestionario fue adaptado al contexto chileno y además fueron agregadas variables que otros manuscritos similares han considerado para la determinación del CI en instituciones de educación superior, identificados en la etapa de revisión bibliográfica.

La escala utilizada para medir el CI contempla siete opciones de respuesta, acorde al criterio evaluativo chileno: malo (1), deficiente (2), insuficiente (3), suficiente (4), bueno (5), muy bueno (6), excelente (7). Adicionalmente, se diseñó un cuestionario aplicado a los cargos directivos de cada unidad académica, obteniendo información sobre la gestión de la unidad. Finalmente, las cifras del desempeño otorgadas por los cargos directivos también fueron proporcionadas por la Dirección de Análisis Institucional de UCN, validándose dicha información.

Validación Del Instrumento De Evaluación

A fin de asegurar la validez de las respuestas del instrumento aplicado, principalmente referidos a la interpretación errónea de preguntas por parte de los académicos encuestados, se utilizan dos mecanismos. El primero considera la aplicación del cuestionario dentro de la Escuela de Ciencias Empresariales, recogiendo comentarios de los académicos y llevando a cabo esos ajustes. El segundo consiste en una entrevista personalizada a cada cargo directivo por unidad académica, revisando preguntas susceptibles a diferencias interpretativas. Además de estas validaciones, cabe mencionar que el instrumento base utilizado y diseñado por Machorro (Machorro, 2013), se encuentra validado por un panel de expertos en la materia.

Confiabilidad Del Instrumento De Evaluación

El cálculo del Alfa de Cronbach del instrumento diseñado, arrojó un resultado por componente de 0,8392 para CH, 0,8203 para CE y 0,7374 para CR, valores mayores a 0,7 (Nunally, 2009), existiendo evidencia que los elementos miden el mismo constructo, es decir, la percepción del capital intelectual.

Resultados

El instrumento de medición del CI en UCN fue aplicado y procesado a fin de analizar la percepción de los académicos de planta sobre el CI presente en sus áreas académicas y en la universidad en general. Con ello se obtuvo un Índice de CI y posteriormente se estimaron modelos de regresión lineal entre desempeño y CI. Los resultados y su análisis se presentan a continuación.

Medición Índice de CI

El Índice de Capital Intelectual fue calculado de manera global y por cada una de las categorías que lo componen: capital humano (CH), capital estructural (CE) y capital relacional (CR).

En términos medios, el índice de CI obtenido, se traduce en una calificación de 4,91 (escala de 1 a 7) considerada suficiente. La calificación obtenida por cada unidad académica oscila entre 5,50 y 4,30, siendo el Departamento de Teología Coquimbo la unidad mejor evaluada (5,50), seguida por la Escuela de Ciencias Empresariales (5,03), ambas consideradas calificaciones buenas. No obstante, la Escuela de Derecho fue la unidad con la calificación más baja del grupo (4,30), considerada una calificación suficiente. Al efectuar el análisis de la varianza mediante el test de Fisher, se detecta evidencia estadística para concluir que existe diferencia significativa entre las distintas unidades académicas en relación a su evaluación del CI, a un nivel de significancia del 5%.

Resultados variables socio-demográficas

Al relacionar cada una de las categorías del CI: CH, CE y CR con las variables socio-demográficas, se puede concluir que la única variable de este tipo que mostró ser significativamente distinta entre las categorías del CI, fue años de antigüedad del académico en UCN, a una significancia del 5%, siendo los académicos que poseen una antigüedad de entre 4 y 6 años en UCN, los que evaluaron más bajo el CI.

Resultados Por Categoría

Las variables mejor evaluadas para la categoría CH fueron las competencias de salida de los estudiantes (5,4) y la motivación de los académicos al perfeccionamiento (5,4), en contraste con las variables competencias de entrada de los estudiantes, variable con la evaluación más baja (3,4) y las competencias de los académicos no doctores (3,8). Las variables mejor evaluadas para la categoría CE fueron el acceso a plataformas (5,4) y la cultura UCN (5,3). A su vez, las variables peor evaluadas para esta categoría fueron la capacidad de la infraestructura del área del académico (4,5) y la infraestructura de la universidad para los estudiantes (4,4). Finalmente, las variables mejor evaluadas para la categoría CR fueron el grado de confianza que otorga UCN a un estudiante (5,6) y la comunicación existente entre los estudiantes, académicos y jefaturas (5,5). Por su parte, las variables peor evaluadas fueron la existencia de convenios con colegios (4,3) y la participación de investigadores doctores en sociedades científicas (4,8).

Relación Entre El CI E Indicadores Del Fondo Basal Por Desempeño

A partir de los resultados obtenidos para las mediciones del CI, se procede a probar la hipótesis inicial referida a la existencia de una relación entre las componentes del CI y los resultados de los indicadores de desempeño de las universidades chilenas.

La técnica utilizada es un análisis de regresión múltiple, estableciendo un modelo lineal entre cada indicador de desempeño y las variables de CI. Se verifica el cumplimiento de los supuestos clásicos del modelo (normalidad, homocedasticidad, independencia de los residuos) y el grado de multicolinealidad. Posteriormente, se utiliza la

técnica de regresión de los mejores subconjuntos, a fin de determinar la estructura del modelo que mejor explica a cada indicador de desempeño (Tabla 4).

Cabe mencionar que la única variable socio-demográfica considerada como parte del análisis es Antigüedad del académico en UCN, por presentar diferencias significativas entre sus niveles.

Tabla 4: Identificación de los modelos de los mejores subconjuntos

Expresión Modelo		Indicadores del Mejor Subconjunto		
General	**Variables mejor modelo**	**R^2**	**R^2 ajustado**	**Cp de Mallows**
$\hat{y}_1 - \hat{\beta}_0 + \hat{\beta}_1 x_1 + \cdots + \hat{\beta}_{17} x_{17}$	x_3, x_4, x_5, x_{10}, x_{11}, x_{12}, x_{14}, x_{15}	73,1%	69,5%	2,1
$\hat{y}_2 = \hat{\beta}_0 + \hat{\beta}_1 x_1 + \cdots + \hat{\beta}_{17} x_{17}$	x_3, x_4, x_5, x_6, x_7, x_{14}	32,0%	25,3%	1,6
$\hat{y}_3 = \hat{\beta}_0 + \hat{\beta}_1 x_1 + \cdots + \hat{\beta}_{17} x_{17}$	x_3, x_4, x_{10}, x_{12}, x_{14}, x_{15}	67,3%	64,0%	3,8
$\hat{y}_4 = \hat{\beta}_0 + \hat{\beta}_1 x_1 + \cdots + \hat{\beta}_{17} x_{17}$	x_2, x_3, x_5, x_7, x_8, x_{15}	31,5%	24,2%	0,5

Los resultados obtenidos no son favorables en cuanto a su calidad, la que oscila entre el 24,2% y el 69,5%, valores bajos, dado un estándar esperado de a lo menos el 75% de explicación del modelo (criterio: R^2 ajustado). Sin embargo, sirven de referencia para calcular los modelos de regresión múltiple con subconjuntos reducidos de variables x_i, resultados que se presentan a continuación, según cada caso.

Resultados caso 1: Modelo para Publicaciones Scopus 2014 (Y_1)

Los mejores modelos agregados fueron los que relacionan las publicaciones Scopus 2014 (Y_1) con la efectividad de la conectividad y acceso a información (x_{12}) y la cantidad de convenios vigentes (x_{14}), así como también el relacionado con la experiencia en investigación (x_4). Las rectas estimadas se presentan a continuación:

$$\hat{y}_1 = 51{,}4 + 26{,}3x_{12} - 34{,}0x_{14} \qquad (R^2_{Ajustado} - 94\%) \tag{1}$$

$$\hat{y}_1 = -3{,}79 + 4{,}02x_4 \qquad (R^2_{Ajustado} = 83{,}3\%) \tag{2}$$

Desagregando los modelos se obtiene:

$$\hat{y}_1 = -303 - 1{,}19x_4 + 85z_{21} - 23{,}2z_{22} + 38{,}8z_{24} - 49z_{25} \quad (R^2_{Ajustado} = 99{,}7\%; \text{ multicolinealidad alta}) \tag{3}$$

$$\hat{x}_4 = -89{,}8 + 21{,}2z_{21} - 8{,}89z_{22} + 15{,}9z_{24} - 13{,}2z_{25} \; (R^2_{Ajustado} = 94{,}6\%) \tag{4}$$

Los modelos obtenidos presentan un alto coeficiente de determinación ajustado, las variables son significativas individual y conjuntamente, sin embargo, en su mayoría se detecta un grado alto de multicolinealidad entre las variables independientes. Al estimar un modelo lineal entre x_4 (variable de la categoría CH) y las variables desagregadas de las categorías CE y CR, la calidad del modelo que considera a x_4 aumenta, concluyéndose que el CH influye indirectamente sobre el desempeño, a través del CE y CR. Finalmente, las variables más significativas para el modelo son: Experiencia en investigación (x_4), Acceso a plataformas (z_{21}) y Convenios de intercambio estudiantil (z_{24}).

Resultados caso 2: Modelo para Académicos jornada completa por cada 100 alumnos matriculados ($\boldsymbol{Y_2}$)

El mejor modelo obtenido relaciona la cantidad de académicos de jornada completa por cada 100 alumnos matriculados con el soporte socio-emotivo (x_7) y la cantidad de convenios vigentes (x_{14}):

$$\hat{y}_2 = 19 - 65{,}5x_7 + 35{,}8x_{14} \tag{5}$$

Sin embargo, la calidad de los modelos lineales obtenida para explicar la variable de respuesta es baja ($R^2_{Ajustado} < 70\%$) y las pruebas de significancia individual y conjunta no son concluyentes, entonces la cantidad de académicos no es una variable explicada por las componentes del capital intelectual. Luego del análisis desagregado de variables se aprecia la relación inversa existente entre las componentes de la variable, éstas son: soporte socio-emotivo a académicos (z_{13}) y el soporte socio-emotivo a estudiantes (z_{14}):

$$\hat{y}_2 = 103 - 46{,}8z_{13} - 8{,}5z_{14} + 37{,}2z_{24} + 5{,}46z_{25} \tag{6}$$

Esto va contra la lógica teórica, por lo que no se consideró una variable relevante para el modelo final de indicadores.

Resultados caso 3: Modelo para académicos que son doctores ($\boldsymbol{Y_3}$)

El mejor modelo obtenido relaciona la cantidad de académicos doctores con la efectividad de la conectividad y acceso a información y la cantidad de convenios vigentes, mismas variables independientes para la cantidad de publicaciones Scopus (caso 1). Esto se explica dada la alta correlación entre Y_1 e Y_3 ($r = 0{,}95$).

$$\hat{y}_3 = 13 + 4{,}06x_{12} - 5{,}74x_{14} \tag{7}$$

Resultados caso 4: Modelo para tasa de titulación en carreras de pregrado ($\boldsymbol{Y_4}$)

El mejor modelo obtenido relaciona la tasa de titulación en carreras de pregrado con las competencias de los académicos, el soporte socio-emotivo, las políticas institucionales adecuadas y las redes de investigación.

$$\hat{y}_4 = 1{,}11 + 0{,}378x_2 - 0{,}320x_7 + 0{,}0895x_8 - 0{,}282x_{15} \quad (8)$$

No obstante, es de extrañar que la tasa de titulación se relacione inversamente con el soporte socio-emotivo y con las labores de investigación. Luego del análisis desagregado de variables es posible concluir que las variables que afectan directamente a la tasa de titulación son las competencias en investigación de los académicos doctores, el trabajo en equipo de los académicos y el soporte socio – emotivo a los estudiantes. Las variables desagregadas que presentan una relación inversa con la tasa de titulación: soporte socio-emotivo a los académicos, las políticas de investigación y la participación en conferencias por parte de los académicos, fueron descartadas para la propuesta final de indicadores.

Luego del análisis estadístico, se concluye que en general, las hipótesis del estudio no son rechazadas, no obstante, las hipótesis 1, 2 y 3 son válidas para un subconjunto de variables.

La Figura 2 esquematiza una síntesis de las relaciones entre las componentes del CI y el desempeño en UCN encontradas a lo largo de la investigación.

Figura 2: Relaciones entre componentes del CI y el desempeño en UCN

Propuesta De Indicadores

A continuación, presenta una tabla resumen con aspectos referidos a la conformación y métrica de los seis indicadores propuestos para mejorar el desempeño en las universidades chilenas (Tabla 6).

Tabla 6: Indicadores de CI

Código	Nombre Indicador	Métrica	Unidad de Medida	Periodicidad	Responsable	Meta
I_1	Experiencia en investigación académicos doctores	I_1 = Año actual - Año desde que publica regularmente	Años	Anual	Director unidad académica	Más de 1 año
I_2	Competencias en investigación	I_2 = Cumplimiento perfil de competencias	Escala 1 a 5 (Likert)	Anual	Director unidad académica	Mayor o igual a 4
I_3	Participación académicos en actividades del área	I_3 = (Cantidad de asistentes / Dotación área)*100	%	Semestral	Director unidad académica	100%
I_4	Satisfacción de los estudiantes en actividades socio-emotivas	I_4 = Índice de satisfacción	Escala 1 a 5 (Likert)	Semestral	Jefatura de carrera	Mayor o igual a 4
I_5	Eficacia uso de plataformas	I_5 = [1-(# de artículos no encontrados por visita / # de visitas)]*100	%	Mensual	Área de Informática	Mayor o igual a 90%
I_6	Convenios de intercambio	I_6 = (# estudiantes en intercambio / # estudiantes matriculados) *100	%	Semestral	Director o jefatura unidad académica	Alza respecto del periodo anterior

Conclusiones

En búsqueda de una propuesta de indicadores de capital intelectual orientada a la mejora de los indicadores de resultado del desempeño de las universidades chilenas, se verificó la hipótesis que establece una correlación entre el desempeño y el capital intelectual en sus tres componentes: capital humano, estructural y relacional. Se obtuvo un conjunto de seis variables significativas para UCN sede Coquimbo: Experiencia en investigación, Competencias en investigación de los académicos doctores, Trabajo en equipo de los académicos, Soporte socio-emotivo de la universidad hacia los estudiantes, Acceso a plataformas y Convenios de intercambio estudiantil. Para llegar a la propuesta definitiva de indicadores se desarrolló un instrumento de medición de percepciones del capital intelectual en UCN sede Coquimbo.

Del análisis de datos es posible concluir que, en términos medios, las percepciones de capital intelectual en UCN para el periodo en estudio oscilaron entre 4,3 y 5,5, obteniéndose un promedio de 4,91 para la universidad, sede Coquimbo. De estos resultados se desprende que los académicos consideran que el capital intelectual es suficiente, pero no muy bueno, dejando abierta la posibilidad de alcanzar una mayor valoración a futuro. Del análisis de las variables socio-demográficas, se desprende que la antigüedad en UCN incide en el índice de capital intelectual.

Cabe mencionar que las unidades académicas que mejor evaluaron el capital intelectual fue Teología y el Departamento de Ciencias Básicas, unidades con escasa o nula productividad investigativa. Esto hace suponer que la percepción del capital intelectual de los académicos de las unidades que sí tienen metas investigativas, tiene un carácter más crítico al momento de evaluar a sus pares y jefaturas, o bien es más exigente en términos de las condiciones que otorga el área para poder desarrollar su trabajo. Lo anterior queda de manifiesto en la evaluación del capital humano, en donde los académicos doctores calificaron de manera más baja a esta categoría con un 4,6.

Luego de las pruebas estadísticas realizadas, se concluye que la cantidad de académicos (indicador de desempeño), no es una variable explicada directamente por las componentes del capital intelectual. No obstante, al efectuar un análisis desagregado de las variables, pudo observarse que dicho indicador sí está relacionado con la variable de capital estructural: acceso a plataformas, y con la variable de capital relacional: cantidad de convenios de intercambio estudiantil. Resulta interesante mencionar, que de las seis variables relacionadas con el desempeño en UCN, cuatro de ellas correspondan a la componente de capital humano (Experiencia en investigación, Competencias en investigación de los académicos doctores, Trabajo en equipo de los académicos, Soporte socio-emotivo de la universidad hacia los estudiantes), una a capital estructural (Acceso a plataformas) y una a capital relacional (Convenios de intercambio estudiantil). Finalmente, podemos mencionar que este artículo presenta una propuesta innovadora sobre la gestión del desempeño en universidades y se espera sirva como referente para futuros estudios y planes de gestión.

Abstract

The increasing degree of motorization has led to traffic congestion and its negative effects (pollution, additional social costs, health problems, landscape degradation, increasing car accidents' number). The degree of motorization of Bucharest is about 850 cars per 1000 inhabitants and it is constantly increasing. Under these conditions, transport planning models must ensure the solution of these problems and ensure the satisfaction of all requests addressed to the transport system in compliance with the social, economic and environmental restrictions imposed by the sustainable development of society.The paper aims to analyse four-step planning models in order to identify its limitations/ difficulties in implementation, so that the solutions obtained by applying them in practice comply with the restrictions imposed by a sustainable development of society.

Keywords: Sustainable Development, Transport Planning, Four-Step Planning Models

Introduction

Satisfying the travel needs, addressed to the society, by motorization, has led to the accentuation of a phenomenon that has negative effects in the economic, social and environmental field — traffic congestion. In cities where transport planning has not been carried out properly, traffic congestion has reached alarming and even worrying levels. (Banister, 1997 and 2008).

Bucharest ranks 4th in the top of the most congested cities in Europe, according to data gathered by the car navigation company TomTom. The company has compiled a report (*TomTom Traffic Index*) showing traffic congestion in 416 cities in 57 countries. In the European top, on the first 5 places are Moscow (59%) (percentage of additional time spent travelling compared to the hours spent outside peak hours), Istanbul (55%), Kiev (53%), Bucharest (52% compared to 41% in 2015) and St. Petersburg (49%) and on the 14th places, 15th and 17th respectively are Paris (39%), Rome (38%) and London (38%). The level of congestion increased between 2018 and 2019 (in the last report an additional 239 cities were included in the list of congested cities), only a number of 63 cities registered measurable decreases. (Univers ingineresc, 2020)

Environmental sustainability entails improvement in the quality of urban environment and reduction of emissions and energy consumption (greenhouse gasses emission variation; pollutant emission variation; impact variation in other sectors). By contrast, social sustainability entails improvement in the quality of life and social equity (e.g.,

easy access to transportation) and improved safety (e.g., reduction in the frequency of accidents). Finally, economic sustainability entails making mobility of people and goods more efficient and effective and ensuring that the economic benefits produced by the project are greater than the costs. (Henke et al, 2020)

The objectives of sustainable mobility can only be achieved if they are outlined for in the transport planning phase. The main objectives of transport planning are presented in Table no. 1. This analysis uses a 9-objective evaluation framework.

Table 1: Objectives of transport planning

Nr. crt.	Objective	Description
1.	Energy Conservation	Reductions in per capita transport energy consumption and CO2 emissions.
2.	Emission Reductions	Reductions in "conventional" pollution emissions, including NOx, VOCs, CO, particulates, toxics, water pollution and noise.
3.	Congestion Reduction	Reduced traffic congestion.
4.	Road and Parking Savings	Reduced road and parking facility costs.
5.	Traffic Safety	Reduced per capita crash damages, injuries and fatalities.
6.	Strategic Land Use Objectives	Reductions in per capita impervious surface, more accessible development patterns, more liveable communities.
7.	Equity Objectives	Improved accessibility for people who are transportation-disadvantaged, and fairer distribution of benefits and costs.
8.	Affordability	Vehicle cost savings and more affordable transport options.
9.	Mobility Benefits	Benefits to consumers from increased mobility.

(Source: Litman, 2005)

The individual strategies are evaluated according to the degree of importance of each objective, using a 7-step scale (+3… -3). The value +3 is defined as the most beneficial effects and -3 as the most harmful. With the exception of equity and affordability, all other objectives are directly dependent on the length of the journey. An important factor in the analysis is the effect that cost has on travel and fuel consumption. It is possible to define the elasticity of travel in relation to the fuel price, which is usually -0.15 on medium term and -0.3 on long term. This means that a 10% increase in the price of fuel reduces the number of trips by 1.5% in one year and by 3% after a few years. The purchase of more efficient vehicles in terms of fuel consumption leads to an increase in the number of km traveled in a year because it reduces fuel consumption/ km, with favorable implications for increasing mobility but with unfavorable implications for traffic safety and congestion. Estimates of the elasticity of the annual distance traveled in relation to the cost / km are between -0.3 and -0.1. For every 1% drop in fuel cost, Americans drive 1.85% more miles (Litman, 2005).

Classic congestion reduction measures focus exclusively on the development of road infrastructure leading to land usage, degradation of the natural landscape, increased risk of accidents (due to increased road width) and attracting new traffic, which will again lead to congestion and the process is cyclical until the expansion of road infrastructure is no longer possible. Thus is described a vicious circle of possibilities to eliminate congestion.

Since 2013, the European Commission has developed a guideline for the Development and Implementation of a Sustainable Urban Mobility Plan, according to which each urban locality must achieve a SUMP through which to achieve a sustainable urban planning in transport. (EC, 2013).

In the Sustainable Urban Mobility Plan for Bucharest-Ilfov Region (2016-2020) a four steps transport model has been developed (SUMP Bucharest Ilfov, p. 241-278). Based on this model measures has been proposed for reducing congestion and encouraging sustainable urban mobility in Bucharest.The problem is that the model used failed to exceed the limits of the four steps planning models presented in this paper and the expected results are delayed.

The knowledge and the interpretation of current transport demand, characterized by mobility, allow the formulation of empirical laws and their use to determine future transport demand. From the primary structure, which tried to

identify globally the requirements of the transport system (pure demand models) and to adjust the supply accordingly, the models were rethought as articulated systems, of demand-supply interaction; starting from aggregate, descriptive, static models they evolved as disaggregated, behavioural models, which reflect the connection between transports, socio-human activities and global dynamism.

The Transport Planning Model

Mobility is traditionally measured by the number of trips per day and per family. Many studies of the transport network development in American and European states show that most often this number is between 4 and 8. (Ben AkivaşiLerman, 1985). It can be broken down into:

- An almost fixed element - *travel in alternating migration* – close to the value 2 (a round trip, on average for the family, to get to and from work), for a proportion of ½ of the active population using a mean of transport. For areas where the return home system is practiced during lunch, this number exceeds 2;
- A variable element – *travel for other purposes* – which depends largely on the standard of living, leisure, car ownership, etc. and which determines the number of trips for shopping, leisure, health or for attending distant schools.

When mobility is limited by some constraints (e.g. budgetary), a hierarchy is established between the types of trips: compulsory travel — alternating and professional migrations — then personal business, shopping, recreation and finally trips to accompany another person.It is easy to understand that as the standard of living increases, optional mobility increases even more, being the main element of the proliferation of transport demand. (Ortuzar and Willumsen, 1994).

All methodologies use, as a basic structure in transport modeling, the standard sequence of the 4 steps: trip generation, trip distribution, modal split, and traffic assignment. (Oppenheim, 1994, Dragu, 2001).

It is important that this mobility is determined correctly, because it conditions the capacity of the necessary infrastructures and therefore of the investments to be made. An overestimation of transport demands will lead to an oversizing, at least temporarily, of the networks, while in the opposite situation, there will be an insufficient supply of transport leading to congestion. The urbanization will be slowed down, in some areas, congestion of some transport axes will be prolonged and there will be a latent transport demand that will not be satisfied. Figure 1 shows the general structure of a transport planning model from which the sequence of elaboration stages and the steps that make up the model are observed.

Fig. 1: The general structure of a transport planning model (source: Dragu, 2001)

In the first step of the planning model, the necessary details regarding trips are obtained together with the information on the land use and the transport situation for the study area. A cordon line defines this area, and the area within it is composed of traffic analysis areas (TAZ), representing the origins and destinations of trips, and is subject to explicit modeling and analysis.

The factors that influence trip generation are:

- Household characteristics (income, household structure, car ownership and driver's license);
- Zone characteristics (land use, land price, residential density, rate of urbanisation);
- Accessibility (extent of transport option from the zone, quality of transport).

The most used method to determine the number of trips generated and attracted is the regression analysis. A linear regression model can be written:

$$Y = a + b_1 X_1 + b_2 X_2 + b_3 X_3 + ..., \quad (1)$$

where Y represent the dependent variable,
X_i - are independent variables/ of influence,
a - constant factor of the regression equation,
b_i - the regression coefficients of the model.

When X has a single value we have a simple linear regression. For generation/attraction X_i represents the socio-economic influencing factors (e.g. income, car ownership, etc.) and Y represents the number of generated/attracted trips. The constant factor and the regression coefficients are calibrated using socio-economic data gathered over a base year. The calibration uses the method of least squares.

An example of a mathematical relation of trip generation is (Salter, 1989):

$$Y = 0{,}0649X_1 - 0{,}0034X_2 + 0{,}0066X_3 + 0{,}9489X_4, \quad (2)$$

where Y represent the average number of daily trips per family;
X_1 – the average number of active persons;
X_2 – the population density;
X_3 – the family total income;
X_4 – the average number of cars pe family.

The difficulties in applying the regression analysis are:

a) multi-colinearity – this phenomenon occurs when one or more of the independent variables X_i also show mutual correlation,
b) how many and which independent variables ?,
c) the nonlinearity of the model,
d) estimating the constant factor from the regression equation,
e) extrapolation,
f) the so-called ecological correlation resulting from the level of aggregation of the data used (we work with aggregated data or with average values).

When there are two options of choice (V1 and V2) to perform or not to perform the trip, the probability of making the trip can be written by the binary Logit model so:

$$P_r(l) = \frac{1}{1 + e^{-(V_1 - V_2)}} \quad (3)$$

It is observed that for V1 = V2 the probability is 0.5, and for V1 << V2 the probability tends to 1 and for V1 >> V2 the probability tends to 0.

The second step of the transport model is *trip distribution*. At this stage the destination origin matrix is defined for the study area. Departures and arrivals from/ in each analysis area are determined using the generation and

attraction models. One of the most used methods (because it has the simplest mathematical apparatus) is the model of growth factors.

The disadvantages of growth factor models are:

- New spatial developments for the study area cannot be accommodated,
- The method depends heavily on the reliability of the data in the individual cells of the base year matrix,
- There are instances when problems can occur with the iteration process (mai ales atuncicândavemcelule cu valoarea zero înanul de referință),
- A significant disadvantage of growth factor methods is their inability to incorporate changes in the transport system, in this instance the transport network.

Modal split is the third step in the conventional four-step transportation forecasting model. It is the step where trips between a given origin and a given destination are split into trips using transport modes and trip by car, and within the modes of public transport among those that exist in the area subject to analysis. Usually, the choice is made between two modes of transport in succession because the mathematical models are simpler and easier to use.

The impedance of travel from i to j on route r with a particular mode of transport can be written as a linear combination of duration T_{ij}^{r} and monetary cost, K_{ij}^{r}. The minimum of this expression, calculated for all routes, is the impedance of movement c_{ij} between i and j:

$$c_{ij} = \min_{r} (T_{ij}^{r} + \frac{K_{ij}^{r}}{\gamma}) , \quad (4)$$

where the value of time γ is expressed in monetary units per time (Euro/hour).

The value of γ indicates that the user will pay γ monetary units for a unit of travel time saved.The travel impedance is expressed in generalized time. The value of γ depends on the person's income and the purpose of the trip.

It has already been established that the number of trips to a destination decreases as the distance to the destination increases. This effect of travel impedance on travel distribution is expressed by the deterrence function,$F(c_{ij})$. The deterrence functions depend on the trip purpose, personal characteristics and even on the transport mode.

The most used functions that define the travel difficulty are of the type:

- Negative power function, $F(c_{ij}) = c_{ij}^{-\alpha}$,
- Negative exponential function $F(c_{ij}) = e^{-\beta c_{ij}}$,
- Combined power and exponential function $F(c_{ij}) = c_{ij}^{-\alpha} e^{-\beta c_{ij}}$.

The parameters α and β are determined throughcalibration,by means of observations in the study area. Figure 2 shows the functional forms of the deterrence functions for different values of the parameters.

Although often used, the exponentially negative function has a major disadvantage. The same absolute increase in travel impedance at low values has the same effect on travel as at high impedance, which is not confirmed by user perceptions. An increase in travel impedance from 4 to 9 minutes does not have the same effect as an increase from 180 to 185 minutes. Therefore, the exponentially negative function is only suitable for certain value ranges of the impedance function.

Sometimes, a deterrence function does not decrease monotonically over the entire range of travel impedance values.In the case of car trips, the values of the deterrence function start from a minimum value, reach a maximum value and decrease as the travel impedance increases. The reason is that the tendency to use the car over short distances will generally be reduced, walking or cycling being the right choice. In such cases, it is possible to use a combination of power and exponential functions to describe the phenomena.

Fig. 2: The deterrence functions (source: Immers & Stada, 1998)

If we assume that the individual utilities can be replaced with an average utility for the whole area, then the following expression can be used for the utility of choosing i as origin, j as destination and making a trip from i to j, using the mode of transport m:

$$U_{ij}^{m} = V_i + V_j + V_{ij}^{m} + \varepsilon_{ij}^{m}, \tag{5}$$

where V_i represent the utility obtained for an activity carried out in iarea(activities carried out at home),
V_j - the utility obtained for an activity carried out in j area(e.g. work),
V_{ij}^{m} - the utility obtained for travelling from i to j, using the mode m,
ε_{ij}^{m} - the term that defines the probabilistic error (error given by the unobserved attributes).

If it is accepted that the terms are independent and have a Gumbel distribution (correct hypothesis for the logit model), then we can reach at:

$$T_{ij}^{m} = a_i b_j e^{V_{ij}^{m}}. \tag{6}$$

The utility is the *effort* required to make a trip from i to j, using the m mode. *The effort* will be a function of the travel impedance between i and j with mode m.

$$V_{ij}^{m} = f^{m}(c_{ij}^{m}) \tag{7}$$

After replacing $e^{f^{m}(c_{ij}^{m})}$ by $F^{m}(c_{ij}^{m})$ we obtain:

$$T_{ij}^{m} = a_i b_j F^{m}(c_{ij}^{m}) \tag{8}$$

and hence:

$$T_{ij}^{mm} = \sum_{ij} T_{ij}^{m} = a_i b_j \sum_{m \in ij} F^{m}(c_{ij}^{m}) \tag{9}$$

Interpreted, this expression means: the distribution of the transport flows across the various transport modes m between an origini and a destination j is proportional to the values of the deterrence function.

The last stage of the transport model is *traffic assignment* and it concerns the selection of routes and it is the one in which the load of the network is determined. Following this stage, any congested areas can be determined and measures can be established to reduce it.

Traffic assignment patterns can be classified according to time variation as follows:

- Static models, they assume that supply and demand are constant over time. Through these models, the traffic is affected in the network only once because the demand and supply are constant. These are also called 2D models because the third dimension, time, is not taken into account;
- Dynamic models, they take into account the variation of transport demand over time and possible changes in transport networks over time.These result in dynamic flows on the network arcs (with variation over time). These are called 3D Models (three dimensional).

Dynamic models of traffic assignment are more recent than static ones that benefit from a longer experience (Xidong Pi, Zhen Qian, 1997).

The simplest static model of traffic assignement is the *all-or-nothing model*. It assigns all trips on the shortest path, regardless of changes in travel impedance caused by network loading. If users perceive the impedance of traffic after a statistical probability distribution, then traffic can be affected on routes stochastically (randomly) in two ways:

a) The first one uses theoretical probability curves;
b) The second one uses traffic simulation.

Like all-or-nothing model, the stochastic model does not take into account the changes in travel impedances due to traffic congestion.

Equilibrium models are those that change the travel impedance of a connection due to congestion**.** The main feature is that the travel impedance of a conectionis a function the traffic load. If the traffic flows increases on connections that were originally the shortest paths, users will search for alternative paths. This will lead to an equilibrium in which users will no longer be able to improve the travel time.Finally, the stochastic traffic assignement model and the equilibrium model can be combined.Stochastic equilibrium models consider the effect of congestion and differences in users' perceptions of travel impedance. These are presented in table no. 2.

Table 2: Classification of static assignments models

		Stochastic effects taken into account?	
		No	Yes
Capacity effects taken into account?	No	All-or-nothing assignment	Stochastic assignment
	Yes	Equilibrium assignment	Stochastic equilibrium assignment

(source: Immers & Stada, 1998)

The prime characteristic of the stochastic traffic assignment models based on simulation is that the travel impedance on a given connection is determined using a random number generator. Consequently, the levels of link traffic impedance are obtained as stochastic variables.

$$C_a = c_a + \varepsilon_a , \qquad (10)$$

where C_a is the random variable of traffic impedance,
c_a - the measured value of traffic impedance,
ε_a - the stochastic error term (random).

When $\varepsilon_a = 0$, c_a can be interpreted as the travel impedance used in all-or-nothing method. Commonly, a normal distribution is used forevaluation of ε_a .

The following relation is used for the impedance of a connection:

$$C_a = c_a + z\sqrt{\varphi c_a}\ , \qquad (11)$$

where z is a random number between 0 and 1 with a normal distribution,
φ - a factor that determines the size of the variance.

A limitation of the four-step transport planning model is that each trip is considered a round trip without considering the chained trips in which a destination turns into a new origin, situation that is common in current activities. This is schematically represented in figure 3, in which the distance, cost and accessibility attributes were written on each arc.

Fig. 3: Schedule of *pick-up* trips

The original contribution of the authors consists in the fact that following the experience gained in the field of transport planning, by using various dedicated software tools (TransCAD and VISUM) or using appropriate analytical models, it was observed that, in practice, not in all cases the expected results could be identified. Feedback and detailed analysis of the implemented measures led to the original identification of limits and boundaries in the application of four-step planning models.

Conclusions

Many transport studies deal with the global demand forecast quite superficially and the solutions are oriented in two directions:

- either the current mobility is adjusted in direct proportion to the increase in the number of the population and to a share of the increase in mobility, resulting from the observations on the individual behaviour;
- or by comparison with other urban agglomerations with a higher standard of living and mobility; an average level of mobility is determined for the forecast horizon.

The first step of the model, the trip generation, is loaded with ambiguity and indeterminacy because the information is obtained through transport surveys which, as we know, are extremely dependent on the correctness/ accuracy of data collected from respondents who may omit or misreport certain aspects. Also, the regression analysis has some difficulties / limits that are presented in the paper - difficulties related to the mathematical apparatus or data distortion at the time of aggregation.

The model aggregates the individual trips at the level of the paths, means of transport (here its capacity is decisive in traffic assignment on a path), by modes and, subsequently, assign them on the itineraries, finally obtaining the network traffic flows. The trips of freight vehicles and the periods of time in which they can move are not taken into account. Segregation of freight and passenger flows can be achieved by establishing time windows for different categories of traffic.

The mathematical models used to determine the travel difficulty do not always succeed in faithfully reproducing human behaviour on the whole range of choices and actions. Human decisions and actions arediverse and show a stochastic behavior that makes them difficult to model or, in other words, the necessary mathematical apparatus is complex and difficult to use.

The assessment of future transport needs is done by extrapolating the origin-destination matrix, which introduces many uncertainties in the model, because it is considered that socio-economic factors keep the same evolution as in the current situation. This is a serious distortion that can lead to erroneous results and improper sizing of the infrastructures of different modes of transport and travel.

Another problem with the four-step transport planning model is that only round trips are taken into account without considering that in the case of trips by car more and more users make pick-up trips, through which they try to maximize its usefulness.

However, the model is useful in obtaining an image of the traffic parameters evolution in order to expand/ develop the components of the transport network by increasing the capacity of the nodes and links or to estimate travel times in different development scenarios.

Abstract

Purpose: The objective of this article is to determine the opportunities for game theory application and promote beneficial impacts from its introduction into education management system. **Methodology**: While doing research the following methods were used: method of expert evaluations, data analysis, economic and mathematical methods. Management content of any economy branch, particularly education, tends to select constant optimal decisions. Use of mathematical framework is one of the ways of effective decision-making processes improvement. The authors offer theoretical and game model to apply for description of education quality challenges. Discrete game in normal form is built up, whose participants are university of state or municipal ownership and state authorities or local territorial community council. Gamers' strategies include their different attitude to education services quality. Payoff matrixes are shaped on the basis of significant advantage multiplied by results. The game solution is achieved within clear strategies focused on non-beneficial university strategies to work formally or 'simulate'. This implies that in the future a number of 'Universities-simulators' will grow whereas the quality of education services will decline. **Conclusions**: To change the situation as for beneficial and non-beneficial strategies for society it is of great necessity to alter the payoff system for both University and State/Community. This situation may alter only in case of institutional changes which, first and foremost, should begin from granting of real autonomy (not formal one which operates these days) as well as freedom to Universities. We should also rethink of the operation of the current National Agency on higher education quality assurance and reconsideration the formula of university funding alongside with taxation approaches.

Keywords: Game Theory, University, State, Community, Education Quality, Quality Assurance, Simulate.

Introduction

This society is observed to face the rise in demand for higher education which, in its turn, requires its further development and improvement. Responding to all today's challenges concerning Ukraine's accession to the Bologna process, we are eager to achieve higher world standards in education. Conversely, it needs the constant focusing on better management of quality education.

Up-to-date mechanisms implementation of state and public administration concerning quality education management as well as quality evaluation considering European and world practices and state, non-governmental and public structures engagement is of actual importance. To the authors' mind, higher educational establishment development

Cite this Article as: Liudmyla ILICH, Olena AKILINA and Alla MYKHATSKA" Using Game Theory to Describe the Ways Of Ensuring Quality Education Challenges " Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

should be based on the principles of strategic management implementation. Higher education as a type of economic activity is presented with the establishments providing educational and complement services. Thus, they are subject of an educational services market which spread the operation the objective market laws. In such a way higher educational establishment as a market player are forced to confront to negative tools of internal and external environment, while working under uncertainty.

Taking into account the necessity to adopt state managerial decisions and their quality dependence on the right justification for the choice of the best decision variant, the use of game theory is an efficient tool. It makes it possible to increase the quality of justification basis and state managerial decisions development as well as enhance the effectiveness of education strategic management. Game theory provides application of mathematical methods to solve socio-economic issues which is of great importance for the head of public or local authority who is forced to choose among social, private and corporate interests while decision-making process. Correspondingly, identified and obvious community's interest should be considered as the basis for strategy and decision-making process, being the purpose of script implementation.

Literature Review

Game theory is a branch of Mathematics which studies mathematical models of strategic interaction among rational decision-makers and applies the method of seeking real events to occur in future as a result of specific actions or inactions by participants in a game or a script. Game theory has a long history. But only John Nash, John von Neumann and Oskar Morgenstern were first who contributed to its systematic development

In 1944 John von Neumann and Oskar Morgenstern, mathematician and economist, published common book 'Theory of Games and Economic Behavior', which is considered classic these days. They developed innovative mathematical theory of economic and social organization which revolutionized economics and led to creation of a new branch in scientific research, game theory.

E. Rowland (1946) claims that general theory of social games offers simplified conceptual model of economic behavior, so the study of this theory may contribute a lot to some basic concepts of economics, in particular, concept of utility.

In 1950 J. Nash (1950) published scientific paper where he developed and described a criterion for mutual consistency of n players' strategies which is widely used in economics these days and known as 'Nash equilibrium' applicable to a wide variety of games.

D. Kreps (1990) states that 'One cannot find a field of economics … in which understanding the concept of Nash equilibrium is not nearly essential to the consumption of the recent literature'.

Up-to-date studies by Pou-Yan Nie, Takashi Matsuhisa, Henry Wang, Pay Ay Zhang 'Game Theory and Applications in Economics' (2014) significantly expand the scope of game theory application to economics, including economic theory, microeconomics, enterprise economy and other applied spheres.

In their turn Zigfrid Berninghaus, Karl-Martin Ehrhart, Annette Kirstein and Stephen Seifert (2002) expand and open up another opportunity for application game theory methods to the sphere of economic counseling.

K. Peleckis in the article 'The Use of Game Theory for Making Rational Decisions in Business Negations: A Conceptual Model' (2015) makes comparative analysis of the world literature on game theory and its application for rational decision-making at negotiations. The article offers an algorithm which combines game theory approach and heuristic algorithms for better representation of negotiations specific nature. This algorithm may be applied to support strategic decisions at negotiations and is of great use for better comprehension of negotiations process strategic management.

Tille Grüne-Yanoff and Paul Schweinzer (2008) conclude that game theory is not a universal theory of rationality. Game-theoretic models consist of a formal game structure and an informal model narrative or story. When game theory is employed to model economic situations, the stories play a central role in interpreting, constructing and solving game structures.

Larry Sanuelson (2016) states that nowadays game theory not only backtracked from its initial origin but has also covered the whole economics. He determines the key challenges of game theory, including constant struggling with

multiple equilibriums and necessity of better integration cooperative and non-cooperative game theory. It is him who explores the possibilities of game theory application to behavioral economy.

Charles A. Holt and Elvin E. Roth (2014) also claim that game theory takes centre stage in economic theory. To the authors' opinion, to make game theory as productive in 50 years' time as it is these days theoreticians of games face the challenge to learn how to employ more varied and realistic models of individual behavior in studying strategic behavior, as well as how to make better use of analytical, experimental and computing tools in complicated strategic environment.

Ukrainian science is also not exempt from the ways of practical application of game theory to solve social and economic challenges in different spheres. Among this country's studies the works by O. Luginin (2016), A. Shiyan (2009) and D. Bikulov (2015) should be mentioned. The study by S. Terepishiy (2015) draws special attention, as it considers perspective of game theory application while decision-making in education.

It can be concluded that a significant number of sciences developed a lot thanks to mathematical methods application. During its history game theory has changed specifically and modified in its own way. Nevertheless, it is still developing and of actual importance in economics as well as in other sciences. Its application can be effectively used in different branches of Ukraine's economy, particularly, in education.

The analysis of world and Ukrainian studies made proves that perspective of game theory application while decision-making in education is not fully covered. It is for this reason the objective of our study is to determine the opportunities for game theory application and its beneficial impact in education management.

Management content in any economic branch, including education, is restricted by constant choice of optimal solutions. The development of this branch depends on effectiveness of managerial decisions. Complicated nature of market economy puts forward severe requirements concerning reasoning behind managerial decisions. Application of mathematical methods to decision-making process is one of the ways to meet these requirements.

Game theory is theoretical basis of mathematical models of optimal managerial decision-making in conflict situations when one opponent wins by means of another one. Alongside this situation in decision-making theory, situations of risk and uncertainty are also considered. They have different models and require different criteria of optimal decision choice. But in practice a number of solutions made under real conditions are strictly limited. Economic situation is often unique, so decisions should be made simultaneously and within uncertainty.

Game Model

Theoretical game model to manage effectively the university lecturer's job was offered by Ukrainian scholar Anatoliy Shiyan in 2009. The authors reconsider this idea and transform such modeling to determine the university's effectiveness. Educational system is the main public institution whose activity provides specialized preparation of the youth according to labor market requirements. Success in this institution's activity is the key element of any society management effectiveness. But scientific literature mentions the theory of 'institutional traps' occurred in socio-economic systems of transitive type which slow down the processes of public transformation (Polterovich V, 1999; Polterovich V, 2004). Institutional trap is considered ineffective but sustainable behavioral norm. It has no economic benefits for society. Nevertheless, the participants of such 'institutional trap' should not reject it due to drawbacks of public and municipal administration. In the situation of 'trap' occurrence the system selects ineffective way of development. The paradox lies in the fact that in such a case the transition to effective way of development can be rather resource-incentive for the system.

Nowadays education quality in Ukraine as well as in the post-Soviet countries is rapidly worsening, in spite of the fact that there was a period of time when Soviet educational system served as a guideline for many world countries. Even these days some British schools learn from Soviet experience of specialized Physics and Mathematics education. These days increasing emergence of 'institutional traps' can be observed in Ukrainian education. Taking into account the fact that these processes are only at initial stage, the chances of addressing their shortcomings are rather high.

So, transformed theoretical game model to describe the problem of education is quality is proposed. Discrete game in normal form is built, their participants are University (of state and municipal ownership) and state authorities (hereinafter referred to as 'State') or relevant council of territorial community (hereinafter referred to as 'Community').

Gamers' strategies are determined by their different attitude to education services quality. Payoff matrix is shaped on the basis of progressive advantage multiplied by results. The given model can be referred to as the process of both 'institutional trap' shaping and exiting from it which promotes the application of this model to education management development in this country.

The right problem shaping and relevant problem statement is one of the main stages of game theory application in practices. Since the legality of a decision is determined by the effects occurred while modeling a real situation according to theoretical game features.

We should consider interaction between 'University' and 'State/Community'. It lies in the following:

1) According to the Law of Ukraine 'On Higher Education', it is the 'University' which undertakes scientific, scientific and technical, innovation and/or methodological activity, provides educational process organization and gets funding from the 'State/Community' as a founder.

2) 'State/Community' on behalf of founder obtains social effect while the population's education level is increasing. According to Ukrainian Legislation 'University' is a non-profit budget institution as it is funded at the cost of state or local budget, which means it is not liable for income tax and gets some tax benefits. Nevertheless, 'State/Community' as a founder benefits from the fact that 'University' must channel 50 per cent of its profit into providing scientific, scientific and technical activity and developing its material base which have to promote improvement in education quality in its turn. Thus, interaction between stakeholders 'University' and 'State/Community' can be presented as a statistic game, as both 'University' and 'State/Community' obtain the same information, so their moves are expected and/or predicted.

At first, all possible strategies of both gamers should be described:

1. To our mind, 'University' should possess the set of the following strategies:

Fig. 1: 'University' Strategies

2. 'State / Community' also possess own strategies:

Fig. 2: Strategies 'State / Community'

So we may conclude that strategies offered for both gamers are relevantly similar, as the common patterns of gamers' behavior are described. It is also comprehensible that conditionally equitable gamers' behavior is presented. The authors assume this conclusion despite existence of the proper dependence and submission between 'University' and its founder.

To complete the standard assignment in game theory the payoff matrix should be given for both gamers which is labour-intensive and responsible stage while decision-making. The mistakes made during payoff matrix shaping are out of the ways computing methods. The typical variant is given in Table 1 in which 'State/Community' payoffs are represented in the right upper corner, whereas University payoffs are given in lower left corner. The evaluation of payoffs is given at 100-pointed scale of education quality. The matrix scales can be non-linear and monotonous. You see, we are interested in complex figure productment. The authors have no necessity to compare real numeric values among them. In such a way we calculate payoffs both for 'University' and 'State/Community'. Within real economy the 'ratio of enforcement' should be found, as it enables comparable the winners' prizes. Though, while setting the following task it is not necessary unlike the comparison between parties' payoffs (Bucharbayeva L, Yegorova Yu., Frantz M., 2017)

Table 1: Allocation of payoffs in the game between 'University' and 'State/Community'

		State / Community		
		Strategy of proper function fulfillment	Strategy of formal function fulfillment	Strategy of imitation
University	Strategy of education quality enhancement	75	-25	100
		50	-100	-100
	Strategy of formal services provision	-75	-50	-100
		-25	0	25
	Strategy of imitation	50	-25	25
		75	-50	-75

Source: author's calculation by the expert evaluations

After compiling the matrix it makes sense to compare the payoffs of 'State/Community', i.e. proper local or municipal authorities for various strategies under the same 'University' strategy:

1. Strategy by 'University' – 'Strategy of quality enhancement' is of most benefits in relevant submissions of state and local authorities imitating their activity, but is of least benefits among those authorities which fulfill their functions formally.
2. Strategy by 'University' – 'Strategy of formal provision with services': the relevant local and municipal authorities give the most benefit from formal fulfillment of its functions, whereas the least is given from imitators who have nothing on offer;
3. Strategy by 'University' – 'Strategy of imitation': the most benefits are obtained by proper state or municipal authorities which accurately obey the law but the least advantages are handed by those who formally execute their functions.

We should compare payoffs of 'University' and various strategies of 'State/Community' to make the University's benefits clearer:

1. Strategy 'State/Community' – strategy of proper compliance with functions will benefit the 'University' the most while the latter imitating its activity: whereas the least one who will take advantage of will be the least among those who providing services.
2. Strategy 'State/Community' – Strategy of formal function observance: 'University' obtains the most benefits, as it provides the most formal services, whilst the least among those who spread quality.
3. Strategy 'State/Community' – Strategy of imitation: the greatest payoff is obtained by 'University' who operated formally, the least one is by those who worked qualitatively, which means much more effort than imitator.

Game solutions achieved in pure strategies. Though, all strategies are focused on 'non-beneficial' for communities ways of development state and municipal authorities: 'work formally' or 'imitate'.

Nash equilibriums are concentrated within the choice of the strategy like 'imitate and work qualitatively' or 'work formally and work formally'. Accepting this viewpoint concerning Nash equilibrium, which most often concerned the rational choice accepted by all gamers, we claim that they were the one who created the conditions of populations' self-organization. It was one of Nash equilibriums that established itself within 'University' – 'State/Community' interaction as well as it maintained the shaping 'University' – 'State/Community' interaction in general. Nash equilibrium is often considered the main tool for institutional trap shaping tool as the set of the institutional traps is limitless within education sphere,

In this case both Nash equilibriums can be pretty effective for gamers for short-period time. As 'University' strategy to work formally is less beneficial for state and municipal authorities wherever strategy is chosen, so in long-term prospective such strategy won't work.

Conclusion

While game solving, we concluded that strategy 'to simulate, to work' will be Nash equilibrium within all the period of time. It means that 'University' always benefits when it chooses the strategy 'to simulate' under prevailing realities in Ukraine. This implies that in the future a number of 'Universities-simulators' will grow whereas the quality of education services will decline. Nowadays we have an opportunity to observe the situation when qualitative education is vanishing, replaced with the simulator of education services. Consequently, in the nearest future we shall experience worsening of labour force qualitative indicators which will negatively impact Ukrainian economy.

To change this situation it is of great necessity to alter the payoff system for both gamers. The system shaped in table 1 in this article relate to institutional peculiarities of contemporary education system, in particular, of current interaction state between 'University' and 'State/Community'. This situation may alter only in case of institutional changes which, first and foremost, should begin from granting of real autonomy (not formal one which operates these days) as well as freedom to Universities.

Rethinking of the operation of the current National Agency on higher education quality assurance which represents the interests of 'State/Community' may also improve the situation.

A new formula of universities funding is another way of problem solution. The indicators according to which funding is allocated should provide the universities with the clear awareness of further course to enhance their status. In particular, until recently the indicator of actual number of students studied at budget cost has been the main determinant for university funding. It encouraged universities to simulate the activity lessening significantly a number of dropout students with poor academic performance. Nevertheless, some progress is being observed. For instance, since 2020 universities have been funded on a formula which assumes that universities with better activity results gain more funding compared with the previous year's budget. Formula for funding includes such indicators as the scope of the university, enrolment, regional ratio, position in international ratings, R&D budget invested to universities by businesses or foreign grants. We believe this list should be added with the indicator of graduates' employment, as it displays the quality of education services in full. Universities' beneficial taxation should have both supportive and incentive nature as well as promote its further development aimed at highly qualified staff assurance in relevant branches of economy.

Quality Management in Education – A Comparative Analysis of School Improvement Practices from Luxembourg, Belgium And Croatia

Malgorzata DZIMINSKA

University of Lodz, Lodz, Poland
e-mail: malgorzata.dziminska@uni.lodz.pl

Abstract

The article presents a qualitative comparative review of school quality improvement practices from Luxembourg, Belgium and Croatia which are analysed against the key principles of the Total Quality Management: 1) management's commitment (leadership); 2) focus on the customer and the employee; 3) focus on facts; 4) continuous improvements; 5) everybody's participation. Interviews with school representatives provided insights which formed the basis for comparing the school quality improvement practices in the three countries and highlighting the key similarities and differences. The analysis contributes to the field of management by revealing strengths and the areas for improvement in the school practices and emphasizing the areas where lessons can be learnt and used to shorten the learning curve on quality improvement based on international experiences.

Keywords: TQM, quality, education, data-based decision making

Introduction

The implementation of the European Erasmus+ project entitled: "DATADRIVE: The Power of Data to Take Smart Decisions for School Improvement" created an opportunity to analyse school quality improvement practices that are currently in place in schools from Luxembourg, Croatia and the German-speaking community of Belgium. Total Quality Management (TQM) has been chosen as the framework to evaluate the practices of schools, because as the literature shows it can be perfectly suitable for educational context (Sallis, 2014). The study explores the school quality-improvement approaches in two schools from Luxembourg, Croatia and Belgium through a set of in-depth interviews with school representatives in order to gain insights on the school quality improvement practices and compare them between the countries.

The article is organized into a literature review section where the TQM methodology is presented with a special attention devoted to its applicability to the field of school education. Then, contextual information about the systems of education in Luxembourg, Croatia and the German-speaking community of Belgium is presented to provide insights on the level of formalization in respect to quality-related actions in schools. The methodology part of the study explains the chosen research approach in order to meet the study objective which was to gain insights on the school quality improvement practices and compare them between the countries. The discussion of results section presents the school quality improvement practices and critically discusses their performance. The TQM pyramid model encompassing key principles of the approach (leadership, focus on the customer and employee, focus on facts, continuous improvement and everybody's participation) formed the theoretical basis for the analysis and interpretation of school quality practices in schools. Finally, the conclusion section summarizes the strengths and the areas for improvement in the approach to quality enhancements in schools and emphasizes the areas where lessons can be learnt and used to shorten the learning curve related to school improvement based on international experiences.

Literature Review

Total Quality Management

Total Quality Management (TQM) has its roots in the contribution of W. Edwards Deming and J. M. Juran to successful transformation of industry through a disciplined management process focused on quality (Deming,

Cite this Article as: Malgorzata DZIMINSKA "Quality Management in Education – A Comparative Analysis of School Improvement Practices from Luxembourg, Belgium And Croatia" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

2000). TQM is both a philosophy and a methodology (Sallis, 2014). It offers a strategic approach to running an organization following a number of principles which emphasize that the customers' needs define the quality standards. This aspect is highlighted in the definition by Corrigan: "TQM is a management philosophy that builds a customer-driven, learning organisation dedicated to total customer satisfaction through continuous improvement in the effectiveness and efficiency of the organisation and its processes" (1995, p. 61). The approach advocates that employees of all levels share the responsibility for quality improvement in an organization, including top managers whose commitment and engagement are vital for the success (De Jager and Nieuwenhuis, 2005).

TQM principles promote building a continuously learning organization where communication between management and employees, teamwork, providing a system of supports (i.e. trainings) encouraging employee participation and ownership of processes as well as long-term commitment to introducing quality improvements are considered of vital importance (Neves and Nakhai, 1993). However, implementation of the TQM approach is not easy, especially for traditional organizations where expenses and effectiveness are the core and they need to switch gear to focus on the customer satisfaction. Such a change calls for a refinement of strategies and going through a deep cultural change requiring redefinition of their values, behaviours and norms (Carson *et al.*, 2000; Ah-Teck and Starr, 2014). On the other hand, TQM has been proven not to be more difficult to implement than other transformational strategies adopted by organizations striving for success (Cândido and Santos, 2011), which makes it a challenging, but rewarding methodology to apply.

Total Quality Management in Education

Although TQM originated in manufacturing sector, there is a common agreement that TQM principles are equally relevant to educational institutions as to any other private or public enterprise (Deming, 2000; De Jager and Nieuwenhuis, 2005). The literature on TQM's application in services, in school education in particular, has been discussed by a number of authors (Logothetis, 1995; Stensaasen, 1995; Schargel, 1996; Winn and Green, 1998; Rampa, 2010; Soria-García and Martínez-Lorente, 2013; Sallis, 2014).

Sallis (2014) helps to understand the reasons why quality matters in education. He presented a list of four "quality imperatives" that drive the quality improvement efforts in schools. The moral imperative refers to the conviction that customers of the education service (students, parents and the community) deserve the best possible quality of education. Professional imperative stems from an internalized professionalism of an employee who is driven by commitment to delivering the highest possible standards both in the classroom practice or in the management of the institution. The competitive imperative draws attention to the fact that education sector is not an exception and it is subject to market rules, just like industry. Quality might be the only differentiator for an educational institution and thus quality might become its key competitive advantage (Powell, 1995). The final imperative refers to accountability which builds upon the expectations of the public that a school needs to demonstrate high standards. Given all the imperatives, care for quality improvement in schools is no longer an option, but a necessity.

The need for quality is evident, but the quality concept entails a big degree of ambiguity. The definition of quality that stems from the TQM principles encompasses many facets. It is defined as "conformance to requirement" (Crosby, 1979), "fitness for use" (Juran and Gryna, 1980), "a predictable degree of uniformity and dependability at low cost and suited to the market" (Deming, 1986), "continuous improvement in the effectiveness and efficiency of the organisation and its processes" (Corrigan, 1995). Juxtaposing these definitions with understanding of quality in education brings up the concepts of many facets of quality defined by Scheerens (2014) including productivity, effectiveness, efficiency, equity or responsiveness. From the perspective of productivity, quality is represented by successful attainment of the desired level of outputs (i.e. students' achievements on tests, graduation rates, level of students' wellbeing, employability levels)(Hampel, 2005; OECD, 2005, p. 14). School quality viewed in terms of effectiveness is focused on the instrumental value of input and process indicators to maximize output and quality as efficiency can be understood as effectiveness of education at the lowest possible costs. Quality seen from the perspective of responsiveness concerns the way input, processes and intended outcomes are fitted to the needs of the context. As Scheerens explains "where effectiveness and efficiency deal with the question of "doing things right", responsiveness may be seen to address the question of "doing the right things", such as choosing educational objectives that form responses to the demands of further education or the labour market" (Scheerens, 2013, p. 6). School quality seen through the lens of equity refers to a situation when personal, social or economic circumstances, such as gender, ethnic origin or family background do not hinder achieving educational potential (fairness) and all students, irrespective of their socio-economic status, reach at least a basic level of skills

(inclusion) (OECD, 2015). In TQM equity is more visible in the principle of involving everybody in the process of change. In summary, the presented definitions from management literature and education field prove their alignment exemplified by the multifaceted perception of quality.

TQM offers a disciplined approach to address the need of quality enhancement in schools. Dahlgaard et al. define TQM in education as "an educational culture characterized by increased customer satisfaction through continuous improvements, in which all employees and students actively participate" (1995, p. 445). Wiedmer and Harris denote it as "a system designed to review educational performance, issues, and practices while bringing groups of professional educators together to identify, analyse, and resolve educational concerns that impact the lifelong learner"(1997, p. 314). The cited definitions highlight the central role of customer needs which are satisfied through the teamwork of professionals that deal with the identified challenges following the continuous improvement approach. Based on the 14 points of TQM that were formulated by Deming (Walton, 1986) Dahlgaard et al. (1995) proposed a TQM pyramid which offers a framework of five major elements that condition quality improvement in education: (1) management' s commitment (leadership) (2) focus on the customer and the employee; (3) focus on facts; (4) continuous improvements; (5) everybody's participation (1995, p. 446).

Management' s commitment (leadership) forms the basis of the TQM pyramid because it is key to any educational institution. It has very significant effects on the quality of the organization's performance and pupil learning. "School leadership is second only to classroom teaching as an influence on pupil learning" (Leithwood, Harris and Hopkins, 2008, p. 28). Leadership serves as a catalyst for unleashing the potential capacities that exist in the organisation. Almost all successful educational leaders follow the proven leadership practices: building vision and setting directions, understanding and developing people, redesigning the organisation, and managing the teaching and learning programme (2008, p. 30).

Focus on the customer and the employee is embodied in TQM through its human-centeredness. It is the customers whose needs, expectations and satisfaction matter most and it is the teams of employees whose joint efforts, skills and commitment drive the quality improvement. Based on the work of Soria-García and Martínez-Lorente (2013) as well as Kanji and Tambi (1999) for higher education, similar typology of customers divided into internal and external can be presented for school education. Internal customers comprise of employees: primary (faculty staff) and secondary groups (administrative services). External customers are divided into external primary (students) and external secondary parties (parents, organizational partners, etc.). They highlighted also that all the employees need to be motivated, engaged and empowered in order to follow the quality-oriented improvements.

TQM pyramid emphasises focus on facts which is operationalized by making decisions based on data (Mukhopadhyay, 2005). In a school setting data-based decision making (DBDM) can be defined as the use of data to improve education (Schildkamp and Kuiper, 2010). Using data as foundational for decision-making is advocated at each stage of the quality improvement cycle of plan-do-check-act (Deming, 2000). Reliable information plays a key role in the school quality improvement process including: goal setting, planning the actions, their implementation, evaluation and assessment whether the goals have been reached and if the improvement actions have led to the expected outcomes (Marsh, Pane and Hamilton, 2006; Mandinach *et al.*, 2008; Schildkamp, 2011; Schildkamp and Poortman, 2015). Obtaining and acting upon feedback on the needs, expectations and satisfaction of stakeholders over time is considered to be a major asset of TQM approach (Deming, 2000; Sallis, 2014).

According to Deming, continuous improvement requires continuous learning. He, therefore, produced another version of the improvement cycle (the Deming cycle: from plan-do-check-act) and named its stages as follows: plan-do-study/learn-act. Continuous improvement requires patience (Madsen and Carlsson, 1995). The process is time-consuming and the effects of changes implemented in a school setting are seen only from perspective. In a business setting companies that kept their TQM initiatives over the years had more time to see benefits stemming benefits from it. According to the findings of Powell (1995), time since adoption of TQM contributed to a greater satisfaction with its implementation. This shows that implementation of the TQM principles requires time and patience. Therefore, implementation of TQM is a long-term commitment.

In TQM approach everybody's participation is seen as a key condition for the quality improvement process. In order to support the employees and win their buy-in the necessary package of information needs to be provided. Dahlgaard et al. advocated proper training which should involve the practice of continuous improvement cycle including such elements as: identification of a problem, definition of its cause(s), planning and implementing

actions to prevent failures and constant reviewing of results in terms of the customers' needs and their satisfaction level (1995, pp. 454–455). Involving in the quality improvement actions all the stakeholders of the educational process can result in teamwork attitude between internal and external customers (Winn and Green, 1998).

School quality context in Luxembourg, Croatia and the German-speaking community of Belgium

Luxembourg

With the amended law of 2 February 2009 on the re-organization of primary education, the notion of school quality development was formally introduced to the elementary schools. The school committees were required to draw up a 3-year school development plan "*plan de réussite scolaire*" (PRS). In secondary schools, school development teams were set up, but the law did not oblige them to draw up the plans. Since 2017, the experiences and feedback from the implementation of the PRS was taken on board. The concept has now been adapted to "plan de développement scolaire" (PDS) for both elementary and secondary schools. On 7th February 2018, the National Observatory of School Quality was created with the mission to bring an objective view of the quality of the school system.

Croatia

Law on Education (2008) in article 88 introduced external evaluation and self-evaluation of school institutions. The Strategy for Education, Science and Technology defined the overall objective for education as to ensure quality education with equal opportunities for every child. The Strategy promotes the following principles: decision-making based on data analysis; efficiency of the system; logical sequence of the introduction of changes; systematic monitoring and evaluation of the results of the measures implemented. It states that quality assurance in education includes both internal quality assurance of institutions (based on self-evaluation) and external quality assurance (based on prescribed standards and criteria and is carried out by an authorised agency that is itself subject to external evaluation).

The German-speaking community of Belgium

Pursuant to Article 20 of the Basic Decree of 31 August 1998, the schools are obliged to carry out systematic school improvement work. Since 2009 all schools in the German-speaking Community of Belgium are externally evaluated every 5 years. The quality framework from the state of North Rhine-Westphalia in Germany – the Orientierungsrahmen Schulqualität (ORS) is used for school evaluation. School development project is the key means of introducing changes in a school. The project involves naming the vision and strengths of a school, developing goals, planning and implementing actions and adopting measures to evaluate the goals achievement.

Methods

The study is guided by the research question of what are the quality-improvement practices in schools from Luxembourg, Croatia and the German-speaking community of Belgium and how they compare across the countries. In order to answer this question, a cross-sectional descriptive and explanatory research was conducted. The study employed interviews as the method of data collection. The interviews were held with 16 school teachers and 6 principals representing elementary schools in each of the three focus countries in order to provide information from the perspective of school community members. The reliability of the study was assured by using a systematized approach to data collection that was consistent with the research question. The internal validity of the study was fostered by disclosing patterns, similarities and differences between the focus countries' data gathered within the study. External validity of the study was limited due to the small non-probability sampling used for the interviews, however, it was strengthened by offering not only case-specific descriptions, but also cross-case analyses coming from literature review on the legal context for quality improvements.

Discussion of Results

Management' s commitment (leadership)

In all the schools the role of a principal was highlighted especially in the area of developing and approving the improvement goals for the school. The decision is usually based on input from the teachers (CRO) or results from the external evaluation (BE). In case of Luxembourg the school president based the decisions on the opinion of a

"school development specialist". Additional input for the decision on what the school should improve comes from such sources as: evaluations (both: external and internal), teachers, students and parents' councils. It has been emphasized across all schools that the leader empowers the school teachers in the process of decision-making. For example, the improvement areas are chosen democratically by the school teams and only then they are verified and approved by the principal (BE, LUX, CRO) and councils or the founder (the city) (CRO).

Focus on the customer and the employee

Although all schools declare that they take into account the voice of students (external primary customers) in their improvement processes it seems that in case of Croatia the input from the students on what interests them and what should be introduced to the curriculum is given much more focused attention than in two other countries. The obligation to do that has been introduced to the new curriculum. In case of Belgium and Luxembourg this knowledge is gained through rather ad hoc conversations with students and parents. In order to better understand the students' needs a diagnosis of their strengths and weaknesses is taking place at various levels and is done by the teachers mainly. In case of Luxembourg and Belgium there is a wider availability of standardized tests to do that than in case of Croatia where teachers and principals report the lack of sufficient professional diagnostic tools and highlight the urgent need for reliable tests especially for gifted students.

All school representatives underline the importance of collaboration with parents. Parents become "colleagues" or "partners", because some of them work so much with their kids at home that they become professionals and offer extremely valid points in discussions over the child's learning (BE). Parents are offered a lot of opportunities to support their kids (materials are posted on the online platform, e-journals have been introduced), but the level of their involvement differs. According to Croatian teachers "it could be much higher". All schools declared inviting parents to various initiatives organized at schools, so that they create bonds with teachers and feel as an integral part of the school ecosystem.

The focus on customer satisfaction is reflected also in the emphasis on well-being of students visible in each of the countries as an important output of educational process. In all countries: good atmosphere in school, good collaboration, satisfaction, motivation, enthusiasm of teachers and good school climate are seem as important factors that contribute to students' wellbeing. The declarations of interviewees from all countries put emphasis on the importance of all the school stakeholders' satisfaction: "(…) basically it's all about good communication and relationships between those that make the school: parents, teachers, students, administrative and technical staff" (CRO). "A good school is the one where both children and teachers like to go (LUX)" and "(…) the staff is valued and personnel is also promoted by the school management (BE)".

Focus on facts

Measurement of school quality is conducted by means of satisfaction surveys (CRO, BE) and various achievement tests (CRO, BE, LUX). In Croatia peer observation and school principal observations are additionally mentioned. The results of the quality measurements are then analysed by: school development specialists (support teachers) (LUX), principals and school teams' members (CRO, BE). The conclusions are used: for discussion during the yearly teachers' reviews (CRO), to improve teaching for better results, to group teachers for learning from/with each other and solving problems (BE), for planning integration activities if the atmosphere is not proper (LUX). The interpretation of assessment data poses however some challenges: "we have just standardized tests, which allow for a national comparison. But on the other hand, it is quite difficult, considering the socio-economic environment that we have, to compare us with others. And we can have from one year to another improvements in areas that we did not expect and which we cannot really explain. So, it's very complicated to see or understand if there is any improvement or not" (LUX). There are also voices which advocate more data use and more suitable tools to measure the improvement: "What we would need is to have some kind of indicators that we could understand and that we could use to put more focus on certain elements, now this is not the case" (LUX).

Continuous Improvements

In all schools there is a common understanding that the development of school quality is a continuous process, "work that never stops" and that there is always area for improvement. In Belgium one of the principals adds though: "there is a question at what cost". The most structured approach to goals' monitoring is in Belgium, as there is a process for monitoring indicators of success and their assessment according to the progress. Based on that the goals are verified and re-examined. In Croatia, the interviewees stated that there are no systematic measures in this respect. If the goals have been achieved "simply shows in the results, students' success in contests or in the collaboration with parents". In Luxembourg "pressure to succeed does not exist" – teachers are asked to report if the goals were achieved, but if not, they are to be moved to the next year, verified or dropped. Looking at the accountability of schools it seems that Luxembourgish schools do not experience pressures related to it. They are given autonomy with little accountability which assumes teachers' professionalism and individual responsibility for what they do and the results they achieve. However, as the teachers and school presidents report "there is no pressure to achieve goals". In case of Croatia the accountability is under development with the new legislation related to evaluation system and the new curricula. Accountability in Belgium is already established. The solutions like external evaluation held every 5 years is already in place, however it is not regarded only as a pressure, but also as a support measure which the schools use to verify the areas for improvement.

Everybody's Participation

All schools' representatives emphasise the importance of active involvement of all the stakeholders of educational process (internal – employees and external customers – students and parents). In case of employees (teachers and other school staff) the cooperation mechanisms are facilitated by the organization of various meetings, achievement of common goals or working on joint projects. In Luxembourg, teachers declare that they stay connected not only during their work at school but also afterwards, in Croatia the collaboration becomes evident especially during organization of competitions or managing some school projects. In Belgium and in Luxembourg lack of hierarchy is highlighted as the preferred feature of collaboration. In each school there are teams that work on quality, sometimes called "school development" (LUX). Discussing quality and deciding about improvement actions takes place at the meetings. They are organized in each school and take the forms of individual or group meetings, i.e.: subject team's meetings, plenary meetings, cycle meetings, quality team meetings, reflective meetings with the principals, etc. No specific details about the way the meetings are prepared, structured or run have been shared. However, they are reported as key measures taken to support communication, decision-making and management in schools. This aspect requires further studies, because if the meetings are used as a key mechanism for decision-making, i.e. also school quality improvement, it would be advisable to investigate in more details how the meetings' structure, agendas, protocols contribute to the quality enhancements.

Conclusions

The results show that in each of the schools there is a mind-set necessary for quality improvement. Teachers and principals understand that the process of quality enhancement is a long-term commitment and that it requires a joint effort of all the stakeholders, therefore they willingly involve parents to co-create their school environment. They understand the need for taking into account the voice of internal and external customers, but in practice it shows that only Croatian schools have a systematic approach to this. The results clearly show also that there is a common understanding that team work, communication and collaboration are key in implementing the quality changes, however some of the solutions like meetings are often organized in abundance and ineffectively (LUX, BE, CRO). The use of data for decision making is reported, but the comments on the lack of more meaningful and actionable data is highlighted. The practices of data use require also more systemic approach and data literacy competences to be developed (LUX, BE, CRO).

All in all, the consent for quality enhancement is present in all the schools under study. Understanding of the importance of continuous improvement, appreciation for collaboration, focus on results, satisfaction and well-being of school customers are clearly articulated. What seems like the area for improvement is the better implementation of actions combating the already recognized challenges. Therefore, the individual teacher's sense of agency, readiness to adjust one's practices and commitment to implement a change comes to the forefront. Diligence in

plans implementation and monitoring, better use of data to inform decisions coupled with a system of supports and resources should offer the proper conditions for further successful total quality improvements.

Acknowledgement

The author based the article on the data collected when she participated (from 1.09.2018 to 30.09.2020) in the project entitled *The Power of Data to take Smart Decisions (DATADRIVE)* financed by the Erasmus+ programme under the agreement nr 2018-1-LU01-KA201-037314. At that time the author was affiliated with Spoleczna Akademia Nauk, Lodz, Poland. The author extends gratitude to the former employer, project coordinator, the partners, and participants for fruitful collaboration.

Abstract

Since 2007, more than half of the world's population has lived in urban areas and it is estimated that the proportion will exceed 68 per cent by 2050. Cities are faced many challenges related to environmental degradation, globalization, inequalities, social segregation etc. Urban strategy is increasing in importance as a tool that guide the city development. The objective of this research is to produce an assessment of the current Russian practices of urban socioeconomic development strategies preparation and elaboration. This research will suggest results of the content analysis of the municipal strategies elaborated in compliance with the requirements of Federal Law No. 172 "On strategic planning in the Russian Federation" and comparative review of methodological approaches to addressing the key tasks of strategic planning. These challenges are related to measuring the achievement of previously set goals, determining the competitive advantages of the city, substantiating the strategic goals for urban development and identifying core strategic indicators. The empirical basis is formed by the official strategies of the following cities: Voronezh, Kazan, Kaliningrad, Magnitogorsk, Penza, Rostov-on-Don, Tver, Tolyatti and Ulan-Ude. The research identified widespread deficiencies in urban strategic planning and diagnosed the main causes of their occurrence and persistence.

Keywords: urban development strategy, key tasks and approaches of strategic planning.

Introduction

The elaboration and implementation of the current strategies for social and economic development of the constituent entities of the Russian Federation and the municipal formations have led to increased interest, on the part of researchers, in studying modern practices in strategy-focused public planning.

It should be especially noted that the current urban socioeconomic development strategies (hereinafter – "the Strategies") differ from the previously-defined strategies not only in regard to lifespan, but also in the content comprising the results in the handling of not only traditional, but also emerging challenges. The formulation of the latter has necessitated the elaboration of approaches to addressing these challenges.

The analysis of such approaches taken by the designers of the Strategies will allow us to make an assessment of the current practices in the municipal strategic planning.

Research Method

To produce a reasonable assessment of the practices employed to create urban strategies, the author's methodological approach providing for the following measures have been proposed and realized:

a) concerning the objects of analysis, the cities with different proportions (population size), representing different federal districts and constituent entities of the Russian Federation are to be selected;

Cite this Article as: Anastasiya CHICHERINA and Igor RISIN" Assessment of Current Russian Practices in Urban Development Strategies Elaboration" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

b) the urban socioeconomic development strategies elaborated for the period up to 2030 (or 2035) in compliance with the requirements of Federal Law No. 172-FZ are to be included in the information base for the analysis;

c) the approaches to addressing the key tasks related to elaboration of the Strategies are to be identified;

d) the content analysis of the Strategies supplemented with the comparative review of the identified approaches and the results obtained when using these approaches is to be applied.

The information base for the analysis features the current strategies for the urban development of Voronezh, Kazan, Kaliningrad, Magnitogorsk, Penza, Rostov-on-Don, Tver, Tolyatti and Ulan-Ude.

The Results and Assessment

The content analysis of the Strategies has made it possible for us to identify the methodological approaches to address the key tasks arising when elaborating these Strategies. The comparative review has allowed us to reveal their distinctive characteristics. Let us systematize the obtained results.

Assessing the success of the previously-defined objectives.

Two basic approaches to solving this task have been identified.

The first approach that has been realized as part of the majority (70% of the total number) of the municipal practices (the urban districts of Kazan, Rostov-on-Don, Kaliningrad, Tolyatti, Penza, Ulan-Ude and Tver) implies the characterization of the attained level of the urban development. This characterization is performed by an economic and statistical analysis of changes in the values of a series of significant socio-economic indicators, the master list of which has included: population size, the aggregate volume of delivered goods, works, services and average monthly salary.

Therein, the number of indicators varies from 20 (Penza) to 127 (Tver). In addition, the periods of time, during which their dynamics has been analyzed, differ substantially. Thus, the strategists of Penza highlight the changes that have occurred over the past year, while the strategists of Rostov-on-Don consider the changes that have happened over the past five years.

In some cases, the strategists make comparisons between the attained level of the urban development and the state of other cities that belong to one federal district (this is the case with Rostov-on-Don and Penza Development Strategies), or the national average values of the analyzed indicators (Tver Development Strategy). Such actions taken by the strategists are certainly productive. The other issue is that they characterize only isolated practices.

Let us bring our attention to the basic deficiency of the described approach - while being oriented towards identification of the dynamics of changes occurring in the urban socio-economic system. It leaves out the assessment of correspondence between the planned trajectory (specified in the acting strategy) and the actual trajectory of their development.

The second approach has been employed by the strategists of Voronezh, Magnitogorsk and Novosibirsk. It has initially been focused on assessing success of the previously-defined targets by the juxtaposition of the planned and the actual values of the socioeconomic indicators. Moreover, the strategists of Voronezh and Novosibirsk have supplemented the results of the assessment with an analysis of the reasons for deviations from the planned indicator values.

It seems obvious that the second approach corresponds to the essence of the task.

Defining the city's relative competitive advantages

Two basic approaches to addressing this task have been identified.

The first approach is based on the associating of the competitive advantages with the strengths of the urban socio-economic system. The strategists of Kazan, Rostov-on-Don, Penza, Tver and Magnitogorsk have identified the city's strengths with a SWOT-analysis and have listed them as the competitive advantages.

The second approach has been implemented in the Voronezh socioeconomic development Strategy. It identified the city's competitive advantages by selecting them from among city's strengths, taking into account the predicted opportunities and threats that may arise in the external environment.

Substantiating the objective function of the city including its mission, strategic goals, tasks and priorities

Three main approaches identified by the strategists have been singled out.

The first approach provides for determination of the above components of the objective function without emphasis on the meaningful connections between them. The example of Rostov-on-Don socioeconomic development Strategy is the epitome of this approach. The priorities, the city brands, the goals, the tasks and the strategic project initiatives are advanced put forward unsystematically, without any connections between them. The same fragmented approach to the objective function components is also inherent in the Penza socioeconomic development Strategy.

This approach is contrary to the systemic principle. Nevertheless, it should be followed in order to maintain the necessary subordination of the objective function components: mission – strategic goals, mission – priorities, strategic goals at different levels, and strategic goals – tasks).

The second approach has been taken by the strategists of Novosibirsk, Kazan and Tver. It involves an interconnected rationale for the first-order strategic goal, priorities, second-order goals, tasks and particular ways of action. However, in this case, it cannot qualify for systematicity because it lacks the mission, which does not allow for the capture of its unique characteristics and intentions for different stakeholder groups and the external environment.

The third approach has been used by the strategists of Voronezh, Magnitogorsk, Tolyatti and Ulan-Ude. It implies a consistent interrelated substantiation of the mission, the overall objective, first-order strategic goals, priorities, second-order strategic goals and tasks of urban socio-economic development.

Identifying the indicators of strategic goals achievement

There are three identified basic approaches to addressing this task. Before presenting their characteristics, let us consider the table 1. By analyzing the information presented in the table, it is possible to characterize the approaches implemented by strategists for composing the set of urban socio-economic development indicators.

The first approach taken by the strategists of Kaliningrad, Tolyatti and Penza implies that only the quantitative indicators provided by the Federal State Statistics Service of the Russian Federation should be used. In this case their values are presented either by stages of the Strategy implementation (Kaliningrad, Tolyatti), or at the end of its validity period (Penza).

In our opinion, this approach, on the one hand, eliminates the possibility of annual operational monitoring of the process and the results achieved in the urban development. On the other hand, and, it leaves out of the field of assessment the qualitative changes taking place in their socio-economic system, which are not reflected in the official statistics.

The second approach, which was employed by the strategists of Novosibirsk, Rostov-on-Don and Ulan-Ude, involves the use of quantitative and qualitative indicators. Its major drawback, as in the previous case, is the lack of values of indicators for each year of the Strategy implementation.

Table 1: Indicators of the results achieved in the urban socio-economic development

Cities	Characteristics of urban socio-economic development indicators
Voronezh	Quantitative indicators that have been listed: – for each year of the Strategy implementation; – within each scenario of the urban socio-economic development; – for the entire range of the strategic goals. The qualitative indicators of the expected results achieved in the implementation of the strategy for each of the third-level strategic goals have been clarified.
Kazan	Quantitative indicators that have been listed: – for each year of the Strategy implementation; – within the accepted scenario of urban-economic development; – for the entire range of the strategic goals. The qualitative indicators have been clarified in terms of the strategic priorities.
Kaliningrad	Quantitative indicators that have been listed: – for each stage of the Strategy implementation; – within the accepted scenario of urban socio-economic development; – for the selective list of the strategic goals. Qualitative indicators are not available.
Magnitogorsk	Quantitative indicators that have been listed: – for each year of the Strategy implementation; – within the accepted scenario of urban socio-economic development; –for the entire range of the strategic goals. The qualitative indicators have been clarified for the selective list of the strategic goals.
Novosibirsk	Quantitative indicators that have been listed: – for each stage of the Strategy implementation; – within the accepted scenario of urban socio-economic development; – for the selective list of the strategic goals. Qualitative indicators have been used to characterize the vision of the future.
Penza	Quantitative indicators that have been listed: – as of the end of the Strategy implementation period; – within the accepted scenario of urban socio-economic development; – for the selective list of the strategic goals. Qualitative indicators are not available.
Rostov-on-Don	Quantitative indicators that have been listed: – for each stage of the Strategy implementation; – within each scenario of urban socio-economic development; – for the entire range of the strategic goals. Qualitative indicators have been specified for all strategic project initiatives.
Tver	Quantitative indicators that have been listed: – for each year of the Strategy implementation; – within the accepted scenario of urban socio-economic development; – for the entire range of the strategic goals. Qualitative indicators have been specified for each third-level strategic goal.
Tolyatti	Quantitative indicators that have been listed: – for each stage of the Strategy implementation; – within each scenario of urban socio-economic development; – for the entire range of the strategic goals. Qualitative indicators are not available.
Ulan-Ude	Quantitative indicators that have been listed: – for each stage of the Strategy implementation; – in the framework of each scenario of the socio-economic development of the urban district's level – for the entire range of the strategic goals Qualitative indicators have been specified for each third-level strategic goal.

The third approach is realized by the strategists of Voronezh, Kazan, Magnitogorsk and Tver. It is notable for applying quantitative and qualitative indicators in their entirety, using the indicators for the whole range of strategic goals and defining the indicator values for each year of the Strategy implementation.
It seems obvious that the third approach can ensure the formation of a full-fledged monitoring of the results reached in the urban socio-economic development in the process of the Strategy implementing.

The performed analysis of the current practices of creating the urban socioeconomic strategy allows us to identify its inherent deficiencies. Among the deficiencies identified are the following:

– low level of diversity in the methods and tools used to achieve the strategic goals;

– the absence of clear, unambiguously-interpretable requirements that determine the required level of quality of the results obtained in solving the key tasks of creating the Strategy;

–the unsystematic nature of the planning process manifested in the weaknesses of consistency among the main substantive components of the Strategy (i.e. weakness of consistency between the mission and strategic goals, strategic objectives and tasks, strategic goals and the indicators of achievement).

The main causes explaining these deficiencies are:

– the absence of methodological recommendations outlining the composition and the substance of the invariant characteristics (that are independent of institutional, economic and other aspects) of the Strategy;

– shortage of well-trained personnel with the competences required for professional solutions of the key tasks related to elaboration of the Strategies;

– underdevelopment of the municipal statistics that narrows the information base for analysis of (i) the determination of the current state of the cities, (ii) the assessment the urban potential, (iii) the identification of their relative (in comparison with other cities) competitive advantages.

To overcome the aforementioned deficiencies, it would be reasonable to introduce a benchmarking assessment that is focused on selecting the best practices in strategic planning. The empirical data describing the positive foreign experience in elaboration of Urban Strategies for local communities can be an important component of the information base for its application.

Restructuring of A Municipal Company

Krzysztof WASOWICZ

Department of Finance for Sustainable Development
Cracow University of Economics, Cracow, Poland
E-mail address: wasowick@uek.krakow.pl

Abstract

This elaboration is to present the management process (restructuring) of a municipal collective transport company in a crisis situation. The theoretical purpose of this article is to depict the key issues regarding restructuring of municipal local collective transport companies. As the methodical goal, presentation of the restructuring process in a public transport company has been deemed. The empirical analysis of the restructuring process based on a specific company was replaced with an original decision-making game that formulated exemplary goals in individual areas of functioning of the enterprise. To enrich the cognitive value, the article includes many diagrams.

Keywords: municipal enterprise, restructuring, municipal collective transport company

Introduction

The environment that companies operate in forces them to quickly address upcoming changes. Every contemporary manager should, on a regular basis, elaborate a transformation plan within the company based on an analysis of the current situation and knowledge of the entity. Changes of radical character, so-called restructuring, are of particular importance. Restructuring is a process that is very strongly connected with the nature of operations of a particular company. Thus, it always requires an individual approach depending on the character of operations, identified problems, as well as circumstances the company operates in. This elaboration is to present the management process (restructuring) of a municipal collective transport company in a crisis situation.

The theoretical purpose of this article is to depict the key issues regarding restructuring of municipal local collective transport companies. As the methodical goal, presentation of the restructuring process in a public transport company has been deemed. The described decision-making game, which reflects addressing the key management problems related to the restructuring process of a collective transport company, is of application character.

Prerequisites of changes and the specific nature of restructuring in a municipal local collective transport company

The proper functioning of every company, also including a municipal transport company, requires appropriate organization and efficient management. Preservation of financial balance, described by a situation in which an entity has the capacity to settle its payments on a timely manner and, at the same time, comply with the principle of rational actions, is the key measure of correct functioning of a business entity. The said rule is universal and superior to detailed goals specified, e.g. by the owner of the entity with regard to maximization of profits, work efficiency, etc. It is of particular importance when it comes to modern economy with a dynamic environment. The changing management conditions force the company to make difficult decisions while managers need fast solutions for diversified and urgent economic problems. There are many techniques that facilitate the decision-making process, yet the majority of tools and methods used today is of financial nature, which indicates that efficient management of a modern company is allowed by economic optimization. The measurement generally adopted by lending institutions or analyzing the reliability in order to assess the condition of companies, with regard to, e.g. the rate of return on invested capital or the capability to generate profit, etc., must undergo special transformations for the purpose of municipal companies that implement tasks from the group of public utilities. Among such companies, a particular role is served by public transport companies in the case of which the commercial approach is often contrary to the tasks imposed on them. Thus, from the practical point of view, financial management of a municipal company

Cite this Article as: Krzysztof WASOWICZ " Restructuring of A Municipal Company" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

rendering public transport services involves adhering to the principle of financial balance, which is expressed through (Wąsowicz, 2018, p. 67):

- efficient management, i.e. the ability of economical use of production factors available at disposal of a business entity,
- profitability, i.e. the expression of acceptance of products (services of a particular business entity by its environment.

The economic conditions of company operations (including a municipal company providing public transport services) shaped by external and internal factors have been presented in Figure 1.

Fig. 1: Forming of economic conditions regarding the operations of a company
Source: Own analysis

The environment supplies the company and, additionally, serves as the recipient of results of the company's activities. Thus, the company is an observer and, simultaneously, a participant of changes in the environment while the said environment, which influences all processes of the company, prevents it from avoiding internal transformations in order to adjust its attitude with regard to the changing conditions. Uncertainty of the environment forces companies to quickly address the upcoming changes. The lack of fast and efficient solutions to problems emerging due to non-compliance of companies to external circumstances, as well as neglecting the needs for timely changes may lead to loss of profitability, serious crises posing a threat to continuance and effective functioning of the company, or even its bankruptcy Taking Diagram 1 into consideration, there might be a major overbalance of costs over revenue. In such a situation, radical changes (considered as the company restructuring) must be implemented to ensure proper functioning of the undertaking.

The definition of restructuring - as it has been highlighted in previous chapters - is formulated in various ways in literature treating on the issue and it depends on the context that the process is conducted in (Table 1). In most definitions, the common denominator is the view of restructuring as a change taking place within various areas of a company.

Table 1: Definitions of restructuring according to selected authors

Author	Definition
I. Durlik	"Restructuring is most often defined as systemic reconstruction, modernization and upgrade or adjustment to the contemporary level of technology and development within the scope of organizational and managerial concepts of structures in an undertaking, company, or institution. In Poland, however, restructuring is associated with privatization and macroeconomic changes"
A. Nalepka	"Restructuring stands for thoughtful reorientation of goals (objectives) of a company according to current or expected future changes in the environment and for related adjustments with regard to technology, organization, economics, and personnel"
B. Pełka	"Company restructuring means systemic changes in a company with regard to methods, technology, organization forms of production, management system, economics and the market, and the organizational and legal status of such a company"
A.Stabryła	"Restructuring constitutes diagnostic and design procedures conducted in order to improve the management system and the exploitation system of a company, whereby the changes, above all, regard transformation of the organizational form, decision-making systems, management, and human resources"

Source: Own analysis based on: (Garstka, 2006, p. 19)

Company restructuring is a complex process that involves specific actions and resources. Two main stages can be distinguished: the preparatory stage that covers analytical works and the implementation stage of the restructuring process. The individual elements of company restructuring have been presented in Figure 2.

Fig. 2: The process of company restructuring

Solutions for key management issues in a collective transport company through an experimental decision-making game

In order to fully demonstrate the core element of functioning of a local collective transport company, one needs to determine the areas of external interactions of the economic environment with such a company. One of the said interactions is the evolution of the population's commuting habits. Cars, as the hallmark of social status, a synonym for luxury, are becoming more and more commonly available. This phenomenon, with significant underlying psychological aspects, results in a constant increase of the automotive ratio (number of individual vehicles per 1000 persons). The tendency is practically imminent until complete saturation, which is determined by the wealth of the population. The growing absolute wealth level of entities (households) contributes to greater qualitative requirements

as part of notified transportation demands. The increase in qualitative requirements forces the operators to adjust their offer to the market situation, with a justified increase of the unit cost per single user. Along with the process of qualitative changes, the raised level of environmental solutions shall also be expedient. The economization of any signs of people's social activity should be considered as another area of influence of economic factors on a city transport company. It is the most important aspect since it extends onto any other area. Unless a local self-government unit is subordinated to economic calculation, it is impossible to determine its social and economic aspects of life. It is the natural consequence of functioning of a collective transport company that constitutes a component of market economy. The said calculation is mainly governed by the adopted model of organization of public transport, which implies the manner and rules with regard to financing of the municipal operator's activity. Financing of transport involves terms such as fare, surcharges, and payment for public transport services. Thanks to efficient management of the company transport policy, it is possible to reach a level at which the proceeds will fully cover the running (operating) costs. The problem of balanced short-term payments, distinguished between individual assets, is determined by the internal limitation of effectiveness of a public transport company and its capacity to minimize fixed costs. Among distinguished areas of influence that define the economic determinants of functioning of a public transport company, Figure 3 depicts two examples of management-related issues that a local collective transport company must face.

Fig. 3: General issues regarding management of a local collective transport company
Source: Own analysis.

Company management refers to structural matters (operations method, ongoing processes), general processes (technology), employment (remuneration, collective agreement), investments (purchases, renovations), etc. There is no such thing as the *only right* method and tool of action. There are well-recognized and proven methods and standards that can be adjusted depending on the type of occurring problems. In this elaboration, in order to confront the existing problems with their solutions, the course of an original decision-making game has been described. The game involved several dozens of people who were divided into groups and assigned roles reflecting those in a public transport company (management board/directors, passengers, owner, employees). Each group was given 2 sets of decision cards. The first set of cards was marked as A. In its case, it was assumed that the flows of funds to the company were significantly limited. Tasks to be undertaken were listed in Table 2 and they were to be assigned with points reflecting the importance of the undertaking.

Table 2: Types of restructuring tasks in Situation A

Action taken	Action significance expressed in points	Areas of company operations
Limitation of transport works		Exploitation
Reshaping of the fare		Exploitation
Utilization of a credit		Financial
Reduction in employment		Personal
Limitation of investments to a necessary minimum		Financial
Change of the course of processes in the company to improve effectiveness		Organizational
Limitation and outsourcing of the technical infrastructure		Technical
Renegotiation of the Collective Work Agreement		Personal
Development of auxiliary activity, e.g. commercial transport, in order to gain additional inflows		Technical
Change in the organizational structure in order to improve system effectiveness		Organizational

Source: own analysis.

The second set of cards was marked as B and it was assumed that public transport services are provided at a technical level unacceptable for the passengers. Table 3 has presented the undertakings that must be implemented.

Table 3: Types of restructuring tasks in Situation B

Action taken	Action significance expressed in points	Areas of company operations
Elimination of a connection assigned with an old fleet		Technical
Fleet credit purchase		Financial
Decrease employment and release funds to purchase a fleet		Personal
Change in the handling method of the transport service (third-party driver, third-party operator)		Exploitation
Change in the management structure to increase system efficiency		Organizational
Purchase of a fleet along with servicing (vehicle charter)		Organizational
Application for increase in financing from the fare or directly from the City/Commune		Financial
Reduction of remunerations in order to acquire funds for investments		Personal
Development of additional transport operations		Exploitation
Increased range of renovations		Technical

Source: own analysis.

In the decision-making game, representatives of individual groups assign points to respective solutions listed in column 1 in the column titled *action significance expressed in points*. In total, they have 18 to 25 points at their disposal (for 10 distinguished actions as part of one problem). If the representatives find an individual solution to be necessary from the perspective of a particular problem, they can assign a maximum of 5 points to it. If, however, they consider a particular action to be completely irrelevant or unfavorable for them, they may assign 0 points to such an

action. In this game, it is very important that the decisions should be made not only from the perspective of its significance for the company, but also for all groups of interest represented by individual participants. In economic practice, specific interests of employees, the owner, the management board or the passengers of a collective transport company may vary. For instance, on very rare occasions would employees of an entity agree to a pay cut or employment reduction despite its poor financial situation. In the third column of Table 2 and 3, each of the proposed problem-solving methods was assigned to one of five general functioning areas of a municipal local collective transport company. Figure 4 has depicted the basic areas of a municipal company, distinguishing the following: organizational, personal, technical, exploitation, and financial area.

Introduction of crucial changes in the said areas can be deemed as restructuring. Restructuring refers to the equity, capital, employment, as well as to organization or the ownership structure. Restructuring allows improvement of financial results generated by the company and, at the same time, it identifies and eliminates any bottle necks that hinder its effective functioning.

Over forty students of the Cracow University of Economics participated in an experiment held in May 2017. The outcome of the analysis of decision-related results, performed by collection of decision cards that were counted and classified, have been presented in Figure 5, 6, 7 and 8.

Fig. 5: Results of the decision-making game with regard to Problem A (lack of financial funds)

Source: Own analysis

The analysis of results of the decision-making game regarding a significant limitation of funds received by the company indicates that the distinguished groups (i.e. management board, owner, passengers) mainly undertook actions in three areas (organizational, technical, and financial). Undertakings in the personal area proved to be the least active, which results from obvious facts: the employees' and the public owner's reluctance towards changes and little interest of passengers in this area. In this area as well, determined actions were taken only by a reasonably functioning management board. In any case, a similar activity level in all domains of company functioning indicates the appropriateness of decisions made by the managers. It is also vital that initiatives of the management are supported by a mindful and rational owner. The outcome of the experiment shows that the other two groups (employees and passengers) consider the possibility of problem solving mainly through the prism of their own advantage.

With regard to Problem B (fleet refurbishment), similarly to the previous case (but in an inverted order) groups, treated as a whole, expressed the highest activity in the following areas: financial, technical, and organizational. In general, all distinguished types of participants (except for employees in the personal area) decided to undertake action. These decisions result from the assigned role and the economic knowledge of the persons taking part in the experiment.

Fig. 6: Results of the decision-making game with regard to Problem B (fleet refurbishment)
Source: Own analysis.

The summarization of total results from both stated issues proves that changes in the financial, technical, and organizational areas are the most essential from the responders' perspective. Less appreciation was given to changes in the exploitation area and the personal area, mainly due to the consequence of the so-called own interest. According to the results presented in Figure 8 by delegated roles, the management board, which pays practically identical attention to every area, exhibits the highest activity. It proves that this group assumes a suitable approach towards solving of management problems in the company. The next most active category is the owner who, in this experiment, served as the "good steward". The next group is the passengers, members of the local community for whom the municipal public transport company is a provider of a specific level of services and the so-called common good they identify with. The last group is employees. Participants of the experiment reflected the behavior of this group, which can be found in economic practice, extremely well.

Elements of the restructuring programme in a municipal transport company

The description of the decision-making game, with specified roles, in the previous part of the chapter is to serve as an introduction to the discussion regarding changes in individual areas of functioning of a municipal local collective transport company that will facilitate its proper operations. Figure 9 has demonstrated the manner of creating a restructuring plan for local collective transport companies.

Fig. 9: Shaping of the restructuring programme for a municipal transport company

Source: Own analysis.

In each of the functional areas of an enterprise, the restructuring process requires different tools, especially in terms of actions taken in order to improve the effectiveness of its functioning.

Organizational restructuring is one of the forms of restructuring an enterprise. It regards modification of the in-house organization by adjusting the internal structures and procedures in the company to match the adopted strategy. In practice, organizational restructuring (as an independent process) is usually commenced after a decrease in performance and limited possibilities for improvement, i.e. after a decrease in effectiveness. Creating a more efficient and productive organization is of utmost importance, mainly in the context of further functioning of a company in the future. When developing a restructuring plan for the organizational area, one must bear in mind the so-called key factor system, that is (Bitkowski, 2010, 63):

- purpose of activities, also divided into detailed objectives – relevant to each organization, formulated in strategic and short-term categories,
- functions and processes – connected with implementation of goals, most often perceived through the prism of pre-characterized basic, auxiliary and regulatory processes,
- organizational structures – positions, cells and divisions, including their established inter-connections,
- resources – the team of people, tangible assets and financial resources of a company.

The basic organizational restructuring tools for companies have been listed in Figure 10.

Fig. 10: Organizational restructuring tools for companies

Source: (Bitkowska, Weiss, 2015, p.42)

Segmentation of the company and isolation of business units is applied in case of enterprises with an extensive organizational structure that require internal simplification through disintegration. Such actions involve isolation of organizational units and cells that are able to function as independent business entities based on separate economic account settling. Leaning of the production system and the management system comprises of a set of rules, terms, and techniques the purpose of which is to eliminate wastage and implement an effective production system (Grabowska, 2017, p.13).

Establishment of external cooperation is an undertaking that involves separating some of the functions performed by a parent company from its organizational structure and transferring them to other business entities. Quality assurance system, on the other hand, is a method of managing organization that is focused on quality, based on involvement of all members of the organization, and aimed at achieving long-term success thanks to customer satisfaction and benefits in favor of all members of the organization and the society (Griffin, 2017, p. 9).

Elaboration of organizational processes is defined as the method of thorough transformation of complete processes in a company in order to optimize three general indicators of effectiveness: quality, costs, and delivery date, which is necessary to maintain the flexibility and competitiveness of the company. This method assumes the need for comprehensive changes in functioning processes and a proposition of re-development of the whole organization (as an institution), if it is to preserve profitability and solvency and improve customer service (Szukalski, Wodnicka, 2016, p. 37).

The organizational structure presented in Figure 11 exemplifies the restructuring process in the said area of a municipal transport company.

Fig. 11: An organizational structure of a municipal local collective transport company
Source: Own analysis.

With increase of efficiency and effectiveness of operations in mind, the entrepreneur should coordinate organizational restructuring with changes taking place in other areas of activity, e.g. the personal area. The key aspect of employment restructuring is to restore the internal stability and balance in relations with the environment by, respectively, application of advanced changes both in terms of the number of employees, their qualifications, scope of duties and responsibility of each individual person, and comprehensive utilization of the company staff. In this aspect, it is important to utilize systems of incentives. An incentive system constitutes a factor that contributes to achieving considerable performance and the economic results of the enterprise. Shaping of motivation is considered to be one of the main managerial functions. In times of intensified competition, success will be possible only for companies that are capable of making skillful changes in the incentive system, as well as of observing own costs, analyzing their structure, and drawing conclusions for future reference. The most important element of an effective incentive system is the ability to strictly connect company objectives with goals of the employees. It appears that in the case of Polish reality, it is impossible to increase the effectiveness of managers employed under a contract of employment. Thus, managerial contracts (classified as civil law contracts) for an economic result become more and more common. Such a solution greatly improves the effectiveness of management.

In the case of a municipal local collective transport company, changes in the personal area include:

- simplification of the Collective Labor Agreement,
- clarification of remuneration,
- connecting remunerations with the market,

- popularization of the employee assessment and incentive system,
- introduction of individual contracts of employment with an unambiguous specification of tasks,
- increase in work efficiency (parametric specification of the employee demand),
- limiting specialization.

Restructuring is a process that is strongly connected with the nature of business of a particular company. It becomes particularly apparent in the technical and exploitation area. The procedure of restructuring within the technical and exploitation area has been presented in Figure 12.

Fig. 12: Procedure of restructuring within the technical and exploitation area

Source: Own analysis based on: (Mozalewski, 2010, p. 223)

In the case of a public transport company, restructuring of the technical and exploitation area means:

- clarification of standards regarding employment in the technical infrastructure,
- designation of an asset management strategy,
- optimization of the supply system, including deliveries and consumption,
- developing auxiliary operations for more effective utilization of the entity's potential,
- technical efficiency adequate for the budget,
- pressure on improving the driver – customer relationship,
- disciplining consumption of power and propellants,
- inspection and verification of the communication system, also within the scope of optimization of vehicle drivers.

Financial restructuring is one of the most crucial and, at the same time, difficult areas of restructuring. The financial situation constitutes a close reflection of the current condition of an undertaking and its functioning capabilities. Reaching a good economic and financial condition is impossible without a properly structured market policy of the

company since it decides whether the entity will generate a proper level of revenue in order to be profitable. Financial restructuring covers a broad range of actions which include:

- financial plans with regard to intended actions,
- control over expenditures and cash flows,
- budgeting and monitoring of areas generating costs and revenue,
- an integrated computer system,
- consolidation of controlling tools,
- contracts for area managers,
- mutual settlements between independent cells,
- performance of tasks (use of resources) solely in accordance with the orders,
- acquisition of a financial partner,
- restructuring of balance sheet elements (assets, equity, especially receivables and liabilities).

Restructuring of balance sheet elements involves techniques based on changes in assets of the company balance sheet: disposal of cost-intensive assets, lease of assets, establishing a subsidiary and transferring assets to that subsidiary in order to separate assets from those held by the parent company and disposal of the subsidiary, division of the company. Techniques based on changes in liabilities are as follows: transformation of debts into shares or stocks, debt-for-debt exchanges, issuance of bonds, shares-for-shares exchanges, increase of the debt, sales of new shares.

Conclusion

The environment of a municipal company forces a relevant approach towards the new reality and adjustments towards the existing circumstances. Nowadays, it often appears that the already utilized typical streamlining procedures prove to be insufficient for a municipal company to reach a balanced status. In such critical situations, it is necessary to conduct determined radical changes, which are referred to as company restructuring. By using managerial methods and experience to implement the restructuring procedure, one may conclude that every company process can be upgraded. However, one must assume a proper approach and utilize appropriate tools.

The restructuring process encompasses many elements, starting from an analysis of the condition of the enterprise, formulation of restructuring, strategic and operational objectives in individual (organizational, technical, exploitation, and financial) areas, ending with determination of realization level measurements. Other crucial elements include attribution of responsibilities, determination of the realization schedule, as well as monitoring, corrective actions with regard to objectives, courses of action and the schedule. The structure of this article has been constructed in accordance with the discussed course of the restructuring process in a municipal collective transport company, which has been exemplified in Figure 13 (depicting the development and proper functioning of a municipal collective transport company after application of appropriate undertakings). The empirical analysis of the restructuring process based on a specific company was replaced with an original decision-making game that formulated exemplary goals in individual areas of functioning of the enterprise. In the said experiment, the selection on utilized solutions was often governed by the entrusted roles reflecting those in a public transport company.

Abstract

Under the current COVID-19 pandemic, the role of effective fiscal policy is rapidly increasing worldwide in the attempt to combat the negative effects on both the labour market and the business sector. In this context, the aim of this paper consists in studying the evolution of the labour market in correlation with the latest labour taxation measures taken to face the pandemic crises. Evidence for the case of Romania is provided. Aspects concerning the national legislative framework of fiscal policies are also briefly discussed. Our analysis shows that the Romanian labour market was facing low unemployment rates in the last period, but labour force participation remained among the lowest values in the European Union. Also, youth unemployment is among the highest in Europe. Forecasts of moderate levels of economic growth are radically changed following the outbreak of the COVID-19 pandemic in early 2020.

Keywords: Fiscal Policy, Labour Market, Unemployment, COVID-19 Pandemic.

Introduction

In the context of the current COVID-19 pandemic crises, finding the most effective fiscal policy solutions to combat the economic shocks on both the business sector and the labour market becomes a major concern worldwide. Economies find themselves under pressure to take proper fiscal decisions to prevent the business environment from collapsing, the labour market demand from contracting and the unemployment rate from skyrocketing. Effective implementation of suitable fiscal solutions are required to smoother the economic recovery from the pandemic effects.

Under such circumstances, it is of extreme importance to better understand the fiscal policy's role and to study the main fiscal tools available to keep the economies on their right track to prosperity and less likely to fall into a steep recession. Of particular attention are the cases of developing economies that tend to have a harder and usually longer recovery from economic crises as compared to more developed countries.

Evidence for Romania" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In general, fiscal policy deals with government spending and fiscal tools to help stabilize the economy. Normally, the government faces large budget deficits during recessions and manages budget surpluses under growing economy. These are known as expansionary and restrictive fiscal policies, respectively (however, in practice, the preferred instrument for restoring unsustainable growth is usually contractionary monetary policy and not fiscal policy, for political reasons).

According to Musgrave and Musgrave (1984), the main functions of fiscal policy are: allocation (measure the desirability of intervention of the state into economy to correct market failures), distribution (has its roots in the existence of inequalities in income distribution) and stabilization (this role depends on budgetary policy).

Fiscal policies aim to reduce fluctuations and economic instability, protect consumer incomes and stimulate development (Ialomitianu et al 2016). It is easy to predict that any state aims or should aim for a sustainable fiscal policy. Although there is no clear and unanimously accepted definition for the notion of sustainable fiscal policy, the European Commission defines public finance sustainability as: the ability of a government to sustain its current spending, tax and other policies in the long run without threatening the government's solvency or without defaulting on some of the government's liabilities or promised expenditures (European Commission, 2019). Molnar (2012) concluded that, if fiscal adjustment is based more on growth than on spending tax debt, stabilization is more likely to occur and this stabilization is sustainable.

Having these into consideration, our paper aims to study the changes in fiscal policies in correlation with the evolutions and transformations of the labour market. Evidence for the case of Romania is provided. Aspects concerning the national legislative framework of fiscal policies are briefly discussed, followed by an analysis of the evolution of the labour market in correlation with the latest labour taxation measures taken to face the current COVID-19 pandemic.

This paper is organized as follows: Section 2 briefly presents the main changes in the Romanian fiscal policy over the last two decades, Section 3 studies the dynamics of the Romanian labour market. Next section discusses future perspectives of the labour market in the context of the COVID-19 pandemic, while Section 5 concludes our investigation.

The History of The Fiscal Policy in Romania

The Romanian fiscal system has undergone major changes since 2000, when a fiscal reform simplified and standardized the Romanian fiscal regime. In 2004, the new Fiscal Code came into effect and introduced important facilities and exceptions. However, in the following years, changes to the Fiscal Code favoured higher taxation (except for the introduction of a 16% income flat tax rate in 2005 for both individuals and companies). Between 2006 and 2008 there was a relaxation of fiscal policy, even though in 2006 Romania was in the process to become an European Union state member. The main fiscal measures consisted in reducing social security contributions by 1.5 percentage points and in introducing excise duties on tobacco and alcohol.

In the first half of 2009, the Government of Romania requested a loan from the International Monetary Fund in order to overcome the 2008 economic crises and to reduce the budget deficit. For this purpose, certain measures to adjust the budget expenditures were taken (in order to better collect the budget revenues and to decrease the capital expenditures to compensate for the additional current expenses and to reach the target deficit proposed for 2009 of 7.8% of GDP). The first part of 2010 brought a number of fiscal austerity measures, some being directly related to taxation and public spending (e.g. the introduction of the *Fiscal Responsibility Law*, VAT rate increased from 19% to 24%, taxation of all income by 16% with no exceptions and the reduction of public sector salaries by 25%).

In the following years, a process of fiscal consolidation took place, which was partially reversed starting with 2016, as a consequence of the new Fiscal Code coming into effect. The new Fiscal Code involved an ample fiscal relaxation, simultaneously enacting some significant increases in expenses (related mostly with salaries and pensions). Between 2016 and 2018, the fiscal policy became expansionistic, a trend that was maintained in the next period. Another major fiscal measure that came into effect on January 1st 2018 was the transfer of social contributions from employers to employees (with the change of total amount from 39.35% to 37.25%), simultaneous with lowering the tax rate for income from salaries, pensions, self-employment and copyright from 16% to 10%.

From 2006 through 2019 Romania practiced a strongly pro-cyclical fiscal policy, stimulating the economy, but in a counterproductive manner during the periods of expansion (2006-2008, 2016-2019) and slowing down during times when the economy underperformed (2010-2015). This contributed to amplifying the economic cycle's fluctuations and accentuated the accumulated imbalances in the economy (The Fiscal Council, 2019).

Keeping in 2017 an expansionist fiscal policy under a positive production gap, only contributed to maintaining the pro-cyclical fiscal policy, which made the position of public finances more vulnerable to shocks. Furthermore, considering that the level of public debt near the end of 2019 was significantly higher than in 2008 (35.2% of the GDP as opposed to 12.4%), it is difficult to imagine the existence of a fiscal space to stimulate the economy in times of recession, putting the sustainability of public debts under risk. Moreover, the miss-fitted expansionistic Romanian policy between 2016 and 2019, together with the unsuccessful attempt to follow the European and national rules, caused the European Commission to maintain their decision to place Romania under the excessive deficit procedure. This decision comes even in the context of the COVID-19 pandemic, with the argument that the violation of European tax rules predates the pandemic and is therefore not attributable to it.

The most important direct taxes levied through the Romanian tax system are *income tax* (paid by individuals at a flat rate of 10%) and *real estate taxes* (taxes on buildings and land collected by municipalities), while indirect taxes include *value added tax (VAT) and excise duties*.

Aside from these direct and indirect taxes, social taxes are also levied, consisting of *compulsory social and health insurance contributions* (social insurance, unemployment insurance, health insurance, health insurance for medical leave and indemnities, work accidents and professional disease insurance, as well as contribution for the salary payment guarantee fund). Since 2018, the social security system underwent major reforms through which the largest part of the contribution burden was shifted to employees.

The budget revenue structure in Romania is mostly focused on indirect taxes and income from social contributions (about 82% of tax revenue), while at European level there is a tendency to balance the share of direct, indirect taxes and income from social contributions. On the expenditure side of salaries in the public sector and pensions, the ratio to budget revenues has advanced at a brisk pace in 2008-2009, reaching a peak of 75.3% in 2009 (the highest share of wages and social assistance expenditures in total budget revenues among Central and Eastern European countries). Following the implementation of the fiscal consolidation program, this share significantly dropped between 2013 and 2015, returning to an inferior level to other CEE countries. Unfortunately, since 2016 this trend was reversed amid aggressive increases of public sector wages and pensions, Romania registering once again the highest level of wages and social assistance expenditure relative to budget revenues (72.1% in 2019 – 4.4 pp over the EU average).

Thus, in 2019 the Romanian economy was in the process of losing rhythm with regard to economic growth. The main reasons for this slowing down are, on the one hand, a slowdown in external demand, and, on the other hand, a contraction of industrial production, both caused by unfavourable external evolutions. Forecasts of moderate levels of economic growth in Romania were radically changed following the outbreak of the COVID-19 pandemic in early 2020. This health crisis amplifies uncertainties in assessing current and future economic policies and developments. After overcoming the acute phase of this crisis, active economic policies could help a faster return to economic coordinates as close to the previous ones as possible. However, it is possible that post-pandemic economies may radically differ from ante-pandemic economies in many aspects.

Among the main fiscal measures undertaken by the Romanian Government in May 2020 in the attempt to fight the pandemic we mention:

(1) all tax obligations with a maturity date past March 21st 2020, which are unpaid, are not classified as arrears and are not subject to interest and late payment penalties; all tax-related seizure proceedings involving seizures are suspended (both measures cease on October 25th 2020);
(2) the deadline for local tax payment has been postponed, from March 31st 2020 to June 30th 2020;
(3) profit tax payers / quarterly advance payment for the first, second and third quarters of 2020 benefits from a 10% discount for payments made on time. The same benefit is available to income tax-payers for micro-enterprises;
(4) the requirement to pay VAT when importing medicinal products, protection equipment, other medical devices or sanitary equipment necessary to fighting the COVID-19 pandemic has been postponed;

(5) tax-payers subject to a specific tax will not be required to pay the tax for the times they partially or completely cease their activity during the state of emergency (there is also an exemption from the payment of the specific tax for an additional 90 days period);
(6) enforcement proceedings by notification of state claims and subsequent recovery through offers are suspended and will not recommence (unless they are established by court decisions in criminal matters), (the suspension ends on October 25th 2020);
(7) for late payment of instalments included in a schedule of instalments remaining outstanding until October 25th 2020, no interest and penalties will be calculated in accordance with the Fiscal Procedure Code.

In order to limit the negative impact of the COVID-19 pandemic on the labour market, the Government adopted several emergency ordinances, concerning the following (European Semester, 2020b):

(1) covering 75% of the salary of employees forced to technical unemployment by companies affected by the crisis if the activity is partially or completely interrupted or reduced as a consequence of the COVID-19 pandemic during the state of emergency;
(2) support is provided to employers who between June 1st 2020 and December 31st 2020 hire permanent full time persons over the age of 50, whose employment has ceased for reasons not attributable to them, during the state of emergency. Assistance is also provided, until December 31st 2020, for the up-to-date employment of permanent contracts of young people aged between 16 and 29, who are registered as unemployed. For each person employed in the categories mentioned above, the employer will receive 50% of the employee's wage, over a period of 12 months, but no more than 2,500 RON (500 EUR) a month.
(3) during the period of the work schedule reduction, employees affected by this measure will receive a 75% compensation from the difference between the gross basic wage provided for in the individual employment contract and the gross basic wage corresponding to the hours actually worked as a result of the reduction of the work schedule;
(4) persons who occasionally engage in unskilled activities (day labourers) will be granted an amount from the state budget equal to 35% of the remuneration due for a working day for a period of 3 months;
(5) employers who have employees with individual employment contracts for a fixed period of no more than 3 months benefit from payment by the state of 41.5% of the employers' wages, but no more than 41.5% of the average gross salary for 2020;
(6) employers are granted a single financial support of 2,500 RON (500 EUR) for every employee who worked remotely, during the state of emergency, for a minimum of 15 working days, in order to support the purchase of technological goods and services necessary for their business;
(7) employees caring for children under 12 years of age can benefit from days off paid by the employer with 75% of the salary (but not more than 75% of the average monthly earnings), while schools are closed as a consequence of the measures implemented by the Government.

The Dynamics of The Labour Market

Analysing the evolution of the Romanian labour market, we note that in the context of economic growth in recent years, labour force participation in Romania has reached among the lowest values in the European Union. The labour market is generally characterized by a slight increase in labour force participation in the years immediately following the economic crisis, as the labour force participation rate reached a low of 62.9% in 2008, then rose to 68.6% in 2019. The first two quarters of 2020 (the only ones for which data are currently available) do not yet capture the effects of the health crisis we are going through. The low values registered in our country compared to the EU can be explained by a number of factors, such as: low internal mobility, non-correlation of demand with labour supply in terms of the need for qualifications, lack of adequate retraining with the supply of jobs, the lack of career counselling, as well as the establishment of generous social benefits that demotivate reintegration into the labour market.

The Romanian labour market was facing low unemployment rates in the last period (3.9% in 2019), but with visible and inevitable growth trends taking into account the current context (in the first trimester of 2020 the unemployment rate was 4.3% and raised to 5.4% in the second trimester). In terms of gender, it is observed that the unemployment rate among women remained throughout the analysed period below the level of the unemployment rate for men, with differences of even 2.8 pp in 2004, but decreasing to 0.9 pp in 2019.

However, in the context of high labour migration, although the unemployment rate in Romania is below the EU average, youth unemployment is among the highest in Europe, reaching even 24% in 2014 and then declining to 16.8% in 2019. This trend, together with the fact that Romania does not yet have effective policies to stimulate the transition from school to the labour market and to correlate the education system with labour market requirements, places Romania in the top 10 countries with higher unemployment among young people in the EU and among the last 5 countries with the lowest employment rates among young people in the EU (approximately 24.7% in 2019). Unfortunately, this new crisis we are facing continues to affect this category of the population. If in the first quarter of 2019 the youth unemployment rate was 15.6%, in the first quarter of 2020 the unemployment rate had increased to 17.6%. It should also be noted that, depending on gender, the situation shows an interesting dynamic: if in the first years after 2000, young female unemployment was 3-4 pp higher than that of the young male unemployment rate, in recent years the situation has reversed (in 2019 the unemployment rate among young women was 1.2 pp higher than the unemployment rate among young male). It will be useful to look at how this crisis will affect young people.

Fig. 1: Registered unemployment at regional level, 2020

Source: raw data from NIS, authors' own calculations and representation

Regarding the evolution of the registered unemployment on the onset of the crisis, at regional level we experienced increases from month to month almost since April, the first full month with measures implemented in order to try to control the effects of the pandemic (state of emergency, many restrictions regarding the economic activities). In comparative terms over the same month of 2019, the unemployment rate has a first strong increase in July, with increases ranging from 0 pp to 0,5pp, with only the North-East region registering a slight decrease as compared to July 2019. The same goes if we compare the registered unemployment rate with the values of March 2020 (set as a starting point of economic/health crisis in Romania). In August the situation continues to deteriorate, the number of registered unemployed rising even more: the overall unemployment rate reaches 3.3% (compared to 2.9% in March), with almost 290 thousand registered unemployed (and even more according to the definition of unemployed from ILO – almost 480 thousand unemployed, corresponding to a 5.3% unemployment rate).

The most affected region so far is the West region, with 0.7 pp increase of the registered unemployment rate since March, equivalent to an increase of approximately 40% of the registered unemployed (from 13.7 thousand persons in March to 19.1 thousand persons in August). Also, the North-West region registered an increase of nearly 30% of the registered unemployed (corresponding to a 0.6 pp increase in the unemployment rate). The region around the capital seems to be the least affected, with zero or a very small increase during these months (0.1 pp in August compared to March for the unemployment rate).

From the perspective of participation on the labour market in Romania, men were on an increasing trend in the period 2005-2019, while the participation of women on the labour market registered slight oscillations, with a maximum level of 63.6% registered in 2000 and the lowest of 55.2% in 2008. Women's participation in the labour market suffered a much slower recovery after the economic crisis of 2008, reaching only 58.9% in 2019, but unable to return to the level recorded in 2000, while the level registered among men for 2019 is higher than in 2000 (78% compared to 75.7%).

Fig. 2: Labour force participation in Romania, by gender and age groups

Source: raw data from NIS and Eurostat, authors' own calculations and representation

Regarding the evolution of labour force participation by age groups in Romania, in the period 2000-2019, there were numerous fluctuations. The largest decrease was registered for the age group 15-24 years (11.8 pp), more pronounced for the female population (13.7 pp compared with 10 pp for the male population). For the 55-64 age segment there is an even more pronounced decrease among women, 10.2 pp, while the participation rate for men in the same age group increased with 3.2 pp.

The first half of 2020, for which there statistical data is available, indicates a consistent downward trend for the 15-24 age group. For the 25-54 age group, the data do not yet indicate a deterioration of the situation generated by the new health crisis, while for the 55-64 age group the data for the first two quarters of 2020 even suggest a slight increase. However, these data should be viewed with caution, especially since in Romania the negative economic effects generated by the COVID-19 pandemic were felt only from the second quarter of this year.

The total employment rate (for 15-64 years) reached a minimum of 57.6% in 2005, following an upward trend in the next years, with a maximum of 65.8% in 2019. In the years following the economic crisis in 2008, the employment rate in Romania registered only a slight decrease, the period 2008-2014 being rather characterized by stagnation. However, when analysing gender differences, we note that while the male population maintained a steady upward trend over the period under review, the female population recorded a decline from 59% in 2000 to 56.8% in 2019.

Regarding the evolution of employment by age groups, both young people (under 25 years) and seniors (over 55 years) recorded decreases during this period: higher in the case of young people (9.3 pp) and slightly lower for those approaching retirement (4.2 pp). As for the 25-54 age group, the increase was modest, of 2.8 pp. The existing data for the first half of this year indicate a slight decrease even for this age group, from 82.2% employment in the second quarter of 2019 to 80.2% in the second quarter of 2020.

Future Perspectives of The Labour Market

During the United Nations Sustainable Development Summit in September 2015, the world leaders adopted a set of 17 Sustainable Development Goals (SDGs). The eighth goal of the 2030 Agenda advances the promotion of inclusive and sustainable economic growth, employment and decent work for all through several pillars to achieve: increase

labour productivity, decrease the informal employment, reduce the gender pay gap and reduce the unemployment rate.

Eichhorst (2017) argues that the future of employment is influenced by four main factors: globalization, technology, demographic change and labour market institutions. While globalization, technology and demographic change might be hard to control, the labour market institution in one country might become a more important vector than it is today. The importance of those institutions may become even more important in this new pandemic situation; they should aim to better shape the functioning of the labour market. In order to overcome the effects of technology and globalization, together with the new developments generated by the sanitary crisis, the labour market institutions should provide different channels of adjustment (either by proposing different types of employment, different working time together with wage flexibility, or/and by adapting the skill profiles to the companies' demands).

For the case of Romania, it is more than obvious that a widespread change in the size and structure of the population already took place, together with the large-scale movement of labour internationally. Due to the aging population it is expected that Romania will experience a slowdown in the growth of the workforce in the next period. Recent projections of Romania's population by Eurostat reflect current trends in fertility rates and net migration flows. Thus, the working age population (20-64 years) of Romania is estimated to decrease by approximately 7.5% by 2025 compared to 2019 and by another 3% between 2025 and 2030. We should expect a significant decrease in the population for most age groups less than 44 years, while for the age group 45-54 years we might even see a slight increase in population.

According to CEDEFOP forecasting (2018) regarding the sectoral employment trends in Romania, the highest increase during the next period (2021-2030) will be in the non-marketed services sector, while among the shrinking sectors, Construction is expected to be the sector experiencing the sharpest decrease up to 2030, together with manufacturing and primary sector and utilities. The economic crisis in 2008 has reduced employment in the primary sector, in construction, as well as in the manufacturing industry in the period 2008-2013. However, employment, especially in the financial services sector, but also in the distribution and transport services sector, as well as non-commercial services (especially related to the public sector), continued to increase during that period.

Regarding the occupations movement, the highest number of openings is expected to be for professionals and skilled agricultural workers, but also in legal, social and cultural professions and health professionals.

Three main areas of intervention should return to the attention of most countries (Eichhorst, 2017) and, we believe, even more so to the attention of Romania: education, the regulation of labour market and active labour market policies. Regarding the education, both youth and adult formation should be considered important, and the curricula should align with the needs of the labour market. From the labour market regulation point of view, the policy makers should aim to increase both labour force mobility and job security and flexibility. Attention should be also paid to forms of employment such as free-lancer or self-employed, both from the perspective of social insurance (pension, unemployment) and from the perspective of other aspects (minimum wage, work schedule). As of the active labour market policies, they can be a superior tool compared to employment protection because they target the protection of workers rather than jobs (Scarpetta, 2014).

As it becomes more and more obvious that this public health crisis is one of the worst in the last century, the world also became aware that the current economic crisis is a serious and lasting one. Moreover, it is not just an economic crisis, but also a job crisis, with many casualties in terms of unemployment and hours worked dropping sharply (OECD, 2020). Unemployment is expected to reach 10% in OECD countries by the end of 2020, up from 5.3% at year-end 2019, while jobs recovery is not expected until after 2021.

Conclusions

Labour market reforms can lead to tax costs - either directly, by changing taxes or unemployment benefits, or indirectly, using tax compensation to reduce the distributional effects of the reforms (IMF, 2014). Some labour reforms affect fiscal instruments and thus have direct budgetary implications. A clear example is the reduction of the tax burden on labour costs - the difference between the cost of labour borne by employers and the net salary of employees, due to income tax and social security contributions. Reducing the tax burden could lower labour costs and stimulate job creation, but would lead to losses in tax revenues. Active labour market policies and changes in

unemployment insurance schemes can also have a direct effect on the budget. The reduction in payroll taxes has a considerable fiscal impact. IMF (2014) showed that, taking into account the effect of the business cycle and inflation on nominal budget revenues from labour tax, the reduction of the tax burden by a percentage is, on average, associated with a loss of budget revenue equal to 0.3 % of GDP.-The nature of jobs is constantly changing, with technological progress, globalisation and ageing populations re-shaping the labour markets. Also, new organisational business models and worker preferences are contributing to the appearance of new forms of work. Moreover, the future of work is here, more rapid than everyone expected, due to the pandemic declared by World Health Organisation since March 2020. Specialists argue (OECD) that this economic crisis will hit harder the labour markets than the 2008 financial crisis (already the hours worked fell by 12%, compared to only 1.2 in the first months of the previous crisis).

In Romania, at national level, the unemployment rate in 2009 was 1.1 pp higher than the unemployment rate in 2008, and increased with another 0.3 pp in the next 2 years. In the first trimester of 2020 the unemployment rate was 4.3% and rising to 5.4% in the second trimester, being already with 1.5pp above the level registered in late 2019. The registered unemployment does not reflect this sharp increase, mainly due to the definition of the unemployed. In addition, in the months of lockdown the unemployed were unable to actively seek for jobs. We should also mention the fact that the measures taken by the Government in order to support labour market (workers, their families and companies) may lead to a drop in hours worked, with the employees maintaining their jobs, instead of massive firings.

Countries all over the globe reacted with unprecedented measures to contain damages and support, among other sectors and the labour markets. But in the months and years to come, new and better labour market policies, along with optimal fiscal policies must be designed and implemented in accordance with the specifics of each country, taking into account the strategic objectives already proposed, such as reducing inequalities in society, the poverty and the wage gap.

Abstract

The article considers the problems of the influence of cooperation on the development of credit resources market for agricultural sector. The analysis of activity of agricultural goods producers of Cherkasy region on capacity of farmland, majority of which are small-scale, has been carried out. Due to limited access to credit resources on credit resources market in general and preferential lending, growth of tax burden in particular, small-scale agricultural companies are in a difficult financial situation, which makes it impossible for them to operate on the principles of self-financing and self-sufficiency. The solution to this problem is possible through the creation of production, service and credit cooperatives and on their basis – the Agrarian Bank. The basic principles of functioning of agricultural cooperatives have been studied. It has been determined that the development of credit cooperation in this sector of the economy is mainly through the prism of lending, while leveling other important functions that can contribute to the sustainable development of small-scale agrarian sector. The peculiarities of the development of agrarian cooperation in Ukraine have been revealed, and functioning of the information-consulting center for consulting farmers has been singled out in the structure of the rural cooperative. It has been found that cooperation is one of the key institutions that will improve the efficiency of agricultural economy.

Keywords: Cooperation, Cooperative Movement, Agricultural Cooperatives, Credit Cooperation.

Introduction

State food security, health of the population, quality of life of rural society, ecological sustainability of territorial socio-economic systems, the effectiveness of innovation in agriculture, agribusiness, management technologies

depend on the state of development of rural economy. When using local territorial resources, cooperative form of organization of economic entities is the most acceptable. The main motive of cooperative interaction of members of rural society is the formation of the economic basis for improving the quality of life, given that the development of agricultural sector in modern conditions is possible only with the reform of small agricultural producers through agricultural cooperation. In addition, agricultural cooperation in Ukraine since the end of the 19th century is a unique global experience of reorganizing potential without any foreign investment.

Analysis of the latest studies and publications

A significant contribution to the development of cooperative movement in Ukraine has been made by V. Zinovchuk, M. Malik, L. Moldavan, F. Horbonis, etc. I.Kolokolchikova, N. Pavlenchyk, A. Sholoiko, H. Trosian, O. Chakh-ni, etc. have studied foreign experience. At the same time, not all issues related to the possibility of adapting foreign experience are sufficiently studied and resolved, which indicates the need for further research in this area.

Methodology

Methods of analysis and synthesis were used to consider cooperative aspects of rural development and formulate proposals for further functioning of agricultural cooperatives.

Statement of basic materials

A cooperative is a voluntary association of individuals to meet their own social, economic and other needs, which carry out aggregate economic and other activities.

The revival of cooperative movement is the most important direction in the development of the domestic agricultural sector. This trend should cover the organization of cooperatives for the production and processing of agricultural products of farms and personal subsidiary farms, supply and marketing, as well as credit cooperatives. Their creation will help support small-scale agricultural producers, the accumulation of their resource potential, and the unifying factor for the functioning of production cooperatives in rural areas should be a credit cooperative.

Cherkasy region, as an agricultural industry, is characterized by a large number of business entities of various organizational and legal forms (Table 1). The presented data show that the size of operating entities has a negative impact on production and financial activities. The results of the study show that small-scale agricultural enterprises predominate in the region among the existing economic entities, functioning of which on the terms of expanded reproduction, self-financing and self-sufficiency is hampered due to the impossibility of their introduction of advanced technologies and compliance with agro-technical conditions of management. In 2019, economic entities of agricultural production for the calculation of land per enterprise were divided into the following groups:

Table 1: Differentiation of existing agricultural producers of Cherkasy region by the capacity of farmland in 2019

	The number of enterprises	Percentage to the total number of enterprises	Area of farmland, ha	Percentage to the total area of farmland
Enterprises that had farmland, units	1677	88,1	9047000	100,0

Source: data of the Main Department of Statistics in Cherkasy region

From the list of agricultural goods producers, the share of small-scale ones with the area of up to 1000 hectares is 1450 or 86.5% of their total number. Small commodity production is one of the reasons for inefficient agricultural production, because such economic entities do not have the opportunity to use advanced technologies of agricultural production, invest in the purchase of new equipment, attract people who are able to create added value in combination with fixed and current assets. Hence the high level of unemployment in rural areas.

Solving the problems of efficiency of small business entities is possible as a result of the creation of cooperatives, including credit, which can positively affect the market of credit resources of farmers.

Credit cooperation is a new economic institution in the countryside, able to solve the problem of lack of financial resources in agricultural production (especially in small commodity). An agricultural credit cooperative is not a mutual aid fund, but a complex socio-economic institution whose activity, unlike credit unions, is to serve the legal entity of farmers, not consumers, unlike credit unions. In view of this, rural credit cooperatives can unite individuals and legal entities: owners of personal farms, peasant farms, large agricultural goods producers.

The availability of funds is the most necessary (after land) resource. However, after the peasants received the land in the early 1990s, many of them were unable to cultivate it, which led to the mass transfer of land for rent, including long-term, for up to 49 years. The creation of a system of cooperatives in rural areas will make it possible to invest in the purchase of modern equipment, plant protection products, elite seeds and productive livestock, increase production and sales of organic products.

An important structure of village cooperative is the functioning of information and consultation center, which is responsible for consulting farmers and employees of other agricultural enterprises, their training, in particular abroad; creation on the basis of the cooperative of a network of information and consultation centers and consultation points for the exchange of experience, advertising of the cooperative and farm products.

The creation of production, supply and marketing cooperatives will increase the volume of production and sales of agricultural goods, search for markets using sales logistics.

In order to detail the influence of the size of economic entities depending on farmland, we used cluster analysis, the purpose of which is to sample the object with its subsequent arrangement into relatively homogeneous groups. Cluster analysis of economic entities in agricultural sector of the region by the size of farmland allows us to identify several types of enterprises with different specialization depending on the size of farmland (Table 2).

Table 2 : The results of cluster analysis of economic entities of Cherkasy region depending on the area of farmland on average for 2016 - 2019.

Index	Groups						On average per totality
	1	2	3	4	5	6	
The number of enterprises	125	99	21	92	59	31	427
The average area of farmland, ha	984	779	1063	2842	3566	4021	1918
The share of crop production in total sales, %	97,4	90,1	96,4	52,3	55,7	53,4	56,5
The share of livestock products in total sales, %	2,6	3,0	1,1	31,9	31,3	30,9	32,1
Share of processed goods to total sales, %	X	x	X	8,9	9,5	10,6	8,2

Source: data of the Main Department of Statistics in Cherkasy region

It should be noted that different types of economic entities of agricultural sector of the region, depending on the size of available farmland, correspond to different levels of specialization of their production. Given the results of cluster analysis, it should be noted that the enterprises of the first–third cluster are small-scale in their use, the land area is on average from 779 to 1063 hectares. These are small-scale agricultural producers specializing exclusively in the cultivation of crop products, the share of which in the total volume of sold goods is from 90.1% of the second group to 97.4% – the first group. In view of this, in these groups, livestock goods in the overall structure of sales are insignificant and range from 1.1% in the first group to 3.0% – the second group. The enterprises of the first–third cluster are not engaged in processing own production at all and they do not have trade networks for selling their own production.

At the same time, economic entities of the fourth, fifth, sixth groups have from 2842 to 4021 hectares of farmland at their disposal. These diversified enterprises specialize in growing crop products, producing livestock products and processing their own products at their own facilities. For the most part, these enterprises have their own trade networks through which agricultural products are sold. Closed production cycle has a positive effect on the duration of turnover of current assets in these groups. In particular, the duration of current assets turnover in the diversified entity of the sixth cluster is 253 days, and in the group of enterprises of the first cluster – 489 days.

The analysis gives grounds to claim that economic entities of the fourth, fifth and sixth clusters provide profitable production, the average size of which for the analyzed period is from 20.7 to 35.0%. Enterprises of the fourth–sixth clusters attract significant investments in production, the amount of which is 679.4 644.1 and 872.8 UAH per 1 ha of farmland, respectively.

The analysis of the activity of small-scale economic entities of agricultural production of the region shows that their further development under current conditions is possible only under the conditions of their reform of small-scale agricultural cooperatives. In addition, agricultural cooperation in Ukraine since the end of the 19th century is a unique global experience of reorganizing potential without any foreign investment. A cooperative is a voluntary association of persons who, in order to meet their own social, economic and other needs, carry out aggregate economic and other activities.

The revival of cooperative movement is the most important direction in the development of domestic agricultural sector. This trend should cover the organization of the functioning of both production cooperatives and cooperatives for processing agricultural goods of all economic entities of agricultural production, including farms and private subsidiary farms. In combination with production cooperatives, supply, sales, and credit cooperatives should be fully operational. Their creation will help support small-scale agricultural producers, the accumulation of their resource potential. Production cooperatives are a new economic institution in the countryside, which will solve the problem of lack of financial resources in agricultural production (especially in small-scale production).

The development of cooperative movement in the region's agriculture needs to address many issues. One of them, which requires a systematic approach in its solution, is the issue of consolidation of small farms and cooperation of personal subsidiary farms. In turn, when addressing the organizational form of cooperation in agricultural sector of the region, it is necessary to follow the basic principles:

- volunteering in joint cooperation;
- preservation of economic independence of a business entity that is a part of cooperative association;
- financial interest of the business entity of its employees in the development and improvement of production efficiency;
- increasing production and sales, improving its quality, increasing productivity and cost reduction;
- economic feasibility of creating a new organizational–production system aimed at sustainable development of farms;
- democratic nature of joining new organizational structure and adopting new normative legal documents;
- exclusion of economically unjustified intermediaries between partners;
- development and strengthening of production and economic ties;
- elimination of monopoly position of certain economic entities.

Farms and small-scale producers, due to insignificant volumes of production and sales, low level of creditworthiness carry out production activities without attracting bank loans in general and preferential in particular. Due to small-scale production, they are virtually deprived of access to both ordinary bank loans and those provided on concessional terms. Therefore, we believe that the issue of credit support for farms is a priority for the government, as over the years of market transformation, they have become an integral part of agricultural sector and the national economy. Therefore, the formation and development of small businesses in agricultural production depends largely on their participation in the processes in financial markets. Today, most of these businesses do not have a credit history and liquid collateral, and therefore have difficulty obtaining bank loans. Modern scientific community has largely ignored the study of the peculiarities of the functioning and development of rural credit cooperation, despite the urgent need for theoretical generalization and explanation of this phenomenon. Therefore, currently the development of credit cooperation in this sector of the economy is mainly through the prism of lending, while leveling other important functions that can contribute to the sustainable development of the small-scale agricultural sector.

In general, it can be argued that administrative and economic reforms that accompanied and stimulated socio-economic development of the village, distorted the functional role of credit cooperation and leveled its basic feature – sustainable development of rural areas and small-scale production. After all, branching out the sphere of influence of credit cooperation and expanding the range of its functions has a positive effect on the revival and development of all spheres of life of rural communities and territories, as well as encourages optimization of current assets management of agricultural enterprises.

The current situation in the financial sector of the domestic economy indicates the need to develop a state system of its regulation. The results of the study conducted by V.V. Honcharenko on the creation of a credit system for domestic agricultural production in five stages deserve attention. First of all, in his opinion, the process of self-organization of credit unions should be carried out and this process should be completed with the creation of cooperative banks and the Agrarian Bank. There are other proposals for the stages of formation of credit cooperation, in particular, T. Herasimova based on the conducted studies, proved that the most effective is the creation of a three-level credit system in rural areas. These include credit cooperatives as the main institution of agricultural lending and regional cooperative banks. The third level is the Agrarian Bank. Without denying the expediency of a three-level system of financial and credit support of economic entities, the function of creating the first and second levels of the credit

system should be entrusted to the Agrarian Bank. Therefore, to solve the problem of financial and credit services to agricultural entities completely and finally, it is appropriate to create a credit system similar to the classical Western systems, that is a system of rural credit cooperation, which should be built on bottom-up basis and consist of here levels, each of which has suitably matched activities (Table 3).

Credit cooperatives, which cooperative unions can join, will be the basic institutions of cooperative system and will be its first level*. Their main activity is lending to farmers – members of the cooperative, accepting deposits, and while making appropriate changes to the law, making utility and other payments, providing other financial and non-financial services.

Table 3: Recommendations for the introduction of a multilevel system of lending agricultural production in Ukraine

Level	Institutions	Areas of activity
First	Credit cooperatives in the countryside and credit unions	1. Short-term and long-term lending to personal subsidiary farms and peasant (farming) husbandries; 2. Acceptance of deposits; 3. Making utility and other payments, 4. Provision of other financial and non-financial services.
Second	Universal commercial banks	1. Short-term and long-term lending to large-scale agricultural entities on the basis of various special credit goods; 2. Special credit goods for small-scale entities of agricultural production; 3. Provision of financial services to local rural cooperatives.
Third	The Agrarian Bank	1. Representing the interests of agriculture as a separate segment of bank lending at the national and international levels; 2. Development of issues related to financial support of the main areas of agricultural policy together with the Ministry of Economic Development, Trade and Agriculture, the provision of concessional loans; 3. Interaction with the NBU in the field of refinancing on a concessional basis; 4. Refinancing commercial banks and credit cooperatives in order to further provide loans to all categories of agricultural production; 5. Investment lending to agriculture; 6. Development of land mortgage lending.

To ensure more efficient functioning of local credit unions, appropriate institutions of the second level should be established. These are universal commercial banks, provided they accumulate authorized capital. The activities of the second level institutions are short-term and long-term lending to large and small agricultural entities on the basis of various special credit goods. In addition, their functional responsibilities include serving the needs of local rural cooperatives by providing them with additional financial services (liquidity support, development of new financial products, clearing, internal payments, settlement, currency and investment operations, etc.). To complete the formation of a full-fledged cooperative system of financial mutual assistance of the population is the organization of the third level – Agrarian Bank, established by institutions of the first and second level to represent the interests of agriculture as a separate segment of bank lending at the national and international levels; development of issues related to financial support of the main directions of agricultural policy together with the Ministry of Economic Development, Trade and Agriculture; interaction with the NBU in the field of refinancing on a concessional basis; refinancing of commercial banks and credit cooperatives in order to further provide loans to all categories of agricultural production; investment lending to agriculture; development of land mortgage lending. In addition, Agrarian Bank provides first and second level institutions with additional financial services such as leasing, factoring, insurance, etc.

In Ukraine, the need to create the Agrarian Bank to serve farmers is theoretically justified, however, the problem is not solved due to lack of financial resources, lack of regulations on the sale of agricultural land after lifting the moratorium on their sale. The source of formation of the authorized capital of the Agrarian Bank may be part of the funds received from the sale of agricultural land. When selling agricultural land, a tax on alienation of agricultural land subject to change of ownership should be introduced, with the direction of funds to a special state fund with

their intended use – to replenish the authorized capital of the Agrarian Bank. The creation of the Agrarian Bank with the state's share in the authorized capital is not only expedient and necessary for the following reasons:

- investment and credit services for farmers, in particular, secured by land and property, property and other rights to use;
- prevention of unregulated movement of land;
- trust management of property and land and funds of insolvent entities;
- providing consulting services to members of the cooperative;
- servicing of export and import operations carried out by them;
- methodological support for taxation, lending, insurance, marketing, accounting.

The newly established Agrarian Bank should be given functional responsibilities to represent the interests of farmers as a separate segment of bank lending at the national and international levels, develop issues for financing the main areas of agricultural policy together with the Ministry of Economic Development, Trade and Agriculture, provide soft loans. In addition to state support, functioning of the Agrarian Bank in Ukraine is possible by involving farmers in the formation of its authorized capital. Such cooperation is one of the prerequisites for the operation of a branch bank in Ukraine, as banks that provide loans and farmers who receive them become full partners. Under such conditions, banks are interested in the results of farmers, as they can provide certain preferences when lending. Raising the capital of borrowers in the formation of the loan portfolio is possible on self-supporting terms and the interest of the latter in investing.

Among the areas of influence of bank lending on the competitiveness of agricultural goods, the implementation of projects aimed at improving their lending in operating and investment activities should be identified. The newly established Agrarian Bank will undoubtedly play a positive role in the process of stimulating bank lending to agricultural sector of the economy. In Ukraine, state support for cooperatives has not become a component of agricultural policy. Two attempts by the Government (2008 and 2018) to quickly organize financial support for cooperatives failed. At the same time, the decision to establish the Agrarian Bank did not take effect due to the lack of regulations on its establishment and lack of financial resources for its functioning.

Until now, lending to farmers is carried out through a number of commercial banks, interest rates on loans in which are much higher than their level of profitability. Farmers are practically left without financial state support. The motivation of the protectionist state policy on agriculture is the need to support not only the economic function of the industry.

Western agro-economic science has recognized multifunctional purpose of agriculture, which also includes the performance of social functions – ensuring food security and food independence of the country, promoting employment and settlement of rural population, rural development and more.

Despite the unstable economic situation in the country against the background of rising energy resources prices, fertilizers, fuels and lubricants for agricultural sector, the Verkhovna Rada of Ukraine adopted amendments to the State Budget of Ukraine which imply receiving 1 billion UAH by farms for the first time, which will help create a competitive environment and allow cooperatives to increase production and sales, the main prerequisites for the creation of processing cooperatives.
In general, the budget of Ukraine provides for expenditures for 2019 in the amount of 3.099 billion UAH, of which the general fund amounts to UAH 1139.0 million, the special fund – 1.96 billion UAH.
It is worth noting that the level of support for agricultural sector entities in the EU differs significantly from the state support for domestic farmers. In particular, Greek farmers receive about 700 euros per hectare of land, in Bulgaria – 190, in Lithuania – 143, in Estonia – 112 euros, and in Ukraine – less than 20 euros. In addition, in the European Union, farmers can take a loan at 3–5% per annum.

One of the areas of state support for agricultural cooperatives is the introduction of a special tax regime.

The specificity of the production activities of cooperatives due to the seasonality of production, the temporary gap in the receipt of funds from sales, the disparity in prices for agricultural and industrial products determines the application of a special regime of their taxation.

The instability of tax legislation, increase in monetary assessment and single tax rates (fourth group) from 01.01.2015, the abolition of a special VAT regime at the request of the IMF from 01.01.2017 led to an increase in the tax burden on agricultural producers.

Given this, the association of agricultural producers of all organizational and legal forms of ownership is timely, which will allow them to increase sales of finished products, to operate on the basis of self-financing and self-sufficiency.

Conclusion

The positive changes in agricultural sector have a serious influence on the process of production, distribution and consumption of agricultural products, and reforms supporting cooperation provide new opportunities and chances for Ukraine's economy. At the current stage of development of the agricultural sector of the economy, it is important to make full use of the experience of foreign countries in the development of agricultural cooperation and at the same time to treat real situation in the country reasonably.

The development of cooperative movement in Ukraine could be a driving force for qualitative changes not only in agricultural sector but also in the country as a whole. But this requires the combined efforts of villagers, NGOs and government officials. The relevant laws need to be updated, and the very idea of cooperation needs more coverage and discussion. According to world experience in a market economy, cooperatives are the third force or alternative to public and private enterprise.

Thus, the involvement of farms, private farms and other small agricultural producers in agricultural cooperatives, which will receive state aid for the purchase of equipment for storage and processing of agricultural products, repayment of interest on loans, will help bring it out of the shadows and increase income of its producers. The mechanism of taxation of agricultural producers, which should be based on common methodological approaches to all forms of agricultural business in the countryside, needs to be further developed.

Abstract

The complexity of the project and the uncertainty related to its unique character are important factors affecting the risk associated with the implementation of a given project. The subjects of the analysis were the risk factors related to the organization of marathons classified as mass sports events. None of such events can be flawlessly planned and none can be carried out strictly according to a previously developed plan. Risk management, as a sequence of separate activities during the organization and course of a sports event, especially the identification and prioritization of threats, helps the event organizers to cope with the uncertainty related to individual aspects of the event. This gives more space for manoeuvre, allowing the organizers to pay special attention to those risk factors, the minimization or elimination of which at an early stage allows minimising the probability of negative effects and creates the greatest probability of achieving positive results. Risk, if left unattended, tends to degrade the running event value and the effective risk management adds extra value to it. The research aimed at analysing identified risk factors for marathons in the context of defining the character of managerial decisions related to marathons organisation. As the results of the research verification of risk factors and their logical grouping were conducted. The authors carried out the validity assessment of the research instrument (the Cronbach's alpha statistics was used) as well as conducted the cluster and factor analyses to illustrate the research results and provide results of higher quality in the context of taking risk mitigation actions for marathon organization.

Keywords: Risk Factors Analysis, Running Events, Priorities In Risk Management.

Introduction

Recreational running is typical for the modern lifestyle model of a significant group of the society, a relatively cheap one that does not require any special sports arenas (Czkór, 2014; Shipway, Holloway & Jones, 2013). Everyone can run regardless of the time of a year, age, gender, physical fitness, social status and education level, on your own or participate in professional running events, choosing from shorter or longer city runs to ultra marathons. In the world we may observe significant dynamics of the growing interest in participating in long-distance runs. This phenomenon makes the organization of running events important social projects to participants, their families, organizers and a given local community.

Long-distance running events have surged in number and participation in Poland in the last few years. In 2010 nearly 800 different races were registered in Poland, while in 2015, an increase of nearly 132% in comparison with 2010 (1,856 runs) was recorded. In the following years, the number of races grew, although the dynamics were not that significant. In 2018 a total of over 2,500 runs were registered in Poland (www.maratonypolskie.pl). In the top 10

marathons in Poland in 2018 a total of 33,445 runners took part (the statistics include only participants who completed the race).
Surprisingly, 51% of sports events' organizers in Poland do not conduct formal management of the project, which is the organization of a sporting event in accordance with a recognized methodology. 78% of them do not formally estimate the risk of organizing sports events (Miśniakiewicz & Łuczak, 2014). In practice, risk management, as a part of operational management, is often limited to intuitive avoiding threats and meeting existing legal requirements. Therefore, it is probable that decisions related to the organization of the run are not made optimally, perhaps no significant risks are identified and, as a consequence, they are not adequately mitigated (Hanstad, 2012). As a result, a sports event may not bring the expected benefits and its course may be disturbed or even interrupted (Reid & Ritchie, 2011, Helms, 2011). It results in further risks related to the loss of the organizer's reputation and dissatisfaction of the participants, who put a lot of effort into the preparation and often incur specific costs associated with their participation in the running event (Moyle, Kennelly & Lamont, 2014; Nohr, 2009). What is more, dramatic incidents and deaths in several high-profile running events have understandably contributed to misgivings regarding the safety of such events and encourage their organizers to think of professional risk management (Bjarnason & Cannell, 1999, Berlonghi, 1990).

The majority of marathons in Poland do not meet the criteria of mass events. It means that they are not a subject to expansive legal regulations related to providing their security. It significantly facilitates their organization and at the same time leaves the responsibility for their management to the experience of the organizers (Żuryński, 2013). The organizers should identify potential risks within the running event and implement adequate measures to control them (Fuller & Drawer, 2004).

The decreasing number of marathon finishers on the one hand as well as the growing number of events available on the running market, and, thus, growing competition, on the other hand motivate their organizers to improve the quality and efficiency of such events. Consequently, they aim at professionalizing planning and implementation (Shipway, Holloway & Jones, 2013; Peters & Pikkemaat, 2005; Spengler, Connaughton & Pittman, 2006).

There are no obligatory legal requirements to carry out risk management in large-scale running events today but it is a helpful tool to identify risks, assess and mitigate them to the acceptable levels. It assists sporting event managers in providing a reasonably safe environment and can constitute a fundamental for solving the occurring and potential problems (Berlonghi, 1990; Ammon & Brown, 2007).

Risk, if left unattended, tends to degrade the running event value (Rescher, 1983) and the effective risk management adds extra value to it (Toohey & Taylor, 2008). Yet the event organizers should remember it is impossible to eliminate risk totally without degrading value, so the decision process must follow an optimizing rule, balancing the costs and benefits against overall risk management (Rescher, 1983; Miller, Wendt & Young, 2010). An early understanding of the level of risk, different risk issues, complexity and uncertainty when talking about risk management would help in the determination of the project scope and the ultimate success of a running event (Shone & Parry, 2004; Nohr, 2009). The list of critical risk factors and more conscious risk management of large-scale running events are supposed to be the results of these actions.

That is why risk factors were identified by 15 experts and analyzed by 31 representatives of organizers responsible for 14 marathons in Poland. All the events belong to the group of the 20 largest marathons in Poland (research carried out by Łuczak, Miśniakiewicz, Saavedra**,** Identification and Assessment of Risk Factors for Large-Scale Running Events from The Organizers' Perspective. Marathon Case Study**,** 36th IBIMA Conference).

Methodological Assumptions for the Analysis of Risk Estimation

Authors carried out research aiming to identify risk factors (the Delphi method, a discussed questionnaire, 15 experts, 2017) and to estimate risk (qualitative research, a questionnaire, the e-risk app, 31 representatives of 14 marathons, 2017-2018) (research carried out by Łuczak, Miśniakiewicz, Saavedra**,** Identification and Assessment of Risk Factors for Large-Scale Running Events from The Organizers` Perspective. Marathon Case Study**,** 36th IBIMA Conference). The Cronbach's alpha statistics was used to assess the used questionnaire reliability. Cluster analysis and factor analysis of the most important risks completed the analysis.

The research aimed at analysing data (identified risk factors for marathons) in the context of defining the character of managerial decisions related to organizing marathons. The realization of the research led to the verification of risk factors and their logical grouping (arrangement).

The authors carried out the validity assessment of the research instrument as well as conducted risk assessment - the cluster and factor analyses to better illustrate the research results and provide results of higher quality in the context of taking risk mitigation actions for marathon organization. Reliability analysis (Cronbach, 1951; Peterson, 1994) was applied with the use of the Cronbach's alpha statistics to confirm the adequacy of the applied research instrument (a questionnaire prepared as the result of the preparatory research) (Peterson, 1994; Brzeziński, 1996; Cronbach, 2005; Hornowska, 2001; Peterson, 1994).

The factor analysis was used to distinguish risk factor groups. This method is considered insufficiently objective, however, it is highly important while exploring the structure of multidimensional data (Balicki, 2013). It helped to categorize observations in a proper way so as the distinguished groups were simultaneously coherent due to variables (internally cohesive) and different to others (i.e. characterized by external isolation – Walesiak & Gatnar, 2016). Consequently, the cluster analysis was conducted to distinguish groups of organizers on the basis of attitudes to risk (Hanstad, 2012) as the results showed that risk factors are assessed at various levels. Due to cluster analysis, contrary to the analysis of average risks values, certain attitudes (approaches) to risk of organizing events may be revealed.

On the basis of relevant professional literature (Milligan, 1996) several stages of a typical cluster analysis were distinguished, including the choice of items and variables, data standardization, the selection of a distance calculation method and a classification method, establishing the number of classes and result evaluation (Walesiak, 2004). At the stage of selecting variables we decided to analyze the impact of factors of the highest generated risk (variables were grouped on the basis of the arithmetic average of risk assessment and then we simultaneously applied scree plot and the minimal risk value criterion at level 4 (so as the analyzed risks could be characterized by larger than minimal probability and consequences).

The authors also decided that the selection of insignificant variables is an incorrect approach (Milligan, 1996; Walesiak, 2004), as it may hinder the discovery of a cohesive or relevant class difference within the set. Next, the variables were subjected to normalization with the use of standardization (the application of the average and standard deviation) (Grabiński, Wydymus, Zeliaś, 1989; Wilk et al., 2015).

Having discussed the choice of the most adequate classification method we finally decided to use the hierarchical method (so as to define the number of class on the basis of the dendrogram). Next, the application of the method including the initial classification of items, in which the number of distinguishable classes is known (Gatnar & Walesiak, 2012), was considered valid. Moreover, the method of the increased squared distances sum (also called Ward's method), which optimizes the division obtained by the combination of two elements at all stages, was used by the application of the minimum growth of the total sum of the squared variance of all variables for each item from group average values (Balicki, 2012). Consequently, on the basis of the dendrogram we decided two distinguish 3 clusters.

Next, the k-means clustering was conducted, within which each class was represented by its centroid (Gatnar & Walesiak, 2012). Moreover, the clusters were checked for single-element sets – it might have suggested the occurrence of extreme deviations, which are capable of distorting the cognitive function of cluster analysis.

The factor analysis aimed at revealing a new set of variables – a set, which is less numerous than the original one, but can reflect its variability. These factors should retain a significant portion of information included in the original variables (Walesiak & Gatnar, 2016; Balicki, 2013). Within the factor analysis, as well as within the cluster analysis, not all accessible variables were used – it was limited to the variables of the cluster analysis. It allowed for the comparability of analyses and their internal cohesion.

Analysis of Priorities in Risk Management

The Cronbach's alpha statistics result reached the level of 0.933 (21 positions). According to the classical interpretation the coefficient should have the minimum value of 0.6, whereas the preferable value of the coefficient is approx. 0.9. Thus, the internal cohesion of the research instrument was confirmed.

The presentation of the proper research results begins with the classical approach to risk assessment – the statistical analysis of average values of risk factors accompanied with tagging the ones of the highest risk and the largest frequency. The following part presents four groups of event organizers (according to their attitude to risk) distinguished on the basis of the cluster analysis as well as risk factor groups distinguished on the basis of the factor analysis.

The grouping of the data was arbitrary and was discussed with experts; within this scope the result of factor analysis stemmed from a discussion. The selected factors with the average value of risk at 4.1 or higher (36 most important factors) were standardized. The cut-off was applied with reference to factual evaluation. Not all variables were taken into account on the basis of the analysis of averages. The declining graph of averages of specific variables may be treated as a scree plot. Thus, we may not take into account the variables whose significance was marked as marginal and which might influence the results of grouping after standardization (Guyon & Elisseeff, 2003; Breiman et al., 1984).

It is also adequate to define the probability of occurrence (the average) in reference to the identified risk factors. Three groups of risk factors were distinguished - with the value of probability: at 2.00 or higher – 14 the most probable factors (see Table 1) at 1.20 to 1.99 – 50 factors, and at 1.19 or lower – 12 least probable factors, which may occur only theoretically.

Table 1: The most probable risk factors.

Code	Risk factor	Average
2.5	Time overlapping with another rival event	2.71
4.5.	Inability to receive start packages on the day of competition	2.71
2.2.	Insufficient funding from sponsors	2.38
5.5.	Inappropriate organization of the run – jams after the start	2.19
6.1.	An unattractive start package	2.19
8.3	Lack of information about the event in the national media	2.19
2.4.	Lack of profit at the planned level	2.14
3.6.	A cyber attack – modification, blocking of the website	2.14
9.1.	Downpour	2.10
2.1.	Insufficient income from participant fees	2.05
5.6.	Inappropriate organization of the finish	2.05
5.16.	Limited human resources	2.05
1.2.	An intrusion of a third party onto the running route	2.00
3.4.	Unintended disclosure of personal data	2.00

Respondents considered the factors related to the marathon budget and achieving objectives as the most probable along with the ones linked with physical safety (an intrusion of a third party onto the running route), data protection (a cyber attack, disclosure of personal data) and organization (start and finish, issuing start packages).

Risk assessment aims at indicating priorities within the scope of additional security measures, which reduce risk to an acceptable level. These priorities were defined due to the statistical analysis of factors with tagging the ones that generate the largest risk. Making adequate decisions within the process of organizing a marathon needs taking account of the most probable factors as well as the ones of large impact (consequences).

The analysis of the proper research results included the cluster analysis (Ketchen & Shook, 1996). The choice of the optimal number of clusters is usually unclear – the most popular methods vary from 2 to 4 clusters. However, the biggest cognitive value and distance between clusters may be observed for 3 clusters. Therefore, we made the decision to establish the number of clusters at 3. This choice was also confirmed by creating a dendrogram (the use of hierarchical cluster analysis, Ward's method) (figure 1).

Figure 1: Dendogram with the use of Ward's method, joined clusters (scaled distances)

We may characterize the centers of the three clusters through analyzing them. Taking account of the clusters of variables the following three groups of organizers were distinguished: group A (cluster 1) – "no problem"; group B (cluster 2) – "business"; group C (cluster 3) – "organizers".

- Cluster 1 (group A – "no problem") consists of entities that assess all risks as low, in particular in reference to start packages, the local community, wrong identification and form of the route, difficulty in arriving at the start etc. For them the problems related to financial resources, e.g. funding from sponsors, are of the highest importance. However, even these risk areas reach lower than average values within this group.
- Cluster 2 (group B – "business") is a group that emphasizes financial aspects and associates the highest risk with insufficient profit, insufficient income, limited solvency as well as human resource and promotion problems (an insufficient number of volunteers, lack of their engagement, a rival competition).
- Cluster 3 (group C – "organizers") emphasizes organizational risks (problems with the route, start packages, volunteers, communication, PR, personal data). Moreover, this group does not consider financial risk significant (Table 2).

Table 2: Description of the cluster groups of marathon organizers

		1	2	3
1.3.	A participant of insufficient health condition	0.08878	0.03906	-0.23439
4.7.	An inappropriately narrow route, narrows	0.05270	0.31659	-0.43252
1.2.	An intrusion of a third party onto the running route	0.01008	0.02218	-0.04436
4.2.	Poor organization of the deposit office	-0.00255	0.17926	-0.17366
2.1.	Insufficient income from participant fees	-0.01478	0.86980	-0.83728
2.4.	Lack of profit at the planned level	-0.08423	1.18412	-0.99882
4.5.	Inability to receive start packages on the day of competition	-0.09292	-0.54171	0.74612
3.4.	Unintended disclosure of personal data	-0.15453	0.16998	0.16998
2.3.	Insolvency	-0.17829	1.11465	-0.72240
5.16	Limited human resource	-0.24351	0.97101	-0.43528
5.9.	Delayed start	-0.24754	0.53826	0.00633
2.2.	Insufficient funding from sponsors	-0.32679	0.45191	0.26704
1.1.	A serious accident on the route	-0.36254	-0.01431	0.81189
5.5.	Inappropriate organization of the run – jams after the start	-0.36393	0.64051	0.16013
3.5.	Personal data theft	-0.38584	0.13378	0.71506
8.5.	An insufficient number of participants (too little interest)	-0.45312	-0.05734	1.05421
1.7.	Insufficient medical support	-0.45380	0.22228	0.77609
8.6.	A rival local event	-0.45519	-0.03655	1.03796
2.5.	Time overlapping with another rival event	-0.48626	0.73334	0.33643
9.1.	Downpour	-0.51235	0.86053	0.26664
9.7.	Force majeure	-0.51355	0.50675	0.62306
7.3.	An insufficient amount of water at recovery points	-0.55089	1.62824	-0.41629
9.4.	An overly high temperature	-0.56247	0.84800	0.38943
5.12.	An insufficient number of volunteers	-0.56247	1.30658	-0.06915
1.5.	A terrorist attack (an explosion, shooting, ramming)	-0.57398	0.11287	1.14987
3.6.	A cyber attack – modification, blocking of the website	-0.60697	-0.10142	1.43676
8.1.	Unfavorable media information on the national scale	-0.62795	0.07018	1.31131
4.3.	Difficulty in reaching the start of the marathon	-0.67638	0.34846	1.13957
5.1.	Inappropriate running route identification	-0.71027	0.23439	1.32821
5.13.	Lack of volunteers' engagement	-0.71691	0.73701	0.84019
5.17.	Incompatibility of the running route capacity with the n° participants	-0.72095	0.35790	1.22818
3.3.	Insufficient promotion/information on external websites	-0.72573	1.50666	0.08995
6.1.	An unattractive start package	-0.72684	0.91693	0.68211
5.14.	Faulty time measurement	-0.79141	0.30759	1.43352
5.6	Inappropriate organization of the finish (e.g. inability to finish freely)	-0.82651	0.90917	0.90917
6.3.	An insufficient number of medals	-0.82716	1.29202	0.52773
5.8.	Problems related to organization, time of the event etc.	-0.84511	1.29566	0.56358

While analyzing the results one should note that the data approximating to zero indicate that the average risk assessment in a specific group is typical (identical) of the whole set. In cluster 1 ("no problem") it specifically means:

An intrusion of a third party onto the running route, Poor organization of the deposit office, Insufficient income from participant fees; in cluster 2 ("business"): A participant of insufficient health condition, An intrusion of a third party onto the running route, A serious accident on the route, A rival local event; and in cluster 3 (group C – "organizers") it mainly refers to: Delayed start, An insufficient number of volunteers.

The values higher than zero indicate a higher risk assessment in comparison with the average and, by analogy, values below zero define the risk factors the risk assessment of which was lower than the average. The interpretation of the results (dark/light gray highlighting) is arbitrary. The dark gray fields indicate a considerable difference between the achieved risk assessment value and the average (above 1 or below 1), light gray fields depict a lesser difference (but still significant).

The further the value is from zero, the larger the deviation. Hence, in the group called "no problem" there are no significant deviations, but there are some smaller ones (10 factors), i.e. "Inappropriate organization of the finish (e.g. inability to finish freely)", "An insufficient number of medals", "Problems related to organization, time of the event etc. with the local community and the administration". In the group called "business" large deviations relate inter alia to "An insufficient amount of water at recovery points", "An insufficient number of volunteers", "Insufficient promotion/information on external websites". The group called "organizers" is the most "visible", which stresses the risk group related to organization and at the same time pays little attention to the financial aspect. The large deviations include "A cyber attack – modification, blocking of the website", "Faulty time measurement", "Unfavorable media information on the national scale". On the other hand, lesser deviations within this group embrace 3 factors, e.g. "Insufficient income from participant fees", "Lack of profit at the planned level".

The use of cluster analysis has allowed for distinguishing a number of groups of run organizers' attitudes. It should be noted that these attitudes are radically dissimilar – there is a group within which no problem is considered significant, whereas other groups emphasize organizational and financial risks. Hence, it seems clear that developing universal risk management tools is very difficult. Moreover, the analysis may give rise to a question whether individual characteristics of specific events have been taken into account – depending on the organizers' goals some risks should be controlled (managed), whereas others seem to be irrelevant for the persons responsible for organizing a specific event.

Negative values mean lower than average risk assessment of a given variable within the cluster, whereas positive values denote higher than average risk assessment. This explanation is subordinate to the key characteristics of the three types of organizers. The cluster analysis confirmed the frequently formulated financial and organizational aspects, as well as the approach, which takes account of risk assessment as an essential element of managing and organizing running events. It is reflected in a specific organizer's status. If a city or a municipality organizes the event they consider financial risk less relevant, as the assurance of financial aspects is a part of the institution's budget. Organizational aspects generate more risk for them. The present study uses factor analysis in order to structure data and identify specific interrelations. Within the factor analysis 7 components were identified, which allowed for explaining 91% of data variability (table 3).

Table 3: Identification of components within the factor analysis

	Total sum of squared loadings after rotation		
	Total	**% variance**	**% accumulated**
1	7.105	20.896	20.896
2	6.628	19.495	40.390
3	4.776	14.048	54.438
4	4.355	12.807	67.246
5	2.988	8.789	76.034
6	2.712	7.975	84.010
7	2.273	6.686	90.696

The risk factors explained by specific components were determined. It should be stated that the first factor mainly refers to issues directly related to the route – its identification, time measurement, capacity, start packages, access to water (recovery) and weather. The second and third factors are linked with budget issues and sports-unrelated

questions, which may occur during the event – a terrorist attack, personal data theft, an intrusion of a third party onto the route, or problems with the deposit office (during competition). The fourth factor is associated with occurrences such as health problems of participants and competition in reference to an alternative running event (organized at the same time). The remaining factors include variables such as unintended personal data disclosure, or issues of too little interest from potential participants (table 4).

Table 4: Risk factor groups

Factor 1	Factor 2	Factor 3	Factor 4	Factors 5, 6 and 7
3.3. Insufficient promotion/information on external websites	1.5. A terrorist attack (an explosion, shooting, ramming)	1.1. A serious accident on the route	1.3. A participant of insufficient health condition	3.4. Unintended disclosure of personal data
5.1. Inappropriate running route identification	2.4. Lack of profit at the planned level	1.2. An intrusion of a third party onto the running route	2.5. Time overlapping with another rival event	8.5. An insufficient number of participants (too little interest)
5.6. Inappropriate organization of the finish (e.g. inability to finish freely)	3.6. A cyber attack – modification, blocking of the website	2.2. Insufficient funding from sponsors		8.6. A rival local event
5.8. Problems related to organization, time of the event etc. with the local community and the administration	5.16. Limited human resources	2.3. Insolvency		
5.12. An insufficient number of volunteers		3.5. Personal data theft		
5.13. Lack of volunteers' engagement		4.2. Poor organization of the deposit office		
5.14. Faulty time measurement		4.7. An inappropriately narrow route, narrows		
5.17. Incompatibility of the running route capacity with the number of participants		5.5. Inappropriate organization of the run – jams after the start		
6.1. An unattractive start package		5.9. Delayed start		
6.3. An insufficient number of medals				
7.3. An insufficient amount of water at recovery points				
9.1. Downpour				
9.4.An overly high temperature				
9.7. Force majeure				

During factor analysis one should take into account the fact that it aims at describing and arranging data. Hence, factor analysis supports the alternative grouping of risk factors completed as a result of the preparatory research.

Conclusions

A factor analysis was performed to determine the source of factors, and also to determine in what area it is necessary to dedicate mitigation measures. Carrying out the factor analysis allowed to check if risks from one group are related to each other, or whether there are risk factors assigned in the questionnaire to different groups. As part of the factor analysis, 7 components were identified, explaining 91% of the variability of the data.

In addition clusters were analyzed which allowed distinguishing three groups of marathon organizers. The first focus ("no problem") are low-risk objects. Second focus ("business") emphasizing financial aspects and combining the highest risk with insufficient profit, too little influence, limited liquidity as well as personnel and promotional problems. The third group ("organizers") emphasizes the organizational risks (problems with the route, starter sets, volunteers, communication, image, related to personal data), at the same time the risks associated with finances are low in this group. This information is a great input data in reliable risk management process.

Abstract

The purpose of the article is the analysis of the process of building information modelling (BIM) implementation in the construction industry. One of the objectives of this article is a definition of the basic principles and the scorecard of economic evaluation of BIM introduction in the activities of construction organizations based on the methodological recommendations for the assessment of investment and IT-projects. The article will be useful for organizations that carry out construction projects in the metallurgy industry. At the present time the construction industry is in the process of modernization. As a result, all participants of construction of capital objects and structures (designers, builders, and facility companies, suppliers of materials and machines, financial organization and etc.) put completely new objectives and have the requirements that haven`t previously arisen. The main reasons of changes in the construction process are connected with the high rates of construction, the increase in the number of unique objects that require an integrated and interlinked approach at all stages of the life cycle, and the need to reduce costs and improve the efficiency of management. The established methods have been replaced by the new direction – building information modelling (BIM). The effectiveness of BIM projects must involve a balance of profits and costs, or the feasibility of implementation. In this regard, the process of BIM implementation in the activities of construction organizations can be considered as an investment or IT-project. The efficiency analysis of these projects is made on the basis of already developed guidelines and principles. The assessing of the effectiveness of the BIM projects implementation requires the development of the scorecard, which includes cost-based, organizational, technical, temporal and social groups of indicators. The identification of the scorecard and the stages of evaluation, based on the analysis of economic efficiency of investment and IT-projects, can form the basic principles of economic evaluation of BIM introduction in the activities of construction organization. These principles are the principles of economic efficiency of investments into the BIM project, the preliminary calculation, the independent evaluation and the principle of uncertainties and risks etc.
Listed principles and the scorecard must allow for the possibility of making targets, define new goals and objectives of the construction.

Keywords: Principles, Economic Evaluation, Project of Construction, Effectiveness, Information Technologies, Building Information Modelling, BIM.

Introduction

The use of building information modelling (BIM) in the construction activity to the global trend (USA, UK, China, etc.) is due to significant advantages such as economic benefits in various stages of construction and the reduction of the duration for the project.

Economic evaluation of projects realized within the British sectorial strategy with application of information technologies «Construction 2025» has identified the reduction of start-up costs for the construction and operation of the facility by 33%. Some individual EU countries, particularly France and Germany, have already announced the programs similar to the UK *(Kolrol, 2015).*

The application of information modelling in the international practice leads to the increase of the construction organizations efficiency, which are involved in the construction and reconstruction of objects of the metallurgy industry (hereinafter referred to as "construction organizations"). As a result, there is an objective necessity in BIM for the Russian investment-construction complex. Expected digital modernization of construction processes will reduce the total costs of projects by 20% by the year 2020, hence, economic evaluation of these projects is essential (*Belyuchenko, 2016).*

The introduction of information technologies in the activities of construction organizations has several advantages. There are two direction of development BIM in the world: support of the government (UK, USA) and direct private constriction company interest (Germany, Sweden). Currently, the challenges of implementation and BIM development in practice of construction organizations received additional support from the state in Russia. In particular, the interest of the Ministry of the Russian Federation has been expressed in the approval of the plan of gradual introducing information modelling technologies into the field of industrial and civil construction *(Ministry of Construction Industry, Housing and Utilities Sector, 2014).*

In this connection, the increase in the competitiveness of foreign construction organizations using information technology, as well as practical evidence of the effectiveness of these projects were the impetuses for the BIM development on the Russian market.

The importance of developing principles for economic evaluation of projects aimed at improving the quality of BIM projects and cost reduction in the design process using information modelling. The construction project will have more adequate evaluation because of the user`s application of the developed principles, that covers a wider range of indicators.

Literature Review

The term BIM was introduced by Autodesk in 2002. The architect and strategist of Autodesk in the field of construction applications Phil Bernstein used the term for the first time in its modern form: «Building information modelling». There are various definitions of BIM in different sources. However, these definitions are similar in content. In that paper the term BIM refers to an electronic database containing all the information required for the design, construction and operation of the building and a set of specialized tools to manage these data *(Code of practice «Information modelling in construction. The rules of information model formation of building projects at different stages of their life-cycle contain the following definition of the concept «BIM-project», n.d.).*

However, the interest in information modelling came much earlier. Charles Eastman, a professor of the Georgia Institute of Technology for the first time used the term «Building Description System» in his works in the middle of 1970s *(Smith, 2014)*. The documentation package executed the role of database before computer technologies. There was a whole system of management of these data for creating, editing, storing and ensuring the integrity of the database.

After the emergence of computer programs that allowed you to create, store and edit project documentation (CAD), the opportunity to store information in electronic form appeared. However, the individual parts of information are not connected and there is a necessity to perform a certain amount of manual work to ensure the integrity of the data *(Gushchin and Kopylov, 2005).* For example, if all the constructions were performed in AutoCAD, in the majority of specialized calculation programs the information would need to be entered manually. Despite the fact that the collection of loads, specifications, estimates, descriptions, and results of calculations can be stored in electronic form, the relationship between data is realized only by human.

The attempts to merge the data into one interconnected information space were made a long time ago. Beginning from the format converters to creation of a special format for data storage (*Kozlov, 2010)*. It is hard to say that the process of consolidating the data has been completed, as still there are problems with compatibility of separate programs, but certain results of the solution of this difficult task have been achieved. There are already lines of software products working on BIM which allow executing work practically on all sections of the project and have been proved its efficiency.

Building information modelling has been appeared recently, however, during last years it`s becoming dominant in the world of design and construction practice, replacing all the design methods, which have been used previously. BIM is being actively implemented in companies around the world: China *(Hong et al., 2020), (Hong, Hammad and Akbarnezhad, 2019)*, New Zealand *(Okakpu et al., 2019*), Malaysia *(Mamter, Abd Aziz, Zulkepli and Mamat, 2018)*, Australia *(Hadzaman, Takim and Nawawi, 2015), (Hong et al., 2020),* India *(Ahuja et al., 2018)*, Singapore *(LIAO and TEO, 2017), (Hadzaman, Takim and Nawawi, 2015), (Attarzadeh, Tiong and Nath, 2015)*, Hong Kong *(Hadzaman, Takim and Nawawi, 2015).* Currently there are a number of published books and articles dedicated to the basic BIM functioning, description of the benefits and costs accompanying the process of introducing the technology. The main advantages that have had a decisive influence on the compulsory transition to using BIM are the detection of errors at early stages of the project, control of project implementation, the involvement of the customer and experts in the process, reducing legal risks and costs for approval, increased revenue and reduced downtime.

At the moment it is possible to observe in Russia the initial stage of active BIM implementation in the construction industry. The task included in the process of architectural design innovation, which based on modern organizational and management decisions, has been set in the concept of long-term socio-economic development of the Russian Federation for the period till 2020 and the Strategy of national security of *Russia (The Government of the Russian Federation, 2008).* The priority directions of modernization of the Russian economy were announced at the meeting of the Commission for modernization and technological development of Russian economy from 18.06.2009. One of them is strategic information technology including software development. Therefore, inclusion of the latest effective innovative technologies, materials and designs in structure of the project documentation is a priority in the decision of all project organizations. At the beginning of 2014 the Government of the Russian Federation charged this question to Ministry of Construction Industry which issued the sector order №926/pr «On approval of the plan of gradual introducing information modelling technologies into the field of industrial and civil construction». According to the plan, transition to using BIM during design and construction will be obligatory by 2017, and the number of the projects issued with the use of building information modelling will increase to 50% by 2019 *(Ministry of Construction Industry, Housing and Utilities Sector, 2014).*

In addition, the provision of design documentation for construction of facilities in electronic form with the provision of an information model (BIM) has been compulsory since 2019, when the source of funding is the state budget. According to this, a significant transition to using BIM in the design and construction has been since 2017. Moreover, it was entail the increasing public interest and demand for economic services for the calculation of the effectiveness and feasibility of BIM projects.

Implementation of information modelling projects entails organizational and structural changes in the project team, staff retraining and new software. In this regard, a deficit of highly qualified personnel knew how to use the building information modelling *(The Government of the Russian Federation, 2010).*

Despite the economic benefits of BIM in the design, reorganization of the construction process will require high capital costs of the construction organization in case of implementation of this technology at an initial stage. Considering the low investment climate in Russia, and also availability of sanctions from the foreign IT-industry,

BIM implementation will be difficult for many organizations at the present stage of development of the specialized Russian market of information technologies in construction *(Donchenko, 2016).*

The difficulty connected with assessment of an economic impact of BIM on the construction organizations and cost of buildings has been becoming the subject of serious scientific research [for example, *(Olawumi and Chan, 2020), (Lazaro-Aleman et al., 2020), (Chegu Badrinath and Hsieh, 2019), (Teng, Li, Wu and Wang, 2017), (Muller et al., 2019)*]. It means that the methodology of an economic evaluation of BIM implementation in the construction projects isn`t developed at the moment.

As a result of the research it was revealed that the general algorithm of an economic evaluation of BIM implementation in the construction organizations isn`t elaborated at the moment. Due to the transition to using BIM in designing, the construction industry needs to develop the basic principles of economic approach to the evaluation of the implementation efficiency.

Methods

An analysis of scientific publications on the issue for the period from 2012 was carried out. The study examined the results of scientific publications in scientific conferences that were related to the topic of the study. More than 50 articles with similar themes from the field of «Economics and Business» were taken into consideration. The regulatory legal acts and standards that were issued in Russia and in the world on the problem of building information modelling were analysed also.

Results

The efficiency evaluation of BIM implementation in the activities of construction organizations, which are involved in the construction and reconstruction of objects of the metallurgy industry, can be based on the certain technical and economic indicators providing the purposes of the architectural and construction project. It is necessary to adhere to the methodical principles for creation of these indicators.

The principle of economic efficiency of investments into the BIM project is based on reasons for feasibility of financing of building information modelling in activities of construction organizations, and also the capability of the project to provide income, which is sufficient for defrayal of initial investments and subsequent costs. The principle identifies the necessity of the BIM implementation for the metallurgy industry in the activities of construction companies only if there is a positive result from the use of these technologies.

One of the modern techniques that follow the principle of economic evaluation is the methodology of the total economic effect, developed by Forrester *(Seredenko, 2014)*. The application of this methodology allows analysing the value of BIM project from the position of 4 key elements:

1. Benefits are the positive impact of the implementation of building information modelling in the form of increased efficiency of construction organizations. From the construction process standpoint this element may include the increase of revenues from project of construction, the labour productivity growth of constituent entities of the construction, which positively affects the timing of the implementation of BIM project, a positive change of indicators of capital efficiency and reduced costs at all stages of the life cycle of the object *(Shakhrai, Vilensky and Kosov, 2010).*

2. Costs are measurement costs in the process of introducing and applying building information modelling in construction. It includes cost accounting for planning and a pilot project, the initial investment for BIM implementation, operations with the use of these technologies, maintenance and operation of the BIM-project, etc.

3. The flexibility of BIM-model based on consideration of potential of this model, its ability to integrate processes not only in construction, but also in adjacent areas, and also rapid expansion of categories of objects which performance is possible using BIM.

4. Risks are the analysis of other factors that affect the result of the introduction of information technology based on insufficient research in the field of economic evaluation of the implementation of BIM-models in the construction process and the lack of sufficient experience *(Seredenko, 2014).*

The principle of the preliminary calculation. The efficiency evaluation of BIM implementation in activities of the construction organizations should be calculated before the project with the use of these technologies. In the evaluation of effectiveness of BIM-project should take into account the impact of temporary factors, including changes in the time of economic parameters and other characteristics of an object at different times non-equivalence costs (time value of money), etc. Temporary non-equivalence is a reduction of cash flows of the BIM project by one temporary moment and using the rate of discount *(Ministry of Economy of the Russian Federation, the Ministry of Finance of the Russian Federation, State Building of the Russian Federation, 1999).*

The principle of the independent evaluation suggests that the results of the analysis of the effectiveness of BIM implementation should depend on objective indicators and factors, and not subjective opinion *(Seredenko, 2014)*. This requirement allows limiting the influence of expert judgment and increase the realism of the evaluation.

The principle of the assessment of the comprehensive technology introduction in the construction company. BIM changes must occur in all structural divisions of a construction company to achieve the most significant economic benefits. The implementation of this principle allows making more valid conclusions about the economic result of the implementation of these technologies.

The principle of consideration of the BIM-project lifecycle starting from the project initiation till operation and demolition of the object *(Ministry of Economy of the Russian Federation, the Ministry of Finance of the Russian Federation, State Building of the Russian Federation, 1999).* According to the Russia Federal Law «On contract system in procurement of goods, works, services for state and municipal needs», the customer can set the life cycle cost of the building as criterion. In connection with the claim, the assessment of economic efficiency should be based on the income received from the project, as well as on the expenses that were incurred during all stages of construction of a building or structure. The economic analysis of the BIM-project implementation should include the costs of construction, maintenance, operation during the life of the facility, repair and disposal objects of capital construction and structures of the metallurgy industry.

The principle of multistage evaluation. It implies that the efficiency of BIM implementation is determined at various stages of lifecycle. In this case, it is necessary to evaluate not only the final result from the implementation of the BIM-model, but to make the analysis at each stage of construction, which allows increasing the accuracy of the economic evaluation and identify the stage at which the introduction of building information modelling has had the greatest influence.

The introduction of building information modelling in the design of buildings and structures is an innovative method in construction and may lead not only to positive results, but in certain situations accompanied by negative and costly consequences. Due to the phenomenon of economic evaluation of the BIM implementation in construction organizations must follow the principle of uncertainties and risks *(Ministry of Economy of the Russian Federation, the Ministry of Finance of the Russian Federation, State Building of the Russian Federation, 1999).*

The principle of comparability of the economic results obtained by using BIM-model. It involves the ability to compare performance indicators in the implementation of BIM and their absence for visual evaluation. Furthermore, it is necessary to use the same system parameters to allow assessment equivalent during comparing the variants of the same design *(SUN et al., 2015).*

The principle of variability involves consideration of various parameters of the project construction, which are affected by the introduction of the BIM on, as well as the possibility to choose the most efficient and profitable variant design *(Izosimov and Napreenko, 2013)*. The economic evaluation of implementation of information technologies should be determined by comparison and the analysis of quantitative and qualitative indexes in the construction industry, the organization, the subject of construction, etc.

Discussion

The assessing of the effectiveness of the BIM projects implementation requires the development of the scorecard. The general evaluation system should include cost-based, organizational, technical, temporal and social groups of indicators. The scorecard must allow for the possibility of making targets, define new goals and objectives of the construction *(Davies and Harty, 2013).* Thereby the list of groups is not exhaustive, but demonstrates the presence of multivariate analysis.

The cost-based indicators characterize the efficiency of the BIM-project in monetary terms. This group of indicators includes the evaluation of construction budget, changes, unforeseen costs as a result of finding errors in the design of the construction, and costs connected with spent work time and inefficient use of resources.

The main objective of the organizational group of indicators is the quality analysis of relationships between all subjects of construction and structural departments of the organizations. Organizational characteristics of BIM model can be belonged to a number of possible changes in the project and the number of permissible errors at various stages of the life cycle of the object, the presence of interconnected information database, document management, etc.

The list of analysed indicators that can be included in a technical group is voluminous enough and depends directly on the construction project. The presence of certain technical indicators and objectives of using a building or structure may cause the decision about whether to use BIM for the object and construction of the project as a whole. This group can include the uniqueness of the object, the complexity of the design and construction process, the area, height of the projected object and others.

For example, the building information modelling was introduced in St. Petersburg in the design of the highest complex in Russia named of «Lahta Center». The height of the building is 462 meters. Other examples where technical indicators have had a significant impact on the necessity of BIM implementing are unique stadiums «Matmo Atlantic» in Bordeaux and «Velodrome» in Marseille, which have been prepared for the European Football Championship 2016. BIM-model helped to design metal frames that support complex and unique designs of these structures, to detect various technological conflict.

The coordinated organizational system directly leads to temporary changes in the construction process. In the framework of the temporal group of indicators the particular attention should be paid to the construction period, time to process information and solve specific problems at each stage of the project.

Social indicators reflect the efficiency of BIM-project in terms of public interest. These indicators can be environmental and social impact of this project, the impact on public health, improvement of living and cultural conditions of lodgers and workers, etc.

Conclusions

In modern conditions the project of BIM implementation in design and construction has received strong support from the state (in particular the Ministry of Construction Industry of the Russian Federation). In this regard, evaluation of economic efficiency and feasibility of projects for implementation of BIM in the activities of construction organizations, which are involved in the construction and reconstruction of objects of the metallurgy industry, is extremely important and necessary.

Despite a number of challenges that will be faced in the initial stage, the use of BIM has repeatedly demonstrated the economic benefits and efficiency in the construction of unique objects in Russia and abroad. The use of building information modelling in the construction is due to high economic benefits at various stages of construction, reduction of duration of the project, increasing the competitiveness of the building organizations.

During the evaluation of the possibility of BIM introduction in activity of the construction organization it is necessary to rely on the following principles:

- the principle of economic efficiency of investments into the BIM project;
- the principle of the preliminary calculation;
- the principle of the independent evaluation;

- the principle of the assessment of the comprehensive introduction;
- the principle of consideration of the BIM-project lifecycle;
- the principle of multistage evaluation;
- the principle of uncertainties and risks;
- the principle of comparability of the economic results obtained by using BIM-model;
- the principle of variability.

The scorecard should consider the following directions of analysis: cost-based, organizational, technical, temporal and social.

The recommendations presented in this article don`t set the goals and tasks to cover all methods of effectiveness evaluation. Nevertheless, the formation of principles and the scorecard of the implementation of BIM projects in the activities of construction organizations allow providing a more accurate assessment of economic efficiency and developing an evaluation algorithm of this implementation.

Abstract

This paper highlights self-organization perspective and the economic security of the industrial ecosystems. Such issues as under what conditions self-organization takes place and what mechanisms of industrial enterprises security are underexplored in the academic literature. Modern challenges of digital transformation modify traditional business models. For the sustainable strategic development of the industrial sector, it is necessary to adapt the system of economic security of industrial enterprises. The research of innovation ecosystems is based on the synergistic principle of ecosystem, and a comparative analysis of organizational models. The author's position of determining the innovative industrial ecosystem and the economic security of industrial enterprises in the conditions of collaboration in the horizontal model is proposed. The article analyzes trends in the development of Russian industry, identifies typical problems faced by domestic industrial enterprises in the context of digitalization. The propositions arising from this analysis provide new information that supports academics, policymakers, government, and individual actors with a more appropriate understanding of the practical mechanisms of the economic security and tools that help trigger self-organization and sustainable development of the innovation ecosystems.

Keywords: Innovations, Digital Technologies, Industrial Ecosystems, Organizational Models, Actors, Economic Security, Risks.

Introduction

The global trend towards digital transformation of the economy poses new challenges for the Russian industry. It is impossible to develop the industrial sector of the national economy and increase its competitiveness in the world industry markets without ensuring a high level of economic security of industrial enterprises. To ensure the competitiveness of the national economy at the international level requires digital transformation of industrial enterprises in the context of its management, processes and models, as well as strengthening cooperation of enterprises among themselves and with other market participants in the innovation ecosystem at the micro, meso and macro levels. The formation of the industrial ecosystem contributes to the emergence of new technologies, products, innovations and ideas, which will result in the sustainable development of the country's industry.

Cite this Article as: Andrey BYSTROV, Tatyana TOLSTYKH, Nadezhda SHMELEVA and Ayya AGAYEVA "The Industrial Ecosystem Risks in The Face of Technological Challenges" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In this case, it is important to ensure the economic security of industrial enterprises in the conditions of collaboration of economic market participants within the network ecosystem model. Current technological challenges and the new mentality of relations between economic entities threaten the economic security of enterprises. Thus, it is necessary to form a comprehensive holistic approach, which allows ensuring the management of economic security.

The industrial sector is the most important segment in the country's development strategy. The share of industry in the country's GDP is about 40% [22]. The industrial sector in the national economy is represented by many organizations and enterprises (economic units) operating in various industries. The digitalization trend sets new challenges for organizations, encourages them to review the ways and methods of making management decisions, there is a need to change the speed of decision-making, and the mentality of relationships between market participants is changing. In order to determine the development prospects, the current state of the industrial sector was analyzed (Fig. 1).

Figure 1: Index of industrial production from 2015 to 2018

Source: statistical data of the World Bank

The indicators of industrial production in figure 1 show a positive trend since 2015 in all the analyzed countries, including Russia. The overall growth rate of industrial production in the national economy shows an optimistic view and is 7.6 % from 2015 to 2018. Russia is one of the leading countries in terms of industrial production in the world.

Figure 2 shows the level of GDP in the leading countries and in the Russian Federation.

Figure 2: GDP per capita, in US dollars for the period from 2015 to 2018

Source: statistical data of the World Bank

The GDP per capita growth rate in Russia for the period from 2015 to 2018 was 21 %, which is equal to the average growth rate in other countries, but the level of GDP per capita is lower compared to the leading countries [20].

One of the most important indicators that reflect the development of innovation, as well as improving the efficiency of industry is the activity of R&D, which includes research of various industries. Investment in research and development determines the country's long-term development.

According to the World Bank analysts, South Korea, Switzerland, Japan and Germany are the leaders in R&D. Russia is ranked 13th in the world in 2017. The amount of investment in research and development in Russia was 40 billion US dollars, which is significantly less than in the leading countries. [1,21,23].

Currently, the competitiveness of industrial enterprises depends on the speed and flexibility of responding to external technological challenges, on the efficiency of digital transformation in technological and managerial business processes. Digitalization in the industrial sector is a strategic priority for the national economy. At the legislative level, this direction was set by the national project "Digital economy of the Russian Federation»

The global trend towards digitalization of the economy poses new challenges for the Russian industry. To achieve competitiveness in this industry, the speed of introduction of digital technologies into production processes is crucial (Fig. 3).

Figure 3: Trends in industrial technologies

Currently, the most Russian enterprises are still at an early stage of adaptation to digitalization, limited by management or operational processes in order to increase sales and profitability of the enterprise. For the implementation of new stages of digitalization changes are demanded, including organizational and structural (Fig. 4).

Figure 4: Typical problems of industrial enterprises in Russia

According to the study, the main obstacles to digitalization are insufficient maturity of current processes, low level of modernization of technological processes, lack of competencies, low motivation of employees, and insufficient financial resources. Thus, it is necessary to make a fundamental change in the management approaches at the enterprises of the industry that will allow for effective digitalization of enterprises and organizations, stimulate their innovative activities, and facilitate the initiation and implementation of projects to create new technologies, materials, and business processes.

Literature Review

The industrial ecosystem is getting more and more popular among global researchers. The concept of an innovative ecosystem is based on the biological ecosystem proposed by Arthur Tensley in 1935, who interpreted it as a biosystem consisting of a set of living organisms, their habitat, and communication systems that exchange matter or energy between them.

The approach to the analysis of socio-economic systems, similar to biological systems, attracted many researchers. The concept of "ecosystem" for business was introduced by J. F. Moore, who proposed a definition based on an analogy with biology – "an economic community supported by a basis of interacting organizations and individuals – organisms of the business world" [10,12]. A few years later, the works of R. Edner [15], D. Eisenberg [16,17], which gave rise to a real research "boom" and significantly expand and enrich Moore's concept. And now this approach has become dominant in the formation of new models for managing innovation processes. Indeed, similar to living organisms in biological ecosystems, innovation ecosystems are open, self-organizing systems that include actors (participants in processes) connected to each other by the exchange of knowledge, information, and technologies that are energy for these actors. L. Bertalanfi described the theory of systems, giving the concept of an open, complex, self-organizing, self-regulating and self-developing system, which is characterized by incoming and outgoing flows of energy [13]. According to I. R. Prigozhin and G. Haken, self-organization is a key concept of the 21st century. The synergy of interdisciplinary industries can be the key to solving business problems. The theory of joint action can form new qualities in the whole that are not present separately in economic units [7,13]. The definitions formulated by Kleiner [6] and Proskurnin are more logical from the standpoint of the principles of consistency, balance and self-organization. Kleiner [6] understands an ecosystem as “a localized complex of organizations, business processes, innovative projects and infrastructure entities that are capable of long-term and independent functioning due to the circulation of resources, products and systems.”

As a result of an empirical analysis of the definitions of the industrial ecosystem [6,8,14,15,17,18,19] , we concluded that the main drawbacks in the formulations are: the lack of a systematic vision of the ecosystem, the purpose of its formation and the form of self-regulation. The environment formed by ecosystem participants and the connections between them practically not studied. The environment formed on the basis of complementarities, through connections and energy exchange in the form of new knowledge, competencies, and unique information, is a key link in ecosystems.

In this regard, the industrial ecosystem in the work will be understood as an open and self-developing system of network equality of economic actors, which is self-organized on the basis of a special safe environment formed as a result of energy exchange. New knowledge, technologies, information, or unique resources act as such energy. The key idea around which the ecosystem begins to form can be the initiation and implementation of industrial projects, the creation of new materials, technologies, the development of digital platforms, etc. (Fig. 5)

Figure 5: Functions of actors in the ecosystem

An individual industrial enterprise can be an actor in several ecosystems at the same time, implementing different projects, being, for example, a customer, supplier of unique resources or performer of different projects, and have different functions in the ecosystem as shown in figure 6.

An industrial ecosystem is formed around a central core that sets the rhythm of movement and interaction of actors. The key property of an attractive intellectual core in an ecosystem is a pacemaker, which can be a project, innovation, technology, platform, and actor. The pacemaker creates conditions for a balanced flow of knowledge and energy exchange, creating a coherent communication between actors in the ecosystem.

The pacemaker, which is the heart of the ecosystem, has the property of setting the pace for the functioning of actors in it, and acts as a trigger for it, involving any system in a single specific act of life [9,11]. Relations between the participants of the industrial ecosystem can be different: technological, production, resource, technical, financial, research, information, security, industrial, commercial and social.

An industrial ecosystem is formed based on the principles shown in figure 6.

Figure 6: The system of industrial ecosystems principles

The industrial ecosystem model is based on three coordinate axes: actors, pacemaker, and principles. The principle of dissipative self-organization consists in the process of spatial and temporal ordering in an open system, due to the coordinated interaction of many elements of its components. This principle is characterized by the process of energy exchange with the environment, and chaotically.

The principle of trust (partnership) involves the voluntary acceptance of risk expenditures by actors in the industrial ecosystem, while rejecting explicit contractual security measures.

The goal-setting principle means the unity of agreed goals between all actors and their interrelated elements in the industrial ecosystem. Achievement of goals is possible as a result of building a system for managing the effectiveness and advantages of a single organism over environmental influences.

The principle of decentralization implies equality between actors in the industrial ecosystem. In other words, there is no controlling body, no hierarchical structure of the ecosystem, and it is characterized by full equality between actors.

The principle of customer focus is based on building industry standards in order to deeply understand and meet the needs of customers. By developing the flexibility of its ecosystem, creating standards reflects customer focus in forming a culture, loyalty system, using customer information for decision-making.

The principle of project orientation is related to the idea of implementing an industrial project or a set of projects aimed at achieving an agreed final result within the framework of predefined requirements and restrictions on the part of all actors. The overall objective of the principle is to ensure optimal use of resources and achieve strategic goals while minimizing risks.

Conceptual Framework

The Davos Manifesto, issued for the World Economic Forum in 2019, initiated by Klaus Schwab [24], speaks of a new model of capitalism – stakeholder capitalism –, where companies should stand up for competitive equality in the "game field", especially in the "economy of Internet platform." And this very idea is the basis for the formation of an innovation industrial ecosystem.

The nature of the industrial ecosystem, as an analogue of the natural one, is the absence of vertical hierarchy of administration therein. The association of participants (actors) is self-organizing on the basis of voluntariness, equality, and partnership, which does not imply randomness and spontaneity. Within the ecosystem, lots of projects

can be implemented simultaneously, and each actor of the ecosystem has the opportunity to perform various roles and participate in different projects at the same time.

Cluster associations have been gaining popularity in horizontal communities over the past decade. According to Freeman, innovative clusters are among the stakeholders that interact with each other. Clusters are constantly improving their competitive advantages, industrial and non-industrial organizations that are united by a common field of activity and cooperate on a geographical basis. As a rule, the initiative to create a cluster comes from the federal level. On the contrary the initiation of an ecosystem does not belong to one actor. Integration occurs on the basis of self-organization, when each actor is beneficial to the other. It is self-organization that defines the principles of cooperation and partnership as the basis of relationships between actors. A comparative analysis of ecosystem, network, and cluster models is presented in table 1.

Table 1: Comparative analysis of horizontal organizational models

Comparison criterion	Clusters	Techno park	Industrial park	Ecosystem
The purpose	Improving the competitiveness of an industry or region	Increase the well-being of the local community by promoting an innovative culture, as well as competition between innovative businesses and scientific organizations	Implementation of the import substitution program	Initiating and implementing a digital innovation or unique product
Union boundaries	Geographical or industrial	Geographical	Territorial and spatial	Cross-industrial or territorial
Criteria of unification	By stages of the production process	Experimental Association, R&D for the benefit of participants	Engineering infrastructure of industrial enterprises	Stages of a new product or new technology life cycle
The relations between the parties	Internal competition and cooperation	Internal cooperation	Internal cooperation	Collaboration and partnership
Ability to include or exclude actors	Limit on inputs and outputs	High level of privacy	High level of privacy	High level of openness
Manageability	Availability of government bodies at the Federal or regional levels	Founder	Operating company	Self-organization

The differences in the models are not fundamental but reflect the goals and conditions of specific economic development challenges. The clusters have the potential to degenerate into an ecosystem. In other words, the models of the innovation cluster and the innovative industrial ecosystem largely converge and are the development of cluster models in the context of digitalization [4,5].

For example, the purpose of forming clusters is to increase the competitiveness of a particular region or industry. The decision to create a cluster is usually made at the federal or regional levels of government. The main difference between the ecosystem and cluster models is self-organization and self-development in order to achieve unique competitive advantages of the ecosystem participants. The ecosystem is an evolutionary development of cluster models in the context of digitalization. Moving from the hierarchical legacy of the past and creating a horizontally connected network environment for the free exchange of knowledge, information, technology and innovation in the cross-industry and territory is a new model of the economy. In this regard, the issues of actor's economic security are of great importance for the effective functioning of the industrial innovation ecosystem.

The economic security in the context of digital transformation

The article highlights the economic security of industrial enterprises in the context of digitalization, as the intellectual core in the industrial ecosystem is technologies, innovations, projects and actors related to the industry. We will understand the economic security of an industrial enterprise as the security and sustainable functioning of its scientific, technological, production and information functions from direct or indirect threats associated with the impact of the external environment, and the ability to develop flexibly. The main goal of the economic security of an industrial enterprise is the sustainable and most effective functioning of its economic activities in the industrial ecosystem under various market conditions, ensuring high potential for digital development and growth in the future. The economic security of an industrial enterprise is characterized by the most effective use of collective resources to prevent threats and ensure stable functioning [3,10]. This understanding and application of economic security makes it possible for an enterprise, even in conditions of uncertainty and crises, to seek protection from existing and projected threats.

It is known that any changes in business processes are associated with certain threats. The processes of digital transformation that are currently taking place everywhere in enterprises are no exception. Digital technologies that affect production, logistics, financial and management processes at enterprises include robotics, additive and quantum technologies, artificial intelligence, Big Data, digital avatars, cloud and block chain technologies, mobile and unmanned technologies, etc.

The main goal of economic security in the context of digital transformation is to protect its main components from possible threats, which is implemented through the following tasks:

- data collection, analysis, evaluation, monitoring and forecasting.
- prevention of competitors ' penetration, crime and individuals with illegal intentions into the enterprise;
- high-quality legal protection of all aspects of the system's activities.
- ensuring the protection of the information field, trade secrets and achieving the necessary level of IT in the work of all departments.
- ensuring the technological independence of the system and achieving high competitiveness of its technological potential.
- high level of staff qualification and intellectual potential, efficiency of corporate R&D.

Classification of economic security risks in the ecosystem should be considered at four levels: the actor level, micro-level, meso-level, macro-level.

In the industrial ecosystem at the actor level, new risks are added to existing economic security risks as a result of actors ' collaboration in the process of implementing a common project. The model of economic security risks at the actor, micro, meso, and macro levels that arise during the project implementation in the industrial innovation ecosystem is shown in figure 7.

Figure 7: Risk model in the industrial ecosystem

Risks can be social, demographic, geopolitical, economic, financial, informational, technological, organizational, they can occur at all levels of the ecosystem and carry different degrees of threat to the target settings of actors and the stability of the ecosystem.

Risks that arise at the meso-level have industry specifics: agricultural, industrial, service sector risk, etc. Industry risk factors include the stages of the industry's life cycle, the quantity and quality of resources, the level of competition and concentration of production, the tax, etc.

Collaboration of the industrial ecosystem actors includes risks of economic security at the micro and macro levels. At the initial stage of ecosystem formation, the most destructive thing that threatens the possibility of project implementation is the risk associated with the problem of finding areas of common interests (choosing a pacemaker, partners). At the stage of defining roles and coordinating project work within the industrial ecosystem, there are risks associated with psychological conflicts based on a lack of coherence. There is also a risk of unfair behavior by an actor who may participate in the ecosystem in order to ensure their own interests, which, in the future, may reduce the effectiveness of the relationship or lead to its rupture. The system of ensuring economic security of industrial enterprises depends on the legal framework and the managerial maturity of the enterprise management.

Conclusion and Discussion

The challenges of digitalization modernize existing models of business organization, industry, industry, behavior models of economic entities, mentality, and also reform economic relations between market participants.

The analysis showed that all key indicators for the effectiveness of the national economy are interrelated. The growth of industrial production affects the volume of output, increases the range of goods and services, thereby increasing the volume of trade. Low R&D spending slows down development in technology, knowledge, and innovation. New technologies and knowledge are especially important for the industrial sector, as it is a strategically important segment of the economy.

It is necessary to make a fundamental change in management approaches at the enterprises of the industry that allow for effective digitalization of enterprises and organizations, stimulate their innovative activities, and facilitate the initiation and implementation of projects to create new technologies, materials, and business processes.

Ecosystem transformation of the environment is an objective global trend driven by the technological revolution. The reform of the economic model is to move from the hierarchical legacy and create a horizontally connected network environment for the free flow of knowledge, information, technology and innovation in cross-sectors and territories. Based on the research, it is possible to assume that clusters can be reborn into an innovative ecosystem, which has a number of advantages over other systems of horizontal organizations. For example, in an ecosystem, participants can not only be grouped as a cluster within a single industry, but also preferentially create competitive integrations between actors from different industry structures within the same ecosystem. However, the economic security of enterprises, including information security is getting more relevant.

The peculiarity of digitalization is that its main resource is data, knowledge, and information that is not produced or consumed in the usual way, like other resources. So, there is a direct relationship between the degree of development and speed of implementation of digital technologies in the activities of industrial enterprises and their economic security.

Abstract

In this research authors described the development of accounting for production and sales of alcoholic beverages in Russia in the 17th century. By this time, it had provided a framework for the emergence of a complex accounting system based on principles different from traditional double entry accounting. Authors presented in detail the accounting system applied in Russia before the advent of double entry accounting and successfully performed the specific tasks set before it.

Keywords: Accounting, state revenue, alcoholic beverages, ledger

Introduction

The importance of this research is justified by a number of publications devoted both contemporary issues and historical studies on the industry of production and sales of alcoholic beverages. Only a few studies concern accounting issues: the influence of European and Anglo-American accounting systems on the organization of accounting in the alcohol industry (Blake et al., 1998); the specifics of the winemaking industry due to a lengthy production cycle (Viana and Rodrigues, 2006). Historical studies describe the development of alcohol production in Nigeria from 1870 to 1970, when attempts were made to ensure replacement of alcohol imports from Europe (Heap, 1996); regulation of the wine market in France in the 19th century, where one of the priorities was to preserve the profitability for wine producers (Stanziani, 2009); the act that levied taxes on domestically produced distilled spirits, the so-called Whiskey Tax, passed in 1791 in the USA (Krom and Krom, 2013); evolution of the regulation of alcohol production taxation in the USA since 1933 (Pennock and Kerr, 2005); the British colonial law in Malaysia in the 18th-20th centuries, which included government monopoly on opium and customs duties on alcohol and tobacco (Loo and McKerchar, 2014). These researches are usually based on examination of literary sources, while the materials of actual practice are rarely used (Baladouni, 1981, 1983, 1986; Camfferman and Cooke, 2004; Richard, 2012; Robertson and Funnell, 2012; Kraal and and Kasipillai, 2014).

In Russia there is a shortage of similar studies on the history of accounting and taxation of alcohol sales and production. Different works on Russian history, which do not focus on accounting issues, were studied as the literal sources, for instance, studies on the evolution of legal aspects related to alcohol monopoly (Larina, 2011; Rusakov et al., 2016), system of taxation (Tolkushkin, 2001; Kucher and Gulina, 2006), organization of wine-making enterprises (Lvov, 1887; Borodin, 1910) and alcohol production (Pokhlebkin, 2005; Rodionov, 2012). Archival documents related to wine production and its taxation in the 17th century were studied by Veselovsky (1876-1952) and Razdorsky, who made their modern-language translation (Razdorsky, 2011, 2014, 2015; The receipts and expenditures books…, 1983). However, they did not provide any commentary with regard to the accounting development. Researchers of accounting history have so far described only the documents discussed by Veselovsky, which refer to the practice of government revenue collection at the level of state institutions – the Orders (*prikazi*, sing. *prikaz*), the role of which was discussed in detail by Sokolov (1996) and Malkova (2008). The accounting registers of government wineries introduced for scientific use by Razdorsky in the second decade of the 21st century have not been discussed before in academic works on the history of accounting. Their analysis has revealed specific features of accounting management at these enterprises as compared to other establishments that have been previously described in the works on the history of Russian accounting (Ivanov, 2005; Kuter et al,

ZUGA“ Russian Accounting in the 17th Century: Details on the Production and Sales of Alcoholic Beverages ” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

2019; Sidorova and Nazarov, 2019; Sokolov et al, 2019). This research is based mainly on the study of accounting registers in the wine industry and government authorities in the 17th century.

This paper consists of three parts, an introduction and conclusion. The first part describes the organization of state revenue collection from sales and production of alcohol in Russia and its accounting. The specifics of two forms of tavern (*kabak*) management in practice are described in the second part. The third part focus on the accounting registers applied in taverns (*kabaks*). The main results of the research are given in the conclusion.

The purpose of this research was to analyse in detail accounting in the 17th century in Russian alcohol industry. It is both an area of state control, being an important source of budget replenishment, and an area of private enterprise. Production and sales of alcohol is a source of government revenues in many countries and, thus, is controlled by their governments. This fully applies to Russia.

State accounting for alcoholic beverages in the 17th century

The system of government revenue collection from alcoholic beverages experienced numerous changes: at some periods the government monopoly[1] for production and sales of alcoholic beverages was used; in this case the tavern (*kabak*)[2] was managed "through the oath" (*na vere*); during other periods, revenues were received through the system of farming (*na otkup*). Management of a tavern (*kabak*) "through the oath" meant engaging responsible individual (*kabak* head) to act as manager; this individual was appointed by the government and fully accountable to it. All the revenues collected from production and sales of alcoholic beverages belonged to the government. Management of a tavern (*kabak*) "through faming" meant that private individual would bid and buy out the right to produce and sell alcohol in a certain location from the government (Kucher and Gulina, 2006: 74). The tax farmer and government negotiated a contract that specified the procedure regulating the sales of alcoholic beverages. In this case, government received alcohol revenues in the form of a certain fixed amount (Kucher and Gulina, 2006: 74; Tolkushkin, 2001: 28).

In the 17th century, the development of government collection of revenues from production and sales of alcoholic beverages had the form of successive decisions to establish and then abolish tax farming for tavern (*kabak*) management, government pricing, setting the rate of expenses accepted as reduction of profits, rules of accounting and reporting, etc. The function of revenue collection belonged to a special authority – Orders (*prikazi*). They were vested with different legislative, executive and judicial functions (Liseytsev, 2010: 244; Platonova, 2009: 442). Revenue collection was not attached to a single Order (*prikaz*). For instance, the situation in the towns of European Russia in the 17th century was as follows: in Kursk and Belgorod before the 1680s, revenue collection was performed by *Razriadny*[3] Order (*prikaz*); in Mozhaysk revenues were sent to the Order (*prikaz*) of the Ustyug Quarter[4], while in Vyazma their departmental affiliation kept changing all the time (before 1654/55 and from 1659/60 to 1666/67 - the Order (*prikaz*) of the Ustyug Quarter; in 1655/56-1658/59 - the Order (*prikaz*) of the New Quarter; from 1667/68 to 1669/70 - *Posolsky* Order (*prikaz*), or the Order (*prikaz*) of the Ambassadors). In 1680 collection of tavern (*kabak*) revenues in most towns of European Russia was transferred from different Orders (*prikazi*) to the Order (*prikaz*) *Bolshoi Kazny* (Razdorsky, 2015: 47).

Relationship between the Order (*prikaz*) and tavern (*kabak*) as the source of revenues from production and sales of alcoholic beverages depended on the form of management described above (see details in Razdorsky (2011, 2015)). If a tavern (*kabak*) was managed by private individual through farming (*na otkup*), the farmer at a stated time sent to the treasury an amount fixed beforehand, which consisted of an *oklad*, the target amount set for a particular settlement for the ensuing financial year, and *naddacha* (additional charge). Beyond that, the farmer was given a free hand, and revenues that he received during the lease period belonged to him. Tax farmer submitted no accounting documents for collection of alcohol revenues. Through-the-oath (*na vere*) management of tavern (*kabak*) meant that an elected individual reported directly to the Order (*prikaz*). This individual was also responsible for revenues collection. Tavern (*kabak*) was managed by a *kabak* head, elected among the wealthiest people living in the area where the tavern (*kabak*) was located. *Kabak* head had his assistants: treasurer (*larechny*); guardsmen (*karaulnye*), who guarded the locations needed for wine revenues collection; *khodyashchiye*, who collected duties at the markets; *kabatskiye*, who produced and sold spirits in taverns (*kabaks*). All assistants were called *tselovalniks* (originated from the procedure of taking the office, which involved kissing of the cross - *tselovat* in Russian). *Larechny tselovalnik*, or the treasurer, was the senior aid; literacy was an absolute requirement for this position, since the treasurer was responsible for keeping the necessary records (Razdorsky, 2015: 45).

Records at Order (*prikaz*) were kept in two kinds of books: *oklad* book and receipts and expenditures book. The accounts in these books were executed in a solid text without any division into graphs. It persisted in practice until the 18th century. *Oklad* book became relevant, since in the 17th century tavern (*kabak*) revenues were calculated through the *oklad* system. An estimated minimum amount to be received from alcohol sales was set for every town annually (Razdorsky, 2015: 44). These amounts were recorded in the *oklad* book, which included a list of payers, their tax base and tax obligations (Medvedev, 2011: 283). The fiscal year in Russia used to begin on September 1. At the beginning or at the end of the year, experienced clerks (*dyaks*)[5] compiled *oklad* books (Sokolov, 1996: 223). During the year, money and books were sent to the Order (*prikaz*) for examination. The information from books was compared and recorded into receipts and expenditures books (Medvedev, 2011: 284). Every Order (*prikaz*) was in charge of revenue collection and kept books for the region that was attached to it for covering its expenses. All records in *oklad* books and receipts and expenditures books were kept separately for each town within the district controlled by the Order (*prikaz*). At the beginning of the year, the arrears carried forward from the previous years were calculated for each town, together with the indication of their types (Sokolov, 1996: 223). Receipts and expenditures books were kept for one year; they recorded the flow of received revenues from different kinds of receipts - entered by the type of receipts - as well as expenditures incurred (Sokolov, 1996: 223; Razdorsky, 2011: 40).

Two forms of tavern (*kabak*) management: through the oath vs through farming

Information on revenues was recorded in the receipts sections of books and concerned receipts from separate towns of tavern (*kabak*) revenues, *obrok* payments (money by feudally dependent peasants) in the current year, the arrears carried forward from previous years, and the estimated amounts (*oklad*) for the next year (Razdorsky, 2011: 46). Thus, the book of the Novgorod Quarter for 1619/20[6] included information about receipts of *obrok* payments and *kabak* revenues from 22 towns (Arzamas, Arkhangelsk, Vyatka, Novgorod, Pskov, etc.) (The receipts and expenditures books, 1983: 4, 7-141). Revenues were recorded by towns and types. All the information was compared with the plan (estimated *oklad* obligations). The book for four taverns (*kabaks*) in Pskov for 1619/20 managed "through the oath" (*na vere*) contained the following data (Table 1):

Table 1: Cash receipts from taverns (*kabaks*) in Pskov for 1619/20

Type of receipts	Amount		
	Roubles	**Altyns[7]**	**Dengas**
Profit received in accordance with the plan made on the basis of previous year data	3,669	5	-
In excess of the estimated profit	668	3	-
Total collected sum	**4,337**	**8**	**2**

Source: The receipts and expenditures books, 1983: 18-19.

In another town there was only one tavern (*kabak*), which was managed though farming (*na otkup*), book contained the following data (Table 2):

Table 2: Cash receipts from taverns (*kabaks*) in Ostrov for 1619/20

Type of receipts	Amount		
	Roubles	**Altyns**	**Dengas**
The fixed amount to be paid for tax farming (*otkup*), calculated on the basis of receipts from the previous year	179	30	0.5
Additional receipts (*naddacha*) and duties	23	3	2
Total collected sum	**203**	**-**	**0.5**

Source: The receipts and expenditures books, 1983: 21

Types of records in the books depended on the form of tavern (*kabak*) management. In the case of "through the oath" management, revenues consisted in the amount of profit received in the tavern (*kabak*); while in the case of farming, it was the sum collected for the lease period. The common feature for both forms was that sums were always compared against planned amounts that were set in accordance with the results of the previous year. The significant difference in amounts from the examples above was due to the size of the towns (before 1703, when St

Petersburg was founded, Pskov took the second place as the populous urban centre in Russia after Moscow) and not the form of tavern (*kabak*) management. There were no arrears in the considered towns.
It is possible to compare revenues from alcoholic beverages and estimated obligations in four towns located in the European part of Russia (Kursk, Belgorod, Vyazma, and Mozhaysk) (Fig. 1).

Fig. 1: Comparison between the planned and actual revenues from alcoholic beverages since 1617 to 1681 for four Russian towns (Source: compiled by the authors based on Razdorsky, 2015)

Estimated (*oklad*) amounts for most periods are set strictly in accordance with the indicators of the previous accounting period. Besides, the towns often had uncollected government revenues as compared to the estimated figures. In order to clarify the connection between the size of government revenues and the form of tavern (*kabak*) management, it is necessary to provide information for the years when tax farming was used (Table 3).

Table 3: The use of tax farming in four Russian towns in the 17th century

Indicators	Kursk	Belgorod	Mozhaysk	Vyazma
Periods analysed (years)	1615/1616-1679/1680 (65)	1616/1617-1679/1680 (64)	1615/1616-1680/1681 (62)	1619/1620-1680/1681 (62)
Number of years when taverns (*kabaks*) worked on the basis of tax farming, years	16	10	7	6
Time periods when taverns (*kabaks*) were tax-farmed, reporting years	1615/1616, 1619/1620-1622/1623, 1630/1631-1632/1633, 1634/1635, 1639/1640, 1640/1641, 1666/1667, 1675/1676, 1676/1677	1616/1617, 1631/1632, 1633/1634, 1635/1636- 1640/1641	1622/1623, 1623/1624, 1631/1632-1633/1634, 1635/1636, 1636/1637	1643/1644-1648/1649

Source: Compiled by the authors based on Razdorsky, 2015: 48-49.

Taverns (*kabaks*) in the considered towns were much more often tax-farmed in the first half of the 17th century. The reason was the ban on the farming system introduced in 1652 that was exacerbated by the Thirteen Years' War with Poland for the possession of Ukraine, started in 1654, and the financial crisis in the late 1650s and the early 1660s (Razdorsky, 2015: 49).

Comparison of the data provided in Table 3 and Figure 1 shows the change in the amount of state revenues after the change in the form of tavern (*kabak*) management. In all towns the trend is practically the same. In the first year after the rejection of farming, the estimated amount remains at the same level, which results in the loss of revenues as received and this is taken into account in subsequent estimations; the actual amounts follow the same trend. In a few years, however, amounts of revenues received abruptly return to their former levels and even exceed them.

Accounting registers in tavern (*kabak*)

In a tavern (*kabak*) managed "through the oath" *larechny tselovalnik* compiled a tavern (*kabak*) book. This book contained the necessary information on business transactions so that the results of calculations could be used to determine the profit. The *kabak* head was responsible for sending the profits earned to the higher authority and submit a report on its calculation. The tavern (*kabak*) book served as a reporting document for *kabak* heads.

The earliest tavern (*kabak*) books from among those that have come down to us are six books dated by the first decade of the 17th century. Five books have survived to our days with significant losses, and only one book has sufficient information for analysis, namely, the Olonetsk tavern (*kabak*) book for the period from 4 May to 2 August 1609. Accounting records in it are not formalized: they are written in a solid text without lines or columns. Records were separated with a certain space only by production cycles, and covered the period of three months, i.e. a quarter. This period included six full production cycles, two for each month. Beer and wine were produced in Olonetsk. Production of these two beverages was carried out in strict succession so that every month each product was produced once.

The production cycle in the Olonetsk tavern (*kabak*) consisted of buying raw materials, making the beverage and its retailing (Razdorsky, 2014: 10-15). Accounting records concerning the purchase of raw materials contain information on the type of materials (malt, hops, bread), the amount of the purchased materials, prices for each material and the total cost of every purchase, shipping expenses and the cost of grinding (milling). Then the process of production was described, detailing all kinds of expenses: raw materials used, supplementary materials (firewood), payments for services of hired workers involved in the production of beer or wine and water delivery. The production cycle description ended with records of production output in volume terms, measured in the statutorily prescribed volumetric ware (state *vedro*)[8], with the indication of the amount availed from the whole output and the unit price for the state ware. Total sums for all expenses were calculated, and the profit was assessed by comparing total sums against revenues earned. The final part of the book contained a summary section with the following information: the total amount of profit for all production cycles, how much money was sent to the state treasury and left at the tavern (*kabak*) for the future purchase of raw materials.

Thus, tavern (*kabak*) books contained information on the range of commodities, the volume and turnover of the state alcohol trade, prices for alcoholic beverages, the volume of alcohol profits, techniques used for alcohol production, the cost and volume of raw materials (bread, malt, honey, hops) used for producing bread wine, beer and mead, and the management of tavern (*kabak*) affairs (Razdorsky, 2014: 5; Razdorsky, 2011: 40). Accounting records were maintained both by volume and value. The information on receipts and expenses served as the basis for calculating the profit. Profit was calculated for each production cycle separately and then totalled; the total sum was to be sent to the Order (*prikaz*). The book did not provide summarized information on earnings and expenses for the period, which indicated lack of interest in it both from *kabak* head and inspecting officers at the Order (*prikaz*).

The money sent to the Order (*prikaz*) was accompanied with respective accounting books. In the Order (*prikaz*), they were examined in the part concerning the money received, and a special record was made in the receipts and expenditures book. A profit was compared against the estimated obligations and in case of a variance, if there was a shortage, a decision was made concerning the need to recover the deficient amount from a *kabak* head. Decisions were made both in favour of a *kabak* head and against him. The reason for the shortage and the decision made were included into the book.

Apart from the tavern (*kabak*) book, the so-called *rospisnye spiski* were compiled in the tavern (*kabak*). *Rospisnoy spisok* represented a document that was fundamentally different from those described above. It was made only when the *kabak* head was changed. This was an act of property transfer and a notice of receipt signed by a new *kabak* head and issued to his predecessor confirming that he took the tavern (*kabak*) under supervision. Therefore, this document was an inventory sheet listing the property passed on to the new *kabak* head and, can be regarded as a prototype of inventory balance.

Thus, during the considered period there were important improvements in the accounting process. The material data carrier was replaced to paper ledgers. Also a new kind of accounting register, the tavern (*kabak*) book, appeared due to the introduction of wine monopoly and a new need to control production facilities located far away from the government administrative centre (Order (*prikaz*)) and their heads. The major result of the developments was the emergence and widespread introduction of accounting registers with dynamic and statistical content, with these books being direct predecessors of double-entry bookkeeping and the balance sheet summarizing the accounting data. This can be regarded as a basis for an assumption that, even though the double-entry system that had by the time been used in Italian companies for over a century was not yet known in Russia during the considered period, the foundations for its application had already been laid. An important feature of revenue accounting in the field of production and sales of alcoholic beverages was its focus on calculating the profit. Another important fact was that, according to the data provided by the tavern (*kabak*) book described above, every production cycle fully consumed all the supplies purchased by a *kabak* head; therefore, there were no raw materials left in stock at the end of the reporting period. Besides, all the materials were paid for when they were bought; thus, a tavern (*kabak*) had no accounts payable. A similar situation existed with regard to accounts receivable, since all the sales were paid in cash. The circumstances described above indicate that the records kept in the tavern (*kabak*) in accordance with the cash-basis method were identical to the one that could have emerged if the accrual method had been used.

Conclusion

Summarizing the results of this research, it is possible to emphasize the following key findings:

1) We identified the first surviving documents related to the alcohol industry of the early 17th century, when double-entry bookkeeping based on double entries and a balance sheet was not yet used in Russia, that have not been described before in academic studies on the accounting history. They include accounting registers maintained at taverns (*kabaks*) (tavern (*kabak*) book) and centers of government revenues collection - Orders (*prikazi*) (*oklad* (estimated obligations) book and receipts and expenditures book). They are important for studying the development of accounting, since they have two features: first, they are accounting registers of entities, where the production and sale of alcoholic beverages were simultaneously carried out, and second, this activity belonged to the state monopoly and, therefore, was under the special government control.

2) We have described the practice of profit calculation in accounting registers (tavern (*kabak*) books) in the 17th century. This fact is important for understanding the evolution of accounting practice. Calculation of profit is considered the main advantage of double-entry bookkeeping, which provides for its assessment on the basis of accounting records. Without it, profit would have been calculated using the data of full inventory of assets and obligations, which is typical for single-entry bookkeeping. In Russian tavern (*kabak*) books dated 17th century profit was calculated in a totally different way. As distinct from the single-entry method based on the comparison of static data on the balance of assets and obligations, accounting registers of tavern (*kabak*) assessed profit using the dynamic data based on the data of receipts and expenditures during the period. It is obvious that the method of profit calculation in Russia of the 17th century differed from the contemporary one, since the accrual method was not used for the assessment of profit and losses; all the sums in the tavern (*ledger*) book were recorded using the cash method.

Notes

[1] Monopoly – the exclusive right of the state or individuals to produce and retail alcoholic beverages.
[2] *Kabak* (borrowed from a Low German dialect: *kabacke*, *kaback,* meaning a rundown house, a tattered house, a hut) – a special kind of house where food and drinks were served. The first one was built in Moscow in 1547 (Borodin, 1910: 34). Its appearance was connected with the ban on free sales of vodka.
[3] *Razriad* – a military administrative territorial division in Russia in 16th-17th centuries
[4] Quaters – the central administrative and financial institutions in 2nd half of the 16th– beginning of the 17th centuries. Collected a number of direct and indirect taxes, cash and natural duties; payed salaries to the highest ranks of feudal lords, the top of the provincial nobility and one-off payments to military men, strelets, kozaks, and commanders; judicial and administrative management of population. In 17th century the territories managed by them received a fairly stable distinction (Central State Archive…, 1991: 181).
[5] *Dyak* – a clerk or a chief clerk at administrative offices of different government departments in the Russian state before the 18th century. A *dyak* could even be a head of the Order (*prikaz*) (Medvedev, 2011: 193)
[6] This book is kept in Moscow in the Central state archives of ancient acts. The first protection sheet contains an inscription in the 19th century handwriting: "Books of *obrok*, *oklad* and monetary revenues of the Novgorod Order (*prikaz*). No 14"; there is also an earlier inscription on the book: "after lists certified by *dyak* Andrei Shipov" (The receipts and expenditures books, 1983: 4).
[7] Altyn - a historical monetary unit, as well as dengas, constituted a rouble. From 1534 to the 17th century, 1 rouble equalled 33 1/3 altyns or 200 dengas (Special historical disciplines, 2003: 568).
[8] State *vedro* (backet) - an Old Russian pre-metric liquid measure used for selling alcoholic beverages. In the 17th century there was no single common measurement for this unit; every region used its own measurement ware, while the literature specifies the weight of *vedro* from 21.8 to 48.5 Russian pounds of pure water (Special historical disciplines, 2003: 496).

Abstract

The objective of the paper was to explore the relation between unethical behaviour in organisations and the level of trust in these organisations on the part of witnesses and victims of an unethical action in Polish companies. The study was based on a survey conducted on a group of 309 respondents in Poland. We hypothesized that employees who were being either a victim or a witness of unethical actions had lower trust in the organisation. Our research showed that there are unethical practices in Polish companies that are either experienced or witnessed, most likely driven by humiliation and depreciation and the demonstrating of the power position by people in charge. In large part, the results confirmed the hypothesis, especially in the cases of victims; however, in the case of witnesses, these results differed from expected, showing the increase of trust in organisations in some aspects.

Keywords: Trust, Trust Management, Organisations, Unethical Behaviour, Business Ethics.

Introduction

The questions of both trust in organisations and unethical behaviour within them have been foci of many studies and have become subjects of various theoretical conceptualizations. The two concepts have obviously been regarded as having a mutual impact on each other and as empirically related (Yip, Schweitzer 2015; Hill, Eckerd, Willson, Greer 2009; Lewicki, Tomlinson 2014). Yet, it seems that in many studies both trust (e.g. Zand 1972; Dietz and Den Hartog 2006; Shockley-Zalabak and Ellis 2006; McKnight, Cummings, Chervany 1998; Żółtawska 2014) and un/ethical behaviour have been, principally, treated, separately (e.g. Peterson 2002; Phillips, Margolis 1999; Wimbush, Shephard 1994; Kvalnes 2019; Chudzicka-Czupała 2013). The aim of the present study was to empirically examine the relation between unethical behaviour within Polish companies and the levels of trust in them, on the part of witnesses or victims of an unethical action.

Trust and unethical behaviour

For the purpose of our study, we have accepted Rawling's (2008) general definition of trust: „Therefore, the operational definition of trust for this study is the following: Trust is one party's willingness to be vulnerable to

another party based on the confidence that the latter party is competent and dependable, has integrity, and acts with goodwill" (Rawlins, 2008, p. 5). We also agreed with Paine (2003), Dietz and Den Hartog (2006) and Shockley-Zalabak and Ellis (2006) that trust as a complex concept has five overall characteristic features: (1) it can be understood as a multi-level relation (between workmates, teams, organisations, the public); (2) it is culturally rooted and (3) communication-based; (4) it is dynamic (changing depending on the situations, e.g. after being a victim or a witness of un/ethical actions); and (5) it is multi-dimensional, which means that it comprises cognitive, emotional and behavioural aspects. After Paine (2003, pp. 5-6) we assumed that operationalizable domains of trust covered a series of particular concepts such as competence, integrity, dependability/reliability, openness and honesty, vulnerability, concern for employees, identification, control mutuality, satisfaction and commitment (see Szczepanowski, Zarębski, Pieńkowska 2020).

Particular constructs of ethical and unethical behaviour may depend on several individual and supra-individual factors including individual's beliefs, his or her social role's requirements and expectations, personality traits, but also on the type of culture which a person lives in, organisational/ethical climate or having a particular ethical code in a company (Chudzicka-Czupała 2013, pp. 15-85; De Cremer, Vandekerckhove 2017). Having taken that into account, we refrain from stipulating the particular forms of ethical/unethical sphere in objective terms and, instead, accept the view of the unethical as actions that deviate from multifoci organisational justice (e.g. Rupp, Cropanzano 2002, p. 926-928) as perceived by individuals inside an organisation. Against this background we followed Chudzicka-Czupała (2013) in distinguishing five categories of unethical experiences as respondents perceived them: (1) discrimination, (2) isolation and ignorance, (3) violation of dignity and integrity, (4) humiliation and depreciation of employees, and (5) demonstration of power position by a superior. After the Chudzicka-Czupała's account, we have also considered a framework of a threefold perspective on an act to be virtually perceived as unethical, i.e. the perspective of a victim, of a witness and of a perpetrator (2013, pp. 114-121). The present research focuses on the perspectives of a victim and of a witness, while the perspective of a perpetrator was not relevant for this study.

According to Paine's model, it is claimed that an important component of promoting trust in the organisations consists of various interactions between associates, teams, and alliances on the multiple levels (Paine, 2003). Thus, apart from trust-building factors that are culturally rooted (i.e. norms and values), the model primarily points to the importance of connections between an employee and the organisation. Given this standpoint, Paine argues that there are several communicative behaviours and openness strategies that can potentially boost the establishments of trust (Paine, 2003, p. 5). The specific dimensions describing how connections can positively affect employee's trust are: (i) control mutuality, (ii) satisfaction, (iii) commitment, (iv) exchange relationship, and (v) social relations. In terms of control mutuality, this factor describes the degree to which both parties agree to influence each other by taking into account the imbalance of authority. For example, unjustified attempts by one party to gain control over the other party can decline trust in other's competence and satisfaction. On the other hand, it is believed that consent to exercise mutual control ensures the stability of the organisation. Another dimension is satisfaction, which describes positive feelings towards other partner based on the expectations directed to that party. Positive feelings of satisfaction arise from the fact that benefits prevail over costs and the satisfied employee holds beliefs that positive behaviours of the other partner will be maintained in the future. The subscale of engagement refers to individual's beliefs about confidence in one's own actions and investments into the organisation. Having these beliefs, an individual feels emotional stability within the organisation and has feelings of continuity, both of which are behaviourally expressed in maintaining and promoting the relationship with the organisation. The next dimension of exchange relationship is based on the concept of marketing theory (Bagozzi, Richard P. 1974, p. 77), which assumes that each party should provide the other one with benefits. Such beliefs imply that also the employee is obligated to benefit the partner (the organisation). As the exchange between partners is being reinforced and matured, the building of trust improves and a positive orientation towards maintaining the relationship with the organisation appears. The last dimension of social relationship is a cornerstone of the development and reinforcement of trust in an organisation. This subscale describes beliefs that people should care about each other and provide each other with benefits, even if they receive nothing in return. Pains (2003) suggests that maintaining such beliefs also significantly reduces the likelihood of negative behaviour from stakeholders.

Considering the results of previous studies by Hough et al. (2015), the relationship between unethical behaviours in organisation and trust seems to be crucial for employee's engagement. It was shown that organisational trust fully mediates the relationship of ethical environment on employee's engagement. That means that an ethics environment leads to organisational trust which in turn enhances employee engagement (Hough et al., 2015). In fact,

ethical/unethical behavior in organisations is related to individual and context-specific characteristics, in particular organisational culture (Ardichvili et al., 2009; Cohen,1993; Meyers,2004; Trevino,1986). Therefore, in this study we investigated the relationship between an unehical behaviours from victim and witness standpoints and trust in organisation.

Objective of the study

In our study, it was expected that being a victim or a witness of unethical behaviour would be a predictor of decrease in trust in organisations. The hypothesis has been examined through a series of multiple-regression analyses as set out below.

Method

Respondents

Three –hundred nine part-time graduate students of University of Lower Silesia participated in the study. A total of 309 usable surveys was further analysed (262 women and 47 men). Participants were aged from 19 to 50 (M = 26.65, SD = 7.24). All participants completed informed consent forms before participating in the study. The study was approved by the Research Ethics Committee at the University of Lower Silesia, Wrocław, Poland. The survey was conducted in 2020.

The Questionnaires

The Trust Measurement Questionnaire (TMQ) (Paine 2003) was used to assess multidimensional trust within the organisation. The survey comprises six subscales, i.e. overall trust, control mutuality, commitment, satisfaction, communal relationships, exchange relationship. Although the subscale of overall trust measured beliefs concerning dimensions of integrity, competence and dependability. In this study, the reliability of the entire questionnaire, assessed using Cronbach's alpha rating was 0.937, while reliabilities of the subscales ranged from .738 to .873 (see Table 1).

Table 1: The reliability coefficients of Trust Measurement Questionnaire (TMQ)

Dimension	Cronbach's alpha	Number of items
Overall trust	.859	11
Control mutuality	.828	8
Commitment	.805	8
Social relations	.804	8
Communal relationships	.873	7
Exchange relationship	.738	4
Total	.937	46

The Unethical Behavior in Organization Questionnaire developed by Chudzicka-Czupała (2013) was used to measure the frequency of experiencing unethical behaviours at work from the perspectives of victim and witness. The inventory distinguishes five categories of unethical behaviour: (i) discrimination, (ii) isolation and ignorance, (iii) violation of dignity and integrity, (iv) humiliation and depreciation of employees, and (v) demonstrating the position of power by people in charge (superiors). The respondents were asked to determine the frequency of victimization and witness of unethical behaviour in their workplace. In total, the questionnaire measured 10 dimensions of unethical behaviours. The reliability of the questionnaire, assessed with the Cronbach's alpha rating, was 0.88, while the reliabilities of subscales ranged from 0.78 to 0.89 (Chudzicka-Czupała, 2013).

Statistical Analyses
